A Close Correlation Between Radiologic Progression Severity and Trabecular Bone Loss in Male Patients with Ankylosing Spondylitis

Ki-Jo Kim[1,2], In-Woon Baek[3], Chong-Hyeun Yoon[4,5], Wan-Uk Kim[6] and Chul-Soo Cho[3], [1]Internal Medicine, St. Vincent's Hospital, The Catholic University of Korea, Suwon, South Korea, [2]St. Mary's Hospital, Seoul, South Korea, [3]Internal Medicine, Yeouido St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea, [4]Division of Rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, South Korea, [5]Internal Medicine, Uijeongbu St. Mary's Hospital, The Catholic University of Korea, Uijeongbu, South Korea, [6]Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic, progressive disease characterized by inflammation of entheses. Inflammation is associated with cortical new bone formation leading to progressive ankylosis of the spine and sacroiliac joints but also with trabecular bone loss leading to osteoporosis. The aim of this study is to investigate the association of spinal radiologic progression with bone mineral density in male AS patients.

Methods: Clinical and radiographic data were collected in 116 male AS patients. Spinal radiographs were scored using the modified Stoke AS Spinal Score (mSASSS) and spinal bone mineral density (BMD) of anteroposterior (AP) and lateral (Lat) views was measured by dual-energy x-ray absorptiometry (DEXA).

Results: Seventy three (62.9%) patients had syndesmophyte(s) at their lumbar spine (L-spine) and 45 patients (38.8%) were treated by tumor necrosis factor (TNF) inhibitors. mSASSS and BMD were significantly higher in patients with syndesmophyte(s) (All $P < 0.05$). For the 2nd and 3rd lumbar vertebra, BMD of AP view was significantly higher in vertebrae with syndesmophyte(s) ($P = 0.001$) while BMD of Lat view was decreased and did not differ between those with and without syndesmophyte(s). Moreover, L-spine mSASSS was positively correlated with BMD of AP view ($\gamma = 0.239$, $P = 0.010$) while negatively correlated with BMD of Lat view ($\gamma = -0.209$, $P = 0.025$). These correlations were significant when adjusted for age, HLA-B27, smoking, treatment drugs (NSAIDs, TNF inhibitors, statins and bisphosphonate), body mass index and C-reactive protein.

Conclusion: Trabecular BMD was decreased and correlated with severity of radiologic progression in L-spine of male AS patients, suggesting a parallel progression between cortical bone formation and trabecular bone loss.

Computer Aided Syndesmophyte Measurement on Spinal Radiographs in Axial Spondyloarthritis Patients

F. de Bruin[1], Rosaline van den Berg[1], M. Reijnierse[2], D. van der Heijde[3,4] and B.C. Stoel[2], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Radiology, Leiden University Medical Center, Leiden, Netherlands, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [4]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Quantifying syndesmophyte (Synd) length and angle in axial spondyloarthritis (axSpA) patients (pts) can be a helpful tool in monitoring disease progression. Objective was to evaluate in-house-developed software that aids in quantifying Synds length and angle on radiographs, to test its inter and intrareader reliability and to assess progression over time.

Methods:

The cervical and lumbar spine radiographs at baseline and follow up (24 months) of 18 axSpA pts were analysed twice using the software tool, by two independent readers, blinded for time sequence and the results of the other reader. The software establishes the vertebral body (VB) contours based on signal contrast and anatomical landmarks (figure 1). The length and angle of Synds is based on the distance between the maximum extending point and the 'native' VB corner (figure 2). Length was measured in mm and sum scores were calculated per pt by adding up all Synds. Pts were also analysed using the mSASSS. Inter- and intrareader reliability were analysed using Bland Altman (B&A) plots. Reliability of progression was evaluated using smallest detectable change (SDC) analysis.

Results:

In total, each reader analysed 1728 vertebral corners (VC) of 72 images. B&A plots for intra and interreader variability showed a large variability in length of Synds in both the individual VCs and for the total sum of the patients (figure 3). When analysing change score over time within one patient, SDC showed that almost all progression fell within the SDC (SDC= 12.9 and 20.4 mm) (for reading 1: 11/18 patients (61%) and reading 2: 15/18 (83%)), while those patients did show 'real progression' as measured with the mSASSS.

Conclusion:

Computer aided measurement of Synds on radiographs was not feasible. The restrictions associated with radiographs (overprojection, patient position dependent variability) and the size of the lesions of interest were not compatible. Overall, semi-automatic detection did not have added value to existing manual tools.

Imaging and Clinical Factors Associated with Subchondral Sacroiliac Fatty Marrow in Axial Spondyloarthritis

Kavi Devulapalli[1], Xenofon Baraliakos[2], Daria Motamedi[1] and Lianne S. Gensler[3], [1]Radiology, UCSF, SAN FRANCISCO, CA, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Magnetic resonance imaging (MR) plays an important role in the evaluation of inflammatory and structural changes in axial spondyloarthritis (axSpA) patients. Prior research suggests subchondral fatty marrow is an imaging precursor to ankylosis. The ability to predict new bone formation in patients with axSpA may have treatment implications. The goal of the current study is to evaluate imaging and clinical factors associated with subchondral sacroiliac joint (SIJ) fatty marrow.

Methods:

A retrospective analysis of 91 AxSpA patients who underwent a lumbar spine or pelvis MR with axial and coronal T1 in addition to fluid sensitive sequences was performed. Images were reviewed by a radiologist and evaluated for findings of both active and structural disease in addition to disease distribution. Bone marrow edema was quantified using the Spondyloarthritis Research Consortium of Canada (SPARCC) quadrant based approach method. Clinical variables including gender, age, race, disease duration and classification, current or prior Tumor Necrosis Factor alpha inhibitor (TNFi) therapy, HLA-B27 status, history of uveitis, inflammatory bowel disease and psoriasis were collected. Univariable analyses with c2 and Student's t-Test were performed on dichotomous and continuous variables. Multivariable logistic regression was performed after adjusting for gender and disease duration.

Results:

Of the 91 patients, 76 (83.5%) demonstrated sacroiliac (SI) joint abnormalities on MR with 90.8% of these demonstrating bilateral and 56.6% demonstrating symmetric changes. Distribution of abnormalities included bone marrow edema in 56.7% with a SPARCC score of 7.30 ± 11.53, erosions in 44.7%, fatty marrow in 52.3% and ankylosis in 19.7% of patients. Covariates independently associated with fatty marrow change included disease duration ≥10 years (OR 3.5, 95% CI [1.05-11.9], p=0.04), psoriasis (OR 29.1, 95% CI [1.34-633.5], p=0.032) and symmetric sacroiliitis (OR 4.36, 95% CI [1.30-14.59], p=0.02). There was no association with TNFi therapy (Table 1).

Conclusion:

Our data demonstrates fatty marrow replacement is associated with longer disease duration (≥10 years) and the presence of psoriasis in addition to the imaging finding of symmetric disease distribution. Additional studies are warranted to explore the role of psoriasis in the development of chronic sacroiliitis and ankylosis.

Table 1. Multivariable analysis after adjustment for gender and disease duration

	Odds Ratio	95% Confidence Interval	p-value
Gender	2.24	0.64 - 7.79	0.20
Disease Duration (≥10 years)	**3.54**	**1.05 - 11.87**	**0.04**
Psoriasis	**29.1**	**1.34 - 633.52**	**0.03**
Erosions	0.38	0.12 - 1.23	0.11
Symmetric disease distribution	**4.36**	**1.30 - 14.59**	**0.02**
Bilateral disease distribution	4.25	0.31 - 58.25	0.28

Is There Evidence to Support Replacing Conventional AP Pelvis Radiographs with Dedicated Sacroiliac Joint Views for the Diagnosis of Sacroiliitis?

Ahmed Omar[1], Ismail Sari[1], Mohamed Bedaiwi[1], Nigil Haroon[1] and Robert D Inman[2], [1]Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [2]Immunlogy and Institute of Medical Science, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the development of advanced imaging modalities such as MRI and CT, conventional radiography remains the cornerstone for the diagnosis and classification of Ankylosing Spondylitis (AS). Ease of access and cost may be contributory continued use of X-rays. The AP pelvis radiograph has long been the established standard for the screening and grading of sacroiliitis, despite its well-documented poor reproducibility. There is a lack of recent research that compares the standard AP pelvis (APPx) view with dedicated sacroiliac views. To the best of our knowledge, no previous studies compared AP pelvis vs the angled frontal “Ferguson” view (SIJx), a modality that has been advocated anecdotally by many clinicians. Our aim was to compare the APPx view with the dedicated SIJx view in order to clarify if one modality has a clear advantage for diagnosis and grading of sacroiliitis.

Methods: 103 patients who had simultaneous APPX and SIJx modalities on the same date with an established diagnosis of Axial spondyloarthritis (SpA), either through the modified NY criteria or through the 2009 ASAS criteria were randomly selected from the axial SpA registry. One independent coordinator randomized the sequence of these patients and prepared the x rays to be read on two separate computer terminals with all patient identifiers removed. Two rheumatologist independently reviewed both the SIJx and the APPx and scored the graphs according the modified NY criteria. Intra-reader and inter-reader agreements were obtained for both the APPx and SIJx evaluations by using the Cohen-weighted kappa statistic and the intraclass correlation coefficient (ICC). Mean SIJ scores were also calculated.

Results: A total of 206 radiographs were read (103 for each modality). Intra-observer reliability of the observers showed similar agreements with regards to right and left SIJ evaluation (Table 1) which was also reflected in the kappa for diagnosis of AS (fulfilling NY criteria) between the observers. The inter-rater agreement showed similar values between the imaging modalities. This agreement was also replicated when separately evaluating SIJ’s with score grading of 0 to 2. The SIJ dedicated view did not significantly influence the diagnosis and there was no statistically significant change for the overall population as outlined on Table 1. The average SIJ scores obtained from each observer showed similar values for both modalities.

Conclusion: There was agreement between dedicated SIJ and the AP pelvis x-ray reads. Either modality can be employed to evaluate the sacroiliac joints for sacroiliitis with the dedicated SIJ imaging showing no clear superiority over the standard AP Pelvis view.

Table 1: Comparison of agreement between the two methods of SIJ scoring				
Intra-observer reliability			**Observer 1**	
Observer 2				
Right SIJ		0.46 (0.29-0.59)	0.64 (0.5-0.74)

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Approximately 25% of psoriasis (Ps) patients develop into psoriatic arthritis (PsA) within 10 years. This Ps-to-PsA transition paradigm provides a unique opportunity to recognize preclinical symptoms to prevent further joint destruction by early intervention. Early identification of Ps patients prone to develop PsA, however, has been challenging due to diverse Ps clinical features, limited understanding of the molecular events, and the absence of reliable biomarkers. To fill up these gaps, we focused our studies on DC-STAMP (Dendritic Cell-Specific Transmembrane Protein), a 7-pass transmembrane protein essential for osteoclast (OC) differentiation. We previously demonstrated an elevated frequency of DC-STAMP+ osteoclast precursors (OCP) in PsA patients, suggesting DC-STAMP may serve as a surrogate to monitor DC-STAMP+ OCPs in human blood. To further validate DC-STAMP as a potential biomarker in psoriatic disease diagnosis, herein, we evaluated the circulating OCP frequency, DC-STAMP+ cell frequency, DC-STAMP expression level in healthy control (HC), Ps, and PsA patients.

Methods:

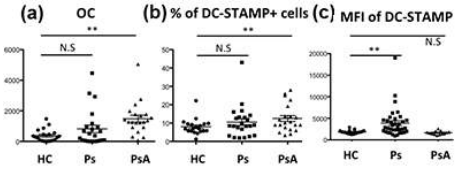
21 PsA, 36 Ps and 20 HC were recruited for this study from the International Psoriatic Arthritis Research Team (IPART) registry. We set up a standard operating procedure (SOP) by collecting blood from 20 HC one week apart. DAS28/DAS44, ESR, CRP, PASI score and disease duration years were collected. The numbers of OCP were assessed by in vitro culture, and the frequency of circulating DC-STAMP+ cells and DC-STAMP expression level (by

mean fluorescence intensity (MFI)) were determined by flow cytometry analysis.

Results:

The disease duration years & PASI score for Ps and PsA were 24.1 ± 14.6 vs. 15.2 ± 7.8 and 6.5 ± 8.2 vs. 4,6 ± 2.4, respectively. The reliability and reproducibility of our SOP for cell isolation, staining, and flow analysis were confirmed by HC blood that were collected one week apart from the same subject. The results of DC-STAMP+ cell frequency and DC-STAMP expression level were summarized by 3 dot-plots shown below.

**: significant; N.S.: not significant; y-axis: cell events or frequency.



Conclusion:

The frequency of OCP (dotplot (a)) and DC-STAMP+ cells (dotplot (b)) were significantly higher in PsA patients than HC. In contrast, the expression level of DC-STAMP as represented by the MFI was significantly higher in Ps than HC (dotplot (c)). These data collectively suggested that the frequency of OCP & DC-STAMP+ cells are good biomarkers of PsA, whereas the DC-STAMP expression level serves better as the Ps biomarker. Our studies also established the ranges of OCP, DC-STAMP+ cell frequency, and DC-STAMP expression level for the cohorts of HC, Ps and PsA. Intriguingly, a subset of Ps patients showed an elevated frequency of DC-STAMP+ cells and an increased DC-STAMP expression level (outliers in dotplots (b) & (c) for Ps). These Ps patients will be followed longitudinally to determine if these markers can predict future PsA onset.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Considerable heterogeneity across clinical domains of psoriatic arthritis (PsA) can make assessment of disease activity challenging. As a result, there has been interest in developing biomarkers to assess disease activity. In rheumatoid arthritis (RA), a multi-biomarker disease activity (MBDA) assay, a weighted composite of 12 serum protein biomarkers, has been shown to correlate with disease activity.[1] Our objective was to investigate if the MBDA score and its biomarker panel correlated with disease activity across different domains of PsA.

Methods:

A cross-sectional sample of 30 adult patients with PsA fulfilling the CASPAR criteria[2] was recruited from UCSD Arthritis Clinics. Clinical data and serum samples were collected and serum was analyzed for MBDA score and its individual components[3], as well as intracellular adhesion molecule 1 (ICAM-1), interleukin 6 receptor (IL-6R), and macrophage-derived cytokine (MDC).

Results:

The table shows patient characteristics:

Table. Patient Characteristics (N=30)

Gender (male), N (%)	15 (50.0)
Age (years), mean ± SE	49.5 ± 11.2
Psoriatic arthritis duration (years), mean ± SE	7.9 ± 8.9
Psoriasis duration (years), mean ± SE	14.7 ± 13.6
Skin psoriasis, N (%)	23 (76.7)
Skin BSA (%), mean ± SE	9.0 ± 23.0
Enthesitis, N (%)	8 (26.7)
Dactylitis, N (%)	2 (6.7)
Nail psoriasis, N (%)	15 (50.0)
Tender joint count 28 joints, mean ± SE	2.9 ± 4.4
Swollen joint count 28 joints, mean ± SE	2.7 ± 3.4
Physician global (VAS 0-10 cm), mean ± SE	3.3 ± 2.8
Patient global (VAS 0-10 cm), mean ± SE	4.4 ± 3.3
HAQ score, mean ± SE	0.7 ± 0.7
CDAI, mean ± SE	13.2 ± 11.5
DAS28, mean ± SE	2.68 ± 1.75
DAS28-CRP, mean ± SE	2.61 ± 1.25
Current biologics, N (%)	15 (50.0)
Current DMARDs, N (%)	14 (46.7)
Current NSAIDs, N (%)	12 (40.0)
Current topical therapy, N (%)	10 (33.3)

Abbreviations: BSA, body surface area; VAS, visual analogue scale; HAQ, health assessment questionnaire; CDAI, clinical disease activity index; DAS, disease activity score; DMARDs, disease modifying antirheumatic drugs; NSAIDs, nonsteroidal anti-inflammatory drugs.

The average MBDA score was 39.6, which would be consistent with a moderate disease activity score in RA patients.[1] In our PsA cohort, the MBDA score was most strongly correlated with physician global assessment (Pearson correlation coefficient, r=0.57), DAS28 (r=0.53), and skin BSA (r=0.50). Correlations were poorer with CDAI (r=0.35), SJC28 (r=0.35), patient global assessment (r=-0.08), HAQ score (r=0.15), and pain score (r=0.12). Analysis of individual biomarkers showed strong correlations, in many cases stronger than the composite MBDA score: e.g., serum amyloid A (SAA), tumor necrosis factor receptor superfamily member 1A (TNF-RI), MDC, and leptin with skin BSA (r=0.85, 0.84, 0.75, 0.72, respectively); leptin and ICAM-1 with DAS28 score (r=0.62 and 0.52); and SAA and vascular cell adhesion molecule 1 (VCAM-1) with physician global assessment (r=0.67 and 0.61).

Conclusion:

These data suggest the MBDA score can correlate with facets of disease activity in PsA. However, individual biomarkers were frequently found to correlate, often more strongly, with different domains of disease activity raising the possibility that specific composite scores could be created for each PsA domain. Whether these serum biomarkers are modulated by therapy and associated with clinical response warrants further study.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: With the growing awareness of disease course of ankylosing spondylitis (AS) and recent development of novel treatments which might be the most effective for early stage of disease, there is an unmet need for markers that can assess disease activity more simply in those individuals at the highest risk for a bad outcome. Bath ankylosing spondylitis disease activity index (BASDAI) has been the most widely used clinical disease activity

measure in AS. However, the BASDAI has no consideration for laboratory inflammatory markers. Furthermore, an elevated ESR or CRP is present in only about 40-50% of patients with active AS. Glycated albumin (GA) was initially viewed as an adjunct to glycated hemoglobin (HbA1c), but it has recently been reported that chronic inflammation is positively correlated with HbA1c level, whereas it is negatively associated with GA. We evaluated the availability of the ratio of HbA1c and GA as an adjunctive marker to the Ankylosing Spondylitis Disease Activity Score (ASDAS) already proposed.

Methods: A total of 58 non-diabetic AS patients who met the modified New York classification criteria were included. ESR, CRP, ASDAS-ESR, ASDAS-CRP, BASDAI, and patient's global assessment (BASG) were assessed.

Results: The median [interquartile range, IQR] HbA1c/GA ratio was 0.42 [0.40, 0.44]. The medians [IQR] of A1C, GA. ESR, CRP, ASDAS-ESR, and ASDAS-CRP level were respectively 5.5 [5.3, 5.6] %, 13.1 [12.4, 13.8] %, 17.5 [6.0, 32.5] mm/hr, 1.5 [0.7, 6.4] mg/l, 2.44 [1.38, 3.03], and 1.92 [1.22, 2.59] in the patients with AS. HbA1c significantly correlated with ASDAS-ESR, ASDAS-CRP, BASDAI and BASG ($r = 0.328$, $p < 0.05$; $r = 0.356$, $p < 0.05$; $r = 0.326$, $p < 0.05$; $r = 0.440$, $p < 0.01$, respectively). GA showed a weak negative association with ESR, CRP and ASDAS score, but there was no significant difference statistically. There were significant correlations between the ratio of HbA1c/GA and disease activity based on ASDAS in AS patients (for ASDAS-ESR, $r = 0.367$, $p < 0.05$; for ASDAS-CRP, $r = 0.462$, $p < 0.01$; for ESR, $r = 0.417$, $p < 0.01$; for CRP, $r = 0.356$, $p < 0.05$).

Conclusion: In patients with AS, HbA1c/GA ratio correlate with disease activity, and consequently combination of these parameters may serve as a better marker of disease severity.

Table Correlation between HbA1c/GA ratio, HbA1c, GA. ESR, CRP, ASDAS-ESR, and ASDAS-CRP in 58 patients with AS

	ESR	CRP	ASDAS-ESR	ASDAS-CRP	BASDAI	BASG
HbA1c/GA	**0.417***	0.356#	0.367#	**0.462***	0.293	0.162
HbA1c	0.257	0.249	0.328#	0.356#	0.326#	**0.440***
GA	-0.281	-0.233	-0.219	-0.105	-0.084	0.073
ESR			**0.624***	**0.423***	0.222	0.089
CRP	**0.421***		0.342#	**0.597***	0.102	0.030

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Enteropathic arthropathy refers to the pattern of inflammatory arthritis seen in association with gastrointestinal pathology. Arthritis in the presence of inflammatory bowel disease can occur in patients with Ulcerative Colitis and Crohn's disease. Typically, patients may present with an asymmetrical pauciarticular pattern of joint disease in conjunction with flares of bowel disease. Anti-cyclic citrullinated (Anti-CCP) antibodies are highly specific in patients with rheumatoid arthritis and its presence is often used as a diagnostic marker, but an association with inflammatory bowel disease remains unclear. We explore the prevalence of Anti-CCP and rheumatoid factor (RF) antibodies in patients with enteropathic arthritis.

Methods:

A retrospective analysis was performed using data collected from consecutive patients with enteropathic arthritis attending general rheumatology clinic.

Baseline demographic data, history and duration of bowel disease, treatment, pattern of inflammatory arthritis, and Anti-CCP and RF titres were recorded. Anti-CCP antibodies were detected using a commercially available fluorescence enzyme immunoassay (Phadia). The same data set were also recorded for consecutive patients with inflammatory bowel disease in the absence of arthritis.

Results:

Full demographic data and characteristics were obtained from 31 patients with enteropathic arthritis and 30 patients without arthritis. In the study population 55% had a diagnosis of Crohn's disease (n=17) and 45% had Ulcerative Colitis (n=14). 26% patients had axial involvement only, 48% presented with peripheral joint disease only (n=15), 26% had evidence of both peripheral and axial disease. Of the patients with peripheral joint involvement, 22% patients were found to be positive for Anti-CCP antibodies (n=5) with small joint involvement and no evidence of erosive disease on radiological assessment. Table 1 demonstrates demographic data in patients with enteropathic arthritis.

The prevalence of Anti-CCP and rheumatoid factor antibodies in the control group was 0.

	Peripheral (n=15)	Axial (n=8)	Peripheral and Axial (n=8)
Mean Age (years)	47.6	40.125	43.75
Range (years)	30-70	27-54	27-71
Male:Female	7:8	7:1	3:5
Ulcerative Colitis	10	5	2
Crohn's Disease	5	3	6
Anti-CCP positive	5	0	0
Rheumatoid Factor positive	3	0	1

Conclusion:

Our results suggest that Anti-CCP antibodies may also be present in patients with enteropathic arthritis who have a small joint peripheral arthritis in the absence of axial disease. These patients may initially be incorrectly diagnosed with rheumatoid arthritis, rather than articular manifestations of their underlying bowel disease, as the pattern of joint involvement is similar. Further investigation with larger numbers is required to explore the association between inflammatory bowel disease and Anti-CCP antibodies.

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Studies have shown a strong prevalence of cardiovascular events among patients with spondyloarthritis (SpA). Recent studies indicate that visceral adipose tissue (VAT) is highly associated with insulin resistance and cardiovascular events. Dual energy X-ray absorptiometry (DXA) is a validated technique able to accurately determine cross-sectionally the mass of discret fat deposits.

The objectives of our study were to assess the 2-year changes in abdominal fat mass in patients with early inflammatory back pain suggestive of SpA, in the DESIR cohort and to identify the variables significantly associated with these changes.

Methods:

Among the 708 patients of the DESIR cohort (inflammatory back pain of less than 3 years duration suggestive of axial SpA), 265 had BMD measurements at baseline and after 2 years of follow-up, and 129 had body composition and abdominal adiposity measurements. Alongside the evaluation of clinical and paraclinical features associated with early SpA and increased cardiovascular risk, DXA was performed to evaluate body composition and abdominal adipose tissue (subcutaneous adipose tissue (SAT) and VAT). We assessed changes in abdominal fat mass (VAT, SAT) over 2 years. Then, we assessed the variables associated with abdominal fat mass changes using linear regressions. Afterwards, we compared the abdominal fat mass changes in patients treated with TNF-blockers or free of TNF-blockers. Finally, we tested the role of inflammation (defined by a CRP >6mg/L or presence of MRI inflammatory signals at the spine or sacro-iliac joint level) in the 2-year abdominal fat mass changes.

Results:

A total of 129 patients of the DESIR cohort (71 men (55.0%), mean age of 33.0 (±8.6) years old) with a mean disease duration of 17.9 (±10.7) months, were included. Their mean body mass index was 23.7 (±3.5) kg/m^2 and the prevalence of obesity (BMI>30 kg/m²) was 6.2%. We did not find any significant changes of SAT over 2 years; VAT tended to increase over 2 years from baseline of 7.3% (±28%) (p= 0.054). 2-year VAT changes was significantly associated with the presence of the baseline ASAS criteria fulfillment (p=0.015), hypercholesterolemia at baseline (p=0.007), hypertriglyceridemia at baseline (p=0.0026) and 2-year changes in BMI (p<0.01).

Thirty nine (30.2%) patients received anti-TNF treatment during the 2 years follow-up period. The SAT changes were not significantly different between patients with and without anti-TNF (+2.9%, p=0.323). However, VAT tended to increase from baseline in the anti-TNF group (+5.2%, p=0.053).

Presence or absence of inflammation had no significant impact on 2-year abdominal fat mass changes (p=0.358 for VAT and p=0.508 for SAT).

Conclusion:

To our knowledge, this study is the first one assessing the abdominal adiposity changes in early inflammatory back pain suggestive of SpA. VAT tended to increase over a 2 years follow-up period, especially in patients receiving anti-TNF. Further studies with larger samples are necessary to confirm or not these results and to evaluate their clinical relevance.

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

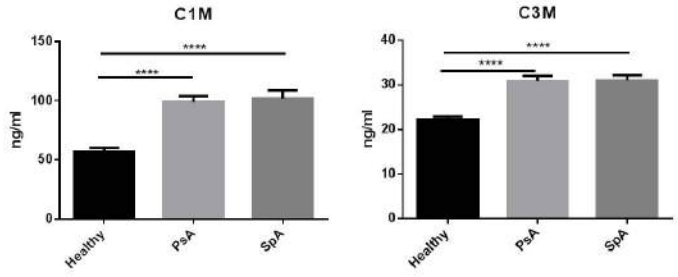
Session Time: 9:00AM-11:00AM

Background/Purpose: AxSpA and PsA are core members of the spondyloarthritis complex. One cardinal characteristic shared by these two conditions is increased remodeling of bone and soft connective tissue in and around peripheral joints, axial skeleton and entheseal insertions leading to synovitis, enthesitis and ankylosis in advanced disease. Studies using seromarkers which reflect extracellular matrix constituent metabolism may provide insight into the activity and dynamics of connective remodeling and thereby pave the way for improved diagnostics and management. The aims of this investigation were to study C1M and C3M, which reflect the turnover of collagen I and III, in order to assess their utility as diagnostic and disease activity markers.

Methods: Ninety-nine patients with PsA, 110 with axSpA and 120 healthy control subjects were included. Demographic and clinical disease measures were recorded.C1M and C3M were quantified using in house competitive ELISAs. Biomarker results are presented as median with 95% CI. Mann Whitney test was applied for inter-group comparisons and correlations were studied using Spearmans test. Receiver operator characteristics (ROC) curve analysis was carried out to evaluate the diagnostic potential of the biomarkers.

Results: C1M and C3M were significantly increased in both axSpA and PsA as compared with healthy controls (Figure). Thus, in axSPA C1M and C3M amounted to 77.6 (71.3-84.6)ng/ml and 27.7 (26.2-29.7)ng/ml respectively, in PsA to 85.6 (78.2-96.2)ng/ml and 28.7 (26.7-31.0)ng/ml versus controls 48.3(43.3-53.2) and 20.9 (20.0-21.7) respectively. C1M and C3M levels did not differ significantly between axSpA and PsA. Serum levels of C1M and C3M were not affected by treatment, or smoking status, but SpA HLA-B27+ patients had significantly higher levels of both C1M (p=0.001) and C3M (p=0.006) compared to HLAB-27- SpA patients. C1M was significantly correlated with DAS28 (PsA: r=0.22, p=0.028, SpA: r=0.40, p<0.0001) and ASDAS (PsA: r=0.29, p=0.003, SpA:r=0.35, r=0.0002). Also C3M was significantly correlated with DAS28 (PsA: r=0.22, p=0.025, SpA: r=0.74, p<0.0001) and ASDAS (PsA: r=0.32, p=0.0013, SpA: r=0.216, p=0.026). C1M and C3M were highly correlated (p>0.0001 in all groups) but they did not correlate with demographics including age, BMI or gender. Segregation between healthy and diseased based on C1M levels resulted in an AUC of 0.83 for PsA (0.76-0.86) and 0.79 (0.73-0.84) for SpA. C3M could also segregate between healthy and diseased with an AUC of 0.77 (0.71-0.82) for PsA and 0.78 (0.72-0.83) for SpA.

Conclusion: These findings indicate that soft connective tissue remodeling is equally increased in axSpA and PsA reflecting disease activity and that collagen type I and III turnover are mediated by closely coupled mechanisms. ROC curve analyses suggest that both C1M and C3M may be useful for diagnostic purposes in axSpA and PsA.



Evaluation of C1M and C3M in Healthy, SpA and PsA. Mann-Whitney tests were used for intergroup comparison, *p<0.05, ** p<0.01, ***p<0.001, ****p<0.0001

Gender Differences in Ankylosing Spondylitis: Men Derive Greater Benefit from Tumor Necrosis Factor Alpha Inhibitors

Jennifer Mandal[1], Michael M. Ward[2], Michael Weisman[3], Jillian Simard[4], Matthew A. Brown[5], MinJae Lee[6], Mohammad H. Rahbar[7], John D. Reveille[8] and Lianne S. Gensler[9], [1]Medicine, University of California San Francisco, San Francisco, CA, [2]NIH/NIAMS, Bethesda, MD, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]University of California San Francisco, San Francisco, CA, [5]The University of Queensland Diamantina Institute, Brisbane, Australia, [6]Biostatistics/Epidemiology/Research Design (BERD) Core | Center for Clinical and Translational Sciences, University of Texas Health Science Center at Houston, Houston, TX, [7]The University of Texas Health Science Center at Houston, Houston, TX, [8]Rheumatology, University of Texas Health Science Center at Houston, Houston, TX, [9]Medicine/Rheumatology, University of California, San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Ankylosing spondylitis (AS) manifests differently in men and women. Women with AS have less severe radiographic disease, yet tend to report more severe symptoms. Little is known about the relationship between gender and disease activity in response to tumor necrosis factor alpha inhibitors (TNFi) in AS. The objective of this study was to explore the longitudinal relationship between gender, TNFi use, and disease activity among patients with AS.

Methods:

In this prospective multicenter cohort study, 659 participants meeting the modified New York criteria were recruited from 2003-2015 and followed every 6 months. Data collection included: demographics, medication history at each visit, comorbidities, depression scales, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and disease activity, measured by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Univariable logistic regression models were performed to identify potential confounders associated with both gender and BASDAI, and these were incorporated into a

longitudinal multivariable mixed effect Poisson regression model using BASDAI as the dependent variable (Table 1). Possible interaction effects were also evaluated while developing the final model.

Results:

Participants were 73.3% men and 79.1% white, with mean age at enrollment of 42.9 ±13.9 years. In the multivariable analysis, gender significantly modified the effect of TNFi on disease activity, measured by BASDAI (p-value for interaction=0.048). TNFi use was associated with better BASDAI scores in both men and women, however men derived a greater reduction in disease activity from TNFi use compared to women (Rate Ratio = 0.79, 95% CI= 0.73-0.85, p <0.0001 for men, and RR= 0.89, 95% CI= 0.81-0.97, p= 0.0059 for women; Figure 1). There was no significant interaction between gender and other pharmacologic agents, including nonsteroidal anti-inflammatory drugs (NSAIDs) and opiates.

Conclusion:

Although men and women with AS both respond to TNFi treatment, men tend to derive greater benefit than women. Gender had a significant modifying effect on the relationship between TNFi use and disease activity. This effect modification, which was not present with NSAIDs or opiates, may suggest an underlying biological mechanism. It is also possible that the specific symptoms reported by men on the BASDAI are more likely to be mediated by TNF compared to the symptoms reported by women.

Free DKK-1 Serum Levels Are Unchanged in Spondyloarthritis Patients Treated By Etanercept

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

DKK-1 and SOST are two inhibitory proteins of the Wnt signaling pathway that lead to decreased bone formation by osteoblasts and osteocytes, respectively. Functional DKK-1 serum levels have been reported to be decreased and dysfunctional in spondyloarthritis (1,2) and a preliminary study involving a limited number of SpA patients suggested that functional DKK-1 serum levels might also decrease under anti-TNF treatment (2). Due to the limited number of patients included in this latest study and the lack of data assessing free DKK-1 and SOST in SpA, a post-hoc examination of the SPARSE study was designed to assess free DKK-1 and SOST serum levels at Baseline and 24 weeks after etanercept or placebo treatment in patients from the SPARSE study.

Methods:

In the SPARSE study, patients were randomized to receive either etanercept (N=42) or placebo (n=48) in case of active AxSpA disease (defined by mini BASDAI ≥ 4) despite optimal NSAIDs intake. Free DKK-1 and SOST serum levels were measured in 90 patients from the SPARSE study at Baseline and at Week 8 (w8). DKK-1 and SOST serum levels were assessed by the use of a classic sandwich ELISA test (Biomedica, Vienna) and results were provided in pmol/L. Changes in DKK-1 and SOST serum levels were adjusted for disease activity, CRP levels, NSAIDs intake, X-ray status and treatment groups.

Results:

LS Mean (SE) serum DKK-1 at Baseline was not significantly different between treatment groups (ETN: 36.2 +/- 1.97; PBO: 37.1 +/- 1.84; p=0.72). At Baseline, DKK-1 was not associated with any patient or disease characteristics: ASDAS-CRP (r=0.096; 95% CI [-0.122, 0.305]); CRP (r=0.002; 95% CI [-0.210, 0.214]); X-ray status (LS Mean (SE): negative 37.4 (+/-2.38) versus positive 36.3 (+/- 1.77); p=0.71). There were no significant differences between treatment groups in the change from Baseline to w8 in the DKK-1 serum levels (p=0.91). We also considered patients with (N=67) or w/o NSAIDs intake (n=19) within the week preceding w8 serum level assessment and found no significant difference (p=0.99). We further assessed DKK-1 serum levels at Baseline according to their Baseline CRP (<6mg/L; ≥6mg/L), X-ray status (Positive; Negative), or NSAIDs intake (Yes; No) within the week preceding w8, and found no significant differences. These analyses were repeated for SOST serum levels at Baseline and with the exception of patients with Negative X-ray status at Baseline having significantly lower values than those patients with Positive X-ray status (p=0.047), no significant differences were observed in terms of the Baseline disease characteristics; Similarly there were no differences between treatment groups in the change from Baseline to w8 for SOST serum levels.

Conclusion:

This post-hoc examination of patients randomized in the SPARSE study suggest that etanercept does not significantly change DKK-1 or SOST serum levels within the 8 first weeks of treatment. Disease activity, CRP, NSAIDs intake and X-ray status were not significantly associated with DKK-1 serum levels. These results should be considered in the context of previous studies suggesting that DKK-1 was dysfunctional in SpA patients (2).

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sustained clinical remission is one of the key benchmarks for treatment of AS over the long term. We aimed to determine the factors predictive of sustained clinical remission on anti-tumor necrosis factor alpha (anti-TNFα) therapy and the role of MRI parameters of inflammation and structural damage at baseline and after treatment.

Methods: In the FOllow-up Research Cohort in AS (FORCAST), AS patients from Northern Alberta attending community and academic practices are assessed for clinical and laboratory outcomes every 6 months, radiography at baseline and 2 years, MRI at baseline, at 3-6 months for patients starting anti-TNFα, and annually. MRI inflammation was assessed using Spondyloarthritis Research Consortium of Canada (SPARCC) Sacroiliac Joint (SIJ) and 23-DVU Spine scores while structural change was assessed independently using the SPARCC SIJ Structural Scores (SSS) for fat metaplasia, erosion, backfill, ankylosis and the Fat Ankylosing Spondylitis Spine Score (FASSS) score for fat metaplasia. Sustained clinical remission was defined as ASDAS<1.3 at two consecutive 6-monthly visits. We used univariate and multivariate logistic regression to assess patient demographics, smoking, B27, NSAID utilization, and baseline CRP, ASDAS, mSASSS, SPARCC scores, SSS, and FASSS scores, adjusted for duration of follow up. We also assessed attainment post-treatment of CRP<6mg/L, ASDAS<1.3, and SPARCC MRI remission (SIJ <2 and spine <3) as predictors of future remission.

Results: We assessed 316 patients on anti-TNF therapy of mean (SD) age 41.2 (12.3) years, 78% males, mean (SD) symptom duration 18.7 (11.1) years, and mean (SD) duration of follow up of 1704 (961.4) days, of whom 144 had MRI evaluation. 98 (31.0%) achieved sustained ASDAS remission after mean (SD) follow up of 848.3 (682.4) days. In univariate analyses, patients attaining ASDAS remission were younger (p<0.0001), had shorter disease duration (p<0.0001), lower baseline ASDAS (p=0.01), were not current smokers (p=0.01), had definite SIJ erosion (p=0.01) but low spinal fat metaplasia (FASSS<5) (p=0.01) and SIJ ankylosis scores (p=0.01), and post-treatment scores indicating SPARCC MRI remission of inflammation (p=0.02), and normalised CRP (p=0.01). In multivariate analyses adjusted for duration of follow up, age, current smoking, baseline ASDAS, and normalized CRP were the strongest clinical predictors. The best models (in terms of *R-squared values)* included age, sex, ASDAS, current smoker, duration of follow up, and an MRI structural parameter (SSS erosion or ankylosis).

Conclusion: Current smoking is negatively associated with attainment of sustained remission to anti-TNF. Sustained remission is more likely in patients attaining normalised CRP, in the presence of definite SIJ erosion, and in the absence of SIJ ankylosis.

	Adjusted R^2	Significant independent variables	OR [95%CI]	P value
Basic Model (age, sex, ASDAS, current smoker, duration of follow up)	0.12	age	0.95 [0.92-0.98]	<0.0001
		Baseline ASDAS	0.65 [0.47-0.90]	0.009
		Current smoking	0.33 [0.14-0.80]	0.014
Basic Model plus post-treatment CRP<6	0.17	Post-treatment CRP<6	10.30 [1.28-82.62]	0.028
Basic model plus SSS erosion ³2	0.38	Baseline ASDAS	0.34 [0.14-0.84]	0.019
		SSS erosion ³2	8.86 [1.57-50.0]	0.013
Basic model plus SSS ankylosis	0.39	Baseline ASDAS	0.34 [0.13-0.92]	0.033
		SSS ankylosis	0.86 [0.76-0.98]	0.019

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Coping may be defined as the set of adaptive processes a patient uses to live well with aspects of disease such as pain. Coping may represent an ability to help manage symptoms in patients with arthritides. This study aimed to explore the influence of patient's ability to cope on patient reported outcome measures (PROs) and composite clinical scores in psoriatic arthritis (PsA), and to determine whether differential ability to cope influences the association between clinical and ultrasonographic (US) findings in PsA.

Methods: In this cross sectional study 141 PsA patients were consecutively recruited from an out-patient clinic. They all fulfilled the CASPAR criteria for PsA. 66 swollen/68 tender joint count (SJC/TJC), PROs and composite scores were registered. US evaluation of 34 joints and additionally joints found to be swollen/tender by 66/68 joint count, 15 tendons, 10 entheses and additionally entheses found to be tender by clinical examination of 19 other entheses was performed. Patients reported their level of coping on a visual analogue scale (VAS, range 0-100 mm, 100 mm worst coping). Gray scale (GS) and power Doppler (PD) sum scores of joints, entheses and tendons were assessed. Correlation analyses were performed by Spearman's rank correlation test (non-parametric distribution of the data). To explore the relation between patient's ability of coping, clinical factors and composite scores we used multiple regression analyses.

Results: We found that coping was strongly correlated ($p<0.001$) to joint pain ($r=0.67$), patient global assessment (PGA) ($r=0.73$) and TJC68 ($r=0.42$). When separating into good (116 patients) and poor (24 patients) ability of coping (defined as ≤50 and >50 mm on a VAS scale, respectively), we found that patients with poor ability of coping had no correlations between several PROs and composite scores, whereas patients with good ability of coping had weak to moderate correlations (table). Patients with poor ability of coping had on average higher Disease Activity Index for Psoriatic Arthritis (DAPSA) (20.0±2.5, $p<0.001$), Composite Psoriasis Disease Activity Index (CPDAI) (2.8±0.5, $p<0.001$), Psoriatic ArthritiS Disease Activity Score (PASDAS) (0.27±0.1, $p=0.006$) score, Disease Activity Score 28 (DAS28) (1.1±0.2, $p<0.001$) and Simple Disease Activity Index (SDAI) (10,7±1.3, $p<0.001$), model adjusted for age, gender and PD sum score.

	Good coping		Poor coping		Good coping		Poor coping	
	GS total	PD total	GS total	PD total	GS joints	PD joints	GS joints	PD joints
TJC 68	NS	NS	NS	NS	NS	NS	NS	NS
SJC 66	0,18*	0,31**	NS	NS	0,27**	0,46***	NS	NS
PGA	NS	0,19*	NS	NS	NS	NS	NS	NS
DAPSA	NS	0,23*	NS	NS	NS	0,23*	NS	NS
DAS28	0,23*	0,27**	NS	NS	NS	0,33***	NS	NS
SDAI	0,23*	0,26**	NS	NS	NS	0,30**	NS	NS

Spearman's rank correlation test, *p<0.05, **p<0.01, ***p<0.001

Conclusion: Patient's ability of coping is influencing PROs in PsA. US evaluation of disease activity is correlated to clinical findings for patients with good ability of coping, but not for patients with poor ability of coping.

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There has been no data reported evaluating MRI parameters of inflammation and structural damage. We aimed to identify factors influencing survival on anti-TNF therapy in real world practice specifically focusing on the role of MRI parameters of inflammation and structural damage.

Methods: In the FOllow-up Research Cohort in AS (FORCAST), AS patients from Northern Alberta attending community and academic practices are assessed for clinical and laboratory outcomes every 6 months, radiography at baseline and 2 years, MRI at baseline, at 3-6 months for patients starting anti-tumor necrosis factor alpha (anti-TNFα), and annually. MRI inflammation was assessed using Spondyloarthritis Research Consortium of Canada (SPARCC) Sacroiliac Joint (SIJ) and Spine scores while structural change was assessed independently using the SPARCC SIJ Structural Score (SSS) for fat metaplasia, erosion, backfill, ankylosis and the Fat AS Spine Score (FASSS) for fat metaplasia in the spine. MRI scans were scored independently by 2 readers and adjudicated by a third reader according to pre-specified rules. We used Kaplan–Meier plots, log rank tests and univariate and multivariate Cox regression

analyses to assess the effects of patient demographics, smoking, B27, NSAID utilization, and baseline CRP, ASDAS, mSASSS, SPARCC scores, SSS and FASSS scores on drug survival. We also assessed early attainment post-treatment of CRP<6mg/L, ASDAS<1.3, and SPARCC remission (SIJ <2, Spine <3) as predictors of anti-TNF survival.

Results: We recruited 480 patients on anti-TNF, mean (SD) age 41.0 (12.7) years, 74.4% males, mean (SD) symptom duration 18.4 (11.6) years, mean (SD) survival on first anti-TNF 1228.1 (1036.9) days. The number discontinuing first-time anti-TNF prescription was 126 (26.3%) after mean (SD) follow up of 814.8 days from first prescription date, of which 28% was for lack of efficacy (LOE), and 17% for adverse events. There were 45 primary and 82 secondary failures. 125 patients had MRI at baseline and 100 had at least one follow up MRI. Univariate analysis showed that male sex (HR 0.56, p=0.002), baseline CRP (HR 0.99, p=0.03) and early post-treatment attainment of ASDAS<1.3 (HR 0.57, p=0.02), and CRP<6mg/L (HR 0.56, p=0.02) were significant predictors of drug survival. Early attainment of SPARCC SIJ remission was the best MRI predictor of drug survival (HR 0.58, p=0.14). In multivariate analysis of clinical predictors, SPARCC SIJ < 2 (adjusted OR=2.2[1.02-4.74]; p=0.043) was a significant predictor.

Conclusion: From an extensive array of patient demographic and disease severity variables, attainment of normalized CRP or low disease activity state within first year of starting an anti-TNF was most strongly associated with survival on treatment. Early remission of MRI inflammation may also be a factor but this requires further study with larger sample size.

Table. Multivariable Cox Regression

Variable	Hazard Ratio	P value	95% CI
Age	0.82	0.47	0.48-1.41
Gender	1.01	0.29	0.99-1.03
Baseline CRP	0.99	0.035	0.98-1.00
CRP<6 post-treatment*	0.46	0.008	0.26-0.82
ASDAS<1.3 post-treatment*	0.54	0.027	0.32-0.93

*Within first year of treatment

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) has become an invaluable tool for early diagnosis of axial spondyloarthritis (axSpA) and several MRI-based studies have identified SpA-related inflammatory or structural findings in the spine. However, the exact frequency of degenerative changes (DCs) at the spine in pts with axSpA as a potential cause of low back pain (LBP) is not completely clarified. Therefore, the aim of this study was to document DCs on lumbar MRI in pts with axSpA and non-specific mechanical (mLBP).

Methods: Pts with chronic LBP were consecutively recruited from our out-patient clinic. All of the pts were assessed for ASAS classification criteria for axSpA and all underwent lumbar spinal MRI. Patients with a history of spinal surgery or injections were excluded. A qualified reader (unaware of the clinical diagnosis and variables) scored anonymized sagittal and axial T1 and T2-weighted MR scans of the lumbar spine. Degree of disc degeneration (DD) (Pfirrmann 5 point scale, class ≤2 considered normal), endplate changes (Modic 3 point scale) and presence of annular rupture, disc bulging, protrusion or extrusion at each spinal level from L1-L2 to L5-S1 were assessed. Patients without definite sacroiliitis on pelvic X-ray were defined as nr-axSpA, and patients with definite sacroiliitis on pelvic X-ray according to modified New York criteria were defined as AS (pelvic X-rays were scored upon consensus of three readers).

Results: Two hundred sixty-seven pts with axSpA (123 nr-axSpA, 144 AS) and 105 pts with mLBP were included (age 18 to 60). Pts with nr-axSpA were

younger (35.43+8.72, years) than pts with AS and mLBP (38.78+7.99, p=0.0008; 41.37+10.77 years, p<0.0001, respectively). Pts with AS had longer symptom duration (11.33+6.93, years) than pts with nr-axSpA and mLBP (6.74, p<0.0001 and 6.13, p<0.0001, respectively). The prevalence of lumbar herniated nucleus pulposus (protrusion or extrusion at any level) in nr-axSpA was higher than pts with AS. In the multivariate logistic regression analysis (adjusted for confounding variables), the presence of MCs (OR, 6.76; 95% CI; 2.09-21.83, p=0.001), LHNP (protrusion or extrusion) (OR , 3.67; 95% CI; 1.57-8. 26, p=0.028), as well as advance age (>50 years) (OR, 33.54; 95% CI; 3.83-293.97 p=0.001) were factors associated with the risk of DD in axSpA. BASMI and BASFI scores were higher and Schober test was more restricted in patients with axSpA who had coexisting DD.

Conclusion: Prevalence of DCs is higher in pts with mLBP than pts with axSpA. However substantial proportion of pts with axSpA had DD at the lumbar spine which increased with age. Spinal DCs might be an alternative explanation for complaints and might interfere with diagnostic decision making in pts with axSpA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease that mainly affects the axial skeleton in which the diagnosis includes diagnostic X-ray changes in the sacroiliac joints. The spectrum of axial spondyloarthritis (axSpA) ranges from non-radiographic (nr) axSpA to AS. Variable rates of progression from nrAxSpA to AS have been reported. However, factors predictive of this progression are poorly defined. In this study, we aimed to identify the characteristics of patients who progressed from nrAxSpA to AS according to modified New York criteria (mNYc).

Methods: In our registry, there were 44 nraxSpA patients according to the ASAS definition who had serial follow-up pelvic X-rays. Two independent readers scored the first and last available pelvic radiographs for each patient and identified the patients who progressed to AS. Discordant results were settled by a third reader. Spinal radiographic damage was assessed by the modified Stoke AS Spinal Score (mSASSS). Baseline information regarding symptom duration, B27 status, biological drug usage, clinical variables, smoking, BASDAI, ESR and CRP were then obtained from the database.

Results:

Characteristics of progressors: Over a median period of 52.5 (25-126) months, 9 (20.5%) out of 44 patients progressed from non-radiographic stage to AS at a rate of 4.7%/year.The median transition time was 47 (23-89) months. There were 8 (88.9%) men and 1 (11.1%)woman. The median age at diagnosis was 22.3 (18-63) years. The median disease duration was 5 (1-19) years. HLA-B27 was positive in 7 (77.8%) patients. Smoking history was positive in 5 (55.6%) patients. The frequency of arthritis, uveitis, enthesitis, dactylitis and family history of AS were 6 (66.7%), 3 (33.3%), 5 (55.6%), 1 (11.1%) and 2 (22.2%) respectively. There were 6 (66.7%) patients who had been treated with TNF-inhibitors (TNFi). **Comparison of progressors vs.**

non-progressors: There were 35 patients who did not progress to AS. The median follow-up of these patients were 33 (24-89) months. Comparison of both groups showed that follow-up duration, disease duration, HLA-B27 status, smoking, extra-articular features, family history, baseline BASDAI, and TNFi treatment were not different between the groups. On the other hand, progressors showed significantly higher baseline CRP, higher frequency of male sex and lower age at onset compared to the non-progressors (Table-1).

Conclusion: Male sex, younger age at onset and higher baseline CRP are factors predictive of progression from nr-axSpA to AS.

Table 1: Comparison of baseline profiles of nr-axSpA progressors *vs* non-progressors.

	Patients progressed to AS (n=9)	Patients without progression (n=35)	P value

Session Title: Systemic Lupus Erythematosus - Animal Models Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We have shown that repeated immunization with antigen causes systemic autoimmunity in mice otherwise not prone to spontaneous autoimmune diseases. Overstimulation of CD4 T cells led to the development of autoantibody-inducing CD4 T (*ai*CD4 T) cell which had undergone *de novo* T cell receptor (TCR) revision. These cells originated predominantly from thymus-passed lymphocytes at the periphery. These *ai*CD4 T cells were capable of inducing a variety of autoantibodies and stimulating CD8 T cells, driving them to become antigen-specific cytotoxic T lymphocytes (CTL). These CTLs could be further matured thru antigen cross-presentation, after which they caused tissue injury identical to that observed in SLE. Thus, systemic autoimmunity appears to be the inevitable consequence of over-stimulating the host's immune system by repeated immunization with antigen to levels that surpass system's self-organized criticality. We have thus proposed the 'eSelf-organized criticality theory' of autoimmunity (Tsumiyama K et al. PLoS ONE 4(12): e8382, 2009), explaining the cause of SLE. Here we identify the *ai*CD4 T cell responsible for inducing SLE as the DOCK8+ CD4 T cell subset.

Methods: BALB/c mice were immunized 12x with OVA. Isolated CD4 subsets were adoptively transferred into naïve recipients, and *ai*CD4 T cells were screened by analysis of the autoantibodies generated in the sera of recipient mice. Membrane fractions of the CD4 T cell subsets responsible for inducing the disease were isolated and examined by mass spectrometry, and candidate proteins specifically expressed in the $CD45RB^{lo}CD122^{lo}$ CD4 T cell fraction were identified by antibody staining. The CD4 T subset expressing the candidate protein of interest was confirmed to be the *ai*CD4 T cell subset by cell transfer into naïve recipients.

Results: Thru fractionation of CD4 T cell subsets and microarray analyses, we found that *ai*CD4 T cells belonged to CD45RB^{lo}CD122^{lo}PD1^{+} CD4 subset. We then isolated membrane and cytoplasmic fractions of these cells and analyzed their proteins by mass spectrometry, and found that among several candidate proteins, DOCK8 was specifically expressed in the membrane fraction of this subset. Adoptive transfer of DOCK8+ CD4 cells from mice immunized 12x with OVA caused an increase in both RF and anti-dsDNA antibody production in the naïve recipients.

Conclusion: The *ai*CD4 T cell subset that induces SLE is identified as DOCK8+ CD4 T cells.

Modulation of IRF4 Function Promotes Expansion of Effector Tregs in Lupus

Alessandra B. Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Acquisition of an effector phenotype is critical for Treg function in chronic inflammatory settings such as those encountered in autoimmune diseases like lupus. Although IRF4 is an essential controller of effector Tregs, the mechanisms orchestrating its function in these cells are largely unknown. In non-Tregs, IRF4 function can be modulated by interaction with DEF6 and its homologue SWAP-70. Mice lacking DEF6 and SWAP-70 (DKO mice) develop a lupus-like syndrome but display normal survival. The purpose of this study was to test the hypothesis that DEF6 and SWAP-70 restrain IRF4 activity in Tregs and that, in DKO mice, Tregs have an increased ability to become effector Tregs and thus blunt disease severity.

Methods: FACS analysis of DKO mice was employed to systematically evaluate Treg frequencies and effector Treg phenotypes during disease development. DKO mice were crossed to Blimp1-YFP-10BiT dual reporter mice to assess expression of the Blimp1-IL10 gene module in DKO Tregs. Selective deletion of IRF4 in the Treg compartment was achieved by crossing DKO mice with Foxp3-Cre IRF4$^{fl/fl}$ mice.

Results:

Unlike naïve T_H cells that express only DEF6, Tregs were found to express both DEF6 and SWAP-70. Analysis of DKO mice demonstrated that the concomitant absence of these two molecules leads to increased numbers of Tregs, which acquire an effector phenotype in a cell-intrinsic manner. In addition, DKO Tregs exhibit enhanced expression of the Blimp-1-IL-10 axis. Notably, DKO effector Tregs survive and expand as disease progresses. The expansion of DKO Tregs was associated with the upregulation of genes controlling autophagy and was found to be IRF4-dependent. Unlike the remarkable accumulation of most effector Tregs, DKO mice exhibited only a minimal expansion of T_{FR} cells resulting in an imbalanced T_{FH}/T_{FR} ratio over time.

Conclusion:

This work uncovers the existence of mechanisms that, by acting on IRF4, can fine-tune the function and survival of effector Tregs and maximize the fitness of effector Tregs in chronic inflammatory conditions. These studies suggest that, despite the presence of autoimmune features such as dysregulated humoral

responses, the existence of a powerful effector Treg compartment that successfully survives in an unfavorable inflammatory environment can effectively limit disease development. Such a scenario is highly relevant to human SLE whose clinical heterogeneity could be linked, at least in part, to the presence/absence of long-lived effector Tregs.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: There is an association between natural antibodies, such as anti-phospholipid antibodies, and vasculature injury in stroke and in SLE models of systemic ischemic damage. There is also a correlation between chronic inflammatory micro-environments and long term neuro-degeneration. Preliminary data in our mild traumatic brain injury model demonstrated the development of long term inflammation at the Blood Brain Barrier (BBB) and mild neurocognitive memory defects. The objective of this study is to determine if the chronic inflammatory microenvironment produced in the BBB in our model, was correlated with increasing preferential association between complement and natural antibodies to mediated vascular damage. We utilized a long-term longitudinal study to explore this relationship.

Methods: Multiple HIFU exposure was used to induce cerebral vascular injury. Briefly, the animals were anesthetized with 5% Isoflurane and the scalp region was cleared of fur using Nair. Animals assigned to the HIFU-exposure (3 exposures 24 hours apart) experienced a one-millisecond pulse while sham animals did not. Animals were harvested at a series of time points 2 hours to 30 days post injury. Immunocytochemistry and Immunofluorescence analysis of brain slices was performed to assess vascular integrity and injury.

Results: In the immune competent (C57Bl/6) strain HIFU injury resulted in the activation of the endothelium of the BBB, increased permeability of the BBB to low molecular weight molecules, and deposition of complement C3b, all of which support disruption of endothelial integrity. In longitudinal studies, a sustained neuro-inflammation was evident 30 days after injury and correlated with neuro-cognitive deficits. Initial data has demonstrated increased IgG deposition on the luminal surface of the BBB endothelium immediately after injury and at 30 days post injury. At the 30 day post injury time point there is an increased susceptibility to vascular injury as evidenced by Ferritin deposits within the Virchow-Robin space of the BBB structural unit, specifically in the hippocampus. At early time points, IgG was associated with complement at the BBB, but epitopes associated with natural antibodies were not dominant. By 30 days, there was a preferential association between natural antibodies and complement deposition. Specifically, anti-phospholipid type epitopes were detected.

Conclusion: Preliminary data suggest that anti-phospholipid type natural antibodies have a stronger association with vascular damage at the 30 day time point than other pathogenic type antibodies. We are currently assessing if the anti-phospholipid antibodies are co-localized with ferritin breaches of the BBB. Elucidating the mechanics of vascular injury which results in both sustained neuro-pathology and neuro-cognitive decline would provide insight into the emergence and progression in vascular associated neuro-degeneration. These finding may illuminate a mechanism in Neuropsychiatric Systemic Lupus Erythematous (NPSLE), although there is a correlation of NPSLE with some antibodies, a well-delineated mechanism of how antibody induced cerebral damage occurs has not been defined.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Response Gene to Complement (RGC)-32 is an intracellular protein initially discovered in rat oligodendrocytes in response to complement activation. It plays a role in cell growth and promotes cell cycle activation and Akt phosphorylation. RGC-32 is also a downstream target of TGF-β in fibroblasts and renal proximal tubular cells and plays a role in renal fibrogenesis. In the immune system RGC-32 is expressed by both T and B lymphocyte subsets. Our prior studies have indicated that RGC-32 promotes Th17 differentiation of mouse CD4 T cells and is highly expressed in human IL-17+ CD4 cells. Whether RGC-32 expression in B cells plays a role their activation, differentiation and development of autoimmunity is not known. To address this question we used WT and RGC-32 KO mice to determine whether lack of RGC-32 impairs B cell differentiation and activation and/or alters autoimmune parameters in the Bm12-into-B6 chronic graft versus host disease (cGVHD) model of lupus.

Methods:

Purified B cells from WT or RGC-32 KO mice were cultured with lps, anti-CD40mAb, IL-21 and IL-6, IL-4 or TGFβ and RGC-32 mRNA and protein expression was determined by flow cytometry and RT-PCR. TLR-dependent and T-dependent B cell differentiation to plasma cells (PC) was induced with lps and with CD40mAb plus IL-4, respectively. The number of $CD138^{hi}B220^{lo}$ PC was determined 3 days later. Bm12-into-B6 cGVHD was induced by i.p. injection of $100x10^6$Bm12 splenocytes into WT or RGC-32 KO recipients. B cell parameters of cGVHD including host B cell number and activation, anti-dsDNA Ab production, GC B cell number and proliferation, PC number in spleen and bone marrow (BM), expression of transcription factors IRF4 and Blimp1 were assessed at 2 and 4 weeks by flow cytometry, RT-PCR, ELISA and ELISPOT.

Results:

RGC-32 mRNA was expressed at baseline in B cells and was upregulated by lps, anti-CD40mAb, IL-21 and IL-6. RGC-32KO B cells failed to differentiate normally to PC in vitro as demonstrated by a 2 fold reduction in PC numbers generated after lps and anti-CD40mAb+IL-4 stimulation and impaired upregulation of Prdm1 and IRF4 mRNA. In vivo, mRNA expression of RGC-32 was significantly upregulated in spleen cells from cGVHD mice compared to uninjected WT B6 mice. RGC-32 upregulation was detected in both $B220^+$ B cells and $B220^+$ PNA^+ germinal center (GC) cells. Induction of cGVHD in RGC-32KO hosts resulted in an attenuated autoimmune phenotype as demonstrated by: 1) decreased production of anti-dsDNA autoAb. 2) decreased number and proliferation of GC B cells. 3) decreased number of IgG anti-dsDNA secreting PC in BM and 4) decreased IRF4 and Prdm1 mRNA expression.

Conclusion:

These results suggest that expression of RGC-32 in B cells is critical for optimal GC proliferation, PC differentiation and autoantibody production in a murine model of lupus. These data support the idea that RGC-32 blockade has the potential to attenuate autoimmune parameters of cGVHD and possibly reverse abnormalities in the T and B cell pathways that contribute to lupus pathogenesis. These observations provide a compelling rationale for further investigating the therapeutic potential of RGC-32 blockade in murine and human lupus.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: BANK1 is a susceptibility gene for SLE, and we have shown that stimulation of TLR9 agonist leads to a reduction in the activation of the translation initiation pathway. Here we investigated the effects of the adaptor *Bank1* in TLR7 signaling using the B6.*Sle1.yaa*mouse, a lupus model that develops disease through exacerbated TLR7 expression.

Methods: Crosses of B6.*Sle1.yaa* with *Bank1*-/-mice were produced and studied for the development of disease and signaling following TLR7 and IFNa stimulation.

Results: Bank1 deficiency maintained several B and myeloid cell phenotypes close to normal wild-type levels. Most striking was the reduction in total serum IgG antibodies, but not of IgM, and reduced serum levels of autoantibodies, IL-6 and BAFF, features accompanied by reduced mortality. Purified B cells from *Bank1* deficient mice had strongly reduced *IFNb*, *Irf7*, *Aicda* and *Stat1* gene expression following TLR7 agonist stimulation. Furthermore, phosphorylation of the transcription factor STAT1 was impaired as was the nuclear translocation of IRF7, a key molecule in TLR7 signaling. As the optimal function of B cells depends on type I interferon, we investigated if *Bank1*deficiency had effects on the IFNAR signaling pathway. We demonstrate that BANK1 controls activation of the eIF4E translation initiation pathway induced by type I IFN, hence controlling interferon-inducible genes.

Conclusion: Our results show that BANK1 controls TLR7 and IFNAR signaling in B cells, modulating transcription and translation initiation events, respectively, and contributing to autoimmune disease development.

The Lymphotoxin/Megakaryoblastic Leukemia 1/Actin Axis As a Master Regulator of TLR Signaling in Lupus

Session Time: 9:00AM-11:00AM

Background/Purpose: Marginal zone macrophages (MZMs) of the spleen are essential for rapid and tolerogenic clearance of apoptotic cells (ACs). MZMs are decreased in two mouse models of lupus and in SLE subject spleens. Absence of lymphotoxin beta receptor (LTβR) signaling in the MZMs in lupus BXD2 mice leads to a defect in megakaryoblastic leukemia 1 (MKL1)/actin polymerization. The purpose of this study was to determine the mechanism underlying the development of inflammatory AC phagocytic MZMs.

Methods: Stimulation of LTβR signaling was carried out *in vitro* with an agonistic anti-LTβR and blocked *in vivo* with a soluble LTβR-Fc. MZMs were analyzed and sorted by flow cytometry. Gene expression analysis was carried out by RT-PCR. Time-lapse imaging was carried out on a Nikon A1R two-photon microscope. ACs were induced by dexamethasone and labeled with DAPI. Actin polymerization was determined using a GFP LifeAct adenovirus transfection of macrophages (Mϕs).

Results: Two-photon live cell imaging revealed defects in actin polymerization and slower cytoplasmic encapsulation of ACs at the surface of Mϕ from BXD2 and B6-*Mkl1*$^{-/-}$ mice. Ingestion of ACs occurred after prolonged membrane interaction (>5 min) with ACs. In contrast, stimulation of BXD2 Mϕ with an agonistic anti-LTβR resulted in strong actin polymerization. These Mϕs exhibited robust proactive degradation of ACs characterized by cytoplasm/actin protrusions, phagocytic cup formation, and digestion of ACs. *In vivo* LTβR signaling blockade of MZMs after administration of LTβR-Fc resulted in an increase in *Il6* and a decrease in *Il10*. There was also a 4-6 fold increase in the expression of serine proteases, normally found in azurophilic granules, including neutrophil elastase (*Elane*), Protenase-3, and Cathepsin G, in MZMs of BXD2 compared to B6 mice. Increases in ELANE activity were observed in BXD2 MZMs following AC phagocytosis or after addition of RNPs but were suppressed by anti-LTβR. Gene analysis shows that there was down-regulation of the intracellular inhibitor of TLR signaling, TRIM30α, in MZMs of BXD2, B6-*Mkl1*$^{-/-}$ or LTβ$^{f/f}$xCD19.Cre mice, compared to that in B6 MZMs. Down-regulation of TRIM30α in MZMs of BXD2 and B6-*Mkl1*$^{-/-}$ was further verified by confocal imaging analysis.

Conclusion: The results show that decreased LTβR signaling in MZMs results in enhanced immunogenic response to ACs via: (1) a defect in actin polymerization and defective AC phagolysosomes formation; (2) a decreased repression of serine proteases that can bind to DNA or RNA protein complexes in the endolysosome to promote inflammatory degradation of ACs that can stimulate TLRs; and (3) a decrease in TRIM30α which is a key inhibitor of downstream TLR signaling from endolysosomes and Mϕ. Since MZMs are essential for tolerogenic uptake of ACs, the work here pinpoints specific cellular mechanistic and molecular defects and suggest novel interventions that may reverse the immunogenic uptake of ACs.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The production of reactive oxygen species (ROS) via the oxidative burst has recently been implicated in regulation of inflammation and protection from arthritis, multiple sclerosis, and psoriasis. The aim of this project was to elucidate the impact of the oxidative burst on lupus-like autoimmunity.

Methods:

The clinical course of pristane-induced lupus (PIL) was compared between WT and ROS-deficient (Ncf1**) mice by analysis of serological markers and organ involvement. *Ex vivo*phagocytosis assays and flow cytometry were employed to analyze uptake and degradation of cell debris. Formation of neutrophil extracellular traps (NETs) was monitored in blood and peritonea. Involvement of the antioxidative response was investigated by qPCR and ChIP.

Results:

Ncf1** mice developed strongly elevated levels of typical lupus-autoantibodies, e.g., anti-dsDNA, anti-histone and anti-Sm/RNP, arthritis, and glomerulonephritis resulting in earlier death. The enhanced inflammation also gives rise to higher serum levels of pro-inflammatory cytokines. Mice with a specific ROS-deficiency in neutrophil granulocytes exhibited an intermediate phenotype. We observed a preferential uptake of dead cell material but not of inert latex beads into inflammatory monocytes and granulocytes, and a dramatically reduced ability to forms NETs in Ncf1** mice. A similar phagocytosis phenotype was observed in patients with SLE. Immunoglobulin G-coating of latex beads significantly enhanced their uptake. Genes related to the antioxidative response dependent on the transcription factor NRF2 were strongly downregulated in Ncf1** mice.

Conclusion:

Our results show that autoimmunity occurring in the ROS-deficient Ncf1** mouse gives rise to exacerbated Rupus. Aberrant phagocytosis in ROS-deficient animals caused by spontaneously occurring autoantibodies to surface molecules of dead cells and a defective regulatory antioxidative response contribute to this phenotype.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Glomerulonephritis (GN) is one of the most serious manifestations of systemic lupus erythematous (SLE). Lupus GN is characterized by severe inflammation and necrosis and it accounts for most morbidity and mortality. Although SLE occurs more often in women, both sexes develop GN and in males often develops earlier and is more severe. There is sex bias in SLE and estrogens may play an important role in GN susceptibility and progression. Interestingly, estrogen receptor alpha (ER-α) in the renal tissue is highly expressed and the renal specific estrogen-induced gene activation is second only to that of reproductive organs. Therefore, we investigated the impact of estrogens on the development of nephritis in both males and female mice by using an inducible model of immune-mediated nephropathy.

Methods: We first investigated the functional status of the immune system in the ER-α KO mice by immunizing them with standard foreign antigen (OVA). We then used the nephrotoxic serum induced nephritis (NTN) model to induce GN in the ER-α KO mice. ER-α WT littermates were used as control. Progression of renal disease was monitored by blood urea nitrogen and body weight. Renal damage was also assessed by histology. Nephrotoxic serum binding and immune complex deposition were determined by immunofluorescence. Quantitative real-time PCR was also performed to measure expression of TNF-α, IL-6, and MCP-1 in the kidneys of KO and WT mice.

Results:

We found that the ER-α KO and WT mice produced similar levels of anti-OVA antibodies upon OVA antigen immunization (p=n.s.). These results suggest that the lack of ER-α does not grossly impair the immune response. We also found that the lack of ER-α protects from NTN as the KO mice have significantly less kidney disease than the WT ($p<0.05$). The most striking differences were less glomerular cellular proliferation and fibrosis. Both sexes were protected albeit the males to a lesser extent. Importantly the NTN model was fully functional in the ER-α KO, as both strains of mice had similar levels of immune complex deposition within the glomeruli; both ER-α KO and WT mice increased the expression of pro-inflammatory cytokines such as TNF-α and IL-6 suggesting that the immune and inflammatory response were similar but that the differences in cellular damage were responsible for the renal protection.

Conclusion: Our results demonstrate that the lack of ER-α allows appropriate immune response but nevertheless protects from NTN, a model of lupus GN. Moreover, our results demonstrate that the protection is secondary to a reduced cellular damage rather than an impairment of the immune system. Interestingly, estrogens influenced the renal outcome also in males albeit to a lesser degree. Based on these results we conclude that estrogens not only play a role in predisposing to SLE but also are important in regulating the cell damage during GN.

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is regarded as a failure of the immune system to maintain tolerance to self-antigens. Despite steady advances defining the importance of inflammatory mediators in the progression and severity of the disease, the underlying mechanisms driving the development of autoimmunity remain unresolved. SLE is characterized by the presence of autoantibodies recognizing components of the cell nucleus. While the contribution of immune system dysfunction to the loss of immunological tolerance is an area of intense investigation, the potential role for alterations in the structure of the nucleus itself has not been considered. The nucleus is stabilized by a network of proteins called lamins, with B-type lamins anchored by associations with Lamin B receptor (Lbr). Lbr spans the inner nuclear membrane and associates with heterochromatin to maintain its distribution at the nuclear membrane margins. Impaired expression of Lbr causes autosomal dominant disruptions in nuclear structure that include the Pelger-Huet Anomaly. In mice, *Lbr* is within lupus susceptibility intervals identified on chromosome 1. Given the role of Lbr in stabilizing nuclear structure and its ability to bind chromatin, we hypothesized

that an autosomal dominant disruption in *Lbr*, would contribute to the development of anti-nuclear autoimmunity when expressed in a lupus-prone genetic background.

Methods: To introduce an autosomal dominant disruption in *Lbr* into a lupus-prone genetic background, c57Bl/6 mice harboring a spontaneous mutation within a splice junction in *Lbr* (B6.Lbr$^{ic/+}$) were crossed with the lupus-prone mouse strain New Zealand White (NZW). The development of autoantibodies and kidney damage was assessed in the (NZW×B6.Lbr^{ic})F_1 offspring.

Results:

Female (NZW×B6.Lbr^{ic})F_1 mice developed splenomegaly and glomerulonephritis with immune complex deposition, perivascular cellular infiltrates, and kidney damage. Titers of anti-chromatin antibodies of the IgG2 subclasses exceeded those of aged female MRL-Fas^{lpr} mice, and autoantibodies recognizing the A-type lamina and histone H3 with covalent modifications associated with gene activation were present. Anti-neutrophil antibodies developed, but the autoreactivity was not directed against myeloperoxidase or proteinase 3, rather it was attributable to anti-calreticulin of the IgM subclass.

Conclusion:

Alterations in nuclear structure contribute to lupus autoimmunity when expressed in a lupus-prone genetic background. Thus, environmental factors that disrupt nuclear architecture, such as viral infection or chemical exposure, may also promote lupus autoimmunity in genetically-predisposed individuals, suggesting a fundamental contribution for cell biology in the development of SLE.

Activation of T-Follicular Helper Cells and B Cells in Ultraviolet Light-Induced Murine Model of Systemic Lupus Erythematosus

Misha Zarbafian[1], Mehran Ghoreishi[2] and Jan Dutz[2], [1]Medicine, University of British Columbia Vancouver Fraser Medical Program, Vancouver, BC, Canada, [2]University of British Columbia Department of Dermatology and Skin Science, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Non-obese diabetic (NOD) mice repeatedly exposed to ultraviolet (UV) light and Toll-like receptor-7 (TLR7) agonist cream (imiquimod) develop lupus-like disease, modeling a possible cutaneous trigger for systemic lupus erythematosus (SLE) in genetically predisposed individuals. T-follicular helper (TFH) cells are known to support B cell maturation in germinal centers, leading to auto-antibody production in the context of SLE. Increased frequency of circulating TFH cells in the peripheral blood of human SLE patients has been associated with more severe disease, characterized by more lupus-associated auto-antibodies and end-organ manifestations. High-mobility group protein B1 (HMGB1) is a pro-inflammatory cytokine, which facilitates auto-antibody production in SLE both locally and systemically. HMGB1 release from the cell nucleus in skin occurs early in sun-induced lesions, and correlates with the progression of SLE disease. We sought to characterize TFH cells and B cells in skin-draining lymph nodes of NOD mice treated with UV and topical imiquimod cream (TLR7 agonist).

Methods: NOD and Balb/C mice received weekly UVB radiation (5000 J/m^2) and 25 µg of topical imiquimod cream. Skin-draining lymph nodes were analyzed by flow cytometry after four treatments to determine the activation status and number of TFH cells and B cells. Serum was collected to measure inflammatory cytokines such as TNFa, IL-6, and IFNg. Extra-nuclear expression of HMGB1 was evaluated in skin samples from both strains after four treatments.

Results: There was expansion of both TFH and B cells, as well as increased expression of the B cell activation marker CD40 in skin-draining lymph nodes of NOD mice following combined UV and imiquimod therapy, in contrast to Balb/C mice. Extra-nuclear expression of HMGB1 was greater in NOD mice, whereas expression in Balb/C mice was largely limited to the nucleus.

Conclusion: Skin-draining lymph node TFH cell expansion is an early event after UV and TLR7 agonist therapy and is correlated with auto-antibody production. HMGB1 redistribution in the skin also correlates with auto-antibody production. Quantification of circulating TFH cells and local HMGB1 expression may serve as markers for predicting SLE onset in genetically predisposed individuals.

PD-1 Signaling Interferes with OX40 to Alter the Suppressive Function and Proliferation of CD4+ Regulatory T Cells in Lupus Mice

Maida Wong[1] and Bevra H. Hahn[2,3], [1]Division of Rheumatology, Department of Medicine, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, [2]Medicine, UCLA David Geffen School of Medicine, Division of Rheumatology, Los Angeles, CA, [3]Rheumatology, Professor Emeritus, Department of Medicine/Rheumatology, David Geffen School of Medicine UCLA, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In systemic lupus erythematosus (SLE), the dysregulated production of autoantibodies is a consequence of disrupted T cell homeostasis. Programmed death-1 (PD1), a negative regulatory signal in T cells, limits certain T-cell mediated immune responses. Increased PD1 expression on T cells inhibits cell activation and proliferation, and its blockade reinstates immune cell function. Our laboratory has shown that attenuated, but not absent PD1 signaling enables T_{reg} to survive, and suppress helper T cells (T_h) and B cells. These suppressors are designated $PD1^{lo}T_{reg}$. Our gene array data have shown that attenuated PD1 expression in T_{reg} down-regulates several members of the TNF receptor family (TNRF). It has been reported that OX40, a member of the TNRF superfamily, is known to be up-regulated in immune cells from patients with autoimmune diseases. We therefore hypothesize that one mechanism by which PD1 sustains T_{reg} proliferation and suppressive function is by reducing OX40 expression on T_{reg}.

Methods: We treated lupus-prone BWF_1 mice with a neutralizing Ab against PD1 or control isotype-matched IgG intraperitoneally. T_{reg} from the spleens were isolated and cocultured with unmanipulated $CD4^+CD25^-$ T_h and B cells. Expression of OX40 and PD1 on T_{reg} was measured by flow cytometry. The ability of T_{reg} to regulate T_h was assessed by measuring the ratio of T_{reg}: T_h after coculture, with the phenotypes defined as: T_{reg} ($Foxp3^+CD4^+CD25^+CD127^-$), T_{h1} ($CD4^+CD25^-IFN\gamma^+$), T_{h2} ($CD4^+CD25^-IL4^+$), T_{h17} ($CD4^+CD25^-IL17a^+$). Cytokine production of T_{reg} and T_h was measured in the culture media by ELISA. Next, we treated T_{reg} with an agonistic OX40 Ab *in vitro*, and set up the colculture experiments and deterrmine cell proliferation and cytokine production as described above.

Results: OX40 expression was lower in $PD1^{lo}T_{reg}$ from anti-PD1-treated mice when compared to $PD1^{hi}T_{reg}$ from controls. In particular, all $Foxp3^+PD1^{lo}T_{reg}$ have either low or no OX40 expression. T_h was predominantly T_{h2} over T_{h1} and T_{h17} in the coculture with $PD1^{lo}T_{reg}$, with decreased expression of IFN-g and IL-17 in the culture media. When $PD1^{lo}T_{reg}$ were treated with agonistic OX40, their suppressive function was attenuated, but not completely abrogated. Although Foxp3 expression in $PD1^{lo}T_{reg}$ was not significantly diminished, there was decreased production of TGFβ . In the coculture, activation of OX40 was associated with increased proliferation of T_{h1}. However, treating $PD1^-T_{reg}$ with antagonistic OX40 could not restore the suppressivity in T_{reg}.

Conclusion: Effective induction of T_{reg} is associated with low expression of PD1, which permits the cells to survive and perform a cell suppressive function. Attentuated PD-1 expression in T_{reg} reduced OX40 expression on T_{reg}, which helped restore the suppressive capacity and proliferation of T_{reg}. The suppressive function induced by low PD1 expression is influenced by, but not dependent on, low OX40 expression. PD1 and OX40 signaling most likely crosstalk to regulate the suppressive capacity and survival of T_{reg} to achieve peripheral tolerance in SLE but are not the only pathways involved.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Past studies reported lymphopenia mouse transfer model which transfer $CD4^+CD25^-$ cells from wild-type BALB/c mouse into athymic nude BALB/c mice produce lupus-like systemic autoantibodies and develop multiple organ-specific autoimmune diseases. Previously, we reported that transferred T cells undergo homeostatic proliferation and differentiate into follicular helper T cells under the presence of intestinal microbiota, which promote germinal center formation and autoantibody production within 4 weeks. Next, we would like to investigate the roles of intestinal microbiota in the pathogenesis of long-term organ-specific autoimmunity in this mouse model.

Methods: $CD4^+CD25^-$ cells taken from spleen of wild-type BALB/c mouse were adoptively injected into nude BALB/c mice. Some recipient mice were orally administrated broad-spectrum antibiotics including ciprofloxacin, imipenem, metronidazole and vancomycin in drinking water. Immunofluorescence, and ELISA were performed to detect ANAs and anti-parietal cell antibodies. Histopathological investigation was performed 5 month after the transfer.

Results: T cell-transferred nude mice developed gastritis, colitis, sialoadenitis and oophoritis at high rates in 5 months. Combination of above 4 antibiotics decreased the incidence of gastritis, colitis and oophoritis, but exacerbated sialoadenitis. Single vancomycin administration inhibited the colitis and exacerbated the others.

Conclusion: Depletion or alteration of intestinal microbiota can ameliorate or exacerbate organ-specific autoimmunity in a lymphopenia-induced autoimmunity mouse model. This result should be noted when we search for the novel microbiological therapeutic approach to autoimmune diseases. Further investigation is needed to detect specific microorganisms involved in the inflammation of each organ.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Excessive exposure to sunlight, particularly ultraviolet B (UVB), induces autoimmune skin inflammation and other skin diseases. Although UVB mainly causes damage to the epidermis, photodamage is followed by inflammatory responses, which can be highly detrimental. Skin inflammation in turn can further exacerbate photodamage and, if recurring or long-lasting, can induce pathogenic alterations. Previous studies from ours and other groups showed that the immediate response in the skin to UVB exposure is to induce the release of TNFα and other inflammatory cytokines from keratinocytes in the epidermis. Neutrophils are the most common circulating leukocyte. Similar to other injury or acute inflammation, neutrophils are also the earliest immune cells recruited to the site of photodamage in response to UVB exposure, followed by the monocyte/macrophages and T lymphocytes. However, little is known about the role of neutrophils in UVB-induced skin inflammation, and previous photobiology studies have mainly focused on the role of other cell types on UVB-induced detrimental effects in skin. Neutrophil NETosis, a novel type of neutrophil cell death, releases neutrophil extracellular traps (NETs) that have been shown to be important in autoimmune inflammation. Given that the induction of TNFα and infiltration of neutrophils both appear within hours after UVB exposure, and neutrophils are unable to become NETotic in TNFα KO mice, we sought to determine whether UVB exposure can induce neutrophil NETosis in vivo.

Methods:

Human primary neutrophils were treated without or with TNFα to study the in vitro effects of TNFα on neutrophil NETosis. To explore the effects of UVB exposure on neutrophil NETosis in vivo during the skin inflammatory responses, we exposed C57/BL6 wild-type and *MRL/lpr* lupus prone mice to UVB according to our published protocol with minor modification.

Results:

In the in vitro study, we found the increased neutrophil NETosis when we treated human primary neutrophils with TNFα, a proinflammatory cytokine that can be induced in UVB-exposed mice. In the in vivo study, our preliminary experiments showed that UVB exposure (250 mJ/cm^2/day for 5 consecutive days) of female wild-type mice significantly induces skin inflammation with infiltration of inflammatory cells, and many of the infiltrated neutrophils become

NETotic in the inflamed skin of the UVB exposed WT mice as compared to sham WT mice without UVB exposure. Similarly, we found that UVB exposure (100 mJ/cm^2/day for 10 consecutive days) can also induce neutrophil NETosis in UVB-irradiated *MRL/lpr* lupus-prone mice

Conclusion:

Our studies indicate that UVB exposure of mice can induce skin inflammation with increased neutrophil NETosis, possibly through the induction of the proinflammatory cytokine, TNFα. Neutrophil NETosis may be involved in UVB-induced skin inflammation.

Type 1 Interferon in the Skin Stimulated By Ultraviolet B Light Generates Immune Suppression Mediated By Idoleamine 2,3-Dioxygenase 1

Clayton Sontheimer[1] and Keith B. Elkon[2], [1]Pediatric Rheumatology, University of Washington, Seattle, WA, [2]Division of Rheumatology, University of Washington, Seattle, WA

Session Title: Systemic Lupus Erythematosus - Animal Models Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Photosensitivity is a common symptom in patients with systemic lupus erythematosus (SLE) and lupus skin lesions show local Type 1 Interferon (IFN-I) profiles similar to that seen in the blood. The pathogenic effect of ultraviolet light (UV) in SLE stands in contrast to the immunosuppressive effects of UV in the normal host, and UV light is used to treat various skin diseases such as psoriasis. Differences in the mechanisms linking UV light to immune suppression versus inflammation and cutaneous flares of lupus are not well understood. Here, we asked whether, and under what conditions, repetitive UVB-exposure induces IFN-I and examined what its biological effects were in the skin in the normal host.

Methods:

Shaved C57BL/6 (B6) and IFNAR KO (B6 background) mice were irradiated with narrowband UVB at 100 mJ/cm^2/day for 5 consecutive days. To inhibit idoleamine 2,3-dioxygenase 1 (IDO1) *in vivo*,1-Methyl-d-tryptophan (1-MT) was added to drinking water (2 mg/mL) and fed to mice *ad libitum*beginning 3 days prior to irradiation until experiment end. Serial punch biopsies (6 mm) were obtained at 3, 24, and 72 hrs following UVB exposure. Skin immune cell populations were analyzed by flow cytometry using CD45, CD11b, Ly6C, Ly6G, MHC II, CD64, and CD3. Skin samples were examined for mRNA expression by QPCR of pro-inflammatory cytokines and Interferon Stimulated Genes (ISG), and skin samples were analyzed histologically by H&E and for IDO1 expression by immunofluorescence

Results:

Repeated UVB exposure in normal wild-type B6 mice induced a modest IFN-I skin response with bimodal peaks at 3 and 72 hrs when compared to mice receiving a single UVB dose and non-irradiated control mice. Surprisingly, UVB-irradiated IFNAR KO mice that were unable to respond to IFN-I, had increased levels of pro-inflammatory cytokines such as TNF and IL-6 at 3 and 24 hr time points and had increased levels of inflammation by pathology scores. These findings suggest a protective role for IFN-I. Since IDO1 is an ISG and a potent suppressor of inflammation, we examined IDO1 expression following UVB. Significantly, UVB induced expression of IDO1 in the skin in B6 but not IFNAR KO mice. Consistent with this finding, inhibition of IDO1 by 1-MT treatment in B6 mice caused increased cellular infiltration, worsened histologic appearance, and increased pro-inflammatory cytokines similar to that seen in IFNAR KO mice. Infiltrating dendritic cells in IDO1-inhibited mice had decreased IL-10 levels compared to B6 mice. IDO1 inhibition in IFNAR KO mice did not alter UVB-induced inflammation consistent with IFN-I and IDO1 being in the same pathway.

Conclusion:

In the normal host, repeated doses of UVB induces an IFN-I response in the skin that attenuates pro-inflammatory signals and limits cellular recruitment. Immunosuppression is at least in part mediated though expression and activity of IDO1. This establishes a unique role for IFN-induced IDO1 in promoting the protective effects of UVB in healthy individuals. Loss of this pathway may contribute to the enhanced UVB response as observed in lupus photosensitivity.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

MicroRNAs (miRs) are an important class of regulators of gene expression that are associated with a variety of biological functions. Deregulation of endogenous miR155 was observed in many autoimmune conditions, including SLE. We herein examine the role of miR155 in the development of systemic manifestations in murine pristane induced lupus by evaluating the severity of organ involvement and assessing serum antibody-levels and T helper cell homeostasis.

Methods:

MiR155-deficient (miR155-PIL) and C57/Bl6 (WT-PIL) mice were injected i.p. with 0.5ml of pristane or PBS as control (WT-PBS). In order to observe the effects of miR155 deficiency in fully developed SLE, we analyzed the mice 8 months after induction.

A blinded specialist appraised histological features of GN using the composite kidney biopsy score (KBS). Histological features of pneumonitis were quantified by an image analysis system: Lungs were scored for the severity of perivascular inflammation by analyzing the numbers of affected vessels and the area of the inflammatory infiltrate. In order to assess the composition of these infiltrates, specimens were stained with B220 (B), CD3 (T), Neu7/4 (neutrophils) and F4/80 (macrophages) and analyzed by cell-identification algorithms for nuclear segmentation (HistoQuest®).

Anti-dsDNA, anti-histone and anti-chromatin antibodies (abs) were measured by ELISA.

Lymphocytes were isolated from spleens and analyzed separately for each mouse by standard FACS procedures. For analysis of the Th1, 2 or 17 subsets, respectively, cells were re-stimulated *in vivo*with anti-CD3 and anti-CD28abs.

Results:

Lungs were affected in both pristane-treated groups, but not in controls. MiR155-PIL had reduced lupus severity as indicated by significantly decreased perivascular inflammatory area with B cells being the most prominent inflammatory cell type in the HistoQuest analysis. Without showing clinical abnormalities WT-PIL had a more severe renal involvement in the kidney biopsy score than miR-PIL. Corresponding with reduced severity in organ involvement, miR155-PIL had lower serum levels of anti-dsDNA, anti-histone and anti-chromatin-abs, decreased frequencies of $CD4^+$ cells (14.24 ± 0.7587 vs. 18.04 ± 1.075, p=0.01) and slightly lower frequencies of activated $CD4^+CD25^+Foxp3^-$ cells (1.539 ± 0.1279 vs. 1.838 ± 0.2259, p=ns.). Interestingly, also frequencies of $CD4^+CD25^+Foxp3^+$ regulatory T cells were lower in Mir155-PIL (1.689 ± 0.1388 vs. 2.375 ± 0.2320, p=0.03). Upon restimulation, $CD4^+$cells showed a more pronounced Th2 and Th17 response in WT-PIL, but no significant differences in Th1 phenotype.

Conclusion:

MiR155 deficiency in PIL mice did not prevent the development of disease, but was associated with less severe lung and kidney involvement, lower serum auto-abs levels and lower Th17 and Th2 frequencies when analyzed in fully established PIL after 8 months. Thus, antagonisation of miR155 might be a beneficial future approach in treating SLE.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Human-papilloma virus vaccine (HPVv) is currently used worldwide. Still this vaccine has been linked to a variety of neurological and autoimmune manifestations. For instance, case series have document adverse events related to the vaccination in systemic lupus erythematosus (SLE). Moreover, the HPVv contains aluminum hydroxide as adjuvant which has been also associated with neurological adverse events. Therefore, our goal was to evaluate the effects of immunization with HPVv or Alum in SLE prone mice.

Methods:

Three groups of NZB/W F_1 mice were vaccinated with HPVv (Gardasil), Aluminum hydroxide (Alum) or the vehicle at 6 weeks of age. The mice received three injections equivalent to the human dose. Mice were followed for lupus and behavior parameters, including anti-dsDNA antibodies titers, urine protein levels, immunoglobulin deposited in the kidney mesangium, behavioral and neurocognitive functions (i.e. novel object recognition, staircase, Y-maze, rotarod and the forced swimming tests).

Results:

Mice immunized with HPVv had higher titers of anti-dsDNA antibodies earlier as well as accelerated proteinuria between the age of 20 to 24 weeks ($p<0.05$) compared with vehicle and alum groups. Similarly, we observed a trend in long and short term memory deficiency following immunization with HPVv. Interestingly, the mice did not show any motor involvement as in the roatorod all the animals had good performance; however in the FST mice immunized with HPVv were immobile for a longer time in comparison to Alum and vehicle which indicates depressive like behavior.

Conclusion:

We demonstrated that immunization with the HPVv accelerates the onset of renal disease in lupus mice. Likewise, we showed that vaccine together with its adjuvant can affect behavioral and neurocognitive functions in particular accelerating the appearance of depressive like behavior.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Glomerulonephritis (GN) represents a major cause of morbidity & mortality. The standard for diagnosing GN is through renal biopsy, but this is not performed uniformly across many centers. There is an unmet need to identify a noninvasive approach for recognizing GN. Recent advances in deep tissue imaging using probes detected by nearinfrared (NIR) wavelengths have enabled the noninvasive probing of biologic activity. Macrophage infiltration of the kidney is observed in early GN and once activated, express the cysteine protease cathepsin B. Thus, renal macrophage activation can be assessed using an NIR probe that becomes fluorescent upon cleavage by cathepsin B. We tested the ability of using NIR optical imaging to assess renal macrophage activation as a noninvasive marker for early-stage GN.

Methods: GN was induced in 129 mice by nephrotoxic serum (NTS) delivered intravenously (IV). Proteinuria was assessed using albumin ELISA &

chromogenic creatinine assay. H&E and PAS stained slides of mouse kidneys were observed using light microscopy. Presence of renal macrophages was confirmed using FACS. NIR optical imaging of anesthetized mice was performed following IV administration of a cleavable sensor for cathepsin B & fluorescence intensity of kidney regions quantified.

Results: In mice with uninflamed kidneys, we confirmed the paucity of renal macrophages. Accordingly, there was minimal renal fluorescence signal as determined by fluorescent molecular imaging of cathepsin B activity. 3 days post-NTS administration, we observed a massive influx of macrophages into the kidney, along with nephrotic range proteinuria. This correlated with a significant increase in renal fluorescence intensity signal in NTS mice compared to control mice.

Conclusion: Induction of GN by NTS caused significant macrophage infiltration, which was detected noninvasively by a cathepsin B-activatable probe and NIR optical imaging. These data establish the proof-of-principle that NIR optical imaging may represent a translatable approach to establishing early stages of GN.

Background/Purpose: Tissue clearing approaches such as CLARITY renders tissue transparent, and in combination with two-photon microscopy, enables microscopic visualization deep internal structures within unaltered organs. These cutting edge approaches have drastically improved the understanding of cellular circuits in the brain. However, application of this approach has only recently been described for the kidney. Here, we clear mouse kidneys to better understand the immune cell architecture following induction of nephrotoxic nephritis (NTN) using a modified lipid removal approach that also worked for human kidney fragments.

Methods: 129 mice were injected intravenously with nephrotoxic serum to induce NTN. Mice were perfused with an acrylamide monomer solution to form the basis of the hydrogel. Lipid removal was accomplished using 8% sodium dodecyl sulfate (SDS). An aminoalcohol solution was used to quench light absorbing heme in red blood cells trapped within the tissue. Cleared mouse kidneys were stained with antibodies specific for B cells, T cells, macrophages, and dendritic cells (DCs). Human kidney fragments were incubated in acrylamide monomer solution, then cleared as mentioned above. Cleared tissue was imaged using two-photon microscopy.

Results: Compared to previously published protocols, perfusion of acrylamide monomers into mice significantly accelerated the tissue clearing process. Enhanced tissue clearing was observed when we incubated kidneys in aminoalcohols. We observed vast networks of lymphocytes, macrophages, and DCs in cleared NTN kidneys compared to control kidneys. Human kidneys also were cleared using this approach, and we noted DC networks in healthy donor controls.

Conclusion: We identified a new protocol that enhanced and accelerated tissue clearing in mouse and human kidneys. Using this approach, we found elaborate networks of lymphocytes and monocyte-derived cells in NTN mouse kidneys. We also observed DC networks in healthy human kidney donor fragments. These data demonstrate the utility of tissue clearing in evaluating cellular architecture in mouse and human kidneys.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Peptidylarginine deiminases (PADs), specifically PAD4, have recently been implicated in the pathogenesis of systemic lupus erythematosus (SLE) through their role in citrullinating histones in myeloid cells and promoting neutrophil extracellular trap (NET) formation. Systemic administration of the pan-PAD inhibitors Cl-amidine and BB-Cl-amidine were previously shown to abrogate lupus manifestations and vascular damage in various murine models of SLE, including improvements in skin disease in the MRL/*lpr* model. Whether topical administration of PAD inhibitors can modulate skin involvement in murine lupus once disease is clinically apparent, without promoting other systemic effects, remains to be determined.

Methods: MRL/lpr mice received topical administration of either vehicle, the pan-PAD irreversible inhibitor Cl-amidine or the PAD4-specific reversible inhibitor GSK484 twice daily at 20 mg/kg, upon the development of skin rash. Only affected skin areas were treated. Mice were euthanized at 17 weeks of age. Autoantibodies were quantified by ELISA. Urinary albumin:creatinine ratios were calculated. Cell subsets in the spleen were quantified by flow cytometry and bone marrow NETosis was measured by fluorescent microscopy.

Results: Upon development of facial alopecia, treament with topical Cl-amidine and GSK484 induced an initial improvement in the area and severity of the lesions compared to the vehicle-treated mice. However, the skin effects observed in the GSK484-treated mice were transient, whereas the Cl-amidine treated mice continued improving to the point that no facial alopecia could be detected at euthanasia. By histology, no mice treated with Cl-amidine developed ulcers, while 25% of GSK484 and vehicle-treated mice did. Otherwise, preliminary histology analysis showed that skin inflammatory scoring was not statistically different between groups. Further, total body, spleen or lymph node weight did not differ among the 3 groups. Skin topical treatment did not modify bone marrow NETosis or circulating autoantibodies. Analysis of splenic immune cell subsets revealed that Cl-amidine-treated mice displayed significant decreases in CD4+ T cells and significant increases in neutrophils.There were no significant differences between GSK484 and vehicle-treated mice in any systemic features.Topical administration was well tolerated by mice.

Conclusion: Topical administration of pan-PAD inhibitors may modulate skin disease in lupus animal models. Future studies should further assess the role of topical PAD inhibition in SLE. This study supports a putative role for PAD inhibition as a therapeutic approach in this disease.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Animal Models Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: DNA, nucleosomes, and other deoxyribonucleoproteins (DNP) are currently believed to be the key autoantigens in SLE. However, these extracellular DNP itself appear to be just a cellular debris without any essential function. This paradox could open up a potential for degradation of the autoantigen and anti-dsDNA-containing ICs. We were to evaluate efficacy and safety of experimental in vivo blood perfusion through DNase I-containing magnetic beads under preliminary short-term examination using rat model of SLE-like alterations of DNP elimination.

Methods: In the experiments we used 20 female Wistar rats (50-54 weeks), randomized in 2 groups. Precalculated group size was 10 rats for each group. All the experimental protocols fulfilled the Declaration of Helsinki of the World Medical Association. The SLE-like disorders of DNP elimination were simulated by method of N. Jiang et al (2003) which was followed by intravenous injection of anti-dsDNA. Magnetic beads were synthesized using the emulsion polymerization technique. In the experimental group after preliminary heparinization blood was perfused through mini column with DNase I-containing magnetic beads (0.2 ml). Beads for the placebo group didn't contain any active substance. Titers of IgG deposited in rat kidneys (IgG_f) were measured by direct immunofluorescence on kidney cryoslices, serum circulating immune complexes (CIC) by polyethylene glycol precipitation assay, and plasma DNA by fluorimetry with PicoGreen. serum anti-dsDNA, CBC, total plasma protein, plasma creatinine, ALT, and AST were determined using conventional methods. All these measurements except IgG_fwere performed before and after perfusion.

Results: There were no significant differences between experimental and placebo groups in the initial marker means. We revealed distinct differences

between the experimental and placebo control groups in DNA ($p<0.001$) and CIC concentrations ($p<0.001$) after the perfusion. Geometric mean of IgG_f titer was significantly higher in placebo perfusion group comparing to perfusion through DNase I-containing beads ($p=0.002$). After the perfusion serum creatinine, being initially increased, demonstrated significant lowering in the experimental group comparing to placebo ($p<0.001$). Other markers didn't reveal any significant changes in both groups.

Conclusion: We have demonstrated clear efficacy of the extracorporeal perfusion in vivo for preventing kidney damage by diminishing of circulating DNA and CIC. As we speculated, the modeling protocol simulates not only glomerular deposition of DNA-containing immune complexes, but also induced filtration disorder. Lowering of DNA and DNA-containing immune complexes by the perfusion could diminish the extent of kidney damage. There was no blood cell destruction or hepatotoxicity during our experiment.

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Renal disease with loss of organ function results in significant morbidity and mortality in SLE. In the kidneys of affected patients, autoantibody-containing immune complexes (ICs) trigger pathological changes via activation of complement cascades and Fc receptors on resident and infiltrating cells. Bruton's tyrosine kinase (BTK) is a tyrosine kinase important for B cell development, Fc receptor signaling, and macrophage polarization. In this study, we explore the role of BTK in the pathogenesis of nephritis in an inducible model of lupus nephritis (LN).

Methods:

We investigated the effects of a novel, highly selective and potent (mouse whole blood CD69 IC_{50}= 13±2 nM) BTK inhibitor, BI-BTK-1 (Boehringer Ingelheim), in female 129 sv/J mice (10 weeks of age) injected with nephrotoxic serum (NTS), an experimental model which closely mimics LN. Mice pre-immunized with rabbit IgG (Day 0) were administered NTS containing rabbit anti-mouse glomerular antibodies (Day 5), inducing a severe IC-mediated crescentic glomerulonephritis. Mice were treated once daily with vehicle alone or BI-BTK-1 (0.3-10 mg/kg, n=16/group), beginning on Day 4. In addition, mice that did not receive the NTS transfer were used as healthy controls.

Results:

NTS-challenged mice treated with BI-BTK-1 exhibited a statistically significant, dose responsive protection from kidney disease compared to control treated mice, despite equal levels of glomerular IgG deposition and mouse anti-rabbit IgG in all experimental groups. Compared to control treated mice, NTS-challenged mice treated with 10 mg/kg BI-BTK-1 had significantly less proteinuria (1220 mg/dl vs 10 mg/dl, respectively, $p<0.0005$), serum creatinine (0.74 mg/dl vs 0.48 mg/dl, respectively, $p<0.03$), and BUN (82 mg/dl vs 25 mg/dl, respectively, $p<0.03$) (Day 11). Histology assessment confirmed marked renal protection in the BI-BTK-1 treatment groups, as evidenced by significantly less immune deposition ($p<0.0001$), endocapillary proliferation ($p<0.0001$), glomerular crescent formation ($p<0.0001$), interstitial inflammation ($p<0.002$), and tubular casts/dilatation ($p<0.0001$). Flow cytometry analysis showed decreased recruitment of inflammatory monocytes from the splenic reservoir in BI-BTK-1 treated mice. Furthermore, serum profiling and kidney gene expression analyses revealed that BTK inhibition was associated with a significant decrease in the levels of key LN-relevant inflammatory cytokines and chemokines (e.g. MIP-1a, MCP-1 and CSF-1).

Conclusion:

Our results suggest an important role for BTK activation in myeloid cells in the pathogenesis of immune complex-mediated nephritis. Studies to examine the effect of treatment initiation after the development of nephritis are now in progress. Taken together with previously published studies, these findings further strengthen the rationale for selective BTK inhibition as a promising approach to the treatment of LN.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pentraxin 3 (PTX3) is an acute-phase protein released by different cell types including renal epithelial cells and immune-competent cells. PTX3 is able to either dampen or fuel inflammation through binding of apoptotic cells and complement fragment 1 (C1q).

Anti-dsDNA and anti-C1q antibodies are associated with lupus glomerulonephritis (LGN). By contrast, we have recently demonstrated a negative association between anti-PTX3 antibodies and LGN and a direct correlation between PTX3 renal staining and proteinuria in SLE patients.

Hereby we aim at exploring effects of anti-PTX3 antibodies in a murine model of SLE, focusing on lupus-like nephritis.

Methods: Thirty New Zealand Black/White (NZB/NZW F1) mice were split into 3 groups of 10 mice each and intraperitoneally injected with 100 µg of PTX3 in 100 µl of alum and 100 µl of phosphate buffer saline (PBS) (group 1), 100 µl of alum and 100 µl of PBS (group 2) or 200 µl of PBS (group 3), 3 times 3 weeks apart from the 11^{th} week of age, until natural death.

We analyzed titers and time of occurrence of anti-PTX3, anti-dsDNA and anti-C1q antibodies by monthly blood sampling since week 11. Antibody serum levels were evaluated by standardized home-made ELISA and expressed as the median (min-max) of the mean optical density of the double of every serum.

Proteinuria was weekly examined by multireactive strips (Siemens). Survival and proteinuria-free survival (<300 mg/dl) were evaluated according to Kaplan-Meier method.

Kidneys, lungs, liver and spleen were harvested at death for histological analysis. Expression of collagen (Coll)-IV and TGF-β mRNA was evaluated on kidney specimens by spectrophotometric analysis.

IBM SPSS Statistics 22 for Windows software (IBM SPSS Inc., USA) was used for statistical analysis.

The study was approved by the National Institutional Animal Care and Use Committee.

Results: Serum autoantibody and proteinuria levels are reported in Table 1. Only group 1 mice developed anti-PTX3 antibodies. Anti-dsDNA and anti-C1q antibodies appeared significantly later and at lower titer in group 1 vs. group 2 and 3 ($p<0.0001$). Group 1 mice lived significantly longer than control mice ($p=0.03$) and had proteinuria significantly delayed and reduced ($p<0.05$, weeks 22 to 28).

Coll-IV and TGF-β mRNA were found less frequently in kidneys from group 1 mice vs. group 2 and 3 (TGF-β, group 1 vs. group 2, $p =0.028$; group 1 vs. group 3 $p=0.042$; Coll-IV group 1 vs. group 2, $p=0.018$; group 1 vs. group 3, $p= 0.029$). No significant difference was found in group 2 vs. group 3.

Harvested organs displayed inflammatory lesions in all mice, albeit milder lesions in group 1. Seven out of 10 mice of group 2 and all mice of group 3 had mesangial hyperplasia and renal perivascular lymphoplasmocitosis, not found in group 1.

Conclusion: Anti-PTX3 antibodies seem to attenuate and delay lupus-like manifestations including LGN in NZB/NZW F1 mice

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We previously reported that Janus kinase/signal transducer and activator of transcription (JAK/STAT) pathway-mediated regulation of interferon (IFN) regulatory factor (IRF)-related genes may have an important role in the disease activity of systemic lupus erythematosus (SLE) through analyzing the difference of gene expression in peripheral blood CD3+ T cells obtained from active and inactive phases of SLE patients. Recently pan JAK inhibitor tofacitinib (TOFA) were developed and successfully applied to patients with rheumatoid arthritis. Therefore, the application possibility of TOFA was investigated for the new therapeutic strategy of SLE.

Methods: Monotherapy with TOFA or dual therapy with TOFA and 0.5mg/kg dexamethasone (DEXA) had been administered to two-lupus model mice with different genetic background, MRL/lpr for ten weeks and (NZB/NZW) F1 for eleven weeks, respectively. We evaluated and analyzed the disease, pathological and immunological condition of these mice. In addition, the gene expression obtained from SLE mouse CD4+ and patients CD3+ T cells were analyzed by DNA microarray and real-time PCR.

Results: Anti-DNA antibody titers and proteinuria were decreased in any TOFA administered groups. Both glomerular and interstitial nephritis were ameliorated in pathological kidney image analysis. Deposition of immunoglobulin and complements in the kidney were also significantly diminished. In CD4+ T cell analysis, $CD44^{low}CD62L^{high}$ naïve cells increased and $CD44^{high}CD62L^{low}$effector/memory cells significantly decreased in TOFA administered groups. Dual therapy with DEXA showed tendency to indicate stronger inhibitory effect comparing with monotherapy through any analysis. After TOFA administration, the gene expression of IFN induced protein with tetratricopeptide repeats 3 (IFIT3) that is related with IFN signaling pathway and contribute to anti-viral mechanism was significantly suppressed in both CD4+ from lupus prone mice and CD3+ T cells from SLE patients.

Conclusion: Both TOFA monotherapy and dual therapy with DEXA could suppress nephritis and modify immunological function in SLE mice with different genetic background. IFN signaling pathway was supposed to be important for the functional mechanism of TOFA to improve the disease condition. TOFA may contribute to the development of a new therapeutic strategy for SLE.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic lupus erythematosus (SLE) is an autoimmune disease that is characterized by high morbidity and mortality and remains challenging in treatment. Dendritic cells (DCs) have been shown to participate in the initiation and perpetuation of lupus pathogenesis. DCs that can induce tolerogenicity appear as potential cell-based therapy in this condition. In this study, we examined the *in vitro* tolerogenic properties of bone-marrow derived DCs (BMDCs) in the murine lupus setting.

Methods:

We used lentiviral transduction of RelB-silencing shRNA to modify expression of RelB, a key transcription factor regulating DC maturation, in BMDCs from MRL/MpJ mice. Tolerogenic properties of RelB-modified DCs were compared to scrambled control (SC)-modified DCs.

Results:

RelB expression was found to be significantly reduced in RelB-modified DCs derived from MRL/MpJ mice, wild type of the same genetic background as MRL/lpr lupus-prone mice. These MRL/MpJ RelB-modified DCs displayed semi-mature phenotype with expression of lower levels of co-stimulatory molecules compared to SC-modified DCs. RelB-modified DCs were found to be low producer of IL-12p70, can induce hyporesponsiveness of splenic T cells from MRL/MpJ and lupus-prone MRL/lpr mice. Furthermore, they downregulated IFN-γ expression and induced IL-10 producing T cells in MRL/MpJ splenocytes, and attenuated IFN-γ and IL-17 expression in MRL/lpr splenic CD4+ lymphocytes. Splenocytes primed by RelB-modified DCs demonstrated antigen-specific suppressive effect on allogeneic splenocytes.

Conclusion:

RelB-silencing in DCs generates DCs of tolerogenic properties with immunomodulatory function and appears as potential option of cell-targeted therapy.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sunlight, via ultraviolet B (UVB) irradiation, is a well-recognized trigger of cutaneous lupus erythematosus (CLE) skin lesions. TNF-like weak inducer of apoptosis (TWEAK), a TNF superfamily member (TNFRSF12), is a soluble cytokine that binds to its sole known signaling receptor, Fn14 (TNFRSF12A). TWEAK and Fn14 are upregulated following tissue inflammation and/or injury, and this signaling pathway is important in critical biologic processes including angiogenesis, cell survival, and local inflammation. Both TWEAK/Fn14 and UVB promote apoptosis and induce the production of proinflammatory cytokines; we wanted to investigate the potential synergism between these two pathways in lupus-associated skin disease by investigating the effects of UVB on lupus-prone mice with or without Fn14.

Methods: To evaluate a possible role for UVB in the pathogenesis of CLE, we exposed female lupus-prone MRL/lpr Fn14 wild type (WT) (n=14) and knockout (KO) mice (n=15) at 14-15 weeks of age to UVB irradiation (2 doses of 50 mJ/cm^2 each, 24 hours apart), and evaluated the severity of skin lesions 24 hours after the last dose. Histology was scored using a numerical system, and skin sections were stained and scored for infiltrating macrophages using IBA-1 immunofluorescence. Additionally, snap-frozen skin was analyzed by RT-PCR for inflammatory cytokine expression.

Results: MRL/lpr Fn14 WT mice developed significantly more severe skin involvement following exposure to UVB when compared to strain, age, and gender matched Fn14 KO mice (mean skin score: MRL/lpr Fn14 WT=3.8±0.4, MRL/lpr Fn14 KO=2.5±0.3, p-value=0.01). Histologically, MRL/lpr Fn14 WT mice had significantly more apoptotic keratinocytes and basement membrane degeneration. MRL/lpr Fn14 WT mice also had increased dermal infiltration by macrophages following UVB (MRL/lpr Fn14 WT=5.1±0.3, MRL/lpr Fn14 KO=3.3±0.3, p-value=0.0002). RT-PCR revealed higher levels of skin expression of CXCL10 (MRL/lpr Fn14 WT=5.5±1.0, MRL/lpr Fn14 KO=2.3±1.0 p-value=0.06) and RANTES (MRL/lpr Fn14 WT=6.8±1.3, MRL/lpr Fn14 KO=1.2±0.3, p-value=0.004) in MRL/lpr Fn14 WT as compared to MRL/lpr Fn14 KO mice.

Conclusion: UVB-induced skin inflammation is significantly attenuated in Fn14 deficient MRL/lpr lupus-prone mice. Our data suggests a novel role for the TWEAK/Fn14 signaling pathway in the induction of cutaneous lupus lesions following exposure to UVB irradiation.

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Commercial curcumin (CU), derived from food spice turmeric, has been widely studied as a potential therapeutic for a variety of oncological and inflammatory conditions. Commercial CU has been found to be safe in very high doses in clinical trials. Turmeric (TU) has been shown to ameliorate human refractory lupus nephritis. Lack of solubility and bioavailability has hindered CU's therapeutic efficacy in human diseases. Previous studies have used CU solubilized in organic solvents or as CU powder supplemented in animal feed. We have solubilized CU with heat/pressure in water, obtaining up to 36-fold increase in solubility. We hypothesized that this ultrasoluble CU, as well as ultrasoluble TU will ameliorate systemic lupus erythematosus (SLE) and Sjogren's Syndrome (SS)-like disease in MRL-*lpr/lpr*mice, a well-studied animal model for both SLE and SS.

Methods:

Eighteen female MRL-MpJ (6-week old) and 18 female MRL-*lpr/lpr* (6-week) mice were used. Female MRL-*lpr* mice develop SLE-like disease at the 10^{th} week and die at an average age of 17 weeks. MRL-MpJ mice, used as control, develop SLE-like disease around 47 weeks and typically die at 73 weeks). Six mice of each strain received autoclaved water (*lpr*-water or MpJ-water group), water with ultrasoluble CU (*lpr*-CU or MpJ-CU group) or water with ultrasoluble TU (*lpr*-TU or MpJ-TU group) in water bottle.

Results:

By 14 weeks of age, 4/6 *lpr*-water group developed severe SLE-like disease with lymphadenopathy (in 5/6 mice), urinary cell casts and proteinuria. *lpr*-CU and *lpr*-TU mice had significantly reduced proteinuria, lymphadenopathy and no urinary cell casts. Sera (1:80 dilution, bleed 3) from 6/6 *lpr*-water group were positive for ANA, weakly positive in *lpr*-CU and negative in *lpr*-TU mice. Anti-dsDNA was positive by week 8 in *lpr*-water and *lpr*-CU, but not in *lpr*-TU mice. Significant levels of anti-RNP and anti-Sm autoantibodies developed by 8th week in *lpr*-water group, but not in *lpr*-CU and *lpr*-TU groups (these groups developed antibodies only by 10^{th} week). *lpr*-CU group had a 20% survival advantage over *lpr*-water group. However, *lpr*-TU group lived an average of 16 days shorter than *lpr*-water group due to complications unrelated to SLE-like illness. CU or TU treatment inhibited lymphadenopathy significantly compared to water treated mice (p=0.03 and p=0.02 respectively). Average lymph node weights were 248±1147, 99±330 and 49±67.49 mg respectively for *lpr*-water, *lpr*-CU and *lpr*-TU groups. TUNEL assay showed that lymphocytes in lymph nodes of TU and CU treated mice underwent apoptosis. Salivary gland histopathology studies show significantly reduced cellular infiltration in *lpr*-CU and *lpr*-TU groups, compared to *lpr*-water group, while there was a trend towards reduced kidney damage in *lpr*-CU and *lpr*-TU groups. Severe tail skin lesions occurred in *lpr*-water group (2 mice) and not in the *lpr*-CU and *lpr*-TU groups (week 24). Surprisingly, as seen with MRL-*lpr* mice, MpJ-water group developed autoantibodies by 8^{th} bleed (but at levels lower than *lpr*-water group). MpJ-CU and MpJ-TU groups did not develop autoantibodies at this time, as observed in *lpr*-CU and *lpr*-TU mice.

Conclusion:

Ultrasoluble CU/TU could prove useful as a therapeutic intervention in SLE and SS.

Lymphocyte Depletion, Recovery and Efficacy in NZBWF1 Lupus Mice Following Continuous or Intermittent Dosing Regimen of Venetoclax (ABT-199), a Potent and Selective BCL-2 Inhibitor

Li Chun Wang[1], Stuart Perper[1], Kimberly Black[1], Regina Mario[1], Candace Graff[2,3], Dawna Hartman[3], Andrew Souers[4], Steven Elmore[4] and Lisa Olson[1,3], [1]Immunology, AbbVie Inc, AbbVie Bioresearch Center, Worcester, MA, [2]DMPK, AbbVie Inc, AbbVie Bioresearch Center, Worcester, MA, [3]AbbVie Inc, AbbVie Bioresearch Center, Worcester, MA, [4]AbbVie Inc., North Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Proteins in the BCL-2 family are key regulators of apoptosis, or programmed cell death. We report here that continuous daily treatment with 30mpk venetoclax (ABT-199), a selective BCL-2 inhibitor, produces a sustained lymphocyte depletion in peripheral blood that correlates with reduced disease severity in NZBWF1 lupus mice. The time course for lymphocyte depletion, recovery and efficacy following multiple dosing regimen was investigated.

Methods:

For lymphocyte recovery studies, C57BL6 mice were treated with a single 30 mpk dose of venetoclax or once daily 30 mpk dose for 7 days. Changes in lymphocytes in peripheral blood were assessed weekly by a Celldyn 3700 blood analyzer. For efficacy studies, venetoclax was administered once daily to NZBWF1 lupus mice by one of three dosing schedules: (1) continuous dosing for 28 weeks (30 mpk); (2) dosing on day 1 of a 7 day cycle for 28 cycles (100mpk); or (3) intermittent dosing on days 1-7 of a 28-day cycle for 7 cycles (30 or 100 mpk). Proteinuria and survival data are presented as Kaplan-Meyer survival curves. B and T cells in peripheral blood were analyzed by flow cytometry.

Results:

While a single 30 mpk dose of venetoclax leads to significant lymphocyte depletion within 24 hours followed by recovery to baseline by day 7, 7 days of continuous dosing is followed by lymphocyte recovery by day 28. Weekly proteinuria and survival endpoints reveal comparable efficacy between the intermittent dosing cycles at 100 mpk dose of venetoclax and continuous dosing at 30 mpk of venetoclax. Numbers of B and T cells from the first two intermittent cycles showed trends toward partial or complete recovery by day 28 versus sustained depletions in animals with continuous dosing.

Conclusion:

We have identified an intermittent dosing schedule for venetoclax that conveys compelling efficacy in NZBWF1 lupus mice without persistent lymphocyte depletion. This dosing regimen may translate into a more favorable benefit-risk profile and hence has been incorporated into a phase 1 trial in SLE patients.

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic inflammation is pathognomonic of autoimmune diseases and contributes to organ damage. Our group has previously shown that moderate daily exercise reduces systemic inflammation in an acute inflammatory mouse model. It has also been shown that social stress results in systemic inflammation. NZM2410 mice develop severe nephritis with an auto-antibody profile similar to that of Systemic Lupus Erythematosus (SLE). We investigated the effects of stress and exercise on chronic inflammatory changes in lupus nephritis.

Methods: All experimental and control studies were carried out using NZM2410 after approval by the IACUC. Mice in the exercise cohort were walked on a treadmill daily at a pace of 8 m/min beginning at 18 weeks. Stress was induced in a separate cohort daily over 6 consecutive days by placing an aggressor male in a cage with a pre-existing social hierarchy. To track disease progression, serum was collected weekly for blood urea nitrogen (BUN) level analysis and weights were documented. Early removal criteria was defined as a BUN level exceeding 50 mg/dL and/or a 20% decrease in weight from baseline. Exercise mice were compared to a non-exercise control group and stress mice were compared to randomly selected, age matched controls upon meeting early removal criteria. Tissues were collected in formalin, paraffin embedded and stained for analysis. Histopathological scoring of coded specimens was performed by a board licensed veterinarian.

Results: At 34 weeks, the entire non-exercise cohort met early removal, whereas 50% of the exercise group survived until 39 weeks and pixel intensity of F4/80 + infiltration was significantly lower in the exercise mice group. In contrast, compared to age matched controls, the mice that underwent social stress showed a significant increase in F4/80 + infiltrate which corresponded to significantly more kidney damage as observed during histopathological analysis.

Conclusion: Exercise and social stress have opposite effects on the NZM2410 chronic inflammatory model of SLE and have significant effects on experimental outcomes. Our data suggest that stress reduction and moderate daily exercise may have positive effects on the clinical course of patients with chronic inflammation associated with systemic autoimmune diseases and should be explored as therapeutic intervention.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) and lupus nephritis (LN) are autoimmune diseases characterized by circulating antibodies to nuclear self-antigens, including reactivities to double-stranded DNA, RNP and Sm. Preclinical mouse models exist that mimic aspects of human SLE/LN disease, and are used to study pathogenic mechanisms as well as to test responses to anti-inflammatory treatments. In clinical samples, autoantibody reactivity to nuclear antigens is heterogeneous, with individual patients exhibiting unique anti-nuclear antibody (ANA) signatures. We postulated that each distinct mouse model of lupus may also exhibit its own ANA signature, and that by identifying ANA reactivity profiles in preclinical lupus models, robust preclinical biomarker strategies and hypotheses for links with particular aspects of human disease may be devised.

Methods: A Genalyte Maverick instrument was used to assess IgG reactivity to 13 clinically-relevant nuclear antigens including: SS-A 60, SS-A 52, SS-B, Sm, Sm/RNP, Scl-70, Jo-1, nucleosome, PCNA, Ku, Centromere A & B, Ribosomal P and dsDNA in a simultaneous manner. Analysis was performed on frozen plasma samples archived from several murine lupus models, including spontaneous NZBW-F1, IFNα-accelerated NZBW-F1, and spontaneous MRL-*lpr*. In some samples, both Maverick technology and in-house ELISA assays were used to assess ANA to dsDNA and Sm/RNP for cross-methodology validation.

Results: Maverick analysis of nuclear antigen reactivities showed that each murine model had a distinct ANA signature. Spontaneous NZBW-F1 mice developed strong reactivity to dsDNA, with a lesser anti-RNP component. However, when NZBW-F1 disease was accelerated via injection of a non-replicative IFNα-inducing adenovirus, ANA reactivity was stronger to RNP nuclear antigen, with a lesser anti-dsDNA component. Both male and female MRL-*lpr* mice showed strong, age-dependent increases in multiple ANAs including reactivity to dsDNA, RNP, Sm, and nucleosome. Maverick assessment of ANA reactivities to dsDNA and Sm/RNP significantly correlated to titers generated by in-house ELISAs. Additional Maverick assessments of ANA from IFNα-accelerated NZBW-F1 mice treated prophylactically with mycophenolate mofetil (Cellcept), showed Cellcept significantly prevented anti-RNP autoantibody production, but only a trend was seen for decreases in anti-dsDNA autoantibody production.

Conclusion: These results show that each murine lupus model may exhibit its own unique ANA signature, and that Genalyte Maverick technology is a quick and useful methodology for identifying this signature via simultaneous assessment of several ANA from a single plasma sample. Furthermore, understanding ANA reactivity profiles in each model may help guide better preclinical biomarker design and will have impact on interpreting efficacy of anti-inflammatory treatments.

Session Title: Systemic Lupus Erythematosus - Animal Models Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by glutathione depletion and oxidative stress in T cells which lead to abnormal lineage development and dysfunction. In turn, treatment with N-acetylcysteine (NAC), which is an amino acid precursor of glutathione, reversed T cell dysfunction, reduced anti-DNA production, and disease activity in a double-blind randomized placebo-controlled clinical trial of SLE patients. Nephritis in Chronic graft versus host disease (cGvHD) has been used as a mouse model of lupus. However, NAC worsened GvHD in a recent clinical trial. Given the nuanced role of oxidative stress in the immune system, we examined the impact of transaldolase (TAL) deficiency, which causes glutathione depletion, and its reversal by NAC on cGVHD.

Methods: Age and gender matched C57BL/6 wild-type (TAL+/+) and TAL-deficient (TAL-/-) mice were fed with drinking water without (TAL+/+ n=18; TAL-/- n=17) or with 10 g/L NAC (TAL+/+ n=8; TAL-/- n=5). 10^8 MHC-mismatched bm12 splenocytes were injected intraperitoneally. Urine and serum were collected at baseline and every 4 weeks until study completion at 23 weeks. Anti-nuclear antibodies (ANA) and proteinuria were measured and expressed relative to day 0, preceding injection of bm12 cells, and standardized at 1.0 for each mouse. CD3, CD19, CD4, CD8, FoxP3, CD25, Helios, mTOR, and glutathione were measured by flow cytometry of splenocytes. Severity of glomerulonephritis was blindly scored by an experienced renal pathologist. Statistical analysis was done by t-tests or ANOVA using GraphPad 5.0 software; with $p<0.05$ considered significant.

Results: Proteinuria was significantly increased in TAL+/+ mice (5.19 ±3.12) relative to TAL-/- mice (0.86 ±0.06; $p<0.01$) at 23-weeks. NAC further increased proteinuria in TAL+/+ mice (10.91 ± 3.45; $p<0.05$) but not in TAL-/- mice. By 12 weeks, TAL+/+ mice on normal water (1.81 ±0.22 ; $p=0.02$) or NAC (7.54 ±3.25; $p=0.01$) as well as TAL-/- mice on NAC had significantly increased ANA production relative to baseline (4.07 ± 0.22; $p=0.009$). In contrast, TAL-/- mice on normal water showed no increase in ANA during the study. Kidney pathology revealed reduced glomerulosclerosis in TAL-/- mice (0.3125 ± 0.1197) relative to TAL+/+ mice (0.7778 ± 0.1726; $p=0.04$). GSH levels were reduced in both T and B cells of TAL-/- mice, while NAC treatment enhanced GSH in both cell types of TAL+/+ and TAL-/- mice. Flow cytometry revealed an expansion of CD8 T cells in TAL-/- mice on normal water (21.6 ±1.3%) relative to TAL+/+ mice on normal (15.2 ±1.0%; $p=0.0003$) and NAC-containing water (14.4 ± 2.0%; $p=0.009$). $CD4^+FoxP3^+Helios^+$ Tregs were depleted from 10.7% in TAL+/+ mice to 5.1% in TAL-/- mice ($p=0.001$). NAC expanded Tregs both in TAL+/+ and TAL-/- mice. B cells were depleted in TAL-/- mice on normal water (48.2 ± 1.9%) relative to all other groups (TAL+/+ mice on normal water: 58.3 ± 1.6%, $p=0.0003$; TAL+/+ mice on NAC: 60.6 ± 3.0%, $p=0.003$; TAL-/- mice on NAC: 60.7 ± 4.4%, $p=0.045$).

Conclusion: Oxidative stress and Treg depletion protect against ANA production and nephritis via the expansion of CD8 T cells and contraction of B cells in cGvHD.

Comparative Efficacy and Safety of Tacrolimus, Mycophenolate Mofetil, and Cyclophosphamide As Induction Therapy for Lupus Nephritis: A Bayesian Network Meta-Analysis of Randomized Controlled Trials

Young Ho Lee and Gwan Gyu Song, Rheumatology, Korea University Medical Center, Seoul, South Korea
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Cyclophosphamide (CYC) regimens improved renal outcomes, and have long been considered the gold standard for inducing renal remission and preventing renal flares in proliferative glomerulonephritis (WHO class III and IV). However, their benefits are outweighed by the significant drug-related adverse effects, such as an increased risk of serious infections and ovarian toxicity. Thus, other immunosuppressive drugs have been used for induction treatment of lupus nephritis, such as mycophenolate mofetil (MMF), and tacrolimus. However, evidence from a small number randomized controlled trials (RCT) comparing the relative efficacy and safety of tacrolimus or MMF with CYC, as induction agents in lupus nephritis, has been inconclusive, mainly because of their small sample sizes. This study aimed to assess the relative efficacy and safety of tacrolimus, MMF, and CYC as induction therapy for lupus nephritis.

Methods: RCTs examining the efficacy and safety of tacrolimus, MMF, and CYC for induction therapy in patients with lupus nephritis were included. We performed a Bayesian random-effects network meta-analysis to combine direct and indirect evidence from the RCTs.

Results: Nine RCTs including 972 patients met the inclusion criteria. There pairwise comparisons were performed, including 11 direct comparisons. Tacrolimus showed a significantly higher overall response rate (complete remission plus partial remission) than CYC (OR 2.35, 95% credible interval (CrI) 1.03–5.45), and was more efficacious than MMF (OR 1.60, 95% CrI 0.70–3.57). MMF was superior to CYC in terms of overall response (OR 1.45, 95% CrI 0.96–2.42). Ranking probability based on the surface under the cumulative ranking curve (SUCRA) indicated that tacrolimus had the highest probability of being the best treatment for achieving the overall response (SUCRA = 0.9321), followed by MMF (SUCRA = 0.5385), and CYC (SUCRA = 0.0294). In terms of safety, tacrolimus showed the highest probability of decreasing the risk of serious infections (SUCRA = 0.9253), followed by MMF (SUCRA = 0.4027), and CYC (SUCRA = 0.1720).

Conclusion: Tacrolimus was the most efficacious induction treatment for patients with lupus nephritis, and had the highest probability of decreasing the risk of serious infections. Higher remission rates combined with a more favorable safety profile suggest that MMF is superior to CYC as induction treatment in these patients.

Background/Purpose:

In Japan hydroxychloroquine (HCQ) is still unavailable due to the banning of chloroquine in 1974 following allegations that it caused severe retinopathy. Therefore, a multicenter, double-blind, randomized, parallel-group trial was conducted to develop HCQ on cutaneous lupus erythematosus (CLE) in Japan (NCT01551069).

Methods:

Japanese CLE patients (age≥18) with or without SLE were included. Patients with Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) activity score <4, and fluctuations of CLASI ≥20% in the screening period, administration of prednisolone >15mg/day, and pain VAS or fatigue VAS of 0 in SLE patients were excluded. The study spanned 55 weeks and fell into three phases: the first was the double-blind (HCQ or placebo in a 3:1 ratio for 16 weeks), the second was the single-blind (using HCQ for 36 weeks), and the third was the follow-up phase lasting 3 weeks. This was a baseline-controlled study and placebo was used as a reference. Primary endpoint was a change in CLASI activity score from baseline to 16 weeks. A change in CLASI activity score during the single-blind period was also measured. As secondary endpoints, Skindex29, 7-point scale global assessment (GA) of skin by patient, 5-point scale central photo evaluation, were assessed at Week 16 and, based on them 7-point scale GA of skin was scored by investigator. In SLE cases, the VAS assessment of pain and fatigue, RAPID 3 (Routine assessment of patient index data 3), and focused BILAG index were assessed at Week 16. Safety was assessed up to 55 weeks.

Results:

103 patients were randomized and 72 in HCQ group, 24 in placebo group were analyzed for efficacy. The CLASI score at Week 16 showed significant improvement in both groups (HCQ group: -4.6±6.4, p<0.0001; placebo group: -3.2±4.5, p=0.002). The placebo group experienced further improvement lasting to Week 52 after switching to HCQ, showing a change of -3.3±4.6 compared with -2.1±3.3 for the HCQ group. Skindex29 improved significantly from baseline to 16 weeks in the HCQ group. The percentage of "≥slightly improved" by GA of skin by patient, "≥improved" by central photo evaluation, and "≥improved" by GA of skin by investigator, were 72.9%, 59.4%, and 51.4% in the HCQ group and 47.8%, 30.4%, and 8.7% in the placebo group, respectively. In 56 SLE patients, pain VAS, fatigue VAS, and RAPID3 improved significantly from baseline to 16 weeks in the HCQ group. Active musculoskeletal system (A-C) defined by BILAG improved to be one letter down in 42.1% of the HCQ group at Week 16. Drug eruption, Stevens-Johnson syndrome, hepatic dysfunction, and cellulitis were noted as serious treatment-emergent adverse events related to HCQ treatment. No retinopathy occurred.

Conclusion:

The first clinical trial of HCQ on CLE confirmed the benefits and tolerability of HCQ.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A comprehensive metabolomic screen comparing sera from patients with systemic lupus erythematosus (SLE) to healthy controls (HC) indicated a relative deficiency in omega-3 fatty acids. A randomized clinical trial of fish oil supplements in patients with SLE was undertaken. This study noted improvements in the fish oil treatment group when compared to a parallel placebo group in quality of life, global disease activity, erythrocyte sedimentation rate (ESR), and the cytokines Interleukin (IL)-12 and IL-13. A follow-up study was performed to verify that serum lipid profiles were impacted by oral fish oil supplementation and to correlate alterations of serum omega-3 fatty acid levels with the clinical improvements noted in the trial.

Methods: Fifty SLE patients were recruited, 25 supplemented with fish oil (FO) and 25 with olive oil placebo. At baseline and after 6 months of FO supplementation, Short Form-36 (SF-36), SLE Disease Activity Index (SLEDAI), Physician Global Assessment (PGA), and serum free fatty acid (FFA)

profiles were completed. Demographic information and clinical laboratory data were collected from the electronic medical record. Liquid-liquid extraction was performed to isolate the FFA from all available serum samples. Quantification of FFA levels was determined by gas chromatography/ mass spectrometry. Data analysis utilized non-parametric statistical testing, Mann-Whitney to compare groups and Spearman for correlation.

Results: Eighteen fish oil and fourteen placebo patients completed the study. Baseline FFA levels and demographics did not differ significantly between the two groups. Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) levels (ng/ul) were converted to percent of total FFA for normalization. The median change in EPA level in the fish oil group was 0.037 [IQR 0.0013– 0.039] compared to -0.0084 [-0.035 – 0.029] in the placebo group, yielding a significant difference between groups (p=0.022). The median change in DHA level in the fish oil group was 0.10 [-0.21 – 1.16] compared to -0.022 [-0.075 – 0.023] in the placebo group, also significant (p=0.013). The change in EPA and DHA levels were compared to change in SF-36 parameters, ESR, SLEDAI, IL-13, and IL-12. Increase in EPA correlated with improvement of SF-36 Pain (r=0.48, p=0.0053) and reduction of ESR level (r=-0.41, p=0.021). Increase in DHA level correlated with reduction of ESR level (r=-0.30, p=0.099) and increase in IL-13 level (r=0.30, p=0.099).

Conclusion: A placebo-controlled clinical trial of fish oil supplements in SLE patients verified the ability to change important serum omega-3 fatty acid levels by dietary intervention. Serum from both treatment and placebo patients completing the trial had comparable fatty acid profiles at baseline, and achieved a significant increase in EPA, DHA, and PUFA levels with oral supplementation of fish oil. Patients with SLE may potentially have reduced EPA and DHA levels due to dietary intake and/or increased metabolism. Oral supplementation can overcome this deficit. Additionally, benefits noted in quality of life, specifically pain, and inflammation may be partially explained by the increases in DHA and EPA levels.

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To explore the impact of SLE disease and belimumab given in addition to standard of care therapy on antibody response after vaccination with PCV13 in SLE patients and healthy controls.

Methods: In total, 47 SLE patients (mean age 50.8 years; 94% female; mean disease duration 16.1 years; mean SLEDAI 1.9) and 21 healthy controls (mean age 43.6 years, 86% female) were immunised with a single dose of PCV13. Of these, 11 patients were treated with belimumab in addition to traditional DMARDs (hydroxychloroquine, HCQ; azathioprine, AZA, o or prednisolone). Mean (range) belimumab treatment duration was 9 (2-31) months. Remaining 36 patients received the following treatments: no DMARD (n=7); HCQ (n=10), HCQ+AZA (n=10), AZA or DMARDs other than HCQ (n=9). In total, 31of 47 (66%) of SLE patients had concomitant prednisolone (mean dose 51mg/week; range 17,5-140 mg/week). The quantification of serotype specific IgG levels to 12 pneumococcal capsular polysaccharides (1, 3, 4, 5, 6B, 7F, 9V, 14, 18C, 19A, 19F and 23F) was performed in serum samples taken immediately before and 4-6 weeks after vaccination using multiplex fluorescent microsphere immunoassay (Luminex). Geometric mean levels (GML) and differences between post- and prevaccination antibody levels (fold increase) were calculated from log transformed pre- and postvaccination antibody levels and then compared using paired T-test. General linear model for repeated measurements was used to determine the impact of SLE diagnosis and different treatments on antibody response for all 12 serotypes tested with adjustment for age. Concomitant prednisolone, AZA/other DMARD or HCL were included separately in the analysis as covariates.

Results: Postvaccination antibody levels to 12 serotypes increased significantly in both SLE patients and controls (p between <0.001 and 0.005). Compared to controls patients with SLE as a group showed significantly lower post-vaccination antibody levels and lower fold increase in antibody levels after vaccination (p=0.004 and p=0.009, respectively; adjusted for age and sex). Higher age was associated with lower antibody levels after vaccination (p<0.001) among SLE patients but not controls. When each treatment group was compared to controls including adjustment for age and sex, SLE on belimumab and SLE on HCQ were not different compared to controls, whereas SLE without DMARD, SLE patients on AZA+HCQ, and SLE on AZA or DMARDs other than HCQ had significantly lower fold increase in antibody levels after vaccination (p=0.007, p=0.004 and 0.047, respectively). When different SLE treatments were compared to each other, including adjustment for age, sex, concomitant prednisolone and concomitant DMARDs, the differences were not significant.

Conclusion: Compared to controls, SLE patients had in general lower antibody levels following vaccination with 13-valent pneumococcal conjugate

vaccine. However, belimumab given in addition to traditional DMARDs or prednisolone did not further impair antibody response. Only higher age was significantly associated with lower post-vaccination antibody levels among SLE patients.

Clinical Characteristics and Relative Factors of Infections in Southern Chinese Patients with Systemic Lupus Erythematosus

Zhongping Zhan, Dongying Chen, Qian Qiu and Liuqin Liang, Department of Rheumatology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the clinical characteristics and to identify relative factors of infection in patients with Systemic Lupus Erythematosus, to provide a data for making the diagnosis and preventable scheme of infection.

Methods: A retrospective review of the medical records of 3827 patients hospitalized with Systemic Lupus Erythematosus admitted in our center from January 2008 to June 2013 were performed.1290 cases were defined as infection group(IG) and 1278 of the other were defined as non-infection group(NIG).The data were analyzed with the statistics software SPSS19.0. Relative factors of infection in patients with SLE were identified with multifactor logistic regress analysis.

Results:

1. 1290 patients (33.7%) suffered at least one infection.The incidence of patients that suffered from 2 infections was 13.41% (173/1290) and the incidence was 1.70 %(22/1290) that suffered from 3. The incidence of nosocomial infection was 22.6 %(341/1507).

2. According to Systemic lupus erythematosus disease activity index, there are 331 stable cases, mild activity for 315 cases (24.4%), moderate activity for 306 cases (23.7%), and severe activity of 338 cases (26.2%). There are 497 cases (38.5%) with multiple system damage and 747 cases (57.91%) with single system damage;

3. the most common infection focus the respiratory tract (66.5%, including upper respiratory tract (28.1%) and lung (38.4%)), digestive tact (7.2%), Skin (7.0%), bloodstream (3.6%).

4. the most common identified pathogenic organism was gram negative bacteria (61.3%). Most of them were Escherichia coli; gram positive bacterial (22.6%). Most of them were Streptococcus pneumonia and Staphylococcus aureus; the fungi (16.2%). Most of them were Candidaalbieans.

5. Multi-factor analysis showed that the risk factors of infection in Patients with SLE included: Age, SLE damage involving the system number, SLEDAI scores, prednisone dosage of average daily, neutral grain percentage (NEUT %), platelet count (PLT), serum creatinine (Scr), total bilirubin (TIBL), blood sedimentation (ESR), c-reactive protein (CRP), immunoglobulin G (IgG), procalcitonin (PCT).

Conclusion: SLE has an increased risk for infection. The rate of of nosocomial infection is high. The respiratory tract was the most affected localization and the bacterial infection was the most common. Opportunistic pathogens and resistant bacteria were frequently seen.The older the patient was, the more system damage involved, the higher the SLEDAI score, or the more prednisone dosage was taken, the risker the patient got infection. It suggest that the patient got an infection when the proportion of neutrophils (NEUT %), platelet count (PLT), serum creatinine (Scr), total bilirubin (TIBL), aspertate aminotransferase (AST), blood sedimentation (ESR), c-reactive protein (CRP), calcitonin (PCT) went up , immunoglobulin G (IgG) went down.

Improvements in Health-Related Quality of Life and Fatigue Following Administration of an IL-6

Monoclonal Antibody (PF-04236921) in an Enriched Population of Subjects with Active SLE

Vibeke Strand[1], Annette Diehl[2], Jared Christensen[2], Joseph Wajdula[2], Sudhakar Sridharan[3] and Paul J Healey[2], [1]Biopharmaceutical Consultant, Portola Valley, CA, [2]Pfizer Inc, New York City, NY, [3]PPD Inc, Rockville, MA

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The 10 mg dose of PF-04236921 showed evidence of efficacy in a phase 2 randomized controlled trial (RCT) in SLE.[1,2] Here patient-reported outcomes (PROs) from this trial are presented.

Methods: Subjects with active SLE (SLEDAI-2K ≥6; BILAG A in ≥1 organ system or B in ≥2 organ systems) received PF-04236921 10, 50, or 200 mg, or placebo, SC every 8 weeks; the 200 mg dose was prematurely discontinued due to safety findings. The primary endpoint was the SLE Responder Index-4 (SRI-4) at Week 24. Secondary endpoints included Short Form-36 (SF-36), Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue, and European Quality of Life (EQ-5D) visual analog scale (VAS). These PROs were analyzed by least squares (LS) mean changes from baseline at Week 24, without imputation. An enriched population of subjects with one or more indicators of high baseline disease activity (SLEDAI-2K ≥10, detectable anti-dsDNA levels, prednisone >7.5 mg/day, and/or low complement) was defined for a post-hoc analysis.

Results: Baseline SF-36 physical (PCS) and mental component summary (MCS), and domain scores were lower than age- and gender-matched US norms and other RCTs in SLE,[3] indicating that subjects enrolled in this trial were more impacted by their disease. In the enriched population, statistically significant improvements in SF-36 PCS scores were reported with 10 mg versus placebo, and physical functioning, bodily pain, general health and vitality domain scores approached statistical significance; all of which exceeded minimum clinically important differences (MCID; Table 1). Numerical improvements in FACIT-Fatigue and EQ-5D VAS with 10 mg exceeded MCID in both total and enriched populations. Improvements reported with 50 mg differed from placebo, but statistical significance was not achieved in either population (Table 1).

Conclusion: These results demonstrate statistically significant and clinically important improvements in SF-36 PCS scores for the 10 mg dose in the enriched population, supported by changes >MCID in 4 of 8 SF-36 domains, FACIT-Fatigue, and EQ-5D VAS. These results are consistent with the primary efficacy data and indicate greater benefit following treatment with PF-04236921 10 mg in the enriched population.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) show a striking increase in risk of atherosclerotic cardiovascular disease (CVD) not explained by Framingham risk, compared to age and gender matched controls. Immune dysregulation and innate immune responses associated to aberrant neutrophils (low density granulocytes, LDGs) and neutrophil extracellular traps (NETs) may play key roles in conferring enhanced CV risk, driving vascular damage and, potentially, atherosclerosis. Whether neutrophils are associated to and predict vascular inflammation and eventually clinical vascular events remains to be determined.

Methods: SLE patients fulfilling ACR classification criteria were compared to age and gender-matched controls. Clinical and demographic characteristics were recorded at each visit. Individuals underwent assessment of a) vascular function of various arterial territories (peripheral arterial tonometry of the

microvasculature (Endopat) and arterial compliance by cardio-ankle vascular index (CAVI)); b) aortic inflammation by FDG-PET/CT; c) anatomical assessment of plaque by coronary CT angiogram. Circulating LDGs were quantified by flow cytometry and NET products in plasma were quantified by ELISA.

Results:

Lupus (n=20) and healthy controls (n=15) did not differ in age, gender, ethnicity, tobacco use, Framingham score, or insulin resistance. Median disease duration was 20.5 years (IQR 9.3-54 years) and SLEDAI was 2+4.8. Arterial stiffness, assessed by CAVI and by Endopat augmentation index (AI), was increased in SLE (CAVI: 7.24[5.6-9.3]) vs. controls (6.53[5.1-8.3]; p = 0.03; AI: 25.7[0.05-78.9]) vs. controls (6.81[-17.4-55.4], p = 0.003). SLE patients displayed enhanced arterial inflammation by FDG-PET/CT (target:background ratio (TBR; SLE 1.67(1.4-2.3) vs. controls 1.52(1.4-1.7), p=0.05). Differences in control and SLE persisted in multivariate regression analysis adjusting for age and gender (TBR and Endopat), and Framingham risk score and BMI (CAVI and Endopat).Use of antimalarials or steroids was negatively associated with arterial stiffness (r=-0.44, p=0.05 and r=-0.51, p=0.02, respectively). LDGs, and plasma NET products were elevated in SLE and associated with enhanced arterial inflammation (TBR) and noncalcified plaque burden

Conclusion: Individuals with SLE demonstrate increased arterial stiffness and prominent arterial inflammation suggestive of enhanced risk for unstable plaque. Dysregulation in neutrophil function and NETosis occurs in vivo in SLE in association with arterial inflammation and vascular dysfunction. These observations indicate that neutrophils may be important drivers of vascular damage in SLE.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Risk of atherosclerotic cardiovascular disease (CVD) is significantly enhanced in systemic lupus erythematosus (SLE) compared to age and gender matched controls. While this risk is not explained by the Framingham equation, lipoprotein abnormalities in phenotype and function have been detected in SLE. Recent studies in the general population suggest that CV risk may be more closely related to atherogenic lipoprotein particle numbers than LDL cholesterol. However, this association in SLE remains incompletely characterized. To this effect, associations between lipoprotein particle subfractions and disease activity, vascular dysfunction, and arterial inflammation in SLE and healthy controls were assessed.

Methods: SLE (n=20) and age and gender matched controls (n=15) underwent vascular function and anatomical assessments measuring peripheral arterial tonometry of the microvasculature (Endopat), arterial stiffness by cardio-ankle vascular index (CAVI), aortic inflammation by FDG-PET/CT, and quantification of plaque by coronary CT angiogram (CTA). Particle concentrations of lipoprotein subfractions and particle sizes were measured by nuclear magnetic resonance spectroscopy (LipoScience).

Results: Lupus and control individuals did not differ in age, gender, tobacco use, standard lipid profile, BMI, or Framingham score. Total HDL, medium HDL, and intermediate–density lipoprotein (IDL) particle counts were significantly decreased in SLE (p=0.02, 0.015, 0.018, respectively) while VLDL and small VLDL particle counts were increased (p=0.048 and 0.035, respectively). In SLE, arterial stiffness assessed by CAVI correlated positively with total HDL particle count (r=0.489, p=0.03) and negatively with large VLDL particle count (r=-0.553, p=0.01). Arterial inflammation, assessed by target:background ratio in FDG-PET/CT, significantly correlated with medium VLDL particle count (r=0.51, p=0.05), while noncalcified burden of the right coronary artery negatively correlated with large+medium VLDL particle counts (r=-0.57, p=0.05). There was a significant difference (p=0.023) in small HDL particle count (p=0.023) between SLE patients on prednisone (median=11.4 [IQR: 7.3-15.1]) and not on prednisone (median=19.9 [IQR: 13.8-21.8]). Furthermore, there was a negative correlation between SLEDAI and total HDL particle count in SLE (r=-0.454, p=0.044).

Conclusion: Individuals with SLE demonstrate significant differences in lipoprotein particle size and composition that associate with markers of vascular risk. The role medications play in these abnormalities remains to be determined. Longitudinal analysis will assess whether abnormalities in lipoprotein composition predict progression of CVD in SLE and determine the utility of following changes in lipoprotein subfractions as therapeutic targets.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

SLE is associated with a significantly increased risk of infection. Both disease activity and the medications required to control disease are contributory factors. Rituximab is used in the treatment of SLE patients refractory to standard immunosuppressive therapy. The objective of this analysis is to describe the frequency and pattern of infections associated with Rituximab use in this cohort of SLE patients.

Methods:

Patients with SLE (≥ 4 ACR 1997 criteria) on Rituximab enrolled in the BILAG-BR, a UK, multicentre, prospective study of safety and efficacy of biologics in SLE were analysed. Infection related events were coded using Medra software. Serious infections (SI) were defined as any infection resulting in treatment with iv antibiotics, hospitalisation, disability or death. For the purposes of the study, infections occurring within 9 months of Rituximab were deemed to be therapy related.

Results:

In the period May 2010-March 2015, 208 Rituximab treated patients were followed for a median (IQR) of 1 (0.5-2) yrs. There were 204 infectious episodes observed in 77 (37%) patients, 173 (85%) of which occurred within the 9 month period of interest. 50 patients suffered multiple infections. There were 25 (14%) serious infections in 20 (10%) patients within the 9 month window. The overall and serious infection rates/100 patient years follow up were 57.9 and 8.3 respectively.

The frequency of all infections and SI's are described in Table 1.The most frequent opportunistic infections reported were Candida (n=8 in 7 patients) and Herpes zoster (shingles) (n=6 in 6 patients).

The highest rate of infections occurred in the first 3 months following treatment with Rituximab: 102 (59%) which declined over time, with 57 (33%) infections occurring between 3 - 6 months and 14 (8%) between 6 – 9 months. A similar trend was noted for SI's with 14 (56%) occurring within 3 months, 8 (32%) at 3-6 months and 3 (12%) at 6-9 months.

There was a higher number and proportion of non-respiratory infections within the first 3 months post-rituximab (non-respiratory infections: < 3 months = 55/102 (54%) vs 3–9 months = 27/71 (38%), OR 1.9 (95% C.I. 1.03-3.5, p = 0.04). There were no significant differences in individual SI's across the time points, although the proportion of non-respiratory SIs was also higher in the first 3 months post-rituximab [8/14 (58%) vs 4/11 (36%)].

No infection related deaths were reported.

Conclusion:

An increased number of infections were observed in the first 3 months post-rituximab therapy with a higher proportion of these early infections being non-respiratory in nature. This could be explained by the period of maximum B cell depletion, the effect of concomitant glucocorticoids or the effect of disease activity before maximum efficacy of rituximab. Physicians and patients should have increased vigilance for infection, particularly in the early months following rituximab therapy.

Table 1. Infection rates in Rituximab treated patients.

	All infections (% all infections)	Serious Infections (% total SI)
Total	173	25
Respiratory	91 (53)	14 (52)
Urinary	30 (17)	3 (11)
Opportunistic	15 (9)	1 (4)
Skin	10 (6)	0 (0)
GI	7 (4)	4 (15)
Other	20 (12)	3 (19)

Mycophenolate Mofetil Suppresses Humoral Response to Pneumococcal Vaccine in Patients with Systemic Lupus Erythematosus and Other Autoimmune Diseases

Mark Tratenberg[1,2], Julia Ash[1], Kirk Sperber[1], Amy Wasserman[3] and Slavica Bobic[1], [1]Rheumatology, New York Medical College, Valhalla, NY, [2]Medicine-Rheumatology, New York Medical College, Valhalla, NY, [3]New York Medical College, Valhalla, NY

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the efficacy of pneumococcal polysaccharide vaccine (PPV-23) in patients on mycophenolate mofetil (MMF) therapy and compare efficacy to other DMARDS.

Methods: In a pilot study, we evaluated 20 patients immunized with PPV-23. The MMF study group included 10 patients (8 SLE, 1 uveitis and 1 dermatomyositis). The control group also included 10 patients (4 RA, 3 SLE, 1 PsA, 1 uveitis) treated with methotrexate, hydroxychloroquine or etanercept. Both groups were similar regarding average age, (put in ages of both groups) gender (put in % female of the both groups) and prednisone use (put in % prednisone use of both groups). Serum samples for 14 pneumococcal serotypes were collected pre-immunization and eight weeks post-immunization. Serum IgG titers were analyzed using ELISA. We calculated the stimulation index (SI) of 14 serotypes by dividing the post-immunization titer by the pre-immunization titer to determine vaccination efficacy. Based on the American Academy of Allergy, Asthma and Immunology (AAAAI) definition of protective titers, the primary endpoints of the study were either a ≥ 2-fold, > 3-fold or > 4-fold increase in post-immunization antibody titers and ≥ 1.3ug/ml antibody concentration in at least 70% of the 14 pneumococcal serotypes.

Results: Humoral responses to PPV23 in patients treated with MMF were significantly lower compared to the control group. Suppressed antibody responses were observed in the MMF group as defined by a lack of 4-fold ($p = 0.0001$), 3-fold ($p = 0.001$), and 2-fold ($p = 0.0163$) increase in the SI vs the control group. Twenty percent of patients receiving MMF (n=3) and fifty percent of patients (n=8) in the control group had a ≥ 2-fold increase in post-immunization antibody titers to 10 of the 14 serotypes. Forty percent of patients in the MMF group had protective antibody levels (> 1.3 ug/ml) as compared to sixty percent on other DMARDS (8.29 + 2.79 vs 9.22 + 4.84, $p = 0.51$). Statistical significant differences were also observed in serotypes 51 and 4 ($p = 0.05$ and $p = 0.025$ respectively) between MMF and the control group.

Conclusion: To our knowledge, this is the first investigation of the efficacy of pneumococcal polysaccharide vaccine (PPV-23) in patients taking MMF for SLE and other autoimmune diseases. In this pilot study, humoral responses following pneumococcal vaccination in patients receiving MMF were suppressed and lower than in patients on other DMARDS. The recommendation for pneumococcal immunization prior to MMF initiation is therefore supported.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Angiotensin converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) are currently used as an adjuvant treatment in lupus nephritis (LN) patients for the optimal control of proteinuria. However, it is not known if these agents have an atheroprotective effect, similar to that described in other at-risk populations. The aim of this study was to assess their atheroprotective role in LN.

Methods: Using the electronic database of the longitudinal observation cohort study of the University of Toronto Lupus Clinic, we identified 144 patients (123 females, mean age at disease onset 34±12.1 years, mean follow up time 14.9±8.6 years) with LN (diagnosis according to 1997 ACR criteria) who were treated with ACEIs/ARBs for, at least, 5 years for proteinuria. The control group comprised of 301 LN patients (262 females, mean age at disease onset 34.1±13.2, mean follow up time 13.4±7.9 years) who did not receive ACEIs/ARBs treatment. All patients were followed for the occurrence of atherosclerotic cardiovascular events (CVEs), consisting of transient ischemic attack and stroke, angina, myocardial infarction (MI), percutaneous transluminal coronary angioplasty (PTCA), coronary artery bypass graft (CABG), congestive heart failure and pacemaker insertion as well as peripheral vascular disease. Patients with pre-existing CVEs were excluded. Statistical software SAS (version 9.3) was used for analysis; $p<0.05$ was considered significant.

Results: There were no significant differences in the cumulative occurrence of CVEs between the two groups [14/144, 9.7% for treated vs 26/301, 8.6% for untreated patients, $p=0.708$]; however, hard events (stroke, MI, CABG, PTCA) were less frequent in treated patients [6/144, 4.17% vs 16/301, 5.32%]. Details on the type of CVEs in the two groups are presented in the table.

	TIA	Stroke	Angina	MI	PTCA	CABG	CHF	Pacemaker	PVD
Treated (n=144)	0	1	8	3	1	1	2	0	1
Non-treated (n=301)	1	6	6	5	2	3	1	2	1

TIA: transient ischemic attack, CHF: congestive heart failure, PVD: peripheral vascular disease

Patients treated with ACEIs/ARBs were more frequently hypertensive [100% vs 52.8%, $p<0.001$] and diabetic [10.4% vs 4.7%, $p=0.021$] whereas the

controls had more frequently hypercholesterolemia [27.9% vs 18.1%, p=0.024] and elevated triglycerides [14% vs 4.9%, p=0.004]; other parameters did not differ significantly. Regression analysis (Weibull parametric model) failed to confirm ACEIs/ARBs non-use as an important predictor of future CVEs. The only significant predictors in both groups were age at LN diagnosis and cumulative corticosteroid dose.

Conclusion: Our data do not support the hypothesis that ACEIs/ARBs may be protective against atherosclerotic CVEs in LN patients. In this cohort, only age at LN diagnosis and cumulative prednisone dose were important predictors for these outcomes.

Optimal Monitoring for Coronary Heart Disease Risk in Systemic Lupus Erythematosus Patients: a Systematic Review

Konstantinos Tselios[1], Barry J. Sheane[2], Dafna Gladman[3] and Murray Urowitz[3,4], [1]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, St James Hospital, Dublin, Ireland, [3]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [4]Rheumatology, U of Toronto, Toronto Western Hospital, Toronto, ON, Canada

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Premature coronary heart disease (CHD) represents a significant cause of morbidity and mortality in systemic lupus erythematosus (SLE). Several studies have been conducted to identify traditional and disease-related factors that have an impact on the atherosclerotic process, as well as methods to quantify the atherosclerotic burden in subclinical stages. Aim of this systematic review was to identify the minimum investigations to optimally monitor the risk of atherosclerotic CHD in SLE in routine practice.

Methods: An English-restricted systematic literature review was performed, using PRISMA guidelines, through Ovid Medline, Embase and the Cochrane Central databases from inception until the third week of May 2014. Specific search-terms included, among others, “systemic lupus erythematosus”, “atherosclerosis”, “coronary artery disease”, “myocardial ischemia”, “acute coronary syndrome”, “myocardial infarction”, “angina pectoris”. Two independent reviewers assessed all articles (5178 in total); upon disagreement, final decision was reached through discussion with a third reviewer. We finally identified 101 eligible articles, 23 with cardiovascular events (CVEs) and 78 with measures of subclinical atherosclerosis as end-points. The Newcastle-Ottawa scale for observational studies was used for quality assessment (all included studies had ≥6 stars).

Results: Both traditional and disease-specific risk factors were identified with independent predictive ability for clinical CHD. The most consistent traditional factors were age (particularly 48 years or in post-menopausal state), male gender, arterial hypertension, dyslipidemia and smoking. SLE factors most commonly associated with clinical CHD were overall disease activity, cumulative damage, disease duration, antiphospholipid antibodies, high sensitivity C-reactive protein and renal disease. Corticosteroids were linked to increased atherosclerotic risk; anti-malarials were shown to be protective. In regard to imaging techniques, only carotid ultrasonography for the assessment of intima-media thickness and plaque area were shown to independently predict future CVEs in lupus patients. Relative risks for CVEs for each identified risk factor are shown in the table.

Parameter						
	Age	Male gender	Hypertension	Dyslipidemia	Smoking	
RR	1.04-5.1	1.56-6.2	1.05-3.5	TC: 3.9-6.9 TG: 1.15-8	2.2-3.7	
	Disease activity	Cumulative damage	Disease duration	Renal disease	aPL	hs-CRP
RR	1.05-1.2	1.3-4.1	1.1-4.5	1.2-6.8	1.74-5.8	1.6-3.4
	IMT	TPA				
RR	2.02	4.26-9.55				

RR: relative risk, TC: total cholesterol, TG: triglycerides, aPL: antiphospholipid antibodies, IMT: intima-media thickness (carotid artery), TPA: total plaque area (carotid artery)

Conclusion: Premature CHD in lupus patients is multifactorial; modifiable traditional risk factors should be monitored initially and at frequent intervals to ensure prompt management. Disease specific factors play a key role in the atherogenetic process and should also be evaluated on a regular basis. Carotid ultrasonography holds promise in predicting cardiovascular events in SLE and should be performed in selected high-risk patients.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Elevated muscle enzymes in the course of systemic lupus erythematosus (SLE) usually represent active myositis or drug-related toxicity. Lipid-lowering agents and, less frequently, antimalarials (chloroquine, CQ and hydroxychloroquine, HCQ) have been implicated. Aim of this observational cohort study was to delineate the possible role of antimalarials in inducing myotoxicity.

Methods: Patients with SLE have been followed prospectively s according to a standard protocol at 2-6 month interval. From this cohort we identified 325 patients who had elevated muscle enzymes, defined as abnormal creatine phosphokinase (CPK) measurements in at least two consecutive visits. Fifty-four patients on statins/fibrates and/or myositis were excluded. The final cohort of 271 patients (cases) were compared to 1453 patients who never had elevated CPK levels during their follow-up (controls) with regard to epidemiological variables and antimalarial treatment. Statistical software SAS (version 9.3) was used for analysis; $p<0.05$ was considered significant.

Results: Cases and controls did not differ with regard to gender, age at disease diagnosis and disease duration. Controls were characterised by higher disease activity and cumulative damage. Black patients were more commonly had elevated CPK levels (57/271, 21% vs. 143/1453, 9.8%, $p<0.001$). Antimalarial use was more frequent in cases (216/271, 79.7% vs 821/1453, 56.5%, $p<0.001$). Total frequency of elevated CPK in antimalarial users was 216/1322, 16.3%. Duration of antimalarial use was longer in patients with elevated CPK levels (4.33±4.96 years vs. 3.84±5.47 years, $p<0.001$). Cox multiple regression analysis showed antimalarials to be strong predictors for CPK elevation [HR=8.6 (CI=5.7-13) for CQ, $p<0.001$ and HR=7.4 (CI=5.2-10.4) for HCQ, $p<0.001$]. The cumulative CQ dose before the first abnormal CPK measurement was 148±324g in 2.0±4.4 years; for HCQ that was 307±426g in 2.6±3.6 years. In all patients CPK levels did not exceed 2-4x the upper limit of normal regardless of the duration of therapy. Over 7.3±5.6 years of follow-up, 18 patients (8.3%) developed clinical myopathy with proximal muscle weakness of the lower limbs. Of 203/216 patients who had more than 2 subsequent clinic visits after the second visit with elevated CPK and continued taking antimalarials, 101 (49.8%) patients had persistent enzyme elevation, 30 (14.8%) had intermittent elevation whereas in 72 (35.4%) CPK normalised immediately or shortly after that visit. Of note, one patient developed HCQ-induced cardiomyopathy after 13 years and a cumulative dose of 1623g.

Conclusion: Chronic antimalarial use is a risk factor for muscle enzyme elevation in SLE patients. In the vast majority of patients, CPK elevation remains a biochemical abnormality as it evolves to clinical myopathy in less than 10%; however, it persists in almost two thirds of the patients with continuous antimalarial treatment. Further studies are needed to assess abnormal CPK value in predicting serious outcomes, such as cardiomyopathy.

Unexplained Decline in Rates of Cardiovascular Events in a Large Cohort of SLE Patients

Michelle Petri[1] and Laurence S Magder[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We have observed a decline in rates of cardiovascular events in systemic lupus erythamatosus (SLE) pateints in our clinic. In this work presented below, we have quantified the decline in rates and assessed the degree to which the decline could be explained by changes in medication use (greater use of hydroxychoroquine, reduced use of corticosteroids), tighter control of cardiovascular risk factors, or demographic changes in our clinic.

Methods: This analysis is based on retrospective data from the Hopkins Lupus Cohort experience since 1993. A cardiovascular event (CVE) was defined as the occurrence of a stroke, myocardial infarction (MI), coronary procedure, incident angina, or claudication. The analysis was performed based on a data set with one record per patient-month of participation in the Hopkins Lupus Cohort. Each record contained data regarding the patient's clinical history up until that time, the most recently measured levels of disease activity, medications taken at that time, and whether a CVE occurred during that month. Using this file, rates of CVE per person-year of follow-up were calculated for subgroups of follow-up defined by date, medication, disease activity, and demographics. Multivariable models were fit using pooled logistic regression.

Results: Table 1 shows the rates of CVE at different periods of time. The rate of events dropped by approximately 50% after 2010. Table 2 shows the rates of events by calendar time in strata defined by potentially explanatory variables. The reduction in CVE rates after 2010 was observed in all strata defined by corticosteroid or hydroxychloroquine use, systolic blood pressure, and lupus disease activity. Based on a multivariable model, the reduced rates of CVE after 2010 persisted after adjusting simultaneously for age, race, sex, recent systolic blood pressure and serum cholesterol, history of diabetes, smoking, recent SLE disease activity, corticosteroid dose and hydroxychloroquine use (Odds ratio comparing 2010-2014 to previous years: 0.53, 95% confidence interval 0.32, 0.88, p-value=0.015)

Table 1: Rate of cardiovascular events during cohort participation by year

Calendar Year	Number of Events	Person-years of Follow-up	Rate per 1000 person-yrs
1993-1998	20	2,009	10.0
1999-2004	50	3,742	13.4
2005-2009	51	3,951	12.9
2010+	25	4,108	6.1

Table 2. Rates of cardiovascular events by period in strata defined by potentially confounding or explanatory variables.

Stratifying Variable	1993-2009			2010-2014		
	Events	Person-Years	Rate per 1000 person-yrs	Events	Person-years	Rate per 1000 person-yrs
Recent Prednisone use	43	4278	10.1	10	2043	4.9
None	28	2364	11.8	7	829	9.1
1-9	24	1262	19.0	2	260	7.7
10-19	21	571	36.8	2	96	20.9

<120	27	1918	14.1	8	807	9.9
120-129	20	1434	13.9	2	641	3.1
130-139	23	1276	18.0	5	500	10.0
140-159	11	302	36.5	3	120	25.1
160+						
Most Recent SLEDAI	33	3558	9.3	8	1656	4.8
0	24	2192	10.9	5	1147	4.4
1-2	27	1561	17.3	3	566	5.3
3-4	26	1197	21.7	8	454	16.4
5+						

Conclusion: The reduced rate of cardiovascular events could not be explained by demographics, medications, cardiovascular risk factors, or lupus-specific variables. Further work is needed to explain the drop in rates. Identifying the reason for the drop in rates could have important implications for CVE prevention among SLE patients.

Long-Term Safety and Efficacy of Tacrolimus for Lupus Nephritis Patients in Real World Setting -Results from 5 Year Interim Analysis of Post Marketing Surveillance of 1376 Patients in Japan-

Tsutomu Takeuchi[1] and Naoko Wakasugi[2], [1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan, [2]Astellas Pharma Inc., Tokyo, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Tacrolimus (Tac) is an immunosuppressive macrolide that blocks T cell activation by specifically inhibiting calcineurin. Some randomized controlled studies have shown that TAC is an effective for induction and maintenance treatment for lupus nephritis (LN). However, there are few reports of the long term outcome of TAC for LN patients in the large real clinical setting.To assess the long-term safety and efficacy of TAC for LN patients in the real clinical setting, post-marketing surveillance was conducted (NCT01410747).

Methods:

All the patients TAC administered for LN were registered between 2007 and 2010, and the registered patients will be followed for 10 years, the safety and efficacy were evaluated at the 28 week and each year. The primary efficacy endpoint is renal failure, and secondary endpoints are urine protein creatinine ratio, serum creatinine (estimated glomerular filtration rate (eGFR)), serum component C3, anti-ds DNA and steroid dosage.

Results:

This interim analysis included all the registered 1376 patients from 292 medical sites, and the median follow up period is 1827.0 days (5 years), including 215 patients with biopsy-proven Class IV and 159 patients with Class V. The most common serious adverse drug events (ADRs) were infections, in which herpes zoster, cellulitis and diabetes mellitus, at incidence rates of 1.0%, 0.9% and 0.8%, respectively. The TAC continuation rate was 83.5% at 1 year and 71.3% at 3 years, and 62.9% at 5 years. There was a significant decrease in urine protein creatinine ratio from the 4 weeks later after TAC treatment, also the serum component C3 and anti-ds DNA antibodies were improved from the 4 weeks later and the eGFR was maintained for 5 years in both Class IV and Class V.

Conclusion:

These results show the long term safety and efficacy of TAC for LN maintenance treatment in the real clinical setting.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Development of atherosclerosis is accelerated in patients with systemic autoimmune diseases. However, underlying mechanisms of accelerated atherosclerosis remains unknown, and the impact of pharmacotherapies such as glucocorticoid on atherosclerosis is still controversial in these patients. Adipose tissue synthesizes and releases physiologically active molecules that are known as adipokines. It have recently been implicated that they are important regulators of several processes including inflammation and they may also play a role in atherosclerosis. We then prospectively investigated the association of adipokines and glucocorticoid therapy with progression of premature atherosclerosis in patients with systemic autoimmune diseases.

Methods: Thirty-eight patients (27 women, mean age of 49.3 ± 15.2 years old) with systemic autoimmune diseases, including systemic lupus erythematosus (n=16) , polymyositis/dermatomyositis (n=14), vasculitis syndrome (n=6) and adult onset Still's disease (n=2) were enrolled in this study. All subjects had active disease and started glucocorticoid therapy (prednisolone at 30 mg or more daily). Patients who had previously taken glucocorticoid or other immunosuppressive drugs were excluded. The carotid arteries were examined by ultrasonography to detect premature atherosclerosis at initiating glucocorticoid therapy and after a follow-up of mean 3 years. Serum levels of 3 adipokines [resistin, leptin, and high molecular weight (HMW)-adiponectin] were measured with respective enzyme-linked immunosorbent assay kit.

Results: Twenty-three of the 38 patients (60.5%) had carotid artery plaques at baseline. Among those without plaque at baseline, 2 patients (5.3%) showed new plaques after follow-up periods. Intima-media thickness (IMT) was significantly increased from median 0.675 (IQR 0.500-0.813) mm at baseline to 0.725 (0.588-0.725) mm at follow-up ($p = 0.04$). Serum resistin levels decreased [from 7.3 (3.7-16.8) to 6.1 (2.9-8.8), $p = 0.013$], while serum leptin [from 2.6 (1.9-10.1) to 24.6 (12.4-54.7), $p < 0.001$] and HMW-adiponectin levels [from 8.3 (3.7-11.8) to 12.4 (7.0-17.8), $p < 0.001$] increased after glucocorticoid therapy. In multivariate analysis, average yearly change in IMT over follow-up periods was positively associated with male sex, diabetes mellitus, and yearly change in serum resistin levels. In contrast, average yearly change in IMT in this analysis was negatively associated with cumulative prednisolone exposure.

Conclusion: This study showed that premature atherosclerosis was detected at high incidence in patients with systemic autoimmune diseases before glucocorticoid therapy. Overall, these patients had an increased IMT during the follow-up periods, which was positively associated with yearly change of resistin. However, increased IMT was negatively associated with prednisolone therapy. Our findings suggest that glucocorticoid may prevent accelerated atherosclerosis, partly through regulating the balance in concentrations of adipokines such as resistin which might be associated with atherosclerotic progression in systemic autoimmune diseases.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Metabolic syndrome is a recently defined clustering of cardiovascular risk (CV) factors associated with insulin resistance (IR) and an increased risk of CV disease. Systemic lupus erythematosus (SLE) patients have an increased prevalence of IR which may contribute to the development accelerated atherosclerosis in these patients. In this study we aimed to establish if IR is associated with increased risk of subclinical atherosclerosis in SL.

Methods: Seventy-two Northern Spanish women with SLE and 72 age and sex matched controls were studied. Traditional CV risk factors were recorded according to a standardized protocol. Carotid ultrasonography was done by a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7–12 MHz linear transducer and the automated software guided technique radiofrequency—Quality Intima Media Thickness in real-time (QIMT, Esaote, Maastricht, Holland) to determine carotid intima-media thickness (cIMT) and plaques, according to the Mannheim Carotid Intima-Media Thickness Consensus. IR was evaluated using the homeostasis model assessment (HOMA-IR) and quantitative insulin-sensitivity check index (QUICKI).

Results:

There were no statistically significant differences in the frequency of smoking, hypertension, dyslipidemia, diabetes mellitus, body mass index, or personal and family history of CV events between SLE patients and controls. Nevertheless, cIMT was significantly higher in SLE patients than in controls (0.654 ± 0.128 mm versus 0.588

±0.097 mm, p= 0.001). This difference remained statistically significant after adjustment for age and body mass index. Moreover, the frequency of carotid plaques was also increased in SLE patients (47% versus 27% in controls; p=0.023), being bilateral in 22% of patients and 13% of controls. The statistically significant difference persisted after adjusting for traditional CV risk factors. However, no correlation between HOMA-IR or QUICKI and cIMT was observed in SLE patients (r=0.06 and 0.034, respectively). Although SLE patients with plaques had higher levels of HOMA-IR (1.45± 1.01) and lower levels of QUICKI (0.35± 0.06) than those without plaques (1.15±0.65 and 0.36± 0.04, respectively), no statistically significant differences were observed.

Conclusion: The increased frequency of subclinical atherosclerosis observed in Northern Spanish SLE patients is not associated with metabolic syndrome features including IR.

Progression of Noncalcified and Calcified Coronary Plaque (by CT Angiography) in SLE

Michelle Petri[1], Armin Zadeh[1], Adnan Kiani[1] and Laurence S Magder[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Accelerated atherosclerosis leading to premature coronary artery disease remains the major cause of late death in SLE. Coronary artery calcium (CAC) is a late phase of atherosclerosis. Noncalcified coronary plaque (NCP) represents an early inflammatory plaque more likely to rupture.

Methods: To determine rates of CAC and NCP progression and identify risk factors for progression, CT angiography was performed at baseline and after several years of follow-up in 38 SLE patients; 36 scans allowed repeat assessment of NCP and 35 for CAC. Duration between assessments was 2-3 years (13%), 3-4 years (53%), 4-7 years (21%) and >7 years (13%). Of the patients, 37% were below 45 years; 76% female; 74% Caucasian and 18% African-American. CAC was quantified by the Agatston score and classified as none, low (1-99) or high (100+). NCP was quantified based on a score that we have previously described and classified as none, low (<0.5) or high (0.5+). SLE disease activity was quantified using the SELENA-SLEDAI and Physician Global Assessment (PGA) indices. To assess the association between quantitative clinical variables and changes in NCP adjusting for time we fit linear regression models.

Results: Tables 1 and 2 show the follow-up classifications for CAC and NCP, respectively, by baseline classification.

Table 1: Number (%) with CAC at follow-up by baseline level

		Follow-up		
		None	Low	High
Baseline	None	23 (96%)	1 (4%)	0 (0%)
	Low	1 (20%)	3 (60%)	1 (20%)
	High	0 (0%)	0 (0%)	6 (100%)

Table 2: Number (%) with NCP at follow-up by baseline level

		Follow-up		
		Low	Medium	High
Baseline	Low	4 (33%)	3 (25%)	5 (42%)
	Medium	1 (6%)	13 (72%)	4 (22%)
	HIgh	0 (0%)	4 (67%)	2 (18%)

For CAC, the pre-post scores agreed qualitatively for 32/35 (91%), while for NCP, the pre-post scores agree qualitatively for 19/36 (53%). Twelve (33%) had an increase in NCP while 5 had a decrease. Change in NCP was positively associated with time between assessments (estimated mean change score of 0.09 per year, p=0.038). Table 3 shows the association between various exposures experienced between the assessments and mean change in NCP score.

Table 3. Mean change in NCP score by various clinical variables, adjusted for time between assessments.		
Clinical Variable	Mean Change*	P-value
SLEDAI at the time of follow-up assessment	0.01 (per 1 unit change)	0.82
PGA at the time of follow-up assessment	-0.16 (per 1 unit change)	0.28
Mean SLEDAI	-0.02 (per 1 unit change)	0.63
Mean PGA	-0.19 (per 1 unit change)	0.20
Mean Systolic Blood Pressure	-0.08 (per 10 mmHg change)	0.19
Mean Total Serum Cholesterol	-0.08 (per 25 mm/dl change	0.26
History of Smoking	-0.12	0.49
Current Smoking	-0.33	0.17
Mean Lupus Anticoagulant (dRVVT)	0.01 (per second)	0.61
Proportion of time with Low C3	0.06 (per 0.5 difference)	0.66
Proportion of time with Low C4	-0.01 (per 0.5 difference)	0.95
Proportion of time with positive anti-dsDNA	0.11 (per 0.5 difference	0.33
Mean Daily Prednisone Dose	-0.19 (per 10 mg/d difference)	0.38
Proportion of time on Plaquenil	-0.07 (per 0.5 difference)	0.71
*Means and proportions calculated over the interval between the two plaque assessments.		

Conclusion: Calcified coronary plaque levels were relatively stable over a period of 2-7 years. Noncalcified coronary plaque levels were more variable and more likely to increase over time. Those with longer duration of follow-up tended to have increases in noncalcified plaque. Traditional cardiovascular risk factors and SLE-related measures did not predict increases in noncalcified coronary plaque. Noncalcified coronary plaque, the plaque most likely to rupture and lead to a cardiovascular event, is likely to increase over time regardless of traditional cardiovascular risk factors and SLE clinical and serologic activity.

IgG Levels Correlate Inversely with Proteinuria Among Participants in the Abatacept and Cyclophosphamide Combination Therapy for Lupus Nephritis Trial, but Hypogammaglobulinemia Was Not Associated with an Increased Risk of Serious Infection

Sara G. Murray[1], Noha Lim[2], Michael Stahly[2], Dawn Smilek[3] and David Wofsy[4], [1]Medicine, University of California, San Francisco, San Francisco, CA, [2]Immune Tolerance Network, Bethesda, MD, [3]Immune Tolerance Network, San Francisco, CA, [4]University of California, San Francisco, San Francisco, CA
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hypogammaglobulinemia has been associated with serious infectious adverse events (SIAE) and may occur during immunosuppressive therapy for lupus nephritis (LN). It is possible that proteinuria contributes to low Ig levels, but this relationship has not been explored. We analyzed data from the Abatacept and Cyclophosphamide Combination Therapy for Lupus Nephritis (ACCESS) trial to evaluate the relationship between proteinuria and IgG levels in patients undergoing treatment for LN with the Euro-Lupus Nephritis (ELN) regimen.

Methods: The ACCESS trial compared abatacept to placebo in LN patients undergoing ELN treatment with cyclophosphamide followed by azathioprine. Shortly after the trial began, the protocol was amended to include quantitative Ig measurements at baseline and weeks 2, 4, 12, and 24 in all subsequent participants (n=102). For the purpose of this analysis, hypogammaglobulinemia was defined by an IgG level <450 mg/dL based on previous studies indicating that this level of IgG is associated with an increased infection risk in people with hereditary immunodeficiency. Urine protein-to-creatinine ratio (UPCR) was calculated using 24-hour urine collections. SIAE were included if they were grade 3 or higher or were associated with hospitalization. Fisher's exact test was used to evaluate categorical relationships, and correlation and linear regression were used to assess continuous relationships between

measurements.

Results: Linear regression analysis showed an inverse correlation between proteinuria and IgG levels (r=-0.42, p<0.0001). At baseline, 24% of participants with UPCR ≥3 had IgG<450 mg/dL, compared with 5% of participants with UPCR <3 (p=0.013). Eleven participants experienced SIAE during treatment. None of the SIAE occurred among the 13 participants with low baseline IgG, compared to 11/89 participants with IgG ≥450 at baseline (0% vs. 12%). Overall, 31 participants had transiently low IgG (<450 mg/dL) at some time during treatment, whereas 71 participants never experienced low IgG. SIAE occurred in 3/31 (10%) participants who had low IgG at some point vs. 8/71 (11%) participants who never had low IgG. Mean IgG levels were lowest approximately 4 weeks following initiation of therapy and then rose (see Figure), so that only 1/78 participants who reached the primary study endpoint at week 24 had IgG <450 mg/dL at that point. Results in the abatacept and placebo subsets were similar.

Conclusion: Our results demonstrate an inverse relationship between proteinuria and low IgG levels in LN. However, low IgG was not associated with an increased risk of SIAE in the ACCESS trial, even among participants with IgG <450 mg/dL. Moreover, among participants who completed 24 weeks of ELN treatment, hypogammaglobulinemia corrected in all but one subject. These findings suggest that low IgG levels should not be a contraindication to immunosuppressive treatment of active LN.

Figure. IgG levels following treatment with the Euro-Lupus Nephritis regimen in the ACCESS trial, in all participants and the subset of participants with baseline IgG<450 mg/dL.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Antagonism of the CD28 costimulation receptor is thought to block T-cell activation, making this a promising target for the treatment of many autoimmune diseases, including systemic lupus erythematosus. Given the cytokine storm seen with the CD28 agonist TGN1412,1 it is important to cautiously characterize the clinical profile of agents targeting CD28. Furthermore, evaluating target engagement and immunosuppression is critical to establishing proof of mechanism before testing in patients. Here, we report the pharmacokinetics (PK), pharmacodynamics (PD) and safety profile of a novel anti-CD28 domain antibody (dAb) from 2 Phase I studies in healthy subjects. **Methods:** Minimal anticipated biological effect level (MABEL) approach was used to select a 0.01 mg starting dose in the single ascending dose (SAD) study. In this double-blind first-in-human study, 9 subjects/panel were randomized

to 9 IV (0.01–100 mg), 3 SC (9–50 mg) or placebo panels. Subsequently, a keyhole limpet hemocyanin (KLH) challenge was performed in 16 subjects/panel, who received 1 of 3 IV doses (9–100 mg) or placebo. In a double-blind multiple ascending dose (MAD) study, subjects received 1 of 3 active SC treatments (6.25 mg 2x/month, 12.5 mg weekly or 37.5 mg weekly) or placebo. PK, PD and safety were assessed. **Results:** A total of 180 subjects were treated and 169 completed the SAD/MAD studies. The PK of anti-CD28 was linear after IV infusion and SC administration, such that C_{max} and $AUC_{(INF)}$ increased dose proportionally. Bioavailability after SC administration was estimated at 68.2%. The half-life was comparable for both administration routes (5–7 days). High levels (≥80%) of receptor occupancy were maintained for ≥2 weeks at doses of ≥9 mg (IV and SC) in SAD and throughout the dosing interval in MAD. Single IV doses of ≥9 mg anti-CD28 inhibited antibody production against KLH for 2 weeks, demonstrating immunosuppressive activity (Figure). No significant serum cytokine changes nor any clinically relevant changes in T/B/natural killer cell numbers were observed in SAD or MAD. There was a low incidence of detectable anti-drug antibodies (≤16.7% in each dose group); no immunogenicity responses were persistent, with no impact on drug clearance nor correlation to AEs. The most commonly reported AEs were headache (SAD) and infections (MAD), which were study drug-related but did not show dose dependency.

Conclusion: The PK of SC anti-CD28 is favorable, with high bioavailability and the ability to maintain serum concentrations over a 2-week dosing interval. Following IV and SC administration, anti-CD28 was safe at all doses studied, without evidence of cytokine release. Anti-CD28 saturates the target receptor resulting in KLH response inhibition. The observed immunosuppressive activity indicates that anti-CD28 has potential to show clinical activity in the treatment of autoimmune disease.

Hydroxychloroquine Retinopathy: Application of the 2011 Screening Guidelines in an Academic Practice

Syed Mahmood Shah, Michelle Petri and Hendrik Scholl, Johns Hopkins University School of Medicine, Baltimore, MD
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The risk of end-stage retinopathy (bull's eye maculopathy) from hydroxychloroquine (HCQ) is low (0.65%, Wolfe and Marmor, 2010). With recent advances in retinal structure and function testing, early changes on optical coherence tomography (OCT), fundus autoflourescence (FAF), multifocal electroretinography (mfERG), and microperimetry (MP) are being used to detect early signs of hydroxychloroquine retinopathy. Risk of retinopathy as defined by combinations of these tests ranges from 7.5-12% in those on HCQ for at least 5 years or longer. The American Academy of Ophthalmology (AAO) revised its guidelines in 2011 advocating the use of OCT, FAF and mfERG as ancillary tests to ophthalmic exam and visual fields.

Methods: Ophthalmic exam, OCT, FAF, mfERG and MP by experienced retina specialists were performed in 72 eyes of 36 consecutive SLE patients meeting SLICC criteria and on hydroxychloroquine.

Results: Eleven of 72 eyes (15%) had abnormal OCT findings with 2 eyes (2%) deemed possibly related to HCQ, 26 eyes had abnormal mfERG (36%) with 3 eyes (4%) deemed possibly related to HCQ, 19 eyes had abnormal MP (26%) and 10 abnormal FAF (13%). No patient showed changes in all 4 tests suggestive of HCQ retinopathy.

Conclusion: Our series demonstrates that, in the absence of baseline pre-HCQ data for the AAO recommended ancillary tests, it may be difficult to interpret changes seen on these tests. Most of the screenings are done by regular ophthalmologists who may lack the equipment and experience with specialized testing such as mfERG, FAF and OCT. Nonspecific abnormalities are common with these tests, which need careful interpretation by retina specialists. We recommend repeat testing in those with abnormal tests and additional testing in patients in whom all four modalities were not used to determine early toxicity. We do not recommend discontinuing hydroxychloroquine based on nonspecific abnormalities alone and/or abnormalities that are not supported by the respective other modalities.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) dose adjustment in patients with impaired renal function has been suggested to prevent toxicity. However, evidence to support this practice is scant. Recently, focus has shifted to applying principles of therapeutic drug monitoring to HCQ to assess the potential for toxicity. We measured HCQ blood levels in connective tissue disease (CTD) patients with normal versus impaired renal function (GFR < 60 ml/min) to assess the impact of renal impairment on HCQ clearance. We also examined the impact of other patient-specific variables on HCQ levels, including age, concomitant medications, body mass index (BMI), ethnicity, HCQ duration, and disease activity level.

Methods: CTD patients on HCQ at a steady state dose of up to 6.5 mg/kg daily meeting ACR Criteria for Systemic Lupus Erythematosus or Rheumatoid Arthritis were eligible. Patients were excluded if they were i) deemed noncompliant through interview, prescription history review or with a resultant whole blood [HCQ] < 200 ng/ml; ii) on hemodialysis; iii) diagnosed with concomitant underlying liver disease; iv) pregnant; v) morbidly obese (BMI > 40); or vi) hypoalbuminemic (<2 g/dl). Whole blood random HCQ levels were quantified using high-performance liquid chromatography assay. Univariate analyses were performed on additional variables to evaluate other possible confounders on HCQ levels. SLE disease activity was calculated using SELENA-SLEDAI score at the time of HCQ level.

Results: There were no statistically significant differences in HCQ levels between the impaired renal function cohort (n = 11, GFR range 21-59 ml/min; mean [HCQ] 1052.7 ng/ml +/- 653.2) and patients with GFR > 60 ml/min (n = 25, range 62-120 ml/min; mean [HCQ] 1010.4 ng/ml +/- 491.5; p = 0.7310). There was no significant association between age, concomitant use of proton-pump inhibitors or prednisone, ethnicity, body mass index, duration of HCQ therapy or SLEDAI score and HCQ level.

Table-1 Comparing HCQ Level by GFR and other variables

Variables	Number of subjects	HCQ Level Mean ± STD	P-value**
GFR			0.7310
GFR≤ 60	n=11	1052.7±653.2	
GFR> 60	n=25	1010.4±491.5	
Age (Years)			0.1253
Age(20-50)	n =23	893.5±396.7	
Age (51-80)	n =13	1253.1±679.5	
PPI use			0.1622
No	n =26	963.8±560.3	
Yes	n =9	1142.2±472.1	
Ethnicity			0.3524
African American	n =9	1078.9±348.0	
Asian	n =8	840±269.8	
Caucasian	n =9	893.3±595.3	
Hispanic	n =10	1237±734.8	
Prednisone use			0.8084
No	n =7	1215.7±885.0	
Yes	n =26	962.7±431.2	
BMI			0.1012
Normal	n = 12	1155.83 ± 578.7	
Overweight	n = 10	728.0 ± 246.0	
Obese	n = 11	1013.6 ± 381.5	
Duration of HCQ therapy			0.6219
0-5 years	n = 11	945.5 ± 655.6	
6-10 years	n = 15	1084.0 ± 565.6	
> 11 years	n = 6	1036.7 ± 398.2	
SLEDAI			
Score (≤4)	n =26	1043.9 ± 463.6	0.4047
Score (>4)	n =8	782.5 ± 363.6	

P Value (*) were obtained using Wilcoxon-Mann-Whitney test and Kruskal-Wallis Test

Conclusion: There is wide inter-patient variability in HCQ blood levels. The influence of impaired renal function on HCQ metabolism and toxicity has yet to be fully elucidated. While recent literature indicates a statistically significant difference in HCQ levels for SLE patients with impaired renal function compared with a large cohort with normal renal function, a clinically significant difference in levels between patient populations was not illustrated. Our smaller study demonstrates the profound variability in levels and associated challenges that must be adjudicated before HCQ level monitoring can have wide clinical applicability. While there is growing interest in utilizing HCQ levels to guide therapy and prevent toxicity, additional studies in larger renal impairment patient populations are required.

Serum Adipocyte Fatty Acid-Binding Protein Level Is Elevated in Patients with Systemic Lupus Erythematosus (SLE) but Not Associated with Biophysical Markers of Cardiovascular Disease

Anselm Mak[1,2], Herbert Schwarz[3], Nien Yee Kow[2], Sen Hee Tay[4] and Lieng Hsi Ling[2,5], [1]National University Health System, Singapore, Singapore, [2]Medicine, National University of Singapore, Singapore, Singapore, [3]Physiology, National Unversity of Singapore, Singapore, Singapore, [4]National University of Singapore, Singapore, Singapore, [5]National Unversity Heart Centre Singapore, National Unversity Health System, Singapore, Singapore

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Adipocyte fatty acid-binding protein (aFABP) is an intracellular lipid-binding protein expressed in adipocytes and macrophages, particularly in inflammatory conditions. Recently, high circulating serum aFABP levels have been shown to predict the development of metabolic syndrome, atherosclerosis and ischaemic stroke. Being an inflammatory disease, circulating aFABP level is expected to be raised in patients with SLE. However, a recent study failed to demonstrate higher aFABP levels in SLE patients than in healthy controls (HC), likely due to the lack of power of the study and optimally matched HC. Here, we aimed to address if serum aFABP level is indeed higher in SLE patients by comparing a larger number of SLE patients with HC stringently matched for age, sex and BMI. In addition, potential associations between serum aFABP levels and clinical and disease-related factors, as well as biophysical markers of cardiovascular (CVS) disease were explored in SLE patients.

Methods: Adult patients who fulfilled the 2012 SLICC classification criteria for SLE and HC matched for age, gender and BMI were recruited. Subjects with a history of hypertension, diabetes mellitus, renal impairment, CVS and cerebrovascular diseases, and those who were on statins were excluded. Clinical parameters including daily prednisolone dose, SLEDAI, SLICC/DI, and serum C3, C4, anti-dsDNA, total cholesterol (TC) and HDL-c levels were obtained. Serum aFABP levels were determined by ELISA. Endothelial function, arterial stiffness and carotid atherosclerosis were assessed by brachial artery flow-mediated dilation (FMD), pulse-wave velocity (PWV) and carotid intima-media thickness (cIMT) respectively using the Prosound Alpha-10 ultrasound system. Relationships between serum aFABP levels and disease-related factors, FMD, PWV and cIMT were explored by bivariate correlations.

Results:

Seventy one SLE patients and 71 matched HC (6 men in each group) were studied. The mean±SD age (year), BMI and atherogenic index (TC/HDL-c) of SLE patients and HC were 39.21±13.4 and 40.37±12.9, 22.06±4.3 and 22.86±4.2 and 3.09±1.6 and 3.22±1.4 (p=0.611) respectively. In SLE patients, the mean ±SD daily prednisolone dose, SLEDAI and SLICC/DI were 13.43±14.4mg, 6.52±5.4 and 0.17±0.4 respectively. SLE patients had significantly lower FMD than HC (3.82±2.9% vs 4.76±3.0%, p=0.027). PWV and cIMT did not differ between both groups (p=0.739 and p=0.762, respectively). Serum aFABP was significantly higher in SLE patients than that in HC (14.82±3.3ng/ml vs. 13.69±4.6ng/ml, p<0.001). However, no association between serum aFABP levels and serum C3, C4 and anti-dsDNA levels, SLEDAI, SLICC/DI, BMI, atherogenic index, daily prednisolone dose, FMD, PWV and cIMT was found in the SLE group. In HC, no association was noted between serum aFABP levels and BMI, FMD, PWV, cIMT and atherogenic index.

Conclusion:

While we confirmed that SLE patients had significantly higher aFABP levels and lower FMD than age, sex-, and BMI-matched HC, no association between aFABP and various biophysical markers of CVS disease was found. Prospective studies addressing the CVS impact of aFABP in SLE by evaluating adjusted mean aFABP levels over time and CVS events in SLE patients are warranted.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To study the association between the metabolic syndrome (MetS) and vascular events, end stage renal failure (ESRF) and mortality in patients with SLE

Methods:

Patients who fulfilled ≥4 1997 ACR criteria for SLE and were followed in the rheumatology clinics of Tuen Mun Hospital, Hong Kong were studied. Inclusion criteria were those who had clinical and laboratory assessment for the presence of the MetS within 5 years of the latest date of follow-up or death.

The MetS was defined by the updated joint consensus criteria, using the Asian criteria for central obesity, when >=3 of the following components were present: (1) Increased waist circumference to ³ 90cm in men or ³ 80cm in women; (2) Elevated blood pressure to ≥130/85mmHg or requiring drug therapy; (3) Elevated serum triglyceride level to ≥1.7mmol/L; (4) Reduced serum high density lipoprotein (HDL)-cholesterol to ≤1.0mmol/L in men and ≤1.3mmol/L in women; and (5) Elevated fasting glucose level to ³5.6mmol/L. Data on vascular complications (cerebrovascular, cardiovascular, peripheral vascular disease) and the occurrence of ESRF were retrieved from our cohort database. The association of the MetS with various vascular events, ESRF and mortality was studied by logistic regression models with adjustment for age, sex and the follow-up time since the onset of SLE.

Results:

660 SLE patients were studied (93% women; age 45.4±14 years). The mean follow-up time of the patients since the onset of SLE was 12.2±7.8 years. 143 SLE patients were excluded (younger age and shorter disease duration; but no difference in the frequency of SLE manifestations compared with the included patients). The mean body mass index (BMI) of the patients studied was 22.4±4.0kg/m^2 (13% >27kg/m^2). 97 (15%) of the studied patients qualified the MetS (28% fulfilling waist; 19% fulfilling blood pressure; 27% fulfilling triglyceride; 32% fulfilling HDL and 10% fulfilling glucose criteria). There were a total of 88 arterial vascular events in 77 (11.7%) patients. The most common arterial events were stroke / transient ischemic attack (57%), followed by acute coronary syndrome / angina (27%), peripheral vascular disease (PVD) (12.5%) and arterial thrombosis at other sites (4.5%). 24 (3.6%) patients in our SLE cohort developed ESRF. Separate logistic regression models revealed that the MetS was associated with any arterial events (odds ratio [OR] 2.84[1.62-5.00]; p<0.001), coronary events (OR 3.41[1.40-8.30]; p=0.007; PVD and other arterial events (OR 6.09[1.84-20.1]; p=0.003), adjusted for age, sex and follow-up time. The MetS, however, was not significantly associated with cerebrovascular events (OR 2.00[0.98-4.06]; p=0.06). The presence of the MetS was associated with mortality (OR 2.27[1.20-4.28]; p=0.01) and the occurrence of ESRF (OR 5.67[2.30-14.0]; p<0.001).

Conclusion:

The MetS, which is a constellation of vascular risk factors, was significantly associated with coronary and peripheral arterial events in patients with SLE. Moreover, the presence of the MetS within 5 years of latest follow-up was associated with mortality and the occurrence of ESRF.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased type I interferon (IFN) activities are associated with the pathogenesis of systemic lupus erythematosus (SLE). Anifrolumab, a fully human, IgG_1 κ monoclonal antibody in clinical development for the treatment of SLE, targets the type-I IFN receptor subunit 1 and blocks type-I IFN signaling. We present its functional properties and mechanism of action.

Methods: Using a 293H ISRE-luciferase reporter assay, we tested the potency of anifrolumab against different subtypes of recombinant human type-I IFNs (including α, β, and ω) and sera from SLE patients. The neutralizing activity of anifrolumab against IFN-mediated STAT1-phosphorylation induced by recombinant human IFN-α2 and CpG-induced plasmacytoid dendritic cell (pDC) culture supernatant was examined in human peripheral blood mononuclear cells (PBMCs) via western blotting and immune flow cytometry detection. Anifrolumab's mechanism of action was determined by studying the binding and internalization of antibody/receptor complex using THP-1 monocytic cells. We further studied the protective effects of a surrogate mouse anti-mouse IFNAR1 (5A3) monoclonal antibody in a murine NZB/W F1 lupus model induced by overexpressing mouse IFN-α through an adenoviral vector.

Results: Anifrolumab binds to human IFNAR1 with high affinity and high specificity. It inhibits the activities of recombinant human type-I IFNs (including 12 subtypes of α, β, and ω) at an average IC_{50} of 0.55±1.8 nM in 293H cell-based assays. It also inhibits natural type I IFNs from the sera of SLE patients by more than 99%, and, in selected patients, inhibits type-I IFN activity with an average IC_{50} of 0.5 nM. Blocking IFNAR1 by anifrolumab led to complete suppression of phosphorylation of STAT1 in human PBMCs stimulated by either recombinant human IFN-α or CpG-stimulated human pDC-derived culture supernatants containing natural type I IFNs. Binding of the antibody to IFNAR1-expressing THP-1 cells induced rapid and complete internalization in 1 to 2 hours. Blocking IFNAR1 by surrogate monoclonal antibody 5A3 protected ADV-IFN-α–accelerated lupus mice from developing proteinuria and renal injury. It also decreased anti-dsDNA autoantibody titers.

Conclusion: Anifrolumab effectively blocks the activity of different subtypes of type-I IFNs, including those from the sera of SLE patients. It induces rapid IFNAR1 internalization on target cells, thus inhibiting receptor signaling induced by type-I IFNs. The data from the mouse lupus study further support that blocking IFNAR1 by anifrolumab could have therapeutic benefits in SLE patients with high type-I IFN activities.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To study the relationship between the serum hydroxychloroquine (HCQ) concentration and flares of systemic lupus erythematosus (SLE) in a longitudinal cohort of Chinese patients.

Methods:

Patients who fulfilled ≥4 of the ACR criteria for SLE and had been treated with HCQ for >6 months were recruited in November 2011. Patients had been prescribed HCQ at dosages of 200 mg/300 mg/400 mg/day at the discretion of physicians. Blood was assayed for the levels of HCQ by an in-house technique using the tandem mass spectrometry (SPE-MS/MS). Patients were stratified according to the HCQ levels; group 1 (<10 ng/ml, total non-compliance); group 2 (10-500 ng/ml, sub-therapeutic); and group 3 (≥500 ng/ml, therapeutic); and were followed longitudinally for serial assessment of disease activity (SELENA-SLEDAI) and the occurrence of mild/moderate or severe SLE flares (SELENA flare instrument). Comparison was made among these groups in the baseline and mean summated SLEDAI over time (AUC), and the annual incidence of mild/moderate and severe flares by the non-parametric Kruskal Wallis test. Bivariate correlation of two covariates was performed by Spearman's rank correlation.

Results:

276 SLE patients were studied (94% women; age 41.0±13.8 years; SLE duration 8.7±6.6 years). HCQ was used for the treatment of mucocutaneous or musculoskeletal manifestations, or both, in 93% of patients. The proportion of patients with HCQ levels of <10, 10-500, ≥500 ng/ml was 11%, 77% and 12%, respectively. The HCQ levels correlated significantly with the prescribed daily dosage (Rho 0.44; p<0.001), which was also correlated with the baseline SLEDAI score (Rho 0.30; p<0.001), indicating higher doses were used for more active SLE manifestations. After a follow-up of 32.5±5.5 months, 153 mild flares and 91 severe flares developed in our patients. The mean summated SLEDAI score over time was: 2.3±2.2 (group 1); 2.6±1.9 (group 2); and 3.5±2.5 (group 3), respectively (p=0.06). The annual incidence of mild/moderate and severe flares was: 0.21±0.32 and 0.14±0.42 (group 1); 0.19±0.33 and 0.12±0.29 (group 2); and 0.32±0.57 and 0.19±0.57 (group 3), respectively (p=NS in all). In patients with clinical and serological remission (SLEDAI=0) (N=73), therapeutic HCQ levels (>500ng/ml) were associated with lower summated mean SLEDAI over time (0.07±0.15) and no occurrence of disease flares (mild/moderate/severe) as compared to the other groups, although the differences were not statistically significant.

Conclusion:

"Sub-therapeutic" serum HCQ levels were frequent in our SLE patients, which was probably contributed by the low dosage prescribed for maintenance treatment in many patients with quiescent disease, as well as non-compliance. Patients with higher HCQ levels tended to have a higher disease activity over time and more frequent flares, indicating they had more refractory manifestations that required higher doses of HCQ for treatment. In patients with clinical and serological remission, therapeutic levels of HCQ were associated with lower disease activity over time and incidence of disease flares. HCQ drug level monitoring may play a role in identifying non-compliance to enhance the long-term efficacy of HCQ.

Estimated Sodium and Potassium Intake Are Associated with Blood Pressure in Patients with Systemic Lupus Erythematosus

April Barnado, Annette M. Oeser, Yahua Zhang, Jens Titze, C. Michael Stein and Cecilia P. Chung, Medicine, Vanderbilt University, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of hypertension is increased in patients with systemic lupus erythematosus (SLE). Sodium (Na^+) and potassium (K^+) intake are modifiable determinants of blood pressure in the general population and can be estimated by measuring urinary Na^+ and K^+. Higher Na^+ and lower K^+ intake, as well as a higher Na^+: K^+ ratio, are associated with elevated blood pressure. However, the contribution of Na^+ and K^+ intake to hypertension in SLE is not known. We hypothesized that urinary excretion of Na^+ and K^+, as an estimate of intake, are related to blood pressure in SLE.
Methods: We studied 178 patients with SLE and 86 control subjects frequency-matched for age, sex, and race. First morning urine specimens were collected and urine Na^+ and K^+ concentrations measured by flame photometry. The Kawasaki formula, a validated method that incorporates age, sex, height, weight, and urinary creatinine, was used to estimate 24 hour urine Na^+ and K^+ excretion. Blood pressure was the average of two resting measurements. Fisher's exact and Mann-Whitney U tests were used to compare categorical and continuous variables, respectively. The associations between systolic (SBP) and diastolic blood pressures (DBP) with estimated 24 hour urinary Na^+, K^+, and Na^+ : K^+ ratio were tested using Spearman correlation and then modeled using linear regression adjusting for age, sex, and race. Two-sided p values < 0.05 were significant.

Results: Descriptive variables including demographics, blood pressure, and urinary values for SLE patients and controls are shown in Table 1. The estimated 24 hour urinary Na^+ excretion was similar in SLE patients vs. controls, but the estimated 24 hour urinary K^+ excretion was significantly lower in SLE patients compared to controls. The urinary Na^+: K^+ ratio was higher in SLE patients than in controls, and this difference remained significant when subjects taking anti-hypertensive drugs, including diuretics, were excluded. In SLE patients, higher urinary Na^+: K^+ ratio was significantly associated with higher SBP [β coefficient (95% CI) =4.01 (0.57-7.46), p=0.023] and DBP [β coefficient=4.41 (1.71-7.11), p=0.002] after adjustment for age, sex, and race. In controls, there was no significant association with estimated 24 hour urinary Na^+, K^+, and Na^+: K^+ ratio and SBP and DBP. **Conclusion:** SLE patients had significantly lower estimated 24 hour urinary K^+ and higher estimated 24 hour urinary Na^+: K^+ ratio than control subjects. The estimated 24 hour urinary Na^+: K^+ ratio was significantly associated with SBP and DBP in SLE patients but not in controls. Our studies suggest that diets with low Na^+ and high K^+ content may reduce the risk of hypertension in SLE patients.

Table 1. Demographics of SLE cases and controls.

Characteristics	SLE (n = 178)	Controls (n = 86)	P value*
Mean age (years ± standard deviation)	40.9 ± 12	41.2 ± 12	0.76
Female sex (%)	88%	86%	0.70
Race/ethnicity (%) Caucasian Non-Caucasian	68% 32%	72% 28%	0.67
Hypertension (%)	44%	19%	< 0.001
Anti-hypertensive use (%)	36%	12%	< 0.001
Mean systolic blood pressure (mm Hg)	120 ± 17_	118 ± 14	0.63
Mean diastolic blood pressure (mm Hg)	73 ± 13	71 ± 10	0.21
Estimated 24 hour urinary sodium (gm)	4.2 ± 1.8	4.5 ± 2.1	0.54
Estimated 24 hour urinary potassium (gm)	2.0 ± 0.7	2.4 ± 0.9	< 0.001
Estimated 24 hour urinary sodium to potassium ratio	2.2 ± 0.7	1.9 ± 0.6	0.001

Exercise Is Associated with Improved Cardiometabolic Risk Factors in Patients with SLE

Michelle J. Ormseth[1], Annette M. Oeser[2] and C Michael Stein[3], [1]Department of Medicine, Division of Rheumatology, Vanderbilt University, Nashville, TN, [2]Medicine, Vanderbilt University, Nashville, TN, [3]Vanderbilt University, Nashville, TN
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased prevalence of insulin resistance and the metabolic syndrome. Exercise has been shown to improve insulin resistance and components of the metabolic syndrome in the general population. However, few studies have evaluated the effects of exercise on the metabolic health of patients with SLE.

Methods: We performed a cross sectional study of 165 patients with SLE and recorded the amount of dedicated exercise performed outside of daily activities as metabolic equivalents in minutes per week (METs). We measured clinical variables, fasting insulin and glucose, and calculated the homeostasis model assessment (HOMA) as a measure of insulin resistance. Metabolic syndrome was defined by the National Cholesterol Education Program Adult Treatment Panel III definition. Current MET expenditure was categorized into quartiles and we used these to determine the relationship between exercise and the metabolic syndrome and its individual components using binary logistic regression and multivariable regression analyses adjusting for age, race and sex.

Results: Patients with SLE (n=165) had a median [IQR] age of 41 years [30-48], 89.1% were female, median BMI was 27.5 kg/m^2[23.6-32.74], and 29% had metabolic syndrome. Median disease duration was 7 years [3-12] and SLEDAI was 4 [0-6]. The median exercise expenditure was 200 MET min/week [0-591.75]. With each quartile increase in METs, resting heart rate decreased by 2.3 beats per minute (95% CI, 0.7-4.0 beats per minute) (P=0.006). The odds of having metabolic syndrome was decreased by 25.9% (0.8-44.6%) for each quartile increase in METs (P=0.044). Each increasing quartile of exercise was associated with a 12.3% (0.2-22.9%) decrease in HOMA (P=0.045), 8.9 mg/dl (0.5-17.3 mg/dl) decrease in triglycerides (P=0.037), and 2.5 mg/dl (0.7-4.3 mg/dl) increase in HDL (P=0.006), but no significant change in the presence of hypertension (P=0.10), fasting glucose level (P=0.14), or BMI (P=0.11). There was a non-significant trend toward decreased waist circumference with increasing exercise (P=0.06).

Conclusion: Some cardiometabolic benefits are associated with the amount of exercise performed in patients with SLE, particularly decreased odds of having metabolic syndrome and improvement in insulin resistance, and triglyceride and HDL levels. Future interventional studies to determine if exercise can prevent or reverse the metabolic syndrome and its associated adverse cardiometabolic risk factors in patients with SLE patients will be of interest.

Real Life Implementation of Lupus Nephritis Randomized Controlled Trials

Angela Pakozdi[1], Ravindra Rajakariar[2], Muhammad Magdi Yaqoob[2] and Dev Pyne[1], [1]Rheumatology, Barts Health NHS Trust, London, United Kingdom, [2]Renal Medicine, Barts Health NHS Trust, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Randomized controlled trials (RCTs) are the gold standard for assessing treatment efficacy. However, due to their often strict design, generalization of research results to real populations may be problematic. Our objective was to estimate the proportion of our lupus nephritis (LN) patients who would have been ineligible to participate in RCTs, as an indicator of how well LN RCT findings could be transferred to our clinical practice.

Methods: A systematic literature search until May 2015 was performed using PubMed, Medline, EMBASE and Cochrane databases to identify full text English publications reporting RCTs on LN. We focused on trial inclusion and exclusion criteria related to lupus. The criteria were classified into 3 broad categories: (1) severe disease (low GFR, high serum creatinine); (2) mild disease (low level proteinuria, serum albumin, relatively preserved GFR) and (3)

prohibited immunosuppressive drugs used at time of LN onset. LN patients with biopsy proven proliferative (class III, IV) or membranous (class V) LN, diagnosed 1995-2013, were identified from our database; their baseline characteristics were compared with each RCT's entry criteria for eligibility.

Results: We identified 137 patients with a biopsy proven diagnosis of active LN, with mean age of 33.6 years (± 11.5 SD) at LN onset. 85.4% (n=117) were female, 50% were Black, 34% were Asian and 16% were White Caucasian. 81% had proliferative (n=111, 30% class III, 51% class IV, with or without membranous component), whilst 19% had pure membranous LN (n=26). Baseline clinical activity showed mean proteinuria of 5.5 g/24hr (± 5.1 SD), serum albumin of 27.3 g/L (± 7.4 SD), and serum creatinine of 159 µmol/L (± 166 SD). Whilst 33% (n=45) had a normal GFR (>90 ml/min/1.73m^2), 18% had a GFR <30 ml/min/1.73m^2. 33 RCTs were selected from the databases, of which only 4 published the number of patients screened, and only two disclosed the factors leading to non-randomization. Overall, on average, 32% of our LN patients were not eligible to enter the RCTs (range 8-73%) (Figure). 26 RCTs (79%) excluded patients with category 1 (severe disease) which would have rejected up to 61% of our patients from trial inclusion; 20 RCTs (63%) excluded patients with category 2 (mild disease) which would have omitted up to 44% of our cohort, and 22 trials (67%) excluded patients with category 3 (prior use of selected immunosuppressive drugs) resulting in ineligibility of up to 16% of our cohort.

Conclusion: Nearly 1/3 of our newly diagnosed active LN population would have been excluded from RCTs by design, due to factors directly related to their renal disease. Clinicians should be aware that trial samples may not adequately reflect their LN population and therefore research results may not be generalizable to all LN patients in clinical practice. Our study highlights the need for more pragmatic trials designed for those with milder or more severe LN.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To investigate serial changes in the prevalence of coronary microvascular dysfunction and coronary artery disease (CAD) by cardiac imaging in a cohort of SLE patients with chest pain.

Methods:

Twenty female SLE patients with chest pain (CP) underwent stress cardiac MRI (CMR) and coronary CT angiography (CCTA) at baseline with follow-up imaging at 5-years in addition to history of major cardiac or vascular events, CAD risk factors, SLE activity, hormones and medications.

1.5T CMR was performed with gadolinium stress and rest 1st-pass perfusion and delayed enhancement. Analysis was conducted semi-quantitatively by myocardial perfusion reserve index (MPRI) and by visual 5-point segmental scoring. Patients also underwent 64-slice CCTA. Images were analyzed for coronary artery calcium score, plaque type, location, and stenosis. In the absence of obstructive CAD, patients with abnormal myocardial perfusion or MPRI <1.84 are suspected to have coronary microvascular dysfunction.

Results:

Of 17 subjects re-enrolled for follow-up, 15 (mean age 47, BMI 26) underwent follow-up imaging: 14 underwent both stress CMR and CCTA and 1 had CCTA alone. Seven of 15 subjects had abnormal imaging at follow-up (Table 1): 4 abnormal CMR with no CAD, 2 normal CMR with nonobstructive CAD, and 1 abnormal CMR with ischemic scar and obstructive CAD. Framingham risk score and Reynold's risk score were </= 1% in all patients, yet 11 (73%) reported CP in the 4 weeks preceding initial study visit. Five of 15 patients (33%) were hyperlipidemic, 10 (67%) menopausal, 2 (13%) diabetic, 5 (33%) smokers, and 7 (47%) with current corticosteroid use. The average SLEDAI in patients that underwent follow-up imaging was 3.6.

In our follow-up cohort, we note a 36% prevalence of abnormal CMR and 20% abnormal CCTA (1 obstructive, 2 nonobstructive CAD). Of 8 subjects with baseline abnormal CMR, half had continued CP and similar or worse CMR on follow-up. Mean MPRI at 5-year follow-up was 2.19 versus 2.04 (p=0.28) at

baseline in the subepicardium and 1.85 versus 1.86 (p=0.70) in the subendocardium. Using Wilcoxon signed-rank test, results were not significantly different between baseline and follow-up MPRI.

Conclusion:

Some patients demonstrate reversible hypoperfusion and others progress to worsening subendocardial disease in the absence of obstructive CAD, suggesting coronary microvascular dysfunction and challenging the theory of SLE-related accelerated CAD. Those with abnormal CCTA at follow-up were >/= 55 years of age, suggesting age-related, not accelerated, increase in coronary atherosclerosis. Abnormal CMR did not correlate with abnormal CCTA. While duration of follow-up was short, no major cardiac events were reported, and macrovascular CAD progression is no more than the general population. Microvascular disease progression and potential cardiac risk-stratifying interventions merit additional studies.

Table 1: Subjects with abnormal imaging

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Women with SLE have an increased incidence of premature cardiovascular disease (CVD). Depression is also common among SLE patients. A relationship between depression and increased inflammation leading to CVD has been proposed. The aim of this study was to evaluate the relationship between depression and the progression of subclinical CVD in women with SLE.

Methods: In a prospective case-control study, the Study of Lupus Vascular and Bone Long-term Endpoints (SOLVABLE), there were 185 women with SLE meeting ACR revised classification criteria and 186 controls. Participants were evaluated at baseline and 5 years, including demographic data, laboratory studies, CVD risk factors, depression screening with the Center for Epidemiologic Studies Depression Scale (CES-D) questionnaire, ultrasound evaluations of carotid artery intima-media thickness (IMT) and carotid plaque, and assessment of SLE disease activity and damage for the SLE cases. Depression was defined as CES-D score > or = 16. Plaque progression was defined by an increase in number of plaques over 5 years. IMT progression was defined as increase in IMT over 5 years. HTN was defined as systolic blood pressure (BP) >140mmHg, diastolic BP >90mmHg, or taking anti-hypertensive medication. Descriptive statistics were calculated for baseline variables. Logistic regression was used to evaluate the association between baseline

depression and the progression of carotid plaque. Linear regression was used for baseline depression and progression of IMT.

Results: A total of 149 participants with SLE and 126 controls completed follow-up over 5 years. The SLE group was younger (48.6 years vs. 52.2, p=0.003) and had more hypertension (HTN) (57.7% vs. 31.8%, p<.0001), diabetes (9.4% vs. 0.8%, p=0.01) and aspirin use (20.8% vs. 7.1%, p=0.001). There were no significant differences between the groups regarding race/ethnicity, BMI, total cholesterol/high density lipoprotein (HDL) ratio, or statin use. The SLE group had a higher rate of depression, 40% compared with 15% in the control group (p <0.001). The average SLE disease duration was 12 years (SD 8.6 years), and baseline SLEDAI 2000 and ACR/SLICC scores were 4.0 (SD 3.6) and 1.6 (SD 1.8), respectively. In Table 1, in both the unadjusted and adjusted models, the presence of baseline depression correlated with increased progression of IMT in the SLE group, but not in the control group. There was no association between depression and carotid plaque in either group.

Conclusion: Women with SLE have higher rates of depression than healthy peers. SLE patients with depression have an increased risk of developing subclinical CVD, as measured by IMT, a more sensitive measure of atheroma burden, but not by carotid plaque. The data suggest that depression, a potentially modifiable risk factor, may contribute to the increased risk of subclinical CVD in women with SLE.

Table 1. Progression of Carotid Plaque and IMT at 5 Years

		Carotid Plaque	Carotid IMT		
		Odds Ratio (95% CI)	Depressed IMT mean change from baseline to 5 years (mm)	Not Depressed IMT mean change from baseline to 5 years (mm)	p-value
SLE Cases	Unadjusted	1.43 (0.68, 3.03)	0.06	0.03	0.02
	Adjusted for Age, BMI, Total Cholesterol/HDL ratio, HTN	1.03 (0.45, 2.40)	0.06	0.03	0.03
Controls	Unadjusted	0.042 (0.05, 3.27)	0.02	0.03	0.8
	Adjusted for Age, BMI, Total Cholesterol/HDL ratio, HTN	0.31 (0.04, 2.66)	0.02	0.03	0.9

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic lupus erythematosus (SLE) is a disease characterized by production and deposition of anti-dsDNA antibody. In recent years, treatment methods targeting antibody-producing B cell line have been reported as new approaches to SLE treatment. Bortezomib is a proteasome inhibitor targeting plasma cells, and is widely used in the treatment of plasma cell tumors. Here, we evaluated the efficacy and safety of bortezomib versus placebo for the treatment of SLE cases in which disease activity could not be controlled by conventional combined use of immunosuppresssants and steroids.

Methods:

Fourteen patients in whom the dose of predonine could not be reduced to ≤10 mg/day despite the concomitant immunosuppressive therapy and moderate disease activity persisted (SLEDAI, ≥6 points; positive for anti-dsDNA antibody) were randomized by using the anti-dsDNA antibody as a randomization factor. Bortezomib, 1.3 mg/m^2, or placebo was administered twice weekly, 8 times in total to patients. Endpoints were changes in anti-dsDNA antibody titer at Week 24 and SLE responder index (SRI).

Results:

Among the 14 patients, 8 and 6 patients were assigned to the bortezomib group and the placebo group, respectively; however, 4 of the 8 patients in the bortezomib group and 2 of the 6 patients in the placebo group discontinued the trial. The reason for discontinuation was inability to continue the trial due to adverse reactions in all of the 4 patients in the bortezomib group, and insufficient effects in both of the 2 patients in the placebo group. In the bortezomib group, only one patient could complete the treatment as planned, while 7 others failed to complete the minimum protocol treatment because of adverse reactions. Four patients each in the bortezomib and placebo groups, who could complete the trial, were included in the following analysis.

The percent change of the anti-dsDNA antibody titer at treatment 24, which was defined as the primary endpoint, was 4.24% in the bortezomib group and -1.96% in the placebo group, which did not support the efficacy of bortezomib. However, when LOCF analysis was used by including the patients who discontinued the treatment, -11.34% and 23.88% were obtained as reference values in the bortezomib and placebo groups, respectively, suggesting that the patients who needed to discontinue the trial because of adverse reactions might have responded well to bortezomib. On the other hand, the SRI at Week 12 was 75% in the bortezomib group and 40% in the placebo group. Although the difference did not reach statistical significance, these results appear to be promising in terms of the efficacy of bortezomib.

Conclusion:

Since bortezomib therapy for SLE is associated with many adverse reactions, it is necessary to select indications carefully and to establish the protocol aiming at the prevention of adverse reactions. On the other hand, we observed improvement of clinical findings such as skin symptoms, regardless of the anti-dsDNA antibody titer, in a patient in the bortezomib group. In fact, SRI tended to be high in the bortezomib group. These findings suggest that bortezomib may be effective in treating various symptoms of SLE though the mechanism other than inhibition of anti-dsDNA antibody production.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-malarial drugs (AMD) such as Hydroxychloroquine (HCQ) and Quinacrine (QC) are effective in the treatment of skin rash and arthritis in systemic lupus erythematosus (SLE). AMD have multiple modes of action, but precisely which mechanism(s) are responsible for their beneficial action is uncertain. Type I interferon, (IFN-I) is strongly implicated in the pathogenesis of SLE as well as rare monogenic 'interferonopathies' such as Aicardi-Goutieres Syndrome (AGS). Recently, a new DNA activated IFN-I pathway, cyclic GMP-AMP (cGAMP) synthase (cGAS), was discovered and linked to AGS. To identify potential inhibitors of the DNA-cGAS interaction, we performed *in silico* screening of chemical and drug libraries.

Methods: *In silico* structure-based drug screening were provided by the CANDO docking algorithm. Predictions made by CANDO were confirmed by Autodock Vina and analyzed via PyMOL. cGAS activity/cGAMP production was analyzed by Thin Layer Chromatography (TLC). DNA-binding to cGAS in the presence or absence of AMD was determined by Electrophoretic Mobility Shift Assay (EMSA). Following DNA cell transfections, cytokines were quantified by qPCR, ELISA or an ISRE-luciferase reporter assay.

Results: *In silico* screening of chemical and drug libraries identified several antimalarial drugs (AMD) including HCQ, QC, Chloroquine (CQ), Primaquine (PQ) and 9-amino-6-chloro-2-methoxyacridine (ACMA), which could potentially inhibit cGAS activity by interacting with the cGAS/DNA dimer complex. These AMD inhibited cGAS activity/cGAMP production in a dose dependent manner. Interestingly, the *in silico* predicted binding affinities of these AMD correlated well with their potency (QC>ACMA>HCQ>CQ>PQ) to inhibit cGAS activity, validating the prediction of our computational analysis. EMSA revealed that AMD disrupted the double stranded DNA-cGAS complex in a dose dependent manner, indicating that AMD blocked dsDNA/cGAS binding. These AMD also inhibited IFN-I expression in THP1 cells transfected with dsDNA and in 293T cells transfected with cGAS/STING plasmids validating that cGAS is a target of AMD. Based on these results and *in silico* modeling, we synthesized several new AMD. One of these compounds, X6, had excellent water solubility and cell penetration. Fluorescence microscopy revealed that X6 localized to the cytosol and had a lower toxicity profile compared to QC. *In vitro* and cell based studies, revealed that X6 was a more potent inhibitor of IFN-I production following dsDNA transfection into reporter cells than HCQ. X6 was also more potent than HCQ in the inhibition of IFN-a production following CpGA stimulation of PBMC.

Conclusion: Our studies identify the cytosolic DNA sensor, cGAS, as a target of AMD activity, which provide a novel mechanism of action of these AMD. This observation together with decades of experience of AMD in human diseases, suggest that this widely used family of drugs with a strong safety profile could be repurposed to target interferonopathies and possibly other autoimmune disorders related to cGAS over-activity.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of lupus nephritis requires aggressive immunosuppressive drugs which includes high dose glucocorticoids. Immunosuppressive treatment is a risk factor for opportunistic infections such as mycobacterium tuberculosis (Tbc). However, the efficacy of isoniazid (INH) chemoprophylaxis has not been evaluated in lupus nephritis patients.

The aim of this study was to investigate the preventive effect of INH chemoprophylaxis on incidence of Tbc infection in patients with lupus nephritis on immunosuppressive treatment.

Methods: In this retrospective cohort study, 332 patients with lupus nephritis were enrolled, who received glucocorticoids and immunosuppressive treatment at Seoul National University Hospital between 2004 and 2015. Information on baseline clinical characteristics and treatment were obtained from electronic medical record review. Incidence rates of Tbc were compared between patients who took INH prophylaxis (prophylaxis group) and those who did not (non-prophylaxis group), using log-rank test. Then, incidence rates of Tbc were investigated in subgroups of patients; those who received prednisolone >= 60 mg/day and high dose glucocorticoid pulse therapy.

Results: A total of 332 patients with lupus nephritis were identified during the study period. The mean age was 35.3 ± 14.8 years and 266 (80.1%) were female. Among 332 patients, sixty-nine (20.8%) patients received INH prophylaxis and 263 (79.2%) patients did not. No case of Tbc developed in 69 patients of INH prophylaxis group while 9 cases of Tbc developed in 263 patients of non-prophylaxis group (0.0/100 person-years (PY) vs 0.53/100 PYs, p=0.236, by log-rank test). INH prophylaxis was effective neither in high dose (>= 60 mg/day or its equivalents) prednisolone group (0.00/100 PYs vs 0.58/100 PYs, p=0.288, by log-rank test), nor in patients who received glucocorticoid pulse therapy (0.00/100 PYs vs 0.69/100 PYs, p=0.161, by log-rank test). No patient died of Tbc infection.

Conclusion: In this retrospective review, INH chemoprophylaxis did not lead to statistically significant prevention of Tbc in lupus nephritis patients.

Table 1. Isoniazid chemoprophylaxis in patients with lupus nephritis

	Prophylaxis (n = 69)	Non-prophylaxis (n = 263)	*p*-value
Age, mean ± SD years	37.78±13.47	34.60±15.07	0.092

Hydroxychloroquine Blood Levels in Systemic Lupus Erythematosus: Clarifying Dosing Controversies and Improving Adherence

Laura Durcan[1], William Clarke[2], Laurence S Magder[3] and Michelle Petri[1], [1]Rheumatology, Johns Hopkins University Hospital, Baltimore, MD, [2]Department of Pathology, Clinical Chemistry., Johns Hopkins University Hospital, Baltimore, MD, [3]Epidemiology and Preventive Medicine, University of MD, Baltimore, MD

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Hydroxychloroquine is at the cornerstone of systemic lupus erythematosus (SLE) management. It is used for both its effect on disease activity and long-term benefits. Poor medication adherence in SLE predicts bad outcomes. One way to assess adherence is to measure blood levels. Conflicting data exist regarding hydroxychloroquine blood levels and disease activity. There is also dosing controversy; rheumatologists recommend weight-based, while ophthalmologists advocate height-based ‘ideal body weight’ dosing. This work was undertaken, in a large lupus cohort, using sequential hydroxychloroquine blood levels to clarify these issues.

Methods:

Patients with SLE in a longitudinal cohort were prescribed hydroxychloroquine not to exceed 6.5mg/kg (max 400mg/day). In hemodialysis, the dose was 200mg after each session, in renal insufficiency it was 200mg daily. Levels were measured at each visit with a therapeutic range of 500-2000 ng/ml. Those with a sub-therapeutic level were informed and counselled on the importance of adherence. Vitamin D levels were measured and patients were prescribed 50,000 units per week if their level was below 40ng/ml. Patients were divided according to baseline blood hydroxychloroquine level. To assess the impact of measurement and counseling on adherence, we compared the proportion of patients with a level of 500ng/ml or higher based on how many prior assessments the patient had.

Results:

The proportion of patients with hydroxychloroquine levels in the therapeutic range differed significantly by age, gender and vitamin D level. There was a trend toward lower levels with renal failure. Blood levels were similar regardless of height, BMI and ideal body weight. Comparing those with undetectable, sub-therapeutic and therapeutic levels, disease activity decreased (SLEDAI 2.92, 2.36 and 2.20)(P=0.04, for trend). There was a correlation between blood levels of vitamin D and hydroxychloroquine levels which increased in parallel (correlation coefficient 0.12, $p<0.0022$). At first measurement, 56% had therapeutic hydroxychloroquine blood levels and by the third measurement this increased to 80% ($p =<0.0001$).

Conclusion:

There was a trend towards higher disease activity with lower hydroxychloroquine levels. We show that weight-based dosing (max 400mg daily) is appropriate and that height does not appear to influence levels. Measurement, counseling and repeated testing can significantly increase adherences rates.

Table 1. Number (%) with Various Levels of Hydroxychloroquine at the first Hydroxychloroquine Assessment by Patient Characteristics.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis(LN) is one of the significant cause of mortality in patients with systemic lupus erythematosus. Tacrolimus, a calcineurin inhibitor widely used in prevention of organ transplant rejections, has been recently applied to the treatment of LN due to its immunosuppressive effects. However, there are few reports regarding the long-term effects of tacrolimus as a maintenance treatment of LN. We aimed to investigate long-term outcomes and tolerability of tacrolimus after being switched from azathioprine or mycophenolate mofetil (MMF) due to intolerability.

Methods: The records of 27 LN patients who received tacrolimus treatment for 39.2month(S.D 1.2) were reviewed retrospectively. Tacrolimus was used as a maintenance therapy alternative to azathioprine (n = 13) or MMF (n = 16) after treatment with high-dose glucocorticoids and cyclophosphamide or MMF in all patients.

Results: After induction therapy with high-dose glucocorticoids and cyclophosphamide or MMF, proteinuria (3.4 ± 3.34 to 1.56 ± 1.78 g/24 hr), GFR (81.83 ± 28.1 to 119.34 ± 32.64 mL/min/1.73m^2), serum C3 (51.64 ± 20.21 to 73.34 ± 19.0mg/dL), C4 (8.54 ± 6.04 to 13.8 ± 6.98 mg/dL) and anti-dsDNA antibody (92.45 ± 74.54 to 72.78 ± 68.67 IU/mL) improved. These improvements were maintained by tacrolimus therapy 39 months after changing from MMF or azathioprine(proteinuria, 0.22 ± 0.19g/24 hr; GFR, 110.06 ± 36.84 mL/min/1.73m^2; serum C3, 77.27± 15.85 mg/dL; C4, 14.88 ± 6.33mg/dL; and anti-dsDNA antibody, 48.87 ± 55.01 IU/mL). One patient developed end-stage renal failure, and the1-, 2- and 3-year renal survival rates were 100%, 96%, and 96%, respectively. Two patients (7.4%) had infections that required hospitalization (urinary tract infection or herpes zoster) and four patients had hair loss. One death occurred because of biliary cancer.

Conclusion: In our study, the efficacy and tolerability of tacrolimus in treating LN as a maintenance therapy was favorable with minor complications. Further detailed investigations to confirm its long term efficacy and safety will be needed for identifying its role as a long-term maintenance agent.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE patients often exhibit signs and symptoms of cardiac ischemia with an overall increased prevalence of coronary artery disease (CAD), microvascular dysfunction and myocarditis in this population. Potentially, these processes may be associated with subclinical changes in myocardial tissue. Elevated native myocardial T1, a cardiac magnetic resonance imaging (CMRI) measure of myocardial fibrosis, has previously been shown in asymptomatic SLE patients, implying subclinical myocardial disease. We assessed the hypothesis that native myocardial T1 would be abnormally elevated in SLE subjects with chest pain.

Methods: We evaluated 13 women with SLE, chest pain but no obstructive coronary disease and 7 matched normal controls using native T1 mapping at 1.5T (Siemens Avanto) CMRI with a 5(3)3 MOLLI sequence in a single mid-ventricular slice. Healthy controls had a normal exercise stress test and no history of cardiovascular disease.

Results: The healthy control group (n=7) and SLE group (n=13) were well matched in age (47.9±9.2 vs 46.4±11, p=0.773) and BMI (24.8±2.6 vs 26.0±7.6, p=0.710). Eight SLE subjects had current or past corticosteroid use and 7 had current or past use of a cytotoxic agent. Average SLE duration was 19.5 years. Native myocardial T1 values were increased in the women with SLE and chest pain compared to reference control women (1049.4±34.3 vs 1003.8±18.9 milliseconds, p=0.005). No significant relationship was shown between native myocardial T1 and age, BMI, disease duration, or SLEDAI. However, native myocardial T1 positively correlated with corticosteroid use (r=0.507, p=0.077) as well as the use of cytotoxic agents (r=0.495, p=0.086).

Conclusion: Among women with SLE, chest pain, and no obstructive coronary disease, native myocardial T1 measured by CMR is consistent with diffuse fibrosis compared to controls.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Immune dysregulation associated with SLE leads to a substantially high background risk of infection. This risk of infection further increases with the use of immunosuppressive drugs like cyclophosphamide. Our objective was to determine the incidence and types of infections (especially pneumocystis jirovecii (PCJ)) in SLE patients treated with cyclophosphamide, and to identify relative contribution of other variables like patient demographics, steroid dose, other immunosuppressive agents, baseline white blood cell(WBC) count and absolute neutrophil count(ANC) to the risk of infection.

Methods:

We did retrospective chart review of SLE patients presented to our institute over the last 10 years, who have received at least 6 doses of monthly cyclophosphamide infusions(induction phase) and were followed up for 6 months post-induction(maintenance phase) for lupus nephritis. The timings and types of infection, cumulative steroid dose, and maintenance phase immunosuppressive regimen were recorded. Statistical analyses were done using SAS software(SAS Institute, Cary, NC).

Results:

Majority (90.5%) of the 31 patients with complete records were female. Mean age was 31.4 years (15- 50 years), 50% Hispanic, 23.8% African American, 11.9% Asian and 14.3% were Caucasian. None of our patients were on routine prophylaxis for infections including PCJ.

There were 42 episodes of infection in 31 patients. Different types of infection were UTI, URI, line sepsis, bacterial pneumonia, PCJ mucocutaneous infections (fungal/ viral/ bacterial) and viral gastroenteritis.

Incidence of infection was significantly higher among Hispanic patients (p value 0.0425).

As expected, the rate of infection was found to be significantly higher during the induction phase (65.9%) compared to the maintenance phase (34.1%) (p

value=0.0041).

Cumulative steroid dose during the induction phase was associated with significantly higher rates of infection (Table 1).

Incidence of infection during maintenance phase tends to be higher in patients on quarterly cyclophosphamide infusion compared to those on daily oral azathioprine or mycophenoalte mofetial.

We did not find any association between baseline WBC count or ANC and risk of infection.

Conclusion:

In our cohort of SLE patients we found higher infection rates among Hispanics.

Patients with higher cumulative steroid dose during monthly cyclophosphamide infusions are at the highest risk of infection. Surprisingly only one episode of PCJ was found in our cohort despite absence of routine prophylaxis.

Maintenance treatment with quarterly cyclophosphamide was associated with higher rates of infection as compared to azathioprine or mycophenolate.

Our study limitations include retrospective review, modest numbers and short duration of follow-up. Larger prospective studies with long-term follow-up are needed to confirm our results.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is a leading cause of death in systemic lupus erythematosus (SLE) and in rheumatoid arthritis (RA). Longer corrected QT segments (QTc) and a high prevalence of repolarization abnormalities have been recently described in the electrocardiograms (EKG) of SLE patients. In addition, both QTc prolongation and ST-T changes have been associated with increased cardiovascular mortality in the general population. Our objective was to evaluate QTc duration and ST-T changes in a tertiary lupus center and compare it with a cohort of RA patients without CVD.

Methods: Fifty SLE patients meeting ACR classification criteria were cross-sectionally evaluated and compared with 139 RA patients without known CVD. Demographics, disease characteristics, disease activity, and comorbidities were ascertained. Linear and logistic regression models were used to assess the associations with QTc duration and ST-T changes, adjusting for CVD risk factors.

Results: SLE patients (38 ±14 years old, 92% females, 73% Hispanic) had a median disease duration of 8 years and median SLEDAI-2K of 6. Forty-four percent had a history of lupus nephritis, 62% were on antimalarials, and 52% and 30% were SSA and SSB antibody positive, respectively. RA patients (59 ± 8 years old, 61% females, 87% white) had a median disease duration of 8 years, a mean DAS28-CRP of 3.6, 68% were anti-CCP antibody positive, and 48% were on biologics. SLE patients were more likely to be smokers (24% vs. 9%), and 7 (14%) had known CVD. There was no difference in the prevalence of hypertension, diabetes, aspirin or statin use between the two groups (Table 1). The prevalence of ST-T changes was higher in SLE vs. RA (58% vs. 15%, respectively; p<0.0001) representing an 8-fold higher odds. After adjusting for age, smoking, CVD, and aspirin use, the difference remained statistically significant (OR=8.5; p=0.0003). The QTc duration was significantly longer in SLE vs. RA patients in the univariable and in the adjusted analyses (435 vs. 418 ms, p=<0.0001; and 438 vs. 423 ms, p=0.0007, respectively) (Figure 1). Similar results were seen when limiting the analysis to only those without CVD. In SLE patients no specific disease characteristics were associated with these EKG changes. In the RA group, biologics were protective for the occurrence of ST-T changes.

Conclusion: More frequent ST-T changes and a longer QTc duration were seen in SLE when compared to RA patients. Longitudinal studies to evaluate the progression of these EKG changes and their risk for life-threatening arrhythmias and cardiovascular death in these patients are needed.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Premature atherosclerosis is a major cause of morbidity and mortality in females with systemic lupus erythematosus (SLE), but little is known about the frequency, extent, and risk-factors of coronary-artery calcifications (CAC) in young patients with SLE.

Methods:

We studied 223 SLE patients (95 males and 128 females) attending our outpatient clinic and 193 healthy subjects (100 males, 93 females) w/o preexisting coronary heart disease, matched by age and race. Patients and controls had a standardized assessment of demographic characteristics and traditional cardiovascular risk factors. In addition, lupus patients had an evaluation of lupus characteristics, medications, and laboratory tests including immunological, extended lipid profile, homocystein, and hsCRP. All patients and healthy controls were screened for coronary-artery calcifications using a 64-slice Multidetector Computed Tomography and the extent of calcification was measured by means of the Agatson score.

Results:

Mean (SD) age of lupus patients and controls was 32.9 (9.4) and 33.5 (9.8) years, respectively. Coronary-calcifications were detected in 25 patients (11%) and 7 (4%) controls (OR 3.35, 95% CI 1.36-9.38, p=0.004). Median calcium score in patients was 15.9 (0.2-576.8), and 7.7 (1.1-140.2) in controls. Calcifications in lupus patients and controls were detected since age 32 and 41 years, respectively. In two patients, calcifications were detected within 3 years of diagnosis. The multivariate analysis showed that age (OR 1.13, 95% CI 1.08 – 1.18), smoking (OR 3.50 95% CI 1.32 – 9.27), male gender (OR 2.62 95% CI 1.04 – 6.57), and SLE diagnosis (OR 4.41 95% CI 1.64 – 11.85) were associated with CAC in the whole population.

Among the lupus patients, those with calcifications were older (42.1 + 8.6 vs 31.8 + 8.9 years, P<0.001), males (68% vs 39%, P=0.006), waist (91.4 + 14.2 vs 85.6 + 12.7 cm, P=0.02), current smoking (32% vs 10%, P=0.006), hypertension (48% vs 28%, P=0.04), homocysteine levels (17.1 + 14.8 vs 11.7 + 6.4, P=0.009), Framingham risk score [5(1-25) vs 1(1-13), P<0.001], MetS (44% vs 15% , P=0.001]. Lupus duration was longer (11.1 + 8.9 vs 5.8 + 4.3 years, P=0.006), and cumulative dose of prednisone higher [61.7(0.24-454.2) vs 49.9(8.5-106.5) grams, P=0.001] in comparison to patients with no calcifications. No difference was observed in lupus manifestations, clinical activity during the course of the disease, autoantibodies, and use of anti-malarials and aspirin. Logistic regression adjusting by disease duration showed an independent association of age (OR 1.12, 95% CI 1.05-1.16, p= P<0.001), smoking (OR 3.69,

95% CI 1.04-13.1, p=0.04) and cumulative dose of prednisone (OR 1.03, 95% CI 1.005-1.06, p=0.02) with calcifications.

Conclusion:

Asymptomatic coronary-artery calcifications are more common, extensive, and present at younger age in SLE patients than in the controls. Their association, principally to traditional risk-factors than lupus characteristics, raise the possibility of modifying their burden.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue, a common symptom in systemic lupus erythematosus (SLE) patients, is ameliorated by physical activity. Adiposity and adipokines may be associated with patient-reported fatigue. We describe associations between adipokines (leptin, adiponectin, and resistin) and fatigue, physical activity, and SLE disease activity.

Methods: We examined adipokines, self-reported fatigue, and objective physical activity in 129 patients meeting ACR revised criteria for definite SLE from the Activity in Lupus to Energize and Renew (ALTER) study. Body mass index (BMI), disease activity (Safety of Estrogens in Systemic Lupus Erythematosus National Assessment – Systemic Lupus Erythematosus Disease Activity Index [SELENA-SLEDAI]), and disease damage (Systemic Lupus International Collaborating Clinics Damage Index [SDI]) were measured. Fatigue was assessed by the Fatigue Severity Scale (FSS). A triaxial accelerometer was worn for 7 days, and physical activity was estimated by total accelerometer vector magnitude (VM) counts. Six patients with <4 valid days of accelerometer wear were excluded from physical activity analyses. Leptin, adiponectin, and resistin were measured in stored serum with a Luminex bead-based assay. Adipokine data were logarithmically transformed for inclusion in linear regression models describing relationships between FSS and adipokines. Spearman correlation coefficients assessed associations between adipokines, physical activity, and SELENA-SLEDAI.

Results: Participants were female (94%), Caucasian (53%), and mean age 45.5 years (SD 10.9). BMI was 28.1 kg/m^2 (8.2). SELENA-SLEDAI was 2.4 (2.8) and SDI was 1.7 (2.2). FSS score was 4.4 (1.6), consistent with clinically relevant fatigue. Mean adipokine levels were: leptin 44.2 ng/ml (47.6), adiponectin 13.5 µg/ml (10.8) and resistin 1.9 ng/ml (1.5). No significant associations were found between adipokines and FSS in any of the regression models (Table 1). BMI ≥ 30 kg/m^2 (obesity) was associated with FSS in adjusted models (p <0.05, data not shown). Weak correlations between leptin, adiponectin, and physical activity, and between adiponectin and SELENA-SLEDAI score, were not significant after adjusting for BMI (Table 2).

Conclusion: No relationships were found between adipokines and fatigue in SLE patients. This study demonstrates that adipokines are correlated with physical activity (leptin and adiponectin) and SLE disease activity (adiponectin), but most of these associations can be explained by BMI.

Pharmacokinetics of the Selective B-Cell Lymphoma-2 (Bcl-2) Inhibitor, ABT-199, in Female Subjects with Systemic Lupus Erythromatosus

Mukul Minocha[1], Shekman Wong[2], Jiewei Zeng[2], Peng Lu[3], Jeroen Medema[2] and **Ahmed Othman**[4], [1]Clinical Pharmacology and Pharmacometrics, AbbVie, North Chicago, IL, [2]AbbVie Inc., North Chicago, IL, [3]AbbVie Inc., Worcester, MA, [4]AbbVie, North Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Selective Inhibition of Bcl-2 pathway may offer clinical efficacy in Systemic Lupus Erythromatosus (SLE) by restoring apoptosis in autoreactive cells, which may lead to immune response resolution. ABT-199 is an orally bioavailable, selective Bcl-2 inhibitor currently under evaluation for treatment of SLE and several oncology indications. This work characterized the pharmacokinetics of ABT-199 in female subjects with SLE following single and multiple dosing

Methods: Single escalating oral doses (10, 30, 90, 180, 300, 500 mg or matching placebo, total 48 subjects) and multiple escalating oral doses (30, 60, 120, 240, 400, 600 mg or matching placebo, total 50 subjects) of ABT-199 were evaluated. The multiple dose evaluation consisted of two cycles each including once daily dosing under non-fasting conditions for 7 days followed by a 21 day washout period. Both evaluations followed randomized, double-blind, placebo-controlled designs (3:1 active: placebo). Serial blood samples were collected for characterization of ABT-199 pharmacokinetics.

Results: ABT-199 followed bi-exponential disposition with peak plasma concentrations observed within 4 to 8 hours post dose. Steady-state exposures were achieved within 4 days of dosing. ABT-199 exposure did not deviate significantly from dose proportionality over the evaluated dose range and the median steady-state accumulation ratio was 1.1 to 1.5. ABT-199 terminal elimination half-life ranged from 7 to 17 hours and the effective half-life, calculated based on C_{max} to C_{trough} ratio at steady state, was 9 to 11 hours. The fraction of ABT-199 dose eliminated unchanged in urine was negligible

Conclusion: ABT-199 displayed favorable pharmacokinetic profile in female subjects with SLE that warrants further clinical evaluations

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

SLE is associated with high prevalence of metabolic syndrome and obesity, which can be related to the high risk of cardiovascular events in this group of patients. Visceral adipose tissue (VAT) correlates more accurately with cardiovascular risk factors than other measures of adiposity. The aim of this study was to evaluate VAT in premenopausal SLE patients compared to controls.

Methods:

The study included 63 premenopausal SLE patients and 186 age-matched healthy women. Demographic, anthropometric, disease and treatment parameters were evaluated. Visceral adipose tissue (VAT) parameters were measured by Hologic dual X-ray absorptiometry (DXA) scanner equipped with APEX 4.0 software.

Results:

SLE patients had mean disease duration of 5.25 ± 3.8 years, mean SLEDAI activity score of 4.35 ± 5.13, mean SLICC damage index of 0.70 ± 0.80, mean current prednisone dose of 11.60 ± 12.10 mg/day and cumulative glucocorticoid dose of 5.27 ± 5.57 g. SLE patients and controls had similar age (31.14 ± 6.87 vs. 30.68 ± 7.70 years, p=0.673), weight (66.87 ± 13.60 vs. 64.84 ± 14.22 kg, p=0.324), height (1.60 ± 0.06 vs. 1.61 ± 0.06 m, p=0.290) and body mass index (25.98 ± 5.05 vs. 24.91 ± 4.94 kg/m^2, p=0.145). SLE patients and controls had similar fat mass (23.31 ± 8.79 vs. 21.92 ± 8.64 kg, p=0.273), fat percentage (33.84 ± 6.45 vs. 33.05 ± 5.98 %, p=0.376) and fat mass/height² (9.09 ± 3.4 vs. 8.65 ± 3.83 kg/m^2, p=1.413). SLE patients had higher values of VAT parameters than controls, namely VAT mass (362.16 ± 196.12 vs. 303.36 ± 187.19 g, p=0.034), VAT volume (391.55 ± 212.07 vs. 329.14 ± 203.57, p=0.038) and VAT area (75.12 ± 40.69 vs. 63.16 ±39.09, p=0.039). SLE patients had higher trunk/legs fat percentage ratio (0.84 ± 0.22 vs. 0.76 ± 0.19, p=0.003) and trunk/limb fat mass ratio (0.84 ± 0.22 vs. 0.76 ± 0.19, p=0.008) than controls. In SLE patients, VAT area correlated with CRP levels (R=0.30, p=0.018) but not with age (p=0.079), disease duration (0.912), SLEDAI disease activity score (p=0.068), SLICC damage index (p=0.054), cumulative glucocorticoid dose (p=0.141) or hydroxychloroquine use (p=0.851).

Conclusion:

This study provides original evidence that SLE is associated with altered adiposity distribution and increased visceral adipose tissue. The observed correlation with CRP levels, independent of disease activity, suggests the role of visceral fat as an additional risk factor for cardiovascular events in SLE patients. Longitudinal studies are necessary to confirm the long-term effect of VAT in cardiovascular events in SLE.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tripterygium Wilfordii (TPW), a Chinese herbal medication, has been widely used in China for various chronic inflammatory and autoimmune diseases, including systemic lupus erythematosus (SLE). Although the immunologic mechanism is poorly understood, studies have shown that TPW inhibits T cell activation, cytokine gene transcription in T cells and T cell expression of interleukin-2. To better inform clinical practice, we systematically analyze randomized controlled trials (RCTs) on the use of TPW in the treatment of SLE.

Methods: We performed a comprehensive search of three Chinese databases, two English academic database and reference lists of published articles through April 2015. We included only RCTs, in which TPW was used for the treatment of adult patients with SLE. The effect of TPW on clinical signs, symptoms and laboratory tests of SLE was measured. The effectiveness rate was determined as the percentage of number of patients with complete and partial response divided by the total number of patients in the study. We also performed random-effect meta-analysis using the number of patients who improved with treatment in the experimental and control groups when appropriate.

Results: We identified 31 potentially relevant studies. Eight RCTs with a total of 431 subjects met eligibility criteria. **Table 1** summarizes the trials evaluating the effect of TPW on the improvement of clinical signs, symptoms and laboratory tests in patients with SLE. All studies were published in China between 1989 and 2014. Studied subjects received TPW (variable dose on different formulation) alone or with steroids (mainly prednisone 0.5-1 mg/kg/day) in experimental group (Leflunamide 10mg bid in one group), compared with prednisone alone in control group (MTX 10mg weekly in one group). Duration of treatments ranged from 0.5 to 6 months. Comparing with a variety of controls, six of the eight studies have shown a statistically significant improvement in clinical signs and symptoms, including rash, arthritis/arthralgia, photosensitivity, fever, pleuritis, cerebritis and hair loss. Improvements of sedimentary rate, C-reactive protein, dsDNA, Complete Blood Count, proteinuria, hematuria, anti-Smith Antibody, complements and renal function were also noted. Meta-analysis showed an increase of clinical effective rate of 33% in experimental patients compared with controls (Risk Ratio (RR)=1.20; 95%CI: 1.06-1.37; p=0.006; **Figure 1**), suggesting that TPW improves the clinical signs, symptoms, abnormal laboratories associated with SLE. No serious adverse events were reported.

Conclusion: Evidence suggests that TPW may be a safe and effective treatment that provides a glimmer of hope in the treatment of SLE. However, standard criteria of improvement were not used, making it difficult to compare the results between different studies. Further rigorously designed and well-controlled RCTs of efficacy of TPW in SLE are warranted.

Table 1. 8 RCTs of *Tripterygium Wilfordii* for SLE treatment

Author Year	Type lupus	N (F:M)	age (mean)	Treatment	control	Duration (month)	outcome measures	P value results
1) Wang 1989	SLE/DLE	42 (18:5)	31.4	TPW 10g tid	prednisone 30-60mg daily	0.5 - 21	effecive: 60% vs 31.6% ineffective: 26.7% vs 63.2% worsen:: 13.3% vs 5.3%	p>0.10 86.7% vs 94.7%
2) He 1993	SLE	41 (39:2)	31.2	TPW 12-15g/day prednisone 1mg/kg/day	prednisone * 1mg/kg/day	18 - 24	effecive: 81.5% vs 50% ineffective: 18.5% vs 50%	p<0.05, 81.5% vs 50%
3) Wang 1996	SLE	31 (29:2)	37	TPW, 10g/day; Chinese herbs prednisone, 40-50mg/day	prednisone 40-50mg daily	1	effecive: 38% vs 27% partial: 50% vs 27% ineffective: 6% vs 33% worsen/death: 6% vs 13%	p<0.05, 87.5% vs 53.3%
4) Xiao 1999	SLE	64 (no data)	29.7	TPW 20mg tid prednisone 30-60mg daily	prednisone 30-60mg daily	No data	effecive: 35.3% vs 13.3% partial: 47% vs 66.7% ineffective: 8.8% vs 16.7% worsen/death: 8.8% vs 3.3%	p<0.05, 35.3% vs 13.3%
5) Dai 2001	SLE	60 (43:17)	21-65	TPW 2-4 pills tid	prednisone 10mg tid	3	effecive: 46.7% vs 36.7% partial: 40% vs 30% ineffective: 13.3% vs 33.3%	p<0.01, 87% vs 67%
6) Sun 2003	SLE	54 (47:7)	33.7	TPW 30-60mg tid	prednisone 20-40mg daily	1.5 - 2	effecive: 50% vs 33.3% partial: 38.9% vs 44.4% ineffective: 11.1% vs 22.2%	p<0.01, 94.4% vs 77.8%
7) Tang 2014	SLE	68 (30:38)	35	TPW1.5mg/kg tid Leflunomide 10mg bid	prednisone 1mg/kg/day taper to 12.5mg/day	1.5 - 2	effecive: 38.9% vs 43.8% partial: 52.8% vs 43.8% ineffective: 8.3% vs 12.5%	p>0.05, 91.67% vs 87.5%
8) Liu 2014	SLE	79 (71:8)	18-70	TPW 20mg tid prednisone 0.5mg/kg/day	prednisone 0.5mg/kg/day MTX 10mg weekly	6	effecive:52.5% vs 46.2% partial: 35% vs 20.5% ineffective: 12.5% vs 33.3%	p<0.01, 87.5% vs 66.7%

1.The diagnostic criteria: 1). Group 1-6: 1982 revised criteria for classification of SLE by ACR; 2). Group 8: 1997 update of 1982 revised criteria; 3). Group 7: 2011 revised criteria for classification of SLE by Chinese college of medicine.
2: outcome measures: 1). effective: clinical symptoms and laboratory tests significantly improved/normalized; 2). partial effective: clinical symptoms and laboratory tests partially improved; 3). ineffective: no changes in the clinical symptoms and laboratory tests;
4). worse/dead: clinical symptoms and laboratory tests worsen/ study subject died.
3. results: the effective rate (%) was determined as the percentage of number of study subjects with effective and partial effective outcome divided by the total number of study subjects, except group 4 which used the number of study subjects with effective outcome divided by total number of study subjects.
*cyclophosphamide2 was added in the control group for the patients who did not respond to steroids.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In the general population, we and others have reported that higher osteoprotegerin (OPG), a protein involved in bone remodeling, is associated with higher levels of coronary artery calcification (CAC). Higher levels of OPG have been reported in SLE associated bone fractures and nephritis. We have previously reported higher CAC in women with systemic lupus erythematosus (SLE) vs. healthy controls (HC) in two SLE case-control studies, HEARTS and SOLVABLE but the association of OPG with CAC in SLE is unknown. Therefore we hypothesized that in HEARTS and SOLVABLE, higher serum OPG would be associated with the higher levels of CAC seen in SLE.

Methods: Levels of OPG were assayed by ELISA in frozen samples of plasma (HEARTS) and serum (SOLVABLE). CAC was measured by CT in both

studies and ordinal logistic regression models were used to estimate adjusted ORs for being in a higher CAC category (0, 1-10, 11-100 and >100) vs. the next lower category.

Results:

Combining HEARTS (n cases /controls=125/124, age and race-matched) and SOLVABLE (n cases/controls= 185/184, age and race-matched), mean age (for cases, controls) was 46, 48 years, % postmenopausal (45, 40%), % African-American (AA) (23, 22%), %current smoking (11, 10%) and %ever smoking (37, 44%). The distribution of CAC among the 620 women was CAC=0: n=397 (218 HC and 179 SLE), CAC=1-10: n=109 (52 HC, 57 SLE), CAC 11-100: n=64 (29 HC, 35 SLE) and CAC>=100: n= 43(9 HC, 34 SLE.) In both studies, OPG was higher for SLE vs. HC, AA vs. white, and post- vs. premenopause ($p<0.05$). Among the entire group, OPG was higher with higher CAC category, with OR (95%CI) = 1.35(1.14, 1.59) per SD OPG and 2.21(1.32, 3.71) for the 4th vs. 1stquartile of OPG (Q4 vs. Q1). Based on the racial differences noted in OPG levels, subgroup analyses were conducted by race and case-control status, showing a consistent positive association for white HC and SLE and AA HC. However, among AA SLE cases (n=67), there was no association of OPG with higher CAC (OR=1.0, p=0.9). Therefore all subsequent analyses excluded AA SLE cases in models adjusted for study, race, LDL-C and smoking. Higher OPG was significantly associated with higher CAC category for SLE cases, OR (95%CI) for Q4 vs. Q1= 2.80 (1.25-6.30) and for HC: 2.40 (1.03, 5.58), in separate models. Among the entire group (HC+SLE), the OR for Q4 vs Q1 OPG in predicting higher CAC was 2.78 (1.57, 4.94), and with adjustment for SLE, was 2.72 (1.53, 4.84). For SLE vs. HC, the OR for higher CAC was 2.20 (1.47, 3.29), and 2.14 (1.43, 3.22) when adjusted for OPG (quartiles). Results were similar in sensitivity analyses restricted to HEARTS only, or white women only, or white post-menopausal women only.

Conclusion:

In 2 SLE case-control studies, higher OPG was associated both with SLE and with higher CAC among cases and controls, except for AA SLE cases. The association of SLE with higher CAC was only slightly attenuated by concurrent levels of OPG. Longitudinal studies in larger samples are warranted to clarify the role of OPG in the increased CAC noted in SLE, and potential differences by race.

Small LDL-P Increases with Increased Disease Activity in SLE

Laura Durcan[1], Deborah Winegar[2], Margery Connelly[2], James Otvos[2], Laurence S Magder[3] and Michelle Petri[1], [1]Rheumatology, Johns Hopkins University Hospital, Baltimore, MD, [2]LabCorp, Raleigh, NC, [3]Epidemiology and Preventive Medicine, University of MD, Baltimore, MD

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic lupus erythematosus (SLE) associates with accelerated atherosclerotic cardiovascular (CV) disease which is not fully explained by traditional CV risk factors. Disease activity, prednisone treatment and immunologic abnormalities are thought to contribute. Dyslipidemia is common in SLE patients, who have mild elevations in triglycerides (TG) and sometimes low HDL cholesterol levels. Recent evidence suggests that low density lipoprotein particle number (LDL-P) is a better marker of cardiovascular risk than LDL cholesterol levels. Lipoprotein subclass analyses have shown that SLE patients have larger VLDL particles and lower levels of large HDL particles compared to control subjects, but little is known about how these markers change with disease activity. We evaluated SLE patients during high disease activity and compared this to no or low disease activity to determine how lipoproteins change with active SLE.

Methods:

Patients were identified as part of a longitudinal lupus cohort. At each visit, plasma samples were collected. Global disease activity was measured using the SLEDAI. Patients were included who had at least one visit with SLEDAI of 4+ (high disease activity) and one visit with SLEDAI<3 (low disease activity). Plasma was analyzed for lipoprotein particle concentrations using nuclear magnetic resonance spectroscopy (NMR). The NMR spectrum also contains a signal termed GlycA derived from the carbohydrate chains of circulating acute phase glycoproteins that is a marker of systemic inflammation. Lipoprotein particle and GlycA levels were compared between high activity and no or low disease activity visits using t-tests. Further analysis compared consecutive visits to see whether changes in lipoprotein parameters were associated with a flare.

Results:

Thirty-three patients met inclusion criteria (97% female, age range 19-76, 48% Caucasian and 48% African American). The mean number of visits per person with high Vs. low disease activity were 2.1 and 2.4 respectively. The total LDL particle number (LDL-P) and small LDL-P levels were higher with disease activity as was VLDL size (Table 1). GlycA levels were unchanged with active disease but were higher than those described for healthy

populations.

Conclusion:

Although the lipoprotein profiles of SLE patients have been previously described, alterations in these profiles with disease activity have not been investigated. Here we demonstrate, for the first time in adult SLE, adverse changes in novel lipid parameters with disease activity. Thus, we can now demonstrate one potential mechanism by which SLE disease activity influences atherosclerosis. GlycA was unchanged with disease activity, but higher than reported controls, which may make it useful in stratification of CV risk in SLE.

Table 1. Mean Person-specific differences in marker level between visits with and without disease activity.

Marker	Mean (SD) during visits with SLEDAI 4+	Mean (SD) during visits with SLEDAI <=3	Mean (SD) Difference	P-value
Total VLDL & Chylomicrons	50.5 (28.0)	53.1 (21.2)	-2.6 (30.1)	0.63
Large VLDL particles	3.3 (2.2)	3.0 (1.9)	0.3 (1.5)	0.30
Medium VLDL particles	13.3 (8.7)	12.3 (8.6)	1.0 (7.3)	0.44
Small VLDL particles	33.9 (23.0)	37.8 (18.9)	-3.8 (26.5)	0.41
Total LDL particles	1047.8 (317.7)	976.6 (309.8)	71.2 (145.9)	0.0085

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

: Women with SLE have increased risk of atherosclerosis (ATH) that is not adequately explained by traditional risk factors. We previously discovered that a high risk score on a panel of traditional and novel biomarkers, the PREDICTS score, confers 28-fold increased odds for the presence of any current, progressive, or acquired carotid plaque, both in patients with SLE and in control subjects, and is significantly associated with higher rates of IMT progression. The biomarkers included in the panel are sTWEAK (≥373 pg/mL), pro-inflammatory HDL (piHDL), age≥48, homocysteine ≥ 12 mmol/L, leptin ≥34 ng/dL, and DMII. It is unknown, however, whether other biomarkers of oxidative stress predict future progression of ATH in SLE.

Myeloperoxidase (MPO) is an enzyme and heme protein that catalyzes the formation of several reactive oxygen species, and has been linked to inflammation and ATH in the general population. Furthermore, MPO is present in NETs, and has been implicated in the generation of piHDL. To determine whether plasma MPO levels might predict future development of subclinical ATH and whether piHDL might mediate this effect, we measured baseline plasma MPO levels and the progression piHDL function and of plaque using carotid ultrasound in a cohort of SLE patients.

Methods:

Female SLE subjects not taking statins at baseline were studied. B-mode and Doppler scanning of carotid arteries was performed at baseline and at 24-36 months. Plasma MPO levels were measured in the baseline blood samples using ELISA (R&D Biosystems).

Results:

Repeat carotid ultrasounds and MPO measurements were completed on 202 women with SLE. The mean age of the SLE group was 43.7 ± 12.5 years. Plaque progression (defined as new or increased plaque) was seen in 42 subjects (21%). Mean baseline plasma MPO levels were significantly lower in SLE patients with plaque progression compared to those without: 17.8 ± 15.2 pg/mL in patients with plaque progression vs. 38.2 ± 60.9 pg/mL in SLE without ($p<0.001$) However, there was no significant difference in baseline MPO levels among subjects with plaque presence at baseline. Baseline MPO levels were inversely correlated with pro-inflammatory HDL function at follow-up ($r=-0.33$, $p<0.001$), but no correlation between MPO levels and presence of pro-inflammatory HDL was observed at baseline. Using logistic regression to control for traditional cardiac risk factors and the PREDICTS risk profile, the variables still significantly associated with plaque progression in SLE included high PREDICTS (OR 27.0 $p<0.001$), MPO levels in the lowest half (OR 4.2, $p=0.005$), and non-Caucasian ethnicity (OR 4.5, $p=0.003$).

Conclusion:

Plasma MPO levels are significantly and independently inversely associated with plaque progression on carotid ultrasound in patients with SLE. Lower baseline MPO levels are also significantly associated with future formation of inflammatory piHDL, suggesting that this could be one mechanism to explain the association.

Target Modulation of a Type I Interferon Gene Signature and Pharmacokinetics of Anifrolumab in a Phase IIb Study of Patients with Moderate to Severe Systemic Lupus Erythematosus

Philip Brohawn[1], Lingning Santiago[2], Chris Morehouse[1], Brandon Higgs[1], Gabor Illei[1] and Koustubh Ranade[1], [1]MedImmune, Gaithersburg, MD, [2]MedImmune, Mountain View, CA
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Anifrolumab is a fully human IgG1 monoclonal antibody directed against subunit 1 of the type I interferon receptor (IFNAR1). Anifrolumab blocks the binding of type IIFN and inhibits the biologic activity of all type I IFNs. The PD and PK effects of anifrolumab were assessed through analysis of the blood of adult patients with moderate to severe SLE enrolled in a Phase IIb study (MI-CP1013).

Methods: Adult patients who satisfied ACR classification criteria for SLE were enrolled in a Phase IIb randomized controlled trial and received anifrolumab 300 or 1,000 mg intravenously every 4 weeks, or placebo, in addition to standard of care. Blood specimens were collected for PK and PD assessments at selected time points from pre-dosage to 422 days after initial administration. Transcript profiling was conducted through real-time quantitative reverse transcription–polymerase chain reaction (qRT–PCR) on a 21-gene type I IFN-inducible gene signature (IFNGS). Neutralization scores were calculated throughout the dosing schedule for each available time point (Days 29 to 365), based on patients' Day-1 baseline expression IFNGS values. Percentage neutralization scores for each dosage arm were summarized (median) for all available time points. Serum anifrolumab concentrations were measured using a validated electrochemiluminescence assay.

Results: A total of 215 of 305 patients (70.5%) were positive at baseline for the IFNGS. Expression of IFNGS in whole blood decreased following anifrolumab administration for all dosages in patients positive for the IFNGS at baseline. In the 300-mg every-4-week dosage arm, a median signature neutralization range (85.2–89.7%) was observed between Day 29 and 365. Maximum median neutralization (89.7%) was observed at Day 169. In the 1,000-mg every-4- week dosage arm, a median signature neutralization range (86.8–91.9%) was observed between Day 29 and 365. Maximum median neutralization (91.9%) was observed at Day 365, although comparable median neutralization was observed earlier, at Day 141 (91.7%). Negligible IFNGS modulation was noted for the placebo arm at each time point assessed. For all patients who received anifrolumab, near maximum median signature neutralization was observed at the first time point assessed (Day 29). As a result of target-mediated clearance, PK exposure of anifrolumab was more than dose-proportional between the 300 and 1,000 mg doses. On Day 169, mean±SD C_{trough}increased more than dose proportionally from 18.8±10.9 to 115±62.9 µg/mL, when the dosage was increased from 300 mg to 1,000 mg every 4 weeks. There were no obvious differences in PK in the study between patients who were IFNGS-positive vs. IFNGS-negative.

Conclusion: Anifrolumab demonstrated expected mechanism of action in SLE. Target engagement of anifrolumab was confirmed with near maximum and sustained inhibition of the IFNGS. These data support the selection of 300 mg every 4 weeks as the dosage for study in Phase III pivotal trials.

Heart Rate Variability Is Associated with SLE Flare and with TNF- and IFN-Mediated Signaling

Aikaterini Thanou[1], Stavros Stavrakis[2], John Dyer[2], Stan Kamp[3], Melissa E. Munroe[1], David Albert[4], Judith A. James[5] and Joan T. Merrill[3], [1]Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Heart Rhythm Institute, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Clinical Pharmacology, Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]AliveCor, Inc., San Francisco, CA, [5]Arthritis and Clinical Immunology, University of Oklahoma Health Sciences Center and Oklahoma Medical Research Foundation, Oklahoma City, OK

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Decreased heart rate variability (HRV), associated with adverse outcomes in cardiovascular diseases, is frequently seen in patients with SLE. The LF/HF ratio, a HRV measure, reflects sympathovagal balance. We examined associations of HRV with SLE activity and cytokine expression.

Methods: 53 SLE patients were evaluated at 2 visits (total 106 visits) with BILAG, SLEDAI, PGA and SFI (SELENA Flare Index). Caffeine, tobacco and medications were recorded. HRV (RMSSD, pNN50, HF, LF/HF ratio) was measured using a 5-minute ECG. Plasma cytokines were assessed by ELISA or a multiplex immunoassay.

Results: Baseline HRV was inversely related to disease activity and flare (table). Changes in HRV between visits were inversely related to changes in SLEDAI and PGA. Hydroxychloroquine dose was associated with increased HRV. Age, caffeine, tobacco and other medications had no impact. Plasma TNFRII and MIG inversely correlated with baseline HRV, and similar trends were observed for BLyS, IL-1α, IFNα and IP-10. Using multivariate linear regression model with backward elimination, TNFRII was an independent predictor of baseline HRV after adjusting for hydroxychloroquine dose and plasma BLyS, IL-1α and IFNα. In a similar model, MIG impact remained significant adjusting for the same variables. Furthermore, changes in the LF/HF ratio between visits were associated with changes in TNFRII (p=0.048) and MIG (p=0.029).

Conclusion: Impaired HRV, particularly the LF/HF ratio, is associated with lupus disease activity, acute flare state, and several cytokines related to TNF

and IFN pathways. The strongest association was with TNFRII and MIG, confirming and expanding previous immune connections to vagal signaling.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to determine the prevalence of periodontal disease (POD) in patients with Systemic Lupus Erythematosus (SLE) and its relationship with cardiovascular risk factors.

Methods: Cross-sectional study. POD was determined in patients diagnosed with SLE (ACR criteria 1982/1997) between the months of May to December 2014, through dental evaluation using the Loe and Sillness index with measurement of bags and plaque on all four sides of each tooth in both jaws. We evaluate: Demographic data: age at diagnosis and time of evolution, use and dose glucocorticoids in the last six months, SELENA-SLEDAI, laboratory variables: erythrocyte sedimentation rate (ESR mm), ultrasensitive PCR (hsCRP mg/l), cholesterol (mg/dl), triglycerides (mg/dl) HDL (mg/dL) and LDL (mg/dl). Cardiovascular variables: presence of metabolic syndrome (ATP III criteria), Body Mass Index (BMI), CVD risk as hsCRP value (Low <1 intermediate 1-3 and high> 3 mg/lt). Presence of Diabetes Mellitus (WHO criteria DBT- 1999), Arterial Hypertension (JNC VIII recommendations), hypercholesterolemia (cholesterol ≥ 200mg / dl) and smoking. Doppler ultrasound of neck vessels was performed using ultrasound with measurement of Intimate Media combined thickness (IMT) of common carotid artery, carotid bulb, and internal carotid and number of plaques. Dental variables: presence of POD according to severity and extent. Statistical analysis: descriptive statistics; for categorical variables: Chi 2 test, Fisher exact test; T test for continuous variables.

Results: Of 123 patients evaluated, 33 were excluded due to dentures in both jaws, 2 for pregnancy, 3 for drug use affecting the dental evaluation and 4 by the presence of other diseases. Finally, 81 patients were included, 91.4% (n = 74) women, mean age of 34.2 ± 11.9 years and mean age at diagnosis of SLE of 25.2 ± 8.1 years, duration of disease 104.8 ± 94.9 months and median SELENA SLEDAI of 2 (0-22). They were treated with GC in the last six months 64.2% (n = 52), 22.2% (n = 18) with doses > 0.5 mg /kg/day. The prevalence of periodontal disease was 48.1% (95%CI 37.3 - 59); 17.3% (n = 14) with mild to moderate type of both arches, 11.1% (n = 9) of an arcade and 12.3% (n = 10) with chronic marginal gingivitis. Of 81 patients, 21% (n = 17) met criteria for diagnosis of MS, 38.3% (n = 31) overweight and 14.8% (n = 12) obese; 29.6% (n = 24) had hypercholesterolemia, 2 were diabetics and three smokers. The mean hsCRP was 8.8 ± 12.9. CVD risk messured by hsCRP was higher at 46.9% (n = 38), intermediate in 24.7% (n = 20) and low in 28.4% (n = 23). Doppler ultrasound of neck vessels was performed in 58 patients with a mean of 0.5 ± 0.7mm MICS. No patient had atherosclerotic plaques. Statistically significant association between the presence of periodontal disease and use of corticosteroids in the last 6 months was found (p = 0.05) but none between POD and MS, DBT, hypercholesterolemia, hsCRP, BMI or SLEDAI (p = NS) in this population.

Conclusion: The prevalence of periodontal disease was 48.8%. There was no association between POD and cardiovascular risk.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We previously reported the influence of traditional and disease-related risk factors on the development of cardiovascular disease (CVD) in patients with systemic lupus erythematosus (SLE) followed for 7 years. The aim of this study was to further investigate their impact on clinical CVD in SLE patients and controls after 15 years of follow-up.

Methods: Two hundred and fifty women with SLE and no prior history of CVD (age 44.5±12 years, disease duration 13.7±9.7 years) and 250 age-matched healthy women (age 44.1±14 years) were recruited between 1998 and 2000. Recorded risk factors at baseline included arterial hypertension, diabetes mellitus, dyslipidemia (total cholesterol, triglycerides, HDL, LDL, VLDL), smoking, family history of premature CVD and body mass index. Patients and controls were prospectively followed for 14±4.1 and 15.9±1.9 years respectively for the development of cardiovascular events (CVEs). CVEs included angina pectoris, myocardial infarction (MI, fatal and non-fatal) transient ischemic attack (TIA), stroke (fatal and non-fatal), and were recorded at clinic visit for patients and by interview and chart review for controls. Statistical software SAS (version 9.3) was used for analysis; $p<0.05$ was considered significant.

Results: Initial risk factor profile revealed a higher prevalence of arterial hypertension (83/250, 33.2% vs 32/250, 12.8%, $p<0.001$) and diabetes mellitus (12/250, 4.8% vs 2/250, 0.8%, $p=0.007$) in patients' group. The frequency of other variables did not differ significantly. Follow-up data, after 15 years, were available for 211 patients and 137 controls. There were 32 deaths in SLE patients and 7 in controls. CVEs occurred in 32/179 patients (17.9%) and 8/130 controls (6.2%), Table 1. Angina and MI were more common in SLE than controls (17/211, 12.8% vs. 9/137, 6.5%, $p=0.005$). There were no statistically significant differences for TIA and stroke.

	Angina	MI (non-fatal)	MI (fatal)	TIA	Stroke (non-fatal)	Stroke (fatal)
SLE (n=211) N (%)	17 (8.1%)	10 (4.7%)	6 (2.8%)	4 (1.9%)	5 (2.4%)	2 (0.9%)
Controls (n=137)	4 (2.9%)	5 (3.6%)	0 (0%)	2 (1.5%)	1 (0.7%)	0 (0%)

Multivariate Cox-regression analysis demonstrated SLE [HR=2.89, 95% CI 1.22-6.81], family history [HR=2.25, 95% CI 1.13-4.45], triglycerides [HR=1.45, 95 CI 1.03-2.02], 10-year Framingham score [HR=1.12, 95% CI 1.05-1.19] and serum creatinine [HR=1.01 95% CI (1.0-1.02)] to be important predictors for CVEs. Patients with SLE with CVEs compared to those without were older (47.6±9.6 vs. 41.5±10.6 years, $p=0.003$), had higher serum creatinine (94.7±59.4 vs. 75.4±23.2 µmol/L, $p=0.003$) and, more frequently, hypertension (43.8% vs. 24.5%, $p=0.028$), hypercholesterolemia (46.9% vs. 27.9%, $p=0.036$) and family history of CVD (56.3% vs. 34%, $p=0.019$).

Conclusion: SLE patients have a 3-fold increased risk for clinical CVD as compared to healthy controls in the long term. Coronary heart disease was significantly more frequent than cerebrovascular disease. SLE itself, as well as traditional risk factors, are important predictors for CVEs.

Recurrence-Rate of Thrombotic Events in SLE Patients Negative for Antiphospholipid Antibodies

Mohammed Attar[1], Jiandong Su[2], Stacey E. Morrison[3], Samar Alharbi[4], Khawla Al-Ghanim[5], Dafna Gladman[2], Murray Urowitz[6,7] and Jorge Sánchez-Guerrero[8], [1]Rheumatology, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Div Rheumatology Rm MP-10-304, Toronto Western Hospital, Toronto, ON, Canada, [4]Rheumatology, University Health Network, Toronto, ON, Canada, [5]Rheumatology, TWH, Toronto, ON, Canada, [6]University of Toronto, Toronto, ON, Canada, [7]Rheumatology, U of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [8]Rheumatology, Mount Sinai Hospital and University Health Network, Toronto Canada, Toronto, ON, Canada

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Thrombotic events (TE) are common in patients with SLE. Antiphospholipid antibodies (aPL) are a risk factor for incident and recurrent TE; therefore these patients receive long term anticoagulation for secondary prophylaxis. SLE patients with negative aPL antibodies are also at increased risk of TE; however, the recurrence rate, type of TE, factors associated, and the optimal duration of anticoagulation is unknown. In the general population, the recurrence-rate of thrombosis at 5 years is 12.4%. The objective of this study is to determine the recurrence-rate of TE, type, and risk-factors associated in SLE patients negative for aPL antibodies according to the Sapporo Criteria.

Methods: The study was conducted within a prospective cohort. We identified patients with negative aPL (aCL and LA), who developed incident arterial (ATE) or venous thrombosis (VTE) during follow-up in the cohort, after 1990 when the aPL antibodies tests became widely available, and enrolled into the cohort within 5 years of SLE diagnosis. The demographic (age, ethnicity), clinical (disease duration, ACR criteria, SLE manifestations), autoantibodies (anti-dsDNA, anti-ENA, C_3, C_4), disease activity (SLEDAI-2K), disease damage (SDI) and treatment (prednisone, immunosuppressants, antimalarials, low-dose aspirin), type of TE (ATE, VTE), and traditional TE risk-factors (smoking, cholesterol levels, hypertension) were assessed. Main outcomes were the recurrence rate of TE, type, and variables associated.

Results: Forty SLE patients with negative aPL antibodies and incident TE were identified; they developed 14 ATE, and 29 VTE (3 patients had both ATE and VTE). Nine (22.5%) patients developed a second TE during 207.31 patient-years (py) of follow-up; recurrence-rate 4.3 TE per 100 py. The first event in seven patients was VTE, one ATE, and one both VTE/ATE. Eight recurrent events were VTE, and only one ATE; the concordance of vascular bed involved between both TE was total. Most (78%) recurrent events developed within 15 months after the first TE. Although non-statistically significant, patients with recurrent TE were female (100% vs. 81%), had younger age (25.8 ± 9.9 vs. 34.2 ± 14.9 yrs.), were predominantly of African ancestry (50% vs 16%), and had shorter SLE duration at first TE (1.7 ± 1.5 vs. 4.8 ± 4.9 years) in comparison to patients with no recurrence. No differences in other clinical manifestations, activity, damage or treatment were observed. The prevalence of traditional thrombotic risk-factors was also similar between groups.

Conclusion: The recurrence-rate of TE is elevated among SLE patients with negative aPL antibodies, particularly VTE. Most recurrent TE happened within 15 months from the first TE and were seen in young female patients, with short disease duration and predominantly in those with African ancestry. If these results are confirmed in larger studies, they should be useful to better stratify recurrence risk and define the length of anticoagulation in this SLE subpopulation.

Musculoskeletal Complications of Systemic Lupus Erythematosus: Risk Factors for and Prevalence of Avascular Necrosis and Osteoporosis

Maeve Gamble[1] and Janet E. Pope[2], [1]Medicine, University of Western Ontario, London, ON, Canada, [2]University of Western Ontario, London, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

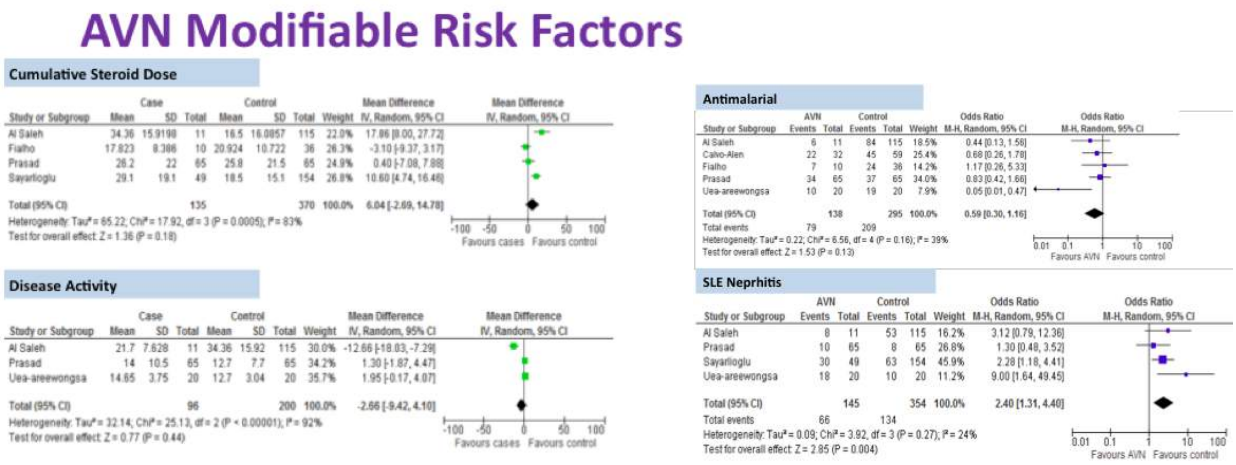
Background/Purpose: Osteoporosis (OP) and avascular necrosis (AVN) are well-recognized musculoskeletal complications of systemic lupus erythematosus (SLE) and cause morbidity. Steroid therapy and the underlying disease process are major contributors to these complications and the degree to which each influences the development of OP and AVN is unclear. Precise rates of AVN and OP are are far higher than the general population. The aim of this study was to identify the prevalence of OP and AVN and modifiable risk factors associated with their development in SLE.

Methods:

A comprehensive review of published articles and unpublished abstracts was conducted using the PubMed, EMBASE, and Cochrane databases. All articles relating to risk factors for AVN and OP in SLE were included. Exclusion criteria were: pediatric OP, publication with 44 or fewer SLE patients, and studies using the same patient population.

Results: Ten articles pertaining to AVN and 13 with OP were included. The prevalence of OP was 12% (range 5%-23%) and osteopenia 38% (9%-50%). Age, cumulative steroid dose, SLE damage, and low BMI were frequently reported risk factors. Other risks in some studies included: white or non-African Caribbean ethnicity, limited physical activity, premature ovarian failure, decreased vitamin D, decreased osteocalcin, low C4, positive anti-Smith antibody, and negative anti-Ro antibody. The cumulative dose of glucocorticosteroids was not significantly related to AVN. There was no difference in disease activity in patients who did and did not develop AVN (p=0.7). SLE renal involvement had more AVN (OR 2.4, 95% CI 1.5,3.8). Other risks in some studies were: cytotoxic drugs (cyclophosphamide and mycophenolate mofetil), serositis, Raynaud's, vasculitis, and seropositivty including anti-Smith and antiphospholip Abs. Antimalarial drugs were not significantly protective for AVN. Figures show some associations with AVN in SLE.

Conclusion: Several risk factors for OP and AVN were identified. Steroids were associated with OP. Renal involvement and vasculitis are associated with AVN.



Disclosure: M. Gamble, None; **J. E. Pope**, None.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with systemic lupus erythematosus (SLE), persistent joint activity and treatment with glucocorticoids are associated with musculoskeletal complications, including hip osteonecrosis. About 30% of these patients develop disability and become candidates for surgical treatment. The frequency of total hip arthroplasty (THA) in these patients has increased progressively. The aim of this study was to evaluate postoperative outcomes and potential risk factors for complications after THA in SLE patients in comparison to other inflammatory and non-inflammatory diseases.

Methods: We performed a retrospective cohort study at a tertiary care center in Mexico City between 1995 and 2013. All patients with SLE (ACR criteria ≥4), who underwent THA were included (n=58). They were compared with a group of patients with rheumatoid arthritis (RA) and other group with

osteoarthritis (OA), matched by gender and date of surgery. All surgeries were performed by the same surgical team. The main outcome was frequency of any postoperative complication during follow-up. The assessed complications were: transfusion requirement, hematoma, thrombosis, infections, aseptic loosening and prosthesis dislocation.

Results: We included 174 patients that underwent THA during the study period. The surgical indication was avascular necrosis in most patients with SLE and RA (98%). Univariate analysis revealed that patients with SLE were younger (p<0.001), and had a longer hospitalization (p=0.001), as well as more transfusional requirements (p=0.004). Other variables are shown in Table 1. Global complications in THA in patients with SLE were more prevalent than in the other groups (36% vs 9%, p<0.001). Most of these events occurred during the postoperative hospitalization. After multivariate analysis, risk factors for THA complications were: SLE (HR 2.8, 95%CI 1.2-6.8; p=0.018) and low postoperative hemoglobin (HR 0.77, 95%CI 0.73-0.83; p<0.001). There was a trend towards a higher risk of complications in patients with history of glucocorticoid treatment (p=0.055). Long-term complications after THA were not different among groups.

Conclusion: To our knowledge, this is the largest single-center study regarding the clinical outcomes after THA in SLE patients. Our data suggest that SLE is an independent risk factor for adverse postoperative outcomes, mainly immediate complications. Particular emphasis should be made on attaining optimal postoperative hemoglobin levels after THA in SLE patients. Our data suggest that even though SLE is associated with increased risk of immediate complications, the long term outcome is good enough to offer surgical treatment, such as THA, that will eventually improve quality of life.

Table 1 Baseline demographic, clinical and laboratory characteristics in patients with total hip arthroplasty

Variables (mean±SEM)	*Total hip arthroplasty in SLE (n=58)*	*Total hip arthroplasty in RA/OA (n=116)*
Age, [years]	**34.4 ± 1.05**	55.1 ± 1.47
SLEDAI, [points]	1.31 ± 0.32	N/A
Preoperative glucocorticoid dose [mg/day]	**2.1 ± 0.49**	0.3 ± 0.12
Cumulative glucocorticoid dose [mg/year]	**755.1 ± 160.49**	125.8 ± 47.26
Postoperative hemoglobin [gr/dL]	**9.0 ± 0.23**	9.6 ± 0.12
Transoperative transfusion requirements (%)	**19/58 (32.7)**	8/156 (6.8)
Hospitalization length, [days]	**11.3 ± 0.86**	8.2 ± 0.13
Global complications (%) • Immediate (same hospitalization period as the surgical event) • Mediate • Late (≥30 days after hospital discharge)	**21/58 (36.2)** **17/58 (29.3)** 0 4/58 (6.8)	11/116 (9.4) 10/116 (8.6) 0 1 (0.68)

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: More Systemic Lupus Erythematosus (SLE) patients are undergoing total knee arthroplasty (TKA) with equivalent benefits to osteoarthritis (OA) patients. While post-surgical adverse events (AEs) are increased after total hip arthroplasty, whether a similar increase occurs after

TKA is unknown. This study compares 6-month AEs in SLE and OA.

Methods: Patients enrolled in institutional arthroplasty and lupus registries who underwent TKA between 2007 and 2014 were eligible for this retrospective case-control study. SLE patients were identified by ICD-9 code 710.0 and confirmed by chart review. OA controls were matched 2:1 with SLE cases on age, sex, year, and procedure. TKA for fractures were excluded. 6-month AEs were collected through chart review and a self-report questionnaire. Baseline characteristics were compared and regression analysis was performed to determine independent predictors of AE.

Results: 52 SLE TKA were matched to 104 OA. There were no differences in mean age and sex (See Table 1). There was no difference in the percentage of SLE vs. OA patients with complete 26-week follow-up (SLE 82.7% vs. OA 79.6%; p-value=0.65). 38.4% of SLE patients had ≥1 Charlson-Deyo comorbidity vs. 17.3% of OA (p-value<0.001; SLE not counted as a comorbidity). Pre- and perioperative "stress-dose" steroid use were increased in SLE (28.8% vs. 1.9%, p-value<0.001; 30.8% vs. 2.9%, p-value=0.01). Patients who received stress-dose steroids did not experience more AEs (37.5% of SLE on steroids had AEs vs. 38.9% SLE no steroids vs. 27.9% OA; p-value=0.40). SLE patients did not experience more major (SLE 25.0% vs. OA 19.2%; p-value=0.41), minor (SLE 15.4% vs. OA 10.6%; p-value=0.39), or total (SLE 38.5% vs. OA 27.9%; p-value=0.18) AEs. In a multiple logistic regression analysis controlling for comorbidities, SLE was not an independent risk factor for AEs (OR 1.61, 95% CI 0.74-3.50). Comorbidities were also not significantly associated with AEs when controlling for diagnosis (OR 1.05, 95% CI 0.46-2.39).

Conclusion: Despite increased comorbidities and steroid use, AEs are not increased in SLE patients after TKA and SLE is not an independent risk factor for AEs. Stress-dose steroid use does not increase risk of AEs. These important findings should guide recommendations for TKA in SLE patients.

Table 1: Patient Characteristics

	SLE (n = 52)	OA (n = 104)	P value
Age (SD)	57.9 (14.7)	58.8 (11.6)	0.72
Female, n (%)	51 (98.1%)	102 (98.1%)	0.99
BMI (SD)	30.2 (8.3)	32.4 (8.2)	0.12
Unilateral, n (%)	22 (42.3%)	50 (48.1%)	0.87

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To study the standardized incidence ratio (SIR), time trend and risk factors of AVN in patients with SLE.

Methods:

The records of all patients who fulfilled >=4 ACR criteria for SLE between 1999 and 2014 were reviewed. Patients who developed AVN at any sites ever since the diagnosis of SLE were identified. SLE controls who did not have AVN were randomly selected from our cohort database in a 4:1 (control/case) ratio, matched for age, sex and SLE duration. The SIR of AVN in SLE and its time trend was calculated by data retrieved from our hospital clinical information registry and the Census data from our Government. Risk factors for AVN in SLE were studied by multivariate logistic regression. A propensity score derived from a separate logistic regression model for the probability of use of high-dose prednisolone (>0.8mg/kg/day) therapy according to the prevalence of different SLE manifestations was used for adjustment.

Results:

55 patients with symptomatic AVN were identified (87% women; age 33.4±12.4 years; SLE duration 61.2±62.2 months) and were matched with 220 control SLE patients without AVN. The point prevalence of AVN in our SLE cohort (N=743) was 7.4%. All the patients with AVN had been treated with glucocorticoids (GCs). Compared to controls, AVN patients had used a longer duration of steroid (51.4±61.2 vs 45.6±46.8 months; p=0.45) and a significantly higher cumulative doses of prednisolone (16.5±14.6 vs 10.7±11.3 grams; p=0.003). The SDI damage score was also significantly higher in AVN patients than controls (3.5±1.8 vs 0.4±0.9; p<0.001). A total of 104 sites of AVN were diagnosed in 55 patients (69% >=2 sites; 12.7% >=3 sites; 5.4% >=4 sites and 1.8% >=5 sites). The hip was the most commonly affected region (82%), followed by the femoral condyle (9%) and the humeral head (5%). Bilateral involvement was present in 67% cases. Surgical treatment (core decompression, vascularized bone graft or joint replacement) was performed in 41% of patients. The age and sex stratified SIRs of AVN in our SLE patients was 131 (86.6-199; p<0.001) in the period 1995-2004 and 56.0 (34.3-91.4; p<0.001) in the period 2005-2014. In both decades, the age stratified SIR was highest in the youngest age group (<19 years of age). Logistic regression revealed the following factors independently associated with AVN, adjusted by the propensity score for high-dose prednisolone: preceding septic arthritis of the involved joint (odds ratio [OR] 15.4[1.3-181.2]; p=0.03), Cushingoid body habitus (OR 2.3[1.0-5.1]; p=0.043), LDL-cholesterol level (OR 1.4[1.0-2.0];p=0.041), maximum daily dose of prednisolone (mg/kg) (OR 6.0[1.2-30.7];p=0.031) and cumulative dose of prednisolone in the first 6 months of treatment of a SLE flare (OR 1.4[1.0-1.8];p=0.047).

Conclusion:

AVN is prevalent in SLE patients, particularly in younger patients. The use of GCs remains the strongest independent factor associated with AVN. Cushingoid body habitus, serum LDL-cholesterol level and preceding septic arthritis of the involved joints are independently associated with AVN. There is a trend of reduction in the SIR of AVN in our SLE patients over the past 2 decades, which is probably attributed by the more judicious use of GCs and the early administration of GC-sparing agents.

Predictability of Musculoskeletal Flares and Hand Deformities in Systemic Lupus Erythematosus By High Resolution Ultrasound : 5-Year Clinical and Imaging Prospective Follow-up Study

Matteo Piga[1], Alessandra Gabba[1], Mattia Congia[1], Fabiana Figus[1], Alberto Floris[1,2], Alberto Cauli[1] and Alessandro Mathieu[1], [1]University of Cagliari, Cagliari, Italy, [2]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

SLE patients develop non-deforming non-erosive (NDNE) arthritis in 70-80%, but 5-15% of cases progresses into Jaccoud's arthropathy (JA) a non-erosive

deforming arthritis. This study was aimed to investigate risk factors for development of JA in SLE patients with a focus on the progression and predictive values of synovitis, tenosynovitis and erosions detected by high-resolution ultrasound (US).

Methods:

Ninety-four consecutive patients diagnosed with SLE and NDNE musculoskeletal involvement were recruited in a 5-year prospective follow-up study. Sixty healthy subject served as controls.

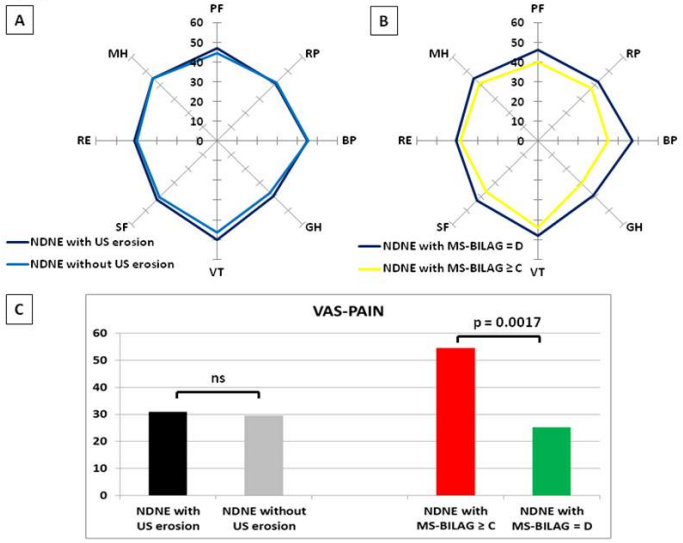
Every 6 months, or more frequently according to clinical needs, each patients underwent physical examination and a large panel of laboratory investigations. The occurrence of musculoskeletal flares was evaluated using the musculoskeletal item of BILAG2004 index. X-ray and US examination were performed at baseline and at the end of study. Patient reported outcomes (PROs) by means of SF36v2, HAQ and VAS-Pain were assessed.

Clinical, serological and US findings were used as covariates to identify risk factors for development of hand deformities (according to Spronk PE, et al. Ann Rheum Dis 1992;51:358-61). Stepwise Cox proportional hazard and logistic regression models were fitted with covariates with $p<0.1$ to predict outcomes; $p<0.05$ was considered significant. Odds ratio (OR) with 95% confidence interval (95% CI) was calculated.

Results:

Eighty patients (mean age 45.5±13.2 years; disease duration 10.7±7.1 years) completed the 5-year follow-up. Hand deformities developed in 5 (6.2%) patients with a JA estimated incidence rate of 1.25 per 100 patient-year. Longer disease duration (p=0.010; OR 1.3 95%CI 1.1-1.5) and MS flares during follow-up (p=0.017 ; OR 7.0 95%CI 1.4-35.5) independently conferred an increased risk for development of JA. Over 860 clinical assessments, 13 musculoskeletal flares (3 “A” severe and 10 “B” moderate) in 10 (12.5%) patients were recorded. US evidence of synovial proliferation with power-Doppler signal in joints or tendons (p=0.005; RR 6.7 95%CI 1.8 – 22.6) was the only independent risk factor for musculoskeletal flare. New US erosions were detected in 13 (19.7%) patients but none of them had erosions on X-ray. Active musculoskeletal involvement was responsible of worse PROs than detection of US erosions (Figure 1).

Figure 1. How each component of the SF36v2 (A and B) and VAS-Pain (C) vary in SLE patients suffering with NDNE according to the presence of US erosions and active MS symptoms classified as MS-BILAG ≥ C.



Conclusion:

Development of JA was more likely in patients with musculoskeletal flares and longer disease duration. US abnormalities identify a subset of SLE patients with more aggressive musculoskeletal involvement, higher risk for flares and, therefore, at risk for development of JA and deterioration of PROs.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Arthritis is a current manifestation of SLE and participates to the SLEDAI composite score calculation (0 to 105). Ultrasonography (US) is a validated and sensitive tool for joint assessment. Published studies showed US joint abnormalities in SLE patients with or without joint pain. Nevertheless, US evaluations were not standardized and no study compared clinical and US assessments. Our objectives were 1) to describe US joint abnormalities in SLE population, 2) to compare clinical and US standardized joint assessments, 3) to estimate the reliability of clinical swollen joint count (C-SJC) and SLEDAI (C-SLEDAI) score *versus* US-SJC and US-SLEDAI.

Methods:

In an observational prospective multicenter study, we recruited consecutive SLE patients (with or without joint involvement). All fulfilled SLICC classification criteria. Evaluation included a clinical standardized joint assessment (on 40 joints), a B-mode and power Doppler (PD) US examination of the same joints, hands X-Rays, biological parameters and ongoing treatments. US was blinded to clinical assessment and performed the same day in accordance of the OMERACT guidelines. Clinical and US joint assessments included wrists, MCP, IPP, elbows, shoulders, knees, ankles and MTP. Twenty six tendons were evaluated by US (wrist extensors, finger flectors and tendons of the ankles). A joint was considered as having synovitis if the grading was ≥1 through B-mode. Reliability between clinic and B-mode US was calculated at patient level using the intraclass correlation coefficient (ICC [95% Confidence Interval]).

Results:

141 SLE patients were recruited in 7 French hospitals. 88.6% were women, mean age was 45.3±14.8 years. SLE duration was 11.7±9.7 years. 58.1%, 72.3% and 20.5% were receiving corticosteroids, hydroxychloroquine and methotrexate respectively. Mean CRP was 6.7±11.6 mg/l and ESR was 19.4 ±19.3mm, 90.6% had increased antinuclear antibody and 46% had increased anti-DNA. Sixty one patients (43.6%) had inflammatory joint pain but 124 (88%) had at least one US abnormality (effusion, synovial hypertrophy, tenosynovitis with or without PD signal). Among the 5,640 joints and 3,666 tendons assessed, 442 effusions (7.8%), 549 synovial hypertrophy (9.7%) and 117 tenosynovitis (3.2%) were detected. 170 joints (3%) had PD signal. Synovitis were mainly detected on the wrists (46.4%), MCP2 (19.8%), MTP1 (26.2%) and MTP2 (18.4%). Tenosynovitis were seen on finger flectors (31%) and extensor carpi ulnaris (10%). Mean US-SJC was significantly higher than C-SJC: 3.5±5.3 *versus* 1.5±3.6. SJC reliability was poor (ICC 0.33 [95%CI 0.16-0.48] between clinical and US assessments. Among 92 patients with a C-SJC equal to 0, 64% (59/92) had at least 1 US synovitis. Mean US-SLEDAI was significantly higher than C-SLEDAI: 4.8±3.4 versus 2.9±3.5. SLEDAI reliability was mild (ICC 0.68 [95%CI 0.27-0.84]) between clinical and US assessments. Nevertheless, US-SLEDAI score was higher than C-SLEDAI in 51% of patients by detecting asymptomatic synovitis.

Conclusion: Joints and tendons US may be useful to assess joint involvement in SLE patients and SLEDAI score calculation.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Women with SLE are at increased risk for HPV-related cervical disease. The qHPV vaccine immunizes and is protective against HPV types that cause the majority of cervical cancer (types 16 &18) and genital warts (types 6 &11).This study evaluated the safety and immunogenicity of qHPV vaccine in SLE.

Methods:

In this trial**,** 34 women ages 19-50 years (yrs.) with a history of mild to moderate SLE by ACR criteria & minimally active or inactive SLE received qHPV vaccine at the standard dosing schedule (0, 2 months, 6 months). This study was approved by the Human Investigation Committee at Wayne State University & the U.S. Food and Drug Administration. Patients were excluded if they had active disease (SELENA-SLEDAI >2), history of severe disease, deep venous thrombosis, on >400 mg/day of hydroxychloroquine, on >15 mg/day of prednisone, or had active infections. Patients were monitored for adverse events (AE), SLE flare, generation of thrombogenic antibodies and thrombosis. Antibody (Ab) levels to HPV 6,11,16 &18 were evaluated pre-vaccine administration and one month after the 3rd vaccine shot. Ab levels were measured by HPV competitive Luminex Immunoassay. Analysis of rise in Geometric Mean Titers (GMTs) was performed using paired t-tests and of seropositivity status (y/n) using McNemar's test.

Results:

The women in the study: African-American (79%), mean age 38.1 yrs., mean age at diagnosis of SLE at 28.6 yrs., 32.4% had a history of smoking, 91% had 4 or more sexual partners, 50% had a history of sexually transmitted diseases, and only 27.3% used condoms on a regular basis. History of abnormal pap smears occurred in 52.9% {range: ASCUS (atypical glandular cells of undetermined significance) to CIN 3 (cervical intraepithelial neoplasia grade 3)}. Vaccine site reactions (VSRs) occurred in 59%, all mild, most common reaction being pain (VSRs in normal women=83.9% for Gardasil® vs. 75.4% for controls). For the non-vaccine site AEs (nvAE), 97% experienced at least one nvAE; there were 487 nvAEs reported from 33 patients and 90% of these were mild. There were 9 serious AEs, none related to vaccine or SLE and all resolved. The most common nvAEs reported were musculoskeletal (n=106) followed by nervous system (n=98, mostly headaches), gastrointestinal (n=49), general disorders (n=45) and dermatologic (n=45). None of the nvAEs were related to vaccine or SLE. No patient experienced any flare of SLE, thrombosis, or generation of thrombogenic antibodies.

Positive HPV Ab titers were seen in 21-53% of the women at baseline for all HPV types (52.9% for HPV 6, 20.6% for HPV 11, 44.1% for HPV 16 & 20.6% for HPV 18), indicating previous exposure to the HPV types in the vaccine. Highly immunogenic responses were seen in all patients. There was a statistically significant rise in mean (GMTs) post vaccine series completion for both HPV naive and HPV exposed women for all 4 HPV types, with a seroconversion rate of 100% in HPV naïve women.

Conclusion:

Preliminary data from our study shows that qHPV vaccine is generally safe, well tolerated, and highly immunogenic in women with SLE. These results suggest that the qHPV vaccine may be of benefit in women with SLE who are at increased risk for HPV-related cervical disease.

How Good a Job Are We Rheumatologists Doing in Screening for Hepatitis B and C before Immuno-Suppressive/s Initiation in SLE?

Chandrahasa Annem[1], Joel A. Block[2] and Meenakshi Jolly[3], [1]RHEUMATOLOGY, RUSH UNIVERSITY, CHICAGO, IL, [2]Rush University Medical Center, Chicago, IL, [3]Department of Medicine, Section of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Hepatitis B & C viral infections are widely prevalent and the potential of immunosuppressive medications (ISM) to exacerbate an underlying viral infection is well reported. Established guidelines are poorly defined regarding Hepatitis B and C screening prior to initiation of ISM, and may result in (a) physician practice variations, (b) missed opportunities for optimal health care and outcomes, and (c) complicate management plans for patients in need of ISM. We sought to better understand existing practices for viral hepatitis screening, and study the prevalence and correlates of Hepatitis B and C screening among Systemic Lupus Erythematosus (SLE) patients on ISM.

Methods: We conducted a retrospective chart review of 100 SLE patients receiving ISM and being followed in outpatient rheumatology clinics. Data collected included demographics, total number, name and current dose of ISMs being currently used, and if testing (and results) for Hepatitis B and C was

ordered prior to ISM initiation. ISM use was defined as current use of any ISM including corticosteroids (CS). Significant ISM use was defined as current use of prednisone > 7.5 mg/day along with an ISM other than hydroxychloroquine. Descriptive statistics were obtained. Chi square test were used to compare discrete variables, while t tests were used to compare continuous variables. Mann –Whitney test was used when data was not normally distributed. P value < 0.05 was considered significant on two tailed tests.

Results: 86% were women and the mean (SD) age was 27.9 ± 4 years. Forty one percent of patients were taking one ISM, 41% were on two and 19% were on three ISMs'. Nearly half of the patients were on CS with a median dose of 5 mg/day. Hepatitis B & C screening tests were performed in 34% and 33% patients respectively. All the patients tested for Hepatitis B Surface Antigen (HBS Ag) were negative. Of those tested, 12/29 had Hepatitis B Surface Antibody (HBS Ab), 2/29 Hepatitis B core Antibody (HBc Ab) & 1/33 had Hepatitis C antibody (HCV Ab). Screening tests were offered more frequently to younger patients, those on more than one ISM, those on CS and those on significant ISM. Among those on significant ISM, 47% were screened for HBS Ag, as compared to 22% of patients not on significant ISM (p=0.007). Likewise, 47% on significant ISM were screened for HCV Ab as compared to 20% not on significant ISM (p=0.004).

Conclusion: Less than 40% of those on ISM received Hepatitis B & C screening in SLE. Less than half of SLE patients that were tested prior to ISM showed immunity against Hepatitis B virus. Nearly 7% of SLE patients tested for Hepatitis B before ISM, showed chronic Hepatitis B, while 3% of SLE patients tested positive for Hepatitis C virus before ISM. These results indicate opportunities to improve screening and detect Hepatitis B/C in SLE patients on ISM. Education of physicians treating patients at higher risk and harmonization of various recommendations on Hepatitis B and C screening is indicated.

Table 1: Descriptives and Correlates of Hepatitis B and C Screening Tests in SLE			
Age (Mean (SD)) years	27.9 (4.9)		
Gender (%) Women	86		
Ethnicity			
White	29		
African American	38

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Infections are an important cause of morbidity and mortality in systemic lupus erythematosus (SLE) patients. These patients are more prone to develop infections, both because of intrinsic immune system abnormalities associated with the disease and immunosuppressive therapy. *Listeria monocytogenes* is a foodborne pathogen that may cause invasive disease, including bacteremia and meningitis, in immunocompromised patients. The aim of this study was to address characteristics and risk factors associated with meningitis by *L. monocytogenes* and to compare them with meningitis caused by other bacteria in SLE patients.

Methods: We performed a retrospective cohort study in a tertiary care center in Mexico City between 2000 and 2015. SLE patients who had a cerebrospinal fluid (CSF) culture positive for *L. monocytogenes* or other gram-positive bacteria were included. All patients fulfilled at least 4 ACR criteria for SLE. We also analyzed patients without SLE with a positive CSF culture for *L. monocytogenes*. Patients with a clinical diagnosis of meningitis but without a positive CSF culture were excluded. Demographic, clinical and serologic features both 3 months before and at the infection were recorded.

Results: Fourteen patients had a positive CSF culture for *L. monocytogenes* during the study period, and 9 of them (64%) had SLE. Among all SLE patients with meningitis proven by a positive CSF culture (n=22), infection with *L. monocytogenes* represented 41%. Group B *streptococcus* and *S. pneumoniae* were the second most common pathogens, each accounting for 14%.

There was no difference in SLEDAI score, complement and anti-dsDNA levels 3 months prior to the infection between both SLE groups. Prednisone and azathioprine dose 3 months before the infection were higher in patients with *L. monocytogenes* meningitis (p=0.025 and 0.043, respectively).

At the time of the infection, there was no difference in complement and antidsDNA levels; SLEDAI and SDI scores; prednisone, immunosuppressive and antimalarial drug dose; and CSF findings between both groups. Most SLE patients with *L. monocytogenes* received ampicillin (89%) during the first 24 hours after admission. SLE patients with *L. monocytogenes* had shorter stays in an intensive care unit (p=0.034) and lower mortality at 6 months (11 *vs* 54%, p=0.04) than those with meningitis by other bacteria. There was also a trend for lower mortality in patients with *L. monocytogenes* meningitis and SLE compared to those without SLE (11 vs 60%, p=0.052).

Conclusion: This is the largest, single-center study regarding *L. monocytogenes* meningitis in SLE patients. *L. monocytogenes* was a common cause for meningitis in our cohort, and SLE patients seemed especially susceptible to this pathogen. Other immunosupressed patients (HIV, transplant recipients, chemotherapy, other rheumatologic diseases) are routinely treated at our institution and the incidence in those patients was clearly lower. Whether a specific immunologic defect predisposes SLE patients to *L. monocytogenes* remains to be determined. On the other hand, mortality and days in an intensive care unit were lower in SLE patients with *L. monocytogenes*, which could be related to the prompt initiation of appropriate antibiotic therapy.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: There is no data in the literature about chikungunya fever (chik) and SLE. Martinique (French West Indies) experienced for the first time an outbreak of chik during the year 2014 that was an opportunity to study the relation between SLE and this viral infection.

Methods: The main objective was to describe the evolution of Chik patients with SLE. We also searched to know (1) if chik could modify SLE disease activity, (2) the role of SLE treatments, particularly immunosuppressive drugs, during the Chik episode. We perform a retrospective, monocentric, systematic evaluation of all SLE patients (fulfilling 1997 ACR criteria) followed in the internal medicine and rheumatology unit of the University hospital, between january 2014 and may 2015, assessing (1) SLE activity, (2) the presence of signs compatible with a chik episode. A systematic viral serology was prescribed with their usual biological follow up for all patients. Chik severity was considered if an encephalopathy, myocarditis, hepatitis, or multiorgan failure was present.

Results:

167 patients were screened for chik by serology, and we had a result for 110 in may 2015. 56 were included with a positive serology for chik (female: 53; male: 3). Their basic parameters were: mean age at serology (46.5 years, range: 23-81), time since SLE diagnosis to chik episode (12.9 years), renal involvement (42.8%), treatment by immunosuppressant drugs (33.9%), hydroxychloroquine or chloroquine (86.8%), prednisone (64.8%), rituximab (n=3). Clinical signs compatible with a Chik episode were found in 82.6% of the patients with a positive serology. Four patients (7%), all younger than 55 years and one treated by mycophénolate, exhibit severe signs of chik including encephalopathy (n=4) associated with bullous cutaneous lesions (n=3), kidney involvement (n=2). One of these 4 patients who was not immunosuppressed, died in a context of systemic capillary leak syndrome and multiorgan failure. Six of 56 positive patients (10.7%) experienced a lupus flare, all after a symptomatic chik fever: 5/6 were on prednisone, 5/6 hydroxychloroquine and 3/6 (50%) immunosuppressive drugs.

Conclusion: SLE can lead to severe Chik infection and should be considered as a group at risk. Chik fever can probably induce SLE flare. Immunosuppressive drugs seem not influence the clinical picture of chik.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Infections are an important cause of mortality and morbidity in systemic lupus erythematosus (SLE) patients. Bloodstream infections (BI), which are especially severe and relatively common in these patients, are associated with a high mortality rate, both during the infectious episode and during follow-up. Whereas there is evidence that bacterial infections can trigger autoimmunity, the relationship between BI and severe lupus flares has not been fully addressed. The aim of this study was to assess whether BI are a risk factor for severe lupus flare.

Methods: We performed a retrospective cohort study comparing 107 SLE patients with an episode of BI and 107 hospitalized or ambulatory SLE patients without BI. All subjects satisfied the ACR classification criteria and none of them had severe lupus flare at baseline. Time zero was considered as: a) The episode of BI in the first group b) Hospitalization for another cause, or the medical assessment prior to the last follow-up visit as an ambulatory patient in the non-BI group. Patients were followed for three months. The primary outcome was severe lupus flare according to SELENA-SLEDAI criteria. Differences between groups were assessed by Student's t test. Cox proportional hazards model was used to estimate the relative risk of severe flare, along with 95% confidence interval.

Results: Thirty patients (14%) developed the primary outcome (severe flare) during follow-up; 25 (83.3%) of them had an episode of BI in the previous three months, compared with 5 (16.6%) without a history of BI ($p<0.001$). A high percentage of patients with severe lupus flare had a SLEDAI score >12 (36.6%). Among these flares, severe thrombocytopenia (33.3%) and renal flare (43.3%) were the most frequent. There was no difference in prednisone, cyclophosphamide and mycophenolate mofetil dose between patients who presented severe lupus flare and those who did not. Nevertheless, the basal SLEDAI, C3, C4, anti-dsDNA and azathioprine dose were significantly higher in the former group. After multivariate analysis, the presence of BI (HR 6.24, 95% CI 1.405-27.725, p=0.016), low C4 levels (HR 3.2, 95% CI 1.272-8.078, p=0.014) and lymphopenia <1000 cells/ml (HR 5.02, 95% CI 1.137-22.23, p=0.033) remained independently associated with severe lupus flare.

Interestingly, while only 10.3% of BI episodes were caused by *S. pneumoniae*, 54.5% of patients infected by that microorganism developed a severe SLE flare. Noteworthy, infection by *S. pneumoniae* remained as an independent risk factor for lupus flare in the BI group (HR 2.75, 95% CI 1.406-5.403, p=0.019).

Conclusion: SLE patients with BI have an increased risk for severe disease flare. Also, lymphopenia and low C4 were significant predictors in our cohort. Among patients with BI, when *S. pneumoniae* was the causing agent, the risk of severe SLE flare augmented significantly. High mortality associated with BI

in SLE patients may not only be related to the infection *per se*, but also to the development of severe disease activity. Patients with an episode of BI, and specifically those who fulfill the other aforementioned characteristics, should be followed up closely in order to detect and treat flares in a timely manner.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Pneumonia, remains as a main cause of mortality in patients with SLE. In patients without autoimmune disease, scores as Pneumonia Severity Index (PSI) and CURB-65 can identify patients at low risk of complications. These indexes has not been validated in patients with SLE.

The aim of this study was to stablish the rate of complications of patients with SLE and pneumonia, identify specific risk factors associated with bad prognosis in these patients and describe the clinical behavior of PSI and CURB-65 to identify patients at low risk of complications.

Methods:

We retrospectively reviewed medical records of patients with SLE (ACR criteria) and pneumonia who attended the emergency room in a single tertiary care center, (January 2010 - March 2015). We collected laboratory and clinical data: demographics, treatment, risk factors commonly associated with poor outcome in pneumonia, and disease activity (SLEDAI-2K). Patients were followed for 30 days after discharge. A composite negative outcome were defined as need of mechanical ventilation (MV), septic shock or death during follow up.

Statistics. Initially we conducted a univariate analysis, using Student T, Mann-Whitney U, Chi squared or Fisher's exact test as appropriate. Thereafter we conducted a multivariate analysis (logistic regression) with all variables with a p value ≤ 0.10.

Results:

We included 163 patients (121 women, 74%), who presented 194 episodes of pneumonia. At evaluation the mean ± SD age was 34.6 ± 12.4 years. Time since diagnosis of SLE 7.1 ± 8.2 years. SLEDAI 2K was 8 ± 5.6.

Duration of hospitalization was 10.7 ± 7.2 days. Fifty seven (29%) patients had the composite outcome: 13 (7%) septic shock, 50 (26%) needed MV and 12 (6%) patients died.

Variables who reach clinical significance in the univariate analysis were: body mass index (BMI) (higher risk for patients with BMI lower than 19), chronic kidney disease, congestive heart failure, use of methotrexate and use of tacrolimus. Clinical variables with significant association were respiratory rate (RR), heart rate (HR), body temperature, oxygen saturation (detected by pulse oximetry), leukopenia, confusion, changes in pH and procalcitonin levels.

In the multivariate analysis remain significant: low BMI (beta exponential 4.02, 95% CI 1.4 – 11.6, p=0.010), RR (beta exp 1.08, 95% CI 1.02 – 1.15, p=0.006), HR (beta exp 1.04, 95% CI 1.02 – 1.06, p=0.001), body temperature (beta exp 0.46, 95% CI 0.28 – 0.75, p=0.002) and arterial pH (beta exp 0.001, 95% CI 0.00001 – 0.079, p=0.002).

Twenty nine patients (14.9%) had zero points in CURB65 (low risk), 4 of them (13.8%) had an adverse outcome. A score of zero in CURB65 had a sensitivity of 93% and specificity of 18% for identifying patients without complications. Sixty patients were classified as Class I in PSI, 7 of them had a negative outcome. Class I in PSI had a sensitivity of 88% and specificity of 39% for identifying patients without complications.

Conclusion:

In this study none SLE associated variable was significant associated with bad prognosis in patients with SLE and pneumonia. PSI and CURB65 are in general accurate but misclassified about 10% of patients as low risk, so clinical judgement must complement these tools.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic Lupus Erythematosis is a systemic autoimmune disease characterised by involvement of multiple organ systems Lupus nephritis (LN) is a severe and frequent manifestation of systemic lupus erythematosis (SLE). Its pathogenesis has not been fully elucidated but immune complexes are considered to contribute to the inflammatory pathology in LN.

The aim of the study to assess the potential role of HMGB1 (high-mobility group box proteins) in SLE and whether urinary and serum levels of HMGB1 reflect renal inflammation and correlate with disease activity,

Methods:

In **a** Case control study 61 Systemic lupus patients fulfilling the classification criteria for the diagnosis of SLE (divided in 4 groups)selected from Internal Medicine Department, Kasr Al-Aini Hospital, Cairo University after ethical committee approval and getting written informed consent from each patient.

Group 1: 21 patients with lupus nephritis ,**Group 2:** 21 patients with lupus activity without nephritis .**Group 3:** 19 patients without activity as estimated by SLEDAI < 4 ,**Group 4:**included 13 healthy volunteers age and sex matched.

Participants were subjected to: Detailed medical history., Complete physical examination. disease activity scoring using SLEDAI.

Laboratory investigations: Complete blood count. ,Kidney function tests , Urine analysis,ESR,ANA,,Anti dsDNA. ,C3, C4 levels. plasma and urinary levels of HMGB1 assessed by ELISA

Study of HMGB1 in renal biopsy from 21 patients with active lupus nephritis The activity index (AI) and chronicity index (CI) were calculated for each specimen with maximum scores of 24 for the AI and 12 for the CI.

Cellular distribution of HMGB1 was determined in the kidney by counting one hundred nuclei (glomerular, tubular, and stromal) in three bright field pictures and scoring both HMGB1-positive (brown) and HMGB1-negative (blue) nuclei

Results:

Plasma and urinary HMGB1 were in lupus with activity however significantly elevated in patients with active LN compared to patients without active nephritis($p<0.037$). and control($p<0.001$).Plasma and urinary HMGB1 and renal tissue levels HMGB1 levels correlated with SLEDAI differentiating SLE without nephritis from SLE with nephritis using ROC curve a higher sensitivity and specificity of HMGB1 in lupus nephritis compared with other groups 95.1% and 100% respectively Similarly, renal tissue of active LN patients showed strong expression of HMGB1 at cytoplasmic and extracellular sites suggesting active release of HMGB1

Conclusion:

The present study demonstrates increase in plasma, urine, renal tissue HMGB1 levels in SLE patients, in particular in those with active LN. Increase in HMGB1 levels correlated to SLE activity index (SLEDAI). Thus we suggest that HMGB1 may play an important role in renal pathology in SLE patients and HMGB1 blocking may be of future interest in development new treatment strategies for lupus nephritis

IGFBP-2 As a Novel Biomarker for Disease Activity and Renal Pathology in Lupus Nephritis

Huihua Ding[1], Chandra Mohan[1] and Tianfu Wu[2], [1]Biomedical Engineering, University of Houston, Houston, TX, [2]Department of Biomedical Engineering, University of Houston, Houston, TX

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Lupus nephritis (LN) is one of the most serious manifestations of systemic lupus erythematosus. Invasive renal biopsy remains the golden standard for the diagnosis and management of LN. The objective of this study is to validate serum IGFBP-2 as a novel biomarker of LN and to examine if it could reflect renal pathology in LN patients.

Methods:

Serum samples from 85 biopsy-proven lupus nephritis patients, 18 chromic kidney disease (CKD) controls and 20 healthy controls were used for ELISA testing of IGFBP-2 levels.

Results:

Compared to CKD patients of origins other than lupus or healthy controls, serum IGFBP-2 levels were significantly elevated in LN patients. Serum IGFBP-2 levels were able to discriminate LN patients from healthy controls with an Area Under the Curve (AUC) of 0.97 [95% CI: 0.93 to 1.00; $P < 0.0001$] and CKD disease controls (AUC: 0.65 [95% CI: 0.52 to 0.78; $P = 0.043$]). In addition, serum IGFBP-2 could serve as a potential indicator of both SLEDAI (active vs. inactive: 448.1 ± 51.9 ng/ml vs. 263.7 ± 41.7 ng/ml; $P = 0.009$) and rSLEADAI in LN patients (active vs. inactive: 429.1 ± 44.5 ng/ml vs. 213.3 ± 49.1 ng/ml; $P = 0.007$). Correlation analysis showed a significant correlation between serum IGFBP-2 levels and SLEDAI score ($r = 0.379$, $P < 0.0001$, $n = 85$) as well as rSLEDAI score ($r = 0.409$, $P < 0.0001$, $n = 85$). Serum IGFBP-2 levels also correlated well with serum creatinine levels ($r = 0.658$, $P < 0.001$, $n = 85$), urine protein-to-creatinine levels ($r = 0.397$, $P < 0.001$, $n = 85$), and eGFR levels ($r = -0.680$, $P < 0.001$, $n = 85$). More importantly, in 19 concurrent patients' samples, serum IGFBP-2 correlate with the chronicity index of concurrent renal pathology ($r = 0.576$, $P = 0.01$).

Conclusion:

Serum IGFBP-2 appears to be a promising biomarker for lupus nephritis, reflective of disease activity and chronicity changes in renal pathology.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is a severe manifestation of Systemic Lupus Erythematosus (SLE). Renal biopsy is gold standard for evaluation of renal activity and damage in LN. Evaluation of new biomarkers for non-invasive assessment of renal pathology is warranted. Ferritin is considered an acute phase protein and studies have reported elevated serum concentrations in patients with active SLE, as compared to patients with inactive disease, and

also correlations with LN. Insulin-like Growth Factor-Binding Protein 2 (IGFBP2) has been found to be a robust diagnostic and prognostic biomarker in malignancies. In animal models, IGFBP2 expression was increased in anti-glomerular basement membrane (anti-GBM) glomerulonephritis and MRL/lpr lupus mice. The role of these molecules in LN has yet to be clarified.

Methods: Serum levels of Ferritin and IGFBP2 were assessed by ELISA (Raybiotech Inc. and R&D Systems, respectively) in 64 patients with biopsy-ascertained active LN before and after completion of induction treatment. Follow-up renal biopsies were performed after a mean time of 8.1 months. Reduced proteinuria by ≥50%, normal or improved estimated Glomerular Filtration Rate (eGFR) by ≥25%, and inactive urinary sediment signified clinical responders (CR). Improvement of Activity Index in the follow-up biopsies by ≥50% signified histopathological responders (HR). Long-term renal outcome after a mean time of 10.9 years was determined by the last eGFR.

Results: Serum Ferritin and IGFBP2 levels declined following induction therapy for LN in both CR and HR ($p<0.001$). In clinical non-responders (CNR), IGFBP2 levels remained unchanged ($p=0.438$) while Ferritin levels declined ($p=0.030$). In histopathological non-responders (HNR), both Ferritin ($p=0.056$) and IGFBP2 ($p=0.158$) levels remained stable.

In patients with proliferative LN (PLN; n=52), Ferritin and IGFBP2 levels declined following therapy in both CR and HR ($p<0.001$). Ferritin and IGFB2 levels declined in CNR ($p<0.05$). In HNR, IGFBP2 levels remained stable ($p=0.086$) while Ferritin levels declined ($p=0.011$).

In patients with membranous LN (MLN; n=12), Ferritin and IGFBP2 levels declined in CR ($p<0.05$), but not in CNR. Ferritin levels declined in HR ($p=0.046$), but not in HNR while IGFBP2 levels remained stable in both HR and HNR.

Follow-up IGFBP2 levels were higher in CNR compared to CR ($p=0.004$). There was no correlation between Ferritin or IGFBP2 concentrations and long-term renal outcome. We noted a correlation between IGFBP2 levels and Chronicity Index at follow-up ($p=0.009$, $r=0.324$).

Conclusion: The decreases in Ferritin and IGFBP2 levels following induction therapy suggest an association of these molecules with renal disease activity. The data also suggest higher follow-up IGFBP2 levels as a biomarker of unfavorable treatment outcome in LN and point to IGFBP2 being a candidate biomarker of histopathological outcome following induction treatment for PLN. Moreover, our results indicate an important role and a potential utilization of both Ferritin and IGFBP2 as biomarkers of treatment response in MLN. The correlation between Chronicity Index and IGFBP2 levels at follow-up suggests IGFBP2 as a biomarker of renal damage in LN patients after induction therapy.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease manifested by multiorgan impairment including glomerulonephritis, cutaneous lesions and arthritis. B cells participate in the onset of SLE. As a downstream signaling molecule of B-cell receptor (BCR) signaling pathway, Bruton tyrosine kinase (Btk) is involved in the development, activation and survival of B cells. It is reported that transgenic mice overexpressing Btk specifically in B cells could produce antinuclear antibody and develop a lupus-like symptoms. The aim of our study was to identify the specific role of Btk in lupus nephritis.

Methods: The percentages of Btk positive $CD19^+$ B cells from 28 SLE patients and 28 healthy donors were examined by flow cytometry. The correlation between the percentages of Btk positive $CD19^+$ B cells and some lupus related clinical indicators were analyzed. Immunohistochemistry was used to detect the Btk expression in kidney biopsies from 8 lupus nephritis (LN) patients and 8 controls. The levels of Btk expression in glomerulus were detected by image-pro plus analysis, and represented by mean optical density (MOD).

Results: The frequency of Btk^+CD19^+ B cells from SLE patients is up-regulated compared with the healthy controls (3.89 ± 0.31 vs 2.61 ± 0.21, $p<0.01$), significantly correlating with the SLE activity (SLEDAI) ($r=0.53$), levels of serum anti-dsDNA antibody ($r=0.41$), levels of serum C3 ($r=-0.41$), and the amount of 24 hours urine protein ($r=0.59$). We also found that the frequency of Btk^+CD19^+ B cells in the patients with lupus nephritis was significantly higher compared with the patients without lupus nephritis (4.71 ± 0.481 vs 3.19 ± 0.30, $p<0.05$). The levels of Btk expression in glomerulus were markedly increased in LN patients compared with controls (0.04 ± 0.01 vs 0.01 ± 0.00, $p<0.001$).

Conclusion: Btk expression is significantly increased in LN, which may be a promising therapeutic target for the molecular therapy of SLE.

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is a severe manifestation of Systemic Lupus Erythematosus (SLE). Renal biopsy is gold standard for evaluation of renal activity and damage. New non-invasive biomarkers are warranted. Axl belongs to the Thyro3-Axl-Mer receptor tyrosine kinase subfamily and is mainly expressed on antigen presenting cells. Tumor Necrosis Factor Receptors (TNFRs) are involved in the pathogenesis of SLE. In previous reports, levels of the soluble forms of Axl and TNFRII were elevated in SLE patients, and Axl levels correlated with disease activity. The role of these molecules in LN remains to be clarified.

Methods: Serum levels of Axl and TNFRII were assessed by ELISA (R&D Systems) in 64 patients with biopsy-ascertained active LN before and after induction treatment. Follow-up renal biopsies were performed after a mean time of 8.1 months. Reduced proteinuria by ≥50%, normal or improved estimated Glomerular Filtration Rate (eGFR) by ≥25%, and inactive urinary sediment signified clinical responders (CR). Improvement of Activity Index (AI) in the follow-up renal biopsies by ≥50% signified histopathological responders (HR). Long-term renal outcome after a mean time of 10.9 years was determined by the last eGFR.

Results: Serum levels of Axl and TNFRII declined following induction therapy for LN in both CR and HR ($p<0.005$). In clinical non-responders (CNR), Axl levels remained unchanged while TNFRII levels declined ($p=0.049$). In histopathological non-responders (HNR), Axl levels remained stable while TNFRII levels declined ($p=0.008$).

In patients with proliferative LN (PLN; n=52), Axl and TNFRII levels declined in both CR and HR ($p<0.005$). Axl levels remained stable in CNR and HNR while TNFRII levels declined ($p<0.05$).

In patients with membranous LN (MLN; n=12), Axl and TNFRII levels declined in CR ($p<0.05$), but not in CNR. TNFRII levels declined in HR ($p=0.046$), but not in HNR, while Axl levels remained stable both in HR and HNR.

Baseline Axl and both baseline and follow-up TNFRII levels correlated inversely with the last eGFR ($p=0.014$, $r=-0.307$; $p=0.021$, $r=-0.290$; $p=0.043$, $r=-0.256$, respectively). Baseline TNFRII levels correlated with AI in baseline biopsies ($p=0.026$, $r=0.279$) and both baseline and follow-up Chronicity Index (CI) scores ($p=0.012$, $r=0.313$ and $p=0.003$, $r=0.373$, respectively). TNFRII levels correlated with CI at follow-up ($p<0.001$, $r=0.535$). Both baseline and follow-up Axl levels correlated with follow-up CI scores ($p=0.022$, $r=0.289$ and $p=0.037$, $r=0.264$, respectively).

Conclusion: Our data suggest Axl as a candidate biomarker of renal activity and treatment response in PLN and TNFRII as a candidate biomarker of renal activity and response in MLN. Higher baseline Axl and TNFRII levels were associated with unfavorable long-term renal outcome, supporting a role of these molecules in more severe renal disease and a more unfavorable prognosis. Moreover, our data suggest Axl as a candidate biomarker of renal damage in LN patients after induction therapy and TNFRII as a biomarker of both renal activity and damage in LN.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematous (SLE) is a multisystem autoimmune inflammatory disease. Lupus nephritis (LN) is one of the most serious complications in patients with SLE. Immunoglobulin binding protein 1 (IGBP1) originally was discovered as a phosphoprotein associated with the immunoglobulin receptor in B cells. This protein interacts with the catalytic subunit of protein phosphatase PP2A (PP2A), highly conserved serine/threonine phosphatase, and regulates differentiation, proliferation, and apoptosis of B cells. It has been reported that expression and activity of its catalytic subunit (PP2Ac) is increased in T cells from patients with SLE. However, the study of IGBP1 in patients with SLE has not been examined. The objective of the present study was to determine IGBP1 levels in SLE patients and identify any correlations between IGBP1 levels with other clinical variables and especially, renal pathology in patients with LN.

Methods: The levels of IGBP1 were measured in plasma and urine of SLE patients with (n=40) or without (n=30) LN, and healthy subjects (n=18). Correlation analyses between IGBP1 levels and the diseases-related variables including c-reactive protein (CRP), erythrocyte sedimentation rate (ESR), anti-double-stranded DNA antibody (anti-dsDNA), and SLE Disease Activity Index (SLEDAI) were examined. In addition, to evaluate if IGBP1 can differentiate LN disease severity, we performed IGBP1 levels regarding classes of kidney biopsy samples and correlation analyses of plasma IGBP1 levels with activity index score or chronicity index score in renal biopsy samples.

Results: Plasma levels of IGBP1 in SLE patients were significantly higher in SLE patients with (8.48 ng/ml) or without (9.69 ng/ml) LN than in healthy individuals (4.90 ng/ml). Among the diseases-related variables, SLEDAI scores were significantly correlated with the levels of IGBP1 in plasma (p= 0.0429) and urine (p= 0.0011). Interestingly, LN patients with Class III and IV had higher IGBP1 levels compared to those of II and V groups. Further, plasma IGBP1 levels had a significant positive association with chronicity index score (p= 0.0072).

Conclusion: This study demonstrates that the levels of plasma and urinary IGBP1 were significantly higher in SLE patients and were correlated with disease activity and chronicity index score of renal pathology. Therefore, IGBP1 might be a valuable tool for determining high disease activity in SLE patients and more severe kidney damage in LN patients.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Proliferating cell nuclear antigen (PCNA) is known to be an autoantigen specifically recognized in patients with SLE. PCNA constitutes PCNA-complex along with several PCNA-binding proteins in vivo. We have consecutively published that autoantibodies to PCNA-binding proteins are easily produced in SLE patients as well as autoantibody to PCNA itself. Furthermore, we have recently published the novel serum autoantibody to chromatine assembly factor-1(CAF-1), which belongs to the PCNA-binding proteins, might be an useful biomarker for neuropsychiatric (NP) SLE. Ribonuclease-H (RNase-H) also belongs to the PCNA-binding proteins and functions as a regulating factor for cell division in coordination with other PCNA-binding proteins such as CAF-1. Therefore, we assume that RNase-H will be a candidate of autoantigen specifically recognized in SLE and investigated the clinical association of anti-RNase-H antibody with SLE patients.

Methods:

Patients sera consisting of SLE (n=57), PM/DM (n=40), SSc (n=39), SS (n=28), MCTD (n=28), RA (n=29), and normal healthy controls (NHCs) (n=73)

were collected from serum bank of Juntendo University Hospital with their informed consent. Immunoreactivity against both RNase-H and CAF-1 recombinant antigens was evaluated by ELISA and was further confirmed by immunoblotting. The cut-off value designating a positive reaction in ELISA was defined as the mean value of NHCs +3 standard deviations.

Results:

Serum anti-RNase-H antibody was observed in 33% of SLE patients. The anti-RNase-H antibody was not recognized in both all control diseases and NHCs. Moreover, the coexistence of anti-RNase-H antibody and anti-U1 RNP antibody revealed high incidence of NPSLE. Moreover, titer of anti-RNase-H antibody was strongly correlated with titer of anti-CAF-1 antibody in regression analysis.

Conclusion:

In the present study, we identified anti-RNase-H antibody as a novel autoantibody specifically recognized in SLE. Measurement of anti-RNase-H antibody can be used for the diagnosis of SLE. Moreover, it might be a useful biomarker for NPSLE when anti-U1 RNP antibody coexists. The strong correlation in titer of anti-RNase-H and CAF-1 antibodies suggested that a breakdown of immune tolerance against component proteins of PCNA-complex lead to elicit autoimmune response to the other components of PCNA-binding proteins. This phenomenon is considered as epitope spreading which plays important role for the autoantibody production in SLE.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To explore the roles of autoantibodies to N-methyl-D-aspartate (NMDA) receptor NR1 subunit in the pathogenesis of neuropsychiatric systemic lupus erythematosus (NPSLE).

Methods: Paired serum and CSF specimens were obtained from 41 patients with NPSLE (22 with diffuse psychiatric/neuropsychological syndromes [diffuse NPSLE] and 19 with neurologic syndromes or polyneuropathy [focal NPSLE]), 21 patients with various rheumatic diseases other than SLE (non-SLERD). Sera were also obtained from 27 SLE patients without neuropsychiatric manifestations (non-CNS SLE). Antibodies to murine NR1 (mNR1) or to 4 different preparations of synthetic 25-amino-acid (AA) peptides of human NR1 were measured by ELISA.

Results: Serum anti-mNR1 levels were significantly higher in NPSLE than in non-SLERD. Sera from NPSLE patients bound efficiently to the AA residues 19-44 from the N-terminus of NR1 (NR1-A) or 57-81 (NR1-C), but not to the AA residues 37-62 (NR1-B) or 75-100 (NR1-D). Accordingly, serum anti-NR1-A and anti-NR1-C were also elevated in NPSLE compared with non-SLERD, although there was no difference between diffuse NPSLE and focal NPSLE. By contrast, CSF anti-NR1-A as well as CSF anti-NR1-C levels were significantly elevated in diffuse NPSLE compared with focal NPSLE or with non-SLERD. Finally, both anti-NR1-A and anti-NR1-C bound to the surface of SK-N-MC cells.

Conclusion: These results demonstrate that autoantibodies to NMDA receptor NR1, especially to the AA residues 19-44 and the AA residues 57-81 from the N-terminus are expressed in NPSLE. Moreover, the data also indicate that anti-NR1-A and anti-NR1-C play a pivotal role in the pathogenesis of diffuse NPSLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG antibodies expressing the idiotope for the 9G4 idiotype, the framework-1 hydrophobic patch (HP) of VH4-34, are expanded in SLE and provide a unique model to understand the participation of different autoantigens in the regulation of this disease. In particular the antibodies to single stranded RNA (ssRNA) have been implicated in viral infections in SLE. Here, we sought to understand the contribution of VH4-34 antibodies that bind to ssRNA in the pathogenesis of SLE.

Methods:

A panel of 9G4 + monoclonal antibodies (mabs) was generated from IgD+ CD27- naïve B cells and IgD-CD27+ memory B cells of SLE patients. A total of 30 monoclonal antibodies, (20 native antibodies and corresponding HP altered mutants) were tested for anti-ssRNA binding by ELISA. Two representative antibodies with strong ssRNA reactivity were also tested against a proteome auantigen microarray and by immunofluorescence.

Results:

Out of the 30 mabs with diverse antigenic binding patterns, 2 derived from SLE memory B cells (22%) had strong autoreactivity with ssRNA. These antibodies also bound other Ags including: apoptotic and B cell binding, dsDNA, chromatin, Ribosomal P, and were also positive for ssRNA. These two antibodies were of the IgG3 subclass and were clonally related with a single amino acid difference within the CDR2, and identical CDR3 regions of the heavy chain. Further, the corresponding 9G4- HP mutant of these two abs showed binding to ssRNA albeit with decreased intensity.

Conclusion:

Our preliminary results suggest that the anti-RNA response may be abundant in SLE memory B cells and mediated by expanded clones with a predominance of IgG3 antibodies. 9G4 mutagenesis experiments indicate that, while the HP may influence binding is not determinant of this type of autoreactivity. These findings are consistent with the lack of ssRNA binding of naïve antibodies and suggests that such autoreactivity is dependent on the conventional antigen binding site and may require somatic hypermutation. Larger studies will be required to understand the structural basis, generation and selection of ssRNA antibodies in SLE. Such studies will shed light into the role of exogenous and endogenous RNA antibodies to SLE autoreactivity.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

1) To identify and characterize miRNAs related to the pathogenesis of CVD in antiphospholipid syndrome (APS) and systemic lupus erythematosus (SLE) patients; 2) To evaluate the effect of specific autoantibodies in the regulation of miRNAs related to the pro-atherothrombotic status in both disorders.

Methods:

In silico searching allowed the identification of a number of miRNAs involved in the regulation of atherothrombosis. Six miRNAs (miR-124a, -125a, -125b, -146a, -155, and -222) were selected and quantified by RT-PCR in leukocytes from 20 APS and 43 SLE patients, and 28 healthy donors. Pro-inflammatory and prothrombotic proteins and oxidative stress markers were evaluated by flow cytometry. Proteins related to the biogenesis of miRNAs were quantified by RT-PCR and Western Blot. The clinical cardiovascular disease (CVD) profile was further recorded in APS and SLE patients.

Monocytes and neutrophils isolated from healthy donors were treated with anticardiolipin IgG isotype (ACA-IgG) and anti-dsDNA antibodies purified from APS and SLE patients' serum, respectively, or with IgG from healthy donors (IgG -NHS). Levels of selected miRNAs and their target molecules were determined. Expression of proteins involved in miRNAs biogenesis (Drosha, Dicer, Ago-1, Ago-2 and 2, and Xpo-5) were further analyzed. Transfections were performed with precursors of the miRNAs found altered, to identify key target proteins in both pathologies.

Results:

The expression levels of the selected miRNAs in neutrophils were significantly lower in APS and SLE than in the control group. Accordingly, gene and protein expression levels of molecules related to miRNA biogenesis were reduced in neutrophils from APS and SLE. In monocytes, miR124a and -125a were low in APS and SLE patients, while miR-146a and miR-155 appeared elevated. Correlation studies showed, in both pathologies, that the altered expression of all selected miRNAs correlated with the disease activity index, and parameters related to autoimmunity, thrombosis, inflammation and oxidative stress. Association studies showed that the occurrence of thrombotic events and the presence of a pathological increase of carotid intima media thickness were also linked to the altered levels of the measured miRNAs. The expression levels of all miRNAs were significantly reduced in neutrophils treated with ACA-IgG and anti-dsDNA compared to those treated with IgG-NHS. Both autoantibodies also decreased the expression of proteins related to miRNA biogenesis in these cells. In monocytes, treatment with ACA-IgG and anti-dsDNA significantly reduced the levels of miR-124a and miR-125b, as well as increased miR-146a and miR-155 expression. Monocyte transfections with pre-miR-124a and miR-125a, either separately or simultaneously, caused a drop in the expression of target molecules related to the atherothrombotic process in APS and SLE.

Conclusion: 1. Specific miRNAs might act as potential biomarkers of atherothrombosis in APS and SLE patients. 2. Some autoantibodies regulate this atherothrombotic status, at least partially, through epigenetic mechanisms such as modulation of miRNAs. Supported by CTS-7940, PI12/01511, SER.

Systemic Lupus Erythematosus Exosomes Contain Distinct RNA Transcripts That Differentiate

Disease Activity and Modulate Cellular Function

Samantha Slight-Webb[1], Krista M. Bean[1], Nicolas Dominguez[1], Mikhail G. Dozmorov[2], Judith A. James[3] and Joel M. Guthridge[1], [1]Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Arthritis and Clincial Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Arthritis & Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease involving multiple organ systems and periods of waxing and waning disease activity. The lack of well-defined disease biomarkers to predict disease flares hinders therapeutic optimization. Exosomes are secreted intraluminal vesicles involved in cell-cell communication and can be sampled from patients using minimally invasive methods. By identifying the role of exosomes in driving SLE disease activity, early biomarkers of flare and disease specific pathways can be identified.

Methods: Exosomes were isolated from plasma of healthy controls (n=10) and SLE patients with either elevated disease activity (SLEDAI≥6; n=5; SLE-hi) or low disease activity (SLEDAI≤4; n=7; SLE-lo) using Exoquick Isolation Reagent (SBI). Total RNA from plasma exosomes were extracted and purified using SBI's Seramir Kit and libraries were constructed using a modified Illumina adapter method and sequenced on an Illumina MiSeq v3 instrument. Cleaned sequences were filtered and sequences with lengths ≥18 nt were aligned using Bowtie 2 against the human genome reference sequences. Hairpin and mature miRNA sequence hits were identified using BLAST in MiRBase. BLAST searches for transkingdom RNAs with known associations in SLE were also performed. Differentially expressed genes were determined using DESeq2 R package. Characterization of exosome size and quantity was determined by electron microscopy and EXOCET Assay (SBI), respectively. Further, isolated exosomes from SLE-hi and SLE-lo disease activity patients and healthy controls were co-cultured with healthy control PBMCS for 48 hours and cellular activation and cytokine production of PBMCs was measured by flow cytometry and ELISA.

Results: SLE-hi patient exosomes had an increased median size (mdn 115.5nm) compared to SLE-lo patients (mdn 103.0nm) ($p<0.0001$), however, the abundance of exosomes did not differ between SLE disease activity or healthy controls (mdn $1.4x10^{12}$/ml). Exosome RNA libraries from SLE-hi patients had significantly more raw and clean RNA reads compared to healthy controls ($p<0.0082$) and SLE-lo patients ($p<0.05$). Further, SLE patients had 77 differentially expressed transcripts compared to healthy controls and 28 differentially expressed transcripts between high and low SLE disease activity ($p<0.05$) including Y RNAs and those associated with Epstein-Barr virus, transcriptional and post-transcriptional regulation, cytokinesis and apoptosis. Interestingly, when exosomes from SLE patients were incubated with healthy control PBMCs, SLE exosomes activated more CD4+ T cells ($p=0.0196$) and monocytes ($p=0.0294$). Further, PBMCs treated with SLE-hi exosomes produced greater amounts of IL-6 ($p<0.05$), but significantly reduced amounts of IL-10 ($p<0.005$) compared to PBMCs treated with exosomes from SLE-lo patients.

Conclusion: Our findings suggest that exosomes from active SLE patients have distinct characteristics and components that contribute to immune cell activation, inflammatory cytokine production, and impaired regulatory cytokine production which may contribute to lupus disease pathogenesis and activity.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Exosomes are 60–150 nm membrane vesicles that are secreted by various cells into surrounding body fluids including blood and urine. As vehicles for intercellular communication, they are involved in immune cell activation. To date, the role of exosomes in pathogenesis of systemic

lupus erythematosus (SLE) hasve not been fully elucidated. This study was aimed to investigate as to whether exosome formation is increased and whether they effectively contribute to proinflammatory cytokine response in patients with SLE.

Methods: Serum samples from SLE patients, rheumatoid arthritis (RA) patients and healthy controls were obtained at Seoul National University Hospital. Exosomes were isolated from sera using ExoQuick and quantified using EXOCET. Healthy peripheral blood mononuclear cells (PBMCs) were stimulated with exosomes from SLE patients, RA patients or healthy controls. After 24 hours, production of interferon (IFN)-a, interleukin (IL)-1b, IL-6, and tumor necrosis factor (TNF)-a were measured using ELISA. Correlation between SLE disease activity index (SLEDAI) and exosome levels was assessed by Spearman correlation.

Results: The purified exosomes were 60-150nm in size and had a membrane bilayer on electron microscopy. Exosomes from SLE induced healthy PBMCs to produce high levels of IFN-a, IL-1b, IL-6, and TNF-a, whereas exosomes derived from RA patients or healthy controls did not (Figure 1). Exosome-depleted SLE serum and SLE exosomes that were mechanically disrupted fail to elicit any significant proinflammatory cytokine production. The serum levels of exosomes were significantly higher in SLE patients than healthy controls ($21.13x10^7 \pm 3.711 x10^7$ *vs*. $110.4 x10^7 \pm 20.62 x10^7$, p=0.037) and their levels correlated with SLEDAI in patients with SLE (r=0.3663, p=0.0371).

Conclusion: These data suggest that exosomes are generated and they contribute to proinflammatory response in patients with SLE. Exosomes might serve as a novel biomarker of disease activity. Treatment targeting exosome might offer a new therapeutic option.

Figure 1. Production of proinflammatory cytokines IFN-a (A), TNF-a(B), IL-1b (C), and IL-6 (D) by the healthy PBMCs after stimulation with exosomes from HC or SLE patients. Data are presented as the mean±SEM. * $p<0.05$; ** $p<0.01$

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Long noncoding RNAs (lncRNAs) have recently been identified to be tightly linked to diverse human diseases. This study was

undertaken to investigate the contribution of the lncRNA NEAT1 which was identified to be involved in innate immune response to the pathogenesis of Systemic Lupus Erythematosus (SLE)

Methods: RT-PCR was used to compare NEAT1 expression between SLE patients and controls. Stimulation and transfection in THP-1 cells were conducted to determine the biologic function of NEAT1. Microarray and Western Blotting were performed to investigate in which pathway NEAT1 was involved. Correlation between NEAT1 expression and the disease activity of SLE patients was evaluated.

Results: NEAT1 expression was abnormally increased in the peripheral blood mononuclear cells (PBMCs) of SLE patients. We sorted the main three subsets of PBMCs (T cells, B cells, Monocytes), then compared the NEAT1 expression between SLE patients and healthy donors in these cell subsets in details and respectively. It was showed NEAT1 dominantly expressed in monocytes and was significantly up-regulated in monocytes of SLE patients compared with normal controls. Additionally, NEAT1 expression was induced by LPS via p38 activation in THP-1, the monocytic cell lines. We wondered whether or not NEAT1 would be involved in regulation of LPS-triggered induction of numerous inflammatory factors and found silencing NEAT1 significantly reduced the expression of a group of chemokines and cytokines, including IL-6, CXCL10, etc., which were induced by LPS continuously and in late stages. Furthermore, it was identified that NEAT1 selectively regulates LPS continuously-induced and late-response genes mainly through affecting the activation of the late MAPK pathway, especially the activation of JNK and ERK. Importantly, it was observed that in SLE patients, the overexpressed NEAT1 level correlates positively with the disease activity and NEAT1-regulated cytokines and chemokines.These indicate NEAT1 may be a potential contributor to the pathogenesis of lupus patients.

Conclusion: NEAT1 regulates a subset of LPS-induced inflammatory factors through affecting the activation of MAPK signaling pathway. The increased NEAT1 expression may be a potential contributor to the elevated production of a number of cytokines and chemokines in SLE patients. Our findings suggest lncRNA contributes to the pathogenesis of lupus and provides potential novel target for therapeutic intervention.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown that patients with systemic lupus erythematosus (SLE) are prone to systemic osteoporosis, bone loss and fracture. Paradoxically, previous studies have shown that inflammation in these patients causes the inhibition of ostoclastogenesis. Recently, serum antibodies to Malondialdehyde-Acetaldehyde (MAA) antibodies have be found in SLE patients. However, their role in disease process has not be determined. Therefore, it was the purpose of this study to explore the role of bone markers in SLE and their interaction with antibodies to MAA modified proteins.

Methods: Eighty-eight SLE patients, all satisfying ACR classification criteria, and 92 controls were examined. Serum antibody levels were measured by enzyme-linked immunosorbent assay (ELISA) for levels of IgG, IgA, and IgM anti-MAA antibodies specific to the MAA epitope, TRAP and BAP. Pearson correlation coefficients were used to examine associations of bone markers with MAA antibodies.

Results: Bone markers were assessed and revealed a decrease in TRAP levels in the SLE cohort (1.41 U/L) as compared to the controls (2.67 U/L) ($P<0.001$) (Figure 1). BAP levels remained unchanged between the two groups. Bone markers were compared to serum IgA, IgG, and IgM anti-MAA levels and showed associations with IgM anti-MAA levels and TRAP ($R=0.273$, $P<0.01$). There were no associations with BAP demonstrated in the study.

Conclusion: These data show that patients with SLE have significantly lower TRAP levels as compared to controls. This decrease could be related to the inhibition of osteoclastogenesis shown in other studies. In addition, TRAP concentrations were associated with anti-MAA IgM levels consistent with the increased inflammatory burden that characterizes SLE. These data may be useful in helping predict disease status in patients with SLE. More work needs to be done to determine other bone markers and their role in SLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anticytokine autoantibodies are pathogenic in many hematologic, pulmonary and infectious diseases. However, a systematic investigation of their presence and significance in autoimmune diseases is lacking.

Methods:

Serum samples from patients with systemic lupus erythematosus (SLE) (n=199), primary Sjšgren's syndrome (SS) (n=150) and rheumatoid arthritis (RA) (n=149) were compared to healthy controls (n=200) for autoantibodies against 24 cytokines using a multiplex bead-based assay. All patients fulfilled ACR classification criteria for their respective diseases. Any anticytokine autoantibody concentration above two standard deviations of the mean of healthy controls for the same target was classified as positive. Biological activity was evaluated by the ability of sera to block cytokine-induced signal transduction or protein expression. RNA sequencing was performed on whole blood in a subset of controls and SLE patients.

Results:

SLE and SS patients had a disproportionate presence of autoantibodies against interferons (IFNs) as well as the IFN-responsive chemokine IFN-inducible-protein-10 (IP-10) (Table. 1). Autoantibodies against type I IFN, IL-12 and IL-22 were neutralizing. In SLE, anti-IFN-γ autoantibodies tracked with increased disease activity, anti-double-stranded-DNA antibodies, and elevated expression of IFN-α/β-inducible genes (Table 2 and Figure 1). Conversely, SLE patients with blocking anti-IFN-α autoantibodies normalized their type I IFN gene signature. Autoantibodies were observed against macrophage-colony stimulating factor, IL-4, IL-7, IL-17 and IL-22, which had not been previously identified in the context of rheumatologic disease. Novel anti-type III IFN (λ2, λ3) and anti-IP-10 autoantibodies were detected.

Conclusion:

Anticytokine autoantibodies are a common feature of autoimmune diseases and extend to more cytokines than previously appreciated. Patterns of anticytokine autoantibodies appeared to be specific to each disease. In particular, anti-IFN autoantibodies were overrepresented in SLE and SS. Autoantibodies against type I and type II IFNs in SLE are biologically active and appear to have distinct functional roles, suggesting a contribution to disease pathogenesis that may alter both expression and the course of clinical disease.

Table 1: Distribution of Anticytokine Autoantibodies in Rheumatologic Diseases.

	SLE (199) N (%)	SS (150) N (%)	RA (149) N (%)
Total Positive	76 (38%)	63 (42%)	30 (20%)

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic lupus erythematosus (SLE) is an autoimmune disorder characterized by the propagation of autoreactive B cell populations leading to the production of pathogenic antibodies directed towards self antigens such as: nuclear antigens, cytokines, and dsDNA. However, this autoreactive B cell expansion within SLE patients is not uniform suggesting specific antigen selection, and skews the antibody repertoire. One such expansion is in antibodies encoded by the VH4-34 gene. This antibody family has been shown to enrich for binding to autoantigens such as dsDNA, and can be uniquely examined due to the expression of the idiotope specific for the 9G4 idiotypic antibody. 9G4+ antibodies are unique in that the VH region expresses a hydrophobic patch (HP)(which acts as the 9G4 idiotope) within the framework 1 region of the heavy chain, which allows for antigen binding independent of the CDR3. This HP is what dictates binding to erythrocytes through interactions with N-acteyllactosamine glycans. Additionally, a secreted glycan binding protein family, the galectins, is also increased within SLE patients and has been shown to bind to many of the same antigenic targets as 9G4+ antibodies. Interestingly, SLE patients exhibit autoantibodies (autoAbs) against galectins, strongly suggesting an importance for galectin autoreactivity and a possible interaction between VH4-34 autoAbs and galectins. The purpose of this study is to understand this role between VH4-34 encoded Ig and galectin binding and/or competition in context of the pathogenesis of SLE.

Methods:

ELISA was utilized to assess total IgG and 9G4-specific anti-galectin autoAb levels of varying galectin family members within the sera of 16 SLE patients and healthy controls (HC). Single-cell sorts of 9G4+ IgG B cell populations followed by monoclonal antibody (mAb) expression and site directed mutagenesis (SDM) of the VH4-34 HP generated pairs of antibodies that could be independently tested for galectin binding either dependent or independent of the HP.

Results:

The VH4-34 gene segment encoded a significant portion of the total galectin-3 autoAbs directed against recombinant human galectins (50% of SLE patients were anti-Galectin-3 positive). Galectin-1 and galecin-9 autoAb titers showed no such relationship however there was 9G4 autoreactivity in 6.25% and 18.75% of SLE patients respectively, and no 9G4+ anti-galectin reactivity within the HC group. There was no correlation of anti-galectin autoAbs and SLEDAI. Two mAb derived from a pool of 20 (6.67%) 9G4+ mAbs and their SDM mutants tested, were cross-reactive between both galectin-1 and galectin-9. This interaction was also determined to be a result of the CDR3 and not the HP.

Conclusion:

These data determine a novel antigen specific interaction between 9G4+ Ig and certain galectins. Understanding how these interactions interfere with galectin biology will be useful in determining the physiologic cost of this relationship within SLE. The derivation of anti-galectin 9G4+ mAb, which binds through the CDR3, suggests galectins to be potent autoantigens. *Work supported by NIH-NIAID 5R37AI049660-12*

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Atherothrombosis in systemic lupus erythematosus (SLE) has been related to the combined effects of autoimmune elements and cells of the immune system, where monocytes play an essential role. Different monocyte subsets with distinct patho-physiological actions have been described in cardiovascular disease (CVD). Netosis suffered by neutrophils in SLE might further contribute to the development of inflammatory and thrombotic processes. Aim: 1. To analyse in vivo the involvement of different leukocyte subsets and netosis in the development of CVD in SLE patients. 2. To evaluate in vitro the role of anti-dsDNA antibodies in these processes.

Methods: The study was conducted in 23 SLE patients and 10 healthy donors. Endothelial function was assessed by measuring the post-occlusive hyperaemia using Laser-Doppler. Monocyte subsets (MON1: CD14+/CD16-, MON2: CD14+/CD16+; MON3: CD14dim/CD16+) were characterized by flow cytometry. Classical (CD14+) and non-classical (MON2/MON3, CD16+) monocytes were purified using immuno-magnetic selection. Various markers of oxidative stress, inflammatory cytokines and prothrombotic mediators were quantified. In purified neutrophils, levels of oxidative stress and elastase were analyzed, as well as the percentage of netosis after labeling with Sytox. Purified neutrophils and monocytes from healthy donors were treated in vitro with anti-dsDNA antibodies isolated from the serum of SLE patients, and markers of inflammation, thrombosis, oxidative stress and NETosis were evaluated.

Results: SLE patients showed impaired micro-vascular endothelial function (reduction of hyperaemia post occlusion area) and increased plasma levels of pro-inflammatory proteins (IL6, IL8, MCP-1 and PCR). Percentage of MON2 was found increased and associated to the disease status. Moreover, this monocyte subset showed an increase in TF, IKK and TNFα expression, and a decrease in intracellular glutathione (GSH) in relation to MON1. Increases in neutrophil elastase levels and the percentage of cells suffering netosis were also identified. Neutrophils further displayed altered mitochondrial membrane potential and a decrease in GSH. The increased percentage of MON2 and molecules related to inflammation and thrombosis, endothelial dysfunction, oxidative status and netosis were associated with the occurrence of thrombotic events, as well as with the presence of anti-dsDNA antibodies. In vitro treatment of monocytes and neutrophils with anti-dsDNA antibodies promoted an increase in the production of NETosis and peroxides, and a number of proinflammatory and prothrombotic molecules.

Conclusion: 1. In SLE patients, the CD16 + monocyte subtype –present in higher proportion than in healthy donors- is associated with disease activity, thrombosis development and endothelial dysfunction. 2. Positivity for anti-dsDNA antibodies is linked to an increase of atherothrombotic markers in SLE patients. 3. Anti-dsDNA antibodies, in vitro, promote NETosis and modulate the expression of various molecules related to inflammation and thrombosis. Together, that data suggest the involvement of such autoantibodies on atherothrombosis development in SLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In SLE, early diagnosis, differentiation to other autoimmune diseases and prognostic stratification are still great challenges. Hence, SLE represents an enormous challenge for the clinical development of effective therapies.Detecting a broad set of SLE-associated autoantibodies might help to investigate the number, co-prevalence and similarities of autoantibody reactivities in SLE patients. Here, we describe the development of a multiplexed autoantibody assay, which enables the comprehensive analysis of 87 autoantibodies in SLE patients

Methods: A Luminex bead-based autoantibody assay was designed by combining traditional with novel antigens. Autoantibodies were selected to be used for the a) diagnosis and b) differential diagnosis of SLE; have previously been linked to c) disease activity, and d) specific organ involvement; e) react with proteins encoded by interferon type I response genes; and f) may have utility for patient subgrouping. Autoantibody reactivity against these antigens was tested in over 700 SLE, healthy control (n=1000), and autoimmune disease samples (n=500).

Results: Based on the individual marker pattern, patients either belong to clusters defined by characteristic markers, or are phenotypically more overlapping with other autoimmune diseases. The analysis of the autoantibody reactivity yields at least four different reactivity groups (G1-G4) including patients: G1: with a higher disease activity score, broad and homogeneous autoantibody reactivity; G2: with broad, but heterogeneous autoantibody reactivity; G3) who have few autoantibodies and G4) with unusual autoantibody pattern.

Conclusion: The multiplexed analysis of autoantibodies in SLE enables defining an autoantibody reactivity score and SLE patient clusters. This might support the stratification of SLE patients into more homogenous subgroups in clinical studies thereby increasing the probability of successful drug development.

Epigenetic Changes in SLE Implicate Enhancers As a Force in Pathologic Cell Behavior

Lihua Shi[1], Li Song[1], Zhe Zhang[2], Michelle Petri[3] and **Kathleen E. Sullivan**[4], [1]Immunology ARC 1216, The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Bioinformatics, Children's Hospital of Philadelphia, Bioinformatics, Philadelphia, PA, [3]Rheumatology, Johns Hopkins University Hospital, Baltimore, MD, [4]Allergy Immunology, The Children's Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We previously identified novel non-coding RNAs that were markedly overexpressed in SLE patient monocytes. Among all classes of RNAs, these non-coding RNAs were by far the most highly over-expressed in SLE. We hypothesized that these novel RNAs represented regulatory RNAs. The purpose of this study was to determine whether the non-coding RNAs mapped to enhancers that regulated gene activity.

Methods: We used transfection of over-expression vectors and knockdown of non-coding RNAs to test their function. ChIP assays for H3K27ac, as a mark of active enhancers, and H3K4me3, as mark for promoter activity were performed. qRT-PCR was used to investigate the putative enhancers and to define

functionality.

Results: Over-expression of noncoding RNAs in control monocytes could be induced by LPS in a p38-dependent manner. We examined two clusters of non-coding RNAs in more detail at the IL-1 and the ADAM28 loci. At both loci, LPS treatment was associated with significant induction of H3K27ac at the site of the non-coding RNA, supporting a role in enhancer activation and defining these specific non-coding RNAs as enhancer RNAs. Acquisition of H3K27ac at the enhancer site was concordant with induction of the non-coding RNA and preceded changes in H3K4me3 at the promoter. LPS induced not only the enhancer RNA but also induced expression of the adjacent mRNA. To investigate the role of the p38 pathway, we examined AP-1, a downstream regulator of p38 activity. We tested for loading onto the enhancer and promoter regions by ChIP assay for c-jun, one of common group of proteins incorporated into the dimer of AP-1. Both at the IL1 and ADAM28 loci, c-jun was loaded onto the enhancer without increased loading at the promoter at early time points. Therefore, LPS induced c-jun loading onto the enhancer with concordant changes in enhancer RNA and acquisition of H3K27ac at the enhancer suggesting that this pathway activated the enhancers. To investigate the function of the enhancer RNAs specifically, we manipulated the amount of expression. Knockdown of one enhancer RNA within the IL1 cluster, led to diminished levels of multiple enhancer RNAs at that locus and diminished expression of IL1. Therefore, the enhancer RNA performs a critical function for gene expression.

Conclusion: These data define a set of disease-specific enhancers that appear to be dysregulated in SLE. Impressive over-expression of these enhancer RNAs suggests that the regulatory network is highly dysregulated in SLE. Enhancers have not been previously examined in SLE and identification of novel disease-specific enhancers is of critical importance in considering new epigenetically-directed therapeutics. This study identifies a specific pathway that activates these normally latent enhancer RNAs in SLE.

H3K4me3 Peak Shape Dictates Transcription and Regulates Differential Expression in SLE

Kathleen E. Sullivan[1], Lihua Shi[2], Li Song[3], Michelle Petri[4] and Zhe Zhang[5], [1]Allergy Immunology, The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Immunology ARC 1216, The Children's Hospital of Philadelphia, Philadelphia, PA, [3]Allergy Immunology, Children's Hospital of Philadelphia, Philadelphia, PA, [4]Rheumatology, Johns Hopkins University Hospital, Baltimore, MD, [5]Bioinformatics, Children's Hospital of Philadelphia, Bioinformatics, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: H3K4me3 is a post-translational modification of histone H3 associated typically with gene activation. We had previously characterized changes in H3K4me3 associated with SLE in monocytes and found that many genes had higher peaks of H3K4me3 in SLE. In the current study, we further analyzed these changes to better define the transcription factors impacting these changes.

Methods: Eight female controls and six female SLE monocyte samples were utilized for analysis. The SLE patients had low to moderate disease activity and were not on high level immune suppression. Using ChIP-seq data from these samples, we analyzed changes in breadth and shape of the H4K4me3 peaks in SLE and then correlated these changes with paired RNA-seq data. H3K4me3 peaks were classified as Narrow, Extended Upstream, Extended Downstream and Extended Symmetric patterns.

Results: We found that there was a strong association between the H3K4me3 breadth and likelihood of differential expression. Genes with narrow H3K4me3 were less likely to have increased expression in SLE while those with extended H3K4me3 downstream of their TSSs were more likely to have increased expression in SLE. We then looked at the change of H3K4me3 breadth in SLE. H3K4me3 peak shape was mostly stable in primary monocytes. Among 907 sites that switched patterns from control to SLE, none of them switched between narrow sites and any of the three broad sites. The most common switch was 131 sites that switched from Extended Symmetric to Extended Downstream. We previously reported that H3K4me3 increases in SLE were associated with increased expression of corresponding genes in SLE patients. To address the impact of location of H3K4me3, we analyzed changes in shape of H3K4me3 peaks in SLE with changes in transcript levels. Expression change was very sensitive to H3K4me3 change at the downstream regions. From 1% to 10%, every one percent increase of H3K4me3 at the immediate downstream region lead to a 1.5% increase in gene expression on average. Of the genes having significantly increased expression in SLE, 78.8% also had increased H3K4me3 at the downstream regions, while the percentages were 55.0% and 47.1% for TSSs and upstream regions, respectively. Indeed, the average H3K4me3 change of these genes peaked (~8%) at approximately 700bp downstream of their TSSs.

Conclusion: This study provides refinement in our understanding of the epigenetic changes associated with SLE. The change may occur adjacent to transcription factor binding where a histone modification enzyme has been recruited. Efforts to identify such transcription factors have typically focused on upstream peaks, whereas our data supports a focus on the downstream peaks. This finding may facilitate identification of epigenetic therapeutics.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In recent work, we showed that a single measurement of several gene signatures in whole blood was associated with levels of disease activity at that time and in the next year. In this study, we assessed the stability of these gene signatures over time, and whether changes in expression coincide with changes in disease activity.

Methods: Blood was collected at clinic visits from 298 members of a well-characterized SLE cohort (SPARE). 82 patients contributed one visit, 194 patients contributed 2 visits, 22 patients contributed 3 or more visits. The interval between visits was approximately 28 to 135 days. Levels of the BAFF gene transcript, plasma cell signature, Interferon (IFN)-α signature and the Low Density Granulocytes (LDG)-associated Neutrophil gene signature were assessed in PAXgene-preserved peripheral blood by global microarray and qPCR. For multi-gene signatures, the geometric mean was calculated. The stability of repeated measures of gene expression was quantified using intra-class correlation coefficients (ICC). To provide a frame of reference we also computed the ICC for systolic blood pressure and weight. SLE disease activity was measured using the Physicians Global Assessment (PGA) and the SELENA-SLEDAI index and its components.The associations between changes in gene expression and changes in disease activity between two visits from the same person were assessed using linear regression models.

Results: Table 1 shows the intraclass correlation coefficients for repeated measures of the gene signatures and also, to provide reference values, for systolic blood pressure and weight. It can be seen that the gene expression markers show more within-person stability than systolic blood pressure. The IFN-α signature exhibited the most stability. Table 2 shows the association between changes in gene signature markers and changes in disease activity indices, adjusting for change in prednisone dose. Few strong associations were observed. A one standard deviation (SD) increase in expression of the plasma cell signature was associated with a 0.57 increase in SLEDAI values.

Table 1: Within-patient Intraclass Correlation Coefficients (ICC) for Four Gene Expression Signatures, Systolic Blood Pressure, and Weight.

Variables	IFN-α	BAFF	LDG	Plasma Cell	Systolic Blood Pressure	Weight
ICC	0.84	0.61	0.79	0.61	0.53	0.99

Table 2: Estimated Expected Change in Disease Activity Index for a One Standard Deviation Increase in Each Gene Marker.

Boimarker	Disease Activity Index									
	PGA		SLEDAI		SLEDAI MS		SLEDAI SKIN		SLEDAI Renal	
	Change	P-value	Change	P-value	Change	P-value	Change	P-value	Change	P-value
IFN-α	0.06	0.34	0.09	0.77	0.07	0.54	-0.11	0.29	0.11	0.56
BAFF	0.03	0.38	0.11	0.57	0.03	0.67	-0.12	0.07	0.14	0.24
LDG	-0.14	0.05	-0.18	0.6	-0.13	0.32	-0.01	0.93	0.08	0.71
PC	0.06	0.19	0.57	0.01	0.14	0.05	0.12	0.08	0.2	0.11

Conclusion: The gene signatures that we studied are relatively stable within patients over time. Although previous work has shown them related to disease activity, within a patient there was not a strong association between changes in gene expression and changes in disease activity. This suggests that these gene signatures may not be dynamic indicators of disease activity under current standard of care therapy, but more likely to be indicators of subsets of patients with different underlying disease processes.

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The integrity of the microRNA machinery is required for the normal reactivity of the immune system both during differentiation and upon antigen engagement. Dicer1 is a pivotal molecule of the microRNA biogenesis. Suppression of Dicer1 in lymphoid progenitors from mice render cells auto-reactive. In this study we have looked into Dicer1 gene expression in relationship with the activation of mononuclear cell subsets in patients with lupus.

Methods: The study was conducted in 36 patients with lupus (34 women) fulfilling ACR classification criteria, of which 21 were considered to have active disease. Circulating monocytes, T cells and B cells were sorted with magnetic beads, and gene expression analysis was carried out using Sybr green based qPCR techniques after RNA isolation and retro-transcription. Statistics were run with SPSS using non-parametric methods.

Results: Levels of Dicer1 in monocytes and in T cells were found to drop in association to c'4 decrease (p 0.09, p 0.03). Lower expression levels of Dicer1 were found in monocytes from patients with anti phospholipid antibodies (p 0.09), while in T cells the fall of Dicer1 levels was associated to lower platelet counts (p 0.002). Patients with positive antiDNA antibodies at the time of the study showed lower levels of Dicer1 in B lymphocytes (p 0.02). There was an inverse association between levels of Dicer1 in B cells and SLEDAI scores (p 0.04), C-reactive protein (p 0.03), and proteinuria (p 0.09). In addition to these activity features, we analysed the relationship between suppression of Dicer1 and mechanisms of cell growth. Globally, the down-regulation of Dicer1 gene expression was associated to an enhancement of miR181a, a master miRNA involved in positive selection of immune cells, in each of the mononuclear cell subpopulations. On the other hand, there was an inverse relationship between Dicer1 levels in monocytes and circulating NK cells (p 0.02).

Conclusion: Overall, the relative suppression of Dicer1 gene expression in patients with lupus identified a subgroup of patients with activation of the complement classical pathway and enhanced lymphocyte survival. Particularly in B cells, the drop of Dicer1 appeared to be a marker of activity and nephritis. Together, our data suggest that a deregulation of the microRNA system contributes to the abnormal activation of immune cells in lupus. In addition, measuring Dicer1 expression could be of interest as a biomarker of distinct subgroups of patients.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose :

Organ damage predicts physical disability and mortality of SLE. Given that men with SLE tend to develop accelerated damage, we selected an X-linked androgen receptor (AR) variant, the short CAG repeat encoding ≤17 copies of polyglutamine that confers enhanced receptor-mediated transcriptional activity associated with more maleness, to test for association with damage in 1,703 (213 male and 1,490 female) SLE patients recruited at multiple centers with mean (±SD) disease duration of 10 (±7.9) years.

Methods:

Association of damage assessed by the SLICC/ACR Damage Index (SDI) with clinical features (gender, ethnicity, age at diagnosis, disease duration and cumulative exposure to glucocorticoids) and/or CAG repeat length (genotyped by PCR) were analyzed using univariate and multivariate regression tests.

Results:

Risk factors identified by univariate analysis associated with greater damage (defined as SDI≥2) were male gender, longer disease duration, higher cumulative prednisone usage and African American (AA) ancestry compared to European American (EA); Asian ancestry protected against damage. Except male gender, all other factors were confirmed in the multivariate model of greater damage: longer disease duration (OR [95%CI] =2.08 [1.72-2.51], *P*=5.0E-14), higher cumulative prednisone usage (1.49 [1.28-1.75], *P*=6.8E-07), AA ancestry (1.99 [1.44-2.74], *P*=2.5E-05), and Asian ancestry (0.32 [0.23-0.44], *P*=1.6E-11). After adjusting for these covariates, the short CAG repeat (≤17) was associated with greater damage in AA (OR_{adj}=1.84 [1.12-3.02], P_{adj}=0.015) and EA patients (OR_{adj}=1.66 [1.03-2.66], P_{adj}=0.037) (Table 1). This genetic association remained statistically significant in AA women and there was a trend toward significance in EA women. Compared to EA/AA patients, fewer proportions of Asians had damage and short CAG repeat and Hispanics (HS) had smaller sample size, contributing to no genetic association. Renal damage defined by SDI (observed in 12.7% patients) was associated with male gender (OR=1.76 [1.18-2.62], *P*=0.006), younger age at diagnosis (OR=1.65 [1.08-2.50], *P*=0.02), longer disease duration (OR=1.50 [1.16-1.96], *P*=0.002), higher prednisone usage (OR=1.60 [1.29-2.00], *P*=3.0E-05), AA (OR=5.09 [3.09-8.37], *P*=1.5E-10) and HS (OR=2.83 [1.54-5.20], *P*=0.001) ancestries. The short CAG repeat was associated with renal damage in AA patients only (OR_{adj}=1.91 [1.04-3.51], P_{adj}=0.038).

Conclusion:

In addition to confirming previously reported risk factors for damage accrual in SLE, we identified short CAG repeats with an enhanced AR transactivation activity to be associated with greater damage in EA and female AA SLE patients and renal damage in AA patients. Our data supports genetic contribution, including a role of X-linked androgen receptor-mediated activity, to organ damage in SLE of multiple ancestries.

Table 1. Association of higher transactivating AR variant(1) with greater damage in African- and European-American SLE patients

Ethnicity	N* (%SDI≥2)	% CAG ≤17 in SDI≥2 vs. SDI<2	OR (95%CI)	P	Adjusted* OR (95%CI)	P
African American	328 (52.7)	75.7 vs. 60.6	2.02 (1.26-3.25)	0.0042	**1.84 (1.12-3.02)**	***0.015***
European American	393 (39.4)	35.5 vs. 25.2	1.63 (1.05-2.54)	0.032	**1.66 (1.03-2.66)**	***0.037***
Asian	840 (23.7)	22.6 vs. 20.0	1.17 (0.80-1.72)	0.42	1.18 (0.79-1.75)	0.42
Hispanics	142 (40.8)	20.7 vs. 17.9	1.20 (0.51-2.80)	0.67	1.00 (0.40-2.49)	0.99

For each female subject, the mean number of CAG repeats is calculated from the average of both alleles (maternal and paternal).
(1): Ding D, et al. Effect of a short CAG (glutamine) repeat on human androgen receptor function. Prostate. 2004;58(1):23-32.
*N: Number of SLE patients.
*Adjusted for disease duration and cumulative prednisone usage. Disease duration was defined as: 0=≤5 yrs, 1=6-20 yrs, 2=>20 yrs; cumulative prednisone usage was defined as: 0=0-10 grams, 1=10-20 grams, 2=>20 grams.

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: It was reported that genetic variations in B cell signal transduction were associated with susceptibility to SLE. However, these studies were limited in number and were performed in only certain populations. In our study, we aimed to evaluate the relationship between some important genetic variations and expressions of these genes in our SLE population. We also determined their association with clinical parameters.

Methods: 84 SLE patients (79F, 5M, mean age: 37.6) and 105 healthy controls (98F, 7M, mean age: 38.2) were included into the study. SLEDAI scores and flares according to SELENA-SLEDAI were also recorded. Genomic DNA and cDNA were obtained from peripheral venous blood. BLK (rs13277113 and rs2736340), LYN (rs7829816 and rs6983130), SYK (rs2613310), CD247 (rs704853) polymorphisms, gene expressions of SRC-B family kinases (BLK, HCK, LCK ve LYN) and SYK kinases (SYK, ZAP70) which are important in B-cell signal transduction and were found to be important in whole genome analyses in various races were studied by Real-time PCR in the Genetics Department.

Results:

The heterozygous genotypic pattern (GA) for rs13277113 polymorphism was more frequent in patients with SLE when compared to controls (48.8% vs. 31.4%, p=0.015). Other genotype variants were similar in SLE patients and controls. In SLE group, the heterozygous genotype (GA) for rs13277113 was significantly less frequent in initially active SLE patients (41.2% vs. 73.3%) and more frequent in anti-Ribosomal-P positive (14.6% vs. 0%) SLE patients (p values for both=0.01).AA genotype for rs2613310 was significantly more frequent in patients with thrombocytopenia (16.9% vs. none, p=0.048), in patients with positive anti-dsDNA (59.3% vs. 32%, p=0.01), and those with anti-nucleosome antibodies (23.7% vs. 4%, p=0.004). SLE flares according to SELENA-SLEDAI flare index was significantly more frequent in GA (rs13277113) (70% vs. 37%) and CT (rs 2736340) genotypes (66.7% vs. 35.2%) than in other genotypes (p values, 0.004 and 0.006). In the group which had flares according to SELENA flare index, the average delta CT value for BLK gene expression tended to be higher than in the group without flares (12.2±2.6 vs. 10.8±1.6, p=0.08). Quantitative relative expression of Syk gene, as calculated by delta-delta-CT method, showed significant difference between the average delta CT value for SLE patients and controls (7.5±1.2 vs. 7.8±1, p=0.02). The relative expression of mRNA for Syk gene to β2 microglobulin was increased by 1.22 fold in patients with SLE as compared to controls.The statistically significant intergenotypic variation in the delta-CT values was found in patients with GG and GA genotypes for rs13277113 (BLK) (10.8±2.1 vs 11.7±2.2, p=0.019). GA genotype showed higher delta-CT value representing lower gene expression at mRNA level. AA genotype groups was very small.

Conclusion: We observed more frequent heterozygous GA genotypic pattern (rs13277113) in our SLE patients compared to controls; and it was associated with BLK expression and disease flare. In spite of the fact that Syk genotype was not increased in SLE patients, Syk expression was seen to be more frequent.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune-mediated diseases appear to share a common genetic basis. Here we describe genetic association of single nucleotide polymorphisms (SNPs) within *CLEC16A* with SLE in a large multi-ancestry cohort of SLE cases and controls. In immune-mediated diseases where this locus has been implicated, it appears to have complex genetic architecture with multiple independent association signals and multiple plausible candidate genes. Few studies to date have focused on the function of human *CLEC16A*. However, recent studies defining the role of the *Drosophila* ortholog of *CLEC16A*, *Ema*, suggest several plausible mechanisms through which variation at this gene might plausibly influence autoimmunity and SLE risk. Here, we also undertake evaluation of one such hypothesis, that variation in *CLEC16A* modulates B-cell receptor (BCR) signaling and thus autoimmunity.

Methods: First, we genotyped a panel of previously reported immune mediated disease susceptibility loci in a large collection of SLE case-matched control samples as part of the collaborative Large Lupus Association Study 2 (LLAS2). As part of the panel, we tested SNPs in *CLEC16A* for genetic association with SLE. After adjusting for admixture using a panel of ancestry informative markers, filtering for SNP missingness, departure from Hardy-Weinberg equilibrium and minor allele frequency, SNPs were tested for association using an additive genetic model. Association testing was carried out in each AIM-defined ancestry subgroup and meta-analysis of the population specific results was also performed. All SLE patients met the 1997 ACR criteria for classification of SLE. In addition, B cells from control subjects were incubated with anti-BCR for 30 min at 4°C, then placed at 37°C as indicated. Cross-linked surface remnant BCR was detected with fluorescent-tag secondary antibody and co-localization with labelled *CLEC16A* was then calculated.

Results: We found evidence for association at previously defined autoimmune susceptibility loci was stronger than expected by chance. In addition to this, a SNP in CLEC16A was associated in each AIM-defined ancestry subgroup (European, African, Asian and Native American/Hispanic Ancestry groups) with the same allele in the same direction. ($P_{meta} < 4.96*10^{-7}$, Phet = 0.6874, N = 15751). We find that while CLEC16A co-localizes with the BCR following BCR internalization. This occurs in the endosomal compartment, where the *Drosophila* ortholog of *CLEC16A*, *Ema*, also operates.

Conclusion: Taken together, our data confirm the association of this locus with SLE in multiple ancestry groups and suggest a role for human *CLEC16A* in BCR signaling in the endosome, where its *Drosophila* ortholog, *Ema* has been shown to operate.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-system, autoimmune disease characterized by autoantibodies to nucleic acids and nucleosomal proteins. The type I interferon pathway is dysregulated in SLE and IFN-α levels are high in patients. We performed a genome-wide association study and found a missense SNP (C297T:gly51ser) in the *PNP* gene that associates with high IFN levels in SLE (rs1049564; $P=1.24 \times 10^{-7}$). PNP is a key enzyme of purine metabolism. PNP deficiency leads to dysregulated deoxynucleotide levels, a block in DNA synthesis, and defective immunity. Previously, the rs1049564 SNP was thought not to impact PNP function. To show a functional link between rs1049564 and SLE, we performed in vitro experiments using HAPMAP cell lines and patient leukocyte samples with and without the PNP variant.

Methods: To determine if the rs1049564 variant alters PNP function, we exposed 6 HAPMAP cell lines (2 homozygous (CC), 2 heterozygous, and 2 homozygous (TT)) to a dose curve of deoxyguanosine (dGuo; nucleotide precursor and a substrate for PNP). One day later cells were analyzed for cell cycle phase using Click-iT plus EdU chemistry combined with FxCycle violet stain and flow cytometry. Various pharmacological agents were tested for their ability to reverse the cell cycle block caused by the PNP variant. A similar approach was used to study PNP function in SLE patient samples with and without the rs1049564 variant. Colorimetric enzyme and ELISA assays were used to measure the functional activity of the different PNP isoforms.

Results: We find that the rs1049564 variant causes increased S phase block and cell death in lymphoblastoid cells. Cell lines homozygous for rs1049564 (TT) had 2 fold increases in S phase block compared to cell lines without the PNP variant (CC). The cell cycle block caused by the PNP variant could be reversed pharmacologically and similar findings were observed in SLE patient cells.

Conclusion: These results suggest that the rs1049564 *PNP* polymorphism is a loss of function variant that leads to altered PNP function and subsequent S-phase block in select cell subsets within the lymphocyte compartment. This may lead to increased frequencies of circulating apoptotic lymphocytes, and higher type I IFN levels in human SLE. These findings have pharmacogenomic implications, as the S-phase block can be rescued in our in vitro experiments, suggesting a potential for personalized therapeutics.

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Many systemic autoimmune diseases share heritable and non-heritable risks, as well as some clinical manifestations. A recent meta-analysis based upon genome-wide genetic studies contrasting and comparing a number of major autoimmune diseases revealed expected and unexpected heritable correlations among different diseases and highlighted the exceptional genetic complexity of human autoimmune diseases even without evaluating the similarities and dissimilarity in clinical prevalence and manifestations. Here, we surveyed systemic lupus erythematosus (SLE) patients and their family members from lupus family registry and repository (LFRR), as well as unrelated unaffected healthy individuals (HC) in attempt to provide valuable insights into the effects of heritable and non-heritable factors on pathogenesis of many of these autoimmune diseases.

Methods:

To assess the concurrency of SLE, rheumatoid arthritis (RA), hypothyroidism, Type I diabetes, systemic sclerosis (SSc), and Sjogren's syndrome (SS) in this collection by surveying 3203 African Americans(AA), 4950 European Americans (EA), and 741 Hispanics (HIS). ACR >= 4 was used to identify SLE patients as well as the family members of the SLE patients. Self-reported RA was further verified by anti-CCP^+, anti-RF^+, and DMARD usage. Self-reported Sjogrens was confirmed by anti-Ro and/or anti-La. Self-reported hypothyroidism was verified by usage of exogenous thyroid hormones. Self-reported Type I diabetes was further confirmed by usage of Insulin. Proportionality, chi-square, and mixed regression tests were used to analyze prevalence differences of concurrent autoimmune diseases, as well as to detect gender effects among different populations.

Results:

In EA, SLE patients were more likely to also meet RA criteria [p<0.01; OR (95% CI), 108.03 (26.45 – 441.19)], SS (p<0.01; 120.18, 16.67 – 866.69), SSc (p<0.01; 36.05, 4.95 – 262.56), and Hypothyroidism compared to HC. Family members of EA SLE patients were also more likely to have RA (p<0.05; 5.55, 1.33 – 23.06), SS (p=0.07; 6.40, 0.86 – 47.47), as well as hypothyroidism compared to HC. However, there was no enrichment of Type I Diabetes in EA family member of SLE patients. AA SLE patients were also more likely to concurrently meet criteria for RA (p<0.01; 142.61, 30.53 – 666.23), SS (p<0.01; 27.62, 5.79 – 131.82), or SSc (p<0.01; 7.19, 2.21 – 23.42) compared to AA healthy controls. Additionally, AA family members of SLE patients were more likely to meet RA criteria (p=0.07; 3.93, 0.88 – 17.66) compared to AA healthy control population. Finally, in the HIS population, SLE patients were more likely to also meet criteria for SS (p<0.01; 29.46, 3.97 – 218.26). No enrichment of assessed autoimmune diseases were noted in HIS family members of SLE patients. The prevalence of majority autoimmune diseases observed in this study is comparable to published works.

Conclusion: In conclusion, genetically similar autoimmune diseases such as RA, SLE, SS, and SSc had higher concurrent prevalence in SLE patients and their family members compared to more genetically distant autoimmune disease like Type I Diabetes and hypothyroidism.

Session Time: 9:00AM-11:00AM

Title: Symptomatic and electrodiagnostic features of peripheral neuropathy in scleroderma

Background/Purpose: Peripheral neuropathy in scleroderma has been poorly characterized and the prevalence is unknown. The purpose of this study was to determine the prevalence of peripheral neuropathy in scleroderma.

Methods: The prevalence of length dependent peripheral neuropathy was rigorously assessed using signs and symptoms of neuropathy derived from a previously validated Total Neuropathy Score (TNS), and standardized nerve conduction study (NCS). Criteria for enrollment was an established diagnosis of scleroderma based upon the 1980 American College of Rheumatology (ACR) criteria for scleroderma, possessing at least 3 of 5 features of the CREST syndrome, or having all 3 of the following features: Raynaud's phenomenon, nail fold capillary changes and a scleroderma-specific antibody. Enrolled subjects underwent a uniform evaluation (TNS) that consisted of neuropathy symptom assessment by questionnaire, physical examination using objective measurement tools (graduated Rydel-Seiffer 64 Hz tuning fork and NeuroPen), and a standardized nerve conduction protocol. Those who were symptomatic or had NCS evidence of peripheral neuropathy underwent laboratory evaluation for secondary causes of neuropathy. We defined the presence of neuropathy to be those who either were screen positive on the TNS and/or electrophysiologic evidence of neuropathy. Statistical analyses were performed using the statistical software (STATA, release 12.1; StateCorp, College Station, Texas). Fischer's exact test was used to analyze differences in dichotomous variables. Differences between means were examined using the Student's t test for continuous variables.

Results: 130 subjects were approached for participation and 60 enrolled. Of the 60 subjects, 50 (83.3%) were female, 37(61.7%) were of the limited cutaneous subtype and 23 (38.3%) were the diffuse subtype of scleroderma. The mean age was 55 ± 11.1 years and mean disease duration was 15.3 ± 10.1 years. 17/60 (28%) had evidence of a peripheral neuropathy as defined by the presence of neuropathic symptoms on the TNS and/or electrophysiologic evidence of neuropathy. Subjects with neuropathy were more likely to be male (60% vs. 40%, p=0.02), African-American (41% vs. 4.6%, p=0.001), have diabetes (17.7% vs 0%, p=0.02), have limited cutaneous scleroderma (82.3% vs. 53.5%, p=0.04), and have RNP antibodies (23.5% vs 0%, p=0.009) than those without neuropathy. A potential non-scleroderma etiology for the peripheral neuropathy was defined in 82.3% (14/17) of subjects with neuropathy.

Conclusion: While symptoms or objective evidence of peripheral neuropathy is common among patients with scleroderma, the cause is usually explained by

co-morbid non-scleroderma related causes.

Session Time: 9:00AM-11:00AM

Background/Purpose:

The Modified Rodnan Skin Score (MRSS) is a semiquantitative assessment of skin thickness which is a commonly used outcome measure in Systemic Sclerosis (SSc) clinical trials. The MRSS has been shown to be reproducible among different observers and within the same observer over time as determined by inter and intraobserver means and standard deviations (SD). The objective of this study was to determine the inter and intrarater reliability of the MRSS in patients with early diffuse cutaneous (dc) SSc in the Prospective Registry of Early Systemic Sclerosis (PRESS) Cohort.

Methods:

A cross-sectional study was conducted over one day. Seven patients meeting ACR/EULAR criteria for SSc, with the diffuse subtype, and from the PRESS Cohort were examined by 10 rheumatologists. Prior to the exercise, the rheumatologists were trained in the MRSS examination as part of an investigator meeting for the Abatacept in Systemic Sclerosis Trial (ASSET.) The MRSS was performed by 10 examiners at 2 separate times on 5 patients. Patients underwent diagnostic testing between examinations, and so significant time elapsed between assessments, decreasing the possibility of recall bias. Data collection sheets were collected by a research coordinator immediately following each examination, and the investigators did not discuss their examinations with each other in order to avoid bias. For the continuous variable MRSS we computed the inter and intrarater reliability by fitting a linear mixed model to

the examiners' ratings with random effects for patient, rater, and patient by rater. For inter/intrarater reliability, the following values represent the following degrees of agreement: <0 – poor; 0-0.2 – slight; 0.21- 0.4 – fair; 0.41- 0.6 – moderate; 0.61-0.8 – substantial; and 0.81-1.0 – almost perfect agreement.

Results:

The mean age of the patients was 41.6 ± 19.8 years and the mean disease duration from the first non-Raynaud's symptom was 2.7 ± 0.8 years. Three patients were female and 4 male.

The interrater reliability for the MRSS was 0.81, and the intrarater reliability for the MRSS was 0.94. The interobserver mean for the MRSS was 14.67 and the within patient standard deviation was 4.04. The intraobserver mean for the MRSS was 15.04 and the within patient standard deviation was 2.30.

Conclusion:

We found the MRSS to have inter and intra-rater reliability of 0.81 and 0.94, respectively, suggesting almost perfect agreement among this group of investigators examining patients with early dcSSc. The within patient standard deviation was 4.04 in our study which is comparable to previously published figures of 4.6.[1] The intra observer patient standard deviation was 2.30 which is also similar to the previously published figure of 2.45. Our study confirms the reliability of MRSS in the study of patients with dcSSc. In-person training for MRSS should be considered before starting a multicenter randomized controlled trial.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

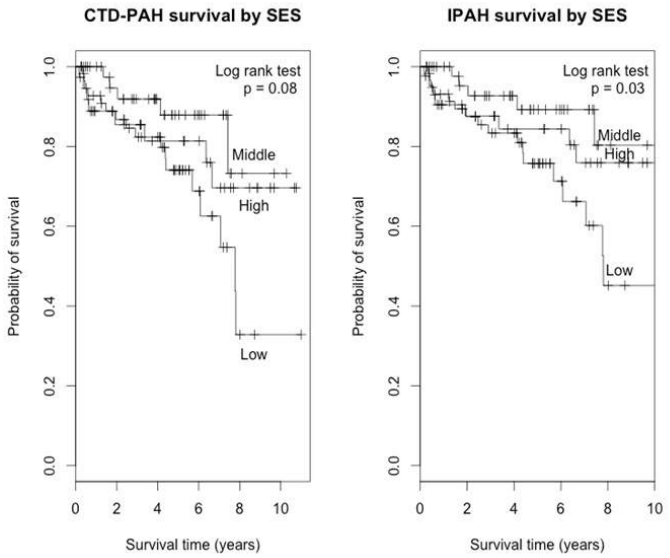
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Poorer health outcomes for persons with chronic diseases have been reported in association with lower socioeconomic status (SES). No such evaluation exists for patients with connective tissue disease associated pulmonary arterial hypertension (CTD-PAH). We evaluated the impact of SES on survival of patients with CTD-PAH and idiopathic PAH (IPAH).

Methods: A retrospective cohort study of patients attending the University Health Network Pulmonary Hypertension Programme and the Toronto Scleroderma Program was conducted. Using postal codes and census information for median household income, SES (low, middle, high) was assigned to each individual. Kaplan Meier curves were used to compare survival in different SES groups.

Results: 600 patients (n=445 CTD, n=155 IPAH) were identified. There were 209 deaths (n=177 CTD, n=32 IPAH). CTD-PAH patients stratified by SES had 5-year survival of 81.4% (95%CI 68.7%, 96.3%) for high SES, 87.9% (95%CI 77.2%, 100%) for middle SES and 74.1% (95%CI 62.2%, 88.3%) for low SES. IPAH patients stratified by SES had 5-year survival of 84.4% (95%CI 73.5%, 96.9%) for high SES, 89.2% (95%CI 79.7%, 100%) for middle SES and 75.7% (95%CI 64.4%, 89.0%) for low SES. IPAH patients with low SES had worse survival (log rank test p=0.03), and CTD-PAH patients had similar findings that bordered on statistical significance (log rank test p=0.08).



Conclusion: Socioeconomic inequalities appear to impact survival. Further research is required to understand the underlying basis for these findings including differences in disease severity, proximity to a hospital and effect of moving from one SES region to another.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In systemic sclerosis (SSc) vasculopathy causes frequent episodes of reperfusion injury and free radical mediated endothelial dysfunction, which may influence the onset of local thrombotic complications. Venous thromboembolism (VTE) is a vascular phenomenon that includes deep vein thrombosis (DVT) and pulmonary embolism (PE). The objectives of this study are to evaluate the prevalence of DVT and PE in SSc and evaluate risk factors for the development of PE or DVT in SSc patients.

Methods: We conducted a retrospective cohort study of patients who fulfilled the ACR–EULAR classification criteria for SSc attending the Toronto Scleroderma Program (Toronto Western Hospital, Mount Sinai Hospital, Toronto General Hospital) between 1970 - 2015. DVT was defined as the presence of thrombus on doppler ultrasound of either upper or lower extremity. PE was defined as the presence of thrombus on CT angiogram of the thorax.

Results: 927 SSc patients were included (761 females, 166 males). There were 31 (1.6%) VTE events, which is 10 times more frequent than would be expected in the general population. The prevalence of DVT was 16/927 (1.7%) and PE was 19/927 (2.1%). Anticardiolipin antibody was present in 1 patient with PE. Lupus anticoagulant was not present in any of the patients with VTE events. Patients with ILD more frequently experienced DVT (RR 2.85 95%CI (1.08, 7.54) but not PE (RR 1.82 (95%CI 0.89, 3.70). There was no significant difference in the occurrence of DVT or PE between SSc subtype (relative risk (RR) 0.95 (95%CI 0.46, 1.97), RR1.1 (95%CI 0.62, 2.04)), or presence of cancer (RR 2.48, (95%CI 0.81, 7.5), RR 0.87 (95%CI 0.20, 3.73), respectively.

Conclusion: Although uncommon, DVT and PE appear to occur more frequently in SSc. DVT occurs more frequently in SSc-ILD patients. VTE do not appear to be related to a hypercoagulable state.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To determine possible association of Cav-1 genetic variants: rs926198, rs959173 and rs9920 with SSc and/or SSc-related ILD progression.

Methods:

Three Cav-1 single nucleotide polymorphisms (SNPs) (rs 926198, rs 959173 and rs 9920) were genotyped in a total of 630 Turkish individuals (410 SSc patients and 220 healthy subjects). Genotyping was performed using TaqMan 5' allele discrimination predesigned assays from *Applied Biosystems*, Foster City, CA, USA) in a LightCycler® 480 Real-Time PCR System (*Roche Applied Science,* Mannheim, Germany). Genotyping call rate was > 98% for all the genotyped SNPs. Serum and sputum samples were collected from 54 SSc-ILD patients at 0, 6, and 12 months. Quantitative CT images were taken at 0,12 months. The possible association of Cav-1 gene SNPs and ILD progression in one-year follow up was determined.

Results:

A total of 402 SSc patients were recruited to the study (Mean age: 48.9 (12-78) and F:M; 390:20). The clinical characteristics of patients were as follows: Limited cutaneous SSc vs diffuse cutaneous SSc were 60.4% (n=243) vs 39.6 %(n=159), respectively. Interstitial lung disease was observed in 58.6% of patients (n=222). Anti-topoisomerase I antibodies (ATA) were found in 42.6% of patients (n=176). No significant association was observed between any CAV1 SNP and ATA. Genotype analysis and minor allele frequencies of the Cav-1 rs926198, rs959173 and rs 9920 SNP in patients with SSc and controls were shown in table 1. Among SSc-ILD patients who carried the rs959173 C minor allele displayed significantly higher CAV-1 in serum and lesser progression in ILD than in those carrying TT genotype (0.364±0.118 vs 0.247±072, $p<0.001$)

Conclusion:

Our results suggest that Cav1 rs959173 C allele may have a protective role in SSc-ILD progressions. Although a clear association of Cav 1 genetic variants and SSc was not determined in the Turkish patients with SSc, similar trends were observed with the previously published Italian cohort by Manetti M[1].

Prevalence and Risk Factors for Left Ventricular Diastolic Dysfunction in Scleroderma

Srikanth Vemulapalli[1] and Vivien Hsu[2], [1]Graduate School of Biomedical Sciences, Rutgers University, New Brunswick, NJ, [2]Medicine, Rutgers University, New Brunswick, NJ

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Left ventricular diastolic dysfunction (LVDD) is more common in systemic sclerosis (SSc) compared to the general population (1). Focal myocardial ischemia and fibrosis are thought to be important in its pathogenesis (2). LVDD leading to heart failure is associated with increased mortality. Risk factors in SSc are not known, although advanced SSc lung complications may be more common (3).

Methods: We collected clinical information from a cohort of SSc (4) outpatients seen consecutively in our Scleroderma Program. LVDD was confirmed by the last echocardiogram (Tissue Doppler) report. Interstitial lung disease (ILD) confirmed by high resolution chest CT (HRCT) and pulmonary hypertension (PH) diagnosed by right heart catheterization. Univariate and multivariate regression analyses were conducted to determine common factors associated with LVDD.

Results: Table 1 shows analysis of 300 patients; 133(44%) had LVDD. Univariate analysis found patient's advanced age, disease duration (from onset of Raynaud's phenomenon), Anti-centromere antibody, presence of SSc lung complications, systemic hypertension, smoking, valvular heart disease, chronic kidney and thyroid diseases were commonly associated with LVDD. However, using multivariable regression analysis, advanced age was the most significant factor associated with LVDD, followed by systemic hypertension, and SSc lung complications.

Conclusion: LVDD was common in our SSc cohort with a prevalence of 44%. Advanced age, systemic hypertension, and the presence of ILD or PH were

independent risk factors for LVDD. LVDD should be considered in any SSc patient with dyspnea. Further research to find more effective treatment for LVDD is needed to improve outcomes in this patient population.

Diagnostic Performance of the 2013 ACR/EULAR Classification Criteria for Systemic Sclerosis: Results from a Brazilian Validation Cohort

Farley Carvalho[1], Cintia Camargo[2], Bruna Fernandez[1] and **Cristiane Kayser**[2], [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]Rheumatology Division, Universidade Federal de São Paulo, São Paulo, Brazil

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: New classification criteria for systemic sclerosis (SSc) were proposed by the ACR/EULAR in 2013, due to the low sensitivity of the 1980 ACR classification criteria for patients with early and limited SSc. This study aimed to evaluate the diagnostic performance of the new ACR/EULAR classification criteria for SSc in clinical practice including patients with early SSc.

Methods: Data from 178 patients with SSc, including 122 patients with established SSc (according to the 1980 ACR criteria) and 56 with early SSc (according to the LeRoy and Medsger 2001 criteria) were consecutively collected from September 2014 to May 2015 from a tertiary outpatient clinic. Data from 141 control patients with systemic lupus erythematosus, dermato/polymyositis, mixed connective tissue disease, undifferentiated connective tissue disease, Sjögren's Syndrome, and primary Raynaud's phenomenon were also collected. The sensitivity and specificity of the old and the new ACR/EULAR criteria were determined in several subgroups of patients with early SSc. The diagnostic performance of each item of the new criteria was also evaluated.

The performance of the new ACR/EULAR criteria in discriminating SSc patients from controls was also evaluated by means of the Receiver Operating Characteristic (ROC) curve analysis. The best cut-off was determined based on the Youden's index criteria.

Results: The new classification criteria showed a sensitivity of 77.6% and a specificity of 98.5% among the 178 patients with established and early SSc, and had a significantly higher sensitivity compared to the 1980 ACR criteria ($p<0.001$) (Table 1). Sixteen of 56 (28.5%) patients who were classified as patients with early SSc, were newly classified as SSc by the 2013 ACR/EULAR criteria. Sensitivity and specificity showed an excellent performance when only early SSc patients with both abnormal nailfold capillaroscopy and positive SSc-related antibodies were included (sensitivity of 90.0% and specificity of 98.5%) (Table 1). For this sample, the new classification criteria presented high accuracy in diagnosing SSc, with an area under the ROC curve (AUC) of 0.996 (95%CI 0.99-1.00; $p<0.001$). The best cut-off was a score of ≥8 (sensitivity of 96.1% and specificity of 97.9%). Abnormal nailfold capillaroscopy and sclerodactily were the individual items with the best performance (sensitivity of 93.3% and 78.2%; specificity of 83.6% and 100%, respectively).

Table 1.Sensitivity and specificity of the 1980 ACR criteria and the 2013 ACR/EULAR criteria in different subsets of patients

	ACR 1980		ACR/EULAR 2013	
	Sensitivity (95% CI)	**Specificity (95% CI)**	**Sensitivity (95% CI)**	**Specificity (95% CI)**
SSc patients (established and early SSc) (n=178)	68% (0.60- 0.74)	100% (0.97- 1.00)	77.6% (0.71-0.83)	98.5% (0.94-0.99)
Established SSc and early SSc with abnormal nailfold capillaroscopy and positive SSc-related antibodies (n=152)	80% (0.73-0.85)	100% (0.97-1.00)	90% (0.85-0.94)	98.5% (0.94-0.99)
Early SSc (n=56)	0% (0-0.06)	100% (0.97-1.00)	28.5% (0.18-0.41)	98.5% (0.94-0.99)
Early SSc subsets				
Raynaud's phenomenon plus abnormal nailfold capillaroscopy and positive SSc-related antibodies (n=13)	-	-	53% (0.29-0.76)	98.5% (0.94-0.99)
Raynaud's phenomenon plus abnormal nailfold capillaroscopy and negative SSc-related antibodies (n=31)	-	-	22% (0.11-0.39))	98.5% (0.94-0.99)
Raynaud's phenomenon plus normal nailfold capillaroscopy and positive SSc-related antibodies (n=12)	-	-	16% (0.04-0.44)	98.5% (0.94-0.99)

Conclusion: The 2013 ACR/EULAR classification criteria for SSc presented higher sensitivity than the 1980 ACR criteria particularly among patients with early SSc. The cut-off of ≥ 8 for total score showed an excellent sensitivity with no loss of the specificity for the classification of patients with SSc in this cohort of patients, and may allow early intervention among patients with early disease.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Interstitial lung disease (ILD) represents one of the most frequent causes of death in systemic sclerosis (SSc) patients. Yet, there are no approved drugs for treatment of SSc-ILD. At present, data on immunosuppressive therapy in patients with ILD and limited cutaneous (lc) involvement are missing.

Methods:

The European Scleroderma Trials and Research (EUSTAR) database was established in 2004 to annually collect data on specialized care of patients with SSc. Data from patients with lc SSc and ILD, where immunosuppressive therapy can be assumed to be mainly intended to treat ILD, were analyzed to describe current use of immunosuppressants and to recognize patterns of treatment choices.

Results:

Out of a cohort of 12,536 SSc patients, we identified 1,814 adult patients fulfilling the 1980 ACR or the 2013 ACR-EULAR criteria, with lc involvement and signs of ILD (either on chest X-ray or high resolution computed tomography) with at least one valid report on immunosuppressive treatment.

Mean age was 58.7±13.1 years, with 88.9% females and a mean SSc disease duration of 10.2±8.6 years. Mean mRSS was 6.1±4.7.

Compared to the 1,119 (62%) patients who had at least one episode of immunosuppressive therapy the 695 (38%) patients without use of immunosuppressants ever were on average 5 years older, had a 2.4 years longer median disease duration, higher DLCO (single breath) and FVC values and consequently less often a pulmonary restrictive defect.

The immunosuppressants most frequently used were prednisolone (pred; 52.6%), azathioprine (aza; 13.9%), cyclophosphamide (cyc; 13.8%), methotrexate (mtx; 11.7%), and mycophenolate mofetil (mmf; 11.0%); all others were prescribed in less than 2%. With regard to highest treatment intensity ever received, 31.6% of the patients got monotherapies and 26.3% combinations of two drugs, while triple therapy was comparably rare with 3.6%. Overall, immunosuppressive treatment was less frequent than in diffuse cutaneous type (82%), this was true for mmf or cyc monotherapy and any combination therapies.

When comparing patient characteristics at the treatment start of the most frequent regimens, differences compared to the “never IS” group and between treatment arms become apparent with regard to age, NYHA class, Scl70 antibodies, mRSS, ground glass opacification, lung function parameters and the proportion with pulmonary restrictive defect (table 1).

Table 1: Patient characteristics in the never IS group and at start of most frequent treatment regimens which are sorted by descending FVC; significant differences (p<0.05) compared to the never IS group are marked with a *.

	never IS (n=695)	MTX (n=47)	Pred (n=350)	MMF (n=49)	AZA (n=66)	Pred+ MTX (n=80)	Pred+ MMF (n=71)	Pred+ AZA (n=104)	CYC (n=32)	Pred+ CYC (n=68)

TLC (%pred.)	91.4	92.9	*84.7	*80.0	*81.9	86.2	*81.6	*77.7	*76.4	*74.7

mRSS= modified Rodnan skin score; DLCO/SB= single breath diffusing capacity for monoxide; FVC= forced vital capacity; FEV1= forced expiratory volume in 1 second, TLC= total lung capacity

Conclusion:

“Everyday” use of immunosuppressants is frequent in SSc-ILD patients with lc involvement, showing a wide variety of single and combined immunosuppressive therapies with distinct patient patterns between treatment regimens. However, prospective studies are still necessary to define indications and outcomes. The EU-funded international FP7 DeSScipher research project was initiated to achieve this goal, comprising 5 prospective observational trials addressing the most frequent medical problems in SSc patients.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Microparticles (MPs) are membrane-bound vesicles derived from vascular and intravascular cells such as endothelial cells (EMPs) and platelets (PMPs). Circulating MPs levels are altered in autoimmune rheumatic diseases (AIRDs) and may act as a diagnostic and prognostic biomarker, but their precise functional role remains to be elucidated. We investigated EMP and PMP numbers across a spectrum of AIRDs with the aim of comparing the levels of, and relationship between, EMPs and PMPs.

Methods:

Patients with Systemic Lupus Erythematosus (SLE) (n=24), Systemic Sclerosis (SSc) (n=24), Primary Raynauds Phenomenon(RP) (n=17) and “other CTD” (n=15) (Primary Sjogrens Syndrome, UCTD or MCTD) as well as 15 healthy controls were recruited. Plasma levels of EMPs (AnnexinV+/CD31+/CD42b-) and PMPs (AnnexinV+/CD31+/CD42b+ or AnnexinV+/CD31-/CD42b+) were quantified using flow cytometry.

Results:

Patients with SLE had significantly higher EMPs compared with healthy controls and SSc patients [(SLE vs health 293,889/ml vs 132,171/ml, $p = 0.03$), (SLE vs SSc 293,889/ml vs 161,271/ml, $p = 0.04$)]. In contrast significantly higher PMP levels were noted in SSc and primary RP when compared to healthy controls and patients in the other CTD cohort [(SSc vs health 186,348/ml vs 41,085/ml, $p < 0.001$), (SSc vs other CTD 186,348/ml vs 58,178/ml, $p < 0.001$)]. No significant difference was observed in PMP levels between SLE patients and those with SSc/RP.

A modest correlation was noted between EMP and PMP levels in health (Spearman $r = 0.6$, $p = 0.017$). This relationship appeared stronger in SLE (Spearman $r = 0.72$, $p < 0.0001$) and other CTD patients (Spearman $r = 0.75$, $p < 0.0001$). The association between EMPs and PMPs was notably less strong in SSc (Spearman $r = 0.45$, $p = 0.014$) and RP (Spearman $r = 0.37$, $p= 0.15$). A significantly lower EMP/PMP ratio was seen in SSc/RP patients in comparison to both healthy controls and SLE/other CTD patients (Figure 1). Improved disease control, following alteration in immunosuppressive therapy, was associated with a reduction in EMP and PMP numbers in SLE, a result that was significant for PMPs (75,969/ml vs 32,171/ml, $p = 0.02$). In contrast, the addition of Asasantin in SSc/primary RP patients did not affect MP levels at follow up.

Conclusion:

MP populations differ across the spectrum of AIRDS, with high PMPs seen in SSc/RP and high EMPs observed in SLE. The ratio of EMPs/PMPs appears to distinguish between SLE/other CTD and SSc/primary RP, suggesting differential production of MPs according to the vascular pathology and bed involved. Improved disease control reduces PMP levels in SLE, but antiplatelet agents do not materially affect MP numbers in SSc/RP. MPs may therefore act as diagnostic and prognostic biomarkers in AIRDs.

Figure 1. The ratio of EMPs/PMPs in SLE, primary Raynauds, Systemic Sclerosis and other CTD patients.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have shown that gastroesophageal reflux disease (GERD) is a risk factor in the progression of idiopathic pulmonary fibrosis. In systemic sclerosis (SSc), esophageal involvement is common; however, it does not generate symptoms in 50% of patients. Therefore, the presence of esophageal dilation and GERD may be a poor prognostic factor in patients with systemic sclerosis and diffuse interstitial lung disease (ILD-SSc) as a result of recurrent episodes of micro-aspiration. Our objective was to analyze whether the presence of esophageal dilation is a poor prognostic factor in ILD-SSc.

Methods: Thirty-one patients with SSc (ACR/EULAR 2013 criteria) and secondary symptomatic ILD, as confirmed by thoracic HRCT, were studied. HRCT images performed at the time of ILD diagnosis were reviewed with particular attention to: *a)*the presence of dilation in the lower two-thirds of the esophagus and b) the extent of ground glass areas and fibrotic changes (honeycombing areas, thickening of the interlobular septa and traction bronchiectasis with architectural distortion). The extent of HRCT lung abnormalities were scored in 3 categories: 1 = involvement of < 25% of total pulmonary parenchyma, 2 = 25-30%, and 3 = > 50%.

Results: Esophageal dilation was detected in the HRCT of 15 (48%) patients. The main clinical characteristics of the patients and the results from the comparative study between groups are shown in the following table:

	Esophageal dilation in the HRCT N= 15	No esophageal dilation in the HRCT N=16	*p*
Age (mean±SD), yrs	54 ± 16	63 ± 15	0.120
SSc Types	Limited :5 Diffuse: 9 SSc sine escleroderma 1	Limited: 12 Difuse: 2 SSc sine escleroderma:2	0.022
SSc disease duration (median ±SD), months	102 ± 143	112 ± 95	0.812
ILD type	NSIP: 12 UIP: 3	NSIP:12 UIP:4	0.095
ILD disease duration (median ±SD), months	35 ± 27	70 ± 44	0.014
Baseline HRCT			
Ground glass areas	Score 1: 6 Score 2: 6 Score 3: 0	Score 1: 10 Score 2: 1 Score 3: 0	0.033
Fibrotic changes	Score 1: 2 Score 2: 4 Score 3: 0	Score 1: 4 Score 2: 0 Score 3: 0	0.035
Baseline PFT			
FVC% (mean ± SD)	83.9 ± 22.1	103.4 ± 19.5	0.015
TLC%	87.9 ± 25.7	110.7 ± 33.9	0.116
DLCO%	57.4 ± 17.9	71.3 ± 24.3	0.095
PFT at the end of the follow-up period			
FVC%	79 ± 20.8	98.3 ± 26	0.031
TLC%	79 ±19.2	98.5 ± 26.8	0.067
DLCO%	48.8 ±15.7	62.2 ±18.3	0.046
Treatment with CYC and/or rituximab	10 (67%)	5 (31%)	0.049
Treatment with proton pump inhibitors	14 (93%)	11 (69%)	0.172

At the time of ILD-SSc diagnosis, patients with esophageal dilation showed a greater extent of *ground glass* areas ($P = 0.033$) and fibrotic changes ($P = 0.035$) in the HRCT. A relatively common finding in these patients was an asymmetry in injury severity with greater involvement in one of the two lungs. In addition, patients with esophageal dilation showed greater deterioration of lung function parameters, although the differences were only statistically significant for baseline ($P = 0.015$) and final ($P = 0.031$) FVC measurements and for the final DLCO measurement ($P= 0.046$). These patients also received more frequent treatment with CYC or rituximab.

Conclusion: The presence of esophageal dilation appears to be a poor prognostic factor in ILD-SSc, which relates to a greater extent of HRCT lung abnormalities and further deterioration in baseline pulmonary function tests (PFT)

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in patients with systemic sclerosis (SSc). Patients with diffuse cutaneous systemic sclerosis (dcSSc) have an increased risk of the development of ILD. High resolution computed tomography of the chest (HRCT) is the radiographic gold standard for the diagnosis of ILD. Pulmonary function testing (PFT) is a common screening method for ILD. However, some SSc patients with entirely normal PFTs have ILD evident on their HRCTs. Our aim was to assess the performance characteristics of PFTs for the diagnosis of ILD in patients with early dcSSc, using HRCT as the reference standard.

Methods: Subjects were enrolled in the Prospective Registry of Early Systemic Sclerosis (PRESS), a multicenter, prospective registry of adults with early dcSSc (disease duration < 2 years from first non-Raynaud's symptom), between April 2012 and June 2015. Subjects were included in this study if they had baseline PFTs. The presence or absence of ILD on HRCT was determined by chest radiologists at each center. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of forced vital capacity (FVC), total lung capacity (TLC), and diffusion capacity for carbon monoxide (DLCO) for the diagnosis of ILD were calculated. A cut-off point of <80 %predicted was defined as abnormal for each PFT parameter.

Results: The mean age of the 91 subjects with baseline measurements of FVC was 52 years (± 15.3); 68% were female and 74% were white. 54% of the 50 subjects who underwent HRCT had radiographic evidence of ILD (Table 1). DLCO had a higher sensitivity for the diagnosis of ILD than either FVC or TLC alone (Table 2). The combination of FVC and DLCO had a higher sensitivity for the diagnosis of ILD than DLCO alone. However, all PFT parameters (either alone or in combination) had only moderate specificity.

Conclusion: Although the combination of FVC and DLCO had excellent sensitivity for the diagnosis of ILD in early dcSSc, this combination only had moderate specificity for the diagnosis of ILD. Given the increased risk of ILD in patients with dcSSc, it may be reasonable to order an HRCT for all patients newly diagnosed with dcSSc, regardless of PFT results. Future work is needed to develop the optimal screening algorithm for ILD in patients with dcSSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In the majority of SSc patients, however, cardiac involvement often remains subclinical. Primary myocardial abnomalities are characterized by fibrosis. Cardiovascular magnetic resonance (CMR) can non-invasively detect subclinical myocardial inflammation and fibrosis. Brain natriuretic peptide (BNP) has become important cardiac biomarkers. We evaluated the association of myocardial abnormalities and LV geometry ,assessed by CMR, with disease characteristic and BNP in SSc patients without cardiac symptoms.

Methods: Patients were recruited from3 hospitals in Tokyo. This study compared consecutive female SSc patients without cardiac symptoms and healthy female controls with no history or clinical findings of systemic and pulmonary hypertension by echocardiography, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, and dyslipidemia. All underwent contrast or non-contrast CMR on a 3.0-T scanner. LV function was measured using ejection fraction (EF), end-systolic volume (ESV), end-diastolic volume (EDV), stroke volume (SV), and cardiac output (CO). LV hypertrophy was measured by absolute LV mass (LVM) and LVM index (LVMI) determined by LVM/body surface area. LGE was obtained to assess myocardial fibrosis. Myocardial inflammation was assessed by black- blood T2WI. Serum BNP concentrations were measured simultaneously.

Results: There were 50 SSc patients with a mean age of 55.1 ± 7.7 years; 25 had diffuse type and 25 had limited type. There were 20 healthy controls with a mean age of 56.9 ± 3.1 years. There were no significant differences in terms of age, gender, and cardiovascular risk factors. Compared with the control, SSc patients had a significantly higher EDV with tendency towards a high LVMI. There was no difference in EF between control and patients of SSc . LGE (+) was detected in 27 of 50 (54%) SSc patients. T2WI was observed in 13 of 50 (26%) patients of SSc. There were no differences in LGE and T2WI between the diffuse and limited type. The mean of BNP level in SSc group was significantly higher than that of the control group ($P = 0.02$). The mean of BNP level in SSc patients with LGE (+) was significantly higher than that of SSc patients without LGE ($P < 0.001$). BNP level in SSc patients was significantly correlated with LVMI ($P < 0.001$) but not correlated with EF. Eccentric hypertrophy was observed in 55% of LGE (+) patients. LGE (+) was correlated with anti Scl-70 antibody ($P=0.004$). Receiver operating characteristic analysis showed BNP reliably detected myocardial abnormalities (area under the curve 0.896; 95% confidence interval, 0.873–0.924). Considering patients with SSc with normal echocardiography, and using a 18.0 pg/ml cut-off concentration, sensitivity and specificity were 91% and 70% in the detection of overall cardiac involvement.

Conclusion: Cardiac involvement is common in SSc even in the absence of cardiac symptoms, and includes myocardial inflammation as well as myocardial fibrosis. Our data suggest that SSc-specific autoimmunity against Scl-70 mediates these changes. BNP level may be useful in future in the study of treatments aimed at preventing or reducing adverse myocardial processes in SSc.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Nailfold videocapillaroscopy (NVC) is a simple, non-invasive and inexpensive imaging technique that allows a detailed assessment of skin microcirculation. Although NVC has face and content validity for the detection of microvascular damages related to systemic sclerosis (SSc), its sensitivity to change has not been assessed in detail. Our aim was to determine in a prospective cohort the merit of NVC to detect meaningful changes over time and whether these changes are associated with disease progression.

Methods: A prospective cohort of 140 SSc patients was recruited over a 12-month period and was followed up on an annual basis for 3 years. NVC was performed at inclusion and repeated once a year by four investigators (ET, GL, CH and AV) according to a standardized procedure. NVC pictures were analysed by one investigator (JA) and classified as early, active and late patterns. Organ progression was defined according to validated definitions. The worsening of the Medsger severity scale (from category 1-2 to category 3-4) was considered as a marker of disease progression.

Results: The mean ± standard deviation (SD) age of the 140 patients (111 women) was 56±11 year old and the mean ± SD disease duration was 9±8 years at baseline. 55 patients had the diffuse cutaneous subset. At least 3 annual NVC evaluations were available for each patient. A change of NVC pattern was observed in 29 SSc patients (21%) during the follow-up period.

A progression from a normal or early NVC pattern to an active NVC pattern was detected in 15 patients (10%). Patients who progressed to the active NVC pattern were more likely to have shorter disease duration (6±7 years vs. 11±9 years, p=0.03). Progression was independent of age, gender, cutaneous subset, past or current digital ulcers (DU), and use of vasodilators at baseline. Patients who progressed to the active NVC pattern were significantly less at risk to develop ischemic DU during follow-up (hazard ratio, HR: 0.78, 95% Confidence Interval, CI 0.17-0.95).

A progression to a late NVC pattern was observed in 14 patients (10%). Patients with the diffuse cutaneous subset and with precapillary PAH at baseline were more likely to progress to a late NVC pattern (HR: 2.39, 95% CI 1.03-7.10 and HR: 13.30, 95% CI 2.46-71.99, respectively). Progression to the late pattern was independent of age, sex, disease duration, past or current DU, and use of vasodilators at baseline. Progression to a late NVC pattern was associated with the occurrence of new ischemic DU (HR: 4.51, 95% CI 1.68-12.14), lung vascular progression (HR: 5.12 95% CI 1.23-21.27), progression of skin fibrosis (HR: 3.70, 95% CI 1.14-11.94) and worsening of Medsger disease severity scale (HR: 4.47, 95% CI 1.63-12.26).

Conclusion: Change of the NVC pattern was observed in 20% of patient with SSc during a follow-up of 3 years. NVC has the ability to detect meaningful changes over time associated with markers of disease progression. Our results support the use of NVC for the routine follow-up of SSc patients in order to improve their risk stratification. NVC might be used in the future to select high-risk patients and change to a late NVC pattern might be regarded as potential surrogate marker for disease severity.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc), Polymyositis (PM) and Dermatomyositis (DM) are characterized by the presence of serum autoantibodies (autoAbs) which are central in the diagnosis, predicting organ involvement, follow-up and therapy. However, patients can be negative for commercially available autoantibody tests such as anti-centromere (ACA), -topo I and RNA polymerase III in SSc and -Jo-1 in PM. Our aim is to apply immunoprecipitation (IP) to SSc and PM/DM patients to identify new and rare autoantibodies, to study their clinical association.

Methods: We investigated sera from consecutive patients with SSc (n=28, out of a total of 98 SSc patients attending our Unit in 2014-2015), PM (n=15) and DM (n=9) by protein-IP of ^{35}S-methionine-labeled K562 cell extract followed by SDS-PAGE and autoradiography. Statistical analysis was performed by Prism (GraphPad Software 4.0) by Fisher exact test and statistical significance at $p< 0.05$.

Results: 28 SSc sera were tested by IP to identify rare autoAbs (see Table). A common set of several proteins of 140/40-25kD that needs further characterization for antigen identification was observed in 8 SSc cases. It is significantly associated with ACA positivity (50%, 8/16 ACA vs 0/12 others; p=0.008), and these patients have severe Raynaud's with digital ulcers requiring IV prostacyclin (75%, 6/8 vs 7/54 ACA+, 13%; p=0.0006), with

esophageal involvement in 4 cases. In 15 PM patients, one each of anti-TIF1 gamma/alpha, -PL-7 and -PL-12 were identified by IP. In 9 DM cases, IP identified 2 anti-Ro/SSA, 2 anti-Mi-2 and 1 anti-TIF1 gamma/alpha: this case had juvenile DM with Hodgkin's lymphoma 3 years before the onset of DM symptoms.

Autoantibody	Disease	Sex	ANA	Disease manifestations	Cancer
Anti-Ku (n=1)	Limited SSc	Female	Speckled	Digital ulcers	No
Anti-replication protein A (n=1)	Diffuse SSc	Female	ACA+ speckled	Alveolitis, GI tract disease, fasciitis and digital ulcers	No
Anti-NOR90 (n=1)	Limited SSc	Male	Speckled+ nucleolar	Pulmonary fibrosis and pulmonary arterial hypertension	Yes
Anti-Ago2/Su (n=1) with anti-topo I	Diffuse SSc	Female	Homogeneous+ nucleolar	Alveolitis and digital ulcers	No
Anti-140/40-25k (n=8)	Limited SSc	Female	ACA	Digital ulcers (n=6), esophageal involvement (n=4)	No
Anti-TIF1 gamma/alpha (n=2)	DM (n=1) PM (n=1)	Female Male	Speckled	High CPK at onset, no organ involved in both cases	Yes in DM
Anti-Mi-2 (n=2)	DM	Female	Speckled	Skin and muscle disease, no organ involvement	Yes in 1 case
Anti-PL-7 (n=1)	PM	Female	Cytoplasmic	Anti-synthetase syndrome	No
Anti-PL-12 (n=1)	PM	Female	Nucleolar	Anti-synthetase syndrome	No

Conclusion: Protein and RNA-IP can be used to identify rare and unknown autoantibodies in systemic autoimmune rheumatic diseases such as SSc and PM/DM and may identify new biomarkers for rare diseases.

Myocardial Fibrosis Detected By Magnetic Resonance Imaging Is a Predictor of Heart Failure in Systemic Sclerosis (SSc) Patients

Tatiana Sofia Rodriguez-Reyna[1], Martha Morelos-Guzmán[2], Pamela Mercado Velazquez[3], Pablo Henrandez-Reyes[4], Karla Montero-Duarte[5], Cynthia Martinez-Reyes[6], Carlos Reyes-Utrera[6] and Carlos Nunez Alvarez[3], [1]Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Radiology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico, [3]Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico, [4]Department of Cardiology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico, [5]Department of Imaging and Radiology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico, [6]Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In previous studies we showed that prevalence of myocardial fibrosis in SSc patients is 45% and is associated to diffuse disease (dcSSc) and lower left ventricle ejection fraction (LVEF); microvascular damage was also very frequent (79%). Our aim was to identify baseline characteristics associated to the development of cardiovascular outcomes (heart failure, coronary artery disease, arrhythmias, vasculopathy, and death) in SSc patients with previously documented myocardial fibrosis and microvascular damage.

Patients and **Methods:** We included 62 SSc patients who participated in the study of prevalence of myocardial fibrosis (2008-2010) and in our local SSc cohort. We performed baseline clinical evaluation, cardiac MRI, coronary angiotomography, transthoracic echocardiogram, and yearly clinical and

cardiovascular evaluation that included Medsger's severity scale items, electrocardiogram, echocardiogram, chest X ray or HRCT and spirometry; we registered presence and severity of internal organ involvement and cardiovascular outcomes. Ordinal variables were analyzed using Chi square test and Fisher test when appropriate, numeric variables were compared using Student's t test or Mann Whitney U when appropriate, logistic regression was used to perform multivariable analysis.

Results: We obtained follow-up information from 61 patients (29 dcSSc, 32 lcSSc), mean follow up was 43.5 months. Univariate analysis showed that elevated basal ultrasensitive CRP was associated to higher overall mortality at the end of follow-up (p=0.003, OR=22, 95% CI 2.3-209), and microvascular damage at baseline was associated to recurrent digital tip ischemic ulcers (p=0.05). Multivariable analysis showed that: myocardial fibrosis, particularly in the middle LV segments was associated to the development of heart failure (p=0.04, OR 8.9, 95%CI 1.07-76); lower LVEF was associated to the development of coronary artery disease (p=0.02, OR 0.66, 95%CI 0.47-0.9); finally, insertion point fibrosis (p=0.01, OR 11.1, 95%CI 2.5-55.5) and elevated ultrasensitive CRP (p=0.04, OR 5.2, 95%CI 1.82-25.6) were associated to recurrent digital tip ulcers.

Conclusion: This study shows that elevated ultrasensitive CRP, the presence of myocardial fibrosis and microvascular damage are predictors of cardiovascular outcomes in SSc patients. Patients with myocardial fibrosis experience progressive decline in LVEF when compared to those without fibrosis. Future studies should focus on therapeutic strategies for this group of patients.

Deficiency in Micronutrients Is a Frequent Burden in Patients with Systemic Sclerosis

Jasmin Laeubli[1], **Rucsandra Dobrota**[1], Britta Maurer[1], Suzana Jordan[2], Benjamin Misselwitz[3], Mark Fox[3] and Oliver Distler[1], [1]Division of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [3]Division of Gastroenterology, University Hospital Zurich, Zurich, Switzerland

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Micronutrients are essential dietary factors involved in many metabolic processes, including oxidative stress, collagen synthesis and wound healing, which are key aspects of the pathogenesis of systemic sclerosis (SSc). Considering the frequent gastrointestinal involvement and impaired nutritional status (1,2), we hypothesized that the micronutrients could be profoundly affected in SSc patients.

Methods: Patients with SSc were prospectively included between 2009 and 2014. Clinical assessment, data recording and quality controls were done according to EUSTAR standards. In addition, the UCLA SCTC-GIT 2.0 questionnaire was applied. The following micronutrients were measured: zinc, selenium, prealbumin, holotranscobalamin, folic acid. Patients with a specific micronutrient deficiency or with deficiency in at least one micronutrient ("any deficiency") were compared to patients with a normal micronutrient pattern. The two-sided Fisher's exact test, the t-test and the Mann-Whitney were used, as appropriate. Multivariable logistic regression was applied to identify predictors of a deficiency in micronutrients in SSc patients.

Results: Nearly half (43.7%) of the 176 SSc patients included had a deficiency in at least one of the measured micronutrients. The most frequent deficit was in selenium (21.9%), followed by folic acid (16.6%) and prealbumin (15.0%). Even more, 19.3% of patients had multiple micronutrient deficiencies. There was a significant association between low levels of selenium and zinc, prealbumin and zinc and folic acid and zinc. Patients with a lower body mass index (BMI) had lower zinc levels, and those with low prealbumin had more stomach symptoms. The strongest ($p<0.01$) clinical parameters associated with any deficiency in micronutrients were lower hemoglobin ($p<0.001$), higher modified Rodnan skin score (p=0.007) and proximal skin thickening (p=0.009), as shown in Table 1. Proximal skin thickening, low hemoglobin and a low BMI were confirmed in the multivariable model as independent predictors of a deficit in micronutrients in patients with SSc.

Conclusion: Our study reveals that micronutrient deficiencies are a frequent burden in SSc patients and correlate with clinical aspects of the disease. Moreover, often more than one micronutrient is affected. In our cohort, patients with proximal skin fibrosis and lower BMI were more likely to show a deficiency in micronutrients, suggesting that screening for micronutrient status should be prioritized in these patients.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a family of diseases unified by the presence of immune activation, vasculopathy and fibrosis. The

concept of SSc subsets cannot be easily measured but is considered to be real. To evaluate the purpose, strengths and limitations of the limited/diffuse subset criteria, and identify areas requiring improvement.

Methods: We conducted a content analytic study consisting of semi-structured interviews with 30 SSc experts. The interview transcripts underwent an iterative process with text deconstructed to single thought units until a saturated conceptual framework with coding was achieved and respondent occurrence tabulated. This was followed by serial cross-referential analyses establishing a set of pervasive complex thought clusters.

Results: Of the 30 experts, 26 (87%) were male, 19 (63%) were from Europe and 11 (37%) were from North America. The experts had seen SSc patients for a mean 23 (SD 10.7) years, and saw a mean of 122 (SD 185) new SSc patients annually. Three thematic clusters were noted regarding the utility of subsetting: to facilitate research and communication, to inform management, and to inform prognosis (prediction of internal organ involvement, survival). The strength of the limited/diffuse system was its ease of use, however 10% stated this system has 'little or no value.' Limitations of the diffuse/limited classification were the risk of misclassification, predictions/generalizations did not always hold true, and that the elbow or knee threshold is arbitrary. 87% use more than 2 subsets including: SSc sine scleroderma, overlap conditions, antibody determined subsets, subsetting based on speed of progression, and age of onset (juvenile, elderly). Considerations for the next phase of criteria development include incorporation of rate of change and hierarchal clustering (limited/diffuse, then by antibodies).

Conclusion: We interviewed international SSc experts and synthesized their views on subset criteria. These results can inform our efforts to develop revised criteria to guide research, prognostication and management.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We evaluated the ability of alveolar and conducting airway nitric oxide (NO) to discriminate between systemic sclerosis (SSc) with and without lung involvement, idiopathic PAH (IPAH), and healthy subjects.

Methods: Consecutive patients in the University Health Network Pulmonary Hypertension Program and Toronto Scleroderma Program were screened. Exhaled nitric oxide was measured at 50, 100, 150, 200 and 250 mL/s using chemiluminescent detection. Alveolar and conducting airway NO were partitioned using a two-compartment model of axial diffusion (CMAD) and the trumpet model of axial diffusion (TMAD).

Results: 60 subjects were recruited: SSc (n=18), SSc-PAH (n=7), SSc-ILD (n=4), SSc-PAH and ILD (n=6), SLE-PAH (n=6), IPAH (n=9) and healthy controls (n=10). Using the CMAD model, healthy subjects had lower median (IQR) alveolar NO than all PAH patients (2.0 ppb (1.5,2.5) versus 3.14 ppb (2.3,4.0), p=0.008). SSc-ILD patients had significantly lower median conducting airway NO compared to controls (1009.5 versus 1342.1 ml*ppb/s, p=0.04). SSc-PAH patients had increased conducting airway NO that inversely correlated with DLCO (Pearson's r -0.88 (95%CI -0.99, -0.26). Median serum BNP values were higher in SSc-PAH patients than SSc patients without pulmonary involvement (358.8 versus 11.6 pg/ml, p=0.01).

Conclusion: Compartmental exhaled NO measurements vary depending on the type of pulmonary pathology present in individuals with SSc, supporting discriminative validity in SSc lung disease.

Subclinical Biventricular Systolic Function Is Impaired in Patients with Systemic Sclerosis with Real Time 3-D Echpcardiography: 1 Year Follow-up Study

Sule Yavuz[1], Taylan Sahin[2], Selen Yurdakul[2], Neslihan Yilmaz[3] and Saide Ertekin[4], [1]Rheumatology, Istanbul Bilim University, Faculty of Medicine,Department of Rheumatology, Istanbul, Turkey, [2]Cardiology, Istanbul Bilim University Dept of Cardiology, Istanbul, Turkey, [3]Istanbul Bilim University, Faculty of Medicine, Rheumatology Department, Istanbul, Turkey, [4]Cardiology, Istanbul Bilim University, Dept of Cardiology, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Silent myocardial involvement is associated with poor prognosis in patients with systemic sclerosis (SSc). Here, we aimed to evaluate subclinical left ventricular (LV) and right ventricular (RV) systolic dysfunction in SSc patients without any cardiovascular disease, by using both strain imaging method, “speckle tracking” (STE) and real time 3-D Echocardiography.

Methods:

Fifty-five SSc patients were screened, 7 patients were excluded because of ischemic heart disease. 25 age and sex-matched healthy controls (HC), without any cardiac disease and with preserved LV-EF were studied as controls. Conventional echocardiography, STE-based strain imaging and real time 3-D echocardiography (Bothell, WA,USA) were performed to assess biventricular deformation analyse. Association with anti-Scl 70 was sought in patients with SSc.

Results:

In SSc patients (Female/Male: 44/4) the mean age was 47.7 years. Anti Scl-70 seropositivity was 22 (45.8%). Left ventricular conventional echocardiographic measurements (LV end diastolic diameter, LV end systolic diameter and LV EF) were similar between SSc and HC (table1). Both LV and RV longitudinal peak systolic strain/ strain rate were significantly impaired in SSc, demonstrating subclinical LV and RV systolic dysfunction ($p \leq 0.001$). LVESV was significantly increased in SSc (44.3±7.3 vs 37.8±2.4; SSc vs HC, $p < 0.001$)

Systolic PAB was negatively correlated with both LV and RV longitudinal peak systolic strain/strain rate (LV: r=-0.552 and r= -0.637, respectively, $p<0.001$ and RV: r=-0.547 and r=-0.638, respectively, p=0.001). Anti Scl -70 positive patients had impaired LV longitudinal peak systolic strain and strain rate values, compared to the others, however the difference did not reach statistical significance (13.01±1.26 % to 13.04±1.90 %, p=0.96 for strain; 0.30±0.06 1/s to 0.31±0.15 1/s, p=0.79 for strain rate). There was a trend for decreasing left ventricular strain and increasing LEVSV in 1 year analysis of SSc patients but it did not reach statistical significance.

Conclusion:

SSc is associated with myocardial systolic dysfunction. Both deformation analysis by STE-based strain imaging and end systolic left ventricular volume analysis by real time 3-D echocardiography are promising modalities that allow us for non-invasive, comprehensive analysis of early deterioration in biventricular systolic function in patients with SSc.

Table1. Speckle tracking echocardiography (STE) and real time 3-D echocardiography results of SSc patiens and healthy controls.

	SSc n=48	**HC n=25**	**p value**
LV longitudinal peak systolic strain (%)	13.3± 0.82	20.35±3.05	0.0001
LV strain rate (1/s)	0.91±0.21	1.70±0.47	0.0001
RV longitudinal peak systolic strain (%)	11.68±1.61	14.63±2.35	0.001
RV strain rate (1/s)	0.31±0.01	2.73±0.4	0.0001
LVEDV (ml)	104.6±16.2	106±17.5	0.63
LVESV (ml)	44.3±7.3	37.8±2.4	0.0001

Values were presented as mean ±SD. LV; left ventricul, RV; right ventricul, LVEDV;left ventricular end diastolic volume,LVESV; left ventricular end systolic volume

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Skin thickness is a hallmark of systemic sclerosis (SSc), and its progression is associated with poor prognosis. The modified Rodnan total skin thickness score (MRSS) is widely used for evaluating extent and severity of skin thickness. Serial changes of MRSS during the disease course are highly heterogeneous among patients with diffuse cutaneous SSc (dcSSc): some show worsening of the score, but others experience regression. This study was aimed to identify parameters that predict worsening of MRSS in patients with early dcSSc using a multicenter prospective cohort conducted by the Scleroderma Study Conference of Japan.

Methods: A total of 171 patients with early dcSSc were selected from the prospective cohort database based on fulfillment of 1980 American College of Rheumatology preliminary criteria, dcSSc, MRSS ≥7 at entry, disease duration <60 months at entry, and valid data for MRSS at one year. Worsening of skin thickness was defined as increase in MRSS ≥3 points and ≥25% from baseline to one year. In univariate analysis, patients who experienced progression of skin thickness were compared with non-progressors, and selected predictive markers were included in multivariate logistic regression analysis.

Results: Only 23 patients (13.5%) experienced worsening of MRSS at one year. In progressors, MRSS increased at one year from 14.4 ± 6.5 to 21.4 ± 7.2 ($P < 0.0001$), and still maintained a high score over 5 years (20.6 ± 9.0 and 16.8 ± 8.7 at 3 and 5 years, respectively). In contrast, non-progressors showed continuous decrease of MRSS in the following 5 years (21.5 ± 8.9 at baseline, 13.0 ± 7.0 at one year, 11.2 ± 7.6 at 3 years, and 9.0 ± 6.4 at 5 years). Univariate analyses identified short disease duration ($P = 0.002$), negative anti-RNA polymerase III ($P = 0.03$), low baseline MRSS ($P = 0.0003$), tendon friction rubs ($P = 0.02$), absence of nailfold bleeding ($P = 0.001$), joint synovitis ($P = 0.01$), high KL-6 ($P = 0.005$), and high erythrocyte sedimentation rate (ESR) ($P= 0.0001$) as predictors for worsening of MRSS at one year. There was no difference in use of immunosuppressant or corticosteroids between progressors and non-progressors. In the multivariate analysis, disease duration (odds ratio 0.93 [0.87-0.99]), baseline MRSS (0.85 [0.77-0.95]), nailfold bleeding (0.25 [0.07-0.85]), and ESR (1.04 [1.01-1.08]) were selected as independent parameters associated with subsequent progression of the disease. Assessment of the best predictive model revealed that patients with disease duration ≤20 months, baseline MRSS ≤20, and ESR ≥21 mm/hour had the high risk of worsening of MRSS within one year, at sensitivity of 57% and specificity of 91% (odds ratio 13.5 [5.0-36.8]).

Conclusion: This study successfully identified dcSSc patients at the high risk of subsequent worsening of skin thickness. This information is useful in selecting patients who require intensive treatment with potential disease-modifying agents and in improving clinical trial design by enrichment for eligible progressors.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a complex disease associating vasculopathy, cutaneous and visceral fibrosis, and autoimmunity. Myocardial microscopic fibrosis may occur and potentially lead to impaired myocardial contraction or cardiac conduction. Cardiac magnetic resonance imaging (CMRI) is now widely used for the non-invasive characterization of myocardium. The aim of this study is to evaluate the impact of CMRI with T1 mapping and multi-b value diffusion-weighted sequences in SSc for the assessment of myocardial fibrosis and perfusion.

Methods: We conducted a single-center prospective study of consecutive patients with SSc. CMRI with T1 mapping and multi-b value diffusion-weighted sequences were performed in all patients. T1 mapping sequences assess collagen myocardial infiltration, defining microscopic fibrosis. Multi-b value diffusion-weighted sequences assess tissue perfusion by measuring F coefficient.

Results: Forty patients, 35 women and 5 men, mean age 54.7 ± 14.6 years, were included. Patients had: diffuse cutaneous forms in 19 cases, limited cutaneous forms in 16 cases, and limited forms in 5 cases. Median modified Rodnan skin score was 6 (0-38) and median time from disease diagnosis to CMRI was 77 months (1-302).

Myocardial microscopic fibrosis, defined on T1 mapping sequences by a value greater than 1250 ms, was found in 21 (53%) SSc patients. Conversely, it was found in none of 20 healthy controls (12 males and 8 females, mean age 28 years).

Demographic characteristics were similar between SSc patients with and without myocardial microscopic fibrosis on CMRI. However, SSc patients with myocardial microscopic fibrosis had more frequent diffuse cutaneous form (67% vs. 26%, P=0.01), higher modified Rodnan skin score (11 vs. 2, P = 0.036) and more frequent infiltrative lung disease (48% vs. 16%, P=0.046). Patients with early diffuse cutaneous form (less than 4 years of evolution) had myocardial microscopic fibrosis in 86%. Patients with anti-RNA polymerase III antibody, anti-Scl70 or anti-fibrillarin antibodies, associated with diffuse cutaneous forms had myocardial microscopic fibrosis in 83%. Conversely, patients with anti-centromere antibodies had a myocardial microscopic fibrosis in 46%.

Analysis of F coefficient in multi-b value diffusion-weighted sequences revealed a perfusion defect (defined by a factor F <0.5) in 25% of SSc patients. All of these patients (100%) had a myocardial microscopic fibrosis, while only 37% of patients without perfusion defect had myocardial microscopic fibrosis (P=0.0005).

Finally, in patients with myocardial microscopic fibrosis, the use of arterial vasodilators was associated with improved tissue perfusion with an F coefficient >0.5 in 67% compared to 29% in patients not receiving arterial vasodilators.

Conclusion: This study investigates for the first time CMRI with T1 mapping and multi-b value diffusion-weighted sequences in SSc. Myocardial microscopic fibrosis is observed in half of the patients, especially in those with diffuse cutaneous forms. Microscopic fibrosis was strongly associated with myocardial perfusion defect, with a beneficial effect of arterial vasodilators on myocardial perfusion.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Low Vitamin D (VD) levels have been observed in several autoimmune diseases, including systemic sclerosis (SSc). Some studies have shown the importance of VD in SSc, but its significance has not yet been determined. We aim to evaluate differences in serum levels of VD in SSc patients compared to a control group, and to correlate such levels with disease activity, clinical and laboratory features.

Methods: We included patients diagnosed with SSc according to ACR 1980 criteria and subtypes according to Le Roy, who consecutively attended the Rheumatology Service in spring and summer during 2 years. Patients with overlapping syndromes, diseases or drugs that interfered with VD serum level 6 months prior to study entry were excluded. A control group of 58 blood donors without autoimmune disease and negative autoantibodies was matched by sex and age. Determination of $25(OH)D_3$ was performed through radioimmunoassay-chemiluminescence assay. Levels between 20 and 29.9ng/ml were classified as VD insufficiency while concentrations lower than 20ng/ml as deficiency. For the SSc group, demographic and clinical data were collected, and mRSS (modified Rodnan Skin Score), scleroderma health assessment questionnaire (S-HAQ), EUSTAR Disease Activity Score and Medsger Severity Score were performed. Statistical Analysis: Numerical variables were compared by Student's t test or Mann-Whitney test and categorical variables by x^2 test. A value of $p<0.05$ was considered significant.

Results: The SSc group included 58 patients; median age of 57 years. The mean value of VD was 19.9±8.7ng/ml in the SSc group, and 29.6±8.6ng/ml in the control group ($P<0.001$). A total of 29 patients (50%) in the SSc group had deficiency, 20 (34.5%) had insufficiency and 9 (15.5%) presented normal levels. In the control group, 6 (10.3%) presented deficiency, 27 (46.6%) insufficiency and 25 (43.1%) normal VD levels. SSc group patients presented a statistically significant higher frequency of deficiency ($p\leq0.001$) but not of insufficiency ($p=0.607$). Out of the 22 patients (38%) with diffuse SSc, 17 (77%) presented deficiency, 4 (18%) insufficiency and 1 (5%) normal VD levels. Among the 36 patients (62%) with limited disease, 12 (33%) had deficiency, 16 (44%) insufficiency and 8 (23%) normal levels. The group of diffuse SSc presented a significantly higher frequency of hypovitaminosis D (VD<30ng/ml)($p=0.005$). Patients with suboptimal levels showed higher Rodnan Score, S-HAQ, EUSTAR Disease Activity Score (all with $p\leq0.001$) and Medsger Score ($p=0.002$) and late SD pattern ($p=0.049$). All presented normal calcemia, calciuria and parathormone. A subgroup of 16 patients (28%) received low doses of steroids (prednisone or equivalent ≤10mg/d) with no significant difference in VD level compared to those who did not receive it.

Conclusion: Hypovitaminosis D was found in more than 80% of SSc patients with a significant difference compared to healthy controls. They presented more frequently the diffuse form, higher cutaneous involvement, more severe and active disease and higher levels of disability.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the benefits and harms of calcium channel blockers (CCBs) versus placebo for the treatment of Raynaud's phenomenon (RP) comparing primary to secondary RP associated with connective tissue disease (CTD), especially systemic sclerosis (SSc).

Methods: The Cochrane library, MEDLINE, EMBASE and Clinicaltrials.gov were searched up to June 2014 for randomized controlled trials (RCTs) examining RP. Outcomes of interest were: Frequency, Duration and Severity of RP attacks, Pain, Patient global, Withdrawals and Serious adverse events. Fixed effects models were used to calculate mean differences (MD) or standardized mean differences (SMD) for continuous outcomes and risk ratios for dichotomous outcomes. Heterogeneity was determined and significant if $I^2>50\%$. Subgroup analyses by: disease type (primary or secondary), CCB dosage (low, medium or high) and CCB drug were performed.

Results: Of the 2337 articles, 939 participants from 36 RCTs investigating the effect of CCBs vs. placebo were included. The majority were crossover RCTs with low to moderate quality using low dose CCBs. CCBs were more effective in reducing the frequency of attacks (22 RCTs, N=978, MD -2.62, 95%CI -3.38,-1.88, $p<0.00001$, Figure) and the severity of attacks (17 trials, N=792, MD -0.73 95%CI -0.99, -0.47, $p<0.00001$).No significant differences in duration, pain or withdrawals between CCBs and placebo occurred. Patient global was only reported in one study. CCBs reduced the frequency and

severity of attacks irrespective of dosage, particularly for primary RP. CCBs reduced frequency of attacks/week in primary RP by 3.9 vs. 0.5 in secondary RP. Similar results were seen in severity of attacks for low dose vs. medium dose CCBs and primary vs. secondary RP. Low dose CCBs reduced the frequency of attacks by 3.3 per week vs. medium dose at 5.6. Crossover studies may have had carryover effects.

Conclusion: Primary RP is more responsive to CCBs than secondary from CTD especially SSc.

CCBs vs. placebo for frequency of attacks

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease involving the skin and visceral organs, most commonly the gastrointestinal tract and lungs. Interstitial lung disease (ILD) is present in up to 75% of cases and is the leading cause of mortality in SSc. Recent studies have shown a correlation between gastroesophageal reflux (GER) and SSc-ILD, however, doubt remains regarding the extent to which GER affects ILD. In this study we compared GER, esophageal dysmotility and lower esophageal sphincter (LES) tone in those with and without ILD, hypothesizing that the presence and extent of esophageal involvement would correlate with presence and extent of ILD.

Methods: A retrospective review identified thirty-nine patient cases of SSc that met diagnostic criteria as set by the American College of Rheumatology. Data were collected from high-resolution computed tomography (HRCT), pulmonary function testing (PFT), esophageal pH-Impedance testing (pH-I) and high-resolution esophageal manometry (HREM) to assess GER, esophageal dysmotility and lower esophageal sphincter tone in those with and without ILD. Significant GER was defined as DeMeester score > 14.72 on pH-I and Goh criteria[3] were used to stage ILD as limited or extensive.

Results: The ILD and non-ILD groups were similar in regards to sex, age, disease duration or modified Rodnan skin score. Patients with ILD had higher rates of significant GER at 75% vs. 33% of controls ($p = 0.01$). The ILD group also had higher rates of absent peristalsis at 100% vs. 59% ($p = 0.009$) and hypotensive LES at 92% vs. 70% ($p = 0.13$). In subgroup analysis of those with extensive ILD vs. limited ILD, 83% vs. 50% had significant GER ($p = 0.19$). These results are listed below in Table 1.

Table 1. Demographics and data of ILD (N=12) vs. non-ILD (N=27) groups and Extensive ILD[3] (N=6) vs. Limited ILD[3] groups (N=6). (mean ± SD)

Demographics	**ILD**	**Non-ILD**	
Age (years)	56.71 ± 11.95	58.50 ±12.72	*p* = 0.67
Sex (male)	17% (2 of 12)	11% (3 of 27)	*p* = 0.62
SSc duration[1] (years)	10.07 ± 8.89	5.58 ± 4.25	*p* = 0.11
MRSS	14.15 ± 12.81	21.00 ± 12.04	*p* = 0.14
Data			
Significant GER[2]	75 % (8 of 12)	33% (9 of 27)	*p* = 0.01
Average DeMeester	43.35 ± 38.92	29.66 ± 56.47	*p* = 0.45
Absent peristalsis	100% (12 of 12)	59% (16 of 27)	*p* = 0.009
Hypotensive LES	92% (11 of 12)	70% (19 of 27)	*p* = 0.13
	Extensive ILD[3]	**Limited ILD[3]**	
Significant GER[2]	83% (5 of 6)	50% (3 of 6)	*p* = 0.19
Average DeMeester	49.83 ± 43.74	36.87 ± 36.31	*p* = 0.59

Abbreviations: ILD = Interstitial lung disease**. SSc** = Systemic sclerosis. **MRSS** = Modified Rodnan Skin Score. **GER** = Gastroesophageal reflux. **LES** = Lower esophageal sphincter. **1:** Defined by first onset of non-Raynaud's phenomenon SSc feature. **2:** Determined as DeMeester score greater than 14.72 on pH-Impedance testing. **3:** As outlined by Goh N.S., et al. Interstitial lung disease in systemic sclerosis: a simple staging system. AJRCCM. 177, 1248-1254 (2008).

Conclusion: We report a statistically significant positive correlation between SSc-ILD and the presence of significant GER or esophageal dysmotility, with a trend toward extensive ILD in those with more severe GER. These findings support the notion that GER likely contributes to the development and progression of SSc-ILD, and that aggressive medical or surgical treatment of GER is warranted to decrease the morbidity and mortality associated with ILD.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

ABSTRACT

Background/Purpose:

Diffuse cutaneous systemic sclerosis (dcSSc) is associated with a poorer prognosis compared to limited cutaneous SSc (lcSSc), due to earlier and more

severe organ involvement (1). Early recognition of dcSSc patients is advantageous to apply timely screening or treatment. Possibly, differences between dcSSc and dcSSc in the early course of disease may be useful for early differentiation of subtypes. To determine whether the timing of both Raynaud's phenomenon (RP) and the first non-Raynaud (non-RP) symptom and the type of the first non-RP symptom, combined with disease specific auto-antibodies are predictive for the development of dcSSc or lcSSc.

Methods: The Nijmegen Systemic Sclerosis cohort consists of prospectively followed SSc patients. Demographic s, data about RP and the first non-RP symptom, and disease specific auto-antibodies were collected at first presentation, patients were followed up at least 1 year after diagnosis to confirm subtype of SSc. Univariate and multivariate logistic regression was used for predictive modeling. Performance was analyzed using discrimination and calibration, in an external cohort of 445 SSc patients from Madrid.

Results: A total of 553 SSc patients were included, 176 (31%) was classified as dcSSc. Time between RP and the first non-RP symptom differed between dcSSc and lcSSc (0.0 vs. 0.4 years; p<0.001). Puffy fingers (37%) and scleroderma (22%) were the most common first non-RP symptoms. The final prediction model had an area under the ROC curve of 0.79 (95% CI 0.75-0.83), a sensitivity of 87% and a specificity of 61%. External validation of this model showed a sensitivity of 78% (95% CI 0.74-0.83) and a specificity of 65%. A simple scoring method was created, with a cut point indicative for dcSSc.

Table 1. Prediction models

	Model 1		Model 2		Model 3		Score
	B	*p-value*	*B*	*p-value*	*B*	*p-value*	*value*
Male	0.9	<0.001			0.4	0.049	0.5
Time RP to non-RP < 3 months	0.9	<0.001			0.7	0.001	1.0
Scleroderma	0.7	0.001			0.6	0.014	1.0
ACA			-2.7	<0.001	-2.4	<0.001	-2.5
ATA			0.8	<0.001	0.7	0.004	1.0
Anti-RNP			-1.1	0.018	-1.1	0.023	-1.5
Constant	-1.8	<0.001	-0.54	<0.001	-1.2	<0.001	

Timing first non-Raynaud: the first non-Raynaud symptom occured less than three months after RP. Scleroderma: scleroderma skin changes of fingers, hands or face. ACA anti-centromere antibodies; ATA anti-topoisomerase-1 antibodies; anti-RNP anti-ribonucleoprotein-1 antibodies. *B* regression coefficient. Score value: rounded B coefficients

Conclusion: This study presents a simple scoring method to improve recognition of patients prone to development of dcSSc. The easy accessible items in the model will help clinicians to recognize patients prone to dcSSc, who are expected to have a poorer prognosis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiac involvement is a common subclinical feature of systemic sclerosis (SSc) and results from the widespread fibrosis observed during disease course. Fragmented QRS (fQRS) patterns are seen in myocardial interstitial fibrosis which is also the characteristic feature of SSc. The aim of this study is to evaluate the frequency of fQRS patterns in SSc patients and investigate its association with other clinical findings by using healthy and diseased controls.

Methods: 63 SSc patients who attended our outpatient clinic for their routine controls, who did not have cardiac symptoms and fulfilled 2013 ACR/EULAR classification criteria were enrolled in the study. Standard 12-lead EKG, pulmonary function tests, and echocardiography were performed in all participants. Fragmented QRS was described as the presence of an additional R wave or R or S wave bridging, or the presence of QRS fragmentation on two consecutive

derivations. Nailfold capillaroscopy and Rodnan skin scores were assessed by an experienced rheumatologist. Serologic and demographic data were obtained from patient records. We also enrolled 87 RA patients and 100 healthy controls as diseased and healthy controls, respectively.

Results: The frequency of QRS fragmentation was similar between SSc and RA patients (χ^2:4.994, p=0.105, df:2), and significantly higher than healthy controls (χ^2:4.382, p=0.036, df:1) (Table). Among 12 SSc patients with fQRS (19%), 5 had notched S waves, 5 had notched R waves, and 3 had rSr pattern. SSc patients had significantly higher rates of QT dispersion when compared to RA and healthy controls (p=0.006). Both SSc and RA patients had significantly higher P dispersion durations than healthy controls (p<0.0001). In univariate analysis, SSc patients with fQRS had longer disease duration, higher Rodnan skin scores, and pulmonary artery pressures, lower forced vital capacity and diffusion capacity, and higher rates of abnormal nailfold capillary patterns. In multivariate analysis, none of these parameters predicted the presence of fQRS.

Conclusion: The frequency of fQRS patterns was higher in our SSc and RA patients. However, this increase in fQRS frequency did not correlate with more severe disease involvement. Longitudinal studies are required to determine whether these fQRS patterns predict early myocardial fibrosis in SSc.

Table.

	SSc (n=63)	**RA (n=87)**	**Healthy Controls (n=100)**	P value
Age (years±SD)	47.3 ± 12.01	52.6 ± 13.1	45.97 ± 10.39	<0.0001
Disease duration (years)	8.22 ± 7.96	9.90 ±10.01		0.272
fQRS	19.0% (12/63)	11.49% (10/87)	8% (8/100)	0.105
QT dispersion	0.035 ± 0.015	0.029 ± 0.016	0.028 ± 0.011	0.006
P dispersion	0.024 ± 0.011	0.024 ± 0.016	0.017 ± 0.009	<0.0001

Are There Risk Factors for Calcinosis in Scleroderma?

Sneha Pai[1] and Vivien Hsu[2], [1]Rheumatology, Robert Wood Johnson Medical School Hospital, New Brunswick, NJ, [2]Medicine, Rutgers University, New Brunswick, NJ

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcinosis is the deposition of calcium hydroxyapatite in the soft tissues in patients with scleroderma spectrum disorders (SSc). Risk factors are unknown and there is no effective medical treatment.

Methods: In this IRB-approved study, we compared clinical characteristics of SSc (1) patients with (SSc-calcinosis) and without calcinosis (SSc-control) seen consecutively in the outpatient Rutgers-RWJ Scleroderma Program. Our analysis included demographic and SSc clinical characteristics, comorbidities (osteoporosis, hypertension, diabetes and thyroid disease), autoantibodies (ANA, Scleroderma and Anti-Centromere) and imaging results. Univariate and multivariate regression analyses were conducted to determine common factors associated with calcinosis.

Results: There were 215 SSc patients enrolled, 65 SSc-calcinosis (81.5% were females) and 150 SSc-controls (77% were females). SSc-calcinosis patients were older (p=0.026) with significantly longer disease duration (20 ± 10.5 years vs 12 ± 8 years, p<0.0001). Twenty nine (45%) SSc-calcinosis patients had diffuse scleroderma and 15 (23%) also had overlap with other rheumatic diseases (2, 3). In the univariate analysis (see Table 1), Caucasian females with limited SSc, advanced age, longer disease duration, presence of osteoporosis and the Anti-centromere antibody were all statistically significant. In the multivariate analysis, SSc-calcinosis patients had significantly less ischemic digital ulcer history, but , longer disease duration and osteoporosis (adjusted for age) remained independently associated with calcinosis.

Conclusion: Calcinosis is common in both limited and diffuse SSc. Those with longer disease duration and osteoporosis may be at higher risk to develop calcinosis. Larger studies are needed to confirm these observations.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Degenerative aortic stenosis (DAS) is the most common form of valvular heart disease associated with advancing age. DAS pathophysiology has not been clearly elucidated, but biomechanical factors, inflammation and atherosclerosis are believed to have an essential role in its development. In the last years we have detected an increased frequency of DAS in systemic sclerosis (SSc) patients, especially in those with pulmonary arterial hypertension (PAH), not found in other forms of PAH.

Objective: To analyze the prevalence and risk factors for DAS in SSc-PAH, compared to patients with other forms of PAH.

Methods: All patients with systemic sclerosis (SSc) followed in the Rheumatology Department between Jan 1990 and May 2015 were included in a prospective data base containing demographic and clinical data. Patients with PAH confirmed by right heart catheterization (RHC) older than 60 y were selected. As a control group, primary or thromboembolic PAH (IPAH/CTEPH) patients older than 60 were selected from the hospital PH registry. Presence of DAS was defined by transthoracic echocardiography, following current guidelines recommendations. Demographic data, cardiovascular risk factors (smoking, systemic arterial hypertension (HPT), dyslipemia, diabetes mellitus, obesity) and time of follow-up from PAH diagnosis were compared between groups. Descriptive statistics, univariate and multivariate logistic regression analysis were performed.

Results: Thirty three SSc-HAP (30w,3m, 71±6 y) and 85 IPAH/CTEPH (50w,35m, 77±6 y) were included. SSc-HAP patients were younger than IPAH/CTEPH (p<.0001), more frequently women (p=.001), less smokers (p=.04), and had more HTP (p<.0001). Time of follow-up from PAH diagnosis was shorter in SSc patients (4±4y vs 6±4y, p=.02). DAS was present in 6/24 SSc-HAP and in 1/75 IPAH/CTEPH (p=.001). Univariate analysis, showed association of DAS with SSc (p=.004) and HTP (p=.003). Multivariate analysis adjusted by age, sex and cardiovascular risk factors showed SSc as the only independent factor associated with DAS (p=.003) in our group.

Conclusion: Prevalence of degenerative aortic stenosis (DAS) is increased in SSc-PAH, compared with other forms of PAH, and this association is independent of age, sex and cardiovascular risk factors. Our results suggest than inflammation present in SSc-PAH and not in other forms of PAH could be a factor involved in the development of DAS in our patients.

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze the usefulness of the DETECT protocol (1) for the prediction of pulmonary hypertension (PH) and pulmonary arterial hypertension (PAH) in routine clinical practice in a systemic sclerosis (SSc) clinic.

Methods: All patients with SSc seen in the Rheumatology Department with a right heart catheterization (RHC) performed between Jan 1998 and May 2015 and with an echocardiography available within 3 months of the RHC were included. The two steps DETECT score was retrospectively obtained. Receiver Operating Characteristic (ROC) curve and area under the curve (AUC) were calculated for the ability of DETECT score to identify PH and PAH patients. Associations of clinical and RHC data, DETECT score, and disparity between PH and PAH diagnosis and DETECT score, were analysed.

Results: The study included 61patients (82% women, 75% limited cutaneous (lc) SSc, 57±15 y). Mean disease duration from first non-Raynaud symptom was 11±10 years. Pulmonary hypertension (PH) was confirmed by RHC in 50 (82%) patients, of those 38 (62%) had PAH. Other causes of PH were pulmonary fibrosis in 10 patients, with associated myocardiopathy in 3. Other 2 patients had non SSc associated valvulopathy. ROC curve showed an elevated discriminatory capacity of the DETECT score for prediction of PH and PAH, with AUC of 0.930 and 0.867 respectively. Disparity between PH in RHC and DETECT score was present in 10 patients. Only one patient, with severe hypertrophic cardiomyopathy and secondary PH had a negative DETECT score. The other 9 patients, 6 with cardiopathy (3 valvulopathy, 3 SSc related cardiomyopathy) had a positive DETECT score but did not present PH in RHC. Other 11 patients presented PH of other causes (1 non SSc valvulopathy, 9 PF, 4 also with SSc cardiomyopathy) Disparity between PH in RHC and DETECT score was more frequent in the presence of any cardiopathy (p<.002), absence of right axis deviation (p<.011) and higher tricuspid jet velocity (TJV)(p<.0001). Disparity between PAH diagnosis and DETECT score was more frequent in males (p=.011), with dcSSc (p=.031), PF (p<.0001) or cardiopathy (p<.0001), higher TJV (p<. 001), lower FVC (p<.001), higher uric acid (p=.007) and less frequent in the absence of right axis deviation (p=.0026) and in ACA+ patients (p=.003). The results were similar when only the 33 patients who would have been included in the DETECT study (disease duration higher than 3 years and DLCO lower than 60%) were analyzed. When the 28 patients who would not have been included in the DETECT study (less than 3 years of disease duration or DLCO higher than 60%), only the presence of dcSSc (p=.013) or cardiomyopathy (p=.013) were associated with disparity between PH in RHC and DETECT score.

Conclusion: The DETECT algorithm performs very well in a routine clinical setting for early detection of PAH and also of PH or other causes in SSc patients. Our results suggest that the algorithm would not perform as well in patients with any type of cardiopathy.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic sclerosis (SSc) display reductions in adipose tissue, particularly intradermal adipose tissue. There are currently no well-validated serum biomarkers in SSc, and adipokines represent an attractive biomarker because of their roles in inflammation, vascular function, and fibrosis. Previous studies have shown an association between circulating levels of the adipokine adiponectin and SSc, particularly in patients with diffuse cutaneous involvement (dcSSc). This study sought to determine if adipokine profiles were associated with dcSSc and measures of SSc organ involvement.

Methods: 82 dcSSc patients and 35 healthy controls were included in the study. All dcSSc patients underwent standard laboratory assessment, pulmonary function tests, and the modified Rodnan skin score (MRSS) within 6 months of the serum collection. 54 patients also had research quantitated echocardiograms within 6 months of serum collection. Serum leptin, adiponectin, and adipsin levels were measured by luminex assays in all patients and controls. Mann-Whitney U test and Kruskall-Wallis tests were used in binary between-group comparisons and testing of inter-group variability.

Results: Distributions of age, sex, and BMI in dcSSc patients and healthy controls were not different although a higher proportion of patients than controls were female (77% vs 58%, p=0.002). Among patients, the mean disease duration was 3.6 years, 29% were Scl70 antibody positive, 44% were RNA polymerase III antibody positive, the mean MRSS was 18.5, the mean predicted forced vital capacity (FVC) was 75%, the mean echo-measured pulmonary artery systolic pressure was 33 mmHg, and 17% had diastolic dysfunction.

Adiponectin (4.3 vs 5.8 µg/ml, p=0.04) and adipsin (7.1 vs 9.0 pg/ml, p=0.001) levels in dcSSc patients were significantly lower than controls. Low levels of adiponectin and adipsin were associated with decreased FVC (p=0.001, and p=0.02, respectively). Patients also had an increased leptin/adiponectin ratio compared to controls (0.31 vs 0.26, p=0.004) and this ratio was associated with diastolic dysfunction (p=0.04) and left ventricular ejection fraction (p=0.05). Leptin was not associated with disease, but among patients, there was an association between higher leptin levels and BMI (p=0.01) and diastolic dysfunction (p=0.01). None of the adipokine levels were significantly associated with antibody status, disease duration, MRSS, or pulmonary artery pressure.

Conclusion: This study affirms the association of decreased adiponectin with dcSSc and finds new associations between decreased serum adipsin and an increased leptin/adiponectin ratio with dcSSc. Adipokine profiles may be useful in assessing risk and monitoring cardiac and pulmonary manifestations of SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The literature supports an increased incidence of certain malignancies in patients with systemic sclerosis (SSc), including lung cancers. Predictors of lung cancer in SSc remain uncertain. We aim to identify potential independent predictors of lung cancer risk in SSc.

Methods:

Our analyses were based on data from the Canadian Scleroderma Research Group (CSRG) registry, an open cohort of 1560 patients with SSc, who were enrolled from 2004 and followed for a maximum of 11 years. Lung cancer cases occuring at any time after the baseline CSRG visit were identified based on physician reports at each annual follow-up visit. Time to lung cancer diagnosis was calculated from the onset of the first non-Raynaud symptoms, with left censoring to account for time between onset of first non-Raynauds symptoms and cohort entry. Demographic, clinical and serological characteristics of patients with and without lung cancer were compared. Cox proportional hazards models were used to estimate adjusted hazard ratios (HRs) with 95% confidence intervals (CIs), with the outcome of lung cancer adjusted for sex, age, race/ethnicity and the number of pack-years smoked.

Results:

Over the 5487.32 total person-years of follow-up, a total of 18 SSc patients were diagnosed with lung cancer (0.33 cancers per 100 person-years). Nine patients (9/27) were excluded from the cox analysis because of diagnosis of cancer prior to cohort entry. Patients with lung cancer were older at cohort entry (60.6 ± 11.4 standard deviation, SD vs. 55.5 ± 12.3 SD years), and more likely to have a past or current smoking history (88.9 vs. 59.1%), a higher prevalence of interstitial lung disease (65.4% vs. 30.2%), lower FVC (87% vs. 91.6% predicted) and more severe gas exchange abnormalities (DLCO 52.3% vs. 72.7% predicted). Male sex (HR, 3.13; 95% CI, 1.06-9.09), the presence of intersititial lung disease at cohort entry (HR, 2.96; 95% CI, 1.10-7.96) and smoking (HR, 6.17; 95% CI, 1.29- 29.50) were independently associated with an increased risk of lung cancer, after adjusting for age and race/ethnicity.

Conclusion:

Smoking history is an important predictor of lung cancer in SSc. Male sex and ILD are also associated with an increased risk of lung cancer in SSc, independent of smoking history.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Although numerous studies have reported different findings on subclinical and definite atherosclerosis (AS) in autoimmune rheumatic diseases, data in systemic sclerosis (SSc) are still challenging. The main objectives of our study were to assess surrogate biomarkers of subclinical AS as measured by carotid ultrasound and to evaluate potential relation with different cardiovascular risk factor in different settings of SSc.

Methods: We conducted a cross-sectional prospective study in 6 European EUSTAR (European Scleroderma Trials and Research) centers on 301 consecutive SSs patients enrolled in the SSAS (Early Accelerated Atherosclerosis in Systemic Sclerosis) cohort (88.3% women, 71.4% limited skin involvement SSc). Traditional (smoking, hypertension, diabetes, abnormal lipid pattern, familial history of cardiovascular disease) and non-traditional cardio-vascular risk factors (disease activity and severity, hsCRP, immune profile, glucocorticoids, synthetic immunosuppressives) as well as surrogate biomarkers for subclinical AS (carotid scanning measuring common carotid arteries intima-media thickness, cIMT, and plaques in common, internal and

external carotid) were collected in all patients as a single point data. Subgroup analysis based on skin extent and serology profile was further performed using SPSS.

Results: We reported an average of 0.65±0.14 mm (0.43-1.20) for cIMT, with a slight tendency of higher values in diffuse cutaneous (dc) SSc subgroup as compared with limited cutaneous (lc) SSc with no statistically significance ($p>0.05$). In addition we identified several statistically significant correlations between cIMT and age, systolic blood pressure, abnormal lipid profile (cholesterol, total chol/HDL-col, triglycerides), disease duration, activity and severity (EUSTAR score, MEDSGER severity scale) ($p<0.05$), maintained in subgroup analysis. However, no significant relation with the glucocorticoid and immunosuppressive intake was demonstrated. At least one carotid plaque causing no or non-significant stenosis was observed in up to one third of cases, particularly in dcSSc, with age, smoking and hypertension independently associated with AS plaques, as well as the cumulative steroid dose ($p<0.05$). Although subgroup analysis suggested a higher values for AS parameters and risk factors in dcSSc as well as anti-SCL and ACA-positive patients, data were not statistically significant ($p>0.05$). Actual results confirm interim analysis data.

Conclusion: SSc is associated with an increased risk of developing subclinical AS, although early AS is not a hallmark of the disease. Age, dyslipidemia and hypertension as well as disease duration, activity and severity are listed as potential risk factors for AS particularly in dcSSc subtype.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SSc-Ca is a poorly understood vascular complication of SSc that usually related to extreme constant pain and infection/amputation risk for persons living with SSc-Ca (PLWSC). No recognized treatment exists for SSc-Ca. There are no standardized measures of therapeutic responsiveness to assess potential medication impact on SSc-Ca. **Results** here reflect the next phases of PROM development.

Methods: Qualitative analysis from 31 PLWSC interviews revealed insight into self-management, quality of life, mental/physical function and natural history of SSc-Ca. Seventy-eight concepts were collectively reported by participants. Of these, 21 items related to any sphere of function or body structure were extracted by iterative analyses. Patient Research Partners (PRP) experienced in SSc research and questionnaires, assisted in formulating potential question stems. Nine PLWSC assisted in field-testing (FT) in face to face interviews and by quantitative response to potential PROM items using a 0-5 Likert rating ‘usefulness' of potential PROM item in indicating improvement/ worsening of SSc-Ca – ‘not applicable to me' was an option. Selection of preferred vocabulary, time reference, context and response scale (RS) format, length, verbiage and images were examined with all participants.

Results: Four PROM domains resulted: Quantity/Frequency (4 items), Pain/Sensation (5), Physical Function (4) and Psychological Impact (6). The MCQ pre-test version is indexed in table 1. Two of 4 quantity items were rated ≥4 by >80%, for which scoring are yet to be determined, quantile scales are considered. For scalable items, there was 100% selection of a 0-10 scale over various formats 0-5, 0-7, 0-9 scales, >90% selected Likert response over VAS, a reflective time reference of ‘2 weeks', and a reflective severity reference of ‘what is the worst degree' with 100% selection for single or brief word descriptors to cap scales i.e. ‘none' to ‘worst possible'. Thirteen of the 17 scaled items were rated ≥4 by >80% of participants and 100% 4 items. Two scaled questions pertaining strictly to Raynauds and digital ulcers may be incorporated as ‘stabilisation' questions scored separately for comparative reference. Only the 2 participants experiencing foot calcinosis rated the ‘walking' item highly; causing consideration for a test question combining upper and extremity physical function in order to create a uniformly weighted instrument.

Table 1. Items, domains, *=rating with >80% participants rating item with ≥4 (very to extremely useful)

Item	Domain	Items rating >4*	Scale
Geographical location	Reference only	*	None, report only
Hemisphere/season	Reference only	*	None, report only
Month	Reference only	*	None, report only
Number of calcinosis lesions (open or closed)	Quantity/Frequency	*	Undetermined
Number of calcinosis lesions you FEEL that you have	Quantity/Frequency	-	Undetermined
Number of digital ulcers	Quantity/Frequency	*	Undetermined/ comparative
Number of digital ulcers you think related to calcinosis	Quantity/Frequency	_	Undetermined
Stem to below items is: 'In the past TWO WEEKS, what is the worst degree that...'			
Raynaud's interfered with daily activities?	Reference	*	0-10 for comparative reference
Digital ulcers interfered with daily activities?	Reference	*	0-10 for comparative reference
Experienced pain from calcinosis?	Pain/Sensation	*	0-10 for scoring
You felt any areas of calcinosis getting tighter or having more pressure?	Pain/Sensation	*100%	0-10 for scoring
You felt any areas of calcinosis GROWING under your skin?	Pain/Sensation	*	0-10 for scoring
Your felt any areas of your calcinosis THROBBING?	Pain/Sensation	*	0-10 for scoring
Your calcinosis has been TENDER to TOUCH?	Pain/Sensation	*100%	0-10 for scoring
You felt the need to PROTECT areas of your calcinosis?	Psychological Impact	*100%	0-10 for scoring
You have been FEARFUL or WORRIED that any of the calcinosis areas are infected?	Psychological Impact	*	0-10 for scoring
You have been worried that a calcinoisis wound might not heal?	Psychological Impact	*100%	0-10 for scoring
Your calcinosis interfered with ability to care for self	Physical Function	*	0-10 for scoring
Your calcinosis interfered with your ability to use your hands?	Physical Function	*	0-10 for scoring
Your calcinosis interfered with walking?	Physical Function	(25%)	0-10 for scoring
Your calcinosis interfered with your ability to work (paid or unpaid)	Physical Function	*	0-10 for scoring
Your calcinosis made you feel down, depressed or hopeless?	Psychological Impact	-	0-10 for scoring
Your calcinosis interfered with your ability to enjoy and 'be there' for your friends and family?	Psychological Impact	-	0-10 for scoring
Your calcinosis interfered with your ability to enjoy recreational activities (hobbies, sports, etc)?	Psychological Impact	-	0-10 for scoring

Conclusion: This is the first known SSc-Ca PROM developed according to FDA Guidance. These items will undergo test/re-test validation with subsequent multi-centre prospective assessment of the surviving MCQ items beginning in July 2015. The MCQ is named in honor of Anne*Mawdsley*- an original research team member, founder of the Raynauds & Scleroderma Association UK, and a PLWSC who raised over £10 million for SSc research, education and advocacy in her lifetime.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic sclerosis (SSc) is characterised by fibrosis and vascular alterations, both of which account for the high morbidity and mortality of SSc. Although several therapies are in clinical use for the treatment of vascular manifestations, no targeted therapies are yet approved for the treatment of fibrosis.

Stimulators of the soluble guanylate cyclase (sGC) have recently been shown to inhibit transforming growth factor-β signaling. Here, we aimed to demonstrate that Riociguat, the drug candidate for clinical trials in systemic sclerosis (SSc), is effective in experimental fibrosis and to compare its efficacy

to that of phosphodiesterase V inhibitors that also increase the intracellular levels of cyclic guanosine monophosphate (cGMP).

Methods:

The antifibrotic effects of Riociguat and Sildenafil were compared in the tight-skin 1 model, in bleomycin-induced fibrosis and in a model of sclerodermatous chronic graft-versus-host-disease (cGvHD). Doses of 0.1 – 3 mg/kg twice a day for Riociguat and of 3 – 10 mg/kg twice a day for Sildenafil were used. In addition to the antifibrotic effects, the effects on cardiovascular parameters were measured in conscious mice implanted with telemetry devices.

Results:

Riociguat dose-dependently reduced skin thickening, myofibroblast differentiation and accumulation of collagen with potent antifibrotic effects at 1 and 3 mg/kg. Riociguat also ameliorated fibrosis of the gastrointestinal tract in the cGvHD model. The antifibrotic effects were associated with reduced phosphorylation of extracellular signal-regulated kinases and effects on cardiovascular parameters. Sildenafil at doses of 3 and 10 mg/kg exerted mild antifibrotic effects that were significantly less pronounced compared with 1 and 3 mg/kg Riociguat.

Conclusion:

These data demonstrated potent antifibrotic effects of Riociguat on experimental skin and organ fibrosis. These findings suggest a role for Riociguat for the treatment of fibrotic diseases, especially for the treatment of SSc. A phase II study with Riociguat in patients with diffuse cutaneous systemic sclerosis (dcSSc) is ongoing.

Stimulators of Soluble Guanylate Cyclase (sGC) Improve Wound Healing in the Tsk-1 Mouse Skin Fibrosis Mode

Peter Sandner[1,2], Christian Beyer[3], Joerg H. W. Distler[3] and Emanuel Haasbach[1], [1]Bayer HealthCare, Bayer Pharma AG, Wuppertal, Germany, [2]Institute of Pharmacology, Hannover Medical School, Hannover, Germany, [3]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic sclerosis (SSc) is a multisystem disorder characterized by thickening of the skin and distinctive involvement of multiple internal organs. In addition to skin fibrosis, SSc causes alterations of the microvasculature and severe peripheral vasculopathies, including perivascular fibrosis, Raynaud´s phenomena and the formation of digital ulcers (DU). Many drugs, proposed to have anti-fibrotic effects, inhibit wound healing and might thus further complicate the healing of ischemic ulcers in SSc.

Soluble guanylate cyclase (sGC) stimulators like Riociguat inhibit the release of collagen in fibrosis models, and improve acral perfusion due to their vasodilatory effects. Therefore we hypothesize that the vasodilatory effects of Riociguat may balance its inhibitory effects on collagen release in wound healing and may thus not negatively affect wound healing in SSc patients. The aim of these studies was to characterize the effects of the sGC stimulators BAY 63-2521 (Riociguat) and BAY 41-2272 on wound healing in the tsk-1 mouse skin fibrosis model.

Methods:

The tight-skin (tsk-1) mouse model of SSc was used to evaluate the effects of the sGC stimulators BAY 63-2521 (Riociguat) and BAY 41-2272 on wound closure in mice with skin fibrosis. During anesthesia, WT mice and tsk-1 mice were bilaterally punched, establishing a defined round wound with 4 mm in diameter. WT mice and tsk-1 mice were treated with either placebo, BAY 63-2521 or BAY 41-2272 and efficacy was measured by reduction of wound area, 3 days after punching.

Results:

In WT mice a reduction in wound size by 68% ± 2% was found after 3 days. Compared to WT mice, wound closure was significantly attenuated in tsk-1 mice with a reduction in wound size of only 52% ± 2 %. Treatment with the sGC stimulator BAY 63-2521 (Riociguat) had no influence on wound healing in WT mice. In tsk-1 mice both sGC stimulators caused a dose-dependent and significant improvement of wound healing. Wound sizes were reduced by 59% ± 4%, 65% ± 3% ($p < 0.05$) and 70% ± 2% ($p < 0.0001$) with 0.3, 1 or 3 mg/kg BAY 63-2521, respectively. And tsk-1 mice treated with 1 or 3 mg/kg BAY 41-2272 showed a reduction of 64% ± 3% and 73% ± 2% ($p < 0.0005$).

Conclusion:

These data imply that the sGC stimulators BAY 63-2521 (Riociguat) and BAY 41-2272 could become a efficacious treatment option for SSc-related vasculopathies, especially for prevention and healing of DU.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

PDE4 catalyses the breakdown of the second messengers cAMP and cGMP to modulate intracellular effects. PDE4 is mainly expressed in inflammatory cells, and its inhibition leads to reduced inflammatory cell activity. In this study, we examined the role of PDE4 inhibition in skin fibrosis and evaluated its potential as an anti-fibrotic target in systemic sclerosis (SSc).

Methods:

We studied the anti-fibrotic effects of the PDE4-specific inhibitor rolipram in the models of bleomycin-induced skin fibrosis and sclerodermatous chronic graft versus host disease (sclGvHD), reflecting local and systemic inflammatory fibrotic disease. To better understand the anti-fibrotic activity of PDE4 blockade, we treated fibroblasts and macrophages obtained from healthy individuals and patients suffering from diffuse cutaneous SSc with rolipram and investigated its effects on fibrosis relevant cytokines.

Results:

PDE4 inhibition had potent dose-dependent anti-fibrotic effects in bleomycin-induced skin fibrosis and sclGvHD. In bleomycin-induced skin fibrosis, the treatment with the higher dosis (5 mg/kg once daily) of rolipram reduced skin thickness by 36% ($p < 0.001$), hydroxyproline content by 42% ($p = 0.004$) and the number of α-SMA-positive myofibroblasts by 24% ($p < 0.001$). The anti-fibrotic activity of PDE4 inhibition was also prominent in sclGvHD in which we observed reductions of skin thickness by 95% ($p = 0.002$) and of activated myofibroblasts by 24% ($p = 0.002$). The hydroxyproline content showed an almost significant decrease upon PDE4 inhibition. In line with the mode of action of PDE4 blockade, we observed reduced leukocytes counts in bleomycin-induced skin fibrosis (by 37%; $p = 0,012$) and in sclGvHD (by 78%; $p = 0.005$).

Consistent with our in vivo findings and the fact that PDE4 is mainly expressed in inflammatory cells, we showed that fibroblasts were not the direct targets of the anti-fibrotic effects of PDE4 blockage. By contrast, PDE4 inhibition decreased the release of pro-fibrotic cytokines IL-6 and 13, TGF-β1 and β2, and fibronectin-1 from activated M2 macrophages obtained from healthy volunteers and SSc patients, resulting in reduced fibroblast activation and collagen release.

Conclusion:

PDE4 inhibition reduces the release of pro-fibrotic cytokines from M2 macrophages, which leads to decreased fibroblast activation and collagen release. Importantly, rolipram is a lead compound of the PDE4 inhibitor apremilast, which is approved for the treatment of psoriatic arthritis. Therefore, our preclinical findings might prompt the use of PDE4 inhibitors in clinical studies with patients suffering from SSc, in particular those with inflammation-driven fibrosis.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is an important complication of systemic sclerosis (SSc) that occurs in around 10% of cases. We have previously shown that an imbalance between TGFbeta and BMPRII signalling in the transgenic mouse strain TβRIIΔk-fib contributes to the development of PH following pulmonary endothelial injury. In this study, we have both prevented and treated PH in this mouse strain using macitentan, an endothelin receptor antagonist licensed to treat PAH in connective tissue disease.

Methods: SU5416 was administered to all TβRIIΔk-fib transgenic (TG) mice and littermate wildtype (WT) animals to induce endothelial injury with subsequent endoluminal proliferation and PH in transgenic mice only. Mice were treated daily with either macitentan or vehicle alone (n=8 each group) from either 2 days before or 8 days following SU5416 administration to assess prevention or treatment respectively. The development of PH in each group was assessed by histology and immunohistochemistry of vessel architecture, *in vivo* haemodynamic studies and RV mass index measurements following 3 weeks of treatment. Microarray analysis of right ventricular tissue was performed.

Results: : All TG mice developed a perivascular inflammatory infiltrate and smooth muscle layer hypertrophy after SU5416 administration. RV mass index was elevated in TG animals receiving vehicle compared to other groups. In particular co-administration of macitentan to TG animals treated with SU5416 resulted in normal RV mass (TG vehicle 0.29±0.007, TG macitentan at day -2 0.24±0.007, $p<0.05$). The increase in RV systolic pressure in TG animals treated with SU5416 was abrogated by macitentan (TG vehicle 28.8±3.2, TG+macitentan at day -2 22.0±2.9, TG+macitentan at day +8, 24.4±1.8, $p<0.05$) without any significant change in systemic arterial blood pressure. Explanted TG lung fibroblasts showed an increase in TGFbeta signalling and downregulation of BMPRII compared with WT littermates following macitentan treatment. Pulmonary arteriolar occlusion occurred in 21% of vessels in TG mice treated with vehicle with no occlusion in any other vessels. Gene expression analysis of whole right ventricle showed alterations in key genes known to be associated with cardiac muscle remodelling and failure. Figure 1 shows the cluster analysis of TG mice treated with SU5416 compared with those also treated with macitentan.

Conclusion: Macitentan prevents and treats the development of histological and haemodynamic PH in this mouse model of SSc. The pivotal role for perturbed endothelin activity in a model that replicates the imbalance in TGFbeta and BMPRII signalling seen in PAH-SSc lung is shown. It underpins the value of this model as a platform for experimental therapeutic studies.

Figure 1: Heatmap of genes downregulated by macitentan in right ventricles of SU5416 treated mice

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the relationship between vascular biomarkers reflecting the vascular injury and neoangiogenesis with nailfold capillaroscopic changes in systemic sclerosis (SSc).

Methods: Seventy-two SSc patients (66 female) fulfilling Leroy and Medsger classification criteria were evaluated, including clinical findings, nailfold videocapillaroscopy (NVC) was performed qualitatively (early, active and late scleroderma patterns) in all patients (Cutolo M, et al. J Rheumatol 2000). Serum samples of patients were collected for flow-cytometric analysis of CD40L, tPA, MCP-1, sE-selectin, IL-8, IL-6, VEGF, sP-selectin, TGF-β1 and VCAM levels (Bender MedSystems, Vienna, Austria) at the same time with NVC. **Results** were compared with Pearson chi-square / Fischer's, Mann Withney U ve Kruskal Wallis tests.

Results: The mean age of the patients was 44.9 and disease duration from the appearance of Raynaud's and non-Raynaud symptoms were 5.8±5.9 and 3.2±2.4 years. Of the patients 23 (%32) had diffuse and 49 (%68) limited cutaneous involvement, 15(%21) were anti-centromere(+) and 34(%47) were anti-Scl70(+).

When we compared with healthy subjects; tPA (p=0.02), MCP-1 (p=0.001), sE-selectin (p=0.008) and TGF-β1(p=0.001) levels were significantly higher, sP-selectin (p=0.011) ve IL-8(p=0.001) levels were lower in SSc patients (table-1)(figure-1). SSc patients grouped according to NVC patterns as 'early'(n=10), 'active'(n=37) and 'late'(n=25). Between groups according to NVC patterns, only sCD40L(pg/ml) levels were significantly lower in the 'late' group (p=0.043), higher in patients with limitted cutaneus involvement (p=0.01) and smoking history (n=32,%44) (p=0.033). The other markers were similar between NVC groups.

Table-1: Vascular Biomarkers in Healthy Controls, Systemic Sclerosis and NVC patterns

Biomarker Levels (mean ±SD)	Healthy Controls (n=20)	Systemic Sclerosis (n=72)	NVC Early (n=10)	NVC Active (n=37)	NVC Late (n=25)
sCD40L (pg/ml)	**24620±13051**	**27847±33315**	**27584±14694**	**34656±42750**	**17877±16911¶**
tPA (pg/ml)	2415±1279*	4036±6961	3173±1364	4835±9577	3199±1742
MCP-1 (pg/ml)	907±300**	1302±550	1096±433	1372±636	1282±437
sE-selectin (ng/ml)	205±78**	269±106	212±69	283±110	272±107
IL-8 (pg/ml)	49±73**	22±80	7±14	22±82	30±93
IL-6 (pg/ml)	0	0.6±2.8	17.9	13.3	9.3/2.8
VEGF (pg/ml)	704±363	776±591	996±904	745±570	733±464
sP-selectin (ng/ml)	364±137*	287±86	316±83	292±98	267±62
TGF-β1 (pg/ml)	2421±4785**	8277±8592	12115±9511	8128±9140	6964±7155
VCAM (pg/ml)	3231±1435	3945±1754	3951±1062	4091±1771	3727±1973

**p<0.05, **p<0.01 When healthy controls and sytemic sclerosis patients were compared with Mann-Whitney tests, ¶ p<0.05 When early, active and late NVC patterns in systemis sclerosis patients were compared with Kruskal-Wallis test*

Conclusion: There was lower sCD40L serum levels in patients with late NVC patterns, although the levels were similar to healthy controls in patients with early, active NVC patterns. CD40L may be a key molecule in the early/active phase of vascular involvement. Higher concentrations of sCD40L in patients with limited cutaneous disease and smoking history might be related to its role in vascular pathology. NVC is a useful method for investigating the vascular pathogenesis in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune-inflammatory cells participate together with endothelial cells and myofibroblasts in the tissue damage that characterizes fibrotic diseases, including systemic sclerosis (SSc) (1). Among immune cells, alternative activated macrophages (M2) are implicated in the pathogenesis of fibrosis through the production of profibrotic molecules (i.e. fibronectin and TGFβ), as observed in lung fibrosis and cancer (1). M2 are characterized by an increased expression of specific markers, such as CD206 (mannose receptor1) and scavenger receptors (CD204 and CD163) and we investigated their presence in the peripheral blood (PB) of SSc patients (pts) (1). Furthermore, since endothelin-1 (ET-1) has been shown to promote the fibrotic process in SSc, we tested possible *in vitro* effects of ET-1 in inducing the transition of cultured human macrophages into the M2 phenotype (2).

Methods: Twenty-six randomized female SSc pts (65±10 years), who fulfilled the new EULAR/ACR criteria (3), and ten healthy subjects (HS, 62±10 years) were enrolled into the study after EC approval and Informed Consent signed. Nailfold videocapillaroscopy (NVC) was performed to define the pattern of mycroangiopathy (4). PB from SSc pts and HS was analysed by flow cytometry investigating cells positive for CD204, CD206 and CD14 (monocyte/macrophage marker). Cultured human monocyte cells (THP1, $1x10^6$ cells/ml) were activated to macrophages with phorbol myristate acetate (25ng/ml) and then either untreated or treated with ET-1 (100mM) or IL4 (10ng/ml, as inducer of M2) for 72 hrs in growth medium at 5% of fetal bovine serum. Gene and protein expressions of CD204, CD206 and CD163 were investigated by qRT-PCR and immunocytochemistry. Statistical analysis was performed by Mann-Whitney non-parametric test.

Results: SSc pts showed a significant increased percentage of circulating $CD204^+/CD206^+$cells compared to HS ($p<0.05$). NVC analysis identified 13 SSc pts with an "early" pattern and 13 SSc pts with an "active/late" pattern of microangiopathy. Of note, the percentage of $CD204^+/CD206^+$cells was significantly increased exclusively in those SSc pts who showed an "early" pattern ($p<0.05$ vs. HS). The qRT-PCR showed that ET-1 induced a significant increase in the gene expression of CD204, CD206 and CD163 in cultured macrophages ($p<0.05$ vs. untreated cells for all M2 markers). In addition, immunocytochemistry showed that ET-1 further increased the protein expression of CD204 and induced the *de novo* synthesis of CD206 vs. untreated cells. These effects on gene and protein expressions of M2 markers were similar to those induced by treatment with IL4.

Conclusion: Increased percentage of cells with M2 phenotype seems evident in the PB of SSc pts and significantly in those characterized by an "early" NVC pattern of mycroangiopathy. The ability of ET-1 to induce the expression of M2 markers in human macrophages might suggest its possible action in driving the polarization of macrophages into a M2 phenotype.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

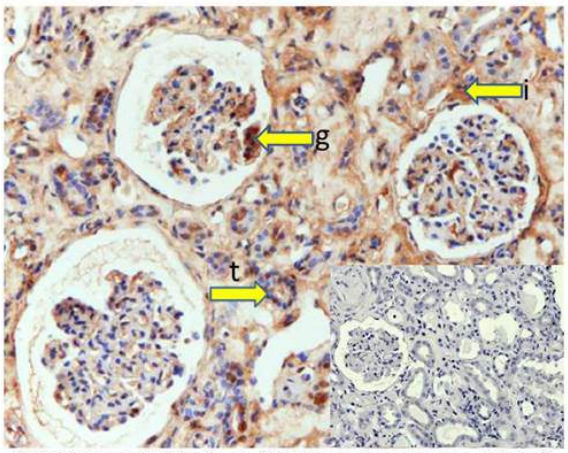
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Renal disease in scleroderma (SSc), including scleroderma renal crisis (SRC), remains a major clinical challenge. Previous studies showed up to 50% of SSc patients have renal involvement. We sought to gain insight into the pathogenesis of SSc kidney disease by examining markers of disease in serum, urine and renal biopsy specimens.

Methods: We collected urine and serum from 80 SSc patients, with or without renal involvement, for comparison with patients with kidney disease of other causes (n=10) and healthy controls (n=12). We performed multiplex analysis of candidate markers of disease activity or severity in SSc and renal injury: MCP-1, MCP-3, IL-6, IL-18, TNFalpha, and VEGF. In a further experiment we examined biopsies of patients with SRC using immunostaining for MCP-1.

Results: 40 SSC patients were in the subgroup with renal involvement ("SSc-CKD") defined by eGFR, urinalysis or a history of SRC. Serum MCP-1 was increased in SSc compared with controls, with SSc-CKD significantly lower than SSc without renal involvement. Mean serum MCP-1 was 132 pg/ml (95% CI 105-162) for SSc with normal renal function compared with 65 pg/ml in SSc-CKD (49-81, $p<0.001$ for this comparison). MCP-1 was not increased in renal disease of other causes (mean 47 pg/ml, 23-85) compared with controls (mean 53 pg/ml, 25-85, $p=0.848$). Conversely, urine MCP-1:creatinine ratio was higher in SSc-CKD (mean 64, 32-111) than in SSc with normal renal function (mean 23, 18-28, $p=0.046$). 20 SRC cases confirmed on histology were stained with IgG antibodies for MCP-1 (see figure). Expression was highest in the tubules, interstitium and vasculature. The number of typical "onion skin" arterial lesions seen was positively correlated with the level of MCP-1 expression in the vasculature overall ($p=0.048$).



MCP-1 immunostaining in an SRC biopsy demonstrates uptake in glomeruli (g), tubules (t) and interstitium (i).
Inset shows MCP-1 IgG control.

Conclusion: This is the first study to measure MCP-1 in the urine of SSc patients. Elevated urine MCP-1 in SSc with renal involvement was corroborated by immunohistochemistry demonstrating marked expression of the chemokine in the kidneys of affected patients. The identification of urine MCP-1 as a marker for local expression in the kidney may help define organ-specific effects of this chemokine, which has previously been reported to be increased in serum in association with pulmonary complications. Our findings support further investigation of urine concentrations of MCP-1 as a marker or mediator of renal disease in SSc.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by vasculopathy and fibrosis of the skin and various internal organs. Glycyrrhizin, a triterpenoid saponin glycoside from the roots of licorice, is a clinically approved for the treatment of chronic hepatic diseases and itching dermatitis and has also been used for Kampo in the Orient from ancient times. Importantly, glycyrrhizin has been shown to modulate the pathological processes of fibrosis, inflammation, and vasculopathy in some experimental disease models. Based on these backgrounds, we investigated the effect of glycyrrhizin on the three cardinal pathological features of SSc, including tissue fibrosis, inflammation, and vasculopathy, utilizing bleomycin (BLM)-treated mice recapitulating the fibrotic and inflammatory aspects of SSc and endothelial cell-specific *Fli1* knockout (*Fli1*ECKO) mice mimicking SSc vasculopathy.

Methods: Wild type C57BL/6 mice were subcutaneously injected with BLM or phosphate buffered saline (PBS) for the indicated period of time together with daily intraperitoneal injection of glycyrrhizin (30mg/kg) or PBS. mRNA and/or protein levels of target molecules were determined by quantitative reverse transcription-PCR, immunostaining, and/or immunoblotting in the skin samples and cultivated cells. Th1/Th2/Th17 polarization of immune response and macrophages polarization were evaluated by flow cytometry. Vascular permeability was evaluated by Evans blue dye injection in *Fli1*ECKO mice.

Results: Glycyrrhizin significantly ameliorated dermal thickness and collagen contents and decreased the number of myofibroblasts in BLM-treated mice. Consistent with these findings, glycyrrhizin significantly suppressed mRNA levels of the *Col1a1*, *Col1a2*, and *Col3a1* genes, while not those of the *Ctgf* and *Tgfb* genes in the lesional skin of BLM-treated mice. Since mRNA levels of the *Thbs1* gene, encoding thrombospondin 1 which activates latent form of TGF-B, were significantly reduced under the same condition, glycyrrhizin is likely to prevent the development of BLM-induced dermal fibrosis at least partially

by blocking autocrine TGF-B signaling in dermal fibroblasts. As for the expression profiles of cytokines and chemokines, the reduction of IL-4 and IL-6 was noted in the lesional skin of BLM-treated mice administered glycyrrhizin. Consistently, glycyrrhizin attenuated the BLM-dependent induction of Th2 cells in draining lymph nodes and spleen, partially contributing to the prevention of BLM-induced dermal fibrosis. Relevant to this finding, the expression levels of M2 macrophage markers were decreased by glycyrrhizin in the lesional skin of BLM-treated mice. With respect to the pathological vascular aspects, glycyrrhizin prevented the BLM-dependent induction of endothelial-to-mesenchymal transition, also associated with the reduction of dermal fibrosis by this agent, and improved the leaky vascular phenotype of *Fli1*ECKO mice.

Conclusion: Glycyrrhizin has potential preventive and/or therapeutic effects on the pathological dermal fibrosis and vasculopathy similar to SSc by acting on fibroblasts, endothelial cells, and immune cells.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lysyl oxidase (LOX) is a copper-dependent amine oxidase whose primary function is the covalent crosslinking of collagens in the extracellular matrix (ECM). Fibrosis is one of the important causes of morbidity and mortality in fibroproliferative disorders such as Systemic sclerosis (SSc). It was recently reported that LOX levels are increased in sera of SSc patients and associated with dermal fibrosis. In this study, we investigated the role of LOX in the pathophysiology of SSc.

Methods: LOX expression was examined in lung fibroblasts from 9 healthy controls (HC), 21 SSc patients, and 10 idiopathic pulmonary fibrosis (IPF) patients by real-time PCR. LOX was detected in HC and SSc lung tissues by immunohistochemistry. *In vivo*, LOX levels were quantified in lungs and sera of mice treated with bleomycin in combination with an endostatin-derived peptide that ameliorates fibrosis. LOX mRNA and activity levels were measured *in vivo* in lung tissues and serum samples using real-time PCR, ELISA and activity assay, respectively. *In vitro*, LOX mRNA levels and activity were measured in primary normal human lung fibroblasts treated with TGF-β and endostatin-derived peptide. To examine the effect of LOX, primary lung fibroblasts and lung tissues were treated with recombinant LOX with or without the inhibitor, β-aminopropionitrile (BAPN), and the expression levels of ECM (collagen and fibronectin) and pro-fibrotic factors (IL-6 and TGF-β) were measured by real-time PCR, ELISA, immunoblotting, and hydroxyproline assay.

Results: : LOX mRNA and protein levels were significantly increased in lung fibroblasts of SSc patients compared to HC and IPF patients. Interestingly, the highest levels of LOX were detected in SSc patients with pulmonary fibrosis. *In vivo*, bleomycin significantly induced LOX mRNA expression in lung tissues. Further, bleomycin increased LOX protein and activity levels in the circulation, suggesting that circulating LOX protein and activity levels paralleled levels in lung tissues. Amelioration of bleomycin-induced pulmonary fibrosis by endostatin peptide reduced LOX expression and activity. *In vitro*, TGF-β induced collagen and fibronectin production, LOX expression and activity. Endostatin peptide abrogated these effects. Recombinant LOX induced collagen and fibronectin production *in vitro* in lung fibroblasts and *ex vivo* in human lung tissues maintained in organ culture. The inhibition of LOX catalytic activity by BAPN failed to abrogate LOX-induced ECM production. LOX increased the production of IL-6 but not TGF-β *in vitro* and *ex vivo*.

Conclusion: LOX expression and activity correlated with fibrosis *ex vivo*, *in vitro*, and *in vivo*. LOX induced ECM production *in vitro* and *ex vivo* via upregulation of IL-6. Therefore, measuring LOX levels and activity serves as a novel biomarker for fibroproliferative disorders and for monitoring response to therapy, and LOX likely plays a direct pathogenic role in SSc independently of its crosslinking function.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Oncostatin M (OSM) is a pleiotropic member of the gp130/ IL-6 cytokine family, produced by a variety of immune cells, including macrophages, neutrophils and activated T cells. OSM signals through two receptors; gp130/ LIF low affinity receptor (LIFR) and gp130/ OSM high affinity receptor (OSMR); activating JAK/STAT, ERK1/2 and p38 MAPK pathways. The rationale for the role of OSM in Systemic Sclerosis (SSc) lies in that key disease components, i.e. inflammation, vascular dysregulation and fibrosis, complement the biological activities of the target.

Methods: Serum OSM levels were measured by custom OSM ELISA in 63 diffuse cutaneous (Dc) SSc and 18 age-matched healthy donors (HD). Transcriptomics data derived from published DcSSc skin biopsies were mined for OSM and known OSM-regulated genes. The presence of OSM, OSMR, and phospho(p)STAT3 in skin biopsies from HD (n=12), involved limited cutaneous (Lc)SSc (n=12), and involved and uninvolved DcSSc (n=13) patients was assessed by immunohistochemistry (IHC). Primary dermal fibroblasts isolated from HD or DcSSc skin were incubated with OSM at 2, 20 or 200ng/ml and cell associated collagen type I (Col-1), and connective tissue growth factor (CTGF) assessed by Western blot analysis at 24hrs and 72hrs.

Results: Serum OSM levels were significantly (P=0.004) increased in DcSSc patients compared with HDs (Table 1). OSM and OSM-regulated genes, including S100A9 and VCAM-1, were upregulated in the DcSSc skin. IHC analysis confirmed OSM, OSMR and pSTAT3 expression in skin biopsies from SSc patients and HDs, with a similar expression pattern in both. SSc skin biopsies exhibited significantly higher inflammatory cell infiltrates compared to HDs, and were strongly positive for OSM, OSMR and pSTAT3. Uninvolved DcSSc skin had significantly more OSM positive immune cell infiltrates and increased pSTAT3 expression than HDs, but not compared to involved DcSSc skin. Involved DcSSc skin exhibited significantly more pSTAT3 positive fibroblasts compared to HDs ($p<0.01$). The number of pSTAT3 positive immune cell infiltrates was further significantly enhanced in involved compared to uninvolved tissue. Increased numbers of positive OSM and pSTAT3 fibroblasts were present in involved versus uninvolved skin. OSM induced CTGF after 24hrs in 4/5 DcSSc dermal fibroblast cell lines tested. No induction above baseline was observed in the two HD dermal fibroblast cell lines. Following 72hrs stimulation, OSM increased Col-I in 5/7 HD fibroblast lines and 4/7 in the DcSSc fibroblast lines.

Conclusion: DcSSc patients have increased OSM serum levels and upregulated OSM and OSM-related genes in skin biopsies. In addition, OSM, OSMR and pSTAT3 are increased in DcSSc skin and dermal fibroblasts from these patients produce Col-I and CTGF in response to OSM. These data support targeted approaches to modulating OSM for the treatment of SSc.

Table 1: OSM levels in SSc serum

Serum OSM Levels	Numbers	Median (pg/ml)	Range
Healthy Donors	18	15	9.77-60pg/ml

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Localised scleroderma can occur in overlap with systemic sclerosis (SSc); nodular and keloidal morphea are rare subtypes but can be disfiguring and challenging to treat. Published literature suggests that keloid scarring and SSc skin share TGFbeta regulated gene expression alterations and that nodular and keloidal morphea represent a spectrum of keloid formation in SSc. This study aims to determine the pathological differences between these conditions and addresses the hypothesis that bone marrow derived fibroblast progenitors (fibrocytes) link them.

Methods: We examined a clinical database of 2200 patients with SSc defined by ACR/EULAR classification criteria to identify patients with a clinical or pathological diagnosis of localised scleroderma. The demographics, clinical features and laboratory parameters of those with nodular or keloidal morphea were examined in detail. We identified structural and biochemical differences by examining paired skin biopsies from these lesions and standard forearm biopsy site in SSc (n=6). Skin biopsies from patients with both early and established diffuse cutaneous SSc were used as controls.

Results: 49 patients (2.2%) had both localised scleroderma and SSc. Data from this group were broadly comparable to the SSc cohort, excepting a higher prevalence in females (female:male ratio 11:1). Three subtypes of localised scleroderma were prevalent: plaque morphea (67%); linear morphea (8.0%) and nodular or keloidal morphea (25%). Plaque and linear morphea patients had predominantly limited cutaneous SSc (88% and 75% respectively) while the majority of nodular/keloidal morphea patients had diffuse cutaneous SSc (92%, $p<0.001$). There were no clear serological associations. Keloid nodules were localised on the upper chest rather than areas of high SSc skin disease activity. Examination of histology in 5 of 12 patients with nodular/keloidal morphea identified acute inflammatory infiltrates, mucin deposition and altered distribution of collagen compared to SSc skin biopsies. Expression analysis of TGFbeta regulated genes identified multiple significant differences in expression within morphea lesions and at other sites in the same patients (figure 1). A significant increase in CCl2 expression may be associated with fibrocyte recruitment.

Conclusion: This is the largest analysis of localised scleroderma in SSc. There are associations of subtypes of localised scleroderma with subsets of SSc which are not related to serology. Paired examination of histological samples and gene expression of nodular or keloidal SSc skin identifies increased TGFbeta downstream activity compared with other biopsy sites suggesting that this mediator may be a key driver of localised scleroderma in SSc.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic sclerosis (SSc) is a systemic autoimmune disease that manifests as progressive fibrosis of the skin and internal organs. SSc is associated with the presence of several autoantibodies (aab) to intracellular targets, with the three most important SSc-specific being anti-centromere antibodies, anti-Scl70 antibodies and anti-RNA polymerase III antibodies, which occur in over 50% of SSc patients. Autoantibody specificities are strongly associated with pattern of organ involvement and disease outcome, making autoantibodies an essential tool in the clinical management of SSc. This highlights the need for additional specific and sensitive diagnostic and prognostic biomarkers in SSc. We have recently conducted high-content autoantibody profiling studies of SSc, systemic autoimmune diseases (AID), and healthy controls and found novel SSc-associated autoantibodies. These novel SSc-associated autoantibody biomarker candidates and their diagnostic value were evaluated by testing samples derived from 2 different SSc cohorts from the University Hospital Düsseldorf and the University Hospital Zurich.

Methods:

Three novel identified biomarker candidates, namely Lysine (K)-specific demethylase 6B (*KDM6B*), Protein Phosphatase Inhibitor 2 (PPP1R2) and Bicaudal Drosophila Homolog 2 (BICD2) were developed into research ELISA Kits using highly purified recombinant antigen and evaluated. Autoantibody specificities were analyzed using an independent and well characterized cohort consisting with sera of patients suffering from SSc (n=198), myositis (n=20), RA (n=20), SLE (n=40) and healthy blood donors (n=132). Assay threshold levels were calculated using a receiver operation characteristic analysis and set for specificities of 90% (KDM6B) and 95% for PPP1R2 and BICD2, respectively.

Results:

Using the respective cut off for the ELISA tests we were able to find autoantibody reactivity against BICD2 in 34 of 198 (17.2 %) of SSc patients and 11 of 212 (5.1%) of control samples, against PPP1R2 in 21 of 198 (10.6%) SSc and 11 of 212 controls (5.1%) and against KDM6B in 25 of 198 (12.6%) SSc patients and 21 of 212 controls (9.9%), respectively. Positive results of anti-BICD2 and anti-PPP1R2 aab co-migrated with anti-Centromere aab, but were also found in anti-Centromere and anti-Scl 70 negative samples. Interestingly, both anti- BICD2 and anti-PPP1R2 aab were found in SSc samples tested negative for anti-RNA Polymerase III auto-reactivity. Epitope mapping of KDM6B revealed reactivity against multiple epitopes of which reactivity against an EBNA-2 like polyproline-stretch in the sequence of the protein was strongest and could be blocked by polyproline. Interestingly, this reactivity occurred also in other AID samples.

Conclusion:

In this study we were able to confirm the diagnostic value and high specificity of the newly discovered autoantigens using ELISA. While PPP1R2 and BICD2 were found to be elevated in patients suffering from SSc, we found that autoantibodies against KDM6B are at least in part generated through a homology to EBNA-2 and could thus be a key target the suspected link between EBNA infection and autoimmune connective tissue diseases.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In this study we aimed to both agonistically investigate alterations in the serum proteome of patients with diffuse cutaneous systemic sclerosis (dcSSc), as well as to identify differentially expressed proteins that correlate with disease severity cross-sectionally and longitudinally. Our goal was to identify a combination of serum proteins that would provide a biological measure of the extent of skin disease and thus have the potential to be used as a pharmacodynamic (PD) biomarker.

Methods: Sera from a cohort of dcSSc patients (n=12) were analyzed by SOMAscan aptamer technology (1129 proteins) for differences in protein levels compared to healthy control sera (n=4), and for correlation of protein levels with the modified Rodnan skin score (MRSS). In a separate cohort of patients, ELISAs were used to validate these proteins in cross-sectional samples (n=31) and in longitudinal samples (n=17). Mixed models were used to define a potential model for a PD biomarker composed of multiple proteins. This longitudinal model was then validated in an independent cohort (n=20). Baseline demographics for each of the four groups are included below.

Results: Forty-three analytes were identified as both differentially regulated in dcSSc patients compared to healthy controls, as well as correlated with MRSS (FDR<0.01). Ten proteins were tested for validation in a separate, larger cohort. Eight out of the ten proteins tested successfully validated as

different from healthy controls and retained moderate cross-sectional correlations with the MRSS. These eight analytes were next examined for longitudinal change. The combination of two analytes (IL1R4 and Spondin-1) was used in a mixed model to best describe longitudinal change, and this model was successfully validated in an independent cohort.

Conclusion: In this study we have discovered that two novel proteins, not previously associated with SSc, are upregulated in patients and correlate with the extent of skin disease both cross-sectionally and longitudinally. Further, we have developed a PD biomarker based on levels of these proteins and show that this biomarker can be applied to assess changes in skin disease in dSSc patients over time, applicable to clinic or clinical trial settings.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent evidences suggest that cytosolic and mitochondrial reactive oxygen species (ROS), play pivotal roles in modulating TGF-β-induced profibrotic responses and are implicated in pathogenesis of systemic sclerosis (SSc). The NAD^+dependent deacetylase SIRT3 is a key regulator of mitochondrial ROS production. Honokiol activates cellular expression and activity of SIRT3. Here we investigated the anti-fibrotic potential of Honokiol and its synthetic analogues.

Methods: The expression of SIRT3 in fibroblasts was inquired in publicly-available microarray datasets and validated by real-time qPCR and Western analysis. The effects of SIRT3 activators on TGF-b-induced profibrotic responses were examined in neonatal foreskin fibroblasts, adult healthy and SSc dermal fibroblasts and normal human lung fibroblasts.

Results: Analysis of published microarray datasets revealed that TGF-β significantly suppresses SIRT3 mRNA expression in both healthy and SSc dermal fibroblasts. These results were validated by qPCR and Western analysis. Honokiol and its analogues stimulated SIRT3 expression and activation and

abrogated TGF-b-induced collagen, a-smooth muscle actin and fibronectin EDA expression in neonatal foreskin fibroblasts and adult normal human lung fibroblasts. These results were confirmed by real-time qPCR, Western analysis and immunofluorescence. Moreover, ectopic expression of SIRT3 in normal fibroblasts dose-dependently abrogated TGF-β-induced collagen synthesis and myofibroblast differentiation. The inhibitory effects of honokiol analogues were diminished in SIRT3-null mouse embryonic fibroblasts.

Conclusion: Our results provide evidence that mitochondrial ROS play a role in fibroblast activation, and SIRT3 is a novel target for anti-fibrotic therapy. Pharmacological modulation of the SIRT3 expression or activity might have a therapeutic potential in SSc.

Genetic Deletion of Toll-like Receptor 4 (Tlr4) Abrogates TGF-β1-Induced Endothelial-to-Mesenchymal Transition (EndoMT) in Murine Pulmonary Endothelial Cells

Peter J. Wermuth[1] and Sergio A. Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic sclerosis (SSc) is a systemic autoimmune disease of unknown etiology whose pathogenesis involves the regulation of a diverse range of molecular pathways. The clinical and pathologic manifestations of SSc arise from fibroproliferative vascular lesions; excessive and progressive synthesis and deposition of collagen and other extracellular matrix (ECM) macromolecules in the skin and various internal organs; and activation of innate and adaptive immunity. Several recent studies indicate a pivotal role for Toll-like receptor (TLR) signaling in the pathogenesis of several autoimmune diseases including SSc. Endothelial-to-mesenchymal transition (EndoMT) may play a role in generating activated myofibroblasts responsible for the uncontrolled ECM production in many fibrotic diseases, including SSc. Thus, the purpose of these studies was to compare the ability of TGF-β1 and the Tlr4 inducer lipopolysaccharide (LPS) to induce EndoMT in endothelial cells (EC) isolated from C57BL6/J or Tlr4 knockout (KO) mice.

Methods: Lung EC were isolated from three C57Bl/6J control and three TLR4 KO mice by enzymatic dissociation and were immumopurified employing sequential immunomagnetic selection with anti-CD31 and anti-CD102 antibodies followed by *in vitro* culture and treatment with either TGF-β1, LPS or TGF- β1 plus LPS. EndoMT was assessed by monitoring EC morphological changes and loss of EC molecular markers. Type I, type III and type IV collagens, α-SMA, fibronectin, and various mesenchymal cell- or EC-specific gene expression was assessed by semi-quantitative RT-PCR in triplicate for three replicates per cell line.

Results: Treatment of lung ECs isolated from C57BL6/J control mice with TGF-β1 induced the expected loss of EC morphology causing them to assume a more spindle fibroblast-like appearance. Remarkably, LPS alone caused similar morphologic EC changes. Both agents caused downregulation of the expression of EC-specific genes and concomitant upregulation of mesenchymal-specific genes, including Col1a1, Col3a1, fibronectin 1 (Fn1) and the Fn-Eda splice variant. In contrast, the EndoMT-associated changes in gene expression induced by TGF-β1 or LPS were completely abrogated in EC from Tlr4 KO mice compared to EC from C57BL6/J control or Tlr4 KO mice and their morphology was unaffected by treatment.

Conclusion: Signaling through Tlr4 can mediate EndoMT in murine lung EC since LPS treatment induces morphologic and gene expression changes associated with the EndoMT process. Further, Tlr4 signaling is required for TGF-β1 EndoMT in murine lung EC since genetic deletion of the Tlr4 gene results in the loss of TGF-β1-mediated EndoMT as shown by the rentention of characteristic EC morphology and failure to downregulate EC-specific genes or upregulate mesenchymal-specific genes. Thus, one mechanism by which Tlr4 signaling can assume a pathogenetic role in SSc-associated pulmonary fibrosis and other fibrotic diseases is by inducing the transdifferentiation of EC to profibrotic activated myofibroblasts. Thus, Tlr4 signaling inhibition in EC could represent an important and novel strategy to ameliorate the fibroproliferative process responsible for fibrotic diseases.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) patients exhibit alterations in innate and acquired cellular responses including an enhanced inflammatory response to toll like receptor (TLR) agonists that lead to increased production of Th1, Th2 and Th17-associated cytokines and may be associated to disease progression and phenotype. Pathogenic mechanisms of these alterations are not fully understood. The aim of this study was to determine the effect of TLR3, TLR4 and TLR9 stimulation of monocyte derived dendritic cells (Mo-DCs) in the production of Th17-related molecules in SSc patients.

Methods: We included 16 SSc patients (4 early limited cutaneous lcSSc, 4 late lcSSc, 4, early diffuse cutaneous dcSSc and 4 late dcSSc patients) and 5 non-related healthy controls. We isolated peripheral blood mononuclear cells (PBMCs) from 55 ml of venous blood. Mo-DCs were differentiated using a commercially available and validated medium containing GM-CSF and IL-4 from ex vivo purified CD14+ monocytes from ex-vivo purified CD14+ monocytes, stimulated with TLR agonists (LPS/TLR4, poly:IC/TLR3, CpG/TLR9) and co-cultured with PBMCs. Cytokine levels in supernatants were measured after 96 h, by Luminex. Differences were evaluated by Mann-Whitney U test.

Results: All SSc patients were females (mean age 48+/-14.4 years). We found significantly higher levels ($p<0.05$) of IL-6, IL-10, IL-17F, IL-22, IL-23, IL-31, IL-1b and IFN-g in LPS/TLR4-stimulated Mo-DCs-PBMC co-culture supernatants from lcSSc patients when compared to those from dcSSc patients. In contrast, Mo-DCs-PBMC co-cultures from dcSSc patients produced higher levels of IL-33 with and without TLR agonist stimulation than lcSSc patients' co-cultures. When SSc patients were categorized as early and late SSc we found that LPS/TLR4-stimulated Mo-DCs-PBMC co-cultures from early SSc patients produced higher amounts of IL-6, IL-10, IL-17F, IL-22, IFN-g and TNF-a when compared to those from late SSc patients. Interestingly, IL-33 secretion was increased with or without stimulation with TLR agonists ($p<0.05$) in Mo-DCs-PBMC co-cultures from late SSc in comparison with those from early SSc patients.

Conclusion: Mo-DCs stimulation with TLR4 ligand potently induces cytokines involved with the pro-inflammatory Th17 phenotype. TLR4-stimulated Mo-DCs from lcSSc patients produce higher amounts of Th17 (IL-6, IL-22 and IL-23) and Th1 cytokines. Early SSc patients exhibit enhanced Th17 responses. Mo-DCs from dcSSc and late SSc patients exhibit enhanced production of IL-33. Our findings suggest that functional variations in the production of Th17 cytokines by Mo-DCs are associated with different SSc clinical subsets and phases

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic Sclerosis (SSc) is an autoimmune disorder of the connective tissue due to excessive extracellular matrix deposition, leading to fibrosis of the skin and lung. The disease is characterized by the presence of elevated levels of IFN-regulated genes implicating plasmacytoid dendritic cells (PDC) and recently, it was shown that CXCL4 levels correlated with lung and skin fibrosis making this chemokine an interesting biomarker and highlighting the role of PDC in the disease pathogenesis (van Bon et al. NEJM, 2014). Our aim is to better understand what is controlling the activation of PDC in SSc patients.

Methods:

Blood was obtained from 33 SSc patients, 9 classified as early diffuse (edSSc), 15 as late diffuse SSc (ldSSc) and 9 limited (lSSc) and from 13 healthy volunteers (HV). PBMC were isolated and PDC purified either using BDCA4 magnetic beads (Miltenyi) or by cell sorting and purity was routinely >96%. The percentage of immune cells in total PBMC was analyzed by flow cytometry. Gene expression was analyzed in PBMC and PDC by Q-PCR. PDC were cultured for 24h and IFNa and CXCL4 secretion analyzed by ELISA.

Results:

First, we observed that the percentage of PDC and CD8+ T cells were significantly decreased in SSc PBMC as compared to HV (0.25%±0.02 vs 0.51% ±0.09; p=0.003 and 13%±0.8 vs 20%±0.9; p<0.001 respectively) while the percentage of monocytes and CD4+ T cells were significantly increased (24% ±1.9 vs 13.8%±2.4; p=0.002 and 42%±2.7 vs 33.2%±2.8; p=0.03 respectively). No difference was observed for B cell in SSc PBMC as compared to HV (6.1±0.9 vs 7.9±1.0; NS). As assessed by qPCR, we observed increased level of IFN-regulated genes in SSc patients, as genes such as ISG54, MxB or IP10 were significantly upregulated as compared to HV (in relative Ct to the housekeeping gene Ubiquitin: 641±85 vs 262±69; p=0.02, 421±35 vs 245±39; p=0.03 and 96±12 vs 52±8.5; p=0.005 respectively). Interestingly, this increase was observed in all the patients irrespective of subtypes. We also observed that purified PDC from SSc patients spontaneously secreted CXCL-4 (17,111±1,855 vs 6,903±662 pg/ml; p=0.001). We also noted a disruption in the expression pattern of TLRs in PDC which was confirmed by functional assay using specific agonists or inhibitors of the TLR pathway.

Conclusion:

Taken altogether our data suggests a role of PDC in the pathogenesis of SSc by the involvement of the TLR pathway. This could explain the abnormal activation state of these cells in patients as suggested by the presence of high IFN responses and the migration of PDC to the sites of inflammation such as the skin and lung of the patients.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare connective tissue disease characterized by fibroblasts activation, increased extra-cellular matrix synthesis associated with autoimmunity. However, the potential role of B lymphocytes in the pathophysiology of SSc is still poorly defined.

Methods: Phenotyping of peripheral blood B cell subpopulations, activating and inhibitory receptor expressions, Interleukin 6 (IL-6) and transforming growth factor-beta (TGF-β) productions were characterized by flow cytometry and multiplex assay. Fibroblasts proliferation rate and collagen production upon incubation with supernatants of B cell isolated from patients or healthy controls were assessed using XTT, BrdU, Ki67 immunofluorescence staining and collagen assay, respectively.

Results:

Eighty patients (including 18 males) with SSc fulfilling the ACR/EULAR criteria, (22 with diffuse SSc, dSSc and 58 with limited cutaneous SSc, lSSc), and 21 healthy controls (HC) were studied. The proportion of IgD^{-} $CD27^{+}$ B cells was significantly lower for SSc patients (Mean±SD 19.33%±11.85) as for HC (25.91%±11.25) (p=0.041). Increased proportions of B cells expressing CD69 (8.29%±7.77 vs 2.36%±2.29 p=0.0017) and CD95 (47.02%±19.82 vs 28.93%±11.21 (p=0.0004)) were found in both lSSc and dSSc. Compared to HC and lSSc, B lymphocytes from dSSc patients also presented with higher

proportions of cells positive for CD5 (24.12%±7.93 for dSSc vs 14.09%±6.58 for lSSc (p=0.0296) and 14.21%±5.34 for HC), CD86 (39.89%±22.11 for dSSc vs 17.72%±13.98 for lSSc (p=0.0007) and 11.68%±11.09 for HC), IL-6R (33.64%±23.12 for dSSc vs 17.91%±13.62 for lSSc (p<0.0001) and 12.08±8.68 for HC) and IL-21R (32.55%±20.19 for dSSc vs 5.76%±4.40 for lSSc (p<0.0001) and 5.93%±3.29 for HC). Intracellular flow cytometry identified a significantly increased proportion of IL-6 (24.53%±6.69 vs 13.23%±4.71 (p<0.0001)) and TGF-β (18.38%±10.22 vs 6.31%±3.62 (p<0.0001)) positive B lymphocytes in patients with SSc as compared to HC. Using multiplex assay, increased production of IL-6 (314.3 pg/ml±317.8 vs 6.10pg/ml±2.58 (p=0.0007)) and TGF-β (1020pg/ml±569 vs 163.8pg/ml±98.69 (p=0.0011)) altogether with reduced production of IL-10 (8.67pg/ml±6.22 vs 333.1pg/ml ±123.7 (p=0.0008)) were detected upon stimulation of B lymphocytes isolated from SSc patients compared to HC. Fibroblast proliferation and collagen production were also significantly increased in the presence of B cell supernatant from SSc patients as compared to HC.

Conclusion: We characterized a differential activation of peripheral B cells of patients exhibiting dSSc with an upregulation of CD5, CD86, IL-6R and IL-21R compare to lSSc patients and HC. B lymphocytes of SSc patients also expressed more CD69 and CD95 compare to HC. Peripheral B lymphocytes secreted both interleukin 6 and transforming growth factor-beta, and activated fibroblasts in patients with SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: During the last years, there was a shift in systemic sclerosis (SSc)-related causes of death, indicating cardiac involvement and inflammatory dilated cardiomyopathy (iDCM) as one of the major cause of death in these patients. Insight from iDCM models revealed that bone marrow derived cells serve as a main source of pathological myofibroblasts. Nevertheless, despite the high unmet clinical need, so far little is known about the etiology of iDCM and the mechanisms leading to heart dysfunction in SSc patients. We hypothesized that the inflammatory myeloid cell compartment might be involved in post-inflammatory cellular remodelling in SSc patients.

Methods: $CD14^+$ monocytes, isolated from peripheral blood of SSc patients and healthy subjects, were differentiated towards a myofibroblast phenotype by 7-day stimulation with TGF-β1/IL-1β/IL-4/IL-10/IL-13 with or without inhibitors of TGF-β receptor I, Smad2/3 or canonical Wnt signalling. We established a co-culture system allowing co-culture of monocytes with human fibroblasts or activated human T cells in order to analyse the role of direct and indirect cell-to-cell-interaction on differentiation potentials. Moreover, an endomyocardial biopsy from a SSc patient, who underwent heart transplantation, was screened with immunohistochemistry.

Results: $CD14^+$ monocytes up-regulated myofibroblast markers (αSMA, fibronectin, collagen I), the transcription factor Fra-2 and different Wnts in cytokine-enriched monoculture. In direct co-cultures: a) with fibroblasts (in the presence of TGF-β1, n=7) or b) with T cells stimulated with IL-2/IL-7/IL-15/IL-21 (activation of common γ-chain receptor, n=3), or c) with CD3/CD28 activated T-cells (activation of T cell receptor, n=2) monocytes differentiated towards a myofibroblast phenotype. Interestingly, activation of the common γ-chain receptor in T cells up-regulated mostly αSMA gene expression, while activation of T cell receptor up-regulated αSMA, fibronectin and collagen I gene expression in the fibroblasts. Inhibition of TGF-β receptor I or the canonical Smad2/3-dependent pathway, and inactivation of extracellular Wnt or TCF/β-catenin-mediated transcription significantly abrogated the myofibroblast differentiation of $CD14^+$ monocytes. Moreover, human myocardium of a SSc patient with iDCM revealed the presence of $CD14^+/Fra\text{-}2^+$ monocyte-derived fibroblast-like cells in the fibrotic myocardium.

Conclusion: We showed here that TGF-β/Wnt/Fra-2 signalling axis mediates the differentiation of circulating monocytes towards a myofibroblast phenotype. Therefore, these cells might be considered as a potential cellular source for pathological myofibroblasts in SSc.

Session Date: Monday, November 9, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze Stat1 and phosphorylated Stat1, the interleukin-6 (IL-6) receptor-Stat3 axis, and membrane bound tumor necrosis factor (mTNF) and TNF receptors 1 and 2 (CD120a and CD120b), in patients with SSc.

Methods: We prepared PBMC of 30 patients with SSc and 42 healthy individuals (HC). CRP, ESR, modified Rodnan skin score (mRSS) and the EULAR activity score were recorded. For determining the percentages of CD120a, CD120b, CD126 and CD130 positive cells, PBMC were directly stained with PE-labelled or control antibodies. Ex vivo and after 15 minutes of incubation with or without recombinant human interferon-γ (IFN γ) or interleukin-6 (IL-6), PBMC were fixed with formaldehyde (2%), permeabilized with methanol (80%), and stained with PE-labelled control antibodies or antibodies to Stat1 or phosphorylated Stat1 (pStat1) or pStat3, respectively. Stained cells were immediately analyzed on a Becton Dickinson FACSCalibur fluorocytometer, independently gating for lymphocytes and monocytes. As a semiquantitative measure of (p)Stat contents, mean fluorescence intensity (mfi) was used. Data were expressed as mean±SD.

Results: Both chains of the IL-6 receptor, CD126 and CD130, were expressed on decreased percentages of SSc lymphocytes (50.2±18.1% vs. 60.0±7.9%, p=0.0086, and 52.6±15.1% vs. 59.6±9.5%, p=0.0212, respectively). This translated into a diminished increase of pStat3 in SSc lymphocytes upon IL-6 stimulation (Δmfi 17.2±12.1 vs. 20.5±9.3, p=0.03, and 35.8±17.1 vs. 54.1±25.0, p=0.0129, respectively). In contrast, the increase in pStat1 upon IFNγ stimulation was more pronounced in SSc lymphocytes (Δmfi 10.5±11.2 vs. 4.8±3.7, p=0.0035), albeit their increased Stat1 contents (mfi 51.2±27.4 vs. 16.7±9.1, p < 0.0001) suggested ongoing activity of the IFN system in SSc. While the percentages of IL-6R positive monocytes were not significantly different from those of HC, their IL-6 induced increase in pStat3 was nevertheless decreased (Δmfi 35.8±17.1 vs. 54.1±25.0, p=0.0129), and their IFNγ induced increase in pStat1 showed a trend towards being higher than normal (Δmfi 60.9±53.3 vs. 44.9±24.9, p=0.32). The percentage of mTNF positive lymphocytes was slightly decreased (2.3±0.8% vs. 3.2±1.8%, p = 0.0357), while mTNF monocytes were increased (68.1±30.0% vs. 24.3±24.4%, p<0.0001). CD120b was increased on both SSc lymphocytes (67.2±18.6 vs. 58.4±11.9, p=0.0017) and monocytes (93.4±9.0% vs. 75.4±19.9%, p < 0,001), whereas CD120a was increased on SSc monocytes (31.3±21.5% vs. 13.6±9.7%, p = 0.001) only.

Conclusion: Our results suggest upregulation of the IFN-Stat1 and the IL-6-Stat3 axis in SSc, with a shift towards increased Stat1 phosphorylation. In addition, increased TNF and TNF receptors were found on SSc monocytes.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-35 (IL-35) is the most recent addition to the IL-12 family, which also comprises IL-12, IL-23 and IL-27. IL-35 consists of two chains, p35/IL-12a and EBI3/IL-27b, and exerts immunomodulatory activities in experimental and human autoimmune inflammatory conditions. Its potential role has been proposed in the pathogenesis of rheumatoid arthritis, sarcoidosis and systemic lupus erythematosus. However, its role in systemic sclerosis (SSc) has not been studied to date. The aim of this study was to assess IL-35 expression in the skin, dermal fibroblasts and circulation of SSc patients and characterize its potential association with SSc-related features.

Methods: Expression of IL-35 in the skin and dermal fibroblasts was quantified by qPCR, immunohistochemistry and immunofluorescence. Serum levels of IL-35 were analyzed by high sensitivity ELISA (Life Sciences, Hubei, PRC), and routine laboratory parameters such as CRP (by turbidimetry), ANA (by immunofluorescence) and autoantibodies of the ENA complex (by immunoblot) were measured in 40 SSc patients who met the EULAR/ACR 2013 criteria for SSc. Serum IL-35 was also determined in 40 healthy volunteers matched by age and sex.

Results: IL-35 chains EBI3 and p35 were overexpressed in the fibrotic skin of patients with SSc compared to that of healthy controls on both mRNA ($p<0.05$, $p<0.05$) and protein level ($p<0.001$, $p<0.001$). In fibrotic SSc skin, in contrast to non-fibrotic healthy skin, prominent staining for both IL-35 subunits was detected in dermal fibroblasts, myofibroblasts and perivascular inflammatory cells. Overexpression of IL-35 persisted in cultured dermal fibroblasts from SSc patients which maintained an increased mRNA ($p<0.05$, $p<0.05$) and protein level of both IL-35 subunits and released increased levels of IL-35 into supernatants ($p<0.05$) compared to healthy dermal fibroblasts. Stimulation with the main pro-fibrotic cytokine, TGF-β, increased the mRNA ($p<0.05$, $p<0.05$) and protein levels of both IL-35 chains, and enhanced the release of IL-35 into the supernatants ($p<0.05$), as well. Incubation with recombinant IL-35 induced an activated phenotype in resting fibroblasts (increased the expression of α-smooth muscle actin and stress fibers) and enhanced the release of collagen in a dose-dependent manner. IL-35 serum levels were increased in patients with SSc compared to healthy controls (median(IQR): 83.9 (45.1–146.1) vs. 36.2 (17.2–49.4) pg/ml, $p<0.0001$). Furthermore, serum IL-35 negatively correlated with disease duration ($p<0.01$, $r=-0.434$), and was increased in patients with early SSc pattern on capillaroscopy assessment compared to those with active and late SSc patterns ($p<0.05$, $p<0.05$). No correlations of serum IL-35 with other SSc-related features were observed.

Conclusion:

The present study demonstrates an overexpression of IL-35 in the skin, dermal fibroblasts and serum of SSc patients. TGF-β induces IL-35, which in turn activates resting fibroblasts and enhances the release of collagen thereby contributing to aberrant TGF-β signaling in SSc. Elevated serum IL-35 is associated with early, inflammatory stages of SSc.

Wnt5a Activates Wnt/PCP-Signaling to Promote Fibroblast Activation and Fibrosis

Chih-Wei Chen[1], Neng-Yu Lin[1], Yun Zhang[1], Jingang Huang[1], Katrin Palumbo-Zerr[1], Alexandra Schambony[2], Christian Beyer[1], Georg Schett[1] and Jeorg HW Distler[1], [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Biology, Development Biology, University of Erlangen-Nuremberg, Erlangen, Germany

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: While canonical Wnt/beta-catenin signaling has been identified as a core pathway of fibrosis in SSc, non-canonical Wnt signaling pathways have not yet been analyzed. A subset of Wnt proteins can activate non-canonical Wnt pathways that are independent of beta-catenin by binding to different cell surface receptors to modulate cellular functions such as proliferation and differentiation.

In this study we aimed to characterize the role of Wnt5a in fibrotic diseases.

Methods: The expression of non-canonical Wnt ligands was analyzed by qPCR, IF and Western blot in patients with SSc, IPF and healthy controls as well as in experimental fibrosis. The effect of fibroblast-specific (col1a2; CreER) as ubiquitous (ubiquitin; CreER) knockout of Wnt5a was evaluated in bleomycin-induced fibrosis and in experimental cGvHD. Wnt5a-induced signaling was analyzed in vitro and in vivo using small molecule inhibitors, siRNA mediated knockdown, Western blots and reporter assays.

Results: The mRNA and protein levels of Wnt5a, but not other non-canonical Wnt ligands, were increased in skin and lungs of patients with SSc and IPF as compared to healthy volunteers. Wnt5a was also upregulated in murine models of fibrosis. Co-staining with cell-type specific markers identified fibroblasts as a major cellular source of Wnt5a in fibrotic diseases. Wnt5a induced myofibroblast differentiation and collagen release *in vitro* and induced pulmonary and dermal fibrosis *in vivo*. In contrast, inducible fibroblast-specific knockout of Wnt5a ameliorated bleomycin-induced fibrosis and experimental cGvHD. The effects of fibroblast-specific knockout were comparable to those in mice with inducible ubiquitous knockout. The pro-fibrotic effects of Wnt5a were independent of Wnt/beta-catenin and Wnt/Calcium signaling, but were mediated by Wnt/PCP signaling with phosphorylation of JNK and cJun. Consistently, pharmacologic or genetic inactivation of JNK or cJun abrogated the pro-fibrotic effects of Wnt5a *in vitro* and *in vivo*. The stimulatory effects of Wnt5a on fibroblasts were biphasic. Western Blots and SBE-reporter assays demonstrated that, at early timepoints, Wnt5a activated JNK, which cross-phosphorylated Smad3 to stimulate the expression of TGFbeta/Smad-dependent genes. This early effect was completely blocked by inactivation of JNK. At later timepoints, Wnt5a induced the expression of TGFbeta to upregulated pro-fibrotic genes. In contrast to the early effects, the delayed effects of Wnt5a were blocked by neutralization of TGFbeta or by TGFbetaRI inhibition.

Conclusion: We characterize Wnt5a as a novel mediator of fibroblast activation in fibrotic diseases. Wnt5a is upregulated in SSc and IPF and induces fibroblast activation and tissue fibrosis. The pro-fibrotic effects of Wnt5a are independent of canonical Wnt signaling and are mediated by JNK-induced activation of Smad3 at early time points and transcriptional upregulation of TGFbeta at later time points.

Salinomycin Induces Potent Suppression of TGF-β1-Mediated Expression of Profibrotic Genes in Cultured Dermal Fibroblasts from Normal Donors and from Donors with Systemic Sclerosis (SSc): A Novel Anti-Fibrotic Treatment for Tissue Fibrosis in SSc

Peter J. Wermuth[1] and Sergio A. Jimenez[2], [1]Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA, [2]Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center,Thomas Jefferson University, Philadelphia, PA

Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Activated myofibroblasts are the primary mediators of the excessive synthesis and deposition of collagens and other extracellular matrix (ECM) macromolecules during the pathogenesis of fibrotic diseases including Systemic Sclerosis (SSc). TGF-β signaling plays a pivotal role in the differentiation and activation of myofibrolasts. Salinomycin, a polyether ionophore antibiotic isolated from *Streptomyces albus* has been shown to cause a selective inhibition of cancer stem cells. Recently, salinomycin has been reported to possess potent anti-myofibroblast properties, specifically targeting TGF-β-mediated myofibroblast activation and to inhibit TGF-β-induced collagen production, cell proliferation, contraction and migration in cultured primary normal human fibroblasts. The purpose of these studies was to perform a dose-response analysis of the effect of salinomycin on the expression of profibrotic genes in cultured dermal fibroblasts isolated from normal donors and donors with SSc to evaluate whether the reported inhibition of the

profibrotic consequences of TGF-β signaling will produce an effect on dermal fibroblasts isolated from SSc donors.

Methods: Normal and SSc dermal fibroblasts were cultured in the presence of 100, 250 or 500 nM salinomycin alone or in combination with 10 ng/mL TGF-β1. After 72 hours, total RNA was isolated and the effects of salinomycin on the expression of profibrotic genes were assess by semiquantitative RT-PCR in triplicate on three replicates per normal and SSc cell line. Levels of ECM proteins in culture media and levels of α-SMA in cell lysates were evaluated by Western blot.

Results: Treatment of both cultured normal and SSc dermal fibroblasts with salinomycin induced a potent concentration-dependent decrease in the expression of several genes associated with fibrosis, including type I and type III collagens (COL1A1 and COL3A1), fibronectin 1 (FN1) and the FN-EDA splice variant as well as decreased expression of the myofibroblast marker α-SMA. A similar effect was observed in TGF-β-treated normal and SSc fibroblasts. Remarkably, treatment of SSc fibroblasts with salinomycin caused a potent downregulation of the elevated levels of profibrotic gene transcripts in these cells.

Conclusion: The observed effects of salinomycin on cultured dermal fibroblasts from normal and SSc donors are consistent with its reported ability to suppress TGF-β-mediated myofibroblast differentiation and activation. Intriguingly, the ability of salinomycin to greatly reduce expression of COL1A1, COL3A1, FN1, FN-EDA and α-SMA was also seen in non-TGF-β treated cells from SSc donors, thus strongly supporting the concept that salinomycin may represent a potent and novel antifibrotic agent for the treatment of SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Nearly all patients with Systemic sclerosis (SSc) suffer from vascular dysfunction as illustrated by the uniform presence of Raynaud's phenomena. The role of vascular smooth muscle cells (VSMCs) in the development of vascular dysfunction is still unknown. In this study, we isolated VSMCs from skin biopsy, and we examined their functional phenotype.

Methods: We obtained 4 mm punch-skin-biopsy from 3 patients with diffuse cutaneous SSc and 3 matched healthy controls. Skin specimens were treated with a mixture of proteases, then after digestion we plated cells in culture media and harvested the primary cell culture after 10 days. VSMCs were isolated by magnetic microbeads using cell surface markers. First, we depleted total cells from CD31+ cells, followed by positive selection for CD146 + cells. To confirm the identity of this cell population (CD31- CD146+), we performed immunoflorocytometry staining for smooth muscle myosin heavy chain 11 (MYH11), Desmin and NG2. We investigated cell proliferation by using Bromodeoxyuridine (BrdU) assay, and cell viability in normal culture conditions as well as low serum conditions using MTT assay.

Results: Out of the total cells obtained from primary cell culture, 15% were CD31- CD146 + (VSMCs). The majority of cells in this population stained for smooth muscle MYH11 (89.1%), in addition to Desmin and NG2, while the CD31+ and the fibroblast cell populations did not. This staining pattern differentiates VSMCs from pericytes. Next, we evaluated cell proliferation using BrdU, and we demonstrated uptake of BrdU by 19% of the control-VSMCs compared to 34% of SSc-VSMCs (P= 0.0031). The MTT assay showed increase cell proliferation of SSc-VSMCs compared to control-VSMCs (0.44 and 0.25, respectively. P= 7.38E-08). Under serum starvation conditions, SSc-VSMCs exhibited more proliferation capacity than control-VSMCs (0.30 and 0.21, respectively. P= 5.73E-13). Also, we performed immunoflorocytometry staining for B-catenin and we demonstrate a cytoplasmic to nuclear translocation of B-catenin in SSc-VSMCs but not in control-VSMCs. This finding may imply potential involvement of B-catenin in the induction of VSMCs activation in SSc.

Conclusion: This is the first report of the successful isolation and initial characterization of SSc-VSMCs. We believe that increased proliferation of SSc-VSMCs in association with resistance to apoptosis may greatly impact the vascular lesion in SSc. Further studies are warranted to fully understand the trigger and maintenance of the abnormal SSc-VSMCs phenotype.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), the mechanisms initiating immune dysregulation leading to joint damage are incompletely understood. Previous studies show that large CD8+ T cell lymphocyte clones occur commonly in RA. We hypothesized that in some RA patients, lymphocytes may have acquired somatic mutations resulting in clonal expansions and abnormal immune reactivity.

Methods: We used flow cytometry and deep T-cell receptor sequencing to assess T-cell clonality in a cohort of 82 newly diagnosed RA patients. These patients fulfilled the ACR/EULAR 2010 criteria for RA. Further, acquired genetic changes either in sorted CD8+ or CD4+ T cells were investigated with a next-generation sequencing panel consisting of 986 known immunoregulatory genes. Mutations discovered with this panel were validated and screened from other patients with the deep Amplicon sequencing method.

Results: Significant (>10%) clonal CD8+ T-cell expansions were present in 51% (34/67) of RA patient peripheral blood samples. In two out of 15 patients (13%) sequenced with the next-generation immunogene panel, somatic, high-confidence missense mutations were discovered. Patient 1 had mutations in *PADI4* (peptidyl arginine deiminase, type IV), *PROM1* (prominin 1) and *C5* (complement component 5) genes, and patient 2 in *IRF1* (interferon regulatory factor 1), *SLAMF6* (SLAM family member 6) and *SEC14L3* (SEC14-like 3 (S. cerevisiae)) genes. These mutations were restricted to the expanded CD8+ T-cell clones and they persisted during immunosuppressive therapy. Functionally, mutated *PADI4* led to decreased expression and enzymatic activity of the PADI4, whereas mutated *IRF1* resulted in increased *STAT1* expression. However, no recurrent mutations in these genes were found in other patients.

Conclusion: Clonal CD8+ T-cell expansions were observed in a significant proportion of RA patients, and in two patients expanded CD8+ T-cell clones harbored acquired somatic mutations in genes (*PADI4* and *IRF1*) known to be causally relevant for the pathogenesis of RA. The mutations in these two genes changed the protein function. Further studies utilizing unbiased sequencing assays are needed to validate the role of somatic mutations as inducers of T-cell activation and autoimmunity in RA.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Specific microorganisms in the gut microbiome may have a pathogenic role in rheumatoid arthritis (RA). Recently, Scher et al. showed that *Prevotella copri*, an intestinal microbe, was over-expanded in stool samples from patients with new-onset RA (NORA). This organism has a sequence for a peptidylarginine deiminase-like (PAD-like) enzyme, which may lead to citrullinated neoepitopes and anti-citrullinated protein antibodies (ACPA). However, little is known about immune responses to *P. copri*, and its role in RA pathogenesis is not yet clear.

Methods:

To address these issues, we used an innovative approach that combines discovery-based proteomics and translational research. Accordingly, we identified microbial and self HLA-DR-presented peptides (T cell epitopes) in patients' synovial tissue, joint fluid or peripheral blood (PB), using tandem mass spectrometry. The identified peptides were synthesized and tested for T cell reactivity with the matching patient's PBMC by IFN-g ELISpot assay. Immunoreactive peptides or source proteins were then tested for T and B cell responses using cells and sera from our cohort of DMARD-naive NORA patients and controls. All RA patients met the 2010 ACR/EULAR criteria for RA.

Results:

From the HLA-DR-presented peptides isolated from the PB of one RA patient (HLA-DRB1*0401/0101), we identified an immunogenic T cell epitope derived from bacterial signal sequence of a 27-kDa protein of *P. copri* (*Pc*-p27), implying that this organism or components of it were present in this patient's circulating phagocytic cells. When testing was done in additional patients, 17 of 40 (42%) NORA patients had T cell reactivity with this single epitope of *Pc*-p27. In addition, 10 of 78 NORA patients (13%) had IgG antibodies to *Pc*-p27; 8 of 78 patients (10%) had IgA antibodies to this protein, but only 1 patient had both IgG and IgA antibody responses. In contrast, no patients with other forms of arthritis or healthy control subjects had T or B cell responses to this protein. IgA antibody responses to *Pc*-p27 correlated with higher serum IL-23 levels (suggestive of Th17 responses) and more frequent ACPA, whereas IgG antibody responses to the protein correlated with lower IL-23 levels and less frequent ACPA, suggesting that patients may have advantageous (IgG) or disadvantageous (IgA) responses to this *P. copri* protein. Moreover, Th1 responses to the identified epitope of *Pc*-p27, as determined by IFN-g secretion, were usually concordant with IgG antibody responses to the protein, but no patients with IgA antibody responses to *Pc*-p27 had this Th1 response.

Conclusion:

The identification of a single T cell epitope in an individual patient provided a bridge to the discovery of a broadly immunogenic *P. copri* protein. There appears to be dichotomous immune responses to this protein. We postulate that Th1 responses and IgG antibodies to *Pc*-p27 more effectively control the expansion or systemic spread of the organism. In contrast, IgA antibodies to *Pc*-p27, which are associated with higher IL-23 levels (suggestive of Th17 responses) and greater frequency of ACPA, may be less effective in controlling the organism and may enhance the development of autoimmune responses.

PLCe1 Mediates Cellular Adhesion Downstream of SDF-1 in T Cells

Adam Mor[1] and Marianne Strazza[2], [1]Rheumatology and Pathology, NYU Langone Medical Center, New York, NY, [2]NYU, New York, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The presentation of chemokines by endothelial cells results in chemoattraction of leukocytes that express the correlative chemokine receptors. In this way, chemokines direct leukocyte trafficking throughout the body. Upon receptor binding, arrested leukocytes, here T cells, firmly adhere to the endothelium and subsequently crawl along the blood vessel wall in search of an area permissive to cellular passage or transmigration. As a result, chemokine induced T cell adhesion is both rapid and polarized. This is in contrast to antigen receptor mediated T cell adhesion, which is characterized by slow kinetics and operates under different physical forces.

Methods:

Thus, the goal of this work was to identify the unique signaling pathways regulating T cell adhesion downstream of chemokine receptors.

Results:

We have shown that SDF-1α induced Rap1 activation is transient in comparison to the sustained Rap1 activation observed following stimulation of the T cell receptor. Using an inhibitory RNA screen we have identified that the guanine nucleotide exchange factor mediating SDF-1α-Rap1 activation is PLCε1. Further studies show that knockdown of PLCε1 in T cells interferes with SDF-1α induced Rap1 activation and firm adhesion, as observed through adhesion studies performed under sheer flow. Through the analysis of morphological changes following stimulation, we show that PLCε1 is also necessary for migration. Structure-function analysis of PLCε1 uncovers the contribution of different domains to its guanine exchange activity.

Conclusion:

In conclusion, we uncover a novel signaling pathway where SDF-1α induces T cell adhesion through activation of PLCε1. While T cell trafficking plays an important role in healthy immune surveillance, inflammatory responses, and autoimmune diseases, chemokine induced signaling cascades are currently understood in only the broadest sense.

IL-17A-Low CCR6+ Th Cell Populations of Patients with Rheumatoid Arthritis Are Pathogenic, Multidrug Resistant and Associated with DMARD and Glucocorticoid Treatment Response

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: CCR6+ T-helper (Th) cells and their pro-inflammatory cytokines including IL-17A are implicated in the pathogenesis of rheumatoid arthritis (RA). However, within the CCR6+ Th population various subpopulations are present and the clinical relevance of each subpopulation in RA is unclear. Therefore, we characterized CCR6+ Th subpopulations with regard to pathogenic potential and treatment outcome in RA.

Methods: Within total CCR6+ Th cells from patients with RA, CCR4+CXCR3- (Th17), CCR4-CXCR3+ (Th17.1), CCR4/CXCR3 double-positive (DP) and double-negative (DN) cells were distinguished and/or sorted by flow cytometry. These subpopulations were: analyzed for Th17/Th1-associated factors; co-cultured with RA-derived synovial fibroblasts (RASF); related to disease-modifying antirheumatic drugs (DMARDs) and glucocorticoid (GC) therapy response; analyzed regarding the expression of multidrug transporters MDR1 and MRP1 and drug efflux potential.

Results: All CCR6+ Th subpopulations expressed the Th17 associated transcription factor, RORC+ and were present in RA peripheral blood and synovial fluid. Despite differential IL-17A, IL-17F, IFNγ and TBX21 expression, all CCR6+ Th subpopulations, including IL-17A low-producing Th17.1, DP and DN cells, showed pathogenic activity in the induction of IL-1β, IL-6, IL-8, COX-2 and MMP-3 expression by RASF. MDR1 expression levels and MDR1 efflux activity were significantly higher in Th17.1 and DN cells, in comparison to the other CCR6+ Th subpopulations and Th1 cells. In contrast, MRP1 expression and efflux activity was present in all CCR6+ Th subpopulations and increased upon DMARD/GC therapy. Moreover, the lack of response of DMARD/GC therapy was accompanied with increased drug efflux potential by CCR6+ Th cell populations.

Conclusion: Despite distinct differences in Th17/Th1 characteristics, including IL-17A production, all CCR6+ Th subpopulations of patients with RA display pathogenic activity. Future treatment strategies towards CCR6+ Th cells in RA may therefore focus on targets shared by all subpopulations. Furthermore, personalized treatment strategies may be improved by using drug efflux potential of CCR6+ Th cells to monitor DMARD/GC therapy response.

Rheumatoid Arthritis Patient T Cells Recognize Neutrophil Extracellular Traps

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The majority of patients with rheumatoid arthritis (RA) harbor anti-citrullinated peptide antibodies, which are correlated with more severe disease. Tetramer based assays have demonstrated that RA patient T cells that recognize citrullinated antigen are more likely to be activated effectors that produce inflammatory cytokines such as IFNg, and less likely to be T regulatory cells. Measurement of citrullinated autoantigen T cell responses could be clinically useful to help predict prognosis or treatment response in patients with RA. A T cell assay that is not restricted to certain MHC II alleles would enable testing of large numbers of RA patients. Since NETing neutrophils externalize targets of RA autoantibodies, we hypothesized that neutrophil NETS could be a source of naturally processed citrullinated antigen to elicit RA patient T cell responses in vitro.

Methods:

All-Trans Retinoic Acid (ATRA) was used to differentiate HL60 cells. Growth rate, nuclear morphology, cell surface CD11b expression, and PAD2, PAD4 and MPO mRNA expression were measured. Differentiated cells were exposed to UV irradiation, PMA and ionomycin and cell death by necrosis, apoptosis and NETosis were compared by immunohistochemistry as well as FACS staining with TOPRO and Annexin V. Citrullination of cells undergoing different types of cell death was compared by western blot. ACPA+ RA and matched control PBMC derived DC were fed granulocytes that had died by various mechanisms and used to probe immediate ex vivo T cell responses using the 40 hour IFNg ELISPOT assay and 18 hour FACS based assays for early activation markers such as CD69 and CD25.

Results:

ATRA treatment of HL60 cells causes them to differentiate into neutrophil like cells as measured by growth curves, CD11b expression and upregulation of PAD2 and PAD4, enzymes that cause citrullination. When treated with UV, ATRA differentiated cells die by apoptosis, while ionomycin and PMA induce NETosis. RA patient but not control T cells produced IFNg and upregulated CD69 and CD25 in response to ionomycin treated ATRA HL60 NET lysate but not ionomycin HL60 (PAD2 and PAD4 low expressing) control lysate.

Conclusion:

RA patients may harbor an expanded population of memory T cells, which recognize NET derived antigen.

This was supported by grants from the Arthritis Foundation and the Rockefeller University CTSA.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: P140 is a 21-mer peptide (sequence 131-151, phosphorylated at position 140) that is derived from the spliceosomal protein U1-70K. In a multicenter, randomized, placebo-controlled phase IIb study, P140/Lupuzor™ had no adverse safety signals and met its primary efficacy end points in

lupus patients[1]. These results confirm data generated in MRL/lpr lupus-prone mice in which the preclinical studies were performed. We found previously that P140 reduces autophagic flux in MRL/lpr B cells[2] and that macroautophagy (the best characterized type of autophagy) is abnormally enhanced in T lymphocytes from lupus mice and patients[3]. More recently, we discovered that in MRL/lpr mice, P140 more precisely targets a selective form of autophagy, chaperone-mediated autophagy. We deciphered the successive steps of P140 action leading *in fine* to a decay of endogenous antigen processing and loading to MHCII molecules and as a consequence, to a lower activation of autoreactive T cells[4]. Here, the mechanism of action of P140 was further studied in peripheral cells from normal and lupus individuals.

Methods: Studies were performed *ex vivo* on B cells from normal donors and lupus patients. A scrambled peptide was used as control. Immunocytochemical analyses were applied to identify the way of P140 enters into B cells. The effect of P140 on MHCII molecules stability was studied using western immunoblotting (WB) and FACS analyses. FACS studies were used to evaluate the effect of P140 on the B cells differentiation into plasmablasts and plasma cells and on BCR signaling amplitude. Microscopy and WB analyses were performed to study the effect of P140 on autophagy.

Results: P140 that is not immunogenic in lupus patients[5] showed no direct effect on BCR signaling in normal B cells (mature, transitional, IgG/IgM memory). As in MRL/lpr mice, P140 enters human B cells via a clathrin-dependent endo-lysosomal pathway and induces a decrease of MHCII expression. Higher the SLEDAI score of patients was, higher the P140 effect was measurable. P140 did not induce apoptosis of B cells from healthy or lupus patients. The autophagic flux was affected in P140-treated B cells.

Conclusion: Our findings provide strong arguments to conclude that the mechanism of action of P140 peptide is similar in MRL/lpr mice and lupus patients. These results shed light on mechanisms by which P140/Lupuzor modulates lupus disease in humans affected by this disorder.

Regulation of T Follicular Helper Cells in Systemic Lupus Erythematosus By E3 Ubiquitin Ligase Cbl-b

William Willis[1], Yun Xiao[2], Nicholas A. Young[1], Wael N. Jarjour[1] and Jian Zhang[2], [1]Immunology and Rheumatology, The Ohio State University Wexner Medical Center, Columbus, OH, [2]Microbial Infection and Immunity, The Ohio State University Wexner Medical Center, Columbus, OH

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Activation of polyclonal $CD4^+$ T cells and B cells is a hallmark of human and murine **lupus**, which suggests a global defect in the maintenance of T and B cell tolerance. Recent studies unveil a central role of T follicular helper (Tfh) cells that is critical in providing help to B cells in the overproduction of pathogenic auto-antibodies and tissue damage in lupus. However, how Tfh cells are deregulated in lupus in mice and humans is currently unknown. The E3 ubiquitin ligase Cbl-b plays a crucial role in T cell activation, tolerance induction, and Th2 cell differentiation. Cbl-b polymorphisms are linked to human lupus, and furthermore, Cbl-b expression has been shown to be reduced in human lupus T cells. However, the role of Cbl-b in lupus pathogenesis is still poorly defined. In this study, we test the hypothesis that Cbl-b targets Bcl6, the master transcriptional regulator for Tfh cell development, for ubiquitination and degradation in mice.

Methods: We introduced Cbl-b deficiency or a point mutation within RING finger domain of Cbl-b, into *lpr* mice (carrying a mutation in *Fas* gene) on a C57BL/6 background (B6-*lpr.Cblb-/-* and B6-*lpr.CblbC373A*, respectively). To test the feasibility of silencing *Cblb* in human T cells, peripheral $CD4^+$ T cells isolated from peripheral blood mononuclear cells (PBMC) of healthy human donors were transfected with siRNA targeting Cbl-b using liposomal or nucleofection-based methods.

Results: B6-*lpr.Cblb-/-* and B6-*lpr.CblbC373A* mice displayed an exacerbated and severe lupus-like syndrome. This was associated with expanded Tfh cells, GC B cells, and plasma cells in the lymph nodes and spleens and heightened anti-dsDNA titers in the sera. At molecular level, Cbl-b bound to Bcl-6 upon Tfh differentiation condition in a Bcl-6 tyrosine-phosphorylation dependent manner. Furthermore, Bcl-6 ubiquitination and degradation was abrogated in T cells lacking Cbl-b. Consistent with this data, Tfh from SLE patients express lower levels of Cbl-b compared to those from healthy donors.

Conclusion: Our results suggest that that Cbl-b may be the E3 ubiquitin ligase that targets Bcl-6 for degradation. Because both B6-*lpr* and human lupus T cells express significantly less Cbl-b, deregulated Cbl-b expression in human and murine lupus may be a driver of heightened Tfh and GC B cells causing overproduction of pathogenic auto-antibodies.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

A previously described transcriptional signature present in circulating CD4+ T cells of early rheumatoid arthritis (RA) patients implicated STAT3 signalling as an early pathophysiological event[1]. We sought to validate this finding through independent replication and microarray meta-analysis.

Methods:

Microarray technology was used to measure gene expression in highly purified peripheral blood CD4+ T cells from treatment-naïve RA patients and disease controls recruited from an early arthritis clinic. Analysis focussed on 12 transcripts identified during the previous study, and concurrent STAT3 pathway activation was determined in the same cells by flow cytometry. A meta-analysis analysis of previous and current gene expression findings employed multivariate and receiver operator characteristic curve analysis.

Results:

In the independent cohort of 161 patients, normalised expression of 11 of the 12 original signature genes differed significantly between RA patients and controls. Differential regulation was most pronounced for the STAT3 target genes PIM1, BCL3 and SOCS3 (>1.3-fold difference; $p<0.004$), each of whose expression correlated strongly with paired intracellular phospho-STAT3, and these 3 genes' expression accounted for the majority of the signature's ability to segregate diagnoses by hierarchical clustering (Figure 1A). The ability of the same 3 genes, or pairs thereof, to segregate RA patients from disease controls was confirmed in the meta-analysis of 279 patients (E.g. Figure 1B). Moreover, both the 12 gene and the 3 gene signatures added independent discriminatory value to a consideration of clinical parameters including age, swollen/tender joint counts and acute phase response with respect to diagnosis (Figure 1C).

Conclusion:

The STAT3 mediated dysregulation of BCL3, SOCS3 and PIM1 in circulating CD4+ T cells is confirmed as an independent early event in RA pathogenesis. The mechanistic and functional implications of this observation are being investigated.

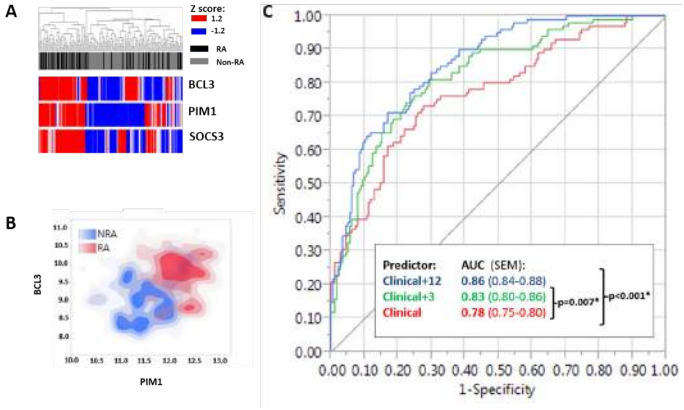

Figure 1. A. Hierarchical clustering based on 3 genes' expression in T cells discriminates early RA patients from disease controls. **B** Non-parametric density plot depicting utility of BCL3 and PIM1 alone in discriminating RA patients. **C**. Adding either a 3 gene or 12 gene CD4+ T cell "signature" to a predictive model based on clinical parameters alone significantly enhanced discrimination of RA from non-RA.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Effector memory T cells of both CD4 and CD8 lineages are key drivers of autoimmunity and are pathogenic in several autoimmune diseases including psoriasis, atopic dermatitis, lupus nephritis, and inflammatory bowel disease among others by both human clinical and animal experimental data. Kv1.3 is a potassium channel required for sustained intracellular calcium influx, proliferation and activation of effector memory T cells. Dalazatide (ShK-186) is a potent, highly specific, first-in-class peptide blocker of Kv1.3 and effector memory T cells. Here we report on the safety, tolerability, pharmacodynamics and immunomodulating proof-of-concept data for dalazatide from a phase Ib study in patients with active plaque psoriasis.

Methods: A double blind trial was conducted in patients with active mild to moderate plaque psoriasis. Cohorts received either 30 mcg (n=10), 60 mcg (n=10 or placebo (n=4) twice weekly subcutaneous injections for 4 weeks with 4 weeks of follow up. Skin lesion biopsies were collected at baseline and at week 4 post treatment for gene expression and immunohistological analyses. Plasma, serum and peripheral blood mononuclear cells were collected at baseline and at several times during the study. Target lesions were evaluated at baseline and at day 32.

Results: The treatment was well tolerated with all subjects completing the study and reporting only mild adverse events. 50% of subjects in 60 mcg group achieved clinical improvement in target lesion. Improvements were observed as early as day 15 and for up to 4 weeks following last dose (day 57, end-of-study). Ongoing improvement continued during follow-up period in some subjects. 90% of subjects in 60 mcg group had reduction in PASI score.

Conclusion: These results demonstrate that twice weekly subcutaneous dosing of Kv1.3 blocker dalazatide is safe and well tolerated in psoriasis patients. Improvement in clinical disease endpoints provides proof-of-concept data for the immunomodulating mechanism of action of dalazatide in a prototypical T cell mediated autoimmune disease

Engaging PD-1 Resuscitates Synovial Treg Cells and Dampens the Joint Infiltrating T Cells in Rheumatoid Arthritis

Dipendra Kumar Mitra[1] and Kaustav Chowdhury[2], [1]Transplant Immunology & Immunogenetics, All India Institute of Medical Sciences, Delhi, India, [2]TRANSPLANT IMMUNOLOGY AND IMMUNOGENETICS, ALL INDIA INSTITUTE OF MEDICAL SCIENCES, New Delhi, India
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Enrichment of regulatory T cells (Treg) has been reported in the synovial fluid (SF) of RA patients, although they fail to alleviate the joint inflammation. These cells utilize programed death receptor-1 (PD-1) mediated pathway to dampen the effector T cell response. We hypothesized that deficit in the PD-1 pathway may be responsible for functional incapacitation of locally accumulated Treg cells in RA patients. To understand the cause of the failure of locally enriched Treg cells in controlling synovial inflammation, we investigated the role of PD-1 in modulating the function of the infiltrating T cells. Here, we demonstrate that lack of PD-L1 on synovial machorphages ($CD14^+$ cells) incapacitates the Treg cells and engaging PD-L1 can functionally resuscitate the Treg cells and dampens the inflammatory T cells.

Methods:

We isolated mononuclear cells from peripheral blood (PBL) and synovial fluid (SF) 25 active RA patients. Surface expression of PD-1 and its ligand (PD-L1) were seen on Treg cells and macrophages ($CD14^+$) by the use of flowcytometry. Anti inflammatory cytokine IL-10, TGF-β in Treg ($CD4^+FoxP3^+$) and proinflammatory cytokines IFN-γ, IL-17A, TNF-α in effector T cells ($CD4^+$) were measured with FACS based intracellular staining after treatment with PD-L1 Fusion chimeric protein (PD-L1 Fc) in presence of TCR engagement.

Results: Our result shows that synovial Treg cells are compromised in their IL-10, TGF-β production in-spite of local enrichment of $PD\text{-}1^+$ Treg ($CD4^+FOXP3^+$) cells. Engaging PD-1 with PD-L1 Fc, IL-10 & TGF-β production by Treg cells. Interestingly, this was accompanied by simultaneous decrease in the frequency of synovial $IFN\text{-}\gamma^+$, $TNF\text{-}\alpha^+$, $IL\text{-}17A^+$ effector T cells and their proliferation. Moreover, blocking IL-10, TGF-β with specific antibody in similar condition(s) failed to suppress the infiltrating T cells of synovial fluid. This suggests, that deficit of PD-1 mediated suppressive pathway incapacitates the locally accumulated Treg cells.

Conclusion:

Our results indicate that deficit of PD-1 mediated suppressive pathway incapacitates the locally accumulated Treg cells and engaging PD-1 may restore the suppressive function of synovial Treg cells via IL-10, TGF-β production. Rejuvenating synovial Treg cells may be used to ameliorate the joint inflammation in rheumatoid arthritis.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Monocyte-derived dendritic cells (MoDCs) differentiate from monocytes under inflammatory conditions like RA, and are very potent in presenting antigen to T cells. GM-CSF-responsive MoDCs have been shown to promote Th17 cell differentiation during experimental autoimmune encephalomyelitis (EAE). Since the pathogenicity of Th17 cells in EAE has been associated with the production of both IL-17 and GM-CSF, this introduces an interesting feedback-loop within the suggested MoDC-Th17 pathway. In this study, we aimed to further elucidate this GM-CSF/Th17 pathway by determining the contribution of GM-CSF-producing cells in driving synovial MoDC levels and promoting Th17 differentiation during experimental arthritis. In addition, we analyzed the GM-CSF expression by CD4+ T cells under Th17 differentiation conditions to further unravel the interaction between these two cytokines.

Methods: Arthritis was elicited in C57Bl/6 mice by intra-articular injections of methylated BSA in combination with subcutaneous injection of IL-1β. To investigate the *in vivo* role of GM-CSF in synovial MoDC and Th17 development, the mice were treated with anti-GM-CSF or control antibodies on day 0, 2, and 4 after arthritis induction. Synovial MoDC and Th17 levels were determined 7 days after arthritis onset. To elucidate which GM-CSF-producing cellular compartment is mainly responsible for synovial MoDC and Th17 development, bone marrow (BM) chimeras were created by transferring BM of GM-CSF knockout mice to irradiated wild-type mice or vice versa, and MoDC and Th17 levels were determined by FACS on synovial tissue 7 days after arthritis induction. In addition, GM-CSF expression by Th17 cells was studied *ex vivo* using naïve murine CD4+ T cells differentiated under various culturing conditions, and both Th17 differentiation efficacy and GM-CSF levels were assessed.

Results: Unexpectedly, inhibiting the GM-CSF pathway during murine experimental arthritis using neutralizing antibodies increased MoDC levels in the arthritic synovium. Interestingly, the percentage of synovial Th17 cells was also increased by this anti-GM-CSF treatment, suggesting a negative feedback of GM-CSF on Th17 development. Our study using bone marrow chimera mice showed that particularly mice deficient for BM-derived GM-CSF had increased levels of synovial MoDCs as well as Th17 cells, confirming the antagonistic regulation of MoDCs and Th17 cells by GM-CSF. Finally, our *ex vivo* studies showed that, while Th17 cells did not produce much GM-CSF, differentiation of naïve T cells under conditions suboptimal for Th17 development resulted in increased levels of GM-CSF, indicating deviating differentiation conditions and antagonistic regulation of IL-17 and GM-CSF by CD4+ T cells.

Conclusion: Our experiments are the first to demonstrate increased levels of synovial MoDCs and Th17 cells after anti-GM-CSF treatment, confirming a loop between GM-CSF and differentiation of MoDCs and Th17 cells. However, contradictory to what has been shown in EAE, GM-CSF was shown to have a negative impact on this loop. This negative regulation between GM-CSF and Th17 cells provides further rationale for a combination blocking strategy of IL-17 and GM-CSF in the treatment of RA.

A Circulating Reservoir of Pathogenic-like CD4+ T Cells Shares a Genetic and Phenotypic Signature with the Inflamed Synovial Micro-Environment

Roberto Spreafico[1,2], **Maura Rossetti**[1,2], Jorg van Loosdregt[1], Carol A. SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic immunological processes are profoundly shaped by the micro-environments where antigen recognition occurs. Identifying molecular signatures distinctive of such processes is pivotal to understand pathogenic immune responses and manipulate them for therapeutic purposes. Unfortunately, direct investigation of peripheral tissues, enriched in pathogenic T cells, is often impossible or imposingly invasive in humans. Conversely, blood is easily accessible, but pathogenic signatures are diluted systemically as a result of the strict compartmentalisation of immune responses. In this work, we aimed at defining immune mediators shared between the bloodstream and the synovial micro-environment, and relevant for disease activity in autoimmune arthritis.

Methods: CD4+ T cells from blood and synovium of patients with juvenile idiopathic arthritis (JIA) were immunophenotyped by flow cytometry. The TCR repertoire of a circulating subset showing similarity with the synovium was analysed through next-generation sequencing to confirm enrichment in synovial clonotypes. Finally, clinical relevance was established by monitoring this subset in the blood of patients with JIA and rheumatoid arthritis (RA).

Results: A small subset of circulating CD4+ T cells replicated the phenotypic signature of lymphocytes infiltrating the inflamed synovium. These circulating pathogenic-like lymphocytes (CPLs) were enriched in synovial clonotypes and exhibited strong production of pro-inflammatory cytokines. Importantly, CPLs were expanded in JIA patients not responding to therapy, and also correlated with disease activity in patients with RA.

Conclusion: CPLs provide an accessible reservoir of pathogenic cells recirculating into the bloodstream and correlating with disease activity, to be exploited for diagnostic and research purposes.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

To study the influence of senescent $CD28^-$T-cells on systemic osteoporosis in rheumatoid arthritis (RA) and patients with primary osteoporosis.

Methods:

Prospective, cross-sectional study on 104 patients with RA (mean age 62.2 [±SD 12.6], 76% female, SDAI 13.5 [±10.2]) and 111 non-RA controls (mean age 60.7 [±11.3], 84.7% female). Bone mineral density (BMD) was determined by DEXA. PBMCs were retrieved at the same day of BMD measurement and were stained with anti-RANKL, CD3, CD4, CD8, CD45RA, CD45RO and/or CD28 mAbs to measure surface and intracellular expression of RANKL on T-cells and to determine the prevalence of T-cell subsets by flow cytometry. The capacity of T-cell subsets to induce osteoclastogenesis was assessed via TRAP staining in the presence of monocytes and M-CSF (25ng/ml) *in vitro*.

Results:

A reduced BMD as determined by DEXA was found in 58.1% of RA patients (14% with osteoporosis, 44.1% with osteopenia) and 56.1% of non-RA controls (38.8% with osteoporosis, 17.3% with osteopenia). RA patients with reduced BMD had higher prevalences of circulating $CD4^+CD28^-$ (3.2% [0.1–41.2] vs. 0.7% [0.1–33.9], p=0.048). In non-RA controls we observed the same effect (3.5% [0.1–30.4] vs. 1.3% [0.1–34], p=0.032).

Surface RANKL expression was higher on $CD4^+CD28^-$ T-cells (3.1% [0-57.9]) compared to naïve $CD4^+CD28^+CD45RA^+$ (1.5 [0-45.3], p<0.001) and memory $CD4^+CD28^+CD45RO^+$ (1.9 [0-38], p=0.006) T-cells. Moreover, surface RANKL expression was higher in RA patients than non-RA controls in all T-cell subsets (all p<0.05). After stimulation with anti-CD3 antibody, RANKL production was higher in $CD4^+CD28^-$ T-cells (intracellular RANKL MFI: 870.2 [±205.9]) compared to naïve $CD4^+CD28^+CD45RA^+$ (713 [±182.3], p=0.001) T-cells, whereas RANKL levels were similar in $CD4^+CD28^-$ T-cells and memory $CD4^+CD28^+CD45RO^+$ (862.2 [±289.7], p=0.207) T-cells. Similar results were obtained after stimulation with PHA or ConA.

The *in vitro* ability of T-cell subsets to induce osteoclastogenesis was higher in senescent $CD28^-$ T-cells compared to their $CD28^+$ counterparts as indicated by TRAP-staining ((27.5 [±15.8] TRAP positive cells vs. 20.5 [±7.9], p=0.128).

Conclusion:

Senescent $CD28^-$ T-cells are linked with the occurrence of systemic bone loss. Increased expression of RANKL on $CD4^+CD28^-$ T-cells compared to other T-cell subsets may result in higher direct stimulation of osteoclastogenesis by this subset.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease that leads to inflammation of the joints and other tissues. Rituximab (Rtx) is a therapeutic monoclonal antibody directed against CD20 that induces an important depletion of B cells. Although little is known about how it modifies the homeostasis of lymphoid subpopulations, it has been successfully used in RA.

The objective of this study was to know whether Rtx modifies the ratio of the different lymphocyte subpopulations from peripheral blood in RA patients.

Methods: We studied 62 RA patients that underwent treatment with Rtx because of active RA and failure to at least one previous anti-rheumatic drug. The patients were divided into those naïve for Rtx treatment (RtxN n=21) and those who had received at least one previous cycle of treatment with Rtx (RtxS n=41). Peripheral blood samples for lymphoid subpopulation analysis were obtained at different times in both RtxN and RtxS patients: before the first infusion of Rtx (baseline) and at 3, 6 and 8 months after it (T3, T6 and T8 respectively).

We studied different combinations of molecules that allowed us to calculate the percentage of T cell subpopulations, including memory and naïve T cells, effector and central memory T cells, follicular T helper cells and regulatory T cells. In the case of B cells, we analyzed memory and naïve B cells, Marginal Zone B cells, follicular B cells and plasmablasts B cells, at each visit. Differences between groups were analyzed by ANOVA test.

Results: At baseline, there was a significant difference in the percentage of a considerable number of B cell subsets. In particular, we observed an important decrease in memory B cells and an increase in follicular B cells. We also detected an increase in CD38+CD24+CD10+ B cells in RtxS.

Regarding T cell subpopulations, we only observed a significant decrease in Th17 cells and in follicular T helper cells in RtxS.

During the follow up period, the differences in T cells observed at baseline became much smaller presumably because of the effects of Rtx. At T3 only CD4 + T cells and memory T cells, defined by the absence of CD62L, were significantly lower in RtxS.

At T6, we observed an increase in the CD8+CCR6- CXCR6- subpopulation in RtxS.

At T8, as some patients had already repopulated B cell subsets, we found differences in B cells, and we detected a decrease in the CD38- B cell population. Taking into account the T cell population, we noted an increase in total T cells in RtxS with a significant decrease in effector-memory T cells.

Conclusion: Depletion of B cells through Rtx treatment leads to a profound change in the subpopulations of peripheral blood B cells, due to repopulation, and also of T cells. This suggests that mature B cells play a relevant role in the homeostasis of T cells.

Potent and Selective Tyk2 Inhibitors Block Th1- and Th17- Mediated Immune Responses and Reduce Disease Progression in Rodent Models of Delayed-Type Hypersensitivity and Psoriasis

Wenyan Miao[1], Craig Masse[1], Jeremy Greenwood[2], Rosana Kapeller[1] and William Westlin[1], [1]Nimbus Therapeutics, Cambridge, MA, [2]Schrodinger Inc., New York, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tyk2 is a member of the JAK family kinases and is a key mediator of IL-12, IL-23, and type I interferon signaling. These cytokines have been implicated in the pathogenesis of multiple inflammatory and autoimmune diseases such as lupus, psoriasis and inflammatory bowel diseases. Supported by compelling data from human genetic association studies, Tyk2 inhibition is an attractive therapeutic strategy for these diseases.

Methods: One of the challenges of developing selective Tyk2 inhibitors is the high sequence homology of the active site among the members of the JAK family kinases. We utilized cutting edge proprietary structure-based drug design tools to identify highly potent and selective inhibitors of Tyk2. These inhibitors were characterized for their potency and selectivity in the enzyme and cell-based assays, and in mouse models of delayed type hypersensitivity and psoriasis.

Results: We have identified Tyk2 inhibitors with up to 720-, 540-, and 210-fold selectivity against JAK1, JAK2, and JAK3 respectively, with potent cellular activity and excellent cellular selectivity against other JAK family kinases in human peripheral blood mononuclear cells. NDI-031301 is a Tyk2 inhibitor with a Ki of 0.5 nM that is 107-, 85-, and 15-fold selective against JAK1, JAK2, and JAK3 respectively. It blocks IL-12 induced phospho-STAT4 and GM-CSF induced phospho-STAT5 in human PBMCs with $IC_{50}$of 0.1 μM and 2.6 μM, respectively. NDI-031301 has excellent selectivity against a panel of 364 kinases, showing less than 70% inhibition at 300 nM against all but 16 of the kinases tested. It also showed less than 50% inhibition up to 30 μM against human CYP enzymes and hERG channel. In addition, NDI-031301 has an attractive PK profile with good oral bioavailability in rodents and dogs. Studies with humans carrying inactive forms of Tyk2 and mice deficient in Tyk2 revealed a role in Th1 and Th17 polarization. We investigated the in vivo activity and mechanism of action of Nimbus Tyk2 inhibitors in a methylated-BSA induced mouse delayed type hypersensitivity model. At 100 mg/kg dose, orally administered NDI-031301 reduced paw swelling and paw weight, as well as Th1 (IFNγ) and Th17 (IL-17A and IL-22) cytokines in the inflamed paws by more than 50%. It also dramatically reduced Th1 cells in the draining lymph nodes and suppressed over 85% of in vitro antigen-induced IFNγ response in the draining lymph node cells. In an IL-23-induced mouse psoriasis model, NDI-031301 dose-dependently reduced skin inflammation with up to 76% inhibition of ear swelling at 100 mg/kg, highlighting the role of Tyk2 inhibition in Th17 pathogenesis. Finally, NDI-031301 was highly efficacious in an imiquimod-induced mouse psoriasis model, showing dose-dependent reduction of psoriasis score, spleen weight, and improved skin histology. 30 mg/kg of NDI-031301 treatment blocked disease progression and 100 mg/kg treatment reversed the disease.

Conclusion: Utilizing unique and innovative structure-based drug design technologies, we rapidly designed highly potent and selective Tyk2 inhibitors for use as potential therapeutics in inflammatory disorders involving Th1, Th17, and type I interferon pathogenesis.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: There is substantial evidence that $CD4^+$ effector memory T (T_{EM}) cells play a crucial role in the pathogenesis of Granulomatosis with polyangiitis (GPA). The activation of $CD4^+$ T_{EM}-cells is uniquely dependent on the voltage-gated potassium Kv1.3 channel. Blocking Kv1.3 channels with the exquisitely specific, highly potent peptide inhibitor dalazatide (formerly ShK-186) has been shown to ameliorate autoimmune disease in animal

models of multiple sclerosis and rheumatoid arthritis. Therefore, selective targeting of pathogenic $CD4^+$ T_{EM}-cells is a very promising selective treatment for GPA patients. The aim of this study is to modulate $CD4^+$ T_{EM}-cell activity via Kv1.3 blockade using a specific peptide inhibitor dalazatide in peripheral blood of GPA patients *in vitro*.

Methods: Peripheral blood of remission GPA patients (R-GPA; *n=24*) and age- and sex-matched healthy controls (HCs; *n=15*) was stimulated *in vitro* with PMA/Ca-Ionomycin in the presence and absence of the Kv1.3 blocker, dalazatide. After stimulation cells were fixed, permeabilized and stained for surface markers (CD3, CD8, CD45RO and CCR7), and intracellular cytokines (IL-4, IL-17, IL-21, IFNγ and TNFα). Relative frequencies of pro-inflammatory cytokine expression were assessed within total $CD4^+$ T-cells and $CD4^+$ T-cell subsets using flow cytometry. Unstimulated samples were used as a guide to delineate positive and negative populations for the cytokine production.

Results: The percentage of $CD4^+$ T_{EM} cells was significantly increased in R-GPA patients compared to HCs. The intracellular cytokine production in total $CD4^+$ T-cells after stimulation was significantly increased in R-GPA patients compared to HCs. Dalazatide suppressed the intracellular cytokine production in total $CD4^+$ T-cells of GPA patients, in a dose dependent manner, to levels observed in stimulated total $CD4^+$ T-cells of HCs. Similar assays performed in sorted $CD4^+$ T-cell subsets revealed that dalazatide predominantly inhibited cytokine production in $CD4^+$ T_{EM}-cells, whereas cytokine production by naïve- and central memory $CD4^+$ T-cells was unaffected. production.

Conclusion: The selective Kv1.3 blocker, dalazatide modulates $CD4^+$ T-cell activity in GPA patients *in vitro*. Importantly, dalazatide was able to normalize the pro-inflammatory cytokine production in $CD4^+$ T cells from GPA patients. Furthermore, the effect of dalazatide predominantly affects $CD4^+$ T_{EM}-cells by reducing intracellular cytokine production while sparing other $CD4^+$ T-cell subsets. These data indicate that dalazatide may hold therapeutic promise in the treatment of GPA by selectively targeting $CD4^+$ T_{EM}-cells. duction by naïve- and central memory $CD4^+$ T-cells was unaffected. production.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In our previous study, the transcriptome profiles of $CD4^+$T cells from 13 active RA cases and 9 healthy controls were accessed by microarrays. a total of 1496 differential genes were identified. To investigate whether these significant differential genes were regulated by miRNAs, further studies were carried out for the new regulating effect of miRNAs in $CD4^+$T cell, the results not only benefit to understanding the pathogenesis of RA, but also explore a new strategy for immunotherapy of RA.

Methods: Peripheral blood $CD4^+$T cells isolated from RA patients and healthy individuals were performed by microarray analysis. The selected candidate genes and miRNA were validated by quantitative real-time PCR (qPCR). Dual luciferase reporter assay system and western blot were used to validate the direct function of miR-30a and SOCS3. In order to determine whether miR-30a affects IL-6 or IFN-r-mediated JAK-STAT pathway by targeting SOCS3. We transfected a synthetic miR-30a mimic or its inhibitor in Jurcat cells, Western Blot was used to detect the SOCS3 and STAT3 protein level after stimulated by IL-6 or IFN-r. To investigate the potential differentiation effect of miR-30a, we over-expressed miR-30a in naïve T cell, and T cell subsets were tested by Flow cytometry. To further show that miR-30a plays a significant role in RA pathogenesis, we constructed CIA models, the synthesis miR-30a antagomir or NC antagomir were injected by tail vein respectively. After injection for 70 days, H&E staining and micro-computed tomography (micro-CT) confirmed that the inflammatory infiltration and bone erosion was reduced in the group of miR-30a antagomir CIA mice compared to the control group.

Results: MiR-30a expression increased in RA patients compared to controls, and it markedly repressed the reporter activity of the 3'untranslated regions (UTRs) of SOCS3, mutation of the 3' UTRs of the repressed gene confirmed that SOCS3 was the target of miR-30a. Consistent with the reporter assays, the expressions of endogenous SOCS3 protein were decreased in 293T cells by over-expression of miR-30a mimic. Over expression of miR-30a increased the phosphorylation level of STAT3, which may be regulated by the IL-6/IFN-r-mediated JAK-STAT activation pathway. Th1 subsets was remarkable higher in naïve T cells transfected by miR-30a mimic, which suggested that miR-30a may promote the differentiation of $CD4^+$T cells, but had no effect in the proliferation. In our animal experiment, the clinical core of CIA mice were lower in the miR-30a antagomir mice (micro-CT) confirmed that inflammatory

infiltration and bone erosion were relieved in the miR-30a antagomir mice.

Conclusion: Over expression of miR-30a in CD4+T cell inhibited the protein level of SOCS3 and promoted the differentiation of Th1 cell, which may be regulated by the IL-6/IFN-r-mediated JAK-STAT pathway. The results also provide evidence that down-regulating expression of miR-30a in CIA mice decreased the arthritis score, as well as reduce the degree of bone erosion and cell invasion.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Antibodies against citrullinated collagen type II (Cit-CII) are common in sera and synovial fluids of Rheumatoid Arthritis (RA) patients, whereas the known CII T-cell epitope is not dependent on citrullination. This study aimed to identify Cit-CII restricted T-cell epitopes relevant to RA and to functionally characterize Cit-CII specific CD4+ T cells with regard to immune function and TCR Vbeta signatures.

Methods: PBMCs from HLA-DRB1*10:01 positive RA patients and healthy donors were stimulated with candidate peptides in vitro. CD154 up-regulation was utilized as a marker of antigen-specific activation. One citrullinated peptide, Cit-CII(311-325) was able to activate CD4+ T cells and was selected for further analysis. Cytokine production measurement by Luminex technology and anti-DR blocking experiments were conducted. Direct binding assays using HLA-DRB1*10:01 and *04:01 monomers were performed. Antigen-specific T cells were CD154-enriched and their T-Cell Receptor (TCR) Vbeta chain was sequenced with high-throughput sequencing.

Results:

A new citrullinated CII peptide was identified based on its ability to activate CD4+ T cells from HLA-DRB1*10:01individuals. When stimulated in vitro, Cit-CII autoreactive T cells produced pro-inflammatory cytokines. Cit-CII(311-325) binds with low affinity to HLA-DRB1*10:01 but not to HLA-DRB1*0401 while the native version was unable to bind either of them. Finally, Highly Expanded Clones (HECs) were identified in the TCR Vbeta repertoire of Cit-CII(311-325) stimulated PBMCs.

Conclusion:

These results illustrate the ability of the citrullination process to create T-cell epitopes from CII, a cartilage-restricted protein relevant to RA pathogenesis. The exclusive binding of Cit-CII(311-325) to HLA*DRB1*10:01 suggests that citrulline T-cell autoimmunity might vary between individuals carrying different RA-associated HLA-DR molecules.

Hypermethylation of Treg-Specific Demethylated Regions in the Ikaros Transcription Factor Family Members, Helios and Eos, in Rheumatoid Arthritis Tregs

Alla Skapenko[1], Viktoria Soentgerath[1], Sonja Haupt[2], Jan Leipe[1] and Hendrik Schulze-Koops[1], [1]Division of Rheumatology and Clinical Immunology, University of Munich, Munich, Germany, [2]Division of Rheumatology and Clinical Immunology, Med.Klinik und Poliklinik IV, University of Munich, Munich, Germany

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Foxp3 is the signature transcription factor of regulatory T cells (Tregs) and facilitates many of the characteristic functions of Tregs. Members of the Ikaros family of transcription factors have been implicated in controlling the phenotype of Tregs, in part by interacting with Foxp3. Ikaros family zinc finger 4 (IKZF4, Eos) mediates Foxp3-dependent gene silencing and is required to maintain the phenotype of Foxp3-positive Tregs, whereas IKFZ2 (Helios) is involved in the suppression of IL2 gene transcription and upregulation of Foxp3. An important regulation level of tissue-specific geneexpression is DNA methylation. In particular, Treg-specific gene expression is controlled by DNA methylation within characteristic clusters, Treg-specific demethylation regions.

Methods: To analyze the DNA methylation status of Treg-specific demethylated regions (TSDR) of Foxp3, Helios and Eos in T cells from patients with rheumatoid arthritis (RA) and to compare the level of methylation to that in T cells from healthy controls.

Results: All analyzed regions were completely methylated in effector T cells from RA patients and controls. In contrast, considerable degrees of demethylation were detected in the regions of interest in CD25+CD127- T cells, in line with the hypothesis of an important regulatory mechanism facilitating Treg-specific gene expression. No differences were detected between Tregs from RA patients and controls with regard to the level of methylation within the TSDR of FoxP3. Importantly, the methylation rate of the CNS CpG island in the Helios gene was significantly higher in Tregs from RA patients than in those from controls (55% vs. 40%, $p<0.05$). Similarly, the CpGs within exon 6 of the Helios gene were demethylated to a significantly different level between RA patients and controls (50% vs. 40% methylation, respectively; $p<0.05$). Finally, in the CNS CpG island of the Eos gene, the methylation level in Tregs from RA patients was also significantly higher as compared to healthy control Tregs (68% vs. 53%, $p<0.01$).

Conclusion: The data are consistent with the hypothesis of Treg specific expression of Helios and Eos regulated by DNA methylation within Treg-specific demethylation regions. Furthermore, the data suggest that impaired function Tregs in RA might be related to an altered expression of Helios and Eos as a consequence of increased DNA methylation. This mechanism might provide a molecular epigenetic insight into the pathogenesis of autoimmune diseases.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A comprehensive analysis of the circulating T cell subtype pattern, including T helper 1 (Th1) cells, Th2 cells, Th17 cells, Th1/Th17 cells, T follicular helper (Tfh) cells, T follicular regulatory (Tfr) cells and T regulatory (Treg) cells in early untreated early RA compared to healthy controls has previously not been published.

Methods: Twenty-six patients with early RA satisfying the ACR 2010 criteria who had not received any DMARDS or prednisolone donated blood together with 18 sex and age matched healthy controls. Peripheral blood mononuclear cells were stained and analyzed by flow cytometry for combinations of

chemokine receptors CCR4, CCR6 and CXCR3 to define Th1, Th2, Th17 and Th1/Th17 cells. Follicular T helper cells were defined using the expression of CXCR5 but lack of FOXP3, while follicular regulatory T cells were defined as expressing both CXCR5 and FOXP3. Regulatory T-cells were defined as expressing either CD25 and low CD127 or FOXP3. Analysis of mRNA expression for the respective transcription factors were performed on flow cytometry sorted cells and cytokine production from the cultured sorted T cells was analyzed to confirm that the chemokine receptor expression correctly defined the T cell subtypes. In addition, CTLA-4 was analyzed on both conventional and regulatory CD4+ T-cells. The disease activity of the patients was measured DAS28 and CDAI. The data was analyzed using multivariate factor analyses followed by univariate analyses.

Results: Multivariate discriminant analysis including all T cell subtypes showed that the best discriminators for early RA were the proportions of Th2 and Th17 cells that were found in higher proportions in early RA than in healthy controls and the Th1/Th17 cells that were found in lower fractions in early RA than in controls. Regulatory T cells were found in higher proportions in early RA than in controls, while the proportions of circulating follicular helper T cells did not differ between the groups. Principal component analysis of the T cells subtypes in the patients showed that Th2 cells clustered with the Th17 cells, Th1/Th17 cells clustered with the Th1 cells and Tfh cells clustered with the Tfreg cells, whereas Tregs and Th0 cells were positioned separately. Strong negative correlations were obtained between Th17 cells and the Th1 cells. The clinical inflammatory activity in untreated early RA was unrelated to any of the proportions of the circulating T cells subtypes except for the proportions of the CTLA-4 positive T cells that were positively related to higher clinical activity.

Conclusion: We found a dominance of circulating Th2 cells together with Th17 cells in early RA and the former should attract more attention in relation to pathogenesis of early stages of the disease. Knowledge on what T cell subtypes dominate in the circulation in early rheumatoid arthritis may also guide us in developing new targeted treatments for this group.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Citrulline autoimmunity is a characteristic of ACPA^{+} Rheumatoid Arthritis (RA). Many autoantigens have been implicated even within patients of the same HLA such as HLA-DR*0401. By HLA-tetramer technology, autoreactive T cells can be captured and studied, but ACPA status cannot predict which T cell specificity will be most abundant. The present study aimed to evaluate the functional and transcriptional character of citrullin-specific T cells from RA synovial fluid and peripheral blood.

Methods: Peripheral blood mononuclear (PBMC) and synovial fluid mononuclear cells (SFMC) were isolated HLA-DR*04:01+ subjects. A pool of HLA DRB1*0401 class II tetramers (Tmr) were used to isolate autoreactive CD4+ T cells recognizing validated T cell epitopes from citrullinated alpha-enolase and vimentin T cell lines were generated following polyclonal stimuli and expansion and their specificity determined by stimulating with the same set of peptides used in the tetramers. Proliferation and cytokine profiling was measured by thymidine incorporation and cytokine bead array respectively. Smart-seq-2 RNA seq methods were used to perform transcriptomical analyses.

Results: By the tetramer pool technology we can reproducibly capture and grow autoreactive T cells even from synovial fluid and from modest cell numbers. Approximately half of the Tmr positive cell lines from both SFMC (42%) and PBMC (47%) were positive upon rechallenge. Citrulline reactivity was confirmed by both proliferation and cytokine output. We also demonstrate proof of principle of single cells transcriptomics (n=24) from RA synovial fluid with identification of approx 3000 genes per cell.

Conclusion: We demonstrated that citrulline specific T cell lines could be generated from both peripheral blood and synovial fluid. By this method we can capture autoreactive T cells even from modest number of cells without knowing the dominant T cell subset. This will enable identification of autoreactive T cell receptors (TCR) and down stream studies of e.g. T cell – APC interaction.

Methylation-Dependent Interference of Two Promoters for the Treg-Specific Protein, Garp, Contributes to Altered Treg Function in Rheumatoid Arthritis

Viktoria Soentgerath[1], Sonja Haupt[2], Jan Leipe[3], Hendrik Schulze-Koops[1] and Alla Skapenko[1], [1]Division of Rheumatology and Clinical Immunology, University of Munich, Munich, Germany, [2]Division of Rheumatology and Clinical Immunology, Med.Klinik und Poliklinik IV, University of Munich, Munich, Germany, [3]Division of Rheumatology, University of Munich, Munich, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, genome-wide studies identified several Treg-specific genes containing hypomethylated regions that are critical for their expression, so called Treg-specific demethylated regions (TSDR). For example, stable expression of the master transcription factor of Tregs, Foxp3, and expression of the Treg-specific surface receptor, GARP, are regulated by epigenetic modifications of intragenic TSDRs. We hypothesized that impaired Treg function in patients with autoimmune diseases, such as rheumatoid arthritis (RA), might be caused by changes in DNA methylation of Treg-signature gene loci.

Methods: In the current study, we investigated the methylation status of the TSDRs of the *FOXP3* and *GARP*genes in RA patients. CD25+ CD127- CD4 Tregs and CD25- CD4 T cells were isolated from the peripheral blood of therapy-naive RA patients as well as of age- and sex-matched healthy volunteers using magnetic cell sorting. Genomic DNA was isolated and processed by bisulfite conversion. The TSDRs were amplified by PCR using primers specific for bisulfite converted DNA. The PCR products were cloned and subsequently sequenced to compare the CpG methylation level and pattern between healthy individuals and RA patients.

Results: No differences in *FOXP3* TSDR methylation were found between Tregs from RA patients and controls. In marked contrast, the TSDRs in the intragenic promoter and in the first intron of *GARP* were surprisingly demethylated to a greater extent in Tregs from RA patients than in Tregs from healthy controls. The higher degree of the demethylation of the *GARP* gene locus in RA was coincident with lower *GARP* mRNA expression upon Treg activation and with higher disease activity. As expected, decreased methylation and decreased *GARP* mRNA expression were reflected by diminished GARP protein expression at the cell surface. In depth molecular analysis revealed that *GARP* expression in Tregs is tightly regulated by two alternative promoters. Binding of the transcriptional machinery to the demethylated intragenic promoter and the intronic TSDR acts like a roadblock resulting in Treg-specific attenuation of *GARP* transcription.

Conclusion: These data indicate that altered methylation in Treg-specific genes, such as *GARP*, in RA might facilitate impaired Treg function and, thus, contribute to disease pathogenesis.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Giant cell arteritis (GCA) is the most common systemic vasculitis in adults aged 50 years or above. Annual incidence rates vary widely from 6.9–76.6 per

10^5 of adults in this age group, depending on the region.[1] Our aim was to determine the incidence rate of GCA in our population.

Methods: We prospectively collected incident cases of GCA from January 1st 2011 to December 31st 2014 at our department of rheumatology which is a part of an integrated secondary/tertiary university teaching hospital that is the only referral center serving a region representing approximately a quarter of the national adult population. Additionally, newly diagnosed cases of GCA between January 1st 2009 and December 31st 2010 were retrospectively identified by searching the electronic patient records for ICD-10 codes M31.5 and M31.6 at our department. The retrospective approach and search strategy was also applied on electronic medical records at the departments of infectious diseases and ophthalmology between January 1st 2009 and December 31st 2014. To further reduce possibility of underreporting, the attached medical faculty's Institute of Pathology provided a list of all temporal artery biopsies examined during the observation period which were then cross-referenced with the hospital's electronic medical records. Annual incidence rate for GCA was then calculated.

Results:

During the six year observation period we identified 137 new cases of GCA (68% female; mean (IQR) age 75.9 (11.1) years) from a well-defined adult white Caucasian population of 235,596 inhabitants aged 50 or above. The temporal artery biopsy was consistent with GCA, negative or not performed in 80.2 %, 19.8 %, and 8.0 % of cases, respectively. Thus, the average six years annual incidence of GCA in our population is 9.7 (95 % CI 8.1–15.5), the highest was in 2010 (11.7 (95% CI 7.7-17.1)), and the lowest in 2013 (7.5 (95% CI 4.4-11.8)) per 10^5 adults aged 50 or above.

Conclusion:

The average annual incidence rate of 9.7 per 10^5 adults aged 50 or above makes GCA the most common systemic vasculitis in our population.

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Leukocyte immunoglobulin-like receptor A3 (*LILRA3A*) encodes a member of a family of immunoreceptors which is predominantly expressed on antigen presenting cells, acting as a soluble receptor for class I major histocompatibility complex (MHC) antigens. Recently published studies have implicated a 6.7 kb genetic deletion of *LILRA3*, comprising the first seven exons of the gene, in the genetic predisposition to rheumatoid arthritis, multiple sclerosis, and Sjögren's syndrome. Given the proposed role of *LILRA3A* in autoimmunity, we aimed to assess whether this deletion represents a novel genetic risk factor for GCA and its main clinical subgroups.

Methods: A total of 969 biopsy-proven GCA patients and 1593 healthy controls of Spanish Caucasian origin were included in the study. The *LILRA3* deletion was genotyped by polymerase chain reaction using specific primers for detecting presence or absence of the complete gene.

Results: No statistically significant differences were found when allele and genotype distributions were compared between GCA patients and controls (allelic p-value= 0.924, OR=1.01, CI 95%=0.87-1.17). Likewise, the subphenotype analysis considering the main clinical complications of the disease (rheumatic polymyalgia, visual manifestations, jaw claudication and stroke) yield similar negative results.

Conclusion: Our data suggest that the *LILRA3* deletion do not play a significant role in GCA susceptibility or severity.

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a large-vessel vasculitis that primarily affects the aorta and external carotid arteries and their branches, leading to ischemic manifestations such as headaches or jaw claudication. Visual loss, commonly secondary to anterior ischemic optic neuropathy, represents the most severe complication. Polymyalgia rheumatica (PMR), characterised by aching and morning stiffness in the neck, shoulder and pelvic girdle, is present in up to 50% of patients. Less often, neurological symptoms, such as transient ischemic attacks and strokes, have been identified in GCA patients. The aim of the present study was to perform a stratified analysis of a published Immunochip to identify genetic factors contributing to the main clinical manifestations of GCA.

Methods: Data from an Immunochip performed on 763 Spanish GCA patients were stratified according to the presence/absence of PMR, jaw claudication, visual manifestations (transient visual loss including amaurosis fugax, permanent visual loss, or diplopia) and stroke. Allele frequencies were compared between the different subgroups of GCA patients and 1,517 unaffected controls, and between patients with and without the considered phenotypes. Logistic regression analyses adjusted by the 3 first principal components and sex were performed using an additive model.

Results: After genotyping and quality control, 132,117 genetic variants were analyzed in GCA patients showing PMR (n=318), jaw claudication (n=331), visual manifestations (n=228) or stroke (n=43). Several *loci* showed suggestive associations with the different clinical manifestations, specifically *MAFB* (a transcription factor involved in the monocyte-macrophage differentiation) was associated with jaw claudication ($p=2.31x10^{-6}$, OR=1.57), *KIR2DL1/KIR2DL4* (transmembrane glycoproteins playing an important role in the immune response regulation) appeared to be involved in PMR ($p=5.26x10^{-6}$, OR=1.69), *ADAMTSL3* (implicated in angiogenesis and up regulated in astrocytes from the optic nerve in patients with glaucoma) showed an association with the development of visual manifestations ($p=9.57x10^{-6}$, OR=1.69), and *SULT6B1* (a sulfotransferase which catalyzes the sulfonation of xenobiotics, hormones and neurotransmitters) was implicated in GCA-associated stroke ($p=1.67x10^{-5}$, OR=2.68). In all cases, the analysis of GCA patients accordingly with the presence/absence of each clinical condition also reached statistical significance (p=0.025, $p=3.89x10^{-3}$, $p=4.94x10^{-3}$ and $p=8.96x10^{-6}$, respectively).

Conclusion: Using a stratified large-scale analysis, we have identified four novel *loci* potentially involved in the development of the main clinical complications occurring in GCA patients.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Giant cell arteritis (GCA), the most common primary vasculitis, can cause irreversible blindness in 20-30% of untreated cases, but glucocorticoid therapy leads to significant toxicity in > 80% of patients. Ultrasound has proven to be effective in diagnosing GCA and has shown advantages in monitoring disease activity. We reviewed data on all patients referred to a single university hospital between August 2014 and March 2015 who were seen in a “fast-track” service established to diagnose and evaluate suspected GCA or a suspected flare. All patients underwent rapid evaluation by a combination of ultrasound (of the temporal and axillary arteries) and standard clinical assessment to reduce the risk of misdiagnosis or instituting unnecessary treatment.

Methods:

We performed a retrospective analysis and comparison of the ultrasound findings with the clinical features, temporal artery biopsy (TAB) results and decision to treat patients with suspected or established GCA. The ultrasound scan was considered positive when we identified the presence of a dark halo around the temporal artery wall or a homogeneous hypoechoic wall thickness > 1.5 mm in the axillary arteries.

Results:

We performed 137 scans in 118 patients (67% females, mean [SD] age 71 ± 11 years). In 89 cases, patients were referred for suspected GCA: 60% were already on high-doses of steroids (mean of 12 ± 10 days); 78% had headache; 62% high inflammatory markers; 43% abnormal vascular examination (e.g. diminished/absent pulse or bruits); 34% scalp tenderness; 33% polymyalgia rheumatica; 25% jaw claudication and 25% visual symptoms. In 32 cases the scan was positive: 9 also had a TAB (4 positive) and all were treated as GCA. In 50 cases the scan was negative: 20 also had a TAB (1 positive) and 5 were treated as GCA. In 7 cases the scan was inconclusive requiring further investigations (e.g. TAB). Patients with a positive scan had a mean CRP of 51.8 ± 50.8 g/dl and a mean ESR of 42.4 ± 40.1 mm/hour; patients with a negative scan had a mean CRP of 14.9 ± 21.9 g/dl and a mean ESR of 26.8 ± 23.5 mm/hour (p=0.003 and p=0.245, respectively). We scanned 48 patients with an established diagnosis of GCA to assess for flare or monitor disease activity: 25 had a positive scan (18 increased medication; 7 were follow-ups with improvement from baseline) and 23 had a negative scan (allowing a safer taper or withdrawal of glucocorticoids). Patients with a positive scan had a mean CRP of 10.7 ± 10.3 g/dl and a mean ESR of 21.4 ± 18.0 mm/hour; patients with a negative scan had a mean CRP of 3.9 ± 4.3 g/dl and a mean ESR of 24.1 ± 17.4 mm/hour (p=0.025 and p=0.663, respectively).

Conclusion:

The combination of rapid clinical evaluation and ultrasound were key elements in diagnosis and monitoring of GCA, allowing more flexible use of glucocorticoid dose regimens and reducing the number of TABs required. The only patient with a negative scan but a positive TAB had already received 20 days of glucocorticoids, suggesting that delay in investigation after starting therapy could affect the results of the scan.

The Performance of Colour-Doppler Sonography of Temporal Arteries in Patients Suspect of

Having Giant Cell Arteritis in Daily Clinical Practice

Alojzija Hocevar, Rok Ješe, Ziga Rotar and Matija Tomšič, Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The Colour-Doppler Sonography of temporal arteries (CDS-TA) has recently gained momentum as a potential non-invasive tool for diagnosing GCA. Our aim was to evaluate the diagnostic value of CDS-TA in suspected GCA cases in daily clinical practice.

Methods: Subjects with suspected GCA underwent CDS-TA prior to temporal artery biopsy (TAB). CDS-TA was performed on a Philips IU22 using a 5–17.5 MHz linear probe. TA were assessed in longitudinal and transversal planes. The "halo sign" (dark hypo echoic circumferential wall thickening), stenosis or occlusion were considered a positive finding. In addition to CDS-TA, clinical examination, extensive laboratory work-up, and TAB were performed. Diagnosis was established in accordance with the American College of Rheumatology (ACR) criteria.

Results: From 1.9.2011 to 31.5.2015 (45 months) 139 subjects with suspected GCA were identified. GCA was diagnosed in 96/139 (69.1%). The remaining 43/139 (30.9%) who were not diagnosed with GCA served as controls. CDS-TA was performed in 138/139 subjects (95/96 GCA patients and in 43/43 controls). The "halo sign" was observed in 74 (77.9%) of GCA patients and in none of the controls. The "halo sign" was unilateral in 28/74 (37.8%) and bilateral in 46/74 of GCA patients. Stenoses were found in 41/95 (43.1%) of GCA patients and in 2/43 (4.7%) controls. TA occlusion was demonstrated in 13/95 (13.7%) of GCA patients and in none of the controls. In our population the CDS-TA had an estimated diagnostic sensitivity of 77.9% and specificity of 95.4% with diagnosis based on the ACR criteria serving as a gold standard. A positive CDS-TA had 97.4% positive and 66.1% negative predictive value for GCA. The TAB for the same group had a diagnostic sensitivity of 80.0% and specificity of 90.3%; and a 95.5% positive and a 63.6% negative predictive value. There was an 80% matching of CDS-TA and TAB (Table 1).

Suspected GCA	positive CDS-TA	negative CDS-TA	CDS-TA not performed	Total
Positive TAB	54	4	1	59
Inconclusive TAB	4	4	0	8
Negative TAB	10	34	0	44
TAB not done	8	20	0	28
Total	76	62	1	

Table 1. Crossmatching of CDS-TA and TAB in suspected GCA

Conclusion:

The diagnostic value of CDS-TA for diagnosing GCA is comparable, if not superior to TAB. In case of characteristic sonographic changes, CDS-TA may obviate the need for TAB.

Risk of Cerebrovascular Accident in Patients with Polymyalgia Rheumatica: A Systematic Review and Meta-analysis

Background/Purpose: Several chronic inflammatory disorders, such as rheumatoid arthritis and systemic lupus erythematosus, have been shown to increase risk of cerebrovascular accident (CVA). However, the data on polymyalgia rheumatica (PMR), another common chronic inflammatory disease in older adults, are limited. Thus, to further investigate this association, we conducted a systematic review and meta-analysis of observational studies that compared the risk of CVA in patients with PMR versus participants without it.

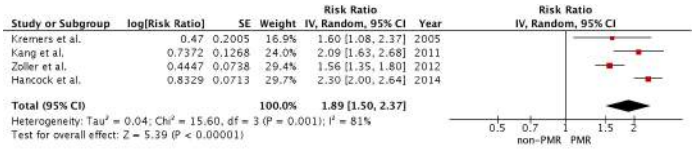
Methods: Two investigators independently searched published studies indexed in MEDLINE, EMBASE and the Cochrane database from inception to April 2015 using the terms "polymyalgia rheumatica" and "PMR" combined with the terms for cerebrovascular disease. A manual search of references of selected

articles was also performed. The inclusion criteria were as follows: (1) cohort or case-control study evaluating the association between PMR and CVA (2) odds ratio (OR), relative risk (RR) or hazard ratio (HR) or standardized incidence ratio (SIR) with 95% confidence interval (CI) were provided. Study eligibility was independently determined by the two investigators. The quality of included studies was, again, independently assessed by the two investigators using Newcastle-Ottawa scale.

RevMan 5.3 software was used for the data analysis. Point estimates and standard errors were extracted from individual studies and were combined by the generic inverse variance method of DerSimonian and Laird. Given the high likelihood of between study variance, we used a random-effect model rather than a fixed-effect model. Statistical heterogeneity was assessed using the Cochran's Q test.

Results: Out of 346 potentially relevant articles, four studies (three retrospective cohort studies and one case-control study) were identified and included in our data analysis. The pooled risk ratio of CVA in patients with PMR was 1.89 (95% CI, 1.50 to 2.37). The statistical heterogeneity of this meta-analysis was high with an I^2 of 81%.

Conclusion: Our study demonstrated a significantly elevated CVA risk among patients with PMR.



Disclosure: P. Ungprasert, None; **N. Srivali**, None; **W. Kittanamongkolchai**, None.

Colour-Doppler Ultrasonography of Epiaortic Arteries in Patients with Giant Cell Arteritis

Alojzija Hocevar, Rok Ješe, Ziga Rotar and Matija Tomšič, Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Giant cell arteritis (GCA) is the most common systemic vasculitis in patients over 50 years of age. Large vessel disease outside temporal arteries is increasingly being recognised. Our aim was to evaluate the involvement of large epiaortic arteries in patients with GCA using Colour Doppler Ultrasonography (CDS) in daily clinical practice.

Methods:

CDS of epiaortic arteries was performed using a 5–17.5 MHz linear probe in patients with newly diagnosed GCA prior to or up to 2 days after starting glucocorticoids. Carotid, vertebral, subclavian, axillary as well as occipital, facial and thyroid arteries were assessed in longitudinal and transversal planes. The “halo sign” (i.e. a hypoechoic circumferential wall thickening, was considered a positive finding.

Results:

From September 1, 2011 to May 31, 2015 CDS of epiaortic arteries was performed in 87 GCA patients. In 33/87 patients (37.9%) involvement of examined arteries was found. (Table 1).A single artery region was affected in 13 patients (39.4%), and 20 patients had more than one vascular region affected.

The group of patients with large artery involvement had significantly longer disease duration (p= 0.009), were more commonly females (p=0.003), had less commonly positive CDS of temporal arteries (p=0,023) and had a higher risk for severe visual disturbances (50% vs. 9.1% permanent visual loss, relative risk 5.5 (95%CI 1.2-25.8)), than those without large vessel involvement. Clinical characteristics of both groups are presented in Table 2.

Arteries	GCA cases with vasculitic changes (%)

Table 1. Large artery disease in GCA patients, assessed by DCS

Table 2. Clinical characteristics of GCA patients with or without large artery disease

Carotid arteries	12.6%
Vertebral arteries	11.5%
Subclavian arteries	17.2%
Axillary arteries	17.2%
Thyroid artereis	3.4%
Occipital arteries	17.8%
Facial arteries	17.8%

Characteristics	GCA with large vessel disease (33)	GCA without large vessel disease (54)
gender (F:M ratio)	10	1.6
age (yrs; median, IQR)	72.1 (66.3; 78.6)	74.9 (68.7; 78.8)
disease duration (days, median, IQR)	60 (30; 101)	29 (14; 60)
general symptoms (%)	84.2%	70.4%
PMR symptoms (%)	15.2%	20.4%
new headache (%)	66.7%	77.8%
jaw claudication (%)	39.4%	42.6%
visual disturbances (%)	18.2%	40.7%
permanent visual loss (% of visual dist.)	50%	9.1%
dry cough (%)	24.2%	16.7%
ESR (mm/h; median , IQR)	89 (59; 109)	81 (58; 101)
CRP (mg/l; median, IQR)	82 (51; 122)	63 (32; 124)
positive TA biopsy (%)	78.3%	85.4%
positive TA CDS (%)	66.7%	88.9%

Conclusion:

Epiaortic large artery involvement was demonstrated in more than 1/3 of our GCA cases. CDS of epiaortic arteries in addition to CDS of temporal arteries increases the diagnostic yield in GCA.

Diagnostic Value of Ultrasonography-Derived Signs in Giant Cell Arteritis: Literature Review and Meta-Analysis

Fanny BUSQUET[1], Léa Rouxel[2], Thomas Barnetche[3] and Thierry Schaeverbeke[4], [1]intern of hospital, BORDEAUX, France, [2]intern of hospital, Bordeaux, France, [3]PHD, bordeaux, France, [4]department head, Bordeaux, France
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Giant Cell Arteritis (GCA) is the most common form of systemic inflammatory vasculitis in elderly people, with prevalence still increasing, and for which there is no consensual diagnostic method. Indeed the relevance of temporal artery wall edema is still a matter of debate, despite two previous meta-analyses by Karassa *et al.* in 2005 and Arida *et al.* in 2010. We re-evaluated the diagnostic value of the ultrasonography-derived signs of the temporal artery for GCA diagnosis.

Methods:

We selected prospective studies concerning patients with suspected GCA published up to February 2015 in the Pubmed, Cochrane library and Embase databases. Studies using ultrasound biomicroscopy were excluded.

Diagnostic performances were determined for the following ultrasonographic signs: halo (unilateral or bilateral), blood flow abnormalities (stenosis and/or occlusions) and unilateral halo associated with BFA. The gold standard used was either the American College of Rheumatology (ACR) 1990 criteria or temporal artery biopsy. Weighed sensitivity and specificity for each sign were assessed, as well as statistical heterogeneity. P-values less than 0.05 were considered as significant.

Results:

We included 16 studies involving 964 patients suspected of GCA. Among these patients, 448 patients were diagnosed by ACR criteria (41% of which were ACR+) and 764 by temporal biopsy (48% of which showed temporal arteritis).

Ultrasound was performed in all patients. The halo sign was found in 29% of cases among which 76% had a positive biopsy. Among patients ACR+, the unilateral halo sign had an overall sensitivity of 68.2% (95% CI 0.58-0.79) and specificity of 93.2% (95 % CI 0.88-0.99). The same sign did not improve when associated to BFA: overall sensitivity of 64.2% (95% CI 0.17-1.17) and specificity of 93.4% (95% CI 0.85-1). The bilateral halo sign among ACR+ patients had an overall sensitivity of 58.2% (95% CI 0.19-0.97). The latter's specificity was about 100% (95% CI 0.92-1) but was only estimated in one study. Among patients with a positive biopsy, the unilateral halo sign had an overall sensitivity of 82.4% (95% CI 0.77-0.88) and specificity of 86.8% (95% CI 0.82-0.92) with the same absence of improvement as in the previous group when associated to BFA. The bilateral halo sign achieved an overall sensitivity of 51.7% (95% CI 0.42-0.62) and specificity of 82.4%(95% CI 0.57-1). It is to be noticed that between-study heterogeneity was very significant for all these calculations ($I2 > 40\%$). A positive biopsy was found in 58 patients among the 439 without the halo sign (13% of false-negative). 80.7% of ACR+ patients had a positive biopsy and 19.3% had a normal biopsy.

Conclusion:

Among all ultrasonography-derived signs, the unilateral halo sign may be sufficient in GCA diagnosis. However, this meta-analysis did not confirm the infallibility of these signs, in particular in case of an absence of ultrasonographic signs. This last situation should be explored in further studies.

Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Color Doppler ultrasound (CDUS) and Magnetic resonance angiography (MRA) has been extensively used in the diagnostics of large vessel vasculitis (LVV) [giant cell arteritis (GCA) and Takayasu arteritis (TA)]. No studies exist, which compare the diagnostic accuracy of CDUS and MRA of LVV in the supra-aortic large vessels. The aim of this study is to perform a head-to-head comparison between CDUS and MRA of temporal arteries and supra-aortic large vessels in a group of LVV patients.

Methods:

MUSES (Magnetic resonance angiography vs Ultrasonography in Systemic large vEssel vasculitis, Clinical Trials.gov NCT02042092), is a prospective cross-sectional study. Patients diagnosed with LVV by ultrasound, MRA, Computed Tomography Angiography or Positron Emission Tomography, were identified and included in MUSES at the Department of Rheumatology, in Kristiansand between January 2014 and January 2015. One ultrasonographer experienced in the use of vascular ultrasound (APD) examined and recruited the LVV patients. MRA imaging was performed within one week after the ultrasound evaluation and one radiologist evaluated the MRA images locally (FL). The common temporal, carotid, subclavian, vertebral, axillary arteries and the thoracic aorta were evaluated. Films and images of CDUS and MRA examinations were recorded. The recorded data has been surveyed by two external experts, one on vascular ultrasound (WAS) and one on MR imaging (JG). Both experts were blinded to clinical and laboratory data and were unaware of distribution and size of the vasculitis lesions. The experts applied a dichotomous score (vasculitis: yes/no) in every evaluated vessel. The identification of vasculitis in any vessel represented an independent result.

Results:

Twenty-seven patients were recruited [(12 males, 15 females, median age 69 years (IQR 62-76)]. Twenty-five patients were diagnosed with GCA and 2 with TA. Eight patients had new onset LVV and 19 had long lasting disease (median disease duration 2 years, IQR 0-5). Median time between CDUS and MRA examination was 2 days (IRQ 1-4). Median CRP was 8 mg/l (IQR 3-24) and ESR 24 mm/hr. (IQR 9-53). In two patients, no vasculitis changes were observed in any vessel, either on CDUS or MRA. In the remaining 25 patients, CDUS revealed vasculitis in all patients, while MRA was positive in 20 patients. The temporal artery and the supra-aortic vessels in which CDUS, MRA or both modalities revealed vasculitis changes are presented in table 1.

Conclusion:

It seems that CDUS is more sensitive to detect vasculitis changes in large vessels. Further, CDUS revealed vasculitis in more patients than MRA. Thus, we recommend CDUS as a first line evaluation in all patients suspected to have LVV.

Table 1.

	CDUS vasculitis only	MRA vasculitis only	Vasculitis in both modalities
Left common temporal	2	1	10
Left parietal temporal	6	1	8
Left frontal temporal	2	3	7
Right common temporal	3	6	7
Right parietal temporal	2	5	8
Right frontal temporal	2	7	8
Left carotid	13	1	1
Right carotid	12	0	4
Left subclavian	10	1	5
Right subclavian	5	1	3
Left vertebral	3	0	0
Right vertebral	2	0	0
Left axillary	11	0	3
Right axillary	15	1	4
Thoracic aorta	2	0	0

Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: There is an increased use of vascular ultrasound (US) for diagnosing giant cell arteritis (GCA). Consequently, extensive and structured training of ultrasonographers performing vascular ultrasound is required in order to ensure standardization of examination technique and machine settings to obtain reliable results**.** The primary aim of this study was to evaluate the results of a standardized training program for ultrasonographers in the diagnosis of temporal artery (TA) vasculitis in GCA.

Methods: Rheumatologists with long-standing experience in musculoskeletal US were extensively trained in the use of vascular US by a specific program. Initially participation in the International Workshop on US in Large Vessel Vasculitis and Polymyalgia Rheumatica in Kristiansand, Norway (5 hours theoretical and 10 hours supervised hands-on education) followed by a two day workshop in Denmark (6 hours of supervised hands-on trainings and 1 hour of image evaluation)with additional training and standardization of scanning technique and optimization of settings . Immediately after this training program a US study on patients suspected for GCA was initiated. Patients were examined with high-end US equipment with high resolution transducers, optimized vascular settings and standardized examination technique. After the US examination of TA, a temporal artery biopsy (TAB) was performed. Pictures and film clips of all three TA branches in two planes were recorded and evaluated by the performing sonographer and by a blinded expert. Detailed feedback on the

US technique was given to the performing sonographer by the external expert.

US was considered positive in the presence of the halo sign (hypoechoic arterial wall swelling) and/or the presence of a positive compression-sign (arterial wall remaining visible upon compression with US transducer).

Results: During 12 months, 37 patients from three Danish Rheumatologic Departments (Esbjerg, Glostrup, Silkeborg) suspected to have GCA were recruited. In 20 patients with a positive TAB for GCA, US was positive in all patients according to both the performing sonographer and the blinded external expert.

In 15 patients with negative TAB, neither the performing sonographer, nor the external reader found signs of vasculitis. In one patient with a negative TAB, US showed vasculitis (both readers) and in one the local sonographer's finding of US vasculitis was rejected by the blinded expert.

In total, 222 branches of TA were scanned and vasculitis changes were observed in 82 branches (expert) and in 80 branches (performing sonographer). The inter-observer agreement between the performing sonographer and the blinded expert was excellent in all three centres/departments (Cohens kappa-coefficient: Esbjerg k=0.88, Glostrup k=0.90 and Silkeborg k=0.82).

Conclusion: Following an intense structured training program on vascular ultrasound using high quality equipment, we were able to obtain an excellent agreement between US of TA and subsequent TAB in patients suspected for GCA. Furthermore, an excellent interobserver agreement between the performing sonographers and the blinded expert reader were seen. This training set-up could be useful in the implementation of US for diagnosing GCA .

Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound and Magnetic resonance angiography (MRA) yields a high sensitivity and specificity regarding the diagnosis of cranial giant cell arteritis (GCA). Ultrasound and MRA can also depict extracranial large vessel vasculitis (LVV) in both GCA and Takayasu arteritis (TA) patients. Until now, no studies have examined the interobserver agreement of the ultrasonographic and MRA findings in LVV patients. Hence, the aim of this study was to examine the interobserver agreement of the ultrasound and MRA examination of temporal arteries and large vessels in LVV patients.

Methods: This study is a part of the MUSES project (Magnetic resonance angiography vs ultrasonography in Systemic large vessel vasculitis), a prospective cross-sectional study. Patients who were diagnosed with LVV by ultrasound, MRA or CTA were identified and included in the study at the Department of Rheumatology, Hospital of Southern Norway Trust in Kristiansand from January 2014 to January 2015. One ultrasonographer experienced in vascular ultrasound (APD) examined and recruited the LVV patients. MRA imaging was performed within one week after the ultrasound evaluation and one radiologist evaluated the MRA images locally (FL). The common temporal, temporal parietal branch, temporal frontal branch , carotid , subclavian , vertebral , axillary arteries, and thoracic aorta were scanned in all patients. Cranial arteries were assessed in T1-weighted high-resolution transverse slices post contrast, and the aorta and supraaortic arteries based on coronal MRA images. Films and images of both ultrasound and MRA evaluation of every artery were recorded, and two experts; one for vascular ultrasound (WAS) and one for MRA (JG) surveyed the data. Both experts were blinded to clinical and laboratory data. To calculate the inter-observer agreement between ultrasonographers (WAS, APD) and radiologists (FL, JG) the Cohen's kappa test has been used.

Results: Twenty-seven patients were included in this study [(12 males, 15 females, median age 69 years (IQR 62-76)]. Twenty-five patients were diagnosed with GCA and 2 with TA. Eight patients had new onset LVV and 19 had long lasting disease (median disease duration 2 years, IQR 0-5). Median CRP was 8 mg/l (IQR 3-24) and ESR 24 mm/hr. (IQR 9-53). None of the patients had affection of the vertebral artery and thoracic aorta on MRA.

The inter-observer agreement for the various arteries for both ultrasound and MRA are reported in table 1.

Conclusion: Ultrasonographic findings of temporal, aorta and supraaortic arteries in patients with LVV appears to be highly detectable and can be recorded in films for further evaluation. The low interobserver reliability in MRA could be partly explained by the sequences used for vascular imaging.

Table. 1

	Kappa values	
	Reliability Ultrasound (WAS, APD)	**Reliability MRA (FL, JG)**
Common temporal	**0.96**	**0.35**
Parietal branch	**0.85**	**0.29**
Frontal branch	**0.78**	**0.46**
Carotid arteries	**0.54**	**0.32**
Subclavian arteries	**0.78**	**0.20**
Vertebral arteries	**0.89**	**(-)**
Axillary arteries	**0.96**	**0.32**
Thoracic aorta	**1.00**	**(-)**

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Ultrasound is emerging as an alternative test to performing a temporal artery biopsy in the diagnosis of giant cell arteritis (GCA). Little is known of the variability in interpretation of these tests by sonographers and pathologists. We undertook an inter-observer analysis to assess agreement between sonographers in interpreting ultrasound videos, and between pathologists for biopsy images, in patients with suspected GCA.

Methods:

We developed a web exercise with 30 cases randomly sampled from patients with suspected GCA recruited to a large multicentre study comparing ultrasound with biopsy for the diagnosis of GCA. We used 5 practice cases, followed by the 30 unique cases and 6 interspersed repeats, showing ultrasound videos of both temporal arteries and high quality scanned images of biopsies. Trained sonographers and pathologists from the study were asked to assess the compatibility of the videos and images with a diagnosis of GCA and indicate how confident they were of the diagnosis. Inter-observer agreement between sonographers and between pathologists was evaluated using two-way random effects analysis of variance to estimate the intra-class correlation coefficient (ICC) for agreement. Intra-observer reproducibility was evaluated using kappa statistics for the 6 repeated cases.

Results:

All 12 sonographers agreed unanimously on 10/30 cases; 4 as GCA and 6 as not GCA. In 5 cases at least 3 sonographers differed from the majority. All 14 pathologists agreed unanimously on 11 cases; 6 as GCA and 5 as not GCA. In 5 cases at least 3 differed from the majority and in 1 case the pathologists were evenly divided between GCA and not GCA. Overall agreement was similar between the two groups: the ICC for sonographers 0.61 (95% CI 0.48, 0.75) and for pathologists 0.62 (95% CI 0.49, 0.76). After allowing for confidence in the interpretation of the videos and images, inter-observer agreement between sonographers (ICC 0.58, 95% CI 0.44, 0.72) was lower than between pathologists (ICC 0.72, 95% CI 0.60, 0.83). Evidence of giant cells was indicated by the original reporting pathologist in 8/30 cases; in 6/8, the pathologists unanimously judged the biopsy images to be consistent with GCA. For intra-observer reproducibility of the repeated cases the sonographers (raw agreement 86%, kappa 0.69) performed less well than the pathologists (raw agreement 92%, kappa 0.83).

Conclusion:

We have shown that the level of agreement between sonographers is similar to that between pathologists for assessing the compatibility of videos or images with a diagnosis of GCA. Pathologists performed better after allowing for certainty in interpretation and for intra-observer reproducibility. However, the level of agreement was not as high as might be expected and suggests scope for improved training for interpreting temporal artery ultrasound and further investigation of how histological abnormalities other than giant cells are interpreted by pathologists. Interpreting results to support or overturn a diagnosis of suspected GCA should be undertaken in the light of these findings.

Specialty of Provider Referring for Temporal Artery Biopsy Affects the Likelihood of Giant Cell Arteritis (GCA) Diagnosis

Lindsay Lally[1] and Robert F. Spiera[2], [1]Rheumatology, Hospital for Special Surgery, New York, NY, [2]Rheumatology, HSS, New York, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Presenting signs/symptoms of GCA can be nonspecific and patients can initially present to a spectrum of clinical specialties. While temporal artery biopsy (TAB) is recommended for confirming a GCA diagnosis, many patients without GCA are referred for TAB and started on high-dose steroids while awaiting the procedure, which can result in toxicity. Several studies have evaluated clinical predictors of positive TAB among patients with suspected GCA but none have evaluated if the specialty of the provider referring for TAB affects the likelihood of a patient ultimately being diagnosed with GCA.

Methods: All TAB performed at a tertiary care center over 5 years were identified. Medical records were reviewed; those without adequate clinical information were excluded. Whether a patient was referred for TAB by a rheumatologist, internist, ophthalmologist, or neurologist was noted. Subjects were categorized according to 1990 ACR criteria and TAB status as having GCA or no GCA: those with GCA and negative TAB met ³3 ACR criteria and were treated as GCA for at least 6mths based on reviewing chart following TAB.

Results: Of 188 subjects analyzed, 52 (27.7%) ultimately were recognized as having GCA. 23 (12.2%) had positive TAB and clinical GCA, and 29 (15.4%) had negative TAB but were clinically diagnosed as GCA. There were a similar number of referrals from each of the 4 specialties. Rheumatologists were responsible for referring 28/52 (53.8%) of cases ultimately diagnosed as GCA for TAB. Compared to all other specialties, rheumatologists had the highest odds of referring a case ultimately deemed to have GCA for TAB. Patients referred by rheumatologists had 5.43 (95% CI: 2.70, 10.99) times the odds of having GCA compared to patients referred by internists, ophthalmologists, or neurologists ($p < 0.001$). Rheumatologists were also more likely to have referred a patient with a positive TAB than other specialists OR 3.41 (95% CI 1.40-8.33) p=0.007. Using rheumatologists as the reference group, patients referred by internists, neurologists or ophthalmologists all had a lower odds of being diagnosed with GCA (Table 1) Adjusting for presenting symptoms (PMR, vision loss, headache) that may cause referral bias, patients referred for TAB by rheumatologists remained more likely than those referred by other specialists to have GCA, OR 5.49(95% CI 2.60-11.63), p<0.001.

Conclusion: In this cohort, patients referred for TAB by rheumatologists had a significantly higher likelihood of having GCA or positive TAB compared to those referred by all other specialties. These data may support more wide-spread implementation of fast-track pathways, where feasible, which would permit a rheumatologic evaluation for all patients with suspected GCA prior to TAB.

Table 1: Odds of GCA Diagnosis By Referring Specialty

	Total Referrals for TAB (%)	GCA cases, (%)	Odds ratio (95% CI)*	P-value

*Odds of having GCA compared to patients referred by rheumatologists

Specialty	TAB, n(%)	n(%)	(95% CI)*	Value
Rheumatology	52 (27.7)	28 (53.8)		
Internal Medicine	47 (25.0)	15 (28.8)	0.40 (0.18-0.91)	0.029
Neurology	53 (28.2)	5 (9.6)	0.09 (0.03-0.26)	<0.001
Ophthalmology	36 (19.1)	4 (7.7)	0.11 (0.03-0.35)	<0.001

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a large- and medium- vessel arteritis characterized by a range of histological patterns of vascular wall injury. The temporal artery biopsy (TAB), although invasive, is still the gold standard for diagnosis. Markers in sera and tissues of the arteries associated with the pathology of GCA might serve as an aid in diagnosing and understanding GCA pathogenesis. Our aim was to determine mRNA levels of selected cytokines, chemokines, acute phase proteins, adhesion molecules and matrix metalloproteinases (MMPs) as well as their inhibitors in TAB specimens of patients with GCA as compared to patients without GCA. We also aimed to determine sera concentrations of 21 selected proteins in patients and healthy blood donors.

Methods: Biopsies of temporal arteries were obtained from subjects suspected to have GCA. In GCA cases, TAB was performed before the introduction of glucocorticoids. Specimens were processed in the TissueLyser (Qiagen) and RNA was isolated (miRCURY, Exiqon). QPCR was used to determine the mRNA expression levels of selected proteins in TABs of GCA (n=6, 5 females, mean age 67) and nonGCA patients (n=6, 4 females, mean age 75). Concentrations of sera proteins were measured by Luminex using custom prepared Premixed kit (R&D Systems, Abingdon) in GCA (n=93, 66 female, mean age 73), nonGCA patients (n=29, 13 females, mean age 72) and blood donors (n=8, 1 female, mean age 44).

Results: Ferritin, MMP9, TIMP1, TIMP2, VCAM and MARCO showed increased mRNA expression in TAB specimens of GCA patients compared to nonGCA patients (Table 1), while mRNA levels of IL-12, IL-8, ApoA1 and MMP2 were decreased. Levels of CRP, SAA, IL-6 and haptoglobin were significantly increased in sera of GCA compared to the nonGCA group (Table 2). MMP9 and MMP2 protein levels had a divergent trend of change, specifically MMP9 was increased in sera of GCA patients as compared to nonGCA, while MMP2 was decreased. Interestingly, CHI3L1, IFNg, IL-10, IL-8, TNFα, VCAM1 sera levels were significantly elevated in GCA patients versus blood donors.

Conclusion: MMP/TIMP ratios in TABs and acute phase protein levels of SAA, CRP, haptoglobin, as well as IL-6 in sera significantly distinguish between nonGCA and GCA patients.

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The most important biomarker in GCA and PMR patients is increased erythrocytes sedimentation rate (ESR) and/ or increased serum level of C-reactive protein (CRP). However, ample evidence indicates that the ESR and CRP are not increased at diagnosis in a subset of patients [1, 2]. Furthermore, recent data indicate that the ability of these inflammatory markers to detect active disease during tapering of corticosteroid may be compromised [3]. SinceT cell play a critical role in the development of both diseases [4], we set out to investigate cellular makers of T cell activation, proliferation and differentiation for their ability to detect active disease in patients with GCA and PMR.

Methods: CD4 counts, CD8 counts and absolute numbers of CD4 and CD8 T cell differentiation subsets were determined by flow cytometry in peripheral blood of 28 newly-diagnosed, untreated GCA/PMR patients, 16 corticosteroid treated GCA/PMR patients in remission and 25 healthy controls. Expression of the activation marker HLA-DR and proliferation marker Ki-67 determined. Receiver operating characteristic (ROC) analysis with area under the curve (AUC) and Spearman's correlation coefficients were performed.

Results: CD4 T cell counts were decreased in newly-diagnosed GCA and PMR patients. Central memory CD4 T cells were decreased in GCA patients only, and terminally differentiated CD4 T cells in PMR patients only. In GCA patients, CD4 T cells showed increased percentages of HLA-DR+ and Ki-67+ cells. No modulations were observed in the CD8 T cell compartment of GCA and PMR patients. Eleven CD4 T cell parameters provided only moderate discrimination between newly-diagnosed GCA/PMR patients and healthy controls, as indicated by AUC's of 0.7-0.8. Of these markers only the percentage of Ki-67+ terminally differentiated CD4 T cells in GCA patient normalized during remission, and correlated weakly with the ESR and CRP.

Conclusion: Although the CD4 T cell compartment was modulated in GCA and PMR patients, cellular markers of CD4 T cell activation, proliferation and differentiation are not useful for detecting active GCA and PMR.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are two closely related syndromes affecting older people. Proinflammatory cytokine IL-6 is found increased in both GCA/PMR patients and in the aged healthy population[1]. Pro-inflammatory monocytes, identified by CD16 and CD14 expression, increase with age and are potent producers of IL-6[2]. Importantly, monocyte-derived macrophages have been identified in the inflamed arteries of GCA and contribute to the immunopathology of GCA[3]. Yet, peripheral monocyte subsets are less well studied in GCA and PMR patients. In the current study, we assessed the distribution of different monocyte subsets in newly diagnosed GCA and PMR patients before and after glucocorticoid (GC) treatment.

Methods: Peripheral blood samples of 16 newly-diagnosed GCA patients, 17 newly-diagnosed PMR patients and 16 age-matched, healthy controls (HCs) were studied. In a prospective, longitudinal study design, samples were obtained from 12 GCA and 10 PMR patients who were in remission after 12 weeks of treatment with GCs. Absolute numbers of total monocytes and classical($CD14^{bright}CD16^{-}$), intermediate($CD14^{bright}CD16^{dim}$) and non-classical($CD14^{dim}CD16^{bright}$) monocytes were determined by truecount and flow cytometry.

Results: Total numbers of circulating monocytes were increased in newly-diagnosed PMR patients but not in GCA patients when compared to age-matched HCs. Following 12 weeks of GC treatment, monocyte numbers normalized in PMR patients. When analysing absolute numbers of classical, intermediate and non-classical monocytes, we found the classical monocytes increased in PMR. No significant changes were noted in GCA. GC treatment in GCA tended to decrease numbers of non-classical monocytes ($p=0.091$).

When analysing relative changes in monocyte composition, the increase in classical monocytes in PMR was mirrored by a relative decrease of non-classical monocytes while proportions of intermediate type monocytes were unchanged. Interestingly, although we did not detect significant changes in absolute numbers, a similar decrease of non-classical monocytes was observed in newly diagnosed GCA patients. Moreover, GC treatment of GCA led to a further relative decrease of non-classical monocytes only.

Conclusion: We are the first to show that peripheral monocyte numbers are modulated during active PMR but not GCA. Treatment with GCs normalised monocyte numbers in PMR. Active disease in both PMR and GCA led to changes in monocyte composition showing decreases of non-classical monocytes. Different dynamics of monocyte subset distribution in PMR and GCA may help to unravel disease pathogenesis. Additional studies on different subsets of monocytes in GCA and PMR are ongoing.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-22 (IL-22) is produced by immune cells but acts only on non-hematopoietic cells, particularly at the barrier interface. We thus hypothesized that IL-22 pathway might be deregulated in giant cell arteritis (GCA), an inflammatory vasculitis affecting large and medium-sized arteries.

Methods: 22 patients subjected to temporal artery biopsy (TAB) at the Arcispedale Santa Maria Nuova-IRCCS (Reggio Emilia, Italy) for a suspicion of GCA were included in the study. They were divided in two groups after histological analysis: GCA patients with TABs showing a transmural immune infiltrate (n=15) and patients with non-inflamed TABs who received a different diagnosis (n=7). Healthy subjects were also included for the analyzes in peripheral blood (n=10). Expression of IL-22 and IL-22 receptor chain 1 (IL-22R1) were determined in TABs by immunohistochemistry. Levels of IL-22 in peripheral blood mononuclear cells (PBMCs) were investigated by real-time PCR and in plasma by ELISA.

Results: IL-22 and IL-22R1 were more expressed in inflamed TABs compared to normal TABs. IL-22 was mainly expressed by granulomas and cells of the media layer. IL-22R1 was mainly expressed by endothelial cells facing the arterial lumen. Expression of IL-22 mRNA was higher in PBMCs from GCA patients compared to healthy subjects. Similarly, GCA patients had an higher concentration of IL-22 in plasma. Levels of IL-22 in plasma positively correlated with IL-22 gene expression in PBMCs and with serum C-reactive protein. Ongoing studies with flow cytometry will allow to determine if Th22 lymphocytes are also deregulated in GCA patients.

Conclusion: Increased production of IL-22 might be involved in GCA pathogenesis.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The performance of ^{18}F-FDG PET/CT in the diagnosis and assessment of disease activity of LVV has not been fully established. The interpretation of data from ^{18}F-FDG PET/CT studies on LVV is difficult mainly due to (1) the scarcity of studies; (2) the heterogeneity of the LVV populations examined in each study; (3) the variety in the qualitative and semi-quantitative methods for imaging analyses. In the absence of gold standard parameters for the assessment of LVV arterial inflammation *via* ^{18}F-FDG PET/CT, there is a great need to develop analytical methodologies useful to properly exploit the information derived from such studies.

Latent class analysis has recently been used to investigate alternative ways to classify LVV in few angiographic and MRI studies, on the basis of distribution patterns of arterial lesions. Other classical techniques - such as principal component analysis (PCA) and cluster analysis (CA) - have not yet been applied to investigate the distribution patterns of LVV, assessed by ^{18}F-FDG PET/CT.

The aim of our study was to investigate whether PCA and CA are useful methods in identifying distinct distribution patterns of LVV, according to the specific diagnostic entity examined (giant cell arteritis, GCA; Takayasu's arteritis, TA).

Methods:

A total of 135 ^{18}F-FDG PET/CT studies performed for extra-cranial evaluation of LVV have been retrospectively examined by a nuclear physician blinded to clinical data. Maximum standardized uptake values (SUVmax) in 14 vascular districts including aortic segments (ascending aorta thoracic aorta, aortic arch, descending thoracic aorta and abdominal aorta) and the main tributaries (carotid, subclavian, axillary, iliac and femoral arteries; each bilaterally) have been measured and then transformed into *Z*-scores. Identification of distribution patterns of vascular involvement has been performed using PCA and agglomerative hierarchical CA (*SPSS Statistics*, version 22nd).

Results:

PCA and CA performed on the entire population of LVV subjects identified 3 groups of vascular districts with similar trends in terms of standardized SUVmax: (1) epiaortic arteries; (2) aortic arch and ascending aorta; (3) descending and abdominal aorta, together with iliac and femoral arteries. The same aggregation pattern has been observed in the PCA and CA performed on the GCA group, but not on the TA group, where a component including the entire aortic district (thoracic and abdominal aorta) was identified.

Conclusion:

PCA and cluster analysis approach revealed a subtle skewing in terms of distribution patterns of arterial involvement between the two main variants of LVV, assessed by ^{18}F-FDG PET/CT SUVmax values. The influence of atherosclerosis and immunosenescence on the different trends in the aorta districts of TA and GCA needs to be further elucidated.

Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Relapses during glucocorticoid (GC) tapering are frequent in giant cell arteritis (GCA). Anemia at the time of GCA diagnosis was a predictor of flare in a recent study.[1] We aimed to determine the markers of relapsing GCA.

Methods:

At a single secondary/tertiary rheumatology center we prospectively followed patients diagnosed with GCA between 01.09.2011 and 30.09.2014. Follow up visits with predetermined clinical and laboratory tests were performed 12, 24, 48, 96 and 144-weeks after diagnosis. Patients who completed follow up visits at 6 months or later were included in the analysis. Patients were treated in line with the EULAR recommendations.[2] In short, patients with uncomplicated GCA with initial oral methylprednisolone (MP) 32-48 mg qd, while those with ischemic complications or large vessel disease first received MP 250 mg on 3 consecutive days intravenously. MP tapering was started 2-4 weeks after treatment initiation slowly to 4 mg qd which was continued for at least 1.5 years. In patients who relapsed during the MP tapering unscheduled visits were arranged and treatment was adjusted.

Results:

During the observation period 74 (71.6% female) new GCA cases were identified, with a median (IQR) age 73.3 (67.3-77.2) years and symptom duration 30 (14-77) days. One patient died of cancer during the initial diagnostic work-up, 1 refused the treatment and 2 were lost to follow up. The remaining 70 (94.6%) patients were followed for a median (IQR) 102 (51–126) weeks. Throughout the observation period GCA relapsed in 32/70 (45.7%) patients. One patient suffered visual loss at relapse. One patient had two relapses, others one episode. Median (IQR) time to relapse was 24.8 (13.5–44.0) weeks. Median (IQR) prednisolone equivalent dose of MP at relapse was 6.0 (4.0-12.0) mg. Treatment adjustments in patients who relapsed included a temporary increase of MP dose (32/32), and add-on therapy with leflunomide 20 mg qd (18/32) or weekly methotrexate (2/32). Baseline characteristics of patients who relapsed and those who did not are presented in Table 1. At baseline, the patients who relapsed had a significantly higher erythrocyte sedimentation rate (p=0.024), C-reactive protein (p=0.007), as well as the serum amyloid A (p=0.002), haptoglobin (p=0.002), and fibrinogen (p=0.031) levels than those who did not. Disease duration before treatment introduction, large vessel disease, GC dosing scheme and anemia were not a predictor of the GCA relapses.

Characteristic	**Relapsed (32)**	**Nonrelapsed (38)**	**p value**

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with giant cell arteritis (GCA) are at an increased risk for aortic structural damage; however, the timing and predisposing characteristics for development of aortic aneurysm is poorly understood. The aim of this study was to evaluate the incidence and predictors of thoracic aortic aneurysm in a large single-institution cohort of patients with biopsy-proven GCA.

Methods: A retrospective review was performed to identify all patients with biopsy-proven GCA from 1998 through 2013. Demographic, clinical, laboratory, radiographic, and treatment data at baseline and subsequent followup visits were collected. Kaplan-Meier methods were used to estimate cumulative incidence and Cox models were used to examine potential predictors of development of aneurysm/dilatation of the thoracic aorta.

Results: The cohort included 286 patients with biopsy-proven GCA (213 females and 73 males, mean [±SD] age 75 [±7.6] years) with a mean (±SD) follow up of 6 (±3.9) years.

130 patients had 280 imaging studies (41% magnetic resonance angiography [MRA], 55% computed tomographic angiography [CTA] and 4% conventional angiography). The median time from diagnosis to first imaging study was 0.2 [interquartile range (IQR) 0.0, 2.7] years. Of the 130 patients, 48% underwent follow up imaging studies.

At the first imaging study, 14 (11%) patients had evidence of aneurysm or dilatation of the thoracic aorta and 28 (22%) patients had thoracic aorta thickening. Excluding prevalent cases, the cumulative incidence (±SE) for aneurysm/dilatation of the thoracic aorta during followup was 0% at both 1-yr and 2-yrs but increased to 9% (±0.4) at 5-years. Among all patients with GCA evaluated with vascular imaging, thoracic aortic aneurysm/dilatation was detected in 11% (±3) at 1-yr, 11% (±3) at 2-yrs, and 15% (±3) at 5-yrs.

Patient baseline demographics, cardiovascular risk, clinical presentation, laboratory values, and initial treatment were assessed to predict incidence of thoracic aortic damage. Baseline thickening of the thoracic aorta was not a risk factor for subsequent aneurysm/dilatation (p=0.99). Neither the presence of relapse (p=0.99) nor the number of relapses (p=0.65) were associated with development of thoracic aortic damage [HR (95% CI): 0.88 (0.50, 1.54); p=0.65]. Furthermore, there was no difference in initial prednisone dose between patients who did and did not develop aortic damage. The sole predictor for development of thoracic aortic aneurysm/dilatation was a history of smoking [HR (95% CI) 28.1: (1.59, 495.71); p=0.023].

Conclusion: In our cohort, thoracic aortic aneurysm/dilatation was seen in 11% of patients at baseline evaluation and increased to 15% at 5-yrs after diagnosis. Former smokers were at a 28-fold increased risk for developing thoracic aortic damage. Surveillance for aortic damage should be pursued in all patients with GCA, particularly those with a smoking history. Prospective investigations into screening methods and optimal frequency are warranted

Title: Healthcare Utilization and Direct Medical Costs of Giant Cell Arteritis

Background/Purpose: Giant cell arteritis (GCA) is the most common systemic vasculitis in patients aged ≥ 50 years. Few studies have evaluated the economic impact of this condition and have been limited to inpatient-only data sources. Although the majority of healthcare for patients with GCA is provided as an outpatient, utilization and costs from this healthcare sector is largely unknown.

Methods: This study utilized a retrospective, population-based cohort of patients diagnosed with GCA, as defined by 1990 ACR criteria, in 1982-2009 and a reference cohort of patients without GCA matched on age, sex, and calendar year from the same population. Standardized cost data (inflation-adjusted to 2014 dollars) for 1987-2014 and outpatient utilization data for 1995-2014 were obtained from the Mayo Clinic Cost Data Warehouse and analyzed from one year before and up to five years after the GCA diagnosis/index date. Utilization and costs were compared between GCA and non-GCA cohorts using signed rank two-tailed paired analyses.

Results: The GCA cohort consisted of 147 patients (118 female, 29 male) with a mean (±SD) age of 77.2 (±8.2). The non-GCA cohort comprised 147 patients with a mean (±SD) age of 76.9 (±8.5) years.

During the year preceding diagnosis, excess healthcare cost related to GCA was only significantly increased in the month immediately preceding GCA diagnosis [mean (±SD) excess cost $1127 (±5154)]. Following diagnosis, significant annual excess outpatient cost was observed for patients with GCA in each of the first four years [mean excess cost (±SD): 0-1 yrs $1307 (±15581), p<0.001; 1-2yrs $908 (±5917), p=0.009; 2-3 yrs $1324 (±4648), p=0.007; 3-4 yrs $609 (±4596), p=0.04] but was similar between GCA and non-GCA subjects in the 5th year. There were no significant differences in inpatient costs between GCA and non-GCA subjects.

Patients with GCA had higher utilization of laboratory visit days annually for each of the first 3 years following diagnosis, as well as increased outpatient physician visits and combined radiology for years 0-1, 1-2, and 3-4 years (see figure). Ophthalmologic procedures/surgery were increased for years 0-1, 1-2, and 4-5. Emergency medicine visits, musculoskeletal and cardiovascular procedures/surgery were similar between GCA and non-GCA groups throughout the study period.

Conclusion: Direct medical costs were increased in the month preceding and outpatient costs were increased in the first 4 years following GCA diagnosis and then return to levels similar to non-GCA subjects. A higher utilization of outpatient physician, laboratory and radiology visits, as well as ophthalmologic procedures among these patients accounts for the observed increased cost of care.

Figure. Costs (upper panel) and utilization of health care resources (lower panel) in patients with GCA and non-GCA subjects by year of followup from one year prior to 5 years after GCA diagnosis/index date

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of vasculitis in the UK, with an incidence of 2.2 cases per 10,000 person-years. Cerebrovascular and cardiovascular disease may be increased in patients with GCA but risk factors are not confirmed. Social deprivation may be associated with visual ischaemic complications in GCA. This study evaluated the risk of cerebrovascular and cardiovascular disease in patients with GCA compared with matched controls, and identified predictors of these outcomes.

Methods: A UK General Practice Research Database (GPRD) from 1991 to 2001 was used for a parallel cohort study of 5,827 patients with GCA and 37,090 controls, matched on age, gender and location (GP practice).A multivariable competing risk model (non-cardiovascular related death as the competing risk) determined the relative risk (subhazard ratio, SHR) between non-GCA and GCA patients for each of the following outcomes "cerebrovascular disease", "cardiovascular disease" or "cardiovascular or cerebrovascular disease" (three analyses). The model adjusted for smoking history, history of hypertension, prior use of anti-hypertensives, history of diabetes or prior use of diabetic medications, history of hyperlipidaemia, prior use of lipid- lowering medications) and Index of Multiple Deprivation (IMD) quintiles. The model was then run on each cohort separately to identify predictors of cerebrovascular and cardiovascular disease (age and gender were now included).

Results: Comparing the GCA cohort with the non-GCA cohort, the SHR (95% CI) for cerebrovascular disease (1.45 [1.31-1.60]), cardiovascular disease (1.49 [1.37-1.62]) and for cerebrovascular or cardiovascular disease (1.47 [1.37-1.57]) were increased. In the GCA cohort only, predictors of the composite outcome of "cardiovascular or cerebrovascular disease" included increasing age (1.98 (1.62-2.42), $p<0.001$ for patients >80 compared with those <65 years); male gender (1.20 (1.05-1.38), $p<0.001$) and those in the most deprived IMD quintile compared with the least deprived (1.34 (1.01-1.78), $p<0.05$). A history of hypertension was predictive of cardiovascular disease within the GCA cohort (1.53 (1.14-2.05), $p<0.01$) but no other significant associations were seen between the other conventional cardiovascular risk factors and either cardiovascular or cerebrovascular disease as either separate or composite outcomes.

Conclusion: Patients with GCA are fifty percent more likely to have cerebrovascular disease or cardiovascular disease than age, gender and location matched controls. This effect is independent of conventional cardiovascular risk factors but may be associated with higher levels of social deprivation.

Giant Cell Arteritis and Risk of Cerebrovascular Accident: A Systematic Review and Meta-analysis

Background/Purpose: Several chronic inflammatory disorders, such as systemic lupus erythematosus and psoriatic arthritis, have been linked to an increased risk of cerebrovascular accident (CVA). However, the data on giant cell arteritis (GCA), one of the most common systemic vasculitides in older adults, are unclear as epidemiologic studies yielded inconsistent results. Thus, to further investigate this association, we conducted a systematic review and meta-analysis of observational studies that compared the risk of CVA in patients with GCA versus participants without it.

Methods: Two investigators independently searched published studies indexed in MEDLINE, EMBASE and the Cochrane database from inception to April 2015 using the terms "giant cell arteritis" and "temporal arteritis" combined with the terms for cerebrovascular accident. A manual search of references of selected articles was also performed. The inclusion criteria were as follows: (1) cohort or case-control study evaluating the association between GCA and CVA (2) odds ratio (OR), relative risk (RR) or hazard ratio (HR) or standardized incidence ratio (SIR) with 95% confidence interval (CI) were provided. Study eligibility was independently determined by the two investigators. Newcastle-Ottawa scale was used to assess the quality of the included studies.

Point estimates and standard errors were extracted from individual studies and were combined by the generic inverse variance method of DerSimonian and Laird. In light of the high likelihood of between study variance, we used a random-effect model rather than a fixed-effect model. Statistical heterogeneity was assessed using the Cochran's Q test. This statistical analysis was performed using RevMan 5.3 software.

Results: Out of 713 potentially relevant articles, five studies (three retrospective cohort studies, one prospective study and one case-control study) were identified and included in our data analysis. The pooled risk ratio of CVA in patients with GCA was 1.29 (95% CI, 1.17 to 1.42). The statistical heterogeneity of this meta-analysis was insignificant with an I^2 of 0%.

Conclusion: Our study demonstrated a significantly increased CVA risk among patients with GCA with 29% excess risk compared with general population.

Do Patients with Giant Cell Arteritis Meet the 2011 United Kingdom Department of Health Guidance on Physical Activity?

Joanna Robson[1], Karolina Lada[2], Anne Miller[3], Wilby Williamson[1], Julia Newton[2] and Raashid Luqmani[4], [1]Rheumatology, University of Oxford, Oxford, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]Nuffield Orthopaedic Center, Oxford., Oxford, United Kingdom, [4]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Physical inactivity is the fourth leading risk factor for global mortality accounting for 6% of deaths. Patients with giant cell arteritis (GCA) are at increased risk of cardiovascular disease and psychological stress due to GCA and its treatment (typically high dose glucocorticoids), which may be helped by introducing or maintaining regular physical activity (PA). According to the 2011 United Kingdom Department of Health guidance on physical activity for all adults, including those with a chronic disease, adults should be exercising every day and adults should perform moderate physical activity totaling ≥2.5 hours per week or perform vigorous physical activity totaling ≥75 minutes per week. We hypothesise that patients are not meeting these guidelines.

Methods: We collected information on demographics and presenting features from hospital records of recently diagnosed patients with GCA. We carried out a postal survey including: the Standardised International Physical Activity Questionnaire (IPAQ) and a questionnaire to identify any barriers to participation in PA and to ask about any advice given to patients regarding PA (from healthcare professionals, family and friends). We compared patient participation in exercise with the 2011 guidelines on physical activity.

Results: The response rate was 51/102. Responding participants had a mean age (SD) of 73.6 years (7.3) and 33 [64.7%] were female. The median time from diagnosis of GCA was 17.5 months [interquartile range (IQR) 11-28 months], median CRP before steroids was 30 mg/l [IQR 10-87]. Presenting features included headache (74.5%), polymyalgia rheumatica (51.0%), transient visual loss (21.6%), permanent visual loss (5.9%) and stroke (3.9%). Twenty two (43.1%) patients reported walking for >10 minutes per day, 7 (13.7%) reported moderate PA and 1 (2.0%) reported vigorous daily PA. Eleven (21.6%) performed ≥2.5 hours/week of moderate PA including 1 patient reporting ≥75 minutes of vigorous PA per week. Reasons for limiting their physical activity included: muscle weakness (53%), stiffness (49%), fatigue (37%) and pain (37%). 23.5% had concerns about the safety of exercise. Patients recalled being given advice about physical activity by general practitioners (33.3%), rheumatologists (37.2%), family or friends (45.1% and physiotherapists (23.5%). **Conclusion:** Physical activity has the potential to improve musculoskeletal, cardiovascular and mental health problems in patients with GCA receiving high dose glucocorticoids, but only 21.6 % of patients met national UK guidance on total duration of physical activity. Only 33.3 % patients received exercise advice from their GP and 37.2% from their rheumatologist. Further work is needed to explore the safety and benefits of physical activity in GCA.

Reasons given by patients for limiting physical activity (PA) since diagnosis of giant cell arteritis (GCA), frequency (%)

	Strongly agree	Agree	Disagree	Strongly disagree	Missing
Fatigue	15 (29.4)	19 (37.2)	10 (19.6)	5 (9.8)	2(3.9)
Pain	8 (15.7)	18 (35.3)	17 (33.3)	6 (11.8)	2(3.9)
Muscle weakness	12 (23.5)	27 (52.9)	10 (19.6)	1 (2.0)	1 (2.0)
Stiffness	5 (9.8)	24 (47.1)	16 (31.4)	4 (7.8)	2 (3.9)
Concerns about safety	2 (3.9)	10 (19.6)	25 (49.0)	11 (21.6)	3 (5.9)

Risk of Mortality of Patients with Giant Cell Arteritis: A Systematic Review and Meta-Analysis

Catherine Hill[1], Rachel Black[2], Johannes Nossent[3], Carlee Ruediger[4], Jem Ninan[5] and Susan Lester[6], [1]Rheumatology Unit, The Queen Elizabeth Hospital, Woodville, Australia, [2]Medicine, University of Adelaide, Adelaide, Australia, [3]Medicine, University of Western Australia, WA, Australia, [4]Rheumatology, The Queen Elizabeth Hospital, Woodville, Australia, [5]Rheumatology, Modbury Hospital, Modbury, Australia, [6]Rheumatology, Basil Hetzel Institute, QEH, Woodville South, Australia

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies of mortality associated with GCA have shown conflicting results.We conducted a systematic review and meta-analysis of observational studies to compare the mortality risk in patients with GCA compared to the general population.

Methods: We searched for published studies indexed in MEDLINE and EMBASE and the Cochrane database from inception to June 18, 2015 using the terms “giant cell arteritis” and “temporal arteritis” combined with the terms for death, mortality and survival. A manual search of references of retrieved articles was also performed.

The inclusion criteria were (1) observational studies of biopsy-proven GCA published as original studies to evaluate the association between GCA and mortality (2) comparison of mortality of patients to general population. No language limitation was imposed. Studies published only in abstract form were excluded.

Study eligibility was independently determined by the two investigators. Differing decisions were resolved by consensus with a third reviewer. The quality of each study was independently assessed by the two investigators using Newcastle-Ottawa scale.

Studies were included in the meta-analysis, if numerical data was extractable from the published paper. This included studies in which the standardised mortality ratio (SMR), relative risk (RR's), hazard ratio (HRs) were provided. If data was only presented in graph form, then the graphs were digitized and the HR estimated from a cumulative complementary log-log regression model. The R library metaphor was used to perform a random effects, inverse variance weighted meta-analysis.

Results: Out of 435 potentially relevant articles, 60 full papers were reviewed and subsequently 23 studies were included. This included 21 studies published in English, one in Norwegian and one in French, with publication dates from 1971-2015. There were 5092 cases of GCA (range 19-1787). The majority of studies were from Nordic countries (n=10), North America (5), France (3), UK (2), Spain (1), Israel (1) and Australia (1). Usable data was obtained from 20/23 studies. The combined SMR for GCA mortality indicated a small increase in mortality with GCA: SMR 1.15, 95% CI 1.01, 1.30), p = 0.035. There was evidence of heterogeneity between studies (I^2 = 77%).

Conclusion: This meta-analysis demonstrated that there is an increased mortality associated with GCA, compared to the general population. However, this increase is small, although statistically significant.

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The aim of our study was to determine the frequency and the predictors of long-lasting remission in a cohort of consecutive patients with biopsy-proven GCA.

Methods:

We recruited all patients with a diagnosis of biopsy-proven GCA performed at our Center between 1986 through 2007. Only patients with a follow-up period longer than 6 months were included in the study. A pathologist with expertise in vasculitis reviewed all temporal artery biopsies (TABs). Demographic, clinical and laboratory data at presentation and at each follow-up visit were retrospectively collected. Long-lasting remission was recorded as the date of permanent discontinuation of treatment without recurrence of symptoms and elevation of inflammatory markers for at least 1 year.Logistic regression was used to calculate the predictors for long-lasting remission.

Results:

182 patients had a diagnosis of biopsy-proven GCA in the study period. 156 patients had a follow-up of at least 6 months and represented our study population. The median of follow-up period for the 156 patients included was 80 (range 49-125) months. The median initial dosage of prednisone was 50 mg/day. The median duration required to achieve a maintenance dose of prednisone less than 5 mg/day was 8.5 months (range 7.0-12.0). The median duration required to achieve a permanent steroid discontinuation was 21 months (range 12.5-36) in our cohort. 58 patients (37%) were able to discontinue treatment at least 1 year before the end of follow-up without ever having flares. At the time of the last follow-up visit 72 patients (46%) were still taking glucocorticoids. Predictive variables for long-lasting remission were age less 70 years (0.030) and male gender (p=0.030).

Conclusion:

37% of patients of our cohort were able to remain in persistent treatment-free remission (no flare during the entire follow-up period). Predictive variables for long lasting remission were age less 70 years and male gender.

Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: It has is been demonstrated the safety and efficacy of Methotrexate (MTX) in the treatment of Giant Cell Arteritis (GCA) in clinical trials, but it is important to know the long-term survival of the drug in real life conditions. The purpose of our study was to analyze, in clinical practice conditions, the long-term survival of MTX in patients with GCA. Factors associated to its discontinuation rate were also investigated.

Methods: This is an observational longitudinal study with a maximum follow-up of 20 years. We included GCA patients treated with MTX and followed in outpatient clinic at Hospital Clínico San Carlos, in Madrid from January 1991 until September 2014. Primary outcome: discontinuation of MTX due to: a) adverse drug reaction (ADR), (classified as moderate when the drug was suspended regardless of the impact, and severe when ADR required hospitalization or death); b) inefficacy; c) improvement or remission; and d) patient decision. Covariables analized were: sociodemographic, clinicals and therapy. Incidence rates of MTX discontinuation (IR) per 100 patient-years with their respective 95% confidence interval [95% CI] were estimated using survival techniques. Associated factors to discontinuation were run by Cox regression models.

Results: Eighty two patients with 96 courses of MTX therapy (168.3 patient-years) were included. They were mostly women (75.6%), the mean age at diagnosis was 76.7±7.3 years. The IR of MTX discontinuation was estimated in 38.6 [30.2-49.2]. The IR due to ADR was 21.3[15.4-29.6] most of them infections and not severe (IR if severe ADR: 6.6 [1.6-7.9]). The IR of discontinuation due to improvement was 11.9 [7, 7-18.42] and the IR due to inefficacy was 1.8 [0.6-5.5]. In the multivariate analysis for risk of discontinuation due to inefficacy, the number of relapses was associated to higher risk to discontinuation whereas elevated ESR and higher average doses of corticosteroids had less risk of discontinuation. In the final model for discontinuation due to ADRs, age at diagnosis, male, visual disturbances, cardiovascular and general symptoms at diagnosis had higher risk of discontinuation. However, treatment with MTX at diagnosis had a lower risk of suspension for ADRs. The independent factors that influenced the suspension due to improvement were

fewer recurrences during the follow-up and the younger the age at onset of disease.

Conclusion: MTX treatment for GCA, seems safe and effective in clinical practice. A low incidence of serious adverse events, a low incidence of discontinuation due to inefficacy and a high incidence of discontinuation due to improvement or remission were observed. We have also found several sociodemographic and clinical factors that can modify its survival.

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Large vessel vasculitis (LVV) with aorta involvement are often refractory to common immunosuppressive therapy. Due to the pathogenic role of IL-6 in, we prospectively treated 10 patients with anti-IL6 receptor monoclonal antibody, tocilizumab (TCZ). Efficacy was assessed by clinical and laboratory parameters and by ^{18}F-fluorodeoxyglucose positron emission tomography ([^{18}F]FDG-PET).

Methods: 10 (9 women/1 men) patients with LVV diagnosed by [^{18}F]FDG-PET imaging who were treated with intravenous TCZ at the dose of 8 mg/Kg/monthly. Prednisone (PDN) at stable dose of 10 mg/day or less was allowed and, based on clinical response, the drug was interrupted thereafter. At baseline and after 6 months of therapy, patients underwent [^{18}F]FDG-PET imaging evaluation. Severity of large vessel inflammation was evaluated by using the standardized uptake value (SUV) of [^{18}F]FDG accumulation and the SUVmax normalized for liver [^{18}F]FDG uptake. Anova test was used for comparison between groups. C-Reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were measured. Pain visual analogue scale (VAS) was evaluated before and after treatment and correlated with percentage of SUVmax variation trough linear regression. SPSS was used for statistical analysis.

Results:

The mean age±SD was 59± 15 years. The underlying conditions were: Takayasu arteritis (n=4 cases), giant cell arteritis (GCA) (n=4), and aortitis (n=2). TCZ was the first biologic drugs used in 5 cases (2 aortitis and 3 GCA). In the remaining cases anti-TNF infliximab was prescribed before TCZ (infliximab at the dose of 5 mg/kg/iv/8 weeks/iv).

After 6 months of TCZ [^{18}F]FDG-PET was repeated, at that time all patients experienced clinical improvement with a reduction of erythrocyte sedimentation rate (ESR) from 55 ± 27SD 1st h to 14±14SD 1sth and C-reactive protein from 5±4 SD mg/dl to 0.2±0.1SDmg/dl.

VAS pain improved form 9.03 ± 0.7 SD cm to 2.35± 1.15 SD cm

Before TCZ , 44% of patients had fever and 22% Polymialgia rheumatica who disappeared after 3 months of treatment.

SUVmax before TCZ was 2.83 ± 0.33 SD after TCZ was 2.08± 0,28 with p value= 0,0001. SUV max normalized for liver before TCZ was 1,24± 0.24 after TCZ was 0.87± 0.18 with p value=0,001.

The greatest percentage of SUVmax variation was correlated with the greatest percentage of VAS pain improvement with a statistical significant correlation of 0.0001. PDN interruption was possible in all patients after two infusions of TCZ.

Conclusion: TCZ appears to be effective in patients with large vessel vasculitis refractory to corticosteroids or to anti-TNF drugs. The well- known diagnostic value of [^{18}F]FDG-PET is enriched by the quantitative evaluation of vessel inflammation that is fundamental for the treatment follow-up.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: GiACTA, a randomized, double-blind, placebo-controlled trial of the interleukin-6 receptor alpha inhibitor tocilizumab (TCZ) in patients (pts) with giant cell arteritis (GCA), is the largest trial conducted in GCA to date (NCT01791153) and the first trial in any disease to use a variable-dose, blinded corticosteroid (CS) taper. The hypothesis is that TCZ is effective at achieving sustained, CS-free remission in pts with GCA. For this analysis, 241 of 251 pts had been enrolled. We report baseline characteristics and compare features of pts with newly diagnosed vs relapsing disease.

Methods: The 4 major inclusion criteria are age ≥50 y, historical ESR ≥50 mm/h or CRP ≥2.45 mg/dL, unequivocal cranial GCA or polymyalgia rheumatica (PMR) symptoms, and positive temporal artery biopsy (TAB) or imaging study (positron emission tomography, computed tomography angiography, or magnetic resonance angiography) showing large-vessel vasculitis. There are 4 arms: TCZ 162 mg subcutaneous (SC) QW + 6-mo prednisone taper; TCZ 162 mg SC Q2W + 6-mo prednisone taper; 6-mo prednisone taper only; 12-mo prednisone taper only. Initial prednisone dose (20-60 mg/d) is at investigator discretion. The taper is blinded at doses <20 mg/d. Data are from a live study database.

Results: Of the enrolled pts, 119 (49%) have newly diagnosed GCA and 122 (51%) have relapsing GCA; mean ages are 68 y (range, 52-84) and 70 y (range, 52-85), respectively; 76% are women, and 75% of all pts have met the ACR 1990 criteria for GCA in addition to the GiACTA inclusion criteria. At diagnosis, 61% of newly diagnosed and 57% of relapsing pts had PMR symptoms, 75% and 78% had cranial symptoms, and 20% and 17% had PMR symptoms only. At diagnosis, 57% of newly diagnosed and 59% of relapsing pts had positive TAB; 47% and 41% had positive imaging results. More than one-third of pts had negative TAB results or no TAB performed but positive imaging results. Baseline comorbidities in newly diagnosed and relapsing pts include hypertension (50% and 59%), osteoporosis (12% and 19%), and diabetes (13% and 15%). Mean [SD] baseline BMI is higher in relapsing vs newly diagnosed pts (men, 28.8 [6.1] vs 25.8 [4.2]; women, 26.2 [4.8] vs 24.7 [3.9]). Mean [SD] baseline prednisone dose for newly diagnosed GCA pts was 39.8 mg [13.2] vs 29.8 mg [11.8] for relapsing pts; 18% of newly diagnosed and 5% of relapsing pts entered the study on 60 mg/d prednisone, whereas 8% of newly diagnosed and 39% of relapsing pts entered the study at 20 mg/d.

Conclusion: Demographics of the GiACTA population reflect the epidemiologic profile of GCA (*Arthritis Care Res*. 2015;67:390). Many pts were enrolled based on large-vessel imaging rather than TAB, reflecting the increased use of imaging to diagnose large-vessel vasculitis since development of the 1990 ACR criteria for GCA. The higher baseline prednisone dose in newly diagnosed pts reflects concern about preventing acute damage (eg, vision loss) in that subpopulation; the lower starting dose received by relapsing pts may indicate early detection of relapse and the need to limit toxicity in this CS-exposed subpopulation. Relapsing pts have more comorbidities, likely due to long-term CS treatment for GCA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

To report the French experience on the efficacy and safety of tocilizumab (TCZ) in patients with giant cell arteritis (GCA) and outcome after treatment withdrawal.

Methods:

A retrospective multicenter study included patients treated with TCZ for their GCA. Treatment efficacy was evaluated at a clinical and biological level. Side effects and outcome after treatment withdrawal were also recorded.

Results:

Thirty-four patients (27 women and 7 males) aged 70.5±8.2 (mean±SD) were included. Diagnosis of GCA was based on the ACR criteria (30 patients) and/or on imaging abnormalities suggestive of GCA (8 patients). Treatment included glucocorticoids in all patients and another immunosuppressant before TCZ introduction in 20/34 patients (59%). TCZ (8 mg/kg monthly) was prescribed after a mean disease duration of 18 months (0-107) and patients were treated for a mean of 6.4±4.5 months. It was effective in all but 6 patients who still had mild symptoms while CRP was reduced from 40.4±45.6 mg/L to 1.5±1.8 mg/L ($p<0.0001$) and glucocorticoids were tapered from 26.3±13.8 to 10.3±8.3 ($p<0,0001$). One patient died from septic shock and TCZ was stopped in 3 patients for severe adverse events (tuberculous pericarditis, liver cytolysis and neutropenia). Among the 23 patients who stopped treatment (planned medical decision in 2O cases, side effects in 3 cases) eight patients experienced relapses occurring after a mean of 3.5±1.3 months and TCZ was started again in 5 of them.

Conclusion:

Under TCZ therapy, patients with GCA have a rapid and sustained improvement. However, side effects were noticeable and should be kept in mind in these patients. Questions remain regarding the suspensive nature of this treatment and this should be specifically addressed in future studies.

Increased Extracellular Water Measured By Bioimpedance Analysis in Polymyalgia Rheumatica Patients – Sign of Volume Overload

Florian Günther[1,2], Boris P. Ehrenstein[2], Martin Fleck[1] and Rainer Straub[1], [1]Department of Internal Medicine I, University of Regensburg, 93042 Regensburg, Germany, [2]Department of Rheumatology/Clinical Immunology, Asklepios Medical Center, 93077 Bad Abbach, Germany
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Water retention is a typical feature of acute inflammatory episodes, chiefly implemented by the sympathetic nervous system (SNS) and the hypothalamic-pituitary-adrenal (HPA) axis. This is an important compensatory mechanism counteracting expected water loss, for example due to sweating. Both SNS and HPA axis are activated in polymyalgia rheumatica (PMR). As retention mechanisms may similarly apply in this disease, we hypothesized increased water retention in PMR.

Methods: Using bioimpedance analysis body composition was investigated in 56 healthy controls and 28 treatment-naive PMR patients. PMR patients were matched to healthy controls for age and weight. All PMR patients satisfied the 2012 EULAR/ACR classification criteria for PMR (including musculoskeletal ultrasound). 28 PMR patients were tested before and after 10 days of glucocorticoid based therapy (CRP and ESR markedly decreased). Correlations of extracellular water, systolic and diastolic blood pressure with parameters of inflammation were investigated in PMR patients as well as in healthy controls.

Results: Fat mass (fat free mass) was higher (lower) in PMR patients than controls, indicating sarcopenia and cachectic obesity in PMR patients (mean ± SD: 38.6 ± 6.7 versus 24.1 ± 5.4% of body weight, $p < 0.001$; 61.3 ± 6.7 versus 75.9 ± 5.4%, $p < 0.001$). Extracellular water (ECW) was markedly higher in PMR patients than controls (mean ± SD: 49.5 ± 6.2% versus 37.8 ± 2.6% of total body water, $p < 0.001$, Figure 1). Systolic and diastolic blood pressure were higher in PMR patients compared to controls, even before glucocorticoid treatment was initiated (mean ± SD: 146.9 ± 18.3 mmHg versus 119.3 ± 5.4

mmHg, p < 0.001; 84.4 ± 12.8 mmHg versus 78.0 ± 1.6 mmHg, p < 0.001). Extracellular water levels did not change in PMR patients upon 10 days of intensified treatment.

Conclusion: This study demonstrated increased extracellular water as sign of fluid overload in patients with PMR. These results indicate that volume changes are imprinted as long-lasting mechanisms as water distribution is not affected by short-term anti-inflammatory therapy.

Sonographic Scoring of the Synovial Components in the Shoulder Revealed That Shoulder Synovitis in PMR Patients Is Milder Than That in Elderly-Onset RA Patients with PMR-like Onset

Takeshi Suzuki, Division of Allergy and Rheumatology, Japanese Red Cross Medical Center, Tokyo, Japan; Division of Rheumatology, Mitsui Memorial Hosipital, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Through the clinical experience, we noted that there seems to be differences not in the kind or the frequency but in the severity of synovial inflammation between polymyalgia rheumatica (PMR) and elderly-onset rheumatoid arthritis with PMR-like onset (polymyalgic-EORA). We compared the severity of the shoulder syonvitis between PMR and polymyalgic-EORA using semi-quantitative US scoring of the synovial components, and also explored the application of the scoring system to the differential diagnosis between the two diseases.

Methods: We analyzed consecutive records of 15 PMR patients and 15 polymyalgic-EORA patients. All of them were examined by US before treatment-start. The severity of tenosynovitis of the long-head of the biceps (LHB), bursitis of shoulder including subdeltoid, subacrominal and subcoracoid bursitis, and joint synovitis of grenohumeral joint (GHJ) were subjectively scored for grey-scale (GS) and power Doppler (PD) on a four-point scale: 0 = absent, 1 = mild, 2 = moderate or 3 = severe. Sum of the scores of one shoulder was defined as "shoulder synovitis score (SSS)", and sum of the scores of both shoulders was defined as "patient-shoulder synovitis score (PSSS)". The correlation between PSSS and serum markers was assessed. Indices contributing to discriminating between the two diseases were explored.

Results: There was a tendency that synovitis in each synovial component in the shoulder in PMR was milder than that in polymyalgic-EORA, while there was no difference in the frequencies of synovitis (Table). There were statistically significant differences in the PD-grade of LHB, GS-grade of LHB, bursitis and GHJ. There was also a significant difference in GS-score of bursitis (0.40 ± 0.62 vs 1.2 ± 1.2, p=0.003), PD-score of bursitis (0.37 ± 0.72 vs 1.0 ± 1.2, p=0.015) and SSS (4.0 ± 2.2 vs 6.2 ± 4.6, p=0.023) (mean ± SD, PMR vs polymyalgic-EORA). PSSS in PMR tended to be lower than that in polymyalgic-EORA (7.7 ± 3.8 vs 12.3 ± 8.6, p=0.072).

PSSS were positively correlated with serum MMP3 (|R|=0.707, p< 0.0001). Both PSSS (|R|=0.602, p= 0.0175) and MMP3 (|R|=0.463, p= 0.095) were positively correlated with serum CRP in polymyalgic-EORA but not in PMR. The ratio of PSSS to CRP (mg/dL) (PSSS/CRP) was significantly lower in PMR than in polymyalgic-EORA (1.35 ± 1.63 vs 5.55 ± 4.46, p=0.003). The ratio of MMP3 (ng/mL) x10^4 to CRP (MMP3/CRP) was significantly lower in PMR than in polymyalgic-EORA (32.2 ± 35.9 vs 101 ± 87.1, p=0.006). These two ratios may be useful for discriminating between the two diseases, because ROC analysis for PSSS/CRP and MMP3/CRP demonstrated areas under the curve of 0.902 and 0.852, respectively.

Conclusion: Semi-quantitative US scoring of the synovial components in the shoulder revealed that shoulder synovitis in PMR is milder than that in EORA patients with PMR-like onset. The application of the scoring system may be useful for discriminating between the two diseases.

Diagnosis	PMR n=30					EORA n=30

Interspinous Bursitis Evaluation By Ultrasound Is Very Useful for Diagnosis of Polymyalgia Rheumatica

Kensuke Kume[1], Kanzo Amano[2], Susumu Yamada[1], Toshikatsu Kanazawa[3], Hiroshi Komori[1], Kazuhiko Hatta[4] and Noriko Kuwaba[5], [1]Rheumatology, Hiroshima Clinic, Hiroshima, Japan, [2]rheumatology., hiroshima clinic, Hiroshima, Japan, [3]rheumatology, hiroshima clinic, hiroshima, Japan, [4]Rheumatology, Hatta Clinic, Kure, Japan, [5]Medical Research, Sanki Clinical Link, Hiroshima, Japan
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is a common inflammatory disease of the elderly, and 2012 provisional classification criteria were suggested, however it is provisional and not meant for diagnosis purpose[1)]. Ultrasound(US), MRI and other modalities were often detected interspinous bursitis in patients with PMR[2)]. To develop 2012 provisional classification criteria, adding interspinous bursitis evaluation by US.

Methods: This is a prospective cohort study. Candidate criteria were evaluated 117 patients with new onset untreated PMR, and 128 patiens non-PMR comparison subjects with conditions mimicking PMR. We compared the sensitivity and specificity of 2012 provisional classification criteria with 2012 provisional classification criteria, adding interspinous bursitis evaluation by US. US evaluation was checked cervical and lumbar spine, and if at least one interspinous bursitis was detected, it was calculated 1 point. Total score(interspinous bursitis evaluation by US score plus 2012 provisional classification criteria with US score) was 5 or more, it is categorised as PMR.

Results: 2012 provisional classification criteria scoring system had 68% sensitivity and 79% specificity. Adding interspinous bursitis by US had significantly increased sensitivity to 86 %($p<0.05$), and not significantly decreased specificity to 76 %($p=0.47$) Surprisingly, PMR patients without cervical or lumbar pain had interspinous bursitis with high prevalence. (74%) No correlation was found between interspinous bursitis by US and spontaneous or provoked pain. ($r=0.12$, $P=0.45$)

Conclusion: Interspinous bursitis by US is very sensitive in patients with PMR. Interspinous bursitis by US should be added classification criteria for PMR. If patients were suspected of PMR, interspinous bursitis by US should be performed with or without cervical or lumbar pain.

Background/Purpose: To characterise the incidence and intensity of ^{18}Fluorodeoxyglucose (^{18}FDG) uptake on whole body PET/CT in untreated patients with newly diagnosed Polymyalgia Rheumatica (PMR).

Methods: Patients with newly diagnosed PMR according to the 2012 EULAR/ACR Classification Criteria[1] were prospectively recruited. A whole body scan from skull vertex to toes (including dedicated hand views) was performed at baseline using a Phillips TF PET/CT machine in all untreated patients. A range of demographic, clinical and laboratory data were collected. Images were reviewed with Medview software by an experienced Nuclear Medicine Physician. Both qualitative and semi-quantitative (standardised uptake value maximum [SUV_{max}]) analysis of joint and vascular ^{18}FDG uptake were performed. Statistical analyses were undertaken using Stata 13.0 (Statcorp, College Station, TX, USA).

Results: Thirteen patients with PMR were recruited. Mean age was 68.47 years, there was a slight male predominance (53.85%) and all were Caucasian. All patients reported bilateral shoulder pain at presentation, but hip symptoms were less common (69.23%). Disease activity was high (mean PMR-AS 80.29) and the median HAQ-DI score was 2.125. In addition to involvement of the shoulder capsule (11/13, 84.62%), hip capsule (11/13, 84.62%), trochanteric bursae (12/13, 92.31%) and interspinous bursae (10/13, 76.92%), a high incidence of ^{18}FDG uptake at the ischial tuberosities (12/13, 92.31%) and knee capsule (9/13, 69.23%) was seen. Involvement of the palmar aspect of the hands/wrists and feet was also observed in 5/13 (38.46%) and 2/13 (15.38%) cases respectively. With respect to SUV_{max} at sites of ^{18}FDG uptake, the highest mean result occurred at the ischial tuberosities (4.38) followed by the shoulder capsule (3.94), interspinous bursae (3.62) and knee capsule (3.48).

Conclusion: Patients with newly diagnosed, untreated PMR exhibit most intense ^{18}FDG uptake at the ischial tuberosities on whole body PET/CT. Frequent involvement of peripheral joints, especially the knee capsule, is also observed.

Figure 1: Intense ^{18}FDG uptake at the ischial tuberosities in a patient with newly diagnosed, untreated PMR.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Abnormalities in B-cell population distribution were recently reported in polymyalgia rheumatica (PMR) and giant cell arteritis, which improved with glucocorticoids. Our objective here was to analyze the subsets of lymphocytes in patients with PMR and to follow their evolution after tocilizumab treatment.

Methods*:*

The TENOR study was an open labelled prospective trial including patients with recent PMR fulfilling the Chuang criteria. The disease duration was less than 12 months, and patients had active disease and were glucocorticoids (GCs) free. Patients with suspected giant cell arteritis were excluded. Patients were treated with tocilizumab infusions (week 0, 4 and 8) without GCs (period 1) and then by low-dose GCs from week 12 to week 24 (period 2). All patients were in clinical remission at the end of period 1 (tocilizumab monotherapy). Peripheral blood lymphocyte profiling was performed by multicolor flow cytometry in 18 patients at week (W) 0 (before first tocilizumab infusion), W2, W12 and W24. They were compared to 16 sex and age-matched healthy controls.

Results*:*

At baseline, total lymphocyte (p=0.31), T cell (p=0.46), B cell (p=0.08) and NK cell (p=0.905) levels were similar between PMR patients and controls. Transitional B cells ($CD24^{high}$, $CD38^{high}$) and mature-naïve B cells ($CD24^{low}$, $CD38^{low}$) were lower in patients with PMR than in controls, 3±6 vs 6±6 per mm^3 (p=0.01) and 46±41 vs 92±53 per mm^3 (p=0.01), respectively. After tocilizumab, total lymphocyte count slightly increased (1739 ± 539/mm^3 at W0, 2030 ±591/mm^3 at W2, 2068 ±775/mm^3 at W12, and 2031 ± 584/mm^3 at W24, p<0.01). The absolute number of T cells and $CD8^+$ T cells rose between W0 and W24, from 1295 ±405/mm^3 to 1541 ±429/mm^3 (p=0.03) and from 357 ±215/mm^3 to 446 ±328/mm^3 (p=0.04) respectively, but proportions were unchanged. The absolute number and proportion of $CD4^+$ T cells and NK cells were unaffected by the treatment. In contrast, both absolute number and proportion of B cells increased between W0 and W12, respectively from 176±105/mm^3 to 260 ±192/mm^3 (p=0.004) and from 10.1% to 13.0% (p<0.001). Among B-cell subsets, these modifications were mainly attributable to the variations of the memory compartment. Unswitched (IgD+CD27+) and switched (IgD-CD27+) memory B-cell absolute number and proportions significantly increased after tocilizumab (p<0.001).

Conclusion:

The drastic clinical improvement following tocilizumab monotherapy in PMR patients is paralleled by an increase in peripheral blood memory B cells. These observations suggest that B cells are involved in disease pathophysiology, and that IL-6 blockade could restore B-cell homeostasis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: polymyalgia rheumatic (PMR) is a chronic inflammatory disorder of unknown etiology that affects elderly people. Glucocorticoids (GC) are still the mainstay of therapy for PMR. Despite this treatment, the disease may relapse or GC dosage cannot be tapered or alternatively, some patients are GC-refractory. Methotrexate (MTX) may be helpful in these cases, but this medication gave contradictory results. Anti TNFa are not effective in PMR. Although the pathogenesis of PMR is unknown, overproduction of proinflammatory cytokines can contribute to its development. It has recently been suggested that IL-6 is probably involved in PMR and giant cell arteritis (GCA). Tocilizumab (TCZ), an anti- IL-6 receptor antibody, gave promising results in single cases of GCA or in open-label studies. **Results** on the clinical efficacy of TCZ in pure or isolated PMR are limited.

Objectives: to report our experience (efficacy and safety) of TCZ in the treatment of patients with isolated PMR who had an inadequate response to GC and/or to other conventional therapies.

Methods: a call for observations of all case of patient with PMR who received TCZ was sent to the members of the French specialist network "Club Rhumatismes & Inflammation" (CRI) (rheumatologist and internal medicine). Patients must satisfied the Healey criteria for PMR and had isolated or predominant PMR clinical features.

Results: 7 cases were declared during a 12 months period. Patients included were 4 men and 3 women, mean age 73.4 ± 7.9 years, disease duration 2.3 ± 1.6 years, mean duration of GC treatment before starting TCZ: 16.1 ± 9.2 months. Clinical features were PMR symptoms for all and only one patient had proved associated GCA but without related clinical manifestations. All the patients were GC refractory requiring a daily dosage of prednisone ranging from 10 to 20 mg. Beside GC and before TCZ administration, patients had received MTX (6 cases), leflunomide (1 case) or a TNFa blocking agent (2 cases). TCZ was given as a monthly infusion (8 mg/kg). The mean number of infusions given were 6.4(range: 3-17). All the patients responded to the treatment with an improvement of the PMR-AS score (score before and after TCZ: 32.3 and 7.8, respectively), and CRP levels (CRP before and after TCZ: 56.9 and 4.6 mg/L). GC dosage was tapered from 15- 20 mg to 2.5-5 mg (5 cases) or stopped (2 cases). Clinical and laboratory improvement were obtained within the first 3 months after the onset of TCZ. The safety was excellent without any adverse event.

Conclusion: As previously reported in GCA, TCZ seems very effective in PMR patients who were unable to taper GC, with a prompt response and a GC-sparing effect. This biological agent may be adequately evaluated in a randomized controlled trial in order to determine its place in the treatment of PMR.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids (GCs) are the cornerstone treatment of polymyalgia rheumatica (PMR) but induce several adverse events.

Methods:

Objectives: To evaluate efficacy and safety of tocilizumab as first line therapy in PMR.

Design: Prospective open label study (ClinicalTrials.gov: NCT01713842).

Setting: 2 university hospitals in France.

Patients: 20 glucocorticoids (GCs) naives patients with recent PMR fulfilling the Chuang criteria, with a disease duration of less than 12 months and an active disease ((PMR-AS)> 10) were included. Patients with suspected giant cell arteritis were excluded.

Intervention: All patients received tocilizumab infusions (week 0, 4 and 8) without GCs (period 1) and then oral GCs from week 12 to week 24 according to the PMR-AS at week 12 (patients with PMR-AS£10 were treated by 0.15mg/kg whereas those with PMR-AS>10 received 0.30 mg/kg). The primary endpoint was the response to tocilizumab based on PMR-AS£ 10 at week 12. Secondary endpoints were the PMR-AS response at weeks 2,4,8,12,16, 20 and 24 and the GCs sparing effect.

Results:

At inclusion, median PMR-AS was 36.6 (IQR: 30.4-43.8). At week 12, all patients reached the primary end point and were included in the low dose corticosteroid group. Median PMR-AS at week 12 and 24 were respectively 4.5 (IQR: 3.2-6.8) p< 0.001 and 0.95 (IQR: 0.4-2) p<0.001. No treatment rescue was necessary. Improvement was moderate by ultrasound, MRI and TEP-CT. The infusions of tocilizumab induced a GCs sparing effect of 70.2%. The sensitivity analysis based on a determined dosage of GC of 15mg/day without taking account of the patient's weight found similar results. Most frequent adverse events were transient neutropenia and leucopenia reported in 3 and 5 patients. One patient received only one infusion of tocilizumab due to adverse event.Limitations**:**Infusions were done every 4 weeks and not every 2 weeks as in systemic disease. This could explain a slower response than supposed with GCs.

Conclusion:

Monotherapy with Tocilizumab has a major efficacy in recent PMR and allows a sparing corticosteroid effect.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyalgia rheumatic (PMR) is an inflammatory rheumatic disease characterized by aching and morning stiffness of body, which is seen almost exclusively in adults over the age of 50. Glucocorticoid has been mainstay of the treatment, and methotrexate is generally recommended in patients resistant to initial steroid therapy. However, since several studies have shown greater toxicity of methotrexate in elderly patients, searching for less toxic immunosuppressive agent is warranted. Mizoribine (MZR) is an immunosuppressive agent which inhibits lymphocyte proliferation via inhibitory effect on the synthesis of inosine monophosphate dehydrogenase. While its efficacy and well tolerability for rheumatoid arthritis, systemic lupus erythematosus, autoimmune nephritis and suppression of rejection in renal transplantation is well established, few studies have examined the use of MZR for PMR.

Methods: We extracted all the patients who were given MZR for treatment of PMR during the period of July 2009 to June 2014. Retrospective medical charts review were performed to check the patients' background, duration and drug survival rate of MZR use, and reasons for discontinuation. Serum inflammatory markers and dose of corticosteroids at the time of last follow-up were compared those at the time of MZR initiation.

Results: Forty-seven PMR patients (16 male and 31 female, mean aged 73.5±7.9 year old) were treated by MZR during the study period. Mean disease duration at the time of MZR initiation and mean duration of MZR use are 415±61 days and 423±345 days, respectively. Twelve patients had discontinued MZR, and the reasons of discontinuation are as follows: remission (4 paitents), ineffectiveness (4patients), and adverse reaction (4 patients). The dose of PSL at the time of last follow-up was significantly lower than the PSL dose at the time of MZR initiation.

Conclusion: Mizroribine shows efficacy and well-tolerability in patients with polymyalgia rheumatica.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Aortitis is often refractory to conventional immunosuppressive (IS) therapy. The use of biological therapy, such as tocilizumab (TCZ) and anti-TNFα agents have been reported.

Our aim was to compare the efficacy of TCZ with anti-TNFα therapy in patients with aortitis.

Methods:

Retrospective multicenter study of patients with aortitis refractory to traditional IS agents.

Results:

We studied 44 patients (36 W/8 M; 51±19 years); 25 with TCZ and 19 with anti-TNFα agents (IFX=14, ADA=3, and ETN=2). Baseline features of patients on TCZ compared to the anti-TNFα group (always in this order) showed a) mean age: 58±20 vs 42±13 years (p=0.003), b) women: 84% vs 79%, (p=0.97), c) underlying conditions: Takayasu arteritis, 8 vs 11 cases (p=0.08); giant cell arteritis, 15 vs 2 (p=0.0025); relapsing polychondritis, 1 vs 1 (p=0.59); ulcerative colitis, 0 vs 1 (p=0.88); Crohn's disease, 0 vs 1 (p=0.88); Behçet's disease, 0 vs 1 (p=0.88); sarcoidosis, 0 vs 1 (p=0.88); psoriatic arthritis, 0 vs 1 (p=0.88); and idiopathic aortitis, 1 vs 0 (p=0.88) d) mean of previous traditional IS agents (1.1 vs 1.7, p=0.069) and biological therapies (0.3 vs 0.1, p=0.23). After 3 months of treatment, most patients in both groups had experienced a clinical and acute phase reactants improvement, as well as a reduction of the corticosteroid dose. This favourable response was maintained over time (Table). The improvement observed by imaging techniques was similar in both groups. After a median follow-up of 12 [9-17] vs 16 [12-36] months (p=0.014), TCZ was withdrawn due to severe neutropenia (n=1); recurrent pneumonia (n=1); cytomegalovirus infection (n=1) and systemic lupus erythematosus (n=1). Other adverse effects were thrombocytopenia (n=1) and infusional hypotension (n=1). One patient died due to a stroke in the setting of an infective endocarditis, and another one discontinued TCZ because of inefficacy. In the anti-TNFα group, 3 patients on IFX discontinued due to inefficacy (n=1), recurrent pneumonia (n=1) and severe infusional reaction (n=1).

Conclusion:

Biological therapy appears effective and relatively safe in patients with aortitis refractory to traditional IS drugs. In this series, TCZ seems to be slightly more effective than anti-TNFα agents.

TABLE

	TCZ (n= 25)	anti-TNFα (n= 19)	p
Partial clinical improvement N; %#			
At 3 months	22; 88% (25)	10; 55% (18)	0.09
At 6 months	18; 90% (20)	11; 69% (16)	0.022

Corticosteroid Use in Idiopathic Aortitis: A Systematic Review

Nancy Maltez[1] and Nataliya Milman[2], [1]Internal Medicine, University of Ottawa, Ottawa, ON, Canada, [2]Division of Rheumatology, University of Ottawa, Ottawa, ON, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Idiopathic aortitis (IA) is a poorly defined entity with no specific pathological or clinical criteria for its classification or diagnosis, except for the presence of aortic inflammation and absence of clinical features of another systemic condition. Most of the present knowledge about IA comes from retrospective series of cases with pathologically identified aortitis. The objective of this systematic review was to clarify available data regarding outcomes in patients treated with corticosteroids and those without treatment.

Methods:

Data sources: Search strategy using terms “aortitis” and “idiopathic/isolated” identified published articles and abstracts using MEDLINE and EMBASE databases.

Study selection: Inclusion criteria required that cases of idiopathic aortitis be confirmed by pathology. Abstracts and case reports were excluded except for abstracts that complemented published manuscripts; reviews were used for triangulation. Authors were contacted for clarifications when required.

Data extraction: Data were extracted independently by two reviewers. Our primary goal was to compare outcomes between patients treated with corticosteroids and untreated patients. The primary outcomes included: development of new vascular lesions, clinical complications, delayed diagnosis of other rheumatological diseases and vascular death. Secondary outcomes included preoperative symptoms, ESR/CRP levels and presence of branch vessel disease.

Results:

Search yielded 262 records of which 10 fulfilled inclusion criteria. The majority of studies were retrospective. Even the few studies that reported on treatment status described very few events of interest: Miller *et al* described no new vascular lesions in two treated patients versus one lesion in 19 untreated patients while Clifford *et al* reported 2 new vascular lesions in 11 treated and 27 in 54 untreated patients. Wang *et al* reported one new vascular lesion (new aortic aneurysm) in the treated group and none in the untreated patients. Two studies described the need for re-operation, reported in two treated and none of the untreated patients in each of the studies. Finally, Liang *et al* reported 4 deaths (of unspecified cause) among untreated patients and none in the treated group.

Conclusion:

Few studies report clinical outcomes in patients diagnosed with idiopathic aortitis treated with corticosteroids. Consequently, there exists a lack of data to guide therapy and long term management of these individuals. The retrospective nature and small cohorts from which data is extracted make it difficult to draw conclusions. Future studies are required to better understand outcomes.

Large Vessel Involvement By IgG4-Related Disease

Cory Perugino[1], Zachary Wallace[1] and John H. Stone[2], [1]Rheumatology, Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

IgG4-related disease (IgG4-RD) is a systemic fibro-inflammatory condition of uncertain etiology. Reports have described inflammatory aortitis and peri-aortitis in the setting of retroperitoneal fibrosis (RPF) but have not adequately distinguished between these two manifestations. The frequency, radiologic features, and response of vascular complications to B cell depletion remain poorly-defined. We describe the clinical features, radiology findings, and treatment response in a large cohort of patients with IgG4-RD affecting the large vessels.

Methods:

All patients had biopsy-proven IgG4-RD. Clinical records of all patients diagnosed with IgG4-RD in our Center were reviewed. All radiologic studies were reviewed independently by two vascular radiologists. We distinguished between primary large blood-vessel inflammation and secondary vascular involvement, defined as disease related to the effects of adjacent inflammation (e.g., peri-aortitis associated with retroperitoneal fibrosis).

Results:

Of the 160 IgG4-RD patients in this cohort, 36 (22.5%) had large-vessel involvement. The mean age of the patients with large-vessel manifestations of IgG4-RD was 54.6 years. Twenty-seven (75%) were male and nine (25%) were female. Fifteen patients (42%) had primary involvement of their vasculature by IgG4-RD (IgG4-related vasculitis). Inflammatory aortic aneurysms (IAA), which affected eleven patients - 7% of the cohort overall - were observed in the abdominal aorta in seven cases, the thoracic aorta in seven, and both the thoracic and abdominal aorta in three. IAA of either the thoracic or abdominal aorta or both comprised the most common manifestation of IgG4-related vasculitis. Three patients had aortic dissection or contained perforation. Peri-aortitis in the setting of RPF accounted for 25 of 27 cases (93%) of secondary vascular involvement by IgG4-RD. Six patients demonstrated evidence of both primary and secondary blood vessel involvement. Twenty-two of the 36 patients with vascular disease were treated with rituximab and 62.5% showed stabilized or improved radiologic findings following treatment.

Conclusion:

IgG4-RD is a unique, distinctive and treatable cause of large-vessel vasculopathy, comprising both primary vasculitis and secondary vascular involvement. The most common manifestation of IgG4-related vasculitis is inflammatory aortic aneurysm. Peri-aortitis with sparing of the aortic wall is the most common secondary vascular manifestation.

Plasma Endothelin-1 parallels the vasoconstriction phase in Reversible Cerebral Vasoconstriction Syndrome

Background/Purpose: Cerebral vasoconstriction is thought to be the underlying pathogenetic mechanism of Reversible Cerebral Vasoconstriction Syndromes (RCVS). However, mediators of the syndrome at molecular levels have not been elucidated. We previously reported that Endothelin-1 (E-1), a potent vasoconstrictor, is increased during the acute vasoconstrictive (ictal) phase in RCVS as compared to matched controls. Herein, we report on the levels of E-1 in the resolution phase of RCVS as compared to the ictal phase.

Methods: 14 paired samples from 7 patients were identified from the Cleveland Clinic prospective RCVS registry, who had blood samples collected during the ictal and resolution phases of RCVS symptoms. Further, E-1 levels were measured from 7 healthy controls of similar race and gender, who were then matched to the RCVS patients using a one-to-one Greedy matching algorithm based on age. Plasma E-1 levels were measured using Quantikine Endothelin-1 enzyme-linked immunosorbent assay kit (from R& D Systems) according to the user manual. Average E-1 levels at the ictal phase of RCVS were compared to the average E-1 levels during the resolution phase and matched healthy patients using mixed effects modeling to account for matched group clustering.

Results: The RCVS and control groups were well matched with respect to age and sex (table 1). During RCVS ictal phase, average plasma E-1 level (pg/ml) was significantly higher compared to resolution phase E-1 levels (2.063 ± 0.593 vs. 1.483 ± 0.278, $p = 0.037$). There was no difference between E-1 levels of RCVS at the resolution phase and healthy matched controls (1.483 ± 0.278 vs. 1.171 ± 0.278, $p = 0.312$). Two RCVS patients (RCVS 4 and 6) did not have complete radiologic resolution of vasoconstriction at follow-up testing. When excluding these 2 patients, the difference between the average E-1 levels during RCVS ictal phase and resolution phase was significantly higher (2.317 ± 0.487 vs. 1.377 ± 0.223, $p = 0.004$), while average E-1 levels at the resolution phase remained not significantly different compared to healthy matched controls (1.377 ± 0.223 vs. 1.115 ± 0.319, $p=0.262$).

Conclusion: Plasma Endothelin-1 (E-1) levels decrease to normal levels during the resolution phase of RCVS. This is more apparent in patients with complete resolution of radiological cerebral vasoconstriction, compared to those with persistent radiological vasoconstriction. These results suggest a major role of E-1 in the pathogenesis of RCVS.

Table 1

RCVS Patient	Age	Sex	RCVS Ictal Phase E-1 level (pg/ml)	RCVS Resolution Phase E-1 level (pg/ml)	Control Patient	Age	Sex	E-1 level (pg/ml)

Imaging Findings of Cerebral Amyloid Angiopathy, Abeta-Related Angiitis (ABRA) and Cerebral Amyloid Angiopathy-Related Inflammation: A Single Institution 25 Year Experience

Carlo Salvarani[1], Jonathan M Morris[2], Caterina Giannini[2], Teresa J. H. Christianson[3], Robert D. Brown Jr.[4] and Gene G. Hunder[5], [1]Rheumatology, Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy, [2]Mayo Clinic, Rochester, MN, [3]Division of Biomedical Statistics & Informatics, Mayo Clinic, Rochester, MN, [4]Department of Neurology, Mayo Clinic, Rochester, MN, [5]Dept Internal Med/Rheum, Mayo Clinic, Rochester, MN
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Vasculitis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the role of imaging in differentiating cerebral amyloid angiopathy (CAA) with and without inflammation.

Methods: We studied 54 patients seen over 25 years with pathological evidence of CAA with or without vascular inflammation and with available neuroimaging at the time of diagnosis. All pathological specimens were reviewed by one neuropathologist to evaluate the presence and distribution of inflammation associated with amyloid. All available neuroimaging findings were reviewed by a neuroradiologist. Clinical data were recorded

Results: Radiologic findings at diagnosis were available in 27 patients with CAA without inflammation, 22 with Aβ-related angiitis (ABRA) and 5 with CAA-related inflammation (CAA-RI). On MRI, leptomeningeal disease alone or with infiltrative white matter was significantly more frequent at presentation in patients with ABRA or CAA-RI compared to those with CAA (8 of 27, 29.6% vs 1 of 27, 3.7%, p = 0.02; and 11 of 27, 40.7% vs 1 of 27, 3.7%, p = 0.002, respectively), while lobar hemorrhage was more frequent in patients with CAA (17 of 27, 62.3% vs 2 of 27, 7.4%, p = 0.0001). Overall, leptomeningeal involvement at presentation was present in 70.4% (19 of 27) of patients with ABRA or CAA-RI and in only 7.4% (2 of 27) of patients with CAA (p = 0.0001). The sensitivity and specificity of leptomeningeal enhancement to identify patients with ABRA or CAA-RI were 70% and 93% respectively, while the positive likelihood ratio (LR) was 9.5. The sensitivity and specificity of intracerebral hemorrhage to identify patients with CAA were 63% and 93% respectively, while the positive LR was 8.5. Prior microhemorrhages at the grey white junction on GRE and/or SWI sequences were more frequently observed in patients with ABRA or CAA-RI compared to those with CAA (19 of 27, 70.4% vs 10 of 27, 37%, p = 0.03).

Conclusion: Leptomeningeal enhancement and lobar hemorrhage at presentation may enable differentiation between CAA with and without inflammation. SWI or GRE image aid in determining the correct diagnosis of ABRA or CAA-RI and aid in the decision regarding treatment.

Electronic Patient Reported Outcome Measures in Systemic Lupus Erythematosus : A Potential Disease Modifying Impact on the Management of Disease Activity Flares and Damage Accrual

Yasser M. El Miedany[1], Sami Bahlas[2], Maha El Gaafary[3], Sally Youssef[4] and Ihab Ahmed[5], [1]Rheumatology, Darent Valley Hospital, Dartford, United Kingdom, [2]Medicine, King Abdulaziz University, Jeddah, Saudi Arabia, [3]Community, Environmental and Occupational Medicine, Ain Shams University, Abbassia, Egypt, [4]Rheumatology and Rehabilitation Departmennt, Ain Shams University, Cairo, Egypt, [5]Medicine, Cairo University, Cairo, Egypt

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: ACR Plenary Session II: Discovery 2015
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose:

Patient reported outcomes measures (PROMs) are changing the landscape in rheumatology care. Electronic PROMs (ePROMs) is a new patient-centric model of collaboration that fully engages patients in the decision making and governance to optimize controlling their disease activity and its management.

Objectives. To assess the value of ePROMs in the assessment and management of SLE disease activity flares observed over a 24-month period; its association with adherence to therapy as well as organ damage adjusted for potential confounding factors.

Methods:

A randomized, controlled crossover study carried out over 24-month duration. 147 SLE patients meeting the revised ACR criteria were enrolled. Disease activity was assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) whereas organ damage was scored using the SLICC/ACR Damage Index (SDI). In the first 12-month, the patients were assessed once every 3-months. Prior to their assessment in the clinic, each patient completed a PROMs questionnaire (paper format) [1]. Flare was defined as an increase ≥4 points in the SLEDAI between two clinic visits. At 12-months, the patients were randomized into a cohort of 73 patients who continued their care in the same style and 74 patients who completed an online ePROMs questionnaire on monthly basis for another 12-month period. The patients were given an appointment in an SLE hot clinic should their SLEDAI shows an increase of more than three points, management was adjusted accordingly. Otherwise every patient was seen every 3-months. The data captured were then retrospectively analysed at the end of the 24-month study period to determine the association between the number of flares and damage accrual. Adherence to therapy was also assessed at the end of the study.

Results:

At the end of the first year of the study, the mean of SLEDAI and SDI were 8.72 (6.1) and 1.9 (2.2) respectively. At the end of the second year the mean SLEDAI and SDI in the ePROMs cohort was 3.1 (2.6) and 1.2 (1.3) respectively, whereas in the control group the SDI an SLEDAI mean was 7.63 (6.7) and 1.8 (2.3) respectively ($p< 0.01$). Adjusting for possible confounding variables, the number of flares, regardless of their severity, was associated with damage accrual (OR 2.03, 95% CI 1.34 to 2.83, $p<0.001$). Adherence to therapy was significantly ($p<0.1$) higher in the ePROMs group whereas stopping DMARDs for intolerability was significantly ($p<0.01$) higher in the control group at 24-months of treatment.

Conclusion:

ePROMs has a potential disease modifying effect as it facilitated close monitoring of disease activity with an option of management escalation whenever indicated. Disease activity as measured by SLEDAI over a 24-month observation period predicted the risk of subsequent organ damage independently of other known risk factors.

Does the Risk of Serious Infections Among Elderly RA Patients Differ By Age of Disease Onset?

Sofia Pedro[1], Ted R. Mikuls[2] and Kaleb Michaud[3], [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]University of Nebraska Medical Center, Omaha, NE, [3]Internal Medicine, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: ACR Plenary Session II: Discovery 2015
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose: Elderly-onset RA (EORA) patients (age of onset>60) are less likely to be treated with biologics even when accounting for disease activity compared to young-onset RA (YORA) patients (age<60) at the same age. We hypothesize that this difference is related to an increased risk of serious infections in EORA vs. YORA patients**.**

Methods: Participants with RA were followed biannually from 1998 through 2014 in a large US longitudinal study. Each EORA patient was matched to 3 YORA patients based on age, sex, and calendar year of study entry, which required all patients to have age>60. Serious infections were defined as those requiring hospitalization, intravenous antibiotics, or led to death within a year after the patient's last observation. Infections were validated from hospitalization, physician, and death records. Survival analysis methods (Cox regression, time to first infection using time-varying covariates and Andersen-Gill multiple failures model) were applied. Confounders included ethnicity, comorbidity index, HAQ, pain, education, prednisone use, urban vs. rural home, previous serious infection, and prior number of DMARDs. DMARD treatments were grouped using the following hierarchical classification: monotherapy MTX (reference), none, non-cytotoxic DMARD, cytotoxic DMARD, TNF, and non-TNF biologic. A risk window of 3 months was considered for all DMARDs except rituximab within the non-TNF group had 12 months.

Results: A total of 1,865 EORA patients were matched with 5,595 YORA patients. In both groups, 25% were male and 91% white and a median age between 65-70. EORA and YORA patients had 4.4 (4.2) and 20.9 (12.6) years of RA duration, respectively. Self-reported prior infections were 4.1% and 7.1% for EORA and YORA patients, respectively (P<0.01). There were 1,198 serious infections, 207 (11.0%) in EORA and 998 (17.8%) in YORA patients. Figure presents incident rates (first and multiple) by age group. Adjusted for other confounders, the HR of EORA vs. YORA was 0.84 (0.64-1.11) for first infection and 1.03 (0.86-1.23) for multiple. Prednisone, cytotoxic DMARDs, and no DMARD treatment were associated with an increased risk of serious infections as well as worse HAQ or pain, prior infections, and comorbidities (Table). Sensitivity analysis stratified patients by decade of age and no differences were found.

Conclusion: We found no increased risk of serious infections in EORA vs. YORA patients. Our results support providing similar treatment for EORA patients as done for elderly YORA patients

Session Date: Monday, November 9, 2015

Session Title: ACR Plenary Session II: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Women with SLE and/or aPL antibodies (SLE/APL) are at increased risk for adverse pregnancy outcomes (APO) yet identification of those destined for complications remains challenging. Murine studies implicate complement activation as an essential and causative factor in fetal loss and growth restriction. Activation of the alternative complement pathway, demonstrated by increased levels of the factor B fragment Bb, occurs in non-autoimmune patients with preeclampsia. Activation of all complement pathways leads to production of terminal complex C5b-9. We hypothesized that Bb and soluble C5b-9 (sC5b-9) would be elevated in the circulation starting early in the pregnancy of patients destined for APOs.

Methods: The PROMISSE Study (**P**redictors of p**R**egnancy **O**utcome: Bio**M**arkers **I**n antiphospholipid antibody **S**yndrome and **S**ystemic **L**upus **E**rythematosus) enrolled pregnant women with ≥4 ACR SLE criteria and/or aPL antibodies and healthy pregnant controls (HC). Subjects were evaluated and blood collected monthly beginning at <12 wks gestation. Exclusion criteria were multi-fetal pregnancy, prednisone >20mg/d, proteinuria >1gm/24hr, and creatinine >1.2 mg/dL. APOs were: fetal death, neonatal death, preterm delivery <36 wks because of preeclampsia or placental insufficiency, and/or growth restriction <5th %ile. Complement split products were measured on serial blood samples in 492 SLE/APL patients and in 201 HC. Levels of Bb and sC5b-9 (by MicroVue™ Bb Plus and SC5b-9 Plus EIA Kits) were compared at each time point using analysis of variance followed by pairwise comparisons with the Bonferroni method. Rates of change in complement activation products through 27 wks of pregnancy were estimated and compared using linear mixed effects models.

Results: APO occurred in 20.5% of SLE/APL pregnancies. Compared to SLE/APL patients with no APO, Bb and sC5b-9 were significantly higher as early as 12-15 wks in those destined for pregnancy complications and remained significantly elevated through 31 wks. Bb and sC5b-9 were significantly higher, starting as early as 12 wks, in SLE/APL patients regardless of outcome, compared to HCs. In all three groups, there was a decrease in Bb as pregnancy progressed, but the rate of decrease was significantly smaller in patients with APO compared to SLE/APL without APO and HC. Because complement activation often precedes and accompanies SLE flares, it is of note that in patients without flares, increased Bb still predicted poor outcomes.

Conclusion: In pregnant SLE/APL patients, increased Bb and sC5b-9 is detectable early in pregnancy and is strongly associated with APO. Our findings support the concept that activation of complement, particularly the alternative pathway, contributes to APO. In addition to identifying those destined for APO, they provide a rationale for blockade of complement to prevent APOs in high risk SLE/APL patients.

Session Title: ACR Plenary Session II: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose:

MTX is the anchor DMARD for RA treatment, but there is limited information about its appropriate use in clinical practice. This claims analysis was aimed at gaining insight into how MTX is employed for RA treatment in the US.

Methods: The analysis used Symphony Health Solutions' anonymized patient-level claims data which captures ~274 million US patients. The analysis included RA patients identified by ICD-9 codes 714.0 and 714.30 who initiated treatment with oral MTX in 2009 and were followed to 2014. Information obtained included: demographic characteristics, switches from oral to subcutaneous (SC) MTX and/or biologics (with or without concomitant MTX), timing of treatment changes, and oral MTX or SC MTX dosing at the times of switches/additions or end of follow-up. Independent t-tests were used to assess significance of differences among treatment paths.

Results: The study included 35,640 patients (Table). Of these, 15,599 (43.8%) continued on oral MTX alone (Group 1), through the end of the follow-up period and 17,528 (49.2%) added or switched to a biologic agent (Group 2). The median time to adding a biologic in Group 2 was 170 days and 41.5% of the patients added a biologic within 90 days of initiating oral MTX. In addition, only 7% of patients switched from oral to SC MTX (Group 3) after a median of 534 days of oral therapy; 14.0% of these patients switched within the first 90 days of oral MTX treatment. Overall, 71% of patients who switched from oral to SC MTX remained on this treatment for approximately 3 years and those who added a biologic did so after a median of 289 days. Median time for progression to a biologic was significantly longer (823 days; time on oral + time on SC) for patients who received SC MTX vs those who received only oral drug (170 days) (P<0.0001).

Oral MTX Initiation 2009		**Duration of Oral MTX Prior to Biologic (days)**	**Oral MTX Dose Prior to Biologic (mg/week)**	**SC MTX Dose Prior to Biologic (mg/week)**	**Duration of SC MTX Prior to Biologic (days)**	**MTX Dose at Last Follow-up 2014 (mg/week)**
N=35,640	n (%)	Mean ± SD Median				
Group 1: Remained on only oral MTX through 2014	15,599 (43.8%)	NA	NA	NA	NA	15 ± 5 15
Group 2: Biologic initiated during follow-up period	17,528 (49.2%)	478 ± 580 170	15 ± 5 15	NA	NA	NA
Group 3: Switched from oral to SC MTX and remained on this treatment or had biologic added	2,513 (7.0%)	729 ± 623[1] 534	17 ± 5[1] 15	21 ± 5[2] 20	457 ± 456[2] 289	21 ± 5[3] 20

1. P<0.0001 vs Group 2

2. For 711 patients who switched to a biologic

3. For 1,802 patients who remained on SC MTX until the end of follow-up

Conclusion:

In the US, MTX is frequently under-dosed, given for an inadequate length of time, and rarely switched to SC before the initiation of biologic therapy. More than 40% of RA patients who initiate treatment with oral MTX switched to or had a biologic added within 90 days after a median dose of only 15 mg/week. Switching to SC MTX prevents the need for or significantly extends time to a biologic. More appropriate optimization of MTX could lead to better control of RA and would be expected to produce significant cost savings.

Title: A National Electronic Health Record-Enabled Registry in Rheumatology: The ACR's Rheumatology Informatics System for Effectiveness (RISE)

Background/Purpose: In 2014, the ACR launched the Rheumatology Informatics System for Effectiveness (RISE), a national electronic health record (EHR)-enabled registry. RISE passively collects data from EHRs of participating practices, provides advanced quality measurement and data analytic capacities, and can be used to fulfill national quality reporting requirements. Here we detail the characteristics of practices participating in RISE, patient characteristics and performance on several nationally endorsed quality measures.

Methods: RISE has achieved certification as a Centers for Medicare and Medicaid Services (CMS) Qualified Clinical Data Registry (QCDR), allowing collection of data on quality of care without individual patient informed consent. Participating practices enter a Data Use Agreement with the ACR, after which local data are mapped, validated and uploaded regularly to the central registry. Practices can access an analytics dashboard that allows review of up-to-date information on quality measures by provider and practice as well as national benchmarks. RISE currently includes data on numerous quality measures regarding rheumatoid arthritis (RA), drug safety, osteoporosis prevention and treatment, low back pain, and preventive health care (e.g. smoking, blood pressure management). We analyzed data between April 1, 2014 and March 31, 2015 to characterize initial practices and patients captured in RISE. We also calculated performance on several RA quality measures recently endorsed by the National Quality Forum (DMARD use, disease activity measurement, functional status measurement).

Results: During the dates examined, RISE included data on 184,858 patients, including 49,205 with RA (Table). Two hundred five clinicians across 39 sites contributed data to RISE; 72% of clinicians were in a group practice, 25% were solo practitioners and 4% were part of a larger health system. Characteristics of patients in RISE are summarized in the Table. For the subset of patients with RA, 50.7% of patients had a disease activity score recorded, 53.2% had a functional status score recorded, and 82.1% were taking a DMARD, as defined by national quality measures.

Conclusion: The ACR has launched a national EHR-enabled registry that aims to provide critical infrastructure for improving quality of care in rheumatology, to fulfill national performance reporting requirements, and to serve as a unique data source to generate new knowledge regarding rheumatic disease. Data validation and mapping is ongoing and RISE will be available to both the research and clinical community to use to advance rheumatology.

Table 1. Baseline characteristics of patients in the ACR's RISE national registry.

Characteristic	Total N (N = Distinct Patient)
Age at last encounter, mean (SD)	59 (± 16.1)
Sex	
Female, n (%)	138,748 (75.1%)
Male, n (%)	46,106 (24.9%)

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: ACR Plenary Session II: Discovery 2015
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose: Increased mortality in RA is believed to be a consequence of inflammation. With improved treatment, mortality would be expected to decrease over time. The objective of our study was to compare mortality risk in RA vs. general population controls across RA incident cohorts of earlier vs. later RA onset.

Methods: We conducted a retrospective cohort study of a population based cohort of all incident RA cases in BC with matched general population controls, using administrative health data. RA cases were selected if they had ≥2 MD visits > 2 mos apart for RA in 01/1996-12/2006, with no prior RA visit since 1990. Cases were excluded if they had ≥2 subsequent MD visits for another inflammatory arthritis; if they saw a rheumatologist and the RA diagnosis was never confirmed; or if there were no subsequent RA visits over a F/U >5 yrs. General population controls were randomly selected, matched 1:1 on birth yr, gender and calendar yr of inclusion. Cohorts were divided into earlier (RA onset 1996-2000) and later (2001-2006) cohorts. Data were obtained on all physician visits and vital statistics data including cause of death from death certificates, until Dec 2010.

Person-years (PY) of F/U were calculated from index date to end of F/U, last health care use, or death. Cases and controls were right censored at 5 yrs of F/U to ensure equal F/U time when comparing mortality rates between earlier and later incident cohorts. Sensitivity analyses including all years of F/U yielded similar results. All cause and cause-specific mortality rates and 95% CI were calculated for RA cohorts and controls, along with mortality rate ratios. In addition, we obtained hazard ratios (HRs) for mortality in RA vs. controls via exponential regression models adjusting for age, testing differences between incident cohorts via an interaction term.

Results: The sample included 24,914 RA cases and controls (66.5% female; mean [SD] age 57.3 [17.4] years) contributing 112,431 and 113,100 PY of follow-up, resp., with 2747 and 2123 deaths observed in RA and controls, yielding all-cause mortality rates of 24.43 and 18.77 per 1000 PY in RA and controls, resp., with a mortality rate ratio of 1.30 (95%CI: 1.23;1.38). Mortality risk in RA vs. controls differed across incident cohorts. Mortality was significantly increased in RA vs. controls in earlier, but not later, incident cohorts, for all-cause as well as cause-specific mortality (Table 1). In the age-adjusted exponential mortality models, a significant interaction between RA (vs. controls) and incident cohort (early vs. late) was found ($p<0.001$) for all-cause, CVD and cancer, but not infection ($p=0.31$).

Conclusion: In our population-based incident RA cohort, the risk of mortality compared to the general population has improved over time. The mortality gap between RA and the general population present in people with RA onset on or before 2000 was no longer present in people with RA onset after 2000.

Table 1: Mortality Risk in RA compared to general population controls				
	Mortality rate RA (per 1000 PY)	**Mortality rate controls (pre 1000 PY)**	**Mortality rate ratio (95% CI) RA vs. controls**	**Adj. Hazard Ratio (95% CI) RA vs. controls**
Entire cohort,	24.43	18.77	1.30 (1.23; 1.38)	1.24 (1.17; 1.31)
all cause mortality	8.49	6.53	1.30 (1.18; 1.43)	1.23 (1.12; 1.36)
mortality from CVD	1.45	0.86	1.69 (1.31; 2.20)	1.61 (1.25; 2.07)
mortality from infection	6.48	5.42	1.20 (1.07; 1.33)	1.14 (1.02; 1.27)
mortality from cancer				
All cause mortality:	32.68	19.90	1.64 (1.52; 1.78)	1.55 (1.43; 1.68)
Incident cohort 1996-2000	18.29	17.88	1.02 (0.94; 1.11)	0.98 (0.90; 1.06)
Incident cohort 2001-2006				
Mortality from CVD	12.30	7.40	1.66 (1.46; 1.90)	1.58 (1.38; 1.80)
Incident cohort 1996-2000	5.66	5.85	0.97 (0.83; 1.12)	0.92 (0.80; 1.06)
Incident cohort 2001-2006

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Antiphospholipid Syndrome: Recent findings
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Antiphospholipid syndrome (APS) is characterized by the presence of arterial and venous thrombosis, and by recurrent abortions, in patients with persistent presence of autoantibodies against phospholipid-binding proteins (aPL), such as β2-Glycoprotein I (β2GPI). Arterial thrombosis has been also related to accelerated atherosclerosis in experimental models, however contrasting findings have been reported in clinical studies of patients with primary APS regarding an increased number of plaques or an abnormal arterial wall thickness. In spite of that, aPL predicts adverse arterial outcomes (Hollan et al Autoimmun Rev 12:1004;2013). Aim of the study was to investigate the role of the anti-β2GPI immune response in atherosclerotic lesions.

Methods:

We investigated the cytokine production induced by β2GPI, and its domains (DI, DII, DIII, DIV, DV) in activated T cells that infiltrate *in vivo* atherosclerotic lesions of patients with primary APS atherothrombosis. We also examined the helper function of β2GPI-specific T cells for monocyte matrix metalloproteinase (MMP)-9 and tissue factor (TF) production, as well as their cytolytic potential and their helper function for antibody production.

Results:

We report that APS patients with atherothrombosis harbor *in vivo* activated $CD4^+$ T cells that recognize β2GPI in atherothrombotic lesions. We characterized the submolecular specificity of plaque infiltrating T cells and found that the majority of them recognize their epitopes within the DI domain. β2GPI and its domains induce T cell proliferation and expression of IFN-g in plaque-derived T cell clones. β2GPI-specific T cells display helper function for monocyte MMP-9 and TF production, and promote antibody production in autologous B cells. Moreover, plaque-derived β2GPI-specific $CD4^+$ T lymphocytes express both perforin-mediated and Fas-FasLigand mediated cytotoxicity.

Conclusion:

β2GPI, and especially DI domain, drive a local Th1 inflammatory response, with subsequent plaque instability which eventually favors atherothrombosis. This finding may explain the association between aPL and arterial thrombosis in spite of the lack of the evidence for surrogate markers of atherosclerosis - such as number of plaques and increased arterial wall thickness - in primary APS patients with high prevalence of arterial events.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Antiphospholipid Syndrome: Recent findings
Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Human leukocyte antigen (HLA)-DRB1*07:01 is one of the susceptibility alleles for antiphospholipid syndrome (APS). Recently we have reported that beta-2-glycoprotein I (b2GPI) /HLA class II complex is targeted by anti-b2GPI antibody. The 3-hydroxy-3-methyl-glutaryl-CoA reductase inhibitors (statins) reduce procoagulant cell activation by anti-b2GPI antibody, thus having potential benefit for patients with APS, although the mechanisms have not been clarified. The aim of this study was to identify the mechanisms involved in the reduction of anti-b2GPI antibody induced procoagulant activity by statins.

Methods: b2GPI was co-transfected into immortalized human umbilical vein endothelial cell (HUEhT-1) and human monocytic cell line (THP-1), together with HLA-DRA*01:01/DRB1*07:01 (HLA-DR7) or HLA-DRA*01:01/DRB1*08:01 (HLA-DR8). Fluvastatin was added to cells in the presence or absence of mevalonic acid. The expression of HLA-DR and b2GPI on the cell surfaces was assessed by flowcytometry (FCM). The binding ability of human monoclonal anti-b2GPI antibody (EY2C9) to these cells was analyzed by FCM. In an *in vivo* study using env-pX rats, as a spontaneous rat model of APS, fluvastatin (200 mg/day) was administered orally for 30 days. The titer of anti-cardiolipin/b2GPI complex (aCL) was sequentially determined every 10 days.

Results: Both the expression of b2GPI and binding of EY2C9 were more highly observed on the surface of HUEhT-1 and THP-1 co-transfected with HLA-DR7 than HLA-DR8. The expression of b2GPI was not detected on the surface of cells transfected with b2GPI alone. In HUEhT-1 co-transfected with b2GPI and HLA-DR7, the addition of fluvastatin suppressed the expression of HLA-DR, as well as the expression of b2GPI presented on HLA-DR (Figure 1A and 1B). This inhibitory effect was reduced by mevalonic acid. In addition, the EY2C9 binding to HUEhT-1 was reduced by fluvastatin (Figure 1C). Similar results were obtained in THP-1 transfected with b2GPI and HLA-DR7. In the rat model experiment, the administration of fluvastatin to env-pX significantly reduced the titer of aCL (Figure 1D)

Conclusion: Fluvastatin inhibited the expression of b2GPI/HLA class II complex, leading to down regulation of anti-b2GPI antibody binding. The aCL titer in env-pX rats was reduced by fluvastatin as well. The inhibition of the pathogenic autoantigen presentation through the reduction of HLA-DR expression might be one of the mechanisms involved in the deprocoagulating effects of statins.

Session Title: Antiphospholipid Syndrome: Recent findings

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Antiphospholipid antibodies, especially those targeting beta-2-glycoprotein I (β_2GPI), have been shown to amplify thrombosis in mice. However, most published models have relied on endothelial injury, induced by either laser or pinch injury. Here, we have characterized a model of deep vein thrombosis (DVT) in which flow through the inferior vena cava (IVC) is restricted without causing complete occlusion, and in which the endothelium is not specifically damaged. This model results in a thrombus that recapitulates the histologic characteristics of human DVT.

Methods: Total IgG fractions were prepared from either healthy volunteers or two different primary antiphospholipid syndrome (APS) patients, both with high-titer anti-β_2GPI IgG. C57BL/6 wild-type mice were treated with two doses (500 µg each) of either control or APS IgG by intraperitoneal injection, 48 hours apart. Around the time of the second treatment, a laparotomy was performed, and a ligature was fastened around the IVC over a blunted 30-gauge needle (which served as a spacer). After removal of the spacer, the abdomen was closed, and the mouse was allowed to recover. The resulting stenosis causes an 80-90% reduction in IVC blood flow. Some mice were additionally treated with infusion of DNase (Pulmozyme/dornase alfa) immediately after surgery. DVT formation was assessed at 6 and 48 hours after surgery.

Results: APS IgG injection resulted in circulating anti-β_2GPI IgG levels of 10-20 SGU (standard IgG units), in contrast to control IgG, which gave undetectable levels. Importantly, mice treated with APS IgG were significantly more likely to form IVC thrombi than mice treated with control IgG. At 6 hours, 40% of control mice formed thrombi, as compared to >90% of APS mice. At 48 hours, these numbers were 50-60% for control mice, and >90% for APS mice. By both histology and western blotting, the thrombi were rich in citrullinated histone H3 (cit-H3; a marker of neutrophil extracellular traps/NETs), There was also a significant increase in circulating cell-free DNA in the APS mice, as compared to controls, at the 6-hour time point. Treatment with DNase was highly effective in preventing thrombus formation at 6 hours, reducing the percentage of clots in APS mice from >90% to ~33%. Further supporting a mechanistic role for NETs, anti-β_2GPI IgG promoted NET release from C57BL/6 neutrophils *in vitro*. Of note, a spontaneous model of APS (NZW x BXSB F_1) was also associated with >90% DVT formation following IVC stenosis; neutrophil characterization and treatment experiments are underway in these mice.

Conclusion: IgG isolated from APS patients increase the frequency of thrombus formation in a model of DVT that recapitulates the histology of human thrombi. This increase can be abrogated by treatment with DNase, suggesting a role for extracellular DNA in thrombus formation. Further, cit-H3 was abundant in non-nuclease-treated thrombi. Overall, these data point to a role for NETs as perpetuators, and possibly initiators, of the prothrombotic phenotype in APS. This line of investigation has the potential to suggest new, non-anticoagulant approaches for the treatment of APS.

Primary Antiphospholipid Syndrome Is Characterized By Endothelial Progenitor Dysfunction and a Type I Interferon Signature

Robert C. Grenn[1], Srilakshmi Yalavarthi[2], Paula L. Bockenstedt[3] and Jason S. Knight[2], [1]University of Michigan, Ann Arbor, MI, [2]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [3]Department of Internal Medicine, Division of Hematology/Oncology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Antiphospholipid Syndrome: Recent findings

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with primary antiphospholipid syndrome (APS) are at risk for endothelial dysfunction and accelerated atherosclerosis. In systemic lupus erythematosus (SLE), there is a well-established defect in the function of circulating endothelial progenitors, which leads to an accrual of endothelial damage over time. This defect has been at least partially attributed to elevated levels of type I interferons (IFNs). Whether these pathways are important in primary APS is unknown.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from patients with primary APS (n=20-30, depending on the specific experiment) or healthy volunteers. The function of circulating endothelial progenitors was measured by culturing PBMCs under pro-angiogenic conditions and then quantifying their differentiation into mature endothelial cells (ECs). APS EC differentiation was tested with freshly-isolated PBMCs from primary APS patients, as well as with control PBMCs cultured in the presence of APS sera. Using quantitative PCR, the expression of three type I IFN-responsive genes was assessed in PBMCs: *PRKR*, *IFIT1*, and *IF144*. Expression levels were compared to age- and gender-matched healthy volunteers, and also to patients with SLE (n=15). The direct role of antiphospholipid antibodies in promoting endothelial progenitor dysfunction was characterized by injecting purified IgG fractions from APS patients and controls into mice.

Results: Primary APS was associated with a defect in endothelial progenitor function. When cultured under pro-angiogenic conditions, APS PBMCs produced fewer mature ECs than controls. Similarly, treatment of control PBMCs with APS sera impaired differentiation into ECs (as compared to heterologous control sera), implicating circulating factors in the defect. Interestingly, injection of purified IgG from "triple-positive" APS patients into mice impaired the function of murine endothelial progenitors, arguing that the antiphospholipid antibodies themselves can set the phenotype in motion. PBMCs from patients with primary APS have upregulated expression of the type I IFN-responsive genes *PRKR*, *IFIT1*, and *IF144*, as compared to healthy controls. The IFN signature of primary APS was similar to that seen in SLE patients, and was most robust in the anti-β_2GPI IgG-positive subpopulation of APS patients.

Conclusion: We describe, for the first time to our knowledge, a type I IFN signature in the PBMC fraction of patients with primary APS. Paralleling this finding, circulating endothelial progenitors appear to be dysfunctional in primary APS. Whether the endothelial progenitor defect is attributable to elevated type I IFN synthesis, or possibly direct toxicity from antiphospholipid antibodies, is currently under investigation. This work has the potential to suggest

novel approaches to preventing vascular damage in APS patients, such as anti-IFN drugs.

Procoagulant Property of a Novel Patient-Derived Autoimmune IgG Type Monoclonal Anticardiolipin Antibody That Binds to Beta 2 Glycoprotein Domain I but Not to Total Beta 2 Glycoprotein I Molecule

Kenji Oku[1], Yusaku Kanetsuka[1], Olga Amengual[1], Hiroyuki Nakamura[1], Kazumasa Oomura[1], Toshiyuki Bohgaki[2], Tetsuya Horita[1], Shinsuke Yasuda[1], Bas deLaat[3] and Tatsuya Atsumi[1], [1]Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]Medicine II, Hokkaido University Graduate School of Medicine, Sapporo, Japan, [3]Department of Biochemistry, Cardiovascular research Institute Maastricht, Maastricht University, Maastricht, Netherlands

Session Date: Monday, November 9, 2015
Session Title: Antiphospholipid Syndrome: Recent findings
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Anti-cardiolipin/β_2 glycoprotein I (aCL/β_2GPI) antibodies are representative antiphospholipid antibodies(aPLs) that target the complex of cardiolipin (or anionic molecules) and β_2GPI. However, aCL is often regarded as an autoantibody with relatively lower specificity and the significance of its detection may considered to have secondary role to detection of aβ_2GPI. Recently, the antibodies to β_2GPI domain I (aβ_2GPI DI) are reported as more specific to the manifestations of antiphospholipid syndrome (APS). In this study, the immunological and functional diversity of aCL/β_2GPI was examined in newly established monoclonal autoimmune aCL derived from a patient with APS.

Methods: B cells from 40 APS patients were immortalized with EBV infection to clone aCL antibody-producing cells using limiting dilution and sorting techniques. A stable cell line containing an IgG-type monoclonal antibody (EV35102) was established by introducing genes in the IgG variable region into CHO-K1 cells. The presence of a homologous antigen of EV35102 was examined by ELISA. The anticoagulation function of EV35102 was evaluated in monocytes from healthy persons using quantification of induced tissue factor (TF) mRNA by real-time PCR after treatment of the cells with EV35102. The activation of intra-cellular signal protein was analyzed with the antibody array kit (Pathscan^{TM} : Cell Signaling Technology, USA). Regarding the result of ELISA tests for the monoclonal antibodies, the cohort of 182 APS patients (with and without systemic lupus erythematosus(SLE) and 141 patients with connective tissue diseases were analyzed of their aPL profiles. Five clotting assays for testing lupus anticoagulant and 7 enzyme-linked immunosorbent assays(IgG/IgM aCL, IgG/IgM aβ_2GPI and aβ_2GPI D1) were performed.

Results: EV35102 bound to cardiolipin only in the presence of β_2GPI, thus behaving as a typical β_2GPI-dependent aCL. However, EV35102 did not recognize total β_2GPI molecule in any conditions (negative for aβ_2GPI). Surprisingly EV35102 bound to domain I of β_2GPI (positive for aDI). EV35102 significantly induced monocyte TF mRNA expression compared with the IgG control (9.23+/-2.79 vs. 2.18+/-0.32, $p<0.05$). The p38 Mitogen-activated protein kinase(MAPK) significantly and specifically phosphorylated in the monocytes stimulated with EV35102 compared with the IgG control (OD value : 2.92+/-0.31 vs 1.23 +/-0.51 , $p<0.05$). Anti CL antibody positive with negative aβ_2GPI IgG was found in 5/141 in non-APS control and 20/182 in APS. Among 20 APS patients with aCL IgG positive and aβ_2GPI negative, 4/20 were aβ_2GPI DI positive. None of the non-APS with aCL positive, ab2GPI negative showed ab2GPI D1 positive.

Conclusion: EV35102 represented a new subset of aCL/β_2GPI in patients with APS; its epitope would locate on domain I of β_2GPI, but the antibodies are undetectable by anti-(total) β_2GPI assay. EV35102 had procoagulant property thus this subset of aCL/β_2GPI is possible to be pathogenic. The diversity in aCL/β_2GPI should be recognised and aCL assay is still useful for screening this subset.

Session Title: Antiphospholipid Syndrome: Recent findings
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Epigenetic anomalies are emerging as striking pathogenic features of autoimmune disorders. MicroRNAs (miRNAs) are small non-coding RNAs with a key role in regulatory networks that might represent a novel class of disease biomarkers. Yet, the contribution of circulating miRNAs to the pathogenesis of antiphospholipid syndrome (APS) and their potential role as biomarkers of this disease are still unknown. Purpose: To determine the circulating miRNA signature of APS and to identify potential circulating microRNAs that might represent non-invasive biomarkers of the disease.

Methods: Total RNAs were isolated from plasma of 10 APS patients and 10 healthy controls, cDNA transcribed and pooled, and human plasma miRNA polymerase chain reaction (PCR) arrays were performed. Then, selected miRNAs were analyzed in a validation cohort consisting of 72 APS patients and 38 healthy donors. To evaluate their patho-physiological relevance, a functional analysis was conducted by using the Ingenuity Pathway Analysis (IPA) software. Association and correlation studies with clinical and serological variables were also performed.

Results: miRNA-PCR-Array showed that 22 circulating microRNAs were differentially expressed in APS patients in relation to the control group (fold change≥2). IPA analysis indicated that a high number of these microRNAs had targets mainly involved in processes related to cardiovascular disease (40%, including arteriosclerosis, hypertension, and coronary artery disease) inflammatory response (50%), and reproductive system disease (45%, i.e endometriosis and preeclampsia). Validation analysis by RT-PCR showed that the levels of three microRNAs (miR-19b, miR-20a and miR-296) were significantly increased in plasma of APS patients. These miRNAs have been further demonstrated to be specifically involved in preeclampsia (miR-296), inflammation and thrombosis (miR-19b and -20a) in other autoimmune and inflammatory disorders. Receiver operating characteristics (ROC) curve analysis showed that the ratio of combination for the three miRNAs could discriminate APS patients from healthy donors with a 70% of sensitivity and specificity and an area under curve (AUC) close to 1 (0,72), thus pointing at these microRNAs as potential diagnostic biomarkers of APS. Analysis of interrelation with clinical variables showed that the expression levels of miR-296 were associated with the occurrence of recurrent thrombosis, while the expression levels of miR-20a were most specifically linked to episodes of arterial thrombosis, and further correlated with the erythrocyte sedimentation rate.

Conclusion: We have identified a set of serum miRNAs as potential APS biomarkers, primarily involved in key clinical features of this autoimmune condition.

Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint: Osteartritis Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose : There is huge interest in the family of “A Disintegrin And Metalloproteinase with ThromboSpondin motifs” (ADAMTS) proteinases, especially aggrecanase-2 (ADAMTS-5), as therapeutic targets in osteoarthritis (OA). CRB0017 is a chimeric murine/human IgG4 monoclonal antibody that specifically recognizes the spacer domain of human ADAMTS-5 and binds it with nanomolar affinity. CRB0017 is under preclinical development as a potential disease modifying osteoarthritis drug (DMOAD).

We previously published a brief report (Chiusaroli, *Osteoarthritis Cartilage*, 2013) showing the efficacy of intra-articular (i.a.) CRB0017 in a model of

spontaneous OA, the STR/ort mouse. In this study we replicated the experiment in the STR/ort mouse and evaluated the activity of CRB0017 in two surgical models of OA in rodents: the Destabilization of Medial Meniscus (DMM) in mice; and the Medial Meniscal Tear (MMT) in rats. Moreover, all data collected were combined in a meta-analysis to estimate the overall effect size of CRB0017 in rodent models of OA.

Methods : Because it is hard to standardize different batches during early phases of a monoclonal antibody development, all experiments were done at the maximum feasible dose (MFD), as determined by the concentration achieved in each batch and by the maximum feasible volume for i.a. injection in rats and mice.

Male STR/ort mice were recruited at 5 months of age, randomized, and treated i.a. in each knee with CRB0017 or vehicle (4µl/knee). Four different experiments were conducted in the STR/ort mouse (MFDs: Exp1 12 µg/knee, n=34 evaluable joints; Exp2 11.2 µg/knee, n=28-29; Exp3 72 µg/knee n=33-38; Exp4 20 µg/knee, n=21-18). Treatment was repeated after 6 weeks (in Exp 4, 3 monthly administrations), and mice were killed 3 months after recruitment.

DMM was performed in C57BL/6J mice (10 weeks old at surgery; CRB0017 i.a. injection [MFD 72 µg in 4 µL] 1 week after surgery; injection repeated after 1 and 2 months; sacrifice at 3 months, n=19-20).

MMT was performed in Lewis rats (9 weeks old at surgery; CRB0017 i.a. injection [MFD 71 µg/knee in 15 µL] 1 week after surgery; sacrifice 3 weeks after treatment, n=15).

At sacrifice, the femorotibial joints were explanted and processed for histology. Scoring procedure was carried out in a blind fashion according to both Mankin's (not shown) and OARSI methods. For quantitative outcome data, Cohen's *d* effect size was used in the meta-analysis of OA models.

Results : CRB0017 markedly reduced the histological damage in spontaneous and surgical models of OA in mice and rats, which is consistent with a disease modifying activity. Pooled data (OARSI score) showed a highly significant overall effect size of 0.726 (Cohen's *d*; see figure).

Figure – Effect size on OARSI score, Cohen's *d*

	Effect size (ES)	Lower limit	Upper limit	p value
STR/ort 1	-0.740	-1.232	-0.249	0.003
STR/ort 2	-0.897	-1.442	-0.353	0.001
STR/ort 3	-0.603	-1.080	-0.126	0.013
STR/ort 4	-0.565	-1.207	0.077	0.084
DMM	-0.781	-1.432	-0.013	0.019
MMT	-0.814	-1.559	-0.069	0.032
	-0.726	-0.958	-0.493	0.000

Effect size (ES) is the best, single indicator of the quantitative efficacy of an intervention vs. the comparator (e.g. placebo/vehicle)

- ES = [(mean change active) – (mean change placebo)]/pooled standard deviation
- ES (absolute value)<0.20 = not clinically relevant; ES>0.20 = small (common clinical outcome for therapeutic interventions in OA); ES>0.50 = moderate; ES>0.80 = large

Conclusion : Aggregate data from clinically relevant models of spontaneous or surgical OA in rodents clearly show the potential of CRB0017 as a DMOAD. The product is slated to enter Phase I in early 2016.

Discovery of an Intra-Articular Injection Small Molecule Inhibitor of the Wnt Pathway (SM04690) As a Potential Disease Modifying Treatment for Knee Osteoarthritis

Charlene Barroga, Yong Hu, Vishal Deshmukh and John Hood, Samumed, San Diego, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint: Ostearthritis Pathogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Wnt has a key role in the formation of bone, cartilage and synovium. Increased Wnt signaling may contribute to initiation and progression of osteoarthritis (OA) by inducing cartilage degradation and reducing its thickness.[1] Polymorphisms in Wnt signaling genes are associated with increased susceptibility to OA.[2] SM04690, a novel, small molecule inhibitor of the Wnt pathway was evaluated in preclinical studies to determine its potential to treat OA.

Methods:

SM04690's capacity to inhibit the Wnt pathway was determined via a cellular screen using a luciferase reporter driven by a Wnt-responsive promoter. SM04690's ability to induce chondrogenesis was established using differentiation of primary human mesenchymal stem cells (hMSC) to chondrocytes, as determined by Safranin-O staining and upregulation of chondrogenic genes. Pharmacokinetics were evaluated by intra-articular (IA) injection in Sprague Dawley rats and Beagle dogs, followed by evaluation of compound concentration in joints and plasma. *In vivo* activity was evaluated in the anterior cruciate ligament transection (ACLT) combined with medial meniscal tear model in rats, in which SM04690 or vehicle control was injected into the IA space of the damaged knee (N=8-12/group), followed by histological evaluation using blinded Osteoarthritis Research Society International (OARSI) scoring [0-24].[3]

Results:

In vitro, SM04690 inhibited Wnt pathway activation with EC_{50}≈3 nM. Consistent with Wnt's role in chondrogenesis, SM04690 induced hMSCs to differentiate to chondrocytes with EC_{50}≈30 nM as measured by staining and expression of chondrogenic markers: SOX9, collagen2A, aggrecan and TIMP1. *In vivo*, a single IA injection of SM04690 into knees of Sprague Dawley rats or Beagle dogs resulted in a joint concentration above target EC_{50} with a residence time of 60-90 days. No compound was detectable in plasma immediately after IA injection or 30–180 days post-injection. In ACLT model, one injection of SM04690 2 weeks post-injury improved cartilage health in a dose-dependent manner relative to vehicle, with no observable toxicity. Histology in ACLT model shows marked cartilage degradation in vehicle (**Figure 1B**), while SM04690 showed cartilage thickness similar (**1C**) to normal (**1A**) non-ACLT knee. At optimal IA dose of 0.3 ug/knee in rats, OARSI scores decreased significantly from 4.7 to 2.5, P=0.006 (**Figure 2**).

Conclusion:

SM04690 was shown to inhibit the Wnt pathway, induce chondrogenesis and improve cartilage health in rat models of OA after a single IA injection. SM04690 was maintained in joint space for up to 90 days with no detectable SM04690 in plasma, consistent with a low potential for systemic toxicity. These data suggest that locally injected SM04690 may have potential as a disease modifying therapy for OA.

WISP1 Aggravates Osteoarthritis By Modulation of TGF-β Signaling and Positive Regulation of Canonical Wnt Signaling

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint: Ostearthritis Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Many osteoarthritis (OA) patients show synovial activation, which is suggested to be involved in joint destruction. Previously, we found synovial overexpression of Wnt ligands in experimental OA models. In addition, we found increased expression of WISP1, a downstream protein of canonical Wnt signaling, in both synovium and cartilage. In this study we investigated the role of WISP1 in experimental OA models in WISP1 KO mice and determined if WISP1 was involved in progression of early human OA.

Methods: Pathway analysis of microarray data from the synovium of a collagenase-induced OA (CIOA) and destabilization of the medial meniscus (DMM) model was performed using DAVID bioinformatics software. Microarray analysis was performed on synovial tissue of patients with early complaints of knee or hip pain, enrolled in the CHECK study. Expression data was correlated with progression between baseline and the five-year follow-up measurement. Progression was defined as decreased joint space width of at least 1 mm and progression of osteophyte formation of at least 4x in size. CIOA, DMM and anterior cruciate ligament transection (ACLT) experimental OA models were induced in WT and WISP1 knockout mice. Joint pathology was assessed by histology. Human OA synovium was obtained after joint replacement surgery and stimulated with WISP1. Smad phosphorylation and β-catenin accumulation were determined using immunohistochemistry.

Results: Pathway analysis showed enrichment of Wnt signaling in both the CIOA and DMM at various time points. In addition, microarray analysis of synovial tissue from patients in the CHECK study showed that WISP1 expression was correlated with the progression of OA between baseline and the five-year follow-up measurement. To further pinpoint the role of WISP1 in the etiopathology of OA, we induced experimental OA in WT and WISP1 KO mice. We found significantly decreased cartilage damage in the knee joints of WISP1 KO mice in three models of experimental OA. Synovium of WISP1 KO mice showed reduced expression of MMPs, which is in line with our finding that stimulation of human OA synovium with WISP1 increased the MMP expression. TGF-β signaling via Smad 2/3 is crucial for maintaining cartilage homeostasis, while signaling via Smad 1/5/8 is associated with chondrocyte hypertrophy. To determine if WISP1 affects TGF-β signaling, we stained WT and WISP1 depleted joints for phosphorylated Smad 2/3 and found increased pSmad 2/3 in the WISP1 KO mice. In addition, recent data showed that WISP1 could regulate the accumulation of β-catenin, and positively control canonical Wnt signaling, further aggravating the OA pathology. Staining for β-catenin indeed showed that WISP1 depleted joints have decreased levels of β-catenin accumulation in the cartilage.

Conclusion: Overexpression of WISP1 in the joint may play an important role in OA pathology via modulation of TGF-β signaling and positive feedback on canonical Wnt signaling. Targeting upstream Wnt signaling likely causes undesired side effects, as the pathway is extremely complex and involved in many processes. Specific downregulation of WISP1 may more specifically target pathological events that take place during OA without interfering with normal processes.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint: Ostearthritis Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Synovial expression of CCR7 has been associated with inflammation and severity of symptoms in patients with meniscal tears and early osteoarthritis (OA). This receptor plays a role in trafficking of leukocytes and aids in the development of chronic inflammation. The current aim was to determine if CCR7 plays a mechanistic role in development of OA-related structural and functional manifestations after destabilization of the medial

meniscus (DMM) in a murine model of knee OA.

Methods: To confirm expression of CCR7 in humans, knee synovial tissues from 15 patients with meniscal tears, and 9 asymptomatic organ donors were collected through IRB-approved biorepositories. Immunoperoxidase staining for CCR7 was evaluated by automated image analysis. To investigate effects of CCR7 deficiency *in vivo*, genetically modified mice lacking expression of CCR7 ($CCR7^{-/-}$) and C57BL/6 congenic controls were obtained from Jackson Laboratory. Male mice were subjected to DMM surgery at 10-12 weeks of age. Six weeks after surgery, groups of 5 mice were sacrificed and knee joints evaluated by histopathology for cartilage degeneration and osteophyte size using standard methods. Synovial lining hyperplasia was scored on a scale of 0-3 with 0 = one cell layer thick, 1= 2-3 cell layers, 2 = 4-5 cell layers, and 3 = >6 cell layers thick. Changes in spontaneous climbing activity were measured longitudinally (up to 16 weeks) after DMM surgery in the two strains, using the LABORAS®laboratory animal behavior analysis system (Metris B.V., Hoofdorp, The Netherlands).

Results: Synovial CCR7 staining was significantly higher in patients with meniscal tears (Mean % area +/- SEM = 12.26 +/- 2.4) compared to asymptomatic donors (3.55 +/- 2.7, p=0.01). Six-weeks after DMM surgery, $CCR7^{-/-}$ mice exhibited reduced cartilage degeneration (Mean +/- SEM = 1.60+/-0.81) and osteophyte size (0.80+/-0.20) compared to their C57BL/6 controls (cartilage = 5.20+/-1.06, osteophyte = 1.40+/-0.24, p<0.0001). Slight increases in synovial hyperplasia in response to DMM surgery occurred in both strains of mice (p=ns). C57BL/6 mice decreased their climbing activity post-operatively starting at 4 weeks, and decreases were maximal at 8 weeks post-DMM surgery (46.87% lower than pre-DMM, p=0.012). In contrast, at 4 weeks post-DMM $CCR7^{-/-}$ mice maintained pre-operative climbing activity and climbing was significantly increased by 8 weeks post-DMM (25.64% higher than pre-DMM, p = 0.001). At 8 weeks, time spent climbing was lower in C57BL/6 DMM mice compared to sham (p=0.0145) and naïve (p =0.00205) controls, while $CCR7^{-/-}$ mice showed no significant differences between DMM-operated, sham and naïve control groups

Conclusion: In the DMM model of OA, $CCR7^{-/-}$ mice showed reduced cartilage degeneration and osteophyte size at 6 weeks post-surgery and improved function (measured by climbing activity) by 8 weeks post-surgery in contrast to their C57BL/6 counterparts. Based on these results, CCR7 may be a potential target for therapy with both structure- and symptom- modifying effects in OA. Future studies will investigate the use of targeted treatments aimed at the blockade of CCR7 and its ligands in this model.

Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint: Ostearthritis Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Adenosine, acting at its receptors, regulates chondrocyte function and inflammation, two components of OA. Mice lacking adenosine A2A receptors (A2AR) have increasing difficulty walking as they age. We report here that A2ARKO mice have changes consistent with OA in their knees and treatment with a liposomal adenosine (lipado) suspension abrogates development of OA in a rat anterior cruciate ligament (ACL) injury model of OA.

Methods: Knee joints of WT and A2ARKO mice (n=5/group) were studied by micro-computed (μCT) analysis and immunohistochemistry. Locomotor activity in mice was measured with open-field and rotarod tests. Primary articular chondrocytes from neonatal WT or A2ARKO mice were studied for altered expression of OA markers. OA was induced in rats by mechanical rupture of ACL. Rats (n=3/group) were treated with intra-articular injection of 100μl of saline, a liposomal formulation containing adenosine (10 mg/Kg) or empty liposomes (lipo) and weight and knee swelling of the rats were monitored. Rat legs were harvested after 56 days to evaluate the joints and plasma cytokine levels were quantitated in rats, WT and A2ARKO mice.

Results: A2ARKO mice did not move as far as WT mice (A2ARKO=664±123 cm vs WT=1404±128 cm, p<0.001); nor did they move as fast (A2ARKO=1.11±0.21 cm/sec vs WT=2.34±0.21 cm/sec, p<0.001) and fell more quickly from the rotarod apparatus (A2ARKO=86±11sec vs WT=145±22 sec, p<0.05). A2ARKO mice had progressive joint damage consistent with OA (e.g. OARSI score at 16 weeks for A2ARKO=3.7±0.6 *vs* WT=1.5±0.2, p<0.01). In contrast, knee joints of 19wk old A2BRKO mice did not differ from WT. Chondrocytes isolated from neonatal A2ARKO mice, but not WT, spontaneously expressed and secreted collagen X, fibronectin, osteopontin and MMP-13. Rats treated with intra-articular lipado were significantly less swollen (difference between uninjured and injured knee was 2.32±0.07mm for saline group, 2.35±0.36mm for lipo-treated and 0.93±0.12mm for lipado-treated, p<0.01, 1-way ANOVA). Macroscopic evaluation of joints showed near-normal appearing cartilage in lipado-treated rats but pitting and loss of cartilage in saline or lipo-treated rats. There was a marked reduction of subchondral bone changes in μCTs of lipado-treated mice as well and plasma

levels of IL-1b, IL-6, IFNg, IL-5, TNFa and RANTES were significantly lower in rats treated with lipado.

Conclusion: These findings suggest that the presence and tonic activation of A2AR in the joint are important for maintaining joint homeostasis. Moreover these results suggest that adenosine receptors may be a novel target for treatment of OA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint: Osteoarthritis Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Tissue-intrinsic circadian molecular clocks control many physiological processes. The function of these clocks in cells of the musculoskeletal system and their contribution to disease is poorly understood however. Here, we investigated the peripheral joint phenotype in mice genetically deficient for the core circadian molecular clock regulator Brain and muscle Arntl-like 1 (*Bmal1*).

Methods: We generated mice with conditional deletion of *Bmal1* in mesenchymal cells of the limbs by crossing *Bmal1*$^{fl/fl}$ and *Prx1-cre* mice. Forepaws and hindfeet of *Bmal1*$^{fl/fl}$ and *Bmal1*$^{fl/fl}$*.Prx1-cre* mice were analyzed by histology and micro-computed tomography at 4, 8, and 12 weeks of age. Germline *Bmal*$^{-/-}$ mice were analyzed in parallel. Gene expression in the Achilles tendon was analyzed by real-time qPCR.

Results: As previously described in *Bmal1*$^{-/-}$ germline knockout mice, *Bmal1*$^{fl/fl}$*.Prx1-cre* mice develop spontaneous Achilles tendon ossification. In addition, both *Bmal1*$^{-/-}$ and *Bmal1*$^{fl/fl}$*.Prx1-cre* mice develop an osteoproliferative arthropathy in their forepaws, most prominently affecting the metacarpophalangeal and proximal interphalangeal joints, with radiographic similarity to the osteophytes seen in human hand osteoarthritis. Both the Achilles tendon and forepaw phenotypes are 100% penetrant by 8 weeks of age. Gene expression analysis of mRNA isolated from the Achilles tendon of *Bmal1*$^{fl/fl}$*.Prx1-cre* mice demonstrated (1) a marked reduction in *Bmal1* expression and (2) loss of the cyclic expression pattern of core clock genes (*Clock*, *Nr1d1*), indicating deregulation of the circadian molecular clock. Longitudinal gene expression analysis revealed up-regulation of genes involved in bone formation (*Alpl*, *Ocn*, *Osx*) in the Achilles tendon. Furthermore, we found induction of canonical target genes of Hedgehog signaling (*Ptch1*, *Gli1*) but not of Bone morphogenetic protein (BPM) or Wnt signaling pathways.

Conclusion: Mice with either global or mesenchymal cell-specific deletion of *Bmal1* develop Achilles tendon ossification and a forepaw arthropathy with marked radiographic similarity to hand osteoarthritis. Disruption of circadian rhythms in peripheral tissues, such as tendons and joints, may contribute to degenerative conditions of the musculoskeletal system.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: We investigated mechanisms driving pathogenic behavior of synovial fibroblasts (FLS) in rheumatoid arthritis (RA).

Methods: FLS from RA patients (1987 classification criteria) were extracted. Expression of 249 inflammation-related genes was measured by nanoString technology. Active transcription was evaluated by primary transcripts. Chromatin accessibility was assessed by FAIRE assay. mRNA decay rates, after blocking transcription with actinomycin D (ActD), were calculated in a semi-log plot. The role of NF-kB and MAPKs was tested with inhibitors iIKK, SB202190, SP600125, U0126.

Results: Using strict criteria (expression level >100 at 72h of TNF-stimulation and >3-fold induction compared to control), a cluster of 34 genes displayed sustained induction (2 independent experiments) (Figure 1A). 18/34 genes retained high mRNA expression levels despite removal (washing) and blockade (infliximab) of TNFa (Figure 1B-C). In unwashed conditions, active transcription at TNF 72h was variably present depending on the gene. High levels of active transcription were maintained in genes such as IL6, IL8, CXCL1, CXCL2, CXCL3, CXCL6 and TNFAIP3, even after removal of TNF (Figure 1D and not shown). Continuous transcription was NF-kB dependent (Figure 1E). Sustained IL6 promoter chromatin remodeling was retained for days post-wash (Figure 1F and not shown). Highly expressed genes, such as CCL5 and MMP3, displayed minimal ongoing transcription (Figure 1D and not shown). Prolonged (4-8h) inhibition of transcription with ActD at TNF 72h (Figure 2A) significantly decreased TNFAIP3 mRNA (Figure 2B). Expression of other genes, such as IL6, IL8, CXCL1, CXCL3, CXCL6, CCL5 and MMP3, was minimally affected by ActD (Figure 2B and not shown), suggesting increased mRNA stability. Decay rates of mRNA for a group of TNF-inducible genes, such as IL6 and CXCL1, gradually decreased with time (Figure 2C), indicating TNF-inducible mRNA stabilization effect, which was MAPK-dependent (Figure 2D). Decay rates of mRNA of other genes were not dynamically regulated by TNF, and were either persistently stable (e.g CCL5) or unstable (e.g TNFAIP3) (Figure 2C).

Conclusion: We have identified a sustained inflammation-related gene expression program in TNF-stimulated RA FLS. Within this program there are different classes of genes based on the relative contribution of transcription and mRNA stability (Figure 2E). TNF drives MAPK-dependent stabilization of certain transcripts and persistent chromatin remodeling in genes such as IL6, indicating TNF-induced memory effect in FLS.

TIARP Attenuates Autoantibody-Mediated Arthritis Via the Suppression of Neutrophil

Infiltration into the Joint

Asuka Inoue[1], Isao Matsumoto[1], Yuki Tanaka[2], Naoto Umeda[1], Hoshimi Kawaguchi[1], Hiroshi Ebe[1], Yoshihiro Matsumoto[3] and Takayuki Sumida[1], [1]Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Department of Internal Medicine, University of Tsukuba, Tsukuba, Japan, [3]Product Research Department, Chugai Pharmaceutical Co., Ltd., Gotemba, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

TIARP (TNFα-induced adipose-related protein) is dominantly expressed in macrophages (Mφ), neutrophils (PMN) and fibroblast-like synoviocytes (FLS). Recently, we found that TIARP functions as a negative regulator in autoimmune arthritis through the suppression of IL-6 production, NF-κB, STAT3 signaling in Mφ, although the molecular mechanism of TIARP-expressing cells in arthritis remains uncertain. The purpose of this study is to elucidate the functional role of TIARP in the pathogenesis of arthritis, especially focusing on PMN and FLS.

Methods:

(1) K/BxN serum-transferred arthritis was induced to TIARP$^{-/-}$or WT, then the ankle thickness was monitored. Mice were also treated with intravenous administration of anti-Gr1 Ab (for the depletion of PMN) or control Ab every other day after the induction of arthritis. (2) RNAs were extracted from TIARP$^{-/-}$or WT PMN, subsequently compared by Gene chip. (3) The expression of CXCR1 and CXCR2 on PMN was analyzed, and the chemoattractant activity of TIARP$^{-/-}$ or WT PMN was tested by trans-well chemotaxis assays. (4) Using TIARP$^{-/-}$or WT FLS, the expression of IL-6, TNFα and CXCL2 after TNFα stimulation were compared. (5) To verify the effect of CXCL2, we performed the chemotaxis assay of PMN by applying to the lower chamber with anti-CXCL2 Ab. (6) The production of IL-17, TNFa and IL-6 from PMN stimulated by immune-complex (IC) were measured by ELISA. (7) Anti-IL-6R Ab was administrated every other day after the induction of serum transferred arthritis.

Results:

(1) The severity of arthritis in TIARP$^{-/-}$ mice was markedly exacerbated, and the recruitment of PMN into the joint was significantly enhanced. TIARP$^{-/-}$mice treated with anti-Gr1 Ab showed significantly reduced cellular infiltrate into the joint, and reduced synovial thickening. (2) Gene ontology analysis of up-regulated genes in TIARP$^{-/-}$PMN demonstrated the enrichment of genes involved in chemotaxis. (3) The expression of CXCR1/2 was significantly higher in TIARP$^{-/-}$ PMN, and the recruitment capacity was enhanced. (4) The expressions of IL-6 and CXCL2 in TIARP$^{-/-}$ FLS were significantly higher than in WT, whereas RANKL, MMP3 and MMP9 were not different. (5) The numbers of migrated PMN were significantly decreased by the addition of anti-CXCL2 Ab. (6) The production of IL-17, TNFa and IL-6 were comparable between WT and TIARP$^{-/-}$PMN. (7) Serum-transferred arthritis in TIARP$^{-/-}$ mice was attenuated by the blockade of IL-6R signaling, and recruitment of PMN into the joint of TIARP$^{-/-}$mice was suppressed.

Conclusion:

TIARP might down-regulate the production of CXCL2 from FLS and the expression of CXCR1/2 in PMN, resulting in the protective ability of neutrophil migration in arthritic joints, probably via the inhibition of IL-6 signaling.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Sjögren's Syndrome (SS) is a systemic autoimmune disease characterized by chronic inflammation involving the exocrine glands, particularly the salivary and lacrimal glands. The pathogenesis of SS is complicated with many respects remaining elusive. IL-27, a member of IL-12 cytokine family, has the pro- and anti-inflammatory properties during immune responses. IL-27 can induce the differentiation of type 1 regulatory T (Tr1) cells from human naive CD4+ T cells. Recent studies have shown that IL-27 was involved in anti-inflammatory functions in SS. However, the underlying mechanism of IL-27 in SS is still unknown. In the present study, Tr1 cells were studied in IL-27 knock-out and wild-type SS models and patients for the purpose to explore the specific mechanism of IL-27 in SS.

Methods: IL-27 mRNA expression in PBMC of SS patients was detected by real-time PCR. Serum IL-10 of SS patients and model animals was determined by ELISA. Infiltrated IL-10+ cells in labial gland of SS patients were assessed by immunohistochemistry. Tr1 cells in human peripheral blood and mice spleen were measured by flow cytometry.

Results: IL-27 mRNA expression was decreased in SS patients. The level of IL-27 mRNA in patients with glandular infiltration was higher than those with extraglandular manifestation (Fig 1).

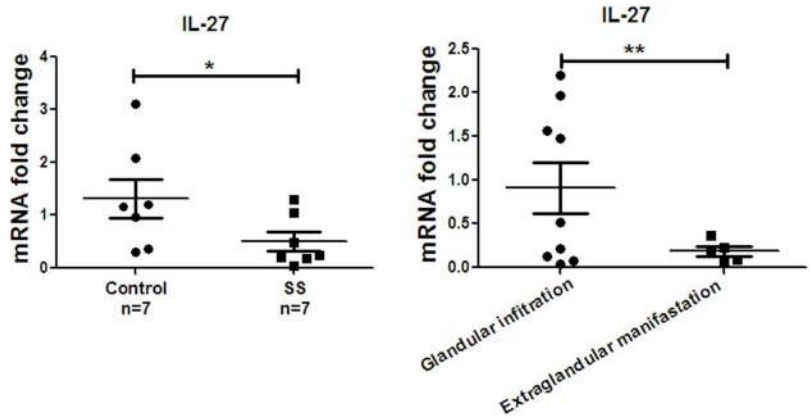

Figure 1

In SS patients, infiltrated IL-10+ cells in labial gland were significantly decreased (Fig 2 A and B). Serum IL-10 was significantly decreased in SS patients than healthy controls (Fig 2C). Compared with control, the frequency of Tr1 cells in peripheral blood of SS patients significantly reduced (Fig 2D).

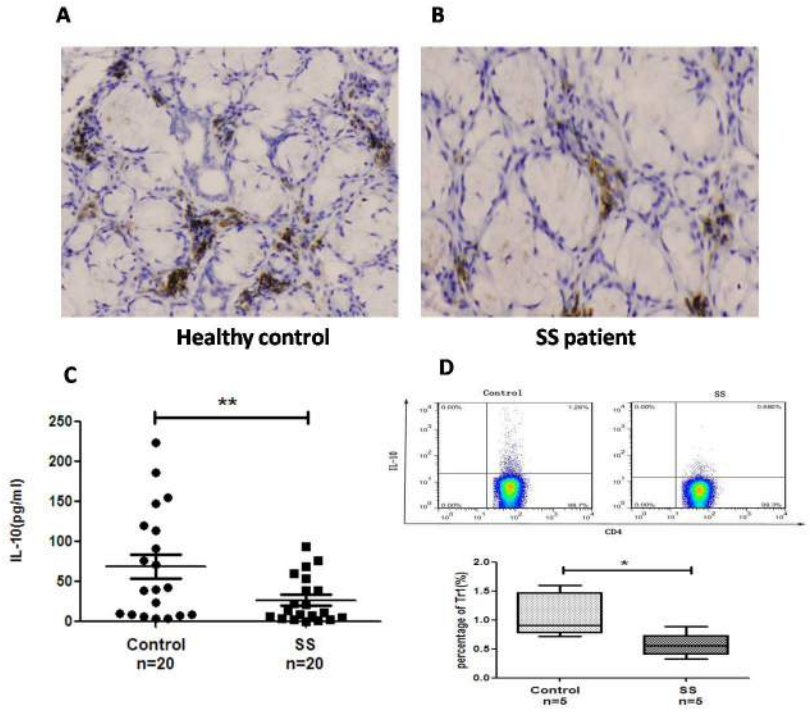

Figure 2

IL-27 deficient NOD (Non-Obese Diabetic) mice displayed more severe SS-like autoimmune disorders than NOD mice. The saliva flow rate was decreased and the submandibular gland weight/body weight index increased (Fig 3A and B). The percentage of CD4+IL-10+ Tr1 cells in splenocytes was significantly lower than NOD mice (Fig 3C). The serum IL-10 also decreased significantly (Fig 3D).

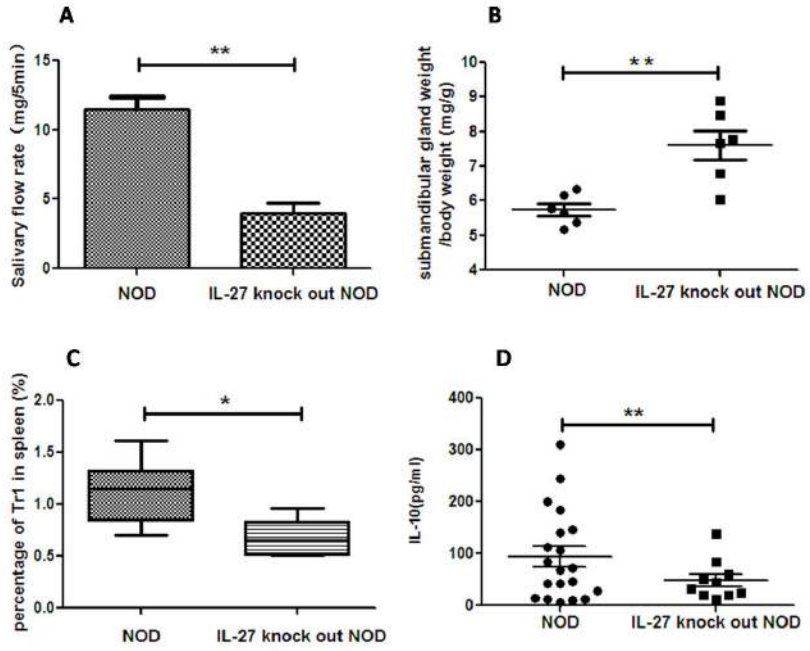

Figure 3

Conclusion: In general, these findings indicated that IL-27 deficiency deteriorated the disease symptoms of SS through loss of inducing Tr1 cells differentiation. Our data suggested that IL-27 and IL-27-induced Tr1 cells played an important role in the pathogenesis of SS.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Pathological angiogenesis is a crucial part of disease progression in rheumatoid arthritis (RA) and is often considered the switch from acute to chronic inflammation. It is a complex process mediated by several different cell types in the inflamed synovium. However, many of the *in vitro*models of angiogenesis focus solely on endothelial cells (EC), even though RA fibroblast-like synoviocytes (FLS) and immune cells also contribute to angiogenesis. Hence, a system that includes RA FLS as well as RA synovial fluid (SF) containing immune cell products such as cytokines, chemokines and growth factors, would be more representative of synovial angiogenesis. We have recently demonstrated that the non-canonical NF-kB pathway, with its main regulatory enzyme NF-kB inducing kinase (NIK), plays an important role in synovial angiogenesis. Therefore, we set out to investigate whether inhibition of this pathway may hold therapeutic potential in mitigating pathological angiogenesis associated with RA.

Objective:

Generate a representative 3D *in vitro*model of RA synovial angiogenesis and screen the effects of targeting the non-canonical NF-κB pathway using siRNA or small molecule pharmacological inhibitors.

Methods:

Human primary EC were co-cultured with RA FLS after pre-incubation with cell tracker dyes and incubated overnight to form spheroids. Subsequently, spheroids were plated in collagen gel and stimulated with 10% RA SF, growth factors (GF) or well-known activators of non-canonical NF-kB signaling (lymphotoxin beta (LT) or LIGHT). To establish NIK dependency, EC were pre-transfected with NIK-targeting siRNA before incorporation into spheroids. Furthermore, several pharmacological inhibitors were screened for their ability to block sprout formation. Spheroids were imaged by confocal microscopy and quantified using Leica QWin Plus software.

Results:

We established a robust 3D model of angiogenesis containing both EC and RA FLS. LT, LIGHT, RA SF and GF stimulations led to significant increases in sprout formation as compared to basal conditions ($p<0.05$). The LT and LIGHT induced sprout formation proved to be NIK dependent as spheroids containing EC transfected with NIK targeting siRNA had significant reductions in vessel formation as compared to the non-targeting controls ($p<0.05$). Sprouting promoted by GF and RA SF was

significantly blocked by the angiogenesis inhibitor Anginex ($p<0.05$). Finally, targeting of the non-canonical pathway using a small molecule pharmacological NIK inhibitor significantly reduced sprout formation caused by LT and LIGHT, and importantly also RA SF-induced sprout formation ($p<0.05$).

Conclusion:

We developed a novel 3D model that incorporates essential elements of synovial inflammation, namely EC, RA FLS and RA SF, which proves to be an effective tool for studying synovial angiogenesis. Using this system, we have further demonstrated a role for the non-canonical NF-kB pathway, and its central regulator NIK, in neovascularization associated with RA. Moreover, we have shown that the 3D model is useful for testing small molecule inhibitors of angiogenesis and found that targeting non-canonical NF-kB signaling is an effective method to block pathological angiogenesis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

The formation of tertiary lymphoid structures (TLS) are known to occur during the development of several diseases, including systemic lupus erythematosus (SLE), but in why and how they are formed is largely unknown and thus under intense investigation. We have recently discovered immune aggregates within the kidney of lupus prone mice resembling TLS. By using gene and protein expression analysis in combination with cell specific analysis and in vivo imaging, we wanted to investigate the formation of TLS in a longitudinal study of murine lupus nephritis.

Methods:

By using immunohistochemistry and immunofluorescent analysis on kidney section from 85 (NZBXNZW)F1 (NZB/W) lupus prone mice and 20 BALB/c control mice the presence of infiltrating immune cells and the formation of highly organized TLS were analyzed. RNA was isolated from: total kidneys; macro dissected TLS from kidneys; and renal lymph nodes (LN) of NZB/W mice at three different disease stages; young (n=5, only total kidney and LN), proven anti-dsDNA ab positive for 4-5 weeks (n=5), and proteinuric (n=5). RNA samples were prepared for sequencing using the Qiagen Allprep total RNA kit (total kidney) or by Trizol extraction (TLS and LN). Sequencing of total kidney mRNA was performed using the Illumina HiSeq 2500. mRNA from TLS and LN was sequenced using the IonTorrent PGM. Differential expression analysis were performed using the edgeR package. To detect the formation of TLS in vivo we performed a pilot study using positron emission tomography (PET) by tail vein injection of the positron-emitting isotope 18-F-fluro-2-deoxy-D-glucose (FDG) combined with computed tomography (CT) for anatomical localization.

Results:

T cells and NK cells were the first cells to infiltrate the kidneys and the detection observed as early as 10 weeks old and before the mice start to produce anti-dsDNA abs. Gene expression profiling of total kidneys demonstrated an increase in genes involved in T cell activation, NK cell mediated cytotoxicity, B cell activation and inflammation mediated by chemokines and cytokines among others. Upregulation of genes specific for LN indicating a functional TLS within the kidneys of lupus prone mice. Comparing the gene expression profile in TLS and LN from anti-dsDNA ab positive mice confirmed this, but demonstrated a slightly different gene expression in TLS compared to LN from the same mice. In vivo imaging of renal uptake of FDG revealed a promising retention of FDG in kidneys of young NZB/W mice with anti-dsDNA ab production compared to ab negative NZB/W mice and control BALB/c mice. The FDG uptake increased further in NZB/W mice with detectable TLS and in proteinuric mice.

Conclusion:

The induction of anti-dsDNA antibodies, formation and deposition of immune complexes, and the formation and expansion of TLS in lupus nephritis, may promote progression into an end stage kidney disease in SLE. Understanding the mechanisms of the disease pathology is important for the development of new diagnostic approaches and treatment strategies. In vivo imaging detecting TLS can be useful for early diagnosis and individualized treatment of SLE patients with lupus nephritis.

DNA Methylation Governs the Ability of Apoptotic Cells to Suppress Inflammatory Arthritis Via Reciprocal Regulation of IL-6 and TGF-Beta

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Apoptotic cells (AC) have potent anti-inflammatory effects. Injection of apoptotic dendritic cells into mice suppresses the severity of antigen-induced arthritis through increased TGFβ production by resident dendritic cells. However, we have shown that AC that have been previously activated with LPS stimulate a spike in IL-6 production in vivo which inhibits TGFβ and abolishes their immunoregulatory capacity. We set out to define the intrinsic properties of AC that govern their immunomodulatory properties.

Methods: Antigen induced arthritis was used to test the effects of AC in vivo. Peripheral blood samples were obtained from patients with rheumatoid arthritis (all fulfilling ACR criteria) and healthy controls. DNA methylation from human and murine AC was assayed by ELISA and HPLC. We modulated the methylation of AC DNA to determine its role in governing the balance between pro- and anti-inflammatory cytokine production. For some experiments DNA isolated from AC were loaded into liposomes to analyse their properties in vivo. All results refer to murine studies except where specified.

Results: DNA from activated AC was significantly demethylated compared to resting AC. Demethylation of DNA using 5-azacytidine prior to apoptosis induction abrogated the protective effect of resting AC upon inflammatory arthritis. DNA from resting and activated AC loaded into liposomes had identical effects in vivo as the AC cells themselves. Remethylation of the DNA isolated from activated AC using CpG methylase and loaded into liposomes restored their ability to suppress inflammatory arthritis. Suppression of disease was associated with the production of TGFβ, and reversal of suppression with significantly increased IL-6. Apoptotic CD4+ T cells from patients with rheumatoid arthritis were significantly demethylated compared to healthy controls and led to significantly increased production of IL-6 when cultured with healthy macrophages compared to

healthy AC which induced increased TGFβ production.

Conclusion: Our results reveal that DNA methylation acts as the molecular switch that controls the TGFβ dependent regulatory properties of AC. Activated apoptotic cells by virtue of their hypomethylated DNA induce the production of IL-6, which suppresses TGFβ and promotes a pro-inflammatory milieu. Manipulation of activated AC DNA can restore their protective properties offering novel therapeutic approaches for inflammatory arthritis and other autoimmune rheumatic diseases.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health II: RA and Lifestyle Factors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Increased salt concentration enhances the production of T_H17 cells, which are highly proinflammatory and are pivotal in rheumatoid arthritis (RA) pathogenesis.[1, 2] A population-based study has identified an increased RA risk among smokers who also consume a high amount of sodium, as well as a significant additive interaction between smoking and high sodium intake for the development of ACPA-positive RA.[3] Based on these results, we aimed at investigating the role of salt consumption, together with smoking, with regard to the development of ACPA-positivity.

Methods:

The analysis involved 1294 newly diagnosed cases recruited from the EIRA project during 2009-2011. Smoking status (categorized as never/ever smoking), smoking intensity (cut-off at 20 pack-years) and other lifestyle related factors were reported through self-administrated questionnaires at baseline. Sodium consumption was calculated using an algorithm based on data from food questionnaire and was categorized as low, median and high intake. We calculated the odds ratio (OR) and 95% confidence intervals (95%CI) associated with combinations of smoking and salt regarding the development of ACPA positivity in a case-only analysis.

Results:

We identified an increased risk of belonging to the ACPA-positive RA subset among ever smokers (OR=1.4, 95%CI: 0.9-2.1) and heavy smokers (OR=2.6, 95%CI: 1.6-4.1) who had a medium to high sodium intake compared with never smokers with low intake. We further observed a dose response effect between pack-years of smoking and sodium intake with regard to ACPA-positivity (light or never smokers/median sodium intake: 1.0 (0.7-1.4); light or never smokers/high sodium intake: 0.9 (0.6-1.3); heavy smokers/low sodium intake: 1.4 (0.8-2.4); heavy smokers/median sodium intake: 2.1 (1.2-3.7); heavy smokers/high sodium

intake: 3.2 (1.7-6.0); p-trend <0.0001).

Conclusion: We observed an increased risk of ACPA-positivity among high sodium intake (heavy) smokers, compared with never smokers with low sodium intake, as well as a dose response effect of sodium intake among heavy smokers.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health II: RA and Lifestyle Factors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Rheumatoid factor (RF), anti-cyclic citrullinated peptide antibodies (anti-CCP) and C-reactive protein (CRP) are known serum biomarkers of inflammatory arthritis (IA) and have potential predictive value in high risk groups. We measured RF, anti-CCP and CRP levels in the PRe-clinical EValuation of Novel Targets in RA (PREVeNT RA) study, a register of first degree relatives (FDRs) of patients with rheumatoid arthritis (RA), and assessed their associations with known lifestyle risk factors for IA. The aim of PREVeNT RA is to study FDRs of RA patients to identify risk factors for developing RA and so help inform the development of interventions for preventing RA.

Methods:

FDRs of patients with established RA are being recruited from across the UK. FDRs are free of IA and >30 years old at time of recruitment. Following informed consent, participants complete an online questionnaire to ascertain lifestyle factors potentially associated with risk of RA and provide a blood sample for central storage and analysis. For this study, we measured RF (normal ≤20 IU/ml), anti-CCP (normal ≤7 U/ml) and high sensitivity (hs) CRP (normal ≤5 mg/l) on FDRs recruited up to April 2015. Associations between these biomarkers and current smoking status, alcohol intake (units/week), body mass index (BMI, kg/m^2 – derived from self-reported height and weight) and self-reported diabetes were assessed with Fisher's exact or Mann-Whitney tests, then adjusted for age and sex with multiple logistic or linear regression.

Results:

Complete data were available for 469 participants. Baseline characteristics are shown in Table 1 and overlap in biomarker status is shown in Figure 1. Associations between biomarkers and lifestyle risk factors are shown in Table 2. On average, RF positive participants drank 5.49 (95% CI (1.92, 9.06)) more units of alcohol a week and those with elevated CRP had a 3.78 kg/m^2 (95% CI (2.64, 4.92)) higher BMI.

Conclusion:

In this FDR cohort lifestyle factors associated with future onset of IA were also associated with biomarkers of serological risk and low-grade inflammation. These initial results suggest that early targeting of 'at risk' lifestyle factors may, at a population level, reduce future risk of RA onset.

Table 1: Baseline Characteristics

Characteristic	All (n=469)
Female	358 (76.3%)
Age (years)	51 (41, 62)
Current smoker	29 (6.2%)
Alcohol intake (units/week)	5 (1, 10)
BMI (kg/m^2)	25.2 (22.4, 28.7)
Obese (BMI≥30)	91 (19.4%)
Self-reported diabetes	16 (3.4%)
RF (IU/ml)	8.3 (6.6, 10.3)
RF positive (> 20 IU/ml)	26 (5.5%)
Anti-CCP (U/ml)	0.8 (0.5, 1.0)
Anti-CCP positive (> 7 U/ml)	7 (1.5%)
hsCRP (mg/l)	1.4 (0.7, 3.2)
hsCRP elevated (> 5 mg/l)	88 (18.8%)

Values are number (%) or median (inter-quartile range)

Figure 1: Venn diagram of serum biomarker status (n=469)

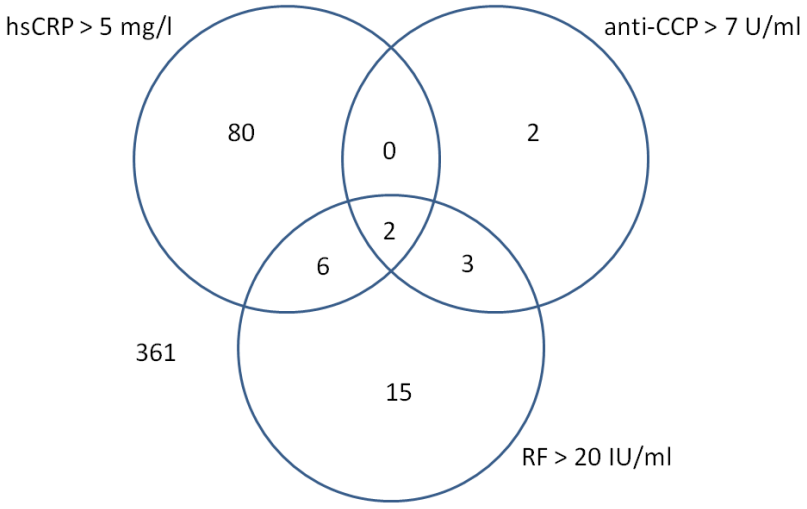

Table 2: Associations between serum biomarkers and lifestyle risk factors (n=469)

Outcome	Predictor					
	RF positive		Anti-CCP positive		hsCRP elevated	
	Test *p*	Regression adj. OR or β	Test *p*	Regression adj. OR or β	Test *p*	Regression adj. OR or β
Current smoking (OR)	0.07	2.93 (0.93, 9.22)	1.00	NA	0.81	1.10 (0.43, 2.82)
Alcohol intake (β)	**0.03**	**5.49 (1.92, 9.06)**	0.69	2.06 (-4.74, 8.85)	0.51	0.09 (-2.04, 2.22)
BMI (β)	0.48	-0.19 (-2.21, 1.82)	0.72	-0.88 (-4.67, 2.92)	**<0.001**	**3.78 (2.64, 4.92)**
Diabetes (OR)	0.61	1.05 (0.13, 8.37)	1.00	NA	0.09	2.82 (0.96, 8.27)

Test: Fisher's exact (current smoking, diabetes) or Mann-Whitney (alcohol intake, BMI) test between outcome and predictor.
Regression: age and sex adjusted logistic regression odds ratio (OR) (current smoking, diabetes) or age and sex adjusted linear regression coefficient (β) (alcohol intake, BMI), with 95% confidence interval.
NAs: perfect prediction in logistic regression (due to small number of anti-CCP positive individuals)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health II: RA and Lifestyle Factors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

<>**Background/Purpose:** Obesity and anti-citrullinated peptide antibodies (ACPA) are risk factors for RA. We investigated whether body mass index (BMI) and ACPA interact in determining RA risk and time to RA. <> <>**Methods:** We conducted a nested case-control study within the Nurses' Health Studies (NHS and NHSII). Self-reported incident RA was confirmed by medical record review for ACR criteria. A blood sample was collected (1989-90 for NHS, 1996-99 for NHSII) prior to diagnosis among pre-RA cases and on a similar date for controls matched on age, menopausal status and hormone use. Seven types of novel ACPA were measured by multiplex bead-based assay (W. Robinson lab, Stanford). For each ACPA, a value ³3 SD above the mean in controls was considered positive. Exposures from biennial questionnaires before blood draw included age, BMI, smoking, and alcohol intake. In the primary analysis, conditional logistic regression models adjusting for covariates provided OR (95% CI) for developing RA, for ACPA (³1 ACPA+), BMI, and a multiplicative interaction of ACPA and BMI (<25 vs. ³25 kg/m^2). In a secondary case-only analysis, multivariable-adjusted Cox regression models provided HR (95% CI) for time to RA. Kaplan-Meier curves and log-rank tests compared time to RA for subgroups of pre-RA cases stratified by ACPA and BMI. <> <>**Results:** Among 255 pre-RA cases and 778 matched controls, mean age was 51.4 (±8.0) years and mean BMI 25.2 (±4.5)

kg/m^2; 98% were White and 11.4% were ACPA+. In multivariable conditional logistic regression, there was a significant interaction between ACPA+ and BMI ³25 for RA risk (p 0.011) (Fig. 1) Among pre-RA cases, mean time to RA was 8.9 (± 5.3) years after blood draw. Time to RA was shortest among those with BMI ³25 and ACPA+ (5.3 ± 4.8 years) and longest in those with BMI<25 and ACPA- (10.5 ± 5.0 years) (log rank p 0.0002). In multivariable Cox models, women with BMI ³25 and ACPA+ had the highest risk for RA (HR 2.3, 95%CI 1.5, 3.5) (Fig. 2). <> <>**Conclusion:** Among women who later developed RA and matched controls, elevated BMI and ACPA+ interacted to increase RA risk, suggesting that these factors are synergistic. Time to RA was shortest in pre-RA cases with both elevated BMI and ACPA+. Obesity may accelerate onset of RA in particular among those who are already ACPA+. The biological mechanism behind our findings warrants further investigation.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health II: RA and Lifestyle Factors
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Studies of fish intake suggest that omega-3 fatty acids (n-3 FAs) could be protective against the development of RA. Previously, we found n-3 FAs were inversely associated with anti-CCP2 positivity in subjects without RA, but at risk for future RA (Gan 2015). In this present study, we investigated whether n-3 FAs were also associated with RF positivity, and if the associations between n-3 FA and these autoantibodies (Abs) differed by HLA shared epitope (SE) positivity, in subjects at risk for future RA.

Methods: The Studies of the Etiology of RA (SERA) cohort includes subjects who are RA-free by 1987 ACR criteria, but who are at increased risk for future RA, based on family history of RA. To examine the association between n-3 FA and Ab positivity, we utilized two approaches: 1) a nested case-control study to determine the association between RF and anti-CCP2 positivity and percent of n-3 FA in erythrocyte membranes (RBC n-3 FA%); 2) a cross-sectional study of the baseline visit of the larger SERA cohort, in which we determined the association between n-3 FA supplement use and RF and anti-CCP2 positivity. We assessed the role of SE as an effect modifier using an interaction term in logistic regression models. As significant n-3 FA*SE interactions were detected for RF, results were stratified by SE status for both RF and anti-CCP2 for comparison.

Results: In the nested case-control study, increases in several RBC n-3 FA%s were associated with a lower prevalence of RF and anti-CCP positivity in SE positive subjects but not SE negative subjects (Table 1). In the larger SERA cohort baseline analyses, n-3 FA supplement use was associated with a lower prevalence of RF positivity in SE positive subjects, but not SE negative subjects; similar trends were seen with anti-CCP2 positivity (Table 2).

Conclusion: We demonstrate that n-3 FAs are inversely associated with RF positivity in SE positive subjects with a familial risk of RA. In combination with our prior work that found n-3 FAs are inversely associated with anti-CCP2 positivity, these data suggests a potential protective effect of n-3 FAs against broader RA-related autoimmunity. Furthermore, the protective effect of n-3 FAs on RA-related autoimmunity may be most pronounced in SE positive subjects. Our findings could be explained by the ability of n-3 FAs to change the conformation of membrane MHC class II molecules and alter antigen presentation and Ab generation (Hughes 1996, Rockett 2015), or other adaptive immune mechanisms yet to be identified. This needs further investigation, as it could lead to the use of n-3 FAs in the prevention of RA.

Table 1: Nested case-control study associations between increasing RBC n-3 FA% and the outcomes of anti-CCP2 and RF by shared epitope status (27 RF positive subjects, 40 anti-CCP2 positive subjects, and 69 antibody negative subjects).

Session Title: Epidemiology and Public Health II: RA and Lifestyle Factors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Little is known about the effect of adherence to the Dietary Guidelines for Americans on risk of developing rheumatoid arthritis (RA). The Alternative Healthy Eating Index 2010 (AHEI-2010) measures how well Americans' diets conform to these guidelines. We aimed to evaluate the association between AHEI-2010 and risk of RA in young and middle-aged women using Nurses' Health Study II (NHS II), a large prospective cohort study.

Methods: The NHS II was initiated in 1989 and comprised 116,430 female registered nurses, aged 25–42 years. RA cases were initially self-reported then confirmed by a connective tissue disease screening questionnaire and medical record review according to the 1987 ACR criteria. Seropositive RA was defined as positive rheumatoid factor or anti-citrullinated peptide antibody and

was determined by chart review or laboratory measurement.Dietary data were obtained from validated food frequency questionnaires at baseline and approximately every 4 years during follow-up. The AHEI-2010 was derived based on foods and nutrients that have been consistently associated with lower risk of chronic diseases in clinical and epidemiologic investigations. Each of the 11 components including vegetables, fruits, whole grains, nuts and legumes, sugar-sweetened beverages, red /processed meat, trans-fat % of energy, long-chain omega-3 fats, polyunsaturated fat, sodium and alcohol has a minimum score of 0 and a maximum score of 10 according to the dietary guidelines and daily intakes. AHEI-2010 ranges from 0 to 110. Time-varying Cox regression models were used to explore the association between cumulative averaged AHEI-2010 and risk of RA after adjusting for potential confounding factors.

Results: During the 1,751,803person-years of follow-up from 1991 to 2011 in NHS II, 347 RA cases (215 seropositive, 132 seronegative) were identified. In the multivariable adjusted model, we found greater adherence to AHEI-2010 was associated with reduced risk of RA. Women in the highest quartile of AHEI-2010 had 33% (HR=0.67, 95% confidence interval 0.49-0.91) reduced risk compared to the women in the lowest quartile (p-trend 0.006) (Table). After additional adjustmentfor BMI, the results were consistent.Further stratified analyses demonstrated that the association of AHEI-2010 with RA risk was stronger in seronegative RA than in seropositive RA.

Conclusion: Data from this large prospective cohort study suggest that better adherence to the Dietary Guidelines for Americans is associated with reduced risk of developing RA in young and middle-aged women. Our results suggest that diet may be particularly important for risk of seronegative RA and further research is warranted to confirm these findings.

Table. Hazard ratios (95% CI) for incident RA according to cumulative AHEI-2010 in Nurses' Health Study II (NHS II, 1991-2010)[1]

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health II: RA and Lifestyle Factors

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Breastfeeding (BF) has been associated with both a decreased and an increased risk of developing rheumatoid arthritis (RA). Regarding oral contraceptive (OC) use and the risk of RA a few studies have shown a negative association but the majority of reports have been unable to demonstrate an association. To the best of our knowledge no previous study has investigated the impact of BF and OC use on the two subgroups of RA, characterized by presence/absence of antibodies to citrullinated peptides (ACPA). Our aim was to study the association between BF history and OC use and the risk of ACPA-positive/-negative RA among women.

Methods: Data from the Epidemiological Investigation of RA (EIRA), a population-based case-control study, comprising women aged 18-75+ living in Sweden, between 1996 and 2013 was analyzed (2637 cases and 4244 controls). For BF, data was available between 2006 and 2013 (884 cases and 1947 controls, parous women). An extensive questionnaire was answered by the participants, including questions regarding duration of BF for each delivered child, OC use and potential confounders (education, smoking, BMI, alcohol consumption, postmenopausal hormone therapy, and reproductive factors). Total BF history among parous women was calculated as the sum of the duration of BF for each delivered child and categorized as 0-6, 7-12 and ≥13 months. Current use of OCs was defined as those who were currently using OCs during the index-year and started at least one year before symptoms debut. Past users were defined as those who used OCs in the past and had stopped at least the year before the index-year. Ever users were defined as current and past users while never users correspond to women who had never used OCs before the index-year. We calculated odds ratios (ORs) with 95% confidence intervals (CI) of developing ACPA-positive/-negative RA, by means of unconditional logistic regression, adjusting for age, residential area and pack-years.

Results: A longer history of BF was associated with a reduced risk of developing RA (OR=0.76, 95% CI 0.62-0.93 and OR=0.91, 95% CI 0.74-1.12 for breastfeeding ≥13 months and 7-12 months respectively, compared with up to 6 months). The trend was significant for ACPA+ RA (*p-value* 0.0088), but not for ACPA- RA (*p-value* 0.2833). These estimates were attenuated when we adjusted for pack-years. Ever users of OC had a decreased risk of developing RA compared with never users (OR=0.88, 95% CI 0.79-0.98), mainly due to a decreased risk among past OC users (OR=0.88, 95% CI 0.80-0.98). The association was significant for ACPA+ but not for ACPA- RA. A longer duration of ever OC use (≥8 years) was significantly associated with a decreased risk of RA overall (OR=0.83, 95% CI 0.73-0.94) and ACPA+ RA (OR=0.82, 95% CI 0.71-0.95), while a borderline association was found for ACPA- RA (OR=0.83, 95% CI 0.69-1.01).

Conclusion: Both BF and OC use were associated with a reduced risk of developing RA, especially for ACPA+ RA. Our study contributes to the knowledge of environmental risk factors and its different impact on the subgroups of RA.

Session Title: Imaging of Rheumatic Diseases II: MRI, PET and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Conventional radiography of the sacroiliac joints (X-SI) is the most commonly used imaging technique to detect structural lesions in axial SpondyloArthritis (axSpA). However, a reliable detection of radiographic sacroiliitis is challenging and might result in misclassification. Next to inflammatory lesions, structural lesions are visible on MRI. We aim to investigate the impact of replacement of X-SI by structural lesions on MRI on the ASAS axSpA classification of patients.

Methods: Patients in the SPondyloArthritis Caught Early (SPACE) cohort (chronic back pain: ≥3 mths, ≤2 yrs, onset <45 yrs) and DEvenir des Spondylarthropathies Indifférenciées Récentes (DESIR) cohort (aged 18-50 with inflammatory back pain (IBP): ≥3 mths, <3 yrs) with (suspicion of) axSpA underwent baseline MRI-SI and X-SI. Three well-calibrated readers, blinded for patient characteristics, read the images. MRI-SI (inflammatory lesions according to ASAS definition) and X-SI (modified New York criteria (mNY)) were considered positive if 2/3 readers agreed. MRI T1-w images were assessed on the presence of structural lesions. Mean scores of 2/3 agreeing readers (ASAS definition) were used in SPACE; in DESIR there were only 2 readers for MRI-SI-s and results were analysed for each reader separately. Previously, we proposed cut-offs to define a positive MRI-SI based on structural lesions (MRI-SI-s) based on <5% presence among no-SpA patients in the SPACE cohort: ≥3 erosions, ≥3 fatty lesions, ≥5 fat lesions and/or erosions. In this analysis, patients were classified according to the ASAS axSpA criteria using MRI-SI-s instead of X-SI and changes were visualized.

Results: In total, 294 (SPACE) and 582 (DESIR) patients were included of which 103 (35.0%) and 418 (71.8%) patients were classified as having ASAS axSpA, respectively. Using the ≥5 fatty lesions and/or erosions cut-off, classification did not change in 275+3+8 (286) patients (97.3%) in SPACE, not in 478+66+23 (567) patients (97.4%) by reader 1 in DESIR and not in 469+43+54 (566) (97.3%) patients by reader 2 in DESIR (table). In SPACE, 5 patients (1.7%) would not be classified as axSpA while 3 patients (1.0%) would be additionally classified as axSpA if only MRI-SI-s was performed. In DESIR, 12 and 10 patients would not be classified axSpA and 3 and 6 patients would be additionally classified axSpA (reader 1 and 2, respectively). Very similar results were found for the presence of fatty lesions or erosions alone (both cut-off of >3).

Conclusion: Replacement of radiographs by assessment of structural lesions on MRI does not lead to a different ASAS axSpA classification in the large majority of patients. These data are promising, however are from two early axSpA cohorts and need to be confirmed in patients with established disease.

	DESIR reader 1	DESIR reader 2	SPACE mean 2/3 readers
Classification remained the same	478	469	275

Session Title: Imaging of Rheumatic Diseases II: MRI, PET and CT
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Modification of structural lesions by anti-TNF therapy has not been demonstrated in a randomized placebo (PBO)-controlled trial. The Spondyloarthritis Research Consortium of Canada (SPARCC) sacroiliac joint (SIJ) score (SSS) assesses the degree of fat metaplasia (new tissue growth after resolution of inflammation), erosion, backfill (new tissue growth at erosion site), and ankylosis observed on MRI in the SIJ. This analysis evaluated the impact on these lesions at 12 wks in patients with non-radiographic axial SpA receiving PBO or etanercept (ETN) in the EMBARK study (ClinicalTrials.gov: NCT01258738).

Methods: Patients had axial SpA per Assessment of SpondyloArthritis international Society (ASAS) criteria without meeting modified NY radiographic criteria; BASDAI score ≥4; symptoms for >3 months and <5 yrs; and had failed ≥2 NSAIDs. Patients were randomized to double-blind ETN 50 mg/wk or PBO for 12 wks, then received open-label ETN. Structural lesions were

scored using the SPARCC SSS method on T1-weighted spin echo (T1WSE) MRI. Two readers independently scored baseline (BL) and 12-wk T1WSE MRI scans, blinded to patients, time point, and inflammation scores assessed by short tau inversion recovery MRI scans. Readers' mean scores were used.

Results: Mean (SD) age was 32 (7.8) yrs, 60.5% were male, duration of disease symptoms was 2.4 (1.8) yrs, 71.6% were human leukocyte antigen B27+, and 80.9% had sacroiliitis on MRI (modified intent-to-treat [mITT] population, N=215). MRI scans from 185 patients (ETN, n=88; PBO, n=97) with BL and 12-wk scans were reviewed. At BL, there were no significant differences in mean SPARCC SSS scores between ETN and PBO (table). From BL to 12 wks, change in mean SPARCC SSS score was significantly greater for ETN than PBO for erosion (-0.57 vs -0.08, respectively, p=0.009) and backfill (0.36 vs 0.06, p=0.021). This treatment difference is also presented in cumulative probability plots (figure).

Conclusion: Treatment with ETN was associated with significantly greater reduction in erosion and increase in backfill at 12 wks vs. PBO, consistent with a very early reparative response to anti-TNF therapy. The impact of this new data on disease progression in SpA should be studied further.

Table. SPARCC SSS scores at baseline, week 12, and change from baseline to week 12

		ETN N=88	PBO N=97	*P*-value* ETN vs PBO Δ BL to week 12
Erosion	Baseline	2.25 (0.33)	1.73 (0.32)	0.009
	Week 12	1.68 (0.25)	1.65 (0.30)	
	Δ BL to week 12	-0.57 (0.16)	-0.08 (0.10)	
Backfill	Baseline	0.76 (0.22)	0.64 (0.20)	0.021
	Week 12	1.13 (0.29)	0.70 (0.23)	
	Δ BL to week 12	0.36 (0.12)	0.06 (0.06)	
Fat Metaplasia	Baseline	0.50 (0.19)	0.27 (0.09)	ns
	Week 12	0.56 (0.22)	0.32 (0.10)	
	Δ BL to week 12	0.06 (0.07)	0.05 (0.05)	
Ankylosis	Baseline	0.15 (0.10)	0.13 (0.11)	ns
	Week 12	0.15 (0.11)	0.13 (0.11)	
	Δ BL to week 12	0.01 (0.01)	0.01 (0.01)	

Values are mean (standard error). Observed case analysis, mITT population.

*2-sample t-test.

BL SPARCC SSS scores did not differ significantly between ETN and PBO.

Treatment differences in Δ BL to week 12 for erosion and backfill remained significant after adjusting for BL SPARCC SSS scores using analysis of covariance models.

Δ, change; ns, non-significant.

Figure. Cumulative probability of change from baseline to week 12 in the etanercept and placebo groups for (A) erosion and (B) backfill.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases II: MRI, PET and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Juvenile Idiopathic Arthritis (JIA) commonly affects the temporomandibular joints (TMJ) and may cause growth disturbance, functional limitation and facial deformity. Early diagnosis and management may minimize these complications. History and clinical examination is of limited value in diagnosing TMJ arthritis. Magnetic resonance imaging with gadolinium is the most sensitive and specific diagnostic tool. Most centers provide only qualitative assessment of TMJ synovitis. The purpose of this study was to develop a technique to quantify synovial enhancement and to apply this to MRIs of TMJs affected by JIA and controls in order to establish a disease threshold, sensitivity and specificity for synovial enhancement.

Methods:

This is a case-control study of children (<16 years) who had MRIs with gadolinium that included the TMJs at Boston Children's Hospital or Massachusetts General Hospital from 2006-2015. Subjects were included in the 'JIA group' if they had a pre-existing diagnosis of JIA and had a subjective assessment of synovitis by the reading radiologist. The 'control group' included subjects without JIA who had an MRI for other reasons (e.g. hearing loss or visual disturbance). Coronal slices of a T1-weighted, gadolinium-enhanced MRI were used to assess the ratio of signal intensity of a $0.2mm^2$ region of interest (ROI) within the TM joint spaces to a $50mm^2$ ROI within the longus-capitus muscle, which controls for time after gadolinium infusion. Two raters carried out independent evaluations. A receiver operating characteristic (ROC) curve was created to determine the sensitivity and specificity of the ratios of enhancement **(Figure 1)**. Independent 2-sample *t* test (2-tailed) was performed for each group with unequal variance assumed. Statistical significance was set at $p<0.05$. Intra and inter-rater reliability was assessed using Intra-class Correlation Coefficient (ICC).

Results:

68 subjects (79% female, mean age 15.3 ± 2.5 yrs) with 112 MRIs with clear visualization of 187 TMJs were included in the JIA group. The control group consisted of 141 subjects (56% female, mean age 11.6 ± 3.5 yrs) with 159 MRIs with clear visualization of 311 TMJs. The mean signal intensity ratio in the JIA group was 3.03 ± 1.4 compared to 1.23 ± 0.16 in the control group ($p<0.001$). The resulting ICC was >0.8 indicating that raters had a high degree of agreement. The ROC analysis indicated a sensitivity of 91.4% and specificity of 98.1% in detecting synovitis with a signal intensity ratio cutoff of 1.66. The area under the curve was 0.978 (95% CI 0.964-0.993, $p<0.001$), and the maximum Youden J-index was 0.98.

Conclusion:

In conclusion, we present a reliable method to quantify TMJ synovial enhancement in MRIs with gadolinium that controls for time after contrast infusion. A signal intensity ratio of 1.66 discriminates TMJs affected by JIA from unaffected controls with a sensitivity of 91.4% and specificity of 98.1%.

Figure 1: Receiver operating characteristic curve showing the sensitivity and specificity of the ratios of enhancement.

Session Title: Imaging of Rheumatic Diseases II: MRI, PET and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Development of a Dual Energy Computed Tomography Scoring System for Measurement of Urate Deposition in Gout

Background/Purpose: Dual energy computed tomography (DECT) can visualize urate crystal deposits in patients with gout and has a potential role as an outcome measure in gout studies. Although automated software is available for urate volume assessment, this method is time-consuming, due to the need to identify regions of interest and exclude areas of artefact. The aim of this study was to develop a semi-quantitative DECT scoring system for measurement of urate deposition in gout.

Methods: Following a structured review of images, a semi-quantitative DECT urate scoring method for foot/ankle scans was developed for testing. This method included four regions, each scored from 0-3, with a maximum total DECT urate score of 12. DECT scans from 224 patients (182 with gout, 42 without gout) were scored by two independent readers. Automated urate

volumes were also measured. Paired scans from eight patients receiving pegloticase were analysed. A timing exercise was undertaken. The properties of the DECT urate score were analysed according to the Outcomes in Rheumatology Clinical Trials (OMERACT) filter.

Results: The inter-reader intraclass correlation coefficient (95%CI) for the DECT urate score was 0.98 (0.97-0.98). All scored regions contributed to the total DECT urate score. DECT urate scores and urate volumes were highly correlated (r=0.91, p<0.0001). Both DECT urate scores and urate volumes discriminated between gout and non-gout control participants, and between the tophaceous gout, non-tophaceous gout and control groups (Figure). Compared with urate volume, the DECT urate score had greater ability to discriminate between responders and non-responders to pegloticase therapy (p<0.001 for DECT urate score and >0.05 for urate volume). The mean (SD) time required for the DECT urate score was 121 (2) seconds and for urate volume was 240 (2) seconds ($p=2x10^{-31}$).

Conclusion: We have developed a novel semi-quantitative DECT scoring method for measurement of urate deposition. This method fulfils many aspects of the OMERACT filter.

Figure: Box and whisker plot showing discrimination between groups.

A. DECT urate scores and B. urate volumes for the following groups: tophaceous gout (tophus, n=89), non-tophaceous gout (no tophus, n=93), hyperuricaemic (HU) controls (n=28) and normouricaemic (NU) controls (n=14). Kruskall-Wallis p<0.0001 for both methods, ****Dunn's multiple comparisons test p<0.0001.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases II: MRI, PET and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Polymyalgia rheumatica (PMR) is a frequent inflammatory condition in elderly people. The place of imaging becomes important for positive and differential diagnosis like malignancy but there is no gold standard. We compared ^{18}f-Fluoro-Dexoxyglucose Positron Emission Tomography (FDG-PET/CT) findings in patients with PMR and controls without rheumatologic disease.

Methods:

Forty-six patients with a diagnosis of PMR, according to 2012 ACR/ EULAR criteria, who have had a FDG-PET/CT have been included. For comparison, fifty-tree patients who have had a FDG-PET/CT for initial staging or follow-up of neoplasm were included as controls. 17 sites where analyzed on PET: 2 shoulders, 2 acromio-clavicular and 2 sterno-clavicular joints, 2 greater trochanters, 2 hips, 2 ischial tuberosities, 2 iliopectinal bursitis, 2 pubic symphysis enthesis and only the interspinous space with the most FDG uptake. We used the semi-quantitative scoring system, by Goerres and al. to evaluate visually FDG uptake (0 to 3 compared to liver uptake) into these sites. We calculated the FDG uptake score corresponding to the mean of intensity over all sites, and the number of sites with significant uptake (FDG uptake 2 or 3) for each patient.

Results:

The two groups were comparable for the median patient age (68,9

for PMR vs. 68,1 years for controls). The characteristics of the patients of PMR group were 55% women, CRP 40,9mg/L, ESR 41,1mm, and an ACR/EULAR score without ultrasound of 4.78/6. Significant differences between the two groups were found for FDG uptake score and for number of sites with significant uptake (Table 1): 1.09 vs. 0.34, and 6.13 sites vs. 1.49 sites, p<0.0001.

With ROC curves analysis, we show that the presence of 3 or more sites with significant uptake is correlated with the diagnosis of PMR with 72% sensibility, 79% specificity [OR = 9.69]. For the FDG uptake score the cut off is 0.53 [Se 76%, Sp 79%; OR 12.1].

We found significant differences in all sites analyzed separately for FDG uptake score and number of sites with significant uptake compared to controls, particularly marked for shoulders, ischial tuberosities and interspinous bursitis (p<0.00001 for FDG uptake score).

Table 1.

	FDG uptake score (0 – 3)	Number of sites with significant uptake (0 – 17)
PMR group (N=46)	1.09 [%CI 1.06-1.11]	6.13 [%CI 4.99-7.26]
Control group (N=53)	0.34 [%CI 0.33-034]	1.49 [%CI 1.38-1.59]
p	p<0.0001	p<0.0001

Conclusion:

FDG-PET/CT for PMR diagnosis is useful: we found significant uptake in articular and peri-articular sites compared to controls particularly shoulders, ischial tuberosities and interspinous space. We propose the number of 3 sites with significant uptake and a FDG uptake score over 0.53 as cut-offs for the diagnosis of PMR.

Fever of Unknown Origin (FUO) and Inflammation of Unknown Origin (IUO): Is 18f-FDG-PET/CT a Useful First Line Diagnostic Strategy?

Verena Schönau[1], Kristin Vogel[2], Matthias Englbrecht[3], Bernhard Manger[3], Daniela Schmidt[4], Torsten Kuwert[4] and Georg Schett[2], [1]Department of Rheumatology and Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Department of Internal Medicine 3, Rheumatology & Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [4]Clinic of Nuclear Medicine, University of Erlangen-Nuremberg, Erlangen, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases II: MRI, PET and CT

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

FUO and IUO are rare but diagnostically challenging clinical problems. Because of the abundance of differential diagnoses, a generally accepted diagnostic guideline has not yet been established. Besides a thorough medical history, physical examination, and laboratory testing, imaging techniques are important tools in the diagnostic workup of FUO and IUO. In the last few years, ^{18}F-FDG-PET/CT has been found to be a suitable diagnostic tool for FUO/IUO, as it is able to detect inflammatory and malignant processes with a high spatial resolution.

Methods:

All patients presenting with FUO or IUO at the University Clinic of Erlangen between 2007 and 2014 were clinically documented and subjected to ^{18}F-FDG-PET/CT scanning with a Siemens Biograph™ TruePoint™ PET/CT. Images were evaluated by specialists at the Departments of Nuclear Medicine and Radiology of the University Clinic of Erlangen. Final diagnosis as documented in the patients´ electronic charts was recorded. ^{18}F-FDG-PET/CT scans were considered positive when a focal uptake of the tracer was detected additionally to the standard areas of physiological tracer uptake. ^{18}F-FDG-PET/CT results were compared to the final diagnosis and classified as helpful or non-helpful in establishing the final diagnosis. Multivariate logistic regression was used to identify clinical parameters that correlated with a helpful ^{18}F-FDG-PET/CT in patients with and without FUO as well as in patients with and without IUO.

Results:

Of the 236 patients enrolled 72 presented with FUO, 139 with IUO and 25 did not fulfill FUO or IUO criteria. 232 patients were included in the multivariate logistic regression model. Final diagnosis was established in 185 patients (78.4%, Table 1). In 123 (52.1% of all patients; 66.5% of diagnosed patients), the ^{18}F-FDG-PET/CT was helpful in finding the diagnosis. The chance was higher in patients without fever (OR=0.252; p=0.001), those aged >50 years (p=0.016; p=0.005, respectively) and those with a CRP level >30 mg/dl (p=0.007; p=0.003, respectively) .

Conclusion:

Our study shows that if the standard diagnostic tests (laboratory, chest x-ray and abdominal ultrasound) did not identify the cause of FUO/IUO, ^{18}F-FDG-PET/CT scanning should be applied in the early stage of the diagnostic process. An early use of a ^{18}F-FDG-PET/CT is especially helpful to establish a final diagnosis in patients with an elevated C-reactive protein and age over 50 years.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Vertebral osteomyelitis is a rare but potentially severe disease: previous works have estimated that neurological complications occurred in up to 59% cases. However, these works were mainly surgical studies, so neurological complications might have been overestimated.

The aim of our study was to evaluate the frequency of neurological deficit (motor deficit: ASIA grade A to D and/or sphincter dysfunction) in a non-selected population of patients with pyogenic vertebral osteomyelitis and to find clinical and MRI signs associated with these complications.

Methods:

We reviewed medical charts of all patients with spondylodiscitis from 2007 to 2014 in a University Hospital and we included patients aged 18 years or older with infectious spondylodiscitis confirmed by MRI and with an identification of the causative agent or a good response to antibiotic therapy if all microbiological samples were sterile.

Results:

One hundred and twenty one patients were included. Mean age was 64.3 +/-15.6 years, mostly men (68.6%, n=83). Median duration of clinical signs before diagnosis on MRI was 21.5 days. Lombo-sacral spine was the most frequently affected (38%, n=46), followed by thoracic (23.1%, n=28), and cervical spine (19%, n=23). The 24 remaining patients (19.8%) had multifocal lesions. Overall, we found that 21.5% (n=26) of the patients had a neurological compromise and 14% (n=17) had surgical therapy for spinal or root nerve decompression. Neurological deficit was present at the time of admission for 14 patients and occurred during antibiotic course for 12 patients, on average 13 days after diagnosis (1-39 days). On MRI, 75.2% of patients (n=91) had an epidural inflammation 39.7% (n=48) had an epidural abscess. Clinical findings associated with motor deficit were: bacteriemiae (OR 3.36, p=0.04), acute onset of symptoms (<7 days) (OR 8.73, p=0.004). We found that several MRI patterns were associated with the presence of a neurological deficit: Cervical spine lesions (OR 3.36, p=0.011), dural compression (OR 5.22, p=0.0012), cerebro-spinal fluid interruption (OR 5.59 p<0,001), signal changes of the spinal cord (OR 6.82, p=0,006). Destruction of more than 50% of the sus-jacent vertebrae volume, kyphosis and erosions of the posterior column were also associated with higher risk of motor deficit: OR 8.45, p=0.017, OR 4.01, p=0.016 and OR 5.58, p=0.032, respectively. Finally, neither epidural phlegmon nor epidural abscesses, multifocal lesions, loss of disk height, nor roots nerve compression were associated with a higher risk of neurological deficit.

Conclusion:

Severe neurological deficit occurred in 1/5 of our patients. Patients with a cervical involvement, major vertebrae destruction and static troubles such as kyphosis, dural compression, cerebro-spinal fluid interruption and signal changes of the spinal cord on MRI were at risk of neurological deficit. In contrast, epidural abscesses or nerve roots compression were not significantly associated with such complications.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Infection-related Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Opportunistic infections are a major risk in with biological drugs therapy, being tuberculosis (TB) one of the most relevant.

Objectives: evaluate the frequency of the TB infections in patients from a national rheumatic disease database treated with biological drugs (BD)

Methods:

Patients included belong to BIOBADASAR, a database of rheumatic disease patients treated with BD in Argentina, created in 2010; this database includes patients diagnosed according with accepted criteria , treated with BD, and controls matched for diagnosis age and sex, not treated with BD.

Demographic, clinical and treatment characteristics were evaluated

The continuous variables are expressed as mean (M), average (m) and standard deviations (SD), inter Quartil range (IQR) or frequency as appropriate. An analysis of logistical regression was made to determine odds ratio (OR) and 95% confidence intervals (CI95%).

Results:

As of march 2015**,** 2928 patients were evaluated, 1709 (58.4%) had treatment with BD, and 1219 (41,6%) matched controls

Diagnoses were: Rheumatoid Arthritis (RA) 2315 (79.1%), Psoriatic Arthritis (PsA) 234 (8 %) and lupus 108 (3.7 %). Women (79.1 %), age 42.9±16.2.

BD include: anti TNF 1770, Abatacept 239, Rituximab 199, Tocilizumab 107, Tofacitinib 32, Belimumab 19, Ustekinumab 2, Anakinra 1; received more than one BD 355 (20.7%).

Of the 2928 patients, 13 (0.04%) had a TB diagnosed according to accepted criteria; 11(0.64%) were treated with BD, other 2 (0.16%) patients belonged to the non biologic treatment group; 12 (92,5%) of the TB patients had RA and 1 (7.7%) PsA

In 1701 patients (58.1%) PPD was performed, 119 (6,9 %) were positive > 5 mm, 93 (68.1%) treated with BD, one later developed TB

In 2100 patients, 71.7% chest x ray was performed with 31 (1.5%) showing pulmonary infiltrates, 25 (80.6%) treated with BD, none developed TB

Pulmonary TB was diagnosed in 11 (84.6%) patients. 2 (15.3%) had extra pulmonary disease; 12 patients (92.3 %) had full recovery one continues on therapy.

Time elapsed from onset of BD treatment until TB diagnosis was 12, RIQ 6-104 months.

Table 1: Tuberculosis risk according to treatment. Analysis of logistic regression

	p	OR	CI 95%
non-biological	0.13	Reference	Reference
Etanercept	0.25	3,72	0,68-20,38
Adalimumab	1.00	3,20	0,44-22,77
Abatacept	0.05	7,14	1,00-51,0
Infliximab	0.10	7,26	0,65-80,97
Tocilizumab	<0.01	15,65	2,17-12,60

Conclusion:

There was a low frequency of TB, with a significant difference in the biological drug treated group

Most the TB patients had pulmonary disease.

Most TB cases appeared after one year of therapy

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Chikungunya fever virus (CHIK) is emerging in the western hemisphere as a mosquito-borne, acute onset

arthritis. The majority of cases progress to persistent moderate to severe polyarthritis that clinically resembles rheumatoid arthritis (RA).[1] As the majority of CHIK arthritis patients reportedly lack rheumatoid factor (RF) and cyclic citrullinated peptide antibody (CCP), differential diagnosis includes seronegative RA.[2] Extracellular 14-3-3η, a chaperonin, is a novel biomarker for joint damage in rheumatoid arthritis (RA) and erosive psoriatic arthritis, with serum elevation occurring in early RA. We previously demonstrated that 21% of patients with early "seronegative" RA and 67% of patients with established "seronegative" RA are 14-3-3η-positive.[3]In order to determine the utility of RF, CCP, and 14-3-3η in the differential diagnosis of CHIK arthritis versus RA, we tested CHIK infected patient serum for 14-3-3η.

Methods: Serum samples were submitted for CHIK IgM and IgG serology. De-identified remnant samples positive for CHIK IgM were tested for 14-3-3η by a proprietary laboratory-developed sandwich ELISA. Rheumatoid factor (RF) isotypes and cyclic citrullinated peptide antibody (CCP) were determined by ELISA.

Results: Of 234 CHIK IgM-positive sera, 223 were also CHIK IgG-positive (95.3%, CI 91.7% to 97.6%). RF IgM was positive in 51 of the CHIK IgM-positive patients (21.8%, CI 16.7% to 27.6%), RF IgG in 7 (3.0%, CI 1.2% to 6.1%), and RF IgA in 10 (4.3%, CI 2.1% to 7.7%). CCP was positive in only 4 patients (1.7%, CI 0.5% to 4.3%). Two isotypes of RF were present in 7 patients, only one of which was CCP-positive. All 3 RF isotypes were present in 1 patient, but the patient was CCP-negative. At least one isotype of RF was positive in 59 patients (25.2%, CI 19.8% to 31.3%). 14-3-3η was positive in 25 patients (10.7%, CI 7.0% to 15.4%). Of those 25, RF was positive in only 6 (24.0%, CI 9.4% to 45.1%) and CCP was positive in only 2 (8.0%, CI 1.0% to 26.0%).

Conclusion: Nearly all patients were positive for CHIK IgG at the time of diagnosis based on a positive CHIK IgM. At least one RF isotype was present in 25.2% of patients. CCP was uncommon. 14-3-3η was present in only 10.7% in contrast to a 64% positivity rate in early RA patients.[4] Therefore, RF may not be helpful in differentiating early RA from CHIK arthritis. However, CCP and 14-3-3η occur less frequently in CHIK arthritis and when present may aid in the differential diagnosis of RA from CHIK arthritis.

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Chikungunya virus (CHIKV) infection causes an acute febrile illness usually accompanied by severe polyarthralgia and polyarthritis. Previous studies have shown that older age, female gender and some comorbid conditions are associated with chronic arthritis. However, the factors associated with acute arthralgia or arthritis are not well known. Thus, we studied the clinical manifestations associated with acute peripheral arthralgia/arthritis in a group of CHIKV patients from Puerto Rico.

Methods: As part of an acute febrile illness surveillance project, patients with fever or history of fever for ≤ 7 days evaluated at the emergency room of a community hospital in Puerto Rico were tested for several pathogens including CHIKV. All patients with positive CHIKV testing by either polymerase chain reaction or IgM enzyme-linked immunosorbent assays from June 2014 to September 2014 were studied. Demographic features, clinical manifestations, and comorbidities were determined. Patients with peripheral arthralgia and/or arthritis were compared to those without peripheral joint symptoms. To examine the differences between the study groups we used bivariable and multivariable analyses adjusting for confounding variables.

Results: In total, 172 patients with CHIKV infection were evaluated, of which 52.9% were female. The mean (standard deviation [SD]) age was 21.1 (± 19.3); 65.5% were ≤ 16 years of age, 25.7% were 17–54 years of age, and 8.8% were ≥ 55 years of age. Peripheral arthralgia/arthritis were seen in 156 (90.7%) patients, of whom 49 (31.4%) had signs of synovitis. In the bivariable analysis, patients with CHIKV arthralgias/arthritis were more likely to be older (21.3 [± 19.6] years vs. 8.2 [± 10.3] years, $p < 0.01$) and to have more myalgias (85.9% vs. 50.0%, $p < 0.01$), back pain (63.5% vs. 6.2%, $p < 0.01$), headaches (87.2% vs. 50.0%, $p < 0.01$), orbital pain (47.4% vs. 6.2%, $p < 0.01$), anorexia (71.8% vs. 37.5%, $p < 0.01$), nausea (62.8% vs. 18.8%, $p < 0.01$), and dizziness (48.1% vs. 12.5%, $p < 0.01$) than those without with peripheral joint involvement. No associations were found for gender, rash, pulmonary symptoms, cardiac manifestations, vomiting, diarrhea, abdominal pain, hematologic abnormalities, elevation of liver enzymes, renal manifestations, or comorbidities such as diabetes, hypertension, cardiac disease, asthma, chronic kidney disease and malignancy. The multivariable analysis is shown in the table.

Clinical manifestations associated with acute peripheral arthralgias/arthritis

Clinical features	OR (95% CI)	*p* value
Myalgias	4.65 (1.48 - 14.72)	<0.01
Back pain	16.77 (3.07 - 313.82)	<0.01
Headache	3.63 (1.06 – 12.53)	<0.05
Ocular pain	8.88 (1.65 – 165.19)	<0.05
Anorexia	5.68 (1.87 – 18.97)	<0.01
Nausea	6.88 (2.05 – 31.49)	<0.01
Dizziness	4.07 (0.98 – 27.69)	0.10

Conclusion: In this population of patients with acute CHIKV infection, peripheral joint involvement was associated with myalgias and back pain as well as non musculoskeletal manifestations such as headaches, ocular pain, anorexia and nausea. Clinicians should be aware that this constellation of symptoms is common in these patients.

Nontuberculous Mycobacterial Diseases Do Not Cause Positive Autoantibody Testing, Results from a Tertiary Pulmonary Care Center

Barbara Goldstein[1], Jeffery J. Swigris[2], Shannon Kasperbauer[1], Pearlanne Zelarney[1] and JoAnn Zell[1], [1]Medicine, National Jewish Health, Denver, CO, [2]National Jewish Health, Denver, CO

Session Title: Infection-related Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: National Jewish Health (NJH) is a tertiary referral center for pulmonary and immunologic disease. The

infectious disease division at NJH specializes in the care of patients with chronic pulmonary infections, especially those with nontuberculous mycobacterial disease (NTM). The NTM patients have bronchiectasis and their sera are sent for autoantibodies to determine if there may be an underlying concomitant rheumatic disease predisposing to infection. It is well known that chronic infectious disease may increase the false positive rate of some immunologic tests. An example is a rheumatoid factor found in tuberculosis and/or hepatitis C. We chose to retrospectively analyze patients with NTM and autoantibodies to determine if these laboratory tests were more frequently positive in the absence of defined rheumatologic illness.

Methods: We queried our electronic medical record from February 2008 through May of 2015. We defined NTM cases as those with positive cultures at our institution or an appropriate ICD-9 code within the medical record. Patients with defined autoimmune disease (ICD- 9 codes with 710 or 714) and tuberculosis were excluded from our entire analysis. Antinuclear antibody (ANA), rheumatoid factor (RF), cyclic citrullinated peptide (CCP), SSA and SSB results were tabulated. We used a Chi-squared analysis to determine if these autoantibodies were more likely to return as positive in the NTM patients when compared with our overall patient population.

Results: During the study period, 3,721 cases of NTM were seen at NJH and 65% had at least one autoantibody resulted. RF, CCP and ANA testing were not more likely to return as positive in the setting of NTM. Furthermore, non-NTM cases within NJH were more likely to have a positive SSA or SSB antibody (OR 0.53, χ^2 19.1 with 1DF, p 0.0001 or OR 0.41, χ^2 10.0 with IDF, p 0.0015 see Table 1).

Conclusion: Patients with NTM were not more likely to have a positive ANA, RF, CCP as compared to the overall population. Additionally, the SSA and SSB were less likely to be positive in patients with NTM. This may indicate that NTM does not cause false positive results as is seen in diseases like tuberculosis. Therefore, in this setting, positive autoantibodies could indicate the presence of occult autoimmune disease.

Autoantibody	NTM+	NTM-

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Infection-related Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Polyarticular septic arthritis (polySA) is rare, but clinically important, with reported mortality rates approaching 30% even with appropriate therapy. Little is known regarding how patients with polySA differ from those with monoarticular septic arthritis (mSA). In addition, there is little known regarding outcomes of patients with polySA who have surgery compared with those who do not. We describe one of the largest cohorts of patients with culture-proven polySA with the aim of characterizing differences in clinical features and outcomes between those with polySA and mSA and between those with polySA treated conservatively or with surgery.

Methods:

We conducted a retrospective study of patients 18 years and older admitted to a single tertiary care center from 1998 to 2015 with culture-positive polySA. Only patients for whom synovial fluid cultures were available for each affected joint were included. Patients with polySA were stratified into operatively managed and conservatively managed groups and compared in aggregate to those with mSA. Microbial profiles, predisposing factors, sites of joint involvement, length of hospital stay (LOS), and 60-day readmission rates were determined.

Results:

Of 41 patients with polySA, 35 received surgical intervention. The most common organisms isolated from synovial fluid were methicillin-sensitive Staph aureus, group B Strep, and methicillin-resistant Staph aureus. The knee was most frequently involved (n = 27), followed by the shoulder (n = 12), wrist (n = 10), hip (n = 8) and elbow (n = 5). Patients with polySA managed surgically had a higher mean ESR ($p < 0.01$), CRP ($p = 0.02$), and synovial polymorphonuclear (PMN) leukocyte % ($p = 0.01$) and a longer mean LOS (18.1 vs. 4.7 days; $p = 0.04$), and a higher rate of discharge to a rehabilitation facility ($p < 0.01$) than their conservatively managed peers. Compared to those with mSA, patients with polySA were more likely to have rheumatoid arthritis ($p = 0.02$), malignancy ($p = 0.02$), or immunosuppression ($p = 0.05$) and had a higher mean peripheral white blood cell (WBC) count ($p < 0.01$), CRP ($p = 0.05$), and frequency of associated sepsis ($p = 0.01$). While rates of surgery were similar between the polySA and mSA groups, those with polySA required more repeat surgeries during the same admission ($p < 0.01$).

Conclusion:

In this large, retrospective cohort, patients with polySA were more medically complex and more likely to have systemic infection at presentation than those with mSA, but ultimately experienced similar outcomes, with the exception of requiring repeat surgery more often. Increased markers of systemic and synovial inflammation were found in patients with polySA managed surgically as compared to their conservatively managed peers. Future research should identify whether the observed differences between patients with polySA and mSA and between surgically or medically managed patients with polySA can be used to guide optimal management.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Oral Session II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Anti-tumour necrosis factor (TNF) molecules have become a valuable addition to the therapeutic armamentarium for patients with severe uveitis. However, direct comparison of safety and efficacy of infliximab (IFX) and adalimumab (ADA) is lacking.

In this French nationwide study, we analyzed the efficacy and safety of IFX and ADA in patients with severe uveitis.

Methods: 203 patients (31 [20-42] years with 57% of women) with severe uveitis treated with anti-TNF alpha (IFX 5mg/kg at week 0, 2, 6 and every 6 weeks or ADA 40mg/2 weeks) were included. Because of the non-randomized design, the comparison of the anti-TNF treatments was performed using a propensity score approach. The probability of receiving either IFX or ADA, conditionally on baseline characteristics, was computed using a logistic regression model. The comparison of efficacy between IFX and ADA was considered as the primary end-point. Ocular involvement response to treatment was evaluated according to the SUN Workgroup criteria.

Results: Uveitis was bilateral in 163 cases (80%). Main etiologies of uveitis included Behçet's disease (38%), juvenile

idiopathic arthritis (20%), spondylarthropathies (11%) and sarcoidosis (5%). The median duration of disease before starting anti-TNF treatment was 42 [15-104] months. Ninety six percent of patients achieved complete or partial response to anti-TNF alpha therapy. In univariate analysis, the factors associated with complete response of uveitis included Behçet's disease (OR=5.89 [1.65-21.0], p=0.006) and more than 5 uveitis flares before anti-TNFα treatment (OR: 2.37 [1.13-4.97], p=0.022). In contrast, previous immunosuppressive use was negatively associated with complete response to anti-TNFα (OR=0.25 [0.11-0.54]; p=0.0004). The complete response rate and the time to first improvement of uveitis were similar regardless the anti-TNFα (IFX or ADA) used (OR 0.88 [0.23-3.35]; p=0.85 and 0.93 [0.41-2.10] months; p=0.86, respectively) in a logistic regression model weighted by the inverse of propensity score. Side effects were reported for 28% of patients and 12% had serious adverse events. No significant difference was observed in terms of serious side effects between IFX and ADA (OR 0.25 [0.047-1.29]; p=0.097).

Conclusion: Overall efficacy and safety were equivalent between IFX and ADA in severe uveitis. Behçet's patients had a 4 times higher odds of complete response to anti-TNFα therapy.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Oral Session II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: ACDC is a hereditary ectopic mineralization syndrome caused by mutations in the NT5E gene that encodes CD73. CD73 is a membrane bound 5' ecto-nucleotidase that hydrolyzes 5'AMP into adenosine and inorganic phosphate. This autosomal recessive disease clinically manifests with extensive mineralization of arteries predominantly of the lower extremities. Claudication and arthralgia complaints are prominent among affected individuals. The anatomic distribution of some of the calcifications in ACDC could be due to a tissue-specific differential of adenosine receptor levels on different cell types, which could apply to not just vessels but the joint capsule as well. The focus of our study is to characterize the rheumatic manifestations of patients with ACDC.

Methods: Six individuals with genetically confirmed disease where assessed clinically, radiologically, immunologically and biochemically. Demographics and complete history and physicals were catalogued.

Results: Four out of 6 patients were female (Table 1). The mean age at onset of symptoms was 16.7 years. In 5 out of 6 individuals, the initial clinical presentation was arthralgia/arthritis and hence the first specialist seen was a rheumatologist. In the 6th instance, the initial presenting complaint was claudication hence culminating in evaluation by a vascular surgeon. The most

common pattern of arthritis was a symmetric, additive, small joint arthritis that in most cases was diagnosed as rheumatoid arthritis at initial presentation. The most common joints affected included PIPs and MCPs including reports of pain, stiffness, swelling and erythema. Episodic flares lasting up to ten days were reported by all subjects and these were responsive to either NSAIDs or short-term corticosteroids. Plain radiography demonstrates joint space loss, capsular calcification, heterotopic bone formation, homogeneous areas of soft tissue calcification and degenerative changes reminiscent of erosive osteoarthritis (image 1). Carpal erosions and meniscal calcifications were not a feature of the disease. All patients were ANA negative.

Conclusion: This is the first study to characterize the rheumatic manifestations of ACDC patients. A mixed degenerative-erosive radiological pattern is highlighted. Rheumatologists may be the first specialists to encounter these individuals and the presenting symptoms may be confused with rheumatoid arthritis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Oral Session II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Corticosteroids, currently the mainstay of uveitis treatment, are associated with adverse events and are not always fully effective. Multiple reports describe the use of biologics, including adalimumab (ADA), in the management of noninfectious uveitis, but there is a paucity of level 1 evidence to support efficacy of these drugs. This study assessed ADA efficacy and safety in patients with active, noninfectious uveitis despite the use of systemic corticosteroid therapy.

Methods: A total of 217 patients aged ≥18 years with active, noninfectious intermediate, posterior, or panuveitis (characterized by active, inflammatory chorioretinal or retinal vascular lesions; anterior chamber [AC] cell grade ≥2+; and/or vitreous haze [VH] grade ≥2+) despite ≥2 weeks of prednisone (10–60 mg/d) were randomized 1:1 to receive placebo or ADA (80 mg loading dose, 40 mg at week 1, followed by 40 mg every other week) for ≤80 weeks. All patients received a mandatory prednisone burst and taper schedule. Primary endpoint was time to treatment failure (TF) at or after Week 6 in ≥1 eye: new, active, inflammatory vascular lesions relative to baseline; worsening of BCVA by ≥15 letters; inability to achieve ≤0.5+ AC or VH grades at Week 6; 2-step increase in AC cell or VH grades after Week 6. Secondary endpoints included change in AC cell grade, VH grade, and logMAR BCVA; time to macular edema (ME); and percent change in central retinal thickness (CRT), all measured from best state achieved before Week 6 to final visit. Area under the curve (AUC) was calculated for AC cell, VH grade, and logMAR BCVA plotted against time.

Results: Patients receiving ADA were less likely to experience TF (HR=0.50; 95% CI, 0.36-0.70; P<0.001), with fewer associated TF causes. Median time to TF was 13 weeks for placebo and 24 weeks for ADA. Statistically significant differences in favor of ADA versus placebo for mean change from best state before Week 6 to the final visit were met for AC cell grade (P=0.011), VH grade (P<0.001), logMAR BCVA (P=0.003), and CRT (P=0.020). A statistically significant difference was not observed for time to OCT evidence of cystoid ME using the full analysis set. In a post-hoc analysis of ME (definition based on CRT, center point thickness 260-340 µm) performed on a subset of patients without macular hole or retinal detachment, ME risk was reduced by 67% in the ADA group versus placebo (HR=0.33; 95% CI, 0.12-0.90; P=0.023). Mean AUC values were significantly higher in the ADA group versus placebo, suggesting better and more durable control of AC cell (mean difference 34.3, 95%CI, 9.2-59.3; P=0.008), VH grade (35.4, 95%CI, 11.3-59.4; P=0.004), and improvement in logMAR BCVA (26.2, 95%CI, 7.0-45.3; P=0.008). Adverse event data were consistent with the safety profile across approved indications for ADA.

Conclusion: In patients with active, noninfectious intermediate, posterior, or panuveitis despite the use of corticosteroids, ADA significantly lowered the risk for recurrence of uveitic activity and BCVA loss. ADA also reduced the risk of developing ME in patients without preexisting macular pathology. The safety profile was consistent with the known safety profile across approved ADA indications.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Oral Session II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: To compare the effects of adalimumab and placebo on the National Eye Institute Visual Functioning Questionnaire 25 (VFQ-25) in subjects requiring high dose corticosteroids for active non-infectious intermediate-, posterior-, or pan-uveitis.

Methods: The VISUAL-1 clinical trial (NCT01148225) was a phase 3, randomized placebo-controlled study. It investigated the efficacy and safety of adalimumab (80 mg loading dose followed by 40 mg every other week) as maintenance therapy in subjects with active non-infectious intermediate-, posterior- or pan-uveitis. The VFQ-25 is a validated measure for assessing the impact of visual impairment from the patient's perspective. The VFQ-25 total score is calculated as the mean of 11 vision-related domains and scores range from 0 (worst vision functioning) to 100 (best vision functioning). The VFQ-25 was administered at every scheduled study visit of the 80 Week trial. As a ranked secondary outcome, the change in VFQ-25 from best state achieved prior to Week 6 to the final/early termination visit was compared between adalimumab and placebo using ANOVA. To investigate the temporal effects of adalimumab and placebo on VFQ-25 in a robust manner, a longitudinal GEE model (which incorporated all VFQ-25 measurements) was estimated.

Results: The VISUAL-1 clinical trial enrolled a total of 217 subjects (110 adalimumab, 107 placebo). The mean VFQ-25 total scores for adalimumab and placebo are similar through the tapering period but subsequently diverge and maintain separation through week 80 (**Figure 1**). The average change in VFQ-25 total score from best state achieved prior to Week 6 to the final / early termination visit was -5.50 for placebo and -1.30 for adalimumab. This corresponds to a statistically significant and clinically meaningful[1] increase of 4.20 (95% confidence interval [CI]: 1.02 – 7.38; P = 0.010) associated with adalimumab relative to placebo. The longitudinal model estimated a statistically significant treatment effect of adalimumab of 3.07 (95% CI: 2.09 – 4.06; P<0.001).

Conclusion: Treatment with adalimumab is associated with statistically significant improvements in visual functioning for subjects with active non-infectious non-anterior uveitis.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Oral Session II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

IgG4 related disease (IgG4-RD) is associated with characteristic pathological changes including lymphoplasmocytic infiltration with abundant IgG4 positive plasma cells, storiform fibrosis and obliterative phlebitis. Recently an increase of plasmablasts in blood has been correlated with IgG4-RD activity. In IgG4-RD lesion tissues, germinal centers (GC) are often observed and could be source of plasmablasts. T follicular helper (Tfh) cells orchestrate antigen driven GC formation and B cell differentiation. Bona fide Tfh cells have been initially recognized in lymph nodes but a circulating counterpart characterized as Tfh like $CD4^+CXCR5^+PD\text{-}1^+$ cells has been reported. We analyzed the Tfh like cells and their subsets in blood of untreated IgG4-RD patients.

Methods:

Thirty patients with IgG4-RD were included prospectively in the study and compared to matched (age and gender) healthy controls (HC) and matched (age) primary Sjögren syndrome (pSS) patients. Patients fulfilled the 2011 comprehensive IgG4-RD diagnostic criteria and the 2002 American-European Consensus Group criteria for pSS. Peripheral blood mononuclear cells (PBMC) of patients and controls were analyzed by flow cytometry on a BD FACS Canto II. Tfh like cells were defined as $CD4^+CXCR5^+PD\text{-}1^+$. Subsets of Tfh were defined as Tfh2 $CCR6^-CXCR3^-$, Tfh-1 $CCR6^-CXCR3^+$ and Tfh-17 $CCR6^+CXCR3^-$.

The cytokine production by PBMC for IL-4, IL-10 and IL-17 was performed with the cytokine bead assay (CBA® kit, BD Biosciences). Statistical analysis was performed on PRISM software.

Results: The frequency and absolute numbers (AN) of $CD4^+CXCR5^+PD\text{-}1^+$Tfh like cells are increased in IgG4-RD when compared to HC ($p<0,001$) and pSS ($p<0,001$). In contrast the frequency ($p=0.1$) and AN ($p=0.2$) of $CD4^+CXCR5^+$ is not different from HC. Tfh-1 were decreased in IgG4-RD when compared to HC ($p=0.0005$) and pSS ($p=0.002$). Tfh-17 frequency only differed between IgG4-RD and pSS ($p=0.04$), increased in pSS. Tfh-2 were significantly increased in IgG4-RD when compred to HC ($p<0.0001$) and pSS ($p=0.01$). Tfh-2 values correlated with IgG4 serum levels ($p=0.03$) and IL-4 production by CBA assay ($p=0.01$) but not with IgG4-RD responder index ($p=0.4$) and plasmablasts numbers ($p=0.1$).

Conclusion: IgG4-related disease is associated with increased levels of T Follicular helper like $CD4^+CXCR5^+PD\text{-}1^+$ cells in blood. The increase of Tfh like cells is mainly related to an increase of the Tfh2 $CCR6^-CXCR3^-$ subset. These finding suggests that T follicular helper 2 cells, characterized by their ability to produce Th2 cytokines, play a role in IgG4-RD pathogenesis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Oral Session II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a widely recognized systemic inflammatory disorder. However, owing to its extremely diverse clinical picture, each clinician encounters a clinically distinct patient (pt) population depending on his/her specialty, and it is difficult to avoid institutional bias in a single center. This prompted us to conduct a relatively large-scale multicenter study with well-experienced physicians of IgG4-RD including rheumatologists, gastroenterologists, pulmonologists and nephrologists. The purpose of this study is to clarify the baseline clinical and laboratory features of IgG4-RD using a relatively large-scale cohort of 333 IgG4-RD pts.

Methods: Between 2001 and 2014, we retrospectively evaluated 333 pts with IgG4-RD in five institutions. The diagnosis of IgG4-RD was made based on the comprehensive diagnostic criteria or criteria of each organ. We analyzed the serum levels of IgG, IgG4, C3, C4, CH50 and CRP, the affected organs, the target organs for biopsy and treatment. We also determined the

prevalence of diabetes mellitus (DM) and malignancy.

Results: Two hundred and four pts were male, and 129 were female (male 61.3%). The mean age was 63.8 years (range 25-91). At diagnosis, mean serum IgG and IgG4 were 2404 mg/dL and 755 mg/dL respectively. Serum IgG4 was elevated in 317 of 332 (95.5%). Hypocomplementemia was seen in 137 of 327 (41.9%), with pts with kidney lesion showing an especially high frequency (59.5% vs. 36.3%, p<0.001). Serum level of CRP was less than 1.0 mg/dL in 90.2%. Mean number of organs involved was 3.2 (range 1-11); salivary gland (SG) was the most frequently involved organ (72.3%), followed by lacrimal gland (LG), pancreas, retroperitoneum (RP)/periaorta, kidney, and lung. Single organ involvement excluding lymph nodes was seen in 63 of 333 (18.9%), with the most frequently affected organs being SG followed by LG. RP/periaorta, lung and kidney were more frequently affected in males than in females, whereas LG and SG were more frequently affected in females than in males. Biopsy was performed in 270 of 333 (81.1%), with SG 45.1%, lung 16.7%, pancreas 15.3%, kidney 15.2%. Corticosteroid therapy was administered to 248 of 313 (79.2%), and the mean initial dose of prednisolone was 30.5 mg/day. The prevalence of DM was significantly higher in those with than without AIP (47.0% vs. 30.0%, p=0.005). The prevalence of malignancy was 16.8%.

Conclusion: The present study clarified the organs most frequently affected by IgG4-RD by a retrospective multicenter study. In addition, we reconfirmed the high frequency of hypocomplementemia in pts with kidney lesion. Moreover, in more than 95% of pts, serum elevated IgG4 levels were useful for the diagnosis of IgG4-RD.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects II: Pediatric Systemic Lupus Erythematosus

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Pancreatitis is uncommon and a life-threatening SLE manifestation in childhood-onset systemic lupus erythematosus (c-SLE) and it has been restricted to case reports or case series. Recently the International Study Group of Pediatric Pancreatitis (INSPPIRE) proposed definitions to standardize pancreatitis in children. However, studies using these new definitions in a large population of c-SLE patients were not performed. Therefore, the objective of the study was to systematically classify pancreatitis in c-SLE according to INSPPIRE and determine the overall prevalence, clinical features, laboratory and

outcome of the first episode.

Methods: A retrospective multicenter study was performed in 852 cSLE patients from 10 Pediatric Rheumatology services of São Paulo state, Brazil. An investigator meeting was held to define the protocol, to harmonize clinical parameters definition, disease activity and damage tools scoring and outcome parameters. Demographic data, clinical, laboratorial, disease activity (SLEDAI-2K), cumulative damage (SLICC/ACR-DI), treatment and outcome were also evaluated.

Results: Pancreatitis was diagnosed in 22/852 (2.6%) cSLE patients. They were classified as: 20 (91%) acute pancreatitis, 2 (9%) acute recurrent pancreatitis and none had chronic pancreatitis. None of them had gallstone, traumatic pancreatitis or reported alcohol and tobacco use. The first pancreatitis episode was identified at disease onset in 6 (27%) cSLE patients. The comparison of patients with pancreatitis (first episode) and without this complication revealed higher median of SLEDAI-2K [21(0-41) vs. 2(0-45), $p<0.0001$]. The frequencies of fever (70% vs. 6%,$p<0.0001$), weight loss (50% vs. 3%,$p<0.0001$), hepatomegaly (36% vs. 2%,$p<0.0001$), splenomegaly (18% vs. 1%,$p<0.0001$), serositis (45% vs. 2%,$p<0.0001$), nephritis (75% vs. 20%,$p<0.0001$), arterial hypertension (59% vs. 12%,$p<0.0001$), acute renal failure (38% vs. 3%,$p<0.0001$), macrophage activation syndrome (36% vs. 0.5%, $p<0.0001$) and death (32% vs. 7%,$p=0.001$) were also higher in patients with pancreatitis. Frequencies of current methylprednisolone pulse ($p<0.0001$) and the median of current prednisone dose [55(15-60) vs. 11(1-90) mg/day, $p<0.0001$] were significantly higher in patients with pancreatitis, however no differences were observed of prednisone cumulative dose, intravenous methylprednisolone cumulative dose and total glucocorticoid cumulative dose in both groups ($p>0.05$). Of note, the two patients with acute recurrent pancreatitis had two episodes, with pain-free interval of 1 and 4 years.

Conclusion: This was the first study phenotyping pancreatitis according to INSPPIRE standardized definitions evidencing that this complication in c-SLE is predominantly an acute subtype with rare recurrence or progression to chronic damage. We also identified an association with current glucocorticoid use, disease activity and severity.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects II: Pediatric Systemic Lupus Erythematosus
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Elevated levels of cell-bound complement activation products (C4d deposition on erythrocytes [EC4d]

and B lymphocytes [BC4d], CBCAPS) have been demonstrated to be sensitive and specific biomarkers in the differential diagnosis of adult systemic lupus erythematosus (SLE) and other rheumatic diseases. We sought to evaluate the usefulness of CBCAPS in the setting of childhood-onset SLE (cSLE).

Methods: This validation cohort included 28 patients with cSLE all diagnosed prior to their 19th birthdays, and 21 patients with juvenile idiopathic arthritis (JIA). All subjects fulfilled American College of Rheumatology SLE classification criteria. Venous blood was collected and shipped overnight to the reference clinical laboratory conducting the diagnostic testing for CBCAPS and autoimmune markers including antinuclear antibodies (ANA), anti-dsDNA antibodies and other cellular autoantibodies. The CBCAPS multi-analyte assay combining these markers in two consecutive tiers of analysis as currently approved by the Department of Health in the State of NY was calculated. Diagnostic test results were reported as positive (suggestive of SLE) or negative (suggestive of non-SLE). Test performances in this validation cohort were assessed using sensitivity, specificity, and positive and negative likelihood ratios (LR). All laboratory personnel were blinded to subject diagnosis during the pre-analytical, analytical and post-analytical phase of testing.

Results: The results of the cSLE and JIA patients are shown in the Table. Elevated CB-CAPS resulted in 28% higher sensitivity for cSLE than low complement, and higher specificity. After employing the two-tier analysis previously described, the CBCAPS multi-analyte assay yielded 81% sensitivity (22/27, one indeterminate test assessment) and a specificity of 84% (16/19, one indeterminate and one equivocal test assessment). Positive LR was 5.4 and negative LR was 0.2. Of note, the 5 cSLE patients presenting with a negative CBCAPS multi-analyte assay assessment were clinically in remission.

Conclusion: These pilot findings suggest that CBCAPS could provide useful markers for cSLE and differentiation from other autoimmune diseases.

Table: Patient demographics and results of CBCAPS assays

	SLE (n=28)	**JIA (n=21)**

Session Date: Monday, November 9, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects II: Pediatric Systemic Lupus Erythematosus
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Involvement of the central nervous system is frequently observed in childhood-onset SLE patients (cSLE). Proton magnetic spectroscopy (1H-MRS) is an important non-invasive method of quantification of biological metabolites. Abnormalities in brain metabolites may predict future damage, such as lesions and atrophy in adults-onset SLE, however 1H-MRS have never been evaluated in cSLE. **Objective:** To determine the presence of axonal dysfunction in cSLE and to determine clinical, laboratory and treatment features associated with its occurrence. To associate axonal dysfunction with sera Th1 (IL-12, TNF-α, IFN-γ), Th2 (IL-6 and IL-10), Th17 (IL-17) cytokines levels and antiribosomal P protein antibodies (anti-P) and S100β.

Methods: We included 77 consecutive cSLE patients [median age 16 years (range 7-31)] from the Rheumatology outpatient unit (State University of Campinas) and 66 healthy controls [median age 18 years (8-32)]. We performed multi voxel 1H-MRS using point resolved spectroscopy sequence over the superior–posterior region of the corpus callosum (3T Phillips®scanner) and signals from N-acetylaspartate compounds (NAA), choline-based compounds (Cho); creatine containing compounds (Cr) and lactate (Lac) were measured and metabolites/Cr ratios were determined. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. Mood and anxiety disorders were determined through Beck Depression and Beck Anxiety Inventory. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current and cumulative drug exposures. Th1 (IL-12, TNF-α, IFN-γ), Th2 (IL-6 and IL-10), Th17 (IL-17) cytokines levels, S100β levels and anti-P were measured by ELISA using commercial kits. Data were compared by non-parametric tests.

Results: NAA/Cr ratio (p=0.017) and Lac/Cr ratio (p=0.014) levels were significantly decreased and Cho/Cr ratio levels (p=0.038) were increased in cSLE patients when compared to healthy controls. We observed that Cho/Cr ratio was associated with symptoms of anxiety (p=0.02), cognitive decline (p=0.03), corticosteroid use (p=0.034) and correlated with IL-6 (r=0.568; p=0.002). NAA/Cr ratio was associated with disease activity (p=0.01) and correlated with IL-4 (r=0.375; p=0.024). Lac/Cr ratio was associated with symptoms of depression (p=0.016), presence of anti-P (p=0.04) and correlated with IFN-γ (r=0.611; p=0.004).

Conclusion: We observed significant axonal dysfunction in cSLE. Decreased NAA/Cr ratio was associated with disease activity and sera IL-4 levels and increased Cho/Cr ratio was associated with neuropsychiatric manifestations, cumulative dose of corticosteroids and IL-6, suggesting brain injury. Lac/Cr was associated with symptoms of depression, anti-P and IFN-γ. NAA, Cho and Lac may be useful as biomarkers in neuropsychiatric cSLE.

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Neurocognitive impairment (NCI) is an important morbidity in childhood-onset systemic lupus erythematosus (cSLE); however, the gold standard formal neuropsychological assessment is difficult to access. Screening for NCI using computerized testing with the Pediatric Automated Neuropsychological Assessment Metrics (PedANAM) is a more feasible option. Four recently derived cognitive performance scores (CPS) use PedANAM raw data and differing statistical methods (weighted average, unweighted average, logistic regression and principal components analysis) to establish suggested cutoff values for patients requiring further evaluation. Our objectives were to examine external, concurrent, criterion and diagnostic validity of the PedANAM-CPS scores using a single-centre multiethnic cSLE cohort.

Methods: Patients were recruited within 18 months of cSLE onset, and all had a formal neuropsychological assessment battery and PedANAM testing on the same day. Validation of the PedANAM-CPS scores utilized sensitivity and specificity analyses in addition to other nonparametric statistical comparisons.

Results: 29 cSLE patients without premorbid NCI completed the study procedures. Median age at testing was 15.2 years, 83% were female. Six (21%) patients had NCI identified by formal testing. All four CPS scores were significantly different in patients with NCI, and predetermined cutoffs were reached only in patients with NCI (Table 1). Two of the 4 CPS scores (one using an unweighted average and the other a logistic regression model) had 100% sensitivity to detect NCI, while the CPS based on principal components analysis had the highest specificity (87%) for detecting NCI (Table 2). All four CPS scores were significantly correlated to 3 of the cognitive domains (visuoconstructive abilities, working memory and psychomotor speed), but not to attention and executive functioning as evaluated by formal neuropsychological testing.

Table 2: Sensitivity and Specificity of PedANAM-CPS for NCI

Table 1: PedANAM-CPS in NCI versus normal cognitive function

	Normal Cognitive Function (N=23)	Patients with NCI (N=6)	p-value
	(median, range)	(median, range)	
PedANAM-CPSmultiscore	3.79 (1.05 - 13.75)	7.37 (1.86 - 15.58)	0.04
PedANAM-CPS UWA*	0.45 (-2.47 - 0.86)	-0.75 (-1.20 - 0.04)	0.002
PedANAM-CPS Logit	-2.80 (-4.78 - 6.41)	-0.43 (-1.46 - 0.86)	0.003
PedANAM-CPS PCA*	1.17 (-8.14 - 2.45)	-2.33 (-3.11 - 0.53)	0.003
	Sensitivity (%, 95% CI)	Specificity (%, 95% CI)	
PedANAM-CPS multiscore	83.3 (43.7 - 97.0)	73.9 (53.5 - 87.5)	
PedANAM-CPS UWA*	100 (61.0 - 100)	73.9 (53.5 - 87.5)	
PedANAM-CPS Logit	100 (61.0 - 100)	56.5 (36.8 - 74.4)	
PedANAM-CPS PCA*	83.3 (43.7 - 97)	87.0 (67.9 - 95.5)	

*UWA = unweighted average; PCA = principal components analysis

Conclusion: The 4 PedANAM-CPS scores have high sensitivity and specificity for NCI in cSLE patients in our multiethnic cohort. The CPS scores are easily calculated by any clinician following administration of the PedANAM test battery, and can be used to discriminate cSLE patients who require referral for a formal neuropsychological assessment.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects II: Pediatric Systemic Lupus Erythematosus
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

All women with anti-Ro antibodies face the risk of cardiac neonatal lupus (cardiac NL), which presents as congenital heart block (CHB) and/or cardiomyopathy in their offspring. While several groups report risk factors for short-term outcomes including mortality, follow up studies beyond infancy are scant. Such information is critical to family counseling as well as formulating strategies for management.

Methods:

Postnatal echocardiograms most distant to birth were evaluated in 178 children with cardiac NL enrolled in the Research Registry

for Neonatal Lupus (mean date of service 2/25/2012 ± 2.51 y). M-mode measurements were analyzed for abnormalities (z score > +2.0) of cardiac and aortic dimensions, as well as qualitative descriptions of abnormal ventricular function, chamber enlargement, and valvular dysfunction (at least moderate stenosis or regurgitation). Bivariate analyses of outcomes were performed with potential risk factors for morbidity including demographics, maternal medications during pregnancy, fetal heart rate at time of detection and lowest documented fetal rate, fetal echo dilated cardiomyopathy (DCM), endocardial fibroelastosis or hydrops, postnatal septal defects, permanent pacemaker (PPM) placement, age at PPM implantation and number of years with PPM.

Results:

Echo reports were available for 15 (8.4%) children age 0-1, 40 (22.5%) >1-5, 34 (19.1%) >5-10, 26 (14.6%) >10-15, 33 (18.5%) >15-20, and 30 (16.9%) >20. Left ventricular (LV) systolic function was qualitatively abnormal in 13.7% and low-normal in 9.1%. Abnormal LV function was more frequent in age groups 0-1 (26.7%) and >20 (26.7%) compared to others (p=0.004). In all ages, decreased LV function associated with lower fetal heart rate at detection of CHB (p=0.012) and nadir rate (p=0.002), as well as fetal DCM (p=0.035) and hydrops (p=0.048). Abnormal LV function also associated with need for PPM (p=0.029), younger age at PPM implantation (p=0.042), longer period of pacing (p=0.014), atrial septal defect (p=0.012) and black race (p=0.019). LV end diastolic dimension was enlarged in 21.5% by z score and 20.6% qualitatively. LV dilation associated with fetal DCM (p=0.04) and black race (p=0.028). The aortic root and/or ascending aorta were dilated in 27.8%, associated with a younger age (p=0.001) and lower fetal ventricular rate at detection (p=0.04). Valvular disease was present in 8.7%, associated with older age (p=0.001), fetal DCM (p=0.033), PPM (p=0.042) and longer period of pacing (p<0.001).

Conclusion:

The majority of cardiac NL children have normal heart size and function on follow up, however over 20% have abnormalities. Depressed LV function is more frequent in the first year of life, possibly due to the ongoing inflammatory insult from anti-Ro exposure in utero. Decreased function is more common again after age 20, which may be a result of long-term pacing. Known risk factors for mortality, including race and fetal factors (heart rate, DCM and hydrops) also predict long-term cardiac dysfunction. Aortic dilation is relatively common, but is noted less frequently in older individuals. Further studies are required to identify optimal pacing techniques and medical management to prevent complications of cardiac NL.

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects II: Pediatric Systemic Lupus Erythematosus

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Vitamin D has an important effect in bone quality and vitamin D deficiency in Juvenile-onset Systemic Lupus Erythematosus patients (JoSLE) may be associated with lower spine and whole body bone mineral density. Besides,

vitamin D has an important immunomodulatory effect that justified its use in autoimmune disease including JoSLE. However, there are no trials that directly addressed the boosting of serum levels of 25-hydroxyvitamin D (25OHD) in bone microarchitecture in JoSLE. The aim of this study was to evaluate the effect of vitamin D supplementation on bone microarchitecture parameters in JoSLE.

Methods: This study was a randomized double-blind placebo-controlled 24-week trial conducted in the Rheumatology Outpatient Clinic, University of Sao Paulo. Forty JoSLE patients (according to ACR classification criteria) up to 25 years old were randomized (1:1) to receive oral cholecalciferol 50,000 IU/week (JoSLE-VitD)(n=22) or placebo (JoSLE-PL)(n=23). Before randomization a three months washout of vitamin D was performed for all patients. Medications remained stable throughout the study. Serum levels of 25OHD were measured using radioimmunoassay. Disease activity was assessed by the SLE Disease Activity Index (SLEDAI). Bone microarchitecture and volumetric bone density were analysed at baseline and after 24 weeks by HR-pQCT (High-resolution peripheral quantitative computed tomography) at tibia site.

Results: At baseline, groups were similar regarding, age, body mass index, organ involvement, glucocorticoid dose, use of immunosuppressive drugs, parameters of bone microarchitecture and volumetric density, SLEDAI and levels of 25OHD. The mean 25OHD serum levels at baseline were similar in JoSLE-VitD and JoSLE-PL groups (19.1 vs. 19.5 ng/ml, p=0.82), as well the mean serum levels of total calcium [9.4 (0.5) vs. 9.1 (0.5) mg/dl, p=0.11]. After 24 weeks, the mean level of 25OHD was higher in the JoSLE-VitD group [31.3 (8.6) vs. 16.5 (5.8) ng/ml, p<0.001] and also a higher decrease was observed in SLEDAI score in JoSLE-VitD [D(final – baseline) SLEDAI: -0.58 ± 2.39 vs. 1.25 ± 3.76, p=0.01)] compared to JoSLE-PL. No difference was observed regarding an improvement of any clinical parameter.

Concerning bone microarchiteture, an increase in trabecular number [DTb.N: 0.162 (0.24) *vs.* 0.028 (0.19) mm, p=0.024] and a decreased in trabecular separation [DTb.Sp: -0.045 (0.06) *vs*. 0.001 (0.04) mm, p=0.017] were observed in the JoSLE-VitD group compared to JoSLE-PL at tibia site. No differences were observed in other structural parameters [trabecular (Tb.Th) and cortical thickness (Ct.Th)] and volumetric bone mineral densities [trabecular (Tb.BMD) and cortical (Ct.BMD)] (p>0.05).

Conclusion: This study suggests that cholecalciferol supplementation for 24 weeks is effective in improving bone microarchitecture parameters in JoSLE patients. Therefore, a therapeutic intervention may be recommended for patients with 25OHD deficiency. (Clinical Trial Registry: NCT01892748).

Hospitalization Trends of Rheumatoid Arthritis and Gout in the United States: A Crossroad

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects II: Infection, Malignancy and Other Comorbidites in RA

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) and gout are the two most common inflammatory *arthritides in the US and beyond*. As hospitalization for these conditions are known to incur substantial resource use, hospitalization trends and associated costs could provide critical benchmarks to the field. Indeed, varying levels of perceived success in their care (including the

effects of new medications) and changing epidemiology (particularly for gout) may have made a substantial impact over the past several decades; however, no relevant data are available. To address this key knowledge gap, we evaluated hospitalization trends between 1993 and 2011 in the US.

Methods: We used the National Inpatient Sample (NIS), a database representative of hospitalizations in the US. We studied hospitalization trends of RA and gout (as the primary/principal discharge diagnosis using ICD-9-CM codes 714.0, 714.2, 714.30-714.33 and 274.0-274.9, respectively) from 1993 through 2011. We used total hospital charge trends as a proxy for total cost trends, as charge data were available for the entire study period. Additionally, we analyzed available cost data during the latest years (2006-2011), as well as the trend of the number of surgeries of total knee replacement, total hip replacement, and other major joint surgeries from 2002-2011, where these data were collected in the NIS.

Results: In 1993, admissions for RA were more than 3 times frequent than those for gout (**Figure 1a**). From 1993 to 2011, the admission rate for RA rapidly declined from 10.9 to 3.6 per 100,000 US adults, whereas that for gout steadily increased from 3.3 to 6.7 per 100,000 US adults, resulting in a reversal of hospitalization frequency between the two conditions in 2011. Inflation-adjusted total hospital charge trends for the two conditions reflected the hospitalization trends and became equal in 2011 ($0.46 billion USD) (**Figure 1b**). The available cost data over the last 6 years reflected the same trend, resulting in $0.13 billion USD for both conditions. Approximately 70% of RA admissions and 3% of gout admissions was associated with total joint replacement or other major joint surgeries from 2002-2011; the trend of the total number of such surgeries in the two conditions reflected overall hospitalization trends.

Conclusion: Our findings based on these nationally representative inpatient data indicate that primary hospitalization rates and the inpatient economic burden for RA have declined substantially over the past two decades, whereas those for gout has increased considerably. These strikingly contrasting trends provide a benchmark for the perceived improvement in RA care (likely related to the use of biologics), thereby preventing joint replacements; they also reflect suboptimal gout care in addition to its increasing prevalence. These data support the need to improve gout prevention and care.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects II: Infection, Malignancy and Other Comorbidites in RA

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

The live herpes zoster (HZ) vaccine is effective in healthy older people to reduce the incidence and burden of HZ. Recent results from a long-term follow-up study of participants in the Shingles Prevention Study trial has shown that its protection attenuates by 10 years. The corresponding duration of protection afforded by vaccination for patients with autoimmune or inflammatory (AI) diseases is unclear.

Methods:

Using Medicare from 2006-2012 for patients with AI diseases, this retrospective cohort study identified HZ vaccinated patients who had no history of HZ before HZ vaccination, and had been continuously enrolled in Medicare Parts A, B and D during the 12 months prior to HZ vaccination (baseline) and throughout follow up. To control for confounding, patients without HZ vaccination were matched 2:1 to those with HZ vaccination on year of vaccination, age, gender, race, AI disease, biologic use, DMARDs and steroids. HZ cases were defined as the presence of an HZ diagnostic code plus concomitant anti-viral therapy. Follow up started one month after vaccination and ended at the earliest date of: HZ, death, loss of Medicare coverage or Dec 31, 2012. Matched patients were censored when vaccinated and then allowed to be included in the vaccination group. We calculated HZ incidence rates (IRs) yearly and used Poisson regression for repeated measures to calculate the adjusted risk ratio of HZ for each year using the first year as the reference.

Results:

In the AI cohort, 46.5% had rheumatoid arthritis, 31.7% psoriasis, 4.5% psoriatic arthritis, 21.1% inflammatory bowel disease, and 1.4% ankylosing spondylitis. Of 43,369 HZ vaccinated patients and 86,738 matched unvaccinated patients, we identified 820 and 2,265 HZ events respectively. IRs among vaccinated increased from 0.75 per 100 person years in the 1st year post vaccination to 1.36 in the 6th year post (Figure). The HZ IRs among unvaccinated remained steady through the 6 years. After multivariable adjustment, vaccinated patients had significantly lower HZ risk compared to those not vaccinated in year 1 (RR 0.52, 95% CI 0.45-0.61), with waning protection over 5 years. By year 6, no significant protection against HZ was demonstrable (RR 0.92, CI: 0.45 – 1.86).

Conclusion:

HZ vaccine effectiveness decreased over time among patients with autoimmune and inflammatory diseases. Protection related to the live HZ vaccine appears to wane over 5 years, and re-vaccination might be considered at that time.

Figure: Incidence rate (IR) and 95% Confidence Interval for herpes zoster over time among patients who had HZ vaccination compared to the matched patients not vaccinated.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects II: Infection, Malignancy and Other Comorbidites in RA
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. The risk of herpes zoster (HZ) was elevated within the tofacitinib clinical development program, although it is unclear how HZ changed over time or whether HZ predicts the development of other events associated with immunosuppression, such as serious infection events (SIEs) or malignancy.

Methods: HZ cases were identified from Phase 1, 2, 3, and long-term extension (LTE) studies of the tofacitinib RA clinical development program (data cut-off April 2014; 1 LTE ongoing, database not locked). Crude incidence rates (IRs; patients with events per 100 patient-years, with 95% confidence intervals [CIs]) were calculated for HZ during discrete 6-month intervals of tofacitinib exposure. Characteristics of HZ events were summarized descriptively. We then evaluated whether HZ predicted subsequent SIE or malignancy (excluding non-melanoma skin cancer [NMSC]). Crude IRs for these outcomes were calculated among patients (pts) with/without prior HZ cases. For SIEs, Cox hazard models were used to evaluate the SIE risk difference between pts with and without prior HZ cases while controlling for other potential risk factors. This approach was not possible for malignancies due to the small number of events.

Results: There were 636 tofacitinib-associated HZ events in 6192 pts with 16,839 patient years of tofacitinib exposure. The overall IR (95% CI) for HZ was 4.04 (3.73, 4.37), with similar IRs across exposure durations (Fig 1). Among HZ cases, 84.3% (536) were female, median age 57 years, and 54.4% (346) were using corticosteroids at baseline. During tofacitinib exposure, 89.6% (570) of pts with HZ received anti-viral agents, and 7.4% (47) had a recurrence of HZ. Most HZ first events (93.9%) involved a single dermatome (95% resolved with treatment; 5% ongoing). None involved visceral dissemination or death. Post-herpetic neuralgia was infrequent (7.4%). Discontinuation due to a first HZ event occurred in 8.0% of cases. Among first non-serious HZ cases, 32 pts had a subsequent SIE (IR: 2.94 [2.01, 4.15]) and 9 pts had a subsequent malignancy (excluding NMSC; IR: 0.81 [0.37, 1.54]). In pts without HZ, IRs for SIEs (2.66 [2.40, 2.94]) and malignancy (0.94 [0.79, 1.12]) were similar. In the multivariable analysis (Fig 2), pts with HZ cases were no more likely to develop SIEs than pts without prior HZ (Hazard Ratio 0.77, p=0.172).

Conclusion: Within the RA clinical development program for tofacitinib, HZ incidence was stable over 90 months of exposure. Pts who developed HZ were no more likely to develop a subsequent SIE or malignancy as compared with those without HZ.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects II: Infection, Malignancy and Other Comorbidites in RA

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Interleukin-6 has a direct protective effect on intestinal cells. Although several cases of lower intestinal perforations (LIP) were reported in clinical trials of tocilizumab (TCZ), the incidence in daily care remains unclear. The event rate is low in patients with rheumatoid arthritis (RA), and several factors may contribute to the risk for LIP. We aimed to examine the incidence of LIP in RA patients treated with biologic or conventional synthetic DMARDs (bDMARDs, csDMARDs).

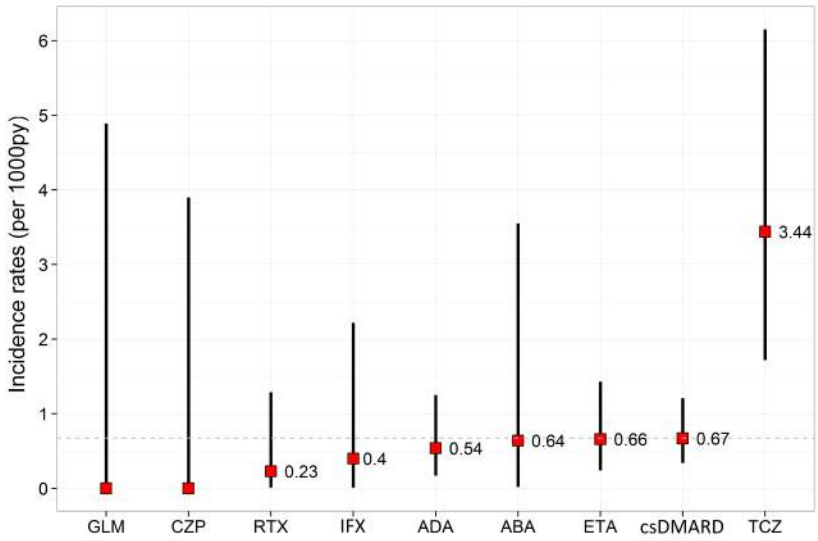
Methods: We used data from the German biologics register RABBIT with 13,600 RA patients included since 2001 at start of a csDMARD or bDMARD after at least one csDMARD failure. All serious gastrointestinal adverse events reported until 30th April 2015 which were possibly associated with perforations (including haemorrhages) were filtered (n=137) and validated with medical records or specific queries, blinded for treatment exposure. Only events with a definite (non-traumatic and non-iatrogenic) perforation of the lower intestinal tract were selected for the analysis. Treatment exposure was defined as treatment given in the last 3-months before the event. Due to low numbers of events multi-variable adjustment was not applied.

Results: In total, 35 LIPs (colon/sigma: 30, appendix: 4, terminal ileum: 1) were observed in 48,102 patient years (PY) - 16 of the patients died. In total, 27 of 35 patients with LIP had concomitant GCs, with a daily dose of ≥7,5mg in 12 patients. In the univariate analysis, current use of glucocorticoids (GC) and age were significantly associated with a higher risk of LIP (hazard ratio (HR) 1.25 per 5mg increase in GC dose [95%CI=1.2, 1.4], and HR 1.5 [1.3, 1.9] per 5 years increase in age).

11 LIP were observed in 1,765 patients treated with TCZ, corresponding to a five times higher incidence rate than in patients receiving csDMARDs only (IRR 5.1 (2.2, 11.8)). The incidence rate was also higher compared to patients treated with other bDMARDs (figure). The increased risk could not be explained by GC use and age of the TCZ treated patients which were similar to patients treated with other bDMARDs.

None of the patients with LIP had a history of diverticulitis known to the treating rheumatologist. Most often, diverticulitis was diagnosed simultaneously with LIP.

The incidence rates in anti-TNF treated patients in RABBIT were similar to those reported by others[1].



Conclusion: This 1st comparison of all bDMARDs available for the treatment of RA showed a significant risk of LIPs in patients treated with TCZ and confirms the signal detected in clinical trials. In none of the patients with LIP a history of diverticulitis was known, which may therefore not constitute sufficient information to support treatment decisions. To avoid additive effects on the risk of LIP concomitant GCs, should be tapered with initiation of TCZ treatment.

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects II: Infection, Malignancy and Other Comorbidites in RA

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The long-term lymphoma risk in patients with rheumatoid arthritis (RA) treated with biologic disease modifying anti-rheumatic drugs (bDMARDs) remains a concern. The aim of this study was to extend assessments of overall and subtype-specific lymphoma risks with bDMARD therapy in RA.

Methods: By linking data from the nationwide Swedish Biologics (ARTIS), Patient, and Cancer Registers, we assembled a cohort of 13,240 RA patients starting a first bDMARD 1998-2012. As comparators we identified a national cohort of bio-naïve RA patients (n=46,568), and an age and gender matched general population referent cohort (n=458,846). Patients were followed until the first of lymphoma, emigration, death, end of study period (Dec 31, 2012) or start of bDMARD (for bio-naïve patients). We estimated hazard ratios (HR) using Cox models for lymphoma overall and for specific lymphoma subtypes according to ICD10-codes, adjusted for age, sex, calendar time, and selected co-morbidities. A histopathological review confirmed agreement between ICD-codes and the clinical subtype diagnosis in >80% of cases.

Results: We found 69 lymphomas during 75,661 person-years (py) in the bDMARD treated patients, 241 lymphomas (237,789 py) in the bio-naïve patients, and 1413 lymphomas (2,890,131 py) in the general population referent cohort. All of the bDMARD treated lymphoma patients were exposed to TNFi, 3 also to abatacept, 2 to anakinra and 2 to rituximab. Compared to the general population both bDMARD treated (HR=2.5; 95% CI 2.0-3.3) and bio-naïve patients (HR=2.2; 95% CI 1.9-2.5) were at increased risk for lymphoma. The lymphoma risk following start of a first TNFi (mean follow-up 5.9 years, maximum follow-up 15 years) or start of a first bDMARD were similar and not significantly increased compared to bio-naïve RA patients (HR bDMARD=1.2; 95% CI 0.9-1.6). There were no significant differences in HRs with age and calendar period at bDMARD start, time since treatment start or time on active bDMARD treatment in bDMARD treated vs. bio-naive RA. We noted a higher point estimate of lymphoma risk in men (HR=1.5) vs. women (HR=1.1); this difference was borderline significant (p=0.04).

There were no clear differences in lymphoma risks for different TNFi drugs (infliximab, etanercept, adalimumab). Due to few events, we abstained from assessing lymphoma risks for specific other bDMARDs.

Compared to the general population, bio-naive and bDMARD-treated RA patients were both at increased risks for most common lymphoma subtypes (Table).

Conclusion: Overall, the lymphoma risk in RA remains increased compared to the general population. TNFi-treatment with a mean follow-up for 5.9 years or overall bDMARD therapy does not substantially influence this risk. The distribution of lymphoma subtypes warrants further assessment.

Table Hazard Ratios for lymphoma overall and for specific lymphoma subtypes in patients with RA, treated with bDMARD (n=13,240) 1998-2012 and bio-naïve RA patients (n=46,568) versus general population comparator subjects (n=458,846) 2001-2012.

Lymphoma subtype[1]	N. lymphoma in bDMARD treated RA vs. general population	HR (95% CI)[6]	N. lymphoma in bio-naive RA vs. general population	HR (95% CI)[6]
All lymphoma	69/1413	2.5 (2.0-3.3)	241/1413	2.2 (1.9-2.5)
B-cell lymphoma	24/515	2.7 (1.7-4.1)	100/515	2.5 (2.0-3.1)
DLBCL[2]	18/371	2.9 (1.8-4.7)	80/371	2.8 (2.2-3.6)

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects II: Infection, Malignancy and Other Comorbidites in RA
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Skeletal muscle loss in rheumatoid arthritis (RA) has been described in association with poor physical functioning. Greater adiposity is simultaneously associated with both greater muscle mass and worse physical function and therefore is a potential confounder in the assessment of relationships between muscle and physical function. We aimed to determine if adjustment of muscle mass estimates for adiposity improves correlations with physical function in patients with RA.

Methods: Three large independent RA cohorts from academic institutions in the US were retrospectively analyzed in a cross-sectional design. Whole-body Dual-Energy Absorptiometry (DXA) measures of appendicular lean mass index (ALMI, kg/m^2) and fat mass index (FMI, kg/m^2) were converted to age, sex, and race-specific Z-Scores using NHANES reference ranges. Fat-adjusted ALMI Z-Scores (ie. standard deviations below average for that level of adiposity) were determined using a novel, comprehensive residual method to adjust for the normal age, sex, and race-specific associations between ALMI and FMI Z-Scores within NHANES. Associations between ALMI Z-Scores (standard and fat-adjusted) and physical functioning were assessed over the range of adiposity adjusting for age, sex, study, and disease activity measures, and assessing for interaction. Functional outcomes assessed included the Health Assessment Questionnaire (HAQ), Valued Life Activities assessment (VLA), and Short Physical Performance Battery (SPPB). Low lean for age was defined as an ALMI or fat-adjusted ALMI Z-Score of ≤ -1.

Results: A total of 415 patients were studied across the cohorts. The combined cohort had a mean ALMI Z-Score of -0.54, mean FMI Z-Score of -0.21, and mean fat-adjusted ALMI Z-Score of -0.53 (all $p<0.001$) suggesting significant muscle deficits compared with national reference ranges before and after adjustment for adiposity. Fat-adjusted ALMI Z-Scores demonstrated stronger associations with all three functional outcomes across all cohorts after adjustment for age and sex (Table). Associations were not attenuated with adjustment for CRP or pain scores. There was an independent association between FMI Z-Score and physical functioning outcomes with a stronger association seen among patients with greater FMI Z-Score (p for interaction <0.05). Fat-adjusted definitions of low lean mass for age more clearly identified those with functional impairment as measured by the HAQ, VLA or SPPB.

Conclusion: Fat-adjusted estimates of skeletal muscle mass deficits demonstrate stronger correlations with physical functioning in RA and thus represent a valid and potentially useful and important outcome measure. Fat mass also demonstrates independent associations with physical function. These observations have far-reaching implications for how we interpret, treat, and study body composition and its impact on physical functioning in RA.

Table 1: Age and sex-adjusted associations between unadjusted/fat-adjusted measures of appendicular lean mass with physical functioning (HAQ, VLA, SPPB) in combined cohort. Observations were similar across all 3 cohorts.

	HAQ (N=415)		Ln(VLA) (N=291)		Ln(SPPB) (N=356)	
	β (95% CI)	p	β (95% CI)	p	β (95% CI)	p

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy III: Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

ABP 501 is being developed as a biosimilar candidate to adalimumab (Humira®), a fully human recombinant monoclonal antibody. Evidence from analytical comparisons indicates that ABP 501 is highly similar to adalimumab. Pharmacokinetic equivalence between ABP 501 and adalimumab has been demonstrated in a phase I study. Here we present results from the Phase 3 study evaluating the efficacy, safety and immunogenicity in subjects with moderate to severe rheumatoid arthritis (RA) for the first adalimumab biosimilar candidate.

Methods:

This was a randomized, double-blind, active-controlled, equivalence study in adult subjects with moderate to severe RA who had an inadequate response to methotrexate. Subjects were randomized 1:1 to receive either ABP 501 (n=264) or adalimumab (n=262) 40 mg subcutaneously every 2 weeks until week 22 followed by safety follow-up to week 26. The primary endpoint was risk ratio (RR) of ACR20 at week 24; clinical equivalence was evaluated by comparing the 90% confidence interval (CI) of RR with an equivalence margin of 0.738–1.355 (1/0.738). Key secondary endpoints included ACR50 and ACR70, safety, and immunogenicity.

Results:

Baseline characteristics were well balanced between groups. At week 24, 74.6% of subjects (194/260) in the ABP 501 group and 72.4% (189/261) in the adalimumab group met the ACR20 response criteria; the RR of ACR20 was 1.039 with the 2-sided 90% CI of 0.954–1.133, which fell within the predefined equivalence margin of 0.738–1.355. At week 24, 49.2% of patients (120/244) in the ABP 501 group and 52.0% (131/252) in the adalimumab group met the ACR50 response criteria, and 26.0% of subjects (64/246) in the ABP 501 group and 22.9% (58/253) in the adalimumab group met the ACR70 response criteria. The incidence of treatment-emergent adverse events (TEAEs) was 50.0% for ABP 501 and 54.6% for adalimumab, and the incidence of any adverse event leading to discontinuation of the investigational product was 1.9% in for ABP 501 and 0.8% for adalimumab. The most frequently reported TEAEs were nasopharyngitis (ABP 501, 6.4%; adalimumab, 7.3%), headache (ABP 501, 4.5%; adalimumab, 4.2%), and arthralgia (ABP 501, 3.0%; adalimumab, 3.4%), cough (ABP 501: 2.7%; adalimumab: 3.1%) and upper respiratory tract infection (ABP 501: 1.5%; adalimumab: 3.8%). The incidence of serious TEAEs was 3.8% for ABP 501 and 5.0% for adalimumab; of note, 0.8% of patients in the ABP 501 group and 1.1% in the adalimumab group experienced serious infections. The incidence of binding antibodies was 38.3% in the ABP 501 group and 38.2% in the adalimumab group; incidence of neutralizing antibodies was 9.1% in the ABP 501 group and 11.1% in the adalimumab group.

Conclusion: Clinical equivalence between ABP 501 and adalimumab was demonstrated. The overall safety and immunogenicity of ABP 501 and adalimumab were similar.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy III: Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: SB4 is a biologic agent developed as a biosimilar of the etanercept reference product (ETN). This study

was a randomized, double-blind, multicenter study and the equivalence of the primary endpoint (ACR20 at Week 24) was shown[1]. In this abstract, the results up to 52 weeks of the study comparing the long term efficacy, safety and immunogenicity, including radiographic progression, between SB4 and ETN are reported.

Methods: Patients with moderate to severe RA (according to the 1987 ACR criteria) despite MTX treatment were randomly assigned to receive weekly dose of 50 mg SB4 or ETN administered subcutaneously for 52 weeks. Efficacy, safety and immunogenicity outcomes were assessed up to Week 52 and radiographic damage was measured by the change in modified total sharp score (mTSS) from baseline to Week 52.

Results: A total of 596 patients with RA were randomized to either SB4 (N=299) or ETN (N=297) and 505 patients completed 52 weeks of treatment (SB4 N=259; ETN N=246). The ACR20 response rate at Week 52 was 80.8% vs. 81.5% in the per-protocol set (PPS) and 70.2% vs. 65.7% in the full analysis set (FAS) with non-responder analysis. The 95% confidence interval (CI) of the adjusted difference in ACR20 response rate was within [–15%, 15%] in both the PPS and FAS. The ACR50 and ACR70 response rates were also similar between SB4 and ETN (Table 1) and the mean change from baseline in mTSS was comparable between the two treatment groups (0.45 for SB4 and 0.74 for ETN).

The safety profile of SB4 was generally comparable to that of ETN (Table 2). Fewer injection site reactions were reported in the SB4 group compared to ETN and the incidence of anti-drug antibody was significantly lower in SB4 compared to ETN ($p<$ 0.001).

Conclusion: Efficacy including radiographic progression and safety were comparable between SB4 and ETN up to Week 52. The immunogenicity profile was lower in SB4 compared to ETN.

Table 1. ACR Response Rates at Week 52 in the Full Analysis Set*

ACR response	Treatment	Response rate	Adjusted difference rate**	95% CI
ACR20	SB4	70.2% (210/299)	4.48%	(–2.90%, 11.87%)
	ETN	65.7% (195/297)		
ACR50	SB4	47.8% (143/299)	5.48%	(–2.32%, 13.29%)
	ETN	42.1% (125/297)		
ACR70	SB4	30.4% (91/299)	5.90%	(–1.12%, 12.93%)
	ETN	24.6% (73/297)		

CI: confidence interval

*FAS follows the intention-to-treat (ITT) principle and includes all patients with at least 1 dose of the study drug. Patients without response at Week 52 were considered as non-responders.

**The difference rate was adjusted for baseline C-reactive protein and stratified by region.

Table 2. Safety and Immunogenicity Results

Patients with	SB4 (N=299) n	(%)	ETN (N=297) n	(%)
At least 1 TEAE	175	(58.5%)	179	(60.3%)
related	88	(29.4%)	109	(36.7%)
At least 1 SAE	18	(6.0%)	15	(5.1%)
related	2	(0.7%)	7	(2.4%)
Serious infection	1	(0.3%)	5	(1.7%)
Tuberculosis	0	(0.0%)	0	(0.0%)
Injection site reactions*	11	(3.7%)	52	(17.5%)
Malignancy	4	(1.3%)	1	(0.3%)
Death	2	(0.7%)	0	(0.0%)
At least 1 ADA positive test result up to Week 52	3	(1.0%)	39	(13.2%)

ADA: anti-drug antibody, SAE: serious adverse event, TEAE: treatment-emergent adverse event

*Numbers are based on high-level group term of administration site reactions.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy III: Biosimilars
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: SB2 is developed as a biosimilar of the infliximab reference product (INF). 30-week efficacy and safety results from a randomized phase III study were recently presented[1]. The objective of this study is to compare the long-term efficacy, safety and immunogenicity between SB2 and INF, including progression of radiographic damage, up to 54 weeks.

Methods: This study is a randomized, double-blind phase III study. Patients with moderate to severe RA (1987 ACR criteria) despite methotrexate (MTX) were randomized in a 1:1 ratio to receive either SB2 or INF (3 mg/kg). Dose increments were allowed after week 30 up to 7.5 mg/kg. Dosing occurred at week 0, 2, 6 and then every 8 weeks until week 46. Efficacy, safety and immunogenicity outcomes were assessed up to week 54 at each visit. Radiographic damage was assessed by the change of modified total sharp score (mTSS) from baseline to week 54.

Results: A total of 584 patients were randomized to either SB2 (N=291) or INF (N=293) and 452 patients completed 54 weeks of treatment (SB2 N=227, INF N=225). The ACR20 response rate at week 54 in the full analysis set (FAS) was 50.7% in SB2 and 52.6% in INF (Figure 1). The ACR50 and ACR70 responses were also similar (32.1% vs. 29.7%; 18.3% vs. 17.7%, Figure 1). Other secondary efficacy parameters at week 54 such as DAS28 or EULAR response were similar between the two treatment groups. The change of mTSS was comparable between the two treatment groups (mean change: 0.38 in SB2 vs. 0.37 in INF; cumulative probability plot is shown in Figure 2). The safety profile of SB2 was generally comparable to that of INF (Table 1). The overall anti-drug antibody positivity up to week 54 was 62.4% in SB2 and 57.5% in INF (p-value = 0.270).

Conclusion: Up to 54 weeks, SB2 showed comparable long-term efficacy, safety and immunogenicity to those of INF and well tolerated. In particular, radiographic progression was comparable between SB2 and INF at 54 weeks.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy III: Biosimilars
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Infliximab (IFX) is the most immunogenic of anti-TNFα drugs available to treat patients with rheumatic diseases. The recent approval of the first infliximab biosimilars in Europe has raised safety and efficacy concerns. Both Inflectra (IFT) and Remsima (RMS), contain exactly the same active molecule produced with the same manufacturing process, but branded differently. One of the main questions is whether patients treated with Remicade (RMC) can be effectively and safely switched to the biosimilar drug. The purpose of the study was to determine if antibodies to infliximab (ATI) in RMC-treated patients cross-react with the biosimilar.

Methods: A total of 256 samples from 256 patients with rheumatoid arthritis (RA) and Spondyloarthritis (SpA) under RMC were retrospectively selected for the study. Serum was collected immediately before the infusion (trough levels) and stored until the analysis. ATI trough levels were measured in parallel with three different bridging ELISA assays: a) Promonitor-ANTI-IFX CE marked kit (Progenika Biopharma SA, Spain) which uses RMC to crosslink patient anti-drug antibodies (ADA); b) the same assay but using RMS, and c) the same assay but using IFT. Briefly, bridging ELISA takes advantage of the two arms of immunoglobulins to crosslink precoated and HRP-conjugated IFX, used as a capture and detection reagent, respectively. The same cut-point (5 AU/mL), as recommended in the kit package insert, was used in the three assays. Spearman´s coefficient and percentages of agreement were used to study the correlation and association between each assay.

Results: In total, 131 samples out of 256 RMC-treated patient samples were tested positive with Promonitor-ANTI-IFX (51.2%, 131 patients). All were ATI-positive when either IFT or RMC bridging assays were used. Only one sample was positive to antibodies to the biosimilars and negative to antibodies against RMC (<5, 5.3 and 7.0 AU/mL of ATI for RMC, IFT and RMS, respectively), with very low ATI levels close to the cut-point, and attributed to experimental variability. Positive and Negative Percentage Agreements were 99.2%/100%, 99.2%/100% and 100%/100%, for RMC *vs.* IFT, RMC *vs.* RMS, and IFT *vs.* RMS, respectively. Spearman´s coefficients were determined to be 0.995, 0.996 and 0.998, for RMC *vs.* IFT, RMC *vs.* RMS, and IFT *vs.* RMS, respectively ($p<0.001$). This is the first study that demonstrates cross-immunogenicity between RMC and biosimilar molecules in patients with rheumatic diseases. Results are in agreement with previous data in patients with inflammatory bowel diseases.

Conclusion: ATI of RMC-treated patients cross-react with either IFT or RMS. Results suggest that the immune response is elicited by the same epitopes regardless of the molecule nature. ATI-positive patients treated with RMC should not be switched to a biosimilar treatment, since preexisting ATI will interact with the new drug, enhance clearance and potentially lead to loss of response and infusion-related reactions. Results also demonstrate that Promonitor-ANTI-IFX test can be used to monitor ATI in biosimilar-treated patients. This finding supports the utility for therapeutic drug monitoring before a switching strategy is considered.

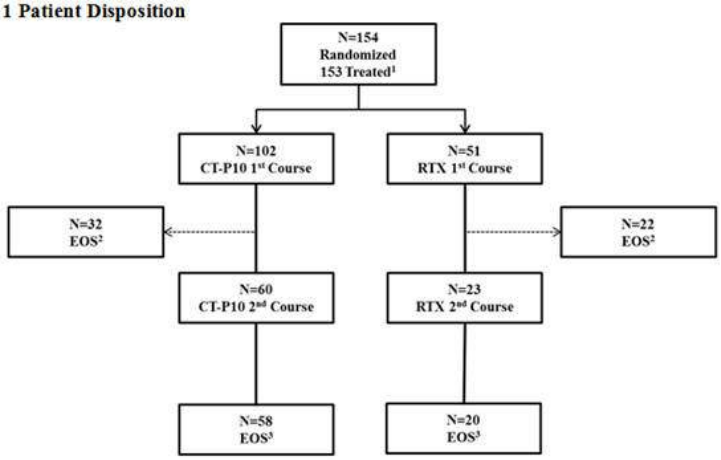
SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy III: Biosimilars
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: CT-P10 is a biosimilar candidate of innovator rituximab (RTX). PK profile and clinical data up to week 24 has been reported at ACR 2013[1]. Additional safety and efficacy were evaluated to confirm similarity between CT-P10 and RTX up to 72 weeks (NCT01534884).

Methods: Patients with active RA (1987 ACR criteria) and intolerant or unresponsive to anti TNF-a blocker were randomized 2:1 to receive 2 infusions (1,000 mg, IV each) of either CT-P10 or RTX, at a 2-week interval, in combination with methotrexate (MTX) and folic acid. The second course of treatment was initiated between weeks 24 ~ 48 based on disease activity and predefined safety criteria. The end of study visit for patients who did not receive the second course of treatment was conducted at week 48 (Figure 1). Efficacy was analyzed in per-protocol population.

Figure 1 Patient Disposition



Note: Patients received 2nd course depending on disease activity and predefined safety criteria from week 24 to week 48. Omitted 2nd course of treatment due to stable disease activity/safety/investigator decision/major deviation: CT-P10, 28/2/2/0; RTX, 19/0/2/1

[1] One patient did not receive a study drug due to difficulty to find the vein.

[2] Patients who did not receive 2nd course of treatment had the end of study visit at week 48.

[3] Patients who received both courses of treatment had the end of study visit at 24 weeks after the 2nd course of infusion.

Results: Of 154 patients randomized at baseline, 132 (85.7%) patients completed the study. The efficacy in terms of DAS28 changes and overall safety were comparable between CT-P10 and RTX treatment groups. The mean decreases from baseline in DAS28 at Week 24 after 1st and 2nd courses of treatment were similar between CT-P10 and RTX treatment groups (Table 1). The proportion of patients experienced at least one adverse event (AE), serious AE, infusion related reaction, infection, malignancy or lymphoma and discontinuation due to AE was similar between CT-P10 and RTX treatment groups (Table 2). Cervix carcinoma stage 0 was reported in a patient from RTX group, and no deaths were reported. B-cell kinetics between the CT P10 and RTX treatment groups were similar at all time points. The mean changes from baseline in IgM, IgG, and IgA were small, and there were no notable differences between the CT-P10 and RTX treatment groups.

Table 1 Efficacy of CT-P10 and Innovator Rituximab by DAS28 Changes

	CT-P10	RTX
DAS28-CRP, Mean ± SD (n)		
Baseline	6.0 ± 0.9 (100)	6.0 ± 0.8 (47)
Changes at Week 24 after 1st Course	−1.9 ± 1.2 (95)	−2.0 ± 1.5 (43)
Changes at Week 24 after 2nd Course	−2.4 ± 1.3 (58)	−2.0 ± 1.2 (20)
DAS28-ESR, Mean ± SD (n)		
Baseline	6.8 ± 0.8 (100)	6.7 ± 0.8 (47)
Changes at Week 24 after 1st Course	−2.1 ± 1.2 (95)	−2.1 ± 1.5 (43)
Changes at Week 24 after 2nd Course	−2.5 ± 1.3 (58)	−2.0 ± 1.2 (20)

RTX, innovator rituximab; DAS28, disease activity score in 28 joints; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; SD, standard deviation

Table 2 Safety Summary of CT-P10 and Innovator Rituximab

	CT-P10	RTX
	N=102	**N=51**
Number of Patients (%) with at Least One		
AE	73 (71.6)	43 (84.3)
Serious AE	14 (13.7)	7 (13.7)
Infusion-related reaction	20 (19.6)	10 (19.6)
Infection	39 (38.2)	21 (41.2)
Malignancy	0	1 (2.0)
Discontinuation due to AEs	6 (5.9)	4 (7.8)

RTX, innovator rituximab; AE, adverse events

Conclusion: CT-P10, a biosimilar candidate of RTX, showed highly similar efficacy and comparable safety profiles to RTX up to

72 weeks.

Tumor Necrosis Factor Inhibitor Tapering Induced Radiographic Progression Is Driven By Weighted Mean Disease Activity over Time, Not Flaring or Lower TNFi Exposition

Alfons A. den Broeder[1], Chantal A.M. Bouman[1], Aatke van der Maas[2], Frank H.J. van den Hoogen[1], Noortje van Herwaarden[1] and R. Landewe[3], [1]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [2]Hengstdal 3, Sint Maartenskliniek, Nijmegen, Netherlands, [3]Department of Internal Medicine, Division of Rheumatology, University Hospital Maastricht, Maastricht, Netherlands

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy III: Biosimilars

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

DRESS, a randomized controlled strategy trial (RCT)[1] investigating disease activity guided tapering of etanercept and adalimumab compared to usual care in RA patients, indicated that minimal radiographic progression is more frequent in patients who attempted TNF inhibitor (TNFi) tapering. Possible explanations include higher mean disease activity, higher incidence of flaring, and/or lower TNFi use in the tapering group.

Methods:

Eighteen months data from the DRESS study were used. Change in Sharp van der Heijde (SvdH) score and percentage of patients with minimal progression (> 0.5 SvdH points) were used as outcomes. Mean time averaged disease activity (Disease Activity Score, DAS28CRP), occurrence and number of (major) flares per patient (flare definition DAS28CRP increase > 1.2, of > 0.6 and current DAS28CRP ≥3.2; major flare lasting > 12 weeks), and TNFi use (normalized percentage of the defined daily dose) during the study were used as independent variables. First, the independent contributions of the four disease activity measures were assessed by univariate and multivariate analyses. Thereafter, linear regression modeling was done with SvdH change as dependent variable, to assess the independent contribution of the disease activity measures and TNFi use, controlled for possible confounders including age, sex, BMI, smoking, baseline SvdH score, DAS28CRP, CRP, RF and ACPA status, and concomitant

sDMARDs.

Results:

All patients with 18 months data available (n=175) were included. Mean SvdH change was 0.75 and 0.15, and minimal radiographic progression was found in 39/121 (32%) and 9/59 (15%) patients in tapering and usual care group respectively (both $p<0.05$, number needed to harm [NNH]=6). Mean DAS28CRP and cumulative incidence of (major) flares were 2.3 (SD 0.5) and 2.1 (0.6) and 73% (12%) and 27% (10%) in tapering and usual care ($p<0.05$). Mean disease activity, but not incidence or number of (major) flares, was independently associated with radiographic progression. No confounding was present.

Conclusion:

The TNFi tapering strategy used in DRESS leads to higher risk for radiographic progression after 18 months than usual care. This is mainly caused by somewhat higher mean disease activity, but not so much by flaring after dose reduction attempts or lower TNFi use itself. Dose tapering of TNFi still seems a safe long-term approach, but long term disease activity should be kept on the lowest level possible using treat to target, and radiologic progression should be checked regularly.

Table 1: linear regression model

	Beta	P-value	95% Confidence interval
Mean DAS28CRP	0.51	0.005	0.15 to 0.86
% of defined daily dose of biological	-0.29	0.39	-0.96 to 0.38
constant	-0.4

Microscopic Bowel Inflammation in Spondyloarthritis As a Baseline Predictor of Anti-TNF Response

Heleen Cypers, Gaëlle Varkas, Filip van Den Bosch and Dirk Elewaut, Rheumatology, Ghent University Hospital, VIB, Ghent, Belgium

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

· **Background/Purpose:**

Microscopic bowel inflammation without associated gastro-intestinal symptoms is present in up to 50% of spondyloarthritis (SpA) patients. Two types of inflammation are distinguished based on histomorphology: an acute type resembling infectious enterocolitis, and a chronic type, resembling early Crohn's disease. Microscopic bowel inflammation in SpA was shown to be associated with a more severe disease phenotype, including more extensive bone marrow edema of the sacro-iliac joints, and an elevated risk of progression to ankylosing spondylitis or to full-blown Crohn's disease. Currently, it is unknown whether microscopic bowel inflammation affects response to therapy, particularly TNF inhibition.

Purpose: To assess the association between the presence of microscopic bowel inflammation, and initiation of and response to

anti-TNF therapy.

· **Methods:**

The Ghent Inflammatory Arthritis and spoNdylitis cohorT (GIANT) is a prospective observational cohort study, following patients with a new diagnosis of axial or peripheral SpA, classified according to the ASAS criteria. Patients underwent an ileocolonoscopy at baseline to assess the presence of microscopic bowel inflammation. For the assessment of response to anti-TNFα treatment ASDAS scores from the moment of anti-TNF initiation and after 3 months were compared. A clinically important improvement was defined as an ASDAS improvement of ≧ 1.1 as recommended by ASAS.

· **Results:**

Of the 93 patients assessed during this study period 39,8 % were started on anti-TNF. The presence or absence of gut inflammation was strongly linked to the rate at which anti-TNF therapy was started ($p<0.01$) (Fig 1 left). Response to anti-TNF was assessed in 24 axial spondyloarthritis patients, of which 46 % had microscopic bowel inflammation (N acute = 4; N chronic = 7). After 3 months of anti-TNF therapy 8 (33.3%) patients had no or slight (△< 1.1) ASDAS improvement, whereas 16 (66.7%) patients showed clinically important improvement. Ten out of 11 (90.9%) patients with microscopic bowel inflammation showed clinically important ASDAS improvement, whereas this was only the case for 6/13 (46.15%) patients with normal bowel histology ($p<0.05$) (Fig 1 right). The association between bowel inflammation and ASDAS response remained significant after correction for CRP using logistic regression analysis ($p = 0.041$; odds ratio 12.55 [1.115-141.269).

· **Conclusion:**

Mucosal inflammation in SpA is a risk factor for more extended and progressive disease resulting in a higher need for TNF inhibition. Most importantly, SpA patients with microscopic bowel inflammation at baseline responded better to anti-TNF therapy than those with normal bowel histology, and this association was independent of CRP. These findings underscore the relevance of gut inflammation in the clinical course of SpA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Inflammatory bowel disease (IBD) is clinically associated with spondylarthropathies (SpA) in 5-15% of cases. Protocol colonoscopic assessment demonstrated asymptomatic inflammation characteristic of Crohn's disease in up to 1/3 of SpA patients. Videocapsule endoscopy (VCE) is a superior diagnostic tool to detect small bowel (SB) mucosal pathology. However, it has been infrequently used to evaluate bowel inflammation in SpA. This study compared the accuracy of VCE to standard ileocolonoscopy (IC) for the detection of inflammatory bowel lesions in patients with SpA, and to describe the clinical and laboratory predictors of SB inflammation in this cohort.

Methods:

Prospective cross-sectional study, involving consenting patients > age 18 with an established diagnosis of SpA. Exclusion criteria included any NSAID use in the previous month or treatment with infliximab, adalimumab or certolizumab. All patients first were evaluated by VCE, followed by IC with biopsies. SB inflammation was quantified using the Lewis Score (LS). Significant inflammation was defined as LS ≥350. Screening tests evaluated included fecal calprotectin (FCP, Buhlmann Laboratories, Basel, Switzerland); levels ≥ 100 ug/g considered positive. A panel of serologic, inflammatory and genetic testing (IBD SGI Diagnostic™) was performed (Prometheus Labs, San Diego, CA). In a subgroup of patients, NOD2 mutations were assessed using a Sequenom array. **Results** were correlated with the presence of significant inflammation on VCE.

Results:

63 patients (54% female, mean age 42±13 years) were recruited; 2 patients refused IC and were disqualified. GI symptoms (chronic diarrhea/abdominal pain/weight loss) were present in 57%. FCP levels were elevated in 47% of patients. Significant SB inflammation was demonstrated by VCE in 25/61 (41%) of patients vs 8/61 (13.1%) by IC (p=0.036). All positive ileal and colonic biopsies were consistent with Crohn's disease. Elevated FCP levels significantly correlated with mucosal inflammation on VCE (r^2 =0.59, p=0.0001, sensitivity 70.6%, specificity 86.6%). Correlation was not observed with the presence of GI symptoms or an elevated CRP. There was no significant correlation between SGI and VCE (r^2 =0.1, p=0.4, sensitivity 26.3%, specificity 82.3%). None of the individual components of SGI was correlated with significant inflammation on VCE. The prevalence of NOD2 mutations was higher in patients with significant SB inflammation (27% vs 11%), however this difference did not reach statistical significance (p=0.22).

Conclusion:

Small bowel lesions consistent with Crohn's disease are more common in patients with SpA than generally acknowledged. VCE is superior to IC in detecting CD in patients with known SpA. Fecal calprotectin levels were significantly correlated with VCE results, while presence of GI symptoms, CRP and SGI results were poor predictors of small bowel inflammation in this patient cohort.

How Reliable Is Self-Evaluation of Symptoms of Inflammatory Back Pain By Patients?

Denis Poddubnyy[1], Inge Spiller[1], Joachim Sieper[1] and Martin Rudwaleit[1,2], [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]Klinikum Bielefeld, Bielefeld, Germany
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Inflammatory back pain (IBP) is regarded as an important clinical parameter of axial spondyloarthritis (axSpA) and is often used in a diagnostic approach. Usually symptoms of inflammatory back pain are evaluated by a physician, however, self-evaluation of IBP symptoms by patients might be a useful approach for self-referral of patients and for time-saving. The aim of this study was to assess the reliability of self-evaluation of symptoms of IBP by patients as compared to an evaluation by a physician.

Methods:

A total of 405 consecutive patients referred to a rheumatologist because of chronic back pain starting at an age <45 years and in whom a diagnosis of axSpA was suspected were included in this multicentre study. A questionnaire containing 8 questions (yes/no) relevant for IBP parameters (duration >3 months, onset prior to 45 years of age, morning stiffness of 30 minutes or longer, insidious onset of back pain, improvement with exercise, improvement with rest, night awakening, alternating buttock pain) were answered by the patient. The same IBP questions were then evaluated by a rheumatologist blinded for presence or absence of other SpA-features and for the diagnosis, and finally by a second, unblinded rheumatologist who was responsible for the final diagnosis. The agreement among the patient and the 2 rheumatologists regarding the fulfilment of the Calin-, Berlin- and ASAS criteria were analysed.

Results:

A total of 180 patients (44.4%) were diagnosed with definite axSpA and in 225 patients (55.6%) SpA was excluded. The agreement on the fulfilment of different IBP criteria sets based on patient's self-assessment and on the judgement of two rheumatologists (blinded and unblinded) is presented in table. As reflected by the kappa-values, there was a moderate agreement on the fulfilment of IBP criteria between the patient and the blinded rheumatologist and fair to moderate between the patient and the unblinded (diagnosing) rheumatologist. The percentage agreement on the presence/absence of IBP was consistent and varied between 73% and 83%. Interestingly, nearly a similar level of agreement was observed between blinded and unblinded rheumatologists. The most consistent agreement results were obtained for the ASAS IBP criteria. Regarding single IBP items, there was a moderate agreement (kappa between 0.4 and 0.6) between patient's and rheumatologist's judgement for the majority of items with a trend for a better agreement between the patient and the blinded rheumatologist (as opposed to the unblinded one).

Conclusion:

The level of agreement between patient and rheumatologist regarding the assessment of IBP was acceptable. Patient's self-reporting of IBP might be used in daily clinical practice.

Table: Agreement on the fulfilment of various IBP criteria sets between patient (self-assessed) and rheumatologists.

		Patient	Blinded rheumatologist	Unblinded rheumatologist
Calin's criteria	**Patient**	-	0.52 (0.42-0.62) 83.2%	0.37 (0.26-0.48) 78.6%
	Blinded rheumatologist	0.52 (0.42-0.62) 83.2%	-	0.43 (0.32-0.53) 80.2%
	Unblinded rheumatologist	0.37 (0.26-0.48) 78.6%	0.43 (0.32-0.53) 80.2%	-
Berlin Criteria	**Patient**	-	0.49 (0.39-0.59) 82.7%	0.31 (0.21-0.41) 73.6%
	Blinded rheumatologist	0.49 (0.39-0.59) 82.7%	-	0.52 (0.43-0.61) 80.0%
	Unblinded rheumatologist	0.31 (0.21-0.41) 73.6%	0.52 (0.43-0.61) 80.0%	-
ASAS criteria	**Patient**	-	0.46 (0.37-0.56) 76.9%	0.42 (0.32-0.52) 76.6%
	Blinded rheumatologist	0.46 (0.37-0.56) 76.9%	-	0.46 (0.37-0.56) 77.3%
	Unblinded rheumatologist	0.42 (0.32-0.52) 76.6%	0.46 (0.37-0.56) 77.3%	-

Cohen's kappa with 95% CI and percent agreement are shown for 405 patients referred because of chronic back pain.

The blinded rheumatologist is unaware of other findings (laboratory, imaging, clinical) of the patient, the unblinded rheumatologist is the treating rheumatologist.

The Survival Impact of Statins in Psoriasis and Psoriatic Arthritis: A General Population-Based Cohort Study

Sian Yik Lim[1], Na Lu[2] and Hyon K. Choi[2], [1]Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Given their lipid-lowering and anti-inflammatory properties, statins may have dual cardioprotective and anti-rheumatic benefits in psoriasis or psoriatic arthritis. These effects may confer survival benefits in this particular patient population, at least similar to those observed in the JUPITER trial among otherwise healthy individuals with low LDL cholesterol but with elevated hsCRP

(i.e., a 20% reduction in overall mortality). However, no relevant data are available in the field. To address this knowledge gap, we evaluated the impact of statin initiation on the risk of mortality among patients with psoriasis or psoriatic arthritis in a general population context.

Methods:

We conducted an incident user cohort study with time-stratified propensity score matching in a United Kingdom general population database. We compared all-cause mortality between statin initiators and non-initiators among patients with a new diagnosis of psoriasis or psoriatic arthritis (n=36,228) between January 2000 and December 2012. To closely account for confounding by indication and potential calendar-time effects, we employed propensity score-matched cohorts of statin initiators and non-initiators within 1-year cohort accrual blocks. Propensity scores (i.e., the predicted probability of statin initiation) were estimated using 50 variables, including disease duration, demographics, socio-economic status, body mass index, lifestyle factors, comorbidities, medication use, and healthcare utilization. We used Cox proportional hazard models to calculate hazard ratios for mortality.

Results:

Of 18,114 statin initiators, 1831 died during the follow up period (mean=4.64 years), whereas among 18,114 matched non-initiators, 2374 died during the follow up period (mean=4.37 years). This corresponds to incidence rates of 21.8/1000 person-years (PY) and 29.9/1000 PY in the statin initiator and comparator groups, respectively. The baseline characteristics were well-balanced in the two groups. Statin initiation was associated with a 30% reduction in all-cause mortality (HR 0.70, 95% CI 0.66-0.75) (**Figure 1a**). When we compared the unmatched cohorts to examine the effectiveness of our propensity score matching, the statin initiators (n=20,120) actually showed a 49% higher risk of mortality (HR 1.49, 95% CI 1.39-1.59) than non-initiators (n=20,120 randomly selected, without propensity score matching) due to confounding by indication (**Figure 1b**).

Conclusion:

Findings from this general population study indicate that statin initiation is associated with a survival benefit among patients with psoriasis or psoriatic arthritis, and its magnitude appears larger than that shown in the JUPITER trial.

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: IL-31 is a newly-described cytokine mainly produced by activated Th2 cells. IL-31 acts through IL31-RA and oncostatin heterodimeric receptors that activate STAT3 and STAT5. So far, IL31 has been mainly involved in airway hypersensitivity and atopic dermatitis. More recent data suggest its involvement in psoriasis and inflammatory bowel disease. We aimed to assess IL-31 serum levels in patients with recent onset axial spondyloarthritis (SpA).

Methods: The DESIR cohort is a prospective, multicenter French cohort of 708 patients with early inflammatory back pain (IBP) (duration >3 months and <3 years) suggestive of AxSpA (mean age 33.8 years; 53.8% women, 57% fulfilled the ASAS criteria). IL-31 and sCD40L were assessed using the multiplex and high sensitive 17-Plex ELISA (Bio-Plex Pro Human Cytokine 17-Plex Immunoassay, BioRad). Serum levels were assessed at baseline in 3 subgroups of patients: i. patients from the DESIR cohort fulfilling the ASAS criteria (ASAS + group, n=443); ii. IBP patients from the DESIR cohort not fulfilling the ASAS criteria (ASAS – group, n= 265); iii. Healthy controls age and sex-matched to a random sample of the DESIR cohort patients (control group, n=80).

Results: IL31 was significantly increased (p<0,001) in the ASAS+ group (median= 7.7 pg/ml ± 15.4, mean 12.6 pg/ml) and ASAS - group (median 6.3 pg/ml ± 16, mean = 11.3 pg/ml) compared to the control group (median=0.0±3.1, mean=1.1 pg/ml). IL31 was correlated with sCD40L(r=0.62; p<0.0001), with DKK-1 (r=0.27; p<0,001), and weakly with IFNg (r=0.12; p=0,016). Patients exhibiting a high level of IL31 had increased CRP (p=0.04), a mSASSS score <1: Yes 7.7 ± 10.7 versus No 13.02±15.07 (p=0.005), and a diagnosis of osteoporosis: Yes 14.1±16.7 versus No 10.7±13.6 (p=0.005). These results were confirmed in the multivariate analyses with a significant and independent association between IL31 and IFNg (p<0.0001), sCD40L (p<0.0001), DKK1 (p=0.02) serum levels, and osteoporosis (p=0.002).

Conclusion: IL31 serum levels are correlated with cytokines involved in a Th1 polarization. IL31 is also significantly correlated with the Wnt signaling inhibitory protein DKK-1 and associated with the osteoporotic phenotype of the patients. These preliminary results suggesting that IL31 might be involved in bone loss observed among SpA patients need to be confirmed in more severe forms of the disease.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: There is a high prevalence of undiagnosed psoriatic arthritis (PsA) in psoriasis patients. Therefore identifying soluble biomarkers for PsA will help in screening psoriasis patients for appropriate referral to a rheumatologist. Our

purpose was to investigate whether serum levels of novel markers discovered by quantitative mass spectrometry (MS) of synovial fluid and skin biopsies, differentiate PsA patients from those with psoriasis without PsA (PsC).

Methods: Serum samples were obtained from 100 patients with PsA, 100 with PsC, and 100 healthy controls. Subjects were group matched for age and sex. No patient was undergoing treatment with biologics at the time of serum collection. Using enzyme-linked immunosorbent assays, four high-priority markers, previously discovered by quantitative MS of synovial fluid and skin biopsies, were analyzed in the serum: Mac-2-binding protein (M2BP), CD5-like protein (CD5L), Myeloperoxidase (MPO), and Integrin-β 5 (ITGB5), as well as previously established markers Matrix metalloproteinase-3 (MMP3) and C-reactive protein (CRP). Data were analyzed using logistic regression (LR), and receiver operating characteristic (ROC) curves were plotted.

Results: The 100 PsA patients (41 females, mean age 51 years) had mean psoriasis duration of 22.9 years, PsA duration of 14.6 years, swollen joint count 3.2, tender joint count 6, and PASI score of 4.7. The 100 PsC patients (45 females, mean age 50 years) had mean psoriasis duration of 20.3 years and PASI score of 4. The 100 controls (52 females) had a mean age of 35 years. Polychotomous LR (Table 1) showed that ITGB5, CRP and M2BP are markers that are significantly different between the three groups. The analyses also showed that CD5L, ITGB5, M2BP, MPO, MMP3 and CRP are independently associated with PsA, while CD5L, M2BP and MPO are independently associated with PsC. When comparing PsA to PsC, ITGB5, M2BP, and CRP were found to be independently associated with PsA (Table 2). ROC analysis (Figure 1) of this model showed an area under the ROC curve of 0.85 (95% CI [0.80, 0.90]).

Conclusion: CD5L, ITGB5, M2BP, MPO, MMP3 and CRP are soluble PsA markers. However, only ITGB5, M2BP and CRP, differentiate PsA from PsC.

Table 1. Polychotomous logistic regression analysis to identify biomarkers associated with PsA and PsC

		PsA		PsC	
Biomarkers	Homogeneity P-value[a]	OR[b] (95% CI)	P-value[c]	OR[b] (95% CI)	P-value[c]

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment III: Biomarkers

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: SLE is a multifaceted disease characterized by immune dysregulation and varied disease activity. Identifying mechanistic mediators of altered disease activity would help prevent damage and improve disease management. This study seeks to identify markers that correlate with disease activity and distinguish African American (AA) SLE patients with impending flare.

Methods: We evaluated changes in plasma soluble mediators preceding SELENA-SLEDAI defined flare in AA SLE patients who developed disease flare 6 or 12 weeks after baseline assessment compared to race, gender, and age (± 5 years)-matched SLE patients without impending flare (non-flare, NF) and healthy controls (n=13 in each group). In addition, mediators were assessed in 18 additional AA SLE patients with impending disease flare compared to a corresponding clinically stable period (self non-flare, SNF) from the same individual. Fifty-two soluble mediators, including innate, adaptive, and shed TNF-receptor superfamily members, were assessed; p-values were corrected for multiple comparisons (q-values). A combined soluble mediator score algorithm was calculated utilizing normalized (Flare vs NF or Flare vs SNF) soluble mediator levels for each patient at baseline (pre-flare) weighted by each patient's SELENA-SLEDAI score at time of disease flare.

Results: Patients with impending flare had significant ($q<0.01$) alterations in 32 soluble mediators at baseline preceding clinical flare by 6 to 12 weeks with significantly higher levels of pro-inflammatory mediators, including innate and adaptive cytokines. Baseline levels of regulatory cytokines, including IL-10 ($q=0.0045$) and TGF-β ($q=0.0004$), were higher in non-flare SLE patients, while pre-flare patients exhibited elevated levels of both innate and adaptive mediators, including IFN-α ($q=0.0008$), IFN-β ($q=0.0080$), IL-6 ($q=0.0004$), IL-12p70 ($q=0.0008$), IL-5 ($q=0.0004$), and IL-17A ($q=0.0004$). In addition, baseline levels of shed TNF-receptor superfamily members TNFRI ($q=0.0017$), TNFRII ($q=0.0394$), TRAIL ($q=0.0008$), FasL (0.0004), and CD40L ($q=0.0008$), but not BLyS ($q=0.5784$), were significantly greater in pre-flare patients compared to NF patients. These mediators were also significantly altered when comparing Flare and SNF samples from the same patient ($q<0.01$). The soluble mediator score was significantly higher in pre-flare SLE patients versus NF patients ($p<0.0001$) or SNF periods of stable disease ($p<0.0001$); every AA SLE patient followed longitudinally exhibited higher soluble mediator scores during their pre-flare period. No differences in the number or type of autoantibody specificities, nor differences in medication use, between pre-flare and NF or SNF SLE patients were noted.

Conclusion: Pro-inflammatory innate, adaptive, and TNF family mediators are elevated in pre-flare lupus patients, while elevated regulatory mediators were noted in AA SLE patients with stable disease. Alterations in the balance between inflammatory and regulatory mediators may help identify AA patients at risk of disease flare and help decipher SLE pathogenic mechanisms.

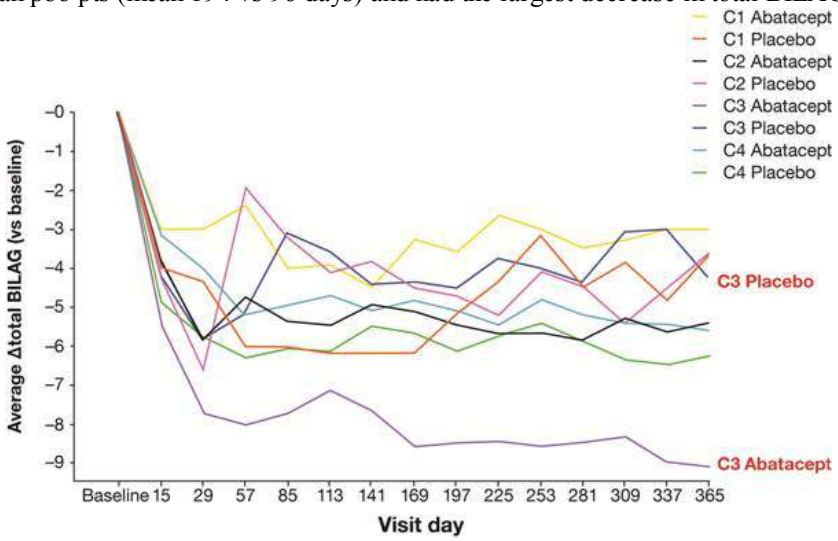
Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment III: Biomarkers

Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The Phase IIb IM101-042 trial was a randomized, double-blind, placebo-controlled trial of abatacept (ABA) in systemic lupus erythematosus patients (pts) with polyarthritis, discoid lesions or serositis. Pts were randomized 2:1 to receive ABA (monthly ~10 mg/kg; n=98) or placebo (pbo; n=46) following a month of high-dose corticosteroids, and with continuing background immunosuppression. To gain insights into responses to ABA in pathologic subsets of SLE, the current study applied a de-convolution algorithm to pts' baseline transcriptomic data from whole blood mRNA. **Methods:** Cell-specific marker genes that were identified for key immune cell types[1] were used in conjunction with a de-convolution algorithm[2] to identify cell proportions from whole blood transcriptomic data obtained by gene chip analysis of PAXgene mRNA in the 144 pt samples collected at trial baseline (before ABA or pbo) and 10 healthy volunteers. The de-convoluted pt-level data were used in an unsupervised analysis to generate consensus clustering for stratification. Pt clusters were then used to perform a *post hoc* analysis of clinical study results. **Results:** The primary study endpoints have been reported.[3] Higher levels of activated natural killer (NK) cells and neutrophils were seen in SLE pts vs healthy volunteers at baseline, while NK and T helper (Th) cells were lower in SLE pts than in healthy volunteers. At baseline, SLE pts were stratified by immune cell fractions into 4 major clusters characterized by a dominance of the listed cell type: C1, high Th cells; C2, high plasma cells (PCs); C3, high neutrophils, activated monocytes and activated dendritic cells; and C4, high B or NK cells. Median and average total British Isles Lupus Assessment Group (BILAG) scores at baseline were similar across all clusters and treatment arms. The C2 cluster (high PCs) contained most of the pts with high levels of anti-dsDNA. C1 cluster pts were the slowest to flare, regardless of treatment allocation (>170 days). In the C3 cluster, ABA-treated pts were slower to flare than pbo pts (mean 194 vs 96 days) and had the largest decrease in total BILAG score and greatest difference from pbo (Figure).



Conclusion: In a re-analysis of the Phase IIb abatacept trial in SLE, whole blood de-convolution identified 4 distinct peripheral blood mononuclear cell phenotypic clusters at baseline. These clusters demarcated distinct clinical characteristics and response to therapy. Whole blood de-convolution might provide insights into specific immune cell-driven disease pathogenesis and might improve patient stratification and enrich interpretation of trial data. 1. Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment III: Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Low complements are included in the SLICC classification criteria for systemic lupus erythematosus (SLE) but are not considered in the ACR classification. As a result, the importance of low complement and its relationship to cumulative organ damage has not been systematically investigated. We evaluated the relationship between low complement, C3 and C4, SLICC criteria and organ damage in SLE.

Methods:

As part of a longitudinal lupus cohort, damage accrual and organ manifestations were evaluated quarterly. Damage was measured using SLICC/ACR Damage Index (SDI). C3 and C4 were measured as part of standard clinical care. Those with and without a history of low complement were compared and an odds ratio calculated and adjusted for ethnicity.

Results:

2399 patients were included in this analysis. 53% were Caucasian and 38% African American, the remainder had other ethnicity, mostly Asian. Low C4 was demonstrated in 47% and low C3 in 55%. The relationship between low complement and the SLICC Classification Criteria is outlined in Table 1. Low complement was more common in those with serositis, renal involvement, hematologic and neurologic criteria.

Addressing the SDI, both low C3 and low C4 associated significantly with stroke, pulmonary hypertension, valvular heart disease and all renal damage parameters. Avascular necrosis, hypertension and osteoporosis were also more common in those who had low complement. Significant relationships were demonstrated between low C4 in particular and seizures, scarring of the panniculum and mesenteric insufficiency while diminished C3 associated with pleural fibrosis and cardiomyopathy. These odds ratios remained significant when adjusted for ethnicity.

Conclusion:

Low complement associated strongly with the components of the SLICC criteria. There was also more damage accrual in those with low complement. This was particularly true in terms of renal outcome but also when considering those components of the damage index which associate with prednisone exposure. This points towards a more severe spectrum of disease in those with low complement and highlights the importance of these serological markers in the diagnosis and prediction of long-term outcomes in SLE. The relationship between low complement, stroke, valvular disease and pulmonary hypertension has not previously been described, but is fascinating given the concern for complement activation as part of antiphospholipid syndrome.

Table 1. The relationship between low C3 and C4 and the SLICC Classification Criteria.

SLICC CRITERIA		Low C3 OR (CI)	Low C4 OR (CI)
Malar rash		1.22 (1.04-1.43)	1.24 (1.06-1.46)
Discoid rash		1.36 (1.11-1.1.67)	1.12 (0.92-1.38)
Photosensitivity		0.8 (0.68-0.94)	0.92 (0.78-1.08)
Oral/Nasal Ulcers		0.74 (0.63-0.87)	0.86 (0.73-1.01)
Arthritis		1.05 (0.88-1.25)	1.31 (1.1-1.57)
Serositis	Pleurisy	1.47 (1.25-1.73)	1.44 (1.23-1.7)

Session Date: Monday, November 9, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment III: Biomarkers
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Increased expression of genes inducible by type 1 interferons has been observed in a subset of patients with systemic lupus erythematosus (SLE). Oral corticosteroids (OCS) are used to manage the signs and symptoms of SLE, with greater dosages needed for more severe disease. We explored associations between elevated expression of type I interferon–inducible genes in blood (IFN-high) and disease activity, complement C3 and C4 levels, autoantibodies to double-stranded DNA (dsDNA) or ribonucleoproteins (Sm, RNP), and use of OCS.

Methods: Baseline disease activity data (N=736) from two randomized controlled trials of sifalimumab (NCT01283139) and anifrolumab (NCT01438489), which enrolled patients with moderate to severe SLE (SLEDAI 2K≥6 and BILAG 1A or 2B and PGA≥1.0 on prednisone and/or immunosuppressants) were pooled. A new investigative-use only assay was used to determine IFN-high. Association between disease activity scores (SLEDAI-2K and CLASI <10 or ≥10), complement C3 or C4 (normal vs. low), autoantibodies to dsDNA, Sm, RNP (negative vs. positive), OCS dosage (< 10 or ≥10 mg/day), and IFN-high was assessed using chi-square tests.

Results: Pooled data from 736 patients were available for analysis. Mean age was 39.6±11.9. Ranges of SLEDAI and CLASI scores were 4–29 and 0–53, respectively, and 61% and 28% had SLEDAI 2K or CLASI scores ≥10. 57% received OCS ≥10 mg/day. 79% were IFN-high and had significantly greater odds of serological and clinical disease activity and of receiving ≥ 10 mg/day of OCS compared with patients who had low levels of type I IFN inducible gene expression in blood (IFN-low, Table).

Conclusion: Significant association of IFN-high with increased serological and clinical disease activity suggests that type I interferons are key drivers of disease in this cohort of patients with SLE. The association between IFN-high and greater OCS use is consistent with these patients having more severe disease.

Association of Baseline Type 1 Interferon (IFN)-Inducible Gene Expression Level in Whole Blood and Serological and Clinical Disease Activity and OCS Use in Patients Enrolled in Phase IIb Studies of Anifrolumab and Sifalimumab

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment III: Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

The present study was aimed at developing an adult Renal Activity In Lupus (A-RAIL) algorithm for Lupus Nephritis (LN) activity assessment using urinary biomarkers (UBMs). A similar index for use in children with LN has been recently proposed.

Methods:

Adult Systemic Lupus Erythematosus (SLE) patients requiring a kidney biopsy as part of their standard care were enrolled. Patient demographics, SLE manifestations, laboratory parameters, renal activity/chronicity measures (R-SLEDAI, SDI-R) and a urine sample were collected at the time of biopsy. One expert read the biopsies in a blinded fashion to report National Institute of Health Activity and Chronicity indices (NIH-AI, NIH-CI). Patients were dichotomized as high activity or not based on the NIH-AI score of 10 as cut-off. UBMs measured included: kidney injury molecule 1, monocyte chemotactic protein 1, neutrophil gelatinase associated lipocalin, ceruloplasmin, adiponectin, hemopexin, alpha-1-acid glycoprotein, hepcidin, lipocalin-like prostaglandin synthase (L-PGDS), transferrin, vitamin D binding protein, transforming growth factor beta, endothelial protein C receptor, and liver type fatty acid-binding protein 1 using standardized ELISA-based assays (except L-PDGS and transferrin, measured by immune nephelometry). Urinary microalbumin and creatinine levels were measured to normalize for proteinuria in the analysis. Candidate RAIL predictors were firstly selected using univariate analyses, followed by stepwise selection in multiple logistic regression models. An A-RAIL algorithm was developed using the selected UBMs, and predictive accuracy calculated using the area under the Receiver Operating Characteristic (ROC) curve (AUC).

Results:

Of the 75 patients studied (age 32.4 ± 10.1 years), 78.7% were females. Caucasian and African American ethnicities were equally represented (46.7%). Mean NIH-AI and CI scores were 4.57 ± 4.11 and 3.23 ± 2.59 respectively. Renal activity was high in 11 (15%). No significant differences were noted for age, gender, ethnicity, or LN stage or laboratory parameters between the two activity groups, except lower C3 in high activity ($p = 0.029$). A-RAIL algorithm was studied using 10 significant UBMs and all analyses controlled for NIH-CI. The predictive accuracy of analysis was reported “outstanding” at the optimal score threshold ([AUC = 0.9 (95% CI 0.84 – 1.00]), and was similar when normalized for urinary creatinine or microalbumin [Table 1].

Conclusion:

The A-RAIL algorithm, termed “liquid biopsy for LN” by some, provides an accurate non-invasive assessment of LN activity. Its robustness and clinical usefulness is confirmed by use of various standards of normalization of proteinuria with LN. These results are very similar to the pediatric RAIL developed using six UBMs. This sets foundation for further studies assessing disease progression and response to therapy.

TABLE 1: Diagnostic Accuracy of A-RAIL Algorithm

Statistic	Adult RAIL Pathway Using 10 UBMs		
	Using Raw Data	Creatinine Adjusted	Microalbumin Adjusted
AUC (95% CI)	0.92 (0.84 - 1.00)	0.94 (0.88, 0.99)	0.90 (0.83, 0.98)
Sensitivity	90.9%	90.9%	90.9%
Specificity	83.6%	83.6%	78.7%
Positive Likelihood Ratio (LR+)	5.54	5.54	4.27
Negative Likelihood Ratio (LR-)	0.11	0.11	0.12
Logit cut	-1.86	-1.72	-1.83

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment III: Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Urinary biomarkers may help in identification, treatment and assessment of response to therapy in patients with lupus nephritis (LN). Osteoprotegerin (OPG) is produced by the kidney and may reflect the renal disease activity better than conventional markers. The data on its utility is sparse.

Methods:

Patients with SLE with active nephritis (AN), active disease without nephritis (active non-renal; ANR) and inactive disease (ID) were enrolled. Disease activity was assessed using renal SLEDAI (rSLEDAI) and SLEDAI. Patients with active nephritis were treated according to the ACR guidelines and followed up every 3 months for 1 year. Urine and serum samples were collected at baseline for all and every 3 months in patients of AN group. Urine samples from 24 healthy subjects (HC) and 20 patients each of rheumatoid arthritis (RA) and diabetic nephropathy (DM) served as controls. Serum (sOPG) and urinary OPG were measured using ELISA and urinary values were normalized for creatinine excretion. Variables are expressed as median (range) and non-parametric tests were used for statistical analysis.

Results:

A total of 121 SLE patients (females 113) were enrolled. At baseline, normalized urinary OPG (uOPG) was significantly higher in AN group as compared to ANR, ID, HC and DM (p-value <0.001 for all) but it was not different from RA. At baseline, uOPG correlated modestly with rSLEDAI (r=0.4, p-value <0.001) and SLEDAI (r=0.317, p-value <0.001) but not with sOPG levels. uOPG but not sOPG could differentiate between AN and ANR groups (Table 1).

Table 1. Baseline characteristics of SLE patients in the three categories

	Active Nephritis (AN)	Active Non-Renal (ANR)	Inactive Disease (ID)
Number	58	24	39
F:M	56:2	19:5	38:1
Median age (yrs)	27 (12 – 50)	28.5 (15 – 50)	28 (14 – 48)
rSLEDAI	8 (4 – 16)	0 (0)	0 (0)
SLEDAI	18 (6 – 28)	10 (5 – 20)	2 (0 – 4)
C3 (mg/dl)	48.5 (<16.9 – 125)	66.7 (17.3 – 163)	117 (34.2 – 194)
C4 (mg/dl)	7.8 (<5.6 – 55.7)	11.05 (<5.6 – 32.2)	24.15 (5.6 – 44.7)
Anti-ds DNA (IU/ml)	200 (24.7 – >300)	186.3 (<6.25 – >300)	51.35 (<6.25 – 200)
U_{Pr}/U_{Cr} ratio	3.3.7 (0.3 – 20.25)	0.37 (0.01 – 1.46)	0.11 (0 – 10.69)
Serum Creatinine (mg/dl)	0.9 (0.4 – 3.87)	0.82 (0.4 – 1.4)	0.8 (0.4 – 1.3)
Serum OPG (pg/ml)	1492.86 (624.09 – 4137.88)	1280.33 (116.16 – 2048.13)	1213.28 (368.37 – 1899.83)**
U_{OPG}/U_{Cr} (x 100 pg/mg)	12.29 (0 – 85.77)	2.36 (0 – 147.13)***	4.63 (0.07 – 42.53)***

p-value **= <0.01 and ***= <0.001 as compared to AN group

In the longitudinal study, uOPG decreased significantly at 3 and 6 months visits as compared to baseline (p-value <0.001) along with reduction in disease activity (Table 2). It showed an insignificant rise at 9 and 12 months. sOPG trends did not correlate with disease activity.

uOPG and not sOPG showed a rise before conventional markers in 2 patients who relapsed at 11 and 12 months respectively. Similarly, in 2 patients who developed chronic kidney disease, uOPG values remained persistently high throughout whereas sOPG did not.

Table 2. Change in different disease activity parameters, serum and normalized urinary OPG in the active nephritis group with treatment over 1 year

	Baseline	3 months	6 months	9 months	12 months
rSLEDAI	8 (4 – 16)	0 (0 – 12)	0 (0 – 4)	0 (0 – 4)	0 (0 – 8)
SLEDAI	18 (6 – 28)	2 (0 – 14)	2 (0 – 6)	2 (0 – 6)	2 (0 – 15)
C3 (mg/dl)	48.5 (16.9 – 125)	81.3 (7 – 161)	91.6 (47.1 – 174)	88.7 (33.4 – 168)	99.1 (35 – 165)
C4 (mg/dl)	7.8 (<5.6 – 55.7)	17.6 (<5.6 – 73.7)	19.6 (<5.6 – 61.1)	20.1 (<5.6 – 76.5)	19.2 (<5.6 – 58.4)
Anti-ds DNA (IU)	200 (24.7 – >300)	74.2 (8.4 – >300)	53.75 (<6.25 – 300)	72 (<6.5 – 300)	63.8 (<6.5 – 300)

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Modulators of Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Dysregulation in the formation of neutrophil extracellular traps (NETs) may contribute to modification and externalization of autoantigens and to organ damage in diverse autoimmune diseases including systemic lupus erythematosus (SLE). In SLE, a distinct subset of proinflammatory low-density granulocytes (LDGs) displays an exuberant capacity to form NETs in the absence of added stimulation. NETosis appears to require generation of reactive oxygen species (ROS). However, whether the process is strictly NADPH-oxidase dependent is unclear. Indeed, the role of other important sources of ROS like the mitochondria, in autoimmune NETosis, remains to be determined. This is particularly relevant as lack of a functional NADPH-oxidase, as seen in chronic granulomatous disease (CGD), is associated with enhanced predisposition to chronic inflammation and autoimmunity including SLE.

Methods: To clarify the contribution of mitochondrial ROS in the context of autoimmunity, mitochondrial activation and ROS were quantified in lupus LDGs by fluorescent microscopy and flow cytometry. Enrichment in oxidized mitochondrial DNA (ox-mitDNA) in isolated LDG NETs versus healthy control NETs was quantified with 8-Oxo-2'-deoxyguanosine antibodies and by calculating 16S/18S ratio by immunoprecipitation and qPCR. Various inhibitors of mitochondrial ROS and other sources of ROS were tested in lupus LDGs. Similar experiments were performed in neutrophils isolated from patients with CGD, to assess the role of NADPH-oxidase independent sources of ROS production. The type I IFN serum signature was quantified by assessing induction of IFN-inducible genes (ISGs) in THP1 cells. Circulating NET products were quantified by ELISA. Finally, the mitochondrial ROS inhibitor mitoTEMPO was administered systemically, continuously to lupus-prone female MRL/lpr mice for 7 weeks and, at euthanasia, lupus clinical phenotype, induction of ISGs, inflammatory cytokines and NETosis were quantified.

Results: Lupus LDGs displayed prominent enhancement of mitochondrial ROS synthesis when compared to healthy controls and lupus normal-density granulocytes. Lupus LDGs spontaneously formed NETs highly enriched in ox-mitDNA that significantly enhanced ISGs in monocytic cell lines. Emphasizing the role of mitochondria-derived ROS in autoimmune NETosis, CGD patients displayed an LDG population with exuberant spontaneous NET formation through enhanced mitochondrial ROS production and also had elevated type I IFN signature. There was a significant correlation between the development of autoimmunity in CGD patients and the serum type I IFN activity. Supporting the in vitro data, both lupus and CGD patients displayed evidence of enhanced in vivo NETosis. Importantly, lupus-prone mice that received mitoTEMPO displayed a significant decrease in proteinuria, autoantibodies, ISGs and proinflammatory cytokines, in association with hampered NETosis.

Conclusion: Mitochondrial ROS synthesis and ox-mitDNA appear to be key drivers of autoimmunity and proinflammatory responses in SLE and CGD and may represent novel therapeutic targets in these diseases.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Modulators of Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Neutrophil extracellular trap generation (NETosis) is a reactive oxygen species (ROS)-dependent cell death pathway implicated in autoimmune disorders such as systemic lupus erythematosus (SLE). However, since deficiencies in NADPH oxidase-mediated ROS production is associated with increased, rather than reduced, autoimmunity, this association has been challenged. Since mitochondria are major generators of ROS, we asked the following questions: i) is mitochondrial ROS required for NET formation? ii) what is the relative contribution and oxidative status of mitochondrial DNA in NETs? and iii) what are the immune stimulatory effects of mitochondrial products following RNP immune complex (IC) activation of neutrophils?

Methods: Mitochondrial ROS was quantified by the fluorescent dye MitoSOX. Diphenyleneiodonium (DPI), thenoyltrifluoroacetone (TTFA), rotenone and mitoTEMPO were used as ROS inhibitors. NET formation was quantified by fluorimetry and the extent of DNA oxidation determined using anti-8-oxo-2'-deoxyguanosine (8-OHdG) antibodies by ELISA or immunofluorescence (IF) microscopy. Immunoprecipitation and qPCR (16/18S ratio) were used to assess the origin and properties of NET DNA. To evaluate the inflammatory potential of mitochondrial DNA (mitDNA), oxidized or non-oxidized NET DNA was transfected into THP1 cells or injected into wild type or STING deficient mice.

Results: Following exposure of neutrophils to RNP IC, mitochondria became hypopolarized and translocated to the cell surface. The IC also stimulated mitochondria to produce ROS at levels similar to PMA stimulation. Mitochondrial ROS proved to be necessary for maximal NETosis since the selective inhibitors of mitochondrial ROS, TTFA and MitoTEMPO reduced NETosis by ~50% ($p<0.0001$, $n=8$). Furthermore, mitochondrial ROS stimulated by IC caused oxidation of DNA and IF revealed that DNA oxidation occurred predominantly in mitochondrial, rather than chromosomal, DNA. Using a dual immunoprecipitation and qPCR technique, we observed that the oxidized NET DNA displayed a high 16S/18S ratio, demonstrating that it was markedly enriched in mitDNA as compared to non-oxidized NET DNA ($p<0.01$, $n=9$). The oxidation of mitDNA was almost completely reversed in the presence of TTFA ($p<0.01$). When the inflammatory properties of oxidized mitDNA and non-oxidized DNA were compared *in vitro*, oxidized DNA was much more potent in inducing IL-6 and type I IFNs ($p<0.001$). Significantly, when oxidized mitDNA was injected into wild type and STING deficient mice, we observed that the oxidized mitDNA stimulated type I IFNs through a pathway that required the DNA sensor, STING ($p<0.001$).

Conclusion: Mitochondria play an important, previously unappreciated role in immune-mediated NETosis. Not only do they contribute to ROS that promotes NETosis but, also, oxidized mitDNA generated during NETosis has potent inflammatory properties *in vitro* and *in vivo* - including stimulation of type I IFN responses mediated through the STING pathway. We suggest that mitochondrial ROS and release of oxidized mitDNA may be instrumental in initiating or perpetuating autoimmunity and type I IFN signature seen in SLE patients.

Session Date: Monday, November 9, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Modulators of Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Familial chilblain lupus is a monogenic form of cutaneous lupus erythematosus caused by mutations in the nucleases TREX1 or SAMHD1. The adapter molecule stimulator of interferon genes (STING) mediates DNA-induced activation of type I interferon (IFN) through binding of its ligand cyclic GMP-AMP (cGAMP). De novo STING mutations cause STING-associated vasculopathy with onset in infancy (SAVI), an autoinflammatory syndrome with vascular, cutaneous and pulmonary manifestations.

Methods: Clinical and genetic characterization of a large non-consanguineous family with chilblain lupus. Identification of the disease gene by exome sequencing. Analysis of skin histology. Functional testing of transfected wild type and mutant STING-cDNA on type I IFN activation. Evaluation of the response to short-term treatment with the JAK inhibitor tofacitimib on the transcriptional signature of IFN-induced genes in blood cells by quantitative RT-PCR.

Results: Five members of the family spanning four generations suffered from chilblain lupus since early childhood. Cold-induced inflammatory chilblain lesions were located at acral locations including fingers, toes, nose, ears, elbows and shins. Lesions presented as bluish-red infiltrations and led to mutilating necrotic ulcerations. In some patients, low-titred ANA and immune complexes were detectable; the skin histology was characterized by perivascular infiltrates and high MxA expression. Affected family members also exhibited increased expression of IFN-stimulated genes in blood. Mutations in TREX1 and SAMHD1 were excluded in the family. Exome sequencing identified a heterozygous STING mutation co-segregating with chilblain lupus. This previously unknown mutation affects a conserved amino acid residue located within the STING dimer interface and is predicted to be deleterious. Mutant STING-cDNA transfected into HEK cells led to phosphorylation of IRF3 and IFN-β production even in the absence of cGAMP stimulation. Treatment of two affected family members with the JAK inhibitor tofacitinib at 5 mg bid for 14 days led to a significant suppression of the transcriptional signature of IFN-induced genes in blood and to relief of symptoms of acral ischemia.

Conclusion: This is the first report of a family with dominant chilblain lupus due to an activating mutation of STING and expands the spectrum of type I interferonopathies. Suppression of chronically activated type I IFN signaling through inhibition of the JAK/STAT pathway with tofacitinib may represent a promising new therapeutic approach.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Modulators of Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Foxp3 is a lineage-specifying transcription factor for $CD4^+$ regulatory T cells (Tregs), but recent studies have shown plasticity and heterogeneity within $CD4^+Foxp3^+$ cells, which include thymus-derived naturally-occurring Tregs (nTregs), peripherally-derived adaptive Tregs, and a subpopulation of activated effecter T cells. It has been reported that the number and function of $Foxp3^+$ Tregs are altered in patients with systemic lupus erythematosus (SLE), although data reported are somewhat conflicting. In this study, we examined phenotype and function of circulating $CD4^+Foxp3^+$ T cells in association with disease activity in SLE patients.

Methods: We enrolled 47 patients with SLE, 31 with organ-specific autoimmune diseases (15 multiple sclerosis and 16 primary immune thrombocytopenia), and 19 healthy subjects. Peripheral blood samples were obtained, and phenotype of $CD4^+Foxp3^+$ T cells was assessed using multi-color flow cytometry. Serial samples were evaluated in some SLE patients. Treg-specific demethylated region of the *Foxp3* gene (TSDR) was evaluated by methylation-specific polymerase-chain reaction using $CD4^+Foxp3^+$ T cells sorted by a flow cytometer. Immunoregulatory function of $CD4^+CD25^+$ T cells was examined by allogeneic mixed lymphocytes reaction. Finally, infiltration of IL-17-expressing $CD4^+Foxp3^+$ T cells was evaluated by immunohistochemistry of renal biopsy specimens obtained from 6 patients with active lupus nephritis (ISN/RPS-IV) and 5 with IgA nephropathy. Clinical information including SLE disease activity index (SLEDAI) at examination was retrospectively collected by review of clinical charts.

Results: $CD4^+Foxp3^+$ T cells were increased in circulation of SLE patients compared with organ-specific autoimmune disease controls or healthy subjects ($P < 0.01$ for all comparisons). Circulating $CD4^+Foxp3^+$ T cells were correlated positively with anti-double-strand DNA antibody levels or SLEDAI, and negatively with serum complement activity ($r > 0.52$, $P < 0.01$ for all correlations). Serial analysis in active SLE patients revealed reduction of $CD4^+Foxp3^+$ T cells after remission induction by immunosuppressive treatment. $CD4^+Foxp3^+$ T cells increased in peripheral blood of active SLE patients were nTregs, as determined by completely demethylated TSDR status. This SLE-specific nTreg subset represented unique phenotype; low expression of CD25, up-regulated expression of CD49d and CD127, expression of authentic Treg markers Helios and CD152, and expression of T helper 17 (Th17) markers CD161 and IL-17. The $CD4^+CD25^+$ T cells obtained from SLE patients exerted immunosuppressive ability comparable to those from healthy subjects. Finally, immunohistochemistry of renal specimens revealed that proportion of $Foxp3^+$ cells in infiltrating $CD4^+IL\text{-}17^+$ T cells was significantly increased in patients with active lupus nephritis than in those with IgA nephropathy (54% ± 10% versus 21% ± 9%, $P< 0.01$).

Conclusion: A unique nTreg subset acquiring both immunoregulatory and Th17 phenotypes is increased in circulation of active SLE patients, and may be involved in pathogenic process of SLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Modulators of Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: SLE is a heterogeneous autoimmune disease marked by immune dysregulation and a spectrum of pathogenic autoantibodies. Why some patients have only moderate symptoms and others develop organ-threatening manifestations such as nephritis is unclear. We previously identified several cytokines that correlate with increased disease activity. This study evaluates the temporal expression of autoantibodies and cytokines during transition from preclinical lupus to SLE in patients who do or do not present with nephritis.

Methods: Sera from 83 SLE cases with serial specimens spanning from time points of no ACR criteria to SLE classification (average timespan= 4.7 years) were obtained from the Department of Defense Serum Repository (DODSR). Samples were tested for SLE-associated autoantibodies and 32 soluble inflammatory and regulatory mediators, including cytokines, chemokines, and soluble receptors, as well as serum interferon-α (IFN-α) activity by cell reporter assay (WISH). Demographic, clinical, medication data and ACR classification criteria were extracted from medical records.

Results: Thirty (36%) patients who transitioned to SLE met renal criteria within 5.2 (± 5.5) months of disease classification (range -5.2 to +12 months). Patients presenting with renal criteria were more likely to be male compared to patients without renal criteria ($p=0.016$). Cases who did not meet renal criteria were more likely to have a history of hydroxychloroquine use prior to SLE classification ($p<0.0001$). Although renal cases experienced earlier onset of autoantibody positivity compared to non-renal cases (mean -3.8 vs -2.6 years relative to SLE classification, $p=0.0442$), no differences in number or type of autoantibody specificity were detected, including anti-dsDNA. Of interest, cases meeting renal criteria exhibited elevated levels of a number of soluble mediators prior to developing nephritis and reaching SLE classification, including the adaptive mediators IL-4, IL-5, IL-12, and IFN-γ, the IFN-mediated chemokine, IP-10, as well as shed TNFRII (all $p<0.05$ compared to matched healthy controls), increasing again at the time of nephritis (all $p<0.02$ compared to pre-nephritis levels), along with the mediator SCF ($p<0.0001$). SCF, IL-5, IFN-γ, MCP-3, IP-10, and TNFRII were significantly increased at SLE classification in patients with renal criterion vs. non-renal patients (all $p<0.0001$). Nephritis occurred independently of BLyS and Type I IFN-α serum activity, as there was no difference in levels between renal and non-renal patients who transitioned to SLE.

Conclusion: The subset of severe onset SLE patients who develop early nephritis cannot be predicted by autoantibodies. However, these patients develop significantly altered levels of certain soluble inflammatory mediators as they move from pre-clinical to classified disease. Singular perturbations in immune mediated inflammatory processes, occurring long before clinical classification, may help identify individuals at high risk of renal involvement for early and continued monitoring and intervention.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Modulators of Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is the archetypic systemic autoimmune disease, caused by a combination of genetic and environmental factors. Animal models in other inflammatory and autoimmune diseases have provided ample evidence of a role for intestinal bacteria in development of the systemic immune responses and autoreactivity, and on the resolution of inflammation and tissue injury.

Methods: To characterize the intestinal microbiome from cross-sectional surveys of an urban SLE patient cohort, we performed community profiling of 16S bacterial rRNA genes using next generation sequencing of 83 stool samples from well-characterized SLE adult patients and 16 healthy controls. Fecal samples were also fractionated for endogenous IgA coated bacteria vs. non-coated bacteria in 28 SLE and all healthy controls.

Results: Based on principal coordinates analysis of genomic bacterial extracts, SLE samples were significantly different in microbial composition from the healthy subjects ($p<0.002$). SLE subjects also demonstrated significantly greater intragroup diversity, yet there was an overlap with the healthy subjects. In terms of the species diversity, as measured by Chao1 alpha diversity metric, SLE microbiomes exhibited less diversity than healthy subjects ($P<0.005$). Similar patterns were observed based on Shannon diversity ($P<0.01$). In SLE, these patterns were seen in both treated patients and in those not taking medications. At a Phylum level, SLE patients displayed a significant increase in Proteobacteria and decrease in Firmicutes compared to controls. In addition, SLE patients had increased representation of specific operational taxonomic units (OTUs). Interestingly the anaerobic species *Prevotella copri,* recently linked to new-onset RA, was expanded in a subset of SLE patients but not in healthy controls. Studies of sorted IgA-coated bacteria also identified differential representation of certain OTU in SLE, which did not appear to be treatment related.

Conclusion: These studies provide the first demonstration that clinical SLE disease is associated with microbiome imbalances, with decreases in taxonomic diversity and blooms of specific OTU, within the intestine. Studies of the intestinal bacteria coated with IgA highlighted that only microbes of certain genera and OTU are immunologically recognized by the lupus host. We speculate that these candidate pathobiont species may act as triggers for disease initiation and flares.

Session Title: ARHP II: Lupus

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The purpose of this study was to assess the influence of socioeconomic status (SES) and measures of reserve capacity on depression and anxiety in patients with systemic lupus erythematosus (SLE). We examined whether reserve capacity/psychosocial variables explained the relationship between SES and levels of depression/anxiety in two separate meditation models. **Methods:** One hundred twenty-eight patients from Southern California with SLE completed self-report measures of demographic factors, disease activity (SLE Disease Activity Index), depression/anxiety (Hospital Anxiety and Depression Score), self-esteem (Rosenberg Self-Esteem Scale), social support (Social Provisions Scale), life orientation and optimism (Life Orientation Test – Revised), personal mastery (Personal Mastery Scale), and helplessness (Arthritis Helplessness Index). Two multiple meditational analyses were conducted utilizing an SPSS macro called "Indirect" (Preacher & Hayes, 2008), a program known to reduce complications with Type I Error and statistical power in multiple mediation models. **Results:** Results of confirmatory factors analyses revealed that social support variables made up an "interpersonal" latent factor; personal mastery, self-esteem, helplessness, and optimism variables made up an "intrapersonal" latent factors; and income, education, and perceived income made up an "SES" latent factor. Multiple mediation results revealed that, after controlling for disease activity and disease duration, features of reserve capacity including self-esteem, personal mastery, helplessness, optimism, and life orientation fully mediated the relationship between SES and depression/anxiety. After controlling for disease activity and disease duration, SES increased by one point and symptoms of depression decreased by .281 and .592 points through the mediating effects of interpersonal and intrapersonal reserve capacity, respectively. Additionally, as SES increased by one point, symptoms of anxiety decreased by .281 and .574 points through the mediating effects of interpersonal and intrapersonal reserve capacity, respectively. **Conclusion:** Results indicate that lower SES is indirectly associated with higher levels of depression and anxiety through the effects of lower psychosocial resilience resources. Providing interventions aimed at modifying reserve capacity variables, such as self-esteem, optimism, and sense of control may ultimately improve anxiety and depressive symptomatology in patients with SLE.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: ARHP II: Lupus

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Hypertension and persistent proteinuria are risk factors for renal disease progression and are associated with high salt intake, poor adherence to medication and smoking. In systemic lupus erythematosus (SLE), proteinuria levels <0.8 g/day at 12 months is predictor of better long-term renal outcome. The aim of this study was to evaluate the effect of a multidisciplinary tight control renoprotective protocol (TCRP) in SLE patients with persistent proteinuria.

Methods:

All SLE patients (ACR criteria) followed at Lupus Outpatient Clinic were evaluated between September 2014 and May 2015. Twelve patients with persistent stable proteinuria >1g/24h (any time after 6-month induction and on regular maintenance therapy) were included in the TCRP (with a target of proteinuria <1g/24h and BP <130/80). The protocol consisted of visits every 2 weeks to assess: 1. Blood pressure (BP) control; 2. adherence to therapy; 3. dietary modifications. No change in immunosuppressive

drugs was allowed during the study period and glucocorticoid dose was lowered as indicated. Clinical, laboratory and treatment evaluation performed at baseline (T0) and after 3 months (T3) included: SLEDAI, 24h proteinuria, serum levels of creatinine, albumin, potassium, complement C3/C4, anti-dsDNA antibodies, change in glucocorticoid dose, renin angiotensin blockage intake.

Results:

Patients had mean age of 38.17 ± 7.85 years and disease duration of 9.75 ± 7.14 years. At nephritis presentation, three (25%) patients had creatinine >1mg/dL, 9 (75%) had positive anti-dsDNA and 8 (67%) had biopsy (5 membranous and 3 proliferative). Induction therapy consisted of mycophenolate (58%) and cyclophosphamide (42%), and maintenance therapy of mycophelonate (92%) and azathioprine (8%). The majority (75%) were under hydroxychloroquine. Renin angiotensin blockage was indicated in all patients as antiproteinuric and/or for BP control. At study entry (T0), 50% had BP > 130/80 mmHg. At least one dose optimization of these regimens and alternative agents were required in all patients during visits. At T3, 10 (83%) patients were using an angiotensin converting enzyme inhibitor, 7 (58%) an angiotensin receptor blocker and 5 (42%) of these patients were under combined therapy. Stable BP target was achieved by 10 (83%) patients at T3 with a significant reduction in diastolic BP ($p=0.029$). Of note, 24h proteinuria (2.06 ± 0.75 vs 0.94 ± 0.51 g/24h, $p<0.001$) reduced significantly, with a mean decline of 47.1 ± 19.2%. All patients had a decline in 24h proteinuria values and more than half (58%) of patients achieved proteinuria < 1g/24h at T3. Serum levels of creatinine (0.76 ± 0.18 vs 0.76 ± 0.18 mg/dL), albumin (3.94 ± 0.36 vs 3.99 ± 0.28 g/dL) as well as potassium, complement C3 and C4, frequency of anti-dsDNA and mean SLEDAI scores were similar at T0 and T3 ($p>0.05$). At T3, a decrease in mean prednisone dose was observed (10.63 ± 6.93 vs 5.83 ± 5.03 mg/day, $p=0.077$).

Conclusion:

This study suggests that a multidisciplinary tight control renoprotective protocol has a remarkable impact in reducing persistent proteinuria providing a brief window of opportunity for achieving the best predictor of long-term outcome in lupus nephritis.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: ARHP II: Lupus
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The heterogeneity and non-specific features of lupus may delay diagnosis. This delay can lead to accrual of organ damage and an increased risk of death. Early detection by frontline providers (primary care and emergency room physicians, physician assistants, nurses, medical students) is critical to decrease the referral time for diagnosis and treatment. Average time devoted to lupus education in the first 2 years of medical school is 45 minutes and lupus education in years 3 and 4 is elective so frontline providers may not have the knowledge to recognize the disease. Given the shortage and high demand of rheumatologists, this project enlisted rheumatology fellows to deliver a standardized presentation.

Methods: Four cities were selected as pilot sites based on minority populations served, availability of rheumatology fellows, and local lupus experts. Fellows were trained to deliver standardized content developed material from the Lupus Initiative to provide a live presentation to frontline providers. Local lupus agencies assisted with outreach to schedule seminars. A voluntary, anonymous, paper-based pre/post assessment was used to evaluate changes in knowledge and confidence and to collect other qualitative data. A paired t-test was used to analyze the continuous variables and frequency tables were used for categorical variables.

Results: Preliminary data from 339 matched pre/post assessments were analyzed and scored on a 10 point scale. Total mean score increased 1.59 ($p<.0001$). Mean score improvement was greatest among nurses and physician assistants (3.09, 2.71 respectively; $p<.0001$) and providers in community health centers (3.00; $p<.0001$). 94% of participants gained confidence in knowing when to consider lupus based on patient history and exam and 93% in recognizing signs and symptoms. Over 90% were satisfied with the content, pace, and delivery of the seminar and 89% would attend another seminar led by a fellow. 100% of participating fellows noted the project as a positive experience.

Conclusion: Rheumatology fellows can effectively educate frontline providers about lupus recognition using a standardized presentation. Further dissemination and evaluation of this program is warranted.

Table 1. Comparison of Pre and Post Assessment Scores

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: ARHP II: Lupus

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

An evaluation was conducted of a monthly hospital-based psychoeducational support group, ongoing since 1985, for people with lupus. Each 2-hour session begins with a provider-led presentation on a lupus-related topic, followed by an evaluative survey and discussion.

Methods:

A 34-item survey with Likert scale and open-ended questions was mailed to 137 members. Items included user demographics, topic choices, satisfaction, impact and areas for improvement. Separate analyses on satisfaction and impact were conducted for core members (defined as attending ≥ 50% of prior year's sessions) and were also stratified by race/ethnicity. Chi-square and Fischer's exact tests were used to examine any differences.

Results:

53 surveys (39%) were returned. Most members (72%) were age 50+; 96% were female. 47% were white, 19% Asian, 14% Latino, 14% African American and 6% bi-racial. 80% had a Master's (51%) or Bachelor's (29%) degree. 50% had Medicare as their primary insurance with commercial insurance (36%) or Medicaid (14%); 28% had private insurance; 10% had Medicare only; average years since diagnosis was 16.

84% of all respondents were satisfied (64% strongly, 20% somewhat) overall; members of color reported ↑ overall satisfaction (88%) than whites (78%) with no significant difference. Members reported 95% satisfaction with the coordinator (69% strongly, 26% somewhat), 91% with speakers (62% strongly, 29% somewhat), 87% with topics (51% strongly, 36% somewhat) and 78% with discussions (52% strongly, 26% somewhat).

Whites reported ↑ satisfaction than members of color with speakers (100% vs. 84%) and the coordinator (100% vs. 91%), with no significant differences.

We assessed impact in 4 areas: knowledge, coping, self-management and social support. 86% agreed (61% strongly, 25% somewhat) their knowledge of lupus increased. 83% agreed (38% strongly, 45% somewhat) the groups helped them to cope. 82% agreed (34% strongly, 48% somewhat) they had ↑ ability to manage their lupus. 74% agreed (54% strongly, 20% somewhat) they had ↑ social support.

Members of color reported ↑ impact than whites for knowledge (88% vs. 71%), and whites reported ↑ ability to cope (88% vs. 80%); differences were not significant.

Core members responded to all measures of satisfaction and impact more highly than non-core members (i.e. 100% were satisfied overall).

Out of 25 topics, the 3 highest-rated were Medications, Arthritis/Joint Problems, and Environmental Triggers.

Responses to open-ended questions underscored the value of social support as well as self-management skills: “talking to others increased optimism,” “a health-saving resource,” and “more confident in talking with doctor.” Primary barriers to attendance were schedule conflicts, health and distance. Suggested improvements were ↑ time for speaker and discussion.

Conclusion:

Although limited by a small sample size, our results demonstrate the overall success of our program, the value it brings to our clients, and next steps for improving the program’s effectiveness. The differences in satisfaction and impact stratified by racial/ethnic groups and attendance rate were not found to be significant; we will continue to monitor and evaluate these identified trends.

Evaluations of Social Support Are Associated with Well-Being Outcomes in Women with Systemic Lupus Erythematosus (SLE)

Stacey E. Morrison[1], Monique A.M. Gignac[2], Paul R. Fortin[3] and Dorcas Beaton[4], [1]Div Rheumatology Rm MP-10-304, Toronto Western Hospital, Toronto, ON, Canada, [2]Instititue for Work and Health, Toronto, ON, Canada, [3]Medicine, CHU de Québec - Université Laval, Québec, QC, Canada, [4]Mobility Program Clinical Research Unit, St Michael's Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: ARHP II: Lupus
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose : Research on SLE and social support has often focused on the total amount of support provided. However, studies also report that some individuals feel under-supported whereas others feel too dependent on others. This study examined: 1) perceived support needs and support received for different domains (e.g., work, household activities) and types of support (instrumental, emotional and informational); 2) perceived concordant and discordant support; and 3) the relationship of support satisfaction with well-being (depression, life satisfaction, meaning of illness, illness intrusiveness) in women with SLE.

Methods : Women with SLE were recruited from the University of Toronto Lupus Cohort and completed a web or paper-based survey. Demographic (age, education), clinical (pain, fatigue, disease activity), and psychological perceptions (Center for Epidemiologic Studies Depression Scale (CES-D), life satisfaction, positive meaning of illness, illness intrusiveness) data were collected. Five domains of support were assessed (work/school, family, recreation, finance & household) along with 3 types of social support (instrumental, emotional & informational). Congruent and discordant support perceptions were created by examining needs and receipt for support, as well as support satisfaction. Separate analyses of variance (ANOVAs) examined differences in support and well-being within each domain and for each type of support.

Results : A total of 163 women with SLE, aged 50.7±16.1 years, with mean disease duration 21.9±13.7 years & mean disease activity ±3 months 2.4±2.6 on a 10-pt VAS responded. Participants reporting unsatisfactory support in at least one domain represented 47.8%, 43.1% & 53.9% of the sample for instrumental, emotional and informational support, respectively.

Although many women reported congruence between support needed and received, women often reported being under-supported in at least one domain of life. Few women reported being over-supported or dependent on others. In the work/school domain, depression and illness intrusiveness scores were significantly greater for those who viewed any type of social support as unsatisfactory compared to those receiving satisfactory support (all p-values < 0.01). Life satisfaction and meaning of illness scores were also significantly lower for those who reported dissatisfaction with their instrumental, emotional or informational support (all p-values < 0.001) in the work/education domain. Similar findings were found for other domains.

Conclusion: Previous research has often focused on the amount of support received. This research highlights that support needs vary and it is dissatisfaction with social support that often arises as a lack of congruence with support needed and received, not the amount of support, that is associated with well-being. These findings have implications for interventions. Further research, especially longitudinal studies, are needed to examine changes in support and well-being.

Predictors of Health Perceptions Among Women with Lupus

Patricia P. Katz[1], Eliza Chakravarty[2], Robert S. Katz[3] and Kaleb Michaud[4], [1]Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, [2]Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Rush University Medical Center, Chicago, IL, [4]Internal Medicine, University of Nebraska Medical Center, Omaha, NE
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: ARHP II: Lupus
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Health perceptions, such as self-rated health, have been shown to predict multiple adverse health outcomes and to have a strong socioeconomic status (SES) gradient. Although SES-related health disparities have been found in lupus, previous studies have not examined the role of SES in health perceptions in lupus, independent of other health factors.

Methods: Data were from the National Data Bank for Rheumatic Diseases (NDB), for which participants complete questionnaires every 6 months. We included in analyses only women with lupus who responded to at least one questionnaire in 2014 (n = 481). Health perceptions were measured with 3 items: (1) health status numeric rating scale ranging from 0 (dead) to 100 (perfect health); (2) health satisfaction ("how satisfied are you with your health?"); responses ranged from very unsatisfied to very satisfied; and (3) overall health rating (excellent, good, fair, poor). The latter two items were dichotomized for analysis (satisfied or very satisfied vs. other; excellent or good vs. fair or poor). Potential predictors of health perceptions included SES (age, education, Medicaid or no health insurance vs other), lupus status (duration, disease activity measured with the Systemic Lupus Activity Questionnaire [SLAQ]), disease damage measured with the Brief Inventory of Lupus Damage [BILD]), and symptoms and other health factors (obesity, pain, physical function, fatigue, comorbidities, depressive symptoms, sleep, and smoking). Multiple linear and logistic regression analyses were conducted to identify independent predictors of health perceptions.

Results: Sample characteristics are shown in Table 1. In models including only age and SES variables, only low education was associated with health perceptions (Table 2). After adding lupus status, symptoms, and other health factors, SES variables were no longer associated with health perceptions. Four variables were consistently associated with each health rating: pain rating, physical function, disease activity, and smoking.

Conclusion: Health perceptions in lupus were primarily driven by health-related variables rather than SES. It is possible, however, that the effects of SES may be indirect; for example, smoking rates are higher among individuals with lower education. Additional study is needed to identify the ability of health perceptions s to predict health outcomes in lupus.

Table 1. Characteristics of sample			
SES variables			
Age, mean ± SD	57.9 ± 13.0	Education ≤ 12 years	22.1%
White	79.4%	Medicaid or no health insurance	13.5%
Lupus status			
Duration	21.0 ± 12.1	Disease damage (BILD)	3.3 ± 2.0
Disease activity (SLAQ)	11.0 ± 7.1		
Symptoms, other health factors			
Pain rating[1]	4.3 ± 3.0	Rheumatic Disease Comorbidity Index[5]	2.7 ± 1.8
Physical function[2]	38.4 ± 27.7	Obesity	33.6%
Fatigue[3]	5.2 ± 3.1	Depressive symptoms[6]	5.9 ± 5.4
Sleep[4]	4.4 ± 3.2	Smoking (current and past)	42.6%
Health perceptions			
Health status rating[7]	63.5 ± 20.9	Satisfied, very satisfied with health	44.8%
Excellent, good health	46.4%		

[1] Pain: 1-10 rating, higher rating = greater pain.

[2] Physical function: SF-36 Physical Function subscale, range 0 – 100, higher score = better function.

[3] Fatigue: 1-10 rating, higher rating = greater fatigue.

[4] Sleep: 0-10 rating of problematic sleep, higher rating = more sleep problems.

[5] Rheumatic Disease Comorbidity Index: Validated index that encompasses 11 comorbid illnesses (England BR, et al. *Arthritis Care Res*2015; 6: 865). Score ranges from 0-9.

[6] Depressive symptoms: from PHQ-8, higher score = more depressive symptoms.

[7] Rating of health state from 0 (dead) – 100 (perfect health)

Table 2. Regression results: Independent predictors of health perceptions*			
Significant associations	Health rating VAS§	Satisfied with health†	Excellent/good health†
Model 1: SES variables only			
Low education	-5.22 (0.10)	0.49 (0.30, 0.79)	0.52 (0.32, 0.87)
Model 2: SES + lupus status, symptoms, other health factors			
Low education		0.45 (0.19, 1.07)	
Pain rating	-1.32 (.02)	0.79 (0.67, 0.93)	0.82 (0.69, 0.99)
Physical function	0.23 (<.0001)	1.02 (1.01, 1.04)	1.05 (1.03, 1.07)
SLAQ	-0.44 (.04)	0.90 (0.83, 0.97)	0.89 (0.82, 0.97)
Smoking (current or former)	-3.84 (.07)	0.46 (0.23, 0.95)	0.29 (0.13, 0.65)
Comorbidity index			0.78 (0.61, 0.99)
BILD		1.22 (0.99, 1.51)

Dendritic Cell-Specific Transmembrane Protein (DC-STAMP) Modulates Bone Resorption in Inflammatory Arthritis and Fracture Repair

Yahui Grace Chiu[1], Tzong-Ren Sheu[2], Jinbo Li[3], Dongge Li[4], Michael Thullen[2], Brendan Boyce[5], Christopher T. Ritchlin[6] and Javier Rangel-Moreno[7], [1]Allergy, Immunology, and Rheumatology, University of Rochester, Rochester, NY, [2]Center for Musculoskeletal Research, University of Rochester, Rochester, NY, [3]Pathology, University of Rochester, Rochester, NY, [4]Allergy, Immunology and Rheumatology, University of Rochester, Rochester, NY, [5]University of Rochester, Rochester, NY, [6]Allergy, Immunology and Rheumatololgy Division, University of Rochester Medical Center, Rochester, NY, [7]Allergy, Immunology & Rheumatology, University of Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Osteoclasts (OC) direct pathologic bone resorption in osteoporosis and inflammatory arthritis. We previously demonstrated that DC-STAMP (Dendritic Cell-Specific Transmembrane protein), a 7-pass transmembrane protein, is not only essential for cell fusion during osteoclastogenesis but mice that lack this molecule also show impaired osteoblast (OB) differentiation. OC precursors arise from CD14+DC-STAMP+ cells in humans and the frequency of CD11b+DC-STAMP+ cells correlates with the extent of bone erosion in the TNF-Tg arthritis model. A rapid recruitment of DC-STAMP+ mononuclear cells to bone fracture sites and delayed bone healing in DC-STAMP knock-out (KO) mice suggested that DC-STAMP may also modulate fracture repair.

Methods:

(1) To investigate the interplay between DC-STAMP+ cells and OB, we examined the recruitment of DC-STAMP+ cells to the vicinity of OB using a mouse strain (collagen-I cre ROSA-rtta TRE-LacZ) whose OB lineage cells can be traced by the blue LacZ expression. OB differentiation was evaluated with the CFU-ALP and bone nodule formation assays. To examine the role of DC-STAMP+ cells in arthritis progression, we **(2)** introduced one copy of DC-STAMP knockout locus into the TNF+ mouse line and examined the effect of DC-STAMP KO on OB & OC differentiation and arthritis development; and **(3)** re-constituted lethally irradiated TNF-Tg mice with bone marrows (BM) from WT or DC-STAMP KO donors and compared arthritis progression between the two groups.

Results:

(1) Histology analysis: TRAP+DC-STAMP+ cells were recruited to the vicinity of LacZ+ OB at the bone fracture sites, whereas OB/OC co-localization was never detected on intact bones without fractures. (2) Genetic analysis: introduction of one DC-STAMP KO locus into the TNF+ background resulted in three phenotypes: (a) bone erosion was less severe; Bone Volume/Total volume (BV/TV: 18.2±5.7 & 12.0±3.1 in TNF+DC-STAMP+/- & TNF+DC-STAMP+/+) mice; (b) 6/15 mice showed asymmetric arthritis, suggesting an alleviated arthritis symptom; (c) OB differentiation was impaired (CFU-f units/well: 112±8 & 225±10 for TNF+DC-STAMP+/- & TNF+DC-STAMP+/+). (3) Bone marrow re-constitution: the expression level of DC-STAMP in the adoptively-transferred cells was up-regulated in the TNF+ background (the mean fluorescence intensity (MFI) in TNF+ and TNF- recipients were 1,205±82 & 723±98, respectively). TNF+ mice that received DC-STAMP+/+ donor cells developed severe arthritis approximately one week earlier than those receiving the DC-STAMP-/- donor cells (deformation scores: 8.0±2.5 & 5.0±3.2 for DC-STAMP+/+ & DC-STAMP-/- donors, respectively, at week-4 post-adoptive transfer).

Conclusion:

Aggregation of DC-STAMP+ cells around OB at fracture sites suggests that DC-STAMP is involved in OB:OC interactions. Arrested OB differentiation in DC-STAMP+/-TNF-Tg mice confirms our initial observations that DC-STAMP is required for adequate OB function. Moreover, DC-STAMP expression level increased in the presence of elevated *in vivo* TNFa concentration. Collectively, our data indicate that arthritis pathogenesis and bone repair can be modulated by the gene copy number and expression level of DC-STAMP.

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Osteoclasts (OC) are the only cell type known to erode bone. Many bone diseases including osteoporosis and arthritis are caused by excessive OC activity. The molecular mechanisms underlying cell-cell fusion, a key step in osteoclastogenesis (OCgenesis), are not well understood. Our studies focused on DC-STAMP (Dendritic Cell-Specific Transmembrane Protein), a 7-pass transmembrane protein which is expressed on the cell surface of OC precursors (OCPs) and is essential for OCgenesis. DC-STAMP knock-out (KO) mice form only mono-nucleated OC, and manifest mild osteopetrosis due to the absence of functional polykaryon OC. Previously, we identified an Immunoreceptor Tyrosine-based Inhibitory Motif (ITIM) on the cytoplasmic tail of DC-STAMP. By engineering a DC-STAMP:rhodopsin photactivatable chimeric molecule that can be activated by light, we demonstrated that the ITIM is a functional motif that alters intracellular Ca^{+2} flux, suggesting the potential role of DC-STAMP in signaling. Herein, we further examined the effect of ITIM deletion on bone erosion, cell mobility, and NFATc1 nuclear translocation.

Methods:

The wild-type (WT) and ITIM-deleted (TD) versions of DC-STAMP were tagged with GFP, and introduced into DC-STAMP-/- cells isolated from the DC-STAMP KO mice. DC-STAMP-/- cells which overexpress WT- or TD- DC-STAMP were tested for complementation to OC-forming deficiency by in vitro culture, bone erosion activity by bone wafer assay, cell surface distribution by confocal microscopy, and cell mobility by the scanning electron microscopy (SEM). The dynamic changes of NFATc1 protein after introduction of the WT DC-STAMP into DC-STAMP-/- cells were examined by Western blotting.

Results:

Deletion of the DC-STAMP ITIM was associated with decreased OCgenesis and altered downstream signaling as summarized by the following key observations. (1) Complementation: The OC-forming deficiency of DC-STAMP-/- cells was complemented when cells were infected with WT- but not TD- DC-STAMP; (2) Cell-cell fusion: Most of the TD-DC-STAMP-expressing cells were mononuclear, whereas a minority fused twice with 3 maximal nuclei per cell. As expected, TD cells showed smaller cell volumes than WT-DC-STAMP expressing cells due to the limited frequency of cell-cell fusion; (3) Bone erosion: TD-DC-STAMP-expressing cells showed decreased bone erosion activity as evidenced by smaller and shallower erosion pits (7.2 & 1.5 mm^2/pit area for WT & TD, respectively), which is associated with a reduced cell mobility revealed by SEM; (4) NFATc1 nuclear translocation: in contrast to WT-DC-STAMP, the NFATc1 proteins in TD-DC-STAMP-expressing cells failed to translocate to the nuclei.

Conclusion:

The ITIM on DC-STAMP is a functional motif that regulates OCgenesis through the Ca^{2+}/NFATc1 axis. Deletion of ITIM on DC-STAMP resulted in decreased bone erosion activity, impaired osteoclast mobility, and diminished nuclear translocation of NFATc1. This is the first demonstration that DC-STAMP regulates the translocation of NFATc1, a master transcription factor of OCgenesis. Targeted inhibition of the ITIM on DC-STAMP may prove an effective strategy to prevent pathologic bone in inflammatory and metabolic bone disorders.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

The destruction of bone is a common feature of diseases like rheumatoid arthritis (RA) and multiple myeloma (MM). CCL3 is significantly elevated in the serum of patients with RA and MM; it is thought to contribute to leukocyte migration. A direct link between CCL3 and the development of osteoclast-dependent erosive bone pathology has not been evaluated previously. We studied CCL3's role in osteoclast (OC) differentiation from human macrophage precursor cells and its impact on bone resorption *in vitro* and *in vivo*.

Methods:

Human OC precursor cells ($CD14^{+ve}$ monocytes) from peripheral blood were seeded onto ivory disks and differentiated into OC using macrophage colony stimulating factor (M-CSF) and receptor activator of nuclear factor kappa-B ligand (RANKL) for 14 days alone or in combination with anti-CCL3 (8ng/mL) or osteoprotegerin (OPG; 8ng/mL). CCL3 was measured in culture supernatants by ELISA over the time-course. OC formation and resorption pits were visualised by tartrate-resistant acid phosphatase (TRAP) and toluidine blue staining respectively. Murine collagen-induced arthritis (CIA) was initiated after two intradermal immunizations of complete Freund's adjuvant and type (II) collagen (day 0 and day 21). Mice received intra-peritoneal injections (5mg/kg) of isotype control antibody (n=6) or anti-CCL3 (n=6) on day 21, 23, 25, 27, 28. Arthritis progression was measured daily to give a clinical score. Mice were culled on day 29. Bone erosion was observed in fixed forepaws and hind limbs by x-ray (12 joints per limb) and counted. OC counts, CCL3 concentration, percentage of the disk area resorbed, and number of eroded joints per mouse are reported as mean ± SEM. Statistical significance determined by 2-way ANOVA, Spearman's rank co-efficient or student's t-test as appropriate.

Results:

OC numbers per disk increased significantly over time (307 ± 81; $p \leq 0.01$ on day 14) with M-CSF and RANKL. A concomitant 5-fold increase in CCL3 levels (day 0 to 14) was observed ($p \leq 0.05$), which significantly correlated with OC number ($p \leq 0.01$, R= 0.32). Neutralisation of CCL3 led to a significant 3-fold reduction in OC differentiation (113 ± 41 OC/disk; $p \leq 0.05$) and were comparable to cultures supplemented with OPG. Anti-CCL3 treatment also significantly reduced the disk area resorbed (0.49 ± 0.13%; $p \leq 0.05$) compared to controls (1.54 ± 0.4%). OPG was more potent than anti-CCL3 in this regard (disk area resorbed = 0.04 ± 0.02%, $p \leq 0.05$ versus control). In CIA, anti-CCL3 had no significant effect on joint swelling, however, radiological progression of arthritis was substantially abated. The number of erosions in anti-CCL3 treated mice was halved (7 ± 2 ($p \leq 0.05$)) versus 15 ± 2 for isotype controls.

Conclusion:

For the first time we show the potent regulatory role of CCL3 in OC differentiation and OC-directed bone resorption in both *in vitro* and *in vivo* models. Our data unmasks the important function of CCL3 in the inflammatory milieu of a diseased joint and identifies this chemokine as target for further investigation as a marker for destructive bone disease associated with arthritis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Genetic disruption of the circadian molecular clock in mice is a powerful tool to dissect the role of circadian rhythms in health and disease. Several bone turnover markers show circadian variation in humans suggesting a function for the circadian molecular clock in bone physiology. In contrast to previous reports, we found that at 8 weeks of age (prior to the onset of heterotopic ossification) mice with germline deletion of the core circadian regulator *Bmal1* (Brain and muscle Arntl-like 1, $Bmal1^{-/-}$) have reduced trabecular and cortical bone compared with wildtype mice. Here, we ask whether the development of this phenotype can be mapped to disruption of the molecular clock in mesenchymal cells, osteoclasts, or both.

Methods: We generated mice with conditional deletion of *Bmal1* in mesenchymal cells of the limbs (*Prx1-cre*) or osteoclasts (*Ctk-cre*). We analyzed the bone phenotype of 8 week-old male mice comparing $Bmal1^{fl/fl}$.*Prx1-cre* mice with $Bmal1^{fl/fl}$ littermate controls, and $Bmal1^{fl/fl}$.*Ctk-cre* mice with $Bmal1^{fl/+}$.*Ctk-cre* littermate controls, respectively. Femurs were examined by micro-computed tomography and histology, and *in vitro*osteoclast and osteoblast differentiation assays were performed.

Results: Deletion of *Bmal1* in osteoclasts had no effect on *in vitro* osteoclast differentiation or resorptive function. Consistent with this, no differences in trabecular or cortical bone parameters were seen in $Bmal1^{fl/fl}$.*Ctk-cre* compared with $Bmal1^{fl/+}$.*Ctk-cre* controls. In contrast, we found a significant reduction of trabecular bone in $Bmal1^{fl/fl}$.*Prx1-cre* mice compared with controls (BV/TV 14.9% vs. 20.5% p=0.002; n=14) with corresponding significant changes in trabecular number, thickness, spacing and connectivity. Cortical parameters were also affected (C.Th. 0.15mm vs 0.17mm, p=0.008; n=14). *In vitro* assays failed to reveal an effect of mesenchymal *Bmal1* deletion on osteoclast formation or function. Differentiation of osteoblasts from $Bmal1^{fl/fl}$.*Prx1-cre* bone marrow stromal cells was also not significantly different from controls.

Conclusion: These results demonstrate that bone mass in mice is controlled by the cell-intrinsic circadian molecular clock in mesenchymal cells, whereas a functioning clock in osteoclasts appears dispensable for maintaining bone homeostasis.

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Immature dendritic cells (iDC) have been shown to act as OC precursors and are important cell players in the pathogenesis of RA. We aimed to investigate the relationship between iDC derived osteoclastogenesis and specific immunity in RA.

Methods:

$CD14^+$ monocytes from PB of $ACPA^+$ RA patients and healthy individuals were first cultured in the presence of GM-CSF and IL-4 to generate iDC or in the presence of M-CSF to generate MΦ and then further differentiated to OC in the presence of RANKL and M-CSF. In parallel, cells were grown on osteoassay surfaces and bone resorption area was quantified by computer assisted image analysis. Mass spectrometry analysis was performed on different stages of differentiation of iDC and MΦ derived OC. ACPA positive and negative polyclonal IgGs were isolated from synovial fluid (SF, n=26) and peripheral blood (PB, n=38) samples of RA patients. Cytokines were measured by cytometric bead arrays in cultures supernatants. Immunohistochemistry (IHC) was used to stain the OCs with murinized monoclonal ACPAs derived from single SF derived B cells. The effect of IL-8 inhibition was tested in the OC cultures.

Results:

Principal component analysis confirmed distinct proteomic profiles during OC maturation from iDC and MΦ, respectively. Vimentin significantly increased during iDC-OC maturation, with citrullinated vimentin peptides detectable in matured OCs. Polyclonal ACPAs enhanced osteoclastogenesis and bone resorption from iDC (fold increase of 1.6±0.2 for OC number and 2.0±0.3 for bone resorption area). Similar effect was observed when the iDC were derived from ACPA+ RA patients (fold increase of 2.3±0.9 for OC number and 2.6±0.1 for bone resorption area). PB derived ACPAs were equally effective with SF ACPAs. Increased osteoclastogenesis was associated with significantly higher levels of IL-8 levels in cultures supernatants (fold increase of 2.4±0.5). Immunohistochemistry demonstrated presence of cit peptides in both iDC precursors and iDC-derived mature OCs suggesting that citrullination is important for iDC-OC differentiation and maturation (Figure 6B). PAD2 and PAD4 showed faint staining in CD14 monocytes with increased staining intensity in both iDC precursors and more mature OCs. The importance of citrullination and PAD enzymes for iDC transdifferentiation was confirmed by a dose-dependent inhibition of OC differentiation using PADi in the presence of RANKL and M-CSF. IL-8 was the main cytokine detected in the culture supernatants of iDC-derived cultures.

Conclusion:

iDC can effeiciently transdifferentiate in OC and are targeted by RA specific antibodies.

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Multiple Myeloma is characterized by the uncontrolled proliferation of plasma cells. This type of malignancy is particularly trophic to bone where it induces osteoclastic destruction of bone. We have recently demonstrated that osteoclast differentiation is dependent upon the autocrine/paracrine expression of the laminin-like matrix protein and chemorepulsant netrin1 and binding of netrin1 to its cellular receptor unc5b. We therefore asked whether targeting netrin1 and its receptors unc5b and DCC could regulate myeloma spread in a murine model of myeloma.

Methods: 10^6 5TGM1-GFP myeloma cells (GFP expressing) were inoculated through the tail vein in 9 week old female C57Bl/KaLwRijHsd mice. Two weeks after inoculation animals were injected with monoclonal antibodies against Netrin-1, Unc5b and DCC weekly for 4 weeks (n=10 each). IVIS was performed for in vivo localization of myeloma bone lesions at the end of the experiment. Bone mineral density was measured by DEXA scanner and vertebrae and long bones were collected and prepared for microCT and histology analysis.

Results: IVIS imaging revealed a marked decrease in bone lesions in the anti-Netrin-1 and anti-Unc5b treated groups (n=6 and 9 mice respectively) when compared to control mice (n=6), whereas treatment results with anti-DCC antibody were more heterogeneous (n=7). There was an increase in total bone mineral density in anti-Unc5b and anti-DCC treated mice (0.63±0.09 g/cm^3 and 0.8±0.09 g/cm^3 respectively vs. 0.42v0.02 g/cm^3, $p<0.5$). microCT analysis revealed no changes in cortical bone parameters (Bone volume/total volume (BV/TV), bone volume (BV), total volume (TV) and Bone Mineral Density (BMD)) for any treatment group, but there was an increase in these parameters in Netrin-1 and Unc5b antibody-treated groups when trabecular bone was analyzed, consistent with the decrease in myeloma lesions (BV: 0.04±0.003 mm^3 and 0.08±0.01 mm^3 respectively vs. 0.02±0.003 mm^3, $p<0.05$; TV: 033±0.005 mm^3 and 0.36±0.01 mm^3 respectively vs. 0.26±0.002 mm^3, $p<0.05$; BV/TV: 2.87±0.3% and 0.08±0.01% respectively vs. 2.37±0.2, $p<0.05$; BMD: 0.64±0.009 g/cm^3 and 0.68±0.01 g/cm^3 respectively vs. 0.58±0.002 g/cm^3). There was also an increase in Trabecular thickness (Tb.Th), trabecular number (Tb.N.) and a decrease in trabecular separation (Tb.Sp.). TRAP staining revealed decreased osteoclasts in both anti-Netrin-1 and -Unc5b treated mice (7±1 and 6±1 cells/hpf respectively vs. 15±1 cells/hpf for control, $p<0.001$, n=5) but not for anti-DCC treated mice (13±1 cell/hpf vs. 15±1 cells/hpf for control, p=ns, n=5), and immunofluorescence analysis reveal a decrease in Cathepsin K positive cells that correlated with the decrease in TRAP-positive osteoclasts.

Conclusion: Anti-netrin-1 and -Unc5b treatment decreases osteoclast formation in a murine model of myeloma and decreases myeloma bone lesions. Targeting Netrin-1 or its receptor Unc5b may be a novel therapeutic approach for multiple myeloma.

Session Title: Epidemiology and Public Health III: Risk Factors, Treatment and Outcomes of Gout and OA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Arthritis and activity limitation are risk factors for cardiovascular (CVD) morbidity and mortality. As arthritis is a major cause of activity limitation, the objective of the present study was to estimate the extent to which increased heart disease risks in persons with arthritis are at least partially mediated through activity limitation pathways and potential variations by gender.

Methods: The longitudinal Canadian National Population Health Survey (NPHS) collected information on sociodemographic variables, self-reported physician-diagnosed chronic conditions, activity limitation, and lifestyle/health behaviors every 2 years from 1994/95 through 2010/11. Cause of death records for ischaemic heart disease and heart failure were confirmed against the Canadian Vital Statistics Database. Included variables were repeated measures of arthritis, activity limitation and heart disease lagged to ensure the proper temporal sequence, and the following baseline covariates: age, sex education, race, diabetes, high blood pressure, physical activity, BMI, smoking, alcohol consumption, use of pain medications and non-CVD comorbidity index. The analysis used a novel approach integrating recent advances in causal mediation with analyses of discrete event occurrence. Direct and indirect effects of arthritis on incident heart disease were obtained by combining estimates from a discrete-time survival model of heart disease regressed on arthritis and activity limitation controlling for all covariates measured at baseline with those from logistic regression of the mediator activity limitation regressed on arthritis and the same baseline covariates, stratified by gender.

Results: The sample included 11, 655 (5282 male, 6373 female) persons aged 18+ with no history of, or prevalent heart disease reported in the first 2 cycles of the NPHS (1994/5 and 1996/97). We identified 1442 incident heart disease events reported from 1998/99 to 2010/11. After adjusting for all covariates, arthritis and activity limitation were significantly associated with incident heart disease (arthritis OR (95% CI): 1.31 (1.10-1.56), activity limitation OR (95% CI) 1.61 (1.36-1.90)) in women, while only activity limitation was significant in men (arthritis OR (95% CI): 0.99 (0.81-1.20); activity limitation OR (95% CI): 1.59 (1.30-193)). Arthritis was significantly associated with activity limitation in both men (OR (95% CI): 3.25 (2.99-3.53)) and women (OR (95% CI): 2.85 (2.67-3.05)). Combining results from both regressions yielded significant direct (OR (95% CI): 1.31 (1.06-1.58)) and indirect effects (OR (95% CI): 1.09 (1.06-1.13)) of arthritis on heart disease with a proportion mediated by activity limitation of 28.5% in women. Only the indirect effect of activity limitation was significant in men (OR (95% CI): 1.09 (1.05-1.15)).

Conclusion: Findings from this longitudinal population based study help elucidate differences in the etiology of heart disease in men and women with arthritis, and have policy implications for arthritis prevention programs with priority for targeted interventions towards reducing disability in persons living with arthritis.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health III: Risk Factors, Treatment and Outcomes of Gout and OA
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: An estimated 21% of disability attributed to arthritis is related to inactivity. This study analyzed data from the Osteoarthritis Initiative (OAI) to evaluate the influence of increasing physical activity on change in disability in previously inactive community-dwelling adults with or at greater risk to develop symptomatic radiographic knee osteoarthritis (OA).

Methods: Physical activity was measured by uniaxial accelerometers at baseline and 2 years. All study participants were inactive at baseline. Baseline inactivity was identified by the absence of a single 10-minute session of moderate or vigorous (MV) activity in a week. At 2 years of follow-up, inactive persons were further classified into three groups according to the Federal physical activity guidelines: those who (1) increased MV activity to meet guidelines (at least 150 minutes/week MV activity acquired in sessions ≥10min), (2) insufficiently increased MV activity (≥ 1 session/week but below guidelines) or (3) remained inactive. Disability domains of daily activity limitation (DAL) and frequency (DAF) assessed by Late-Life Disability Instrument were also ascertained at baseline and two years. Multiple linear regression evaluated the associations of changes in physical activity status with change in DAL and DAF adjusting for socioeconomic factors, health factors, and baseline DAL or DAF scores.

Results: The study included 545 adults with age range of 49-83 years; 64% had radiographic knee OA, 68% had WOMAC pain in at least one knee. At 2 years, 28% improved physical activity status. Compared to baseline, adults who remained inactive on average had worse DAL and DAF (mean change: -1.15 DAL, -0.46 DAF); people who became insufficiently active improved their DAL (mean change: 1.95 DAL, -0.41 DAF); those who met guidelines improved both their DAL and DAF (mean change: 10.31 DAL, 2.68 DAF). There was a significant graded relationship between increased physical activity and improved disability scores in both DAL (trend p-value <0.001) and DAF (trend p-value = 0.027) after adjusting for covariates.

Conclusion: These prospective data demonstrated increased physical activity was associated with reduced severity of disability over two years among previously inactive older adults. A significant graded relationship was found between improved physical activity status and decreased disability. While increasing physical activity to levels recommended by guidelines provided the most benefit, even increasing activity to below guideline levels was beneficial in reducing disability severity. These findings provide support for the encouragement of increasing activity to prevent worsening of disability.

Table. Late Life Disability Limitation and Frequency Average 2-year Changes from Baseline: Compared to those who remained inactive, those who moved from inactivity to more activity had significantly improved disability severity (positive average change)

			Year 2 Activity Status Among Baseline Inactive Adults			
			Remained Inactive	More Active		P value (trend)
				Insufficiently Active	Met Guidelines	
Disability domains of daily activity limitation (DAL)	Mean Change		-1.15	1.95	10.31	-
	Difference compared to Remained Inactive (95% CI)	Unadjusted	Reference	3.10 (0.78, 5.43)	11.46 (5.29, 17.63)	<.001
		Adjusted [a]	Reference	2.57 (0.30, 4.83)	10.15 (4.48, 15.81)	<.001
Disability domains of daily activity frequency (DAF)	Mean Change		-0.46	-0.41	2.68	-
	Difference compared to Remained Inactive (95% CI)	Unadjusted	Reference	0.05 (-0.74, 0.84)	3.14 (1.05, 5.23)	0.084

Knee Pain Burden is Associated with Decreased Motor Performance: Data from the Osteoarthritis Initiative

Background/Purpose: The influence of knee pain perception on daily life motor performance in knee osteoarthritis (OA) patients has not been established. We examined the effect of knee pain on objectively measured cadence, a measure of motor performance in daily life, among community-dwelling adults with or at high risk for knee osteoarthritis.

Methods: Activity was objectively measured by accelerometer on 2,001 participants with or at risk of radiographic knee OA at the Osteoarthritis Initiative (OAI) 48-month clinic visit using ActiGraph GT1M uniaxial accelerometers (ActiGraph; Pensacola, FL). Participants were instructed to wear the sensor for seven consecutive days at least 10 hours per day. Analysis was restricted to those with at least four valid days of wear. Cadence is defined as the number of steps taken in a minute. The average maximum cadence/day was determined by identifying the maximum duration of moderate/vigorous activity (MVPA) and dividing the number of steps taken in the MVPA duration by MVPA minutes per day. These were then averaged over the number of valid days of wear. The Western Ontario and McMaster Universities Arthritis Index (WOMAC) was administered to assess the pain burden. Analysis of covariance was used to estimate sex-specific means (± standard error) of cadence across five categories of WOMAC pain (i.e., no pain and approximate quartiles of the non-zero pain score distribution), with adjustment for age, race, and body mass index.

Results: We included 1937 participants, 55% women, and with mean age of 65.1 (±9.1) years. Figure 1 shows a gradual decline in cadence with increasing WOMAC pain score. Mean cadence was significantly lower among men with WOMAC pain score >6 and significantly lower among women with WOMAC pain score >3, as compared to sex-specific means of participants with no pain.

Conclusion: Higher knee pain burden is associated with decreased motor performance in daily life as measured by cadence in both women and men. With the proliferation of accelerometers in smartphones, cadence may be an important outcome measure for interventions targeting pain in knee OA.

Average Maximum Daily Cadence (steps/minute)

Session Title: Epidemiology and Public Health III: Risk Factors, Treatment and Outcomes of Gout and OA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Obesity is one of the few modifiable risk factors of knee osteoarthritis (OA). However, it is not established whether a mechanical or metabolic mechanism is more important for the development of knee OA. Central adiposity contributes more than peripheral adiposity to cardiometabolic diseases, while analogous associations with knee OA are not known. The aim of this study was to examine the associations of 1) total body fat mass and appendicular lean mass, 2) abdominal subcutaneous adipose tissue (SAT) and 3) visceral adipose tissue (VAT) with knee structural changes in community-dwelling older adults.

Methods:

A subsample (n=866, mean age 73.5±2.9, 525 women, 46% black) of the Health, Aging, Body Composition Study participants (n=3,075, mean age 73.6, 52% women, 42% black) was included in this analysis. Body composition was assessed at baseline using whole body DXA, and abdominal SAT area and VAT area (cm^2) were calculated from a single 10 mm thickness abdominal CT. Knee MRI images were obtained using a 1.5T system at the year 2 or year 3 visit and assessed using the Whole-Organ Magnetic Resonance Imaging Score (WORMS). The presence of any bone marrow lesion (BMLs, grade ≥1), cartilage damage (≥2), meniscus damage (≥1) and synovitis/effusion (≥1) was examined. The associations of body composition or adipose tissue measures with the knee outcomes were examined using logistic regression models stratified by sex. Total body fat mass and appendicular lean mass were entered in models simultaneously. VAT and SAT divided by body weight (cm^2/kg) were entered in separate models. In the final models, age, race, height, study site, education, history of knee injury, knee pain, smoking status, alcohol drinking, total physical activity, time spent watching TV and use of NSAIDs at baseline were adjusted. Correlation of knees within person was taken into account by generalized estimating equations.

Results:

In an analysis of 1,413 knees, higher appendicular lean mass was associated with higher odds of all knee MRI outcomes, but higher total body fat mass was associated only with lower odds of meniscus damage in men (Table 1). In women, higher appendicular lean mass was associated with BMLs and meniscus damage. Total body fat mass was also associated with BMLs, but the adjusted odds ratio was smaller than lean mass. Abdominal SAT or VAT were not significantly associated with any of the knee MRI outcomes in men. In women, higher abdominal SAT was associated with higher odds of BMLs, but no association was found for VAT.

Conclusion:

The stronger association between knee MRI outcomes and lean mass compared to total fat mass and the lack of the association with VAT suggest the importance of overall higher weight rather than total fat or central adiposity specifically for knee structural changes. This could indicate a mechanical rather than a metabolic pathway.

Identification of Gout Flare Using an Administrative Claims Based Algorithm

Lindsey MacFarlane[1], Daniel H. Solomon[1] and Seoyoung C. Kim[2], [1]Rheumatology, Brigham and Women's Hospital, Boston, MA, [2]Division of Rheumatology; Division of Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA

Session Title: Epidemiology and Public Health III: Risk Factors, Treatment and Outcomes of Gout and OA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Gout is a common inflammatory arthritis characterized by repeated acute flares. The ability to accurately identify gout flares is critical for comparative effectiveness studies of gout treatments. Prior studies use claims data to identify gout flares, however, these algorithms have not been validated. This study aimed to develop and validate a claims-based algorithm to identify gout flares.

Methods:

We identified patients receiving care at an academic medical center between 2006 and 2010 with a diagnosis of gout or hyperuricemia using an electronic medical record-Medicare claims linked dataset. We developed 3 algorithms to identify gout flares: 1) International Classification of Diseases, Ninth Revision (ICD-9) code for gout (274.X) and ≤ 1 dispensing for a gout-related medication including colchicine, nonsteroidal anti-inflammatory drugs, COX-2 selective inhibitors, and oral

glucocorticoids ≤ 7 days from the date of gout ICD-9 code. The algorithm was run for any gout-related medication and for the individual medication categories. 2) ICD-9 code for gout and a J code for injectable glucocorticoid or a current procedural terminology (CPT) code for arthrocentesis or joint injection ≤ 7 days from the date of gout ICD-9 visit code. 3) ICD-9 code for gout and a J code for injectable glucocorticoid or a CPT code for arthrocentesis or joint injection on the same day. Gout flares defined by the algorithms were confirmed through medical record review. Physician documentation of gout flare in the record was considered the gold standard. Positive predictive value (PPV) and 95 % confidence intervals (CI) of the algorithms were calculated. A set of 100 patients with a visit coded for gout but without any gout-related medication, arthrocentisis or injectable glucocorticoid claims was used to identify gout without flare and to calculate the negative predictive value (NPV).

Results:

503 flares were identified using the medication algorithm, and 290 were identified using the procedure ≤ 7 days algorithm. The mean age of the patients in the medication algorithm was 75 (±8) years, and 61% were male. The mean age for the procedure algorithm was 76 (±8) years and 68% were male. The PPV of medication claims ranged from 50-54%. The PPV of the procedure claims ≤ 7 days was 59%, the same day procedure claim was stronger with a PPV of 68% (Table). The NPV of the algorithm identifying gout without flare was 88% (95% CI 82, 94).

Table. Positive predictive value of algorithms

Algorithm	Records Identified	Confirmed Gout	Confirmed Flare	PPV of Flare Algorithm
	n	n	n	% (95% CI)
ICD-9 + medication claim for any gout related medications*	503	498	268	53.3 (48.9, 57.7)
ICD-9 + medication claim for colchicine	302	300	163	54.0 (48.4, 59.62)
ICD-9 + medication claim for NSAID/ COX-2 selective inhibitor	174	173	87	50.0 (42.6, 57.4)
ICD-9 + medication claim for glucocorticoids	270	266	145	53.7 (47.8, 59.7)
ICD-9 + CPT or J code within 7 days	290	287	172	59.3 (53.7, 65.0)
ICD-9 + CPT or J code on same day	196	194	134	68.4 (61.9, 74.9)

95% CI= 95% confidence interval; CI % (CI)ICD-9=International Classification of Diseases, 9thRevision; CPT= Current Procedural Terminology; PPV= Positive Predictive Value; NSAID=non steroidal anti-inflammatory; * gout-related medications include colchicine, NSAIDs, COX-2 selective inhibitor, and glucocorticoids

Conclusion:

Our results suggest that a claims-based algorithm utilizing a combination of diagnosis and procedure codes as well as medications may misclassify patients as having a gout flare and caution should be used in interpreting data using claims-based definition of flares. However, as the NPV was high, the claims-based algorithm may be useful to assess the absence of gout flare or to identify

a cohort of gout patients with low disease activity or disease remission.

Session Title: Epidemiology and Public Health III: Risk Factors, Treatment and Outcomes of Gout and OA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: There is a remarkable, rising disease burden of gout and associated cardiovascular-metabolic comorbidities (e.g., hypertension in 74% and obesity in 53% of cases in the US), underscoring an urgent need for holistic strategies to effectively address these conditions together. Individual dietary risk factors have been identified; however, a piecemeal approach focusing on certain specific dietary risk factors is often ineffective or impractical, and does not address comorbidities of gout. In contrast, a dietary pattern approach (e.g., the DASH or Western diet) reflects the way foods are consumed in reality, and can address the net health benefit and enhance applicability and sustainability in practice; however, data on dietary patterns and the risk of gout are scarce. We prospectively examined the relation between 3 major dietary patterns (the DASH, Prudent, and Western Diets) and the risk of gout in a large prospective study of US women.

Methods: We studied the risk of incident gout in 78,906 female participants using the American College of Rheumatology survey criteria for gout. Using dietary information obtained every 4 years over 22 years (1984-2006), we created a DASH dietary score based on its components, which emphasize fruits, vegetables, low-fat dairy foods, and reduced intake of saturated and total fat and sugar-sweetened beverages. We also identified two major dietary patterns (using factor analysis): “prudent” (characterized by higher consumption of vegetables, fruit, fish, poultry, and whole grains) and “western” (characterized by higher consumption of red meat, processed meat, fries, high-fat dairy products, refined grains, sweets, and desserts). We then calculated these pattern scores for each participant and prospectively examined the association between dietary pattern scores and the risk of gout, adjusting for potential confounders.

Results: During 22 years of follow-up, we documented 778 confirmed cases of incident gout. The DASH dietary pattern score was associated with a lower risk for gout (relative risk [RR] for extreme quintiles, 0.67 [CI, 0.53 to 0.84]; P <0.001 for trend). Similarly, the prudent dietary pattern score was associated with a modestly lower risk for gout (RR for extreme quintiles, 0.76 [CI, 0.60 to 0.97]; P = 0.04 for trend). In contrast, the western dietary pattern score was associated with an increased risk for gout (RR, 1.68 [CI, 1.28 to 2.21]; P <0.001 for trend).

Conclusion: The Western dietary pattern is associated with an increased risk of gout, which explains the rising burden of gout in Western countries. In contrast, the DASH diet and prudent dietary pattern are associated with a lower risk of gout. The DASH diet appears to offer an attractive additional nutritional approach for gout, as it also reduces blood pressure in hypertension (present in 74% of gout patients) and is also recommended to prevent CVD (a common comorbidity of gout).

Session Title: Genetics, Genomics and Proteomics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Next generation sequencing has led to the discovery of new diseases and molecules regulating immune function. Hypomorphic mutations in the *TRNT1* gene cause a syndrome of sideroblastic anemia, immunodeficiency, periodic fevers and developmental delay, also known as SIFD. The TRNT1 enzyme catalyzes an essential step for tRNA maturation and protein synthesis, however, the underlying disease mechanisms are largely unknown. We aim to characterize the mechanisms of inflammation in this disease.

Methods: Whole exome sequencing or candidate gene screening was performed in two families, each with two affected siblings, and in three sporadic patients. Patient cells and tissue were used for deep RNA and tRNA sequencing, cytokine profiling, immunophenotyping through multicolor flow cytometry, H&E, immunohistochemistry and electron microscopy.

Results:

We identified seven patients with biallelic missense homozygous or compound heterozygous mutations in *TRNT1*. Four out of six mutations have not been reported. Three patients died of multiorgan failure. Two apparently unrelated patients shared the same genotype and had similar clinical presentation. Deep sequencing of tRNAs isolated from patients' fibroblasts showed a significant down-regulation of mature tRNAs when compared to healthy controls. RNA-sequencing of patients' whole blood revealed up-regulation of neutrophil-related genes. Consistent with these data, lesional biopsies from two patients' colon showed cryptitis with neutrophilic infiltration. Cultured patients' macrophages showed increased expression of proinflammatory cytokines IL-6, TNF-a, IL-1b, and accordingly, monocytes displayed increased phosphorylation of STAT3 ex vivo, possibly IL-6 induced, compared to monocytes isolated from healthy donors. Patients had variable degrees of B cell immunodeficiency with an increased population of immature B cells in the peripheral blood. Four patients had a bone marrow examination that revealed a markedly increased number of immature $CD10^{+}$ $CD20^{-}$B cells, and at the same time a decreased mature B cell population. Electron microscopy of BM smears showed evidence for abnormal morphology of blood vessels and endothelial cells, serum leakage and cellular debris in the stroma. Lymphocytes and monocytes displayed abnormal shape and degenerated mitochondria. Three patients have been on treatment with a TNF-a inhibitor that has shown promising results in attenuating the systemic inflammation and stabilizing the anemia.

Conclusion: Hypomorphic mutations in *TRNT1* are associated with a new, often severe, autoinflammatory disease manifesting a pleiotropic clinical phenotype. Given the essential function and ubiquitous expression of *TRNT1*, multiple cell types are affected. Myeloid cells, macrophages and neutrophils, might play an important role in mediating inflammation. Further studies may lead to the discovery of a new pathway regulating immune function.

Session Title: Genetics, Genomics and Proteomics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The intestinal microbiota plays a pivotal role in both host fitness and disease. Increasing evidence implicates microbial metabolites in the modulation of host immunity in both the gut and the periphery. In this study we used the HLA-B27 transgenic rat model of spondylarthropathy (SpA) to test the hypothesis that HLA-B27, a key SpA risk allele, impacts the host-microbiota metabolome and this may contribute to B27-associated spondylarthropathy.

Methods: We used ultra performance liquid chromatography – tandem mass spectrometry (UPLC-MS/MS) to analyze the metabolic profiles of intestinal contents collected from Fischer HLA-B27/β2m rats and WT controls. Samples were collected at two time points, at 6 weeks of age and at 16 wks. These time points were chosen since they represent time points prior to and subsequent to the development of B27-associated inflammation. Intestinal dysbiosis in this study was analyzed using 16s rRNA sequencing and phyla/species-specific qRT-PCR primers.

For functional studies, microbial metabolities (short chain fatty acids) were administered *p.o.* in drinking water. Animals were treated for 10 weeks, with treatment beginning at 6 wks. The development of HLA-B27-associated inflammatory sequelae was analyzed longitudinally and at necropsy. Inflammatory cytokine expression was determined in intestinal tissue by RNA extraction and qRT-PCR.

Results: UPLC-MS/MS analysis detected the presence of 582 host and microbial metabolites. Changes in metabolites related to energetics, inflammation, redox homeostasis and the microbiome were observed at both time points examined. Microbial metabolites of amino acids and of dietary components were strongly impacted by HLA-B27 expression. Medium chain fatty acids (MCFAs) and short chain fatty acids (SCFAs) were globally dysregulated in HLA-B27+ animals. Moreover, 16s analysis of gut microbiota community structure revealed HLA-B27 expression was associated in a marked loss of SCFA-producing *Clostridial* spp. Strikingly, administration of SCFA propionate led to a significant attenuation of B27-dependent inflammation.

Conclusion: To our knowledge this is the first study to report that expression of SpA-susceptibility allele HLA-B27 profoundly impacts the host-microbiota metabolome. Of the many B27-dependent changes to both host and microbiota metabolic profiles, loss of medium and short chain fatty acids were amongst the most pronounced. SCFAs are a fermentation product of dietary fiber and HLA-B27 expression was associated with reduced colonization by multiple SCFA-producing bacteria. The successful attenuation of B27-dependent spondylarthropathy by targeting these microbial metabolites highlights the translational potential of metabolomic profiling of the intestinal microbiota. These data strongly support further studies of the host-microbiota metabolome in SpA patient populations.

Session Title: Genetics, Genomics and Proteomics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

<h1> **Background/Purpose:** </h1> Immune-mediated inflammatory disorders (IMIDs) share many genetic risk factors.

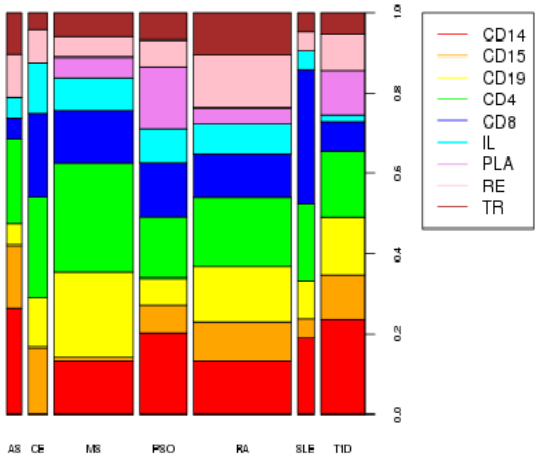
Pleiotropy may exist at different levels and most of the underlying mechanisms are still to be uncovered. GWAS have identified hundreds of risk loci for IMIDs but causative genes have been identified in only a handful of cases. Recent fine-mapping efforts indicate that only a minority of risk variants are coding. This suggests that most risk variants will be regulatory hence affecting disease risk via eQTL effects.

<h1> **Methods:** </h1> To aid in the identification of causative genes for IMIDs, we generated transcriptome information (HT12 arrays) for six blood cell types (CD4, CD8, CD19, CD14, CD15 and platelets) and intestinal biopsies at three anatomical locations (ileum, colon, rectum) for 350 healthy Caucasians. The same individuals were genotyped with SNP arrays interrogating > 700K variants, augmented by imputation from the 1KG project. To detect cis-eQTL we tested variants within 0.5 megabase windows centered on the tested probe. The nominal p-value of the best SNP within a cis-window was Sidak-corrected for the window-specific number of independent tests. The corresponding best, Sidak-corrected p-values for each probe were jointly used to estimate their respective false discovery rate. To identify likely causative genes in GWAS identified risk loci variants and also better understand pleiotropic effects, we (i) developed a method that quantifies the correlation between “disease association pattern” (DAP) and “eQTL association pattern” (EAP) and provides an empirical estimate of its significance, and (ii) evaluated the effect of fitting known risk variants as covariates in the eQTL analysis following Nica et al. (2010). We applied both approaches to celiac disease (CE) and rheumatoid arthritis (RA) and the second one to type one diabetes (T1D), multiple sclerosis (MS), systemic lupus erythematosus (SLE), ankylosing spondylitis (AS) and psoriasis (PSO).

<h1> **Results:** </h1> We detected > 16000 significant cis-eQTL, with a degree of sharing between cell types ranging from 38 to 90% highlighting the utility of our multi-tissue panel. GWAS variants were drivers of ciseQTL effects across the different tissues in 399 tests (23.6%), mostly in CD4 cells (Figure 1), and pinpointing 64 new gene-disease associations (3.7%). The number of shared loci and shared eQTL were highly correlated (rho=0.66).RA and SLE showed the highest degree of sharing.

<h1>**Conclusion:** </h1> We identified new potential candidate genes for IMIDs and characterized pleiotropic effects in terms of sign, magnitude and target tissue, through ciseQTL mapping in GWAS loci. These findings could shed a light on IMIDs pathogenesis and co-occurrence. Latest results will be presented.

Figure 1: Tissue Distribution of eQTLs driven by GWAS loci across IMIDs



Columns' width is proportional to the number of eQTLs.

Session Time: 4:30PM-6:00PM

Background/Purpose: Gout, caused by hyperuricaemia, is a multifactorial disease. Recently, genome-wide association studies (GWASs) of gout have been reported; however, they included self-reported gout cases. Therefore, the relationship between genetic variation and clinical subtypes of gout remains to be clarified. We hereby first performed a GWAS of clinically-defined gout cases only.

Methods: A GWAS was conducted with 945 clinically-defined gout cases and 1,213 controls in a Japanese male population. Additionally, a replication study of 1,048 clinically-defined cases and 1,334 controls was performed.

Results: We identified five susceptibility loci for gout at the genome-wide significance level ($p \quad 5.0 \times 10^{-8}$, which contained well-known urate transporter genes (*ABCG2* and *SLC2A9*) and additional genes reported to have relationships with metabolic pathways: rs1260326 ($p = 1.9 \times 10^{-12}$; OR = 1.36) of *GCKR* (a gene for glucose and lipid metabolism), rs2188380 ($p = 1.6 \times 10^{-23}$; OR = 1.75) of *MYL2-CUX2* (genes associated with cholesterol and diabetes mellitus), and rs4073582 ($p = 6.4 \times 10^{-9}$; OR = 1.66) of *CNIH-2* (a gene for regulation of glutamate signaling). The latter two are identified as novel loci for gout. Furthermore, we demonstrated that the identified SNPs were differentially associated with types of gout and clinical parameters underlying specific subtypes. The effect of the risk allele of each SNP on clinical parameters showed significant linear relationships with the ratio of the case-control ORs for two distinct types of gout ($r = 0.96$ [$p = 4.8 \times 10^{-4}$] for urate clearance and $r = 0.96$ [$p = 5.0 \times 10^{-4}$] for urinary urate excretion).

Conclusion: Our findings provide clues to better understand the pathogenesis of gout and will be useful to develop companion diagnostics of gout.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Genetics, Genomics and Proteomics
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Epigenetic modifications have emerged as important contributing factors in the pathogenesis of autoimmune diseases, including primary Sjögren's syndrome (pSS), and may act as a link between the environment and the genome. The aim of this study was to investigate DNA methylation in multiple tissues and its functional implications for pSS susceptibility.

Methods:

DNA prepared from whole blood samples (patients n=100, controls n=400), positively selected CD19+ B cells (patients n=24, controls n=47) and minor salivary gland biopsies (patients n=15, controls n=13) was analysed on the Illumina HumanMethylation 450k array, covering 485,000 CpG sites across the genome. Age and sex were included as covariates in the association model and a p-value of $<1x10^{-7}$ was considered significant (Bonferroni correction). Genomic coordinates of differentially methylated sites were tested for overlap with histone marks in publicly available data from reference B and T cells, and the association of genetic variants in known pSS risk loci with DNA methylation was investigated. In addition, gene expression was analysed by RNA-sequencing in CD19+ B cells from 16 patients and 24 controls.

Results:

We identified prominent hypomethylation in type I interferon regulated genes in whole blood, CD19+ B cells and minor salivary gland biopsies in patients with pSS. Enrichment for genomic overlap of these differentially methylated sites with histone marks of enhancer and promoter regions was observed. Analysis in whole blood from the controls showed that genetic variants located in or close to the pSS risk loci *DDX6-CXCR5*, *FAM167A-BLK*, *IL12A*, *IRF5-TNPO3*, *STAT4*, *TNIP1,* and within the HLA-region were associated with methylation levels at proximal CpG sites. In CD19+ B cells a correlation between hypomethylation and increased gene expression levels was identified for several interferon regulated genes with prominent hypomethylated sites overlapping enhancer regions, these genes included *MX1*, *IFI44L, IFITM1* and *RSAD2*.

Conclusion:

Our results further emphasize the role of DNA methylation in the pathogenesis of pSS. The importance of genes in the interferon system is highlighted, and the correlation with altered gene expression suggests a potential functional mechanism for differentially methylated CpG sites in pSS.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Genetics, Genomics and Proteomics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Cardiac manifestations of neonatal lupus, comprising atrioventricular conduction defects and cardiomyopathy, occur in fetuses exposed to anti-Ro/SSA antibodies, and carry substantial mortality. There is strong evidence of a genetic contribution to the risk (sibling recurrence risk ratio is ~3,000). Previously, in a case-control genome-wide association study, we reported that the 17 strongest associations were within the Human Leukocyte Antigen (HLA) region. Meisgen (2013) further underscored the potential importance of the HLA region when they observed two-digit classic HLA associations using family-based tests. Here, we report the first large-scale investigation of four-digit classic HLA associations in mothers with cardiac neonatal lupus (CNL) diagnosed children.

Methods: Parent-CNL-affected-offspring (n = 182) trios of European ancestry were genotyped using the Illumina Immunochip single nucleotide polymorphism (SNP) array and merged with 1073 non-lupus out-of-study controls (635 female). Admixture estimates were computed using ADMIXTURE. Classic four-digit HLA alleles in HLA-*A, -B, -C, -DPB1, -DQA1, -DQB1, and –DRB1* were imputed using high-quality SNPs and the software HIBAG. Analyses were computed on HLA alleles with a best guess allele count of at least 10 in cases or controls. Association analyses of CNL mothers vs non-lupus female controls were computed using logistic regression, adjusting for admixture. Transmission/disequilibrium tests (TDT) were computed using best guess HLA alleles to test for differential transmission to affected offspring.

Results: A total of 119 unique HLA alleles met quality control and allele frequency standards. Six HLA alleles met genome-wide significance: A*01:01(3.10, 1.47×10^{-12}), B*08:01(7.40, 2.56×10^{-24}), C*07:01(4.28, 1.27×10^{-17}), DQA1*05:01(8.22, 8.80×10^{-26}), DQB1*02:01(8.47, 6.03×10^{-26}), and DRB1*03:01(8.91, 1.03×10^{-26}) and four additional alleles met an HLA bonferoni threshold of 0.05/119=0.00042: DQA1*01:01(0.15,1.35×10^{-5}), DQA1*03:01(0.15, 1.00×10^{-4}), DQB1*05:01(0.21, 1.41×10^{-5}), and DRB1*01:01(0.11, 9.61×10^{-5}). To consider the joint effects across HLA genes, stepwise modeling was computed (Table).

	Allele Frequency		Single-allele	Stepwise	
HLA-allele	**Cases**	**Controls**	**P-value**	**OR (94% CI)**	**P-value**
B*08:01	0.382	0.121	2.56E-24	2.50 (1.41-4.45)	1.84E-03
DQB1*04:02	0.037	0.022	1.65E-01	6.32 (2.49-16.00)	1.02E-04
DQB1*06:02	0.189	0.132	3.60E-03	4.00 (2.57-6.23)	8.71E-10
DRB1*03:01	0.408	0.121	1.03E-26	7.98 (4.26-14.96)	8.94E-11
DRB1*11:01	0.061	0.046	2.42E-01	5.01 (2.17-11.60)	1.66E-04

None of the HLA alleles in the multilocus model exhibited differential transmission to offspring via a TDT ($p>0.15$). In addition, none of the 119 HLA alleles showed statistically significant evidence of differential transmission to the offspring after adjusting for multiple comparisons.

Conclusion: These analyses demonstrate the importance of the HLA region in mothers of CNL children. However, the four-digit classic HLA allele associations found in the mothers of CNL children were not differentially transmitted to the offspring. These results suggest that the maternal HLA profile contributes to an environment (e.g., anti-Ro antibodies) that increases the risk for CNL.

Session Title: Health Services Research II: Rheumatoid Arthritis Treatment and Healthcare Utilization

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Randomized controlled trials in RA have reported efficacy with both triple therapy (methotrexate [MTX] + hydroxychloroquine [HCQ] + sulfasalazine [SSZ]) and tumor necrosis factor inhibitor and MTX (TNFi-MTX) combinations. However, observational studies of clinical practice have been inconsistent when comparing persistence and adherence of these combinations. This analysis compared adjusted one-year persistence and adherence between triple and TNFi combination therapy in a real-world setting of US Veterans.

Methods: US veterans with RA initiating triple and TNFi combination therapy between Jan 1, 2006 and Dec 31, 2012 after 6-months of VA enrollment without prior triple or TNFi combination therapy were evaluated for 12-months. The index date the date that the last drug (index drug) of triple or TNFi combination was prescribed. To assure that the start of the index drug was intended as part of combination therapy, we required that all other drugs in the triple or TNFi combination have sequential dispensing within 90-days after initiation of index drug. A sensitivity analysis employed three different termination definitions of combination therapy: 1) Any drug in the combination drugs discontinued (i.e., gap $\geq$ 90 days); 2) New DMARD started, treatment reduced to monotherapy with non-biologic DMARD, or all DMARDs discontinued; 3) Same as #2 but switching within class (TNFi or other DMARDs) was allowed. To compare adherence, the Proportion of Days Covered (PDC)>80% was determined for each drug and the drugs in combination over the12 months. Propensity score matched weights were used to balance covariates when comparing risk ratios for each outcome among triple and combination therapy.

Results: A total of 3,204 TNFi-MTX and 1,160 triple therapy patients met the eligibility criteria (mean [SD] age at index 61 [11] vs. 62 [10], 16.0% vs. 9.0% female). After 12 months, persistence in the TNFi-MTX arm was significantly greater by all three approaches in both crude and propensity score weighted models (table1); favoring TNFi combination treatment. Twelve-month adherence to TNFi-MTX was approximately 41% higher than adherence to triple therapy [24% vs. 17%, RR: 1.41 (95%CI: 1.20,1.66)].

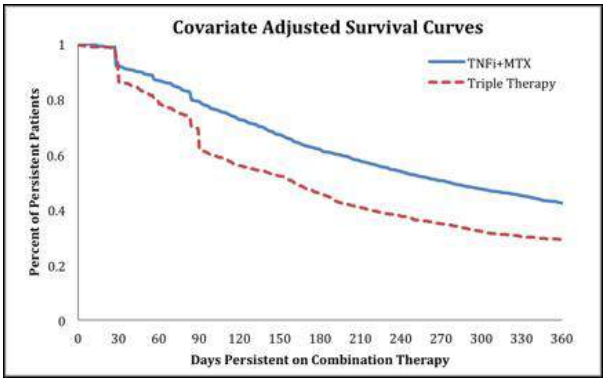

Table 1 Crude and Adjusted Estimates of Persistence

Outcomes	Crude Model				Matching Weights Adjusted Model			
	TNFi-MTX N=3,204	Triple Rx N=1,160	P Value	Relative Risk (95% CI)	TNFi-MTX	Triple Rx	P Value	Relative Risk (95% CI)
Definition 1	42.48%	29.22%	<0.001	1.45 (1.32-1.60)	42.31%	29.21%	<0.001	1.45 (1.29, 1.62)
Definition 2	55.09%	47.41%	<0.001	1.16 (1.09, 1.24)	53.67%	47.26%	0.0022	1.14 (1.05, 1.23)
Definition 3	60.46%	49.74%	<0.001	1.22 (1.14, 1.30)	59.16%	49.63%	<0.001	1.19 (1.10, 1.29)
Adherence Outcome	24.19%	17.33%	<0.001	1.4 (1.21, 1.61)	24.49%	17.34%	<0.001	1.41 (1.20, 1.66)

Conclusion: US Veterans initiating TNFi-MTX therapy consistently showed significantly greater persistence and adherence than those receiving triple therapy in clinical practice. Given differences between treatment strategies in terms of cost, tolerability, and patient preference, additional research focused on identifying factors that account for the observed differences in persistence and adherence will be important in informing RA management.

Session Title: Health Services Research II: Rheumatoid Arthritis Treatment and Healthcare Utilization

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Monitoring of drug use and costs can: describe trends in expenditures over time, identify regional variations in access and indicate physicians' uptake of best-practice guidelines. Our aim was to describe drug use and costs of biologic (bDMARD) and conventional synthetic Disease Modifying Anti-Rheumatic drug (csDMARDs) in the context of single-payer universal drug coverage.

Methods: We performed a population-based analysis, identifying all RA patients (from 1995 to 2013) who were aged 65 years and older using a validated algorithm (1) (n=37,012). All patients received identical public drug coverage from a single public payer. Prescriptions were determined using the pharmacy claims database of the Ontario Drug Benefit Program. For each patient we recorded the annual number of prescriptions and costs for csDMARDs and bDMARDs and region of residence. Trends in annual drug use and costs were graphed by drug class and regional health authority.

Results: The total number of patients receiving RA medications tripled from 14,222 in 1995 to 37,012 in 2013. During that same time period csDMARD use and costs increased from $2.1M in 1995 to $8.5M in 2013(Fig 1.). When bDMARDs were introduced in 2001, 105 patients received bDMARDs (0.4%) increasing to 3226 patients (11%) in 2013. During that period the costs of bDMARDS increased from $0.78M to $54.6M (Fig 1.).

In 1995, per-patient drug costs in each regional health authority were an average of $500 per patient per year(Fig 2.). Since the introduction of bDMARDs in 2001, total cost and per-patient cost variation among regions has increased considerably, with drug expenditure in 2013 ranging from $1200 per patient per year to $2500 per patient per year(Fig 2.).

Conclusion: The number of patients with RA increased linearly over time from 1995 to 2013. The proportion of patients receiving csDMARDs grew at the same rate as the population of patients with RA. The introduction of bDMARDs was associated with an exponential rise of bDMARD use and cost over time driving the increase in total drug costs however the use of bDMARDs was lower than in the US where 27% of patients with a mean age of 70 received bDMARDs (2).

When analyzed by region, adoption of bDMARDs was associated with differential and widening variation in regional drug costs over time, indicating unequal use of bDMARD not explained by differences in reimbursement criteria. We hypothesize that regional access to rheumatology care and rheumatologist's varying propensity to prescribe bDMARDs are the primary drivers of inequitable utilization of bDMARDs.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Health Services Research II: Rheumatoid Arthritis Treatment and Healthcare Utilization

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Doctors and patients make treatment decisions after weighing benefits and harms. For harms, while people prefer treatments with smaller risks, how they react to ambiguity—i.e., uncertainty arising from limitations in the reliability, credibility, or adequacy of risk information (often presented as a range of risks) – is less well understood. The objective of this study was to determine the relative importance of the magnitude of risk and ambiguity in the treatment decision-making context.

Methods: We invited members of an online panel to complete a survey which sought choices between two hypothetical rheumatoid arthritis treatments based on different levels of 4 attributes: probability of benefit (40%,55%,70%), probability (risk) of iatrogenic harm requiring treatment withdrawal (10%,20%,30%), ambiguity regarding risk of harm, expressed by risk estimate imprecision (none: point-estimate, low: range+/-5%, high: range+/-10%), and life expectancy (8,9,10 years). Each respondent

answered 10 pairwise Discrete Choice Experiment questions indicating strength of preference for each treatment, described using differing levels for each attribute as generated by a D-efficient experimental design. Conditional and mixed logit models were used to estimate coefficients for each attribute level and allow for estimation of marginal willingness to pay (WTP), in this case the duration of life they would be willing to give up to move between each of the attribute levels in the survey.

Results: Of 252 respondents, the mean age was 34 (range 20-67), 68% were male, and 52% had an education level of high school or less. Respondents placed greatest value on greater probability of benefit (WTP=1.34 years for 70% vs 40%, $p<0.001$), with lower but significant values for lower risk of harm (WTP=0.4 years for 10% vs 30%, $p<0.001$), and lower ambiguity (WTP=0.14 years, none vs high, $p<0.001$). Preliminary investigation of interactions suggested respondents were ambiguity-seeking when the risk of harm was low (10%), ambiguity-averse when the risk was high (30%), and ambiguity-neutral at the intermediate risk (20%). The degree of ambiguity aversion at high risk (30%) increased with the degree of imprecision in the risk estimate.

Conclusion: Current rheumatology patient information sources present harms of treatments by either providing point estimates (e.g. 3%, and ignore the ambiguity) or by providing ranges of risk estimates (e.g. 2-5%). This study suggests that providing ranges to communicate ambiguity make treatments more appealing when risks are small, but less appealing when risks are larger. While more research is needed to quantify differences in responses to ambiguity at other levels of risk, and for other outcomes, treatments, and disease states, this study highlights the implications of how risks are described, and the importance of developing strategies to communicate ambiguity in risk information.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Health Services Research II: Rheumatoid Arthritis Treatment and Healthcare Utilization

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Anti-TNF-α drugs are effective treatments for patients with inflammatory arthritis (IA). They are however expensive and their use carries a significant cost burden to the payer. Anti-TNF-α dose reduction in patients with stable disease in remission could lead to significant cost savings.

The aim of this prospective, non-blinded, non-randomised, observational study was to observe whether patients with IA (rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA)) could successfully dose reduce anti-TNF-α over a 4 year period and to estimate the total cost savings associated with dose reduction.

Methods:

Anti-TNF-α dose reduction was offered to patients with IA who were in remission as defined by standardized disease activity indices (DAS-28 <2.6, BASDAI < 4). Patients on etanercept were reduced from 50mg weekly to 50mg fortnightly. Patients on adalimumab were reduced from 40mg fortnightly to 40mg monthly. Patients who agreed to dose reduction were invited to participate in the study which commenced in 2010. Patients were assessed for disease activity at 3, 6 , 12, 24, 36 and 48 months. Patients who remained in remission were encouraged to stay on the reduced dose anti-TNF-α. The primary end-point was the

number of patients remaining on reduced dose anti-TNF-α at 4 years. Cost savings were estimated by deducting the actual total cost of anti-TNF-α used from the theoretical cost of using full dose anti-TNF-α had dose reduction not occurred.

Results:

79 patients with IA in remission were recruited. 57% had RA (n=45) ,13% PsA (n= 10) and 30% AS (n= 24). 57% (n=45) were on etanercept and 43% (n=34) were on adalimumab. The percentage of patients who remained on reduced dose anti-TNF-α at 4 years was 36% (n=29) (See figure 1). This resulted in net estimated savings to the exchequer of $1,373,761. The average cost saving per patient included in the study per year was $4346. A majority (53% n=37) of dose reduction failures occurred within the first year . Of the patients who successfully dose reduced at year 1 (n=42), a majority (69%, n=29) were able to maintain the dose reduction up to year 4. A greater percentage of AS patients (52 % n=12) were able to maintain dose reduction up to year 4 but this was not significant.

Conclusion:

Dose reduction of anti-TNF-α therapy in patients with IA in remission is feasible and can yield significant cost savings. Further studies could be designed to help define which patients are more likely to successfully dose reduce.

Session Date: Monday, November 9, 2015

Session Title: Health Services Research II: Rheumatoid Arthritis Treatment and Healthcare Utilization

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Several trials suggest that triple therapy with non-biologic disease-modifying antirheumatic drugs (ttDMARD) has similar efficacy compared to biologic DMARDs (bDMARD) for patients with RA. However, data on the use of ttDMARD in typical clinical practice and factors associated with intensification to ttDMARD have not been thoroughly examined. We evaluated progression to ttDMARD or bDMARD use after initial non-biologic DMARD (nbDMARD) prescription among patients with RA.

Methods: We used medical and prescription claims data from a large US commercial insurance program to evaluate ttDMARD use in RA between 1/1/2009 and 6/30/2014. Patients with a visit for RA and initial nbDMARD prescription were included after 180 days of continuous eligibility. ttDMARD use was defined as prescriptions for methotrexate, sulfasalazine, and hydroxychloroquine within 60 days. We calculated frequencies and rates for 6-month periods for the intensification to ttDMARD or bDMARD after initial nbDMARD prescription. We evaluated temporal, geographic, sociodemographic, clinical, and healthcare utilization factors as possible correlates of intensification to ttDMARD after initial nbDMARD using Cox regression models to estimate hazard ratios (HR), 95% confidence intervals (CI), adjusting for potential confounders.

Results: We analyzed 24,576 patients with initial nbDMARD prescription for RA during the study period. In this sample, 78% were female and mean age was 50.3 (SD 12.3) years. Methotrexate, sulfasalazine, or hydroxychloroquine were initially prescribed for 21,584 (88%) patients. During the entire 66-month study period, 2,739 (11.1%) intensified treatment to bDMARD compared to 181 (0.7%) who intensified to ttDMARD (see **Figure**). There was no increase in ttDMARD use over the study period. US geographic area was associated with intensification to ttDMARD: West (HR 1.82, 95% CI 1.14-2.88), South (HR 1.57, 95% CI 1.01-2.43), and Midwest (HR 1.78, 95% CI 0.99-3.20) compared to Northeast. Glucocorticoid use (HR 2.09, 95% CI 1.52-2.88) and nonsteroidal anti-inflammatory drug (NSAID) use (HR 1.62, 95% CI 1.19-2.21) prior to cohort entry date were significantly associated with subsequent ttDMARD intensification. Age, sex, year of entry into the cohort, median residence income, comorbidities, history of serious infection, rheumatologist appointment, and healthcare utilization factors were not associated with intensification to ttDMARD after initial nbDMARD prescription.

Conclusion: Despite reports during our study period suggesting equivalent efficacy of ttDMARD and bDMARD for RA, the use of ttDMARD after initial nbDMARD was infrequent and did not increase over time in this large nationwide study. Only 0.7% of RA patients were prescribed ttDMARD, despite 88% initially being prescribed methotrexate, sulfasalazine, or hydroxychloroquine. Further research investigating the use of ttDMARD for RA is warranted.

Session Date: Monday, November 9, 2015

Session Title: Health Services Research II: Rheumatoid Arthritis Treatment and Healthcare Utilization

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Combination therapy with methotrexate (MTX), sulfasalazine (SUL), and hydroxychloroquine (HCQ) [triple therapy] is an effective treatment for rheumatoid arthritis (RA). Randomized controlled trials (RCTs) evaluating triple therapy have concomitantly added either SUL+HCQ to MTX or started all three drugs concurrently. Nevertheless, the frequency that providers actually initiate triple therapy in this manner is unknown. Understanding provider practices with the initiation of triple drug therapy is important as these practices might impact treatment effectiveness.

Objectives: To explore patterns of initiation of MTX, SUL and HCQ employed in patients who received triple therapy in real-world settings.

Methods: Using national Veterans Affairs (VA) databases, RA patients receiving triple therapy at any time between January 1, 2006 and December 31, 2012 were identified. Triple therapy was defined by evidence of any overlapping prescription of all three drugs within a 90-day period. Drug prescribing was considered concurrent (e.g. SUL+HCQ) if the initial prescriptions for the agents occurred within 30 days of each other, with subsequent prescription refills demonstrating intent to continue to prescribe all agents simultaneously. DMARD use in the six months prior to initiation of triple therapy was described herein to better understand treatment patterns leading to triple therapy.

Results: Triple therapy was prescribed in 1,160 patients. This cohort had a mean age of 62, was 91% male, 65% positive for RF and 59% positive for anti-CCP antibodies. Only 59 (5%) patients initiated all 3 drugs simultaneously; 171 (14%) had SUL and HCQ added concurrently to MTX (Table). There were 657 (57%) patients who were on MTX either alone or in combination with SUL or HCQ as a foundation to which other agent(s) were added. There were 666 (57%) patients who received drugs in a step-up fashion where the 3 drugs were added sequentially over time with more than 30 days between initiating each drug. In 38 (3%) patients, 2 drugs were added to either background HCQ or SUL. Triple therapy was started in 229 (19%) patients who were initially started on dual therapy then later escalated to triple therapy.

Sequence of drug therapy initiation (n=1,160)				
First drug(s)	Second drug(s)	Third drug	Number	Percent
Triple Drug Initiation Concordant with RCT Protocols (n=230 – 20%)				
HCQ+MTX+SUL			59	5.1%
MTX	SUL+HCQ		171	14.7%
Triple Drug Initiation Discordant with RCT Protocols (n=930 – 80%)				
MTX	HCQ	SUL	224	19.3%
MTX	SUL	HCQ	102	8.8%
MTX+HCQ	SUL		134	11.6%
MTX+SUL	HCQ		26	2.2%
HCQ+SUL	MTX		66	5.7%
HCQ	MTX	SUL	171	14.7%
HCQ	SUL	MTX	72	6.2%
HCQ	MTX+SUL		19	1.6%
SUL	MTX+HCQ		19	1.6%
SUL	MTX	HCQ	47	4.1%
SUL	HCQ	MTX	50	4.3%
TOTAL			1,160	

Conclusion: The spectrum of utilization patterns involved in initiation of individual drugs that comprise triple therapy is much wider in clinical practice than in RCTs. In contrast to initiation strategies evaluated in RCTs, only 20% of US Veterans initiating triple therapy either initiated all agents simultaneously or stepped up from MTX by concomitantly adding SUL/HCQ together. Rather, the additional drugs were commonly added in sequence rather than concurrently. Since clinical response and patient experience during sequential DMARD initiation may affect decisions to progress to triple therapy, RCT results describing the benefits of triple therapy may not generalize to clinical practice.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Metabolic and Crystal Arthropathies I: Therapeutics
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Gout is a common form of inflammatory arthritis, often treated with allopurinol as a first-line urate lowering therapy. We have designed a large cluster-randomized study to examine the impact of a pharmacist-driven intervention as a means of optimizing allopurinol administration in gout. With enrollment and follow-up ongoing, completed efforts have focused on the development and implementation of the intervention and an interim assessment of its impact on allopurinol dose escalation and serum urate (sUA) testing.

Methods: An expert panel defined allopurinol treatment algorithms relevant for gout patients initiating therapy. The panel considered several allopurinol treatment decisions using the RAND/UCLA Appropriateness Method. Endorsed decisions were incorporated into an algorithm with pharmacist-led interventions that includes patient outreach designed around gradual allopurinol dose escalation with the goal of achieving and maintaining a sUA < 6.0 mg/dl. Ambulatory pharmacists conduct outreach primarily via telephone interactive voice recognition (IVR) system to assess adherence, facilitate sUA testing, provide education, and to adjust allopurinol dosing. Medical offices in the Kaiser Permanente Southern California health system were cluster randomized by geographic proximity (n = 103 clusters) to deliver either the pharmacist led intervention or usual care to patients receiving new allopurinol prescriptions. All participants received an introductory letter that included a gout information booklet and an opt-out option. The algorithm served as a guideline and the pharmacist was allowed to deviate from the guideline based on clinical circumstances.

Results: Two allopurinol treatment algorithms were developed, one for patients with CKD stage I/II and one for patients with CKD stage III/IV (stage V excluded); both incorporated a treat-to-target strategy of dose titration to achieve sUA ≤ 6.0 mg/dl. To date, 441 patients have enrolled in the intervention with 810 participants receiving usual care; 71 patients have opted out. Characteristics of gout patients enrolled between July 2014 and May 2015 are shown in addition to the number of allopurinol prescriptions dispensed, frequency of dose change, and sUA testing.

Conclusion: To address the typically suboptimal titration of allopurinol, we are conducting a large pragmatic cluster-randomized trial to examine a highly automated, exportable, pharmacist-driven intervention to optimize allopurinol treatment in gout. Deploying a treatment algorithm developed with expert input, approximately 1 of every 4 intervention patients has received allopurinol dose escalation, more than twice that observed in usual care. Novel elements of this intervention and its unique study design features will inform future gout care.

Racial Disparities in the Risk of Hospitalized Severe Allopurinol Hypersensitivity Syndrome – a US Nationwide Study (2009-2011)

Na Lu[1], Sharan K. Rai[2], Jeewoong Choi[3] and Hyon K. Choi[1], [1]Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Experimental Medicine, University of British Columbia, Vancouver, BC, Canada, [3]Massachusetts College of Pharmacy and Health Sciences, Boston, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Metabolic and Crystal Arthropathies I: Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Allopurinol is the leading choice of urate-lowering therapy for gout (>95% of treated cases); however, it is associated with the rare but potentially fatal allopurinol hypersensitivity syndrome (AHS) (i.e., Steven Johnson Syndrome [SJS] and Toxic Epidermal Necrolysis [TEN]). Beyond renal dosing to help reduce the risk of AHS, the recently discovered strong associations between HLA-B*5801 allele carriage and AHS led to the 2012 ACR recommendation to screen for this marker among high-risk Asians, but not Whites, given the higher allele frequency in Asians. This leaves several open questions: 1) are Asians at a higher risk of developing AHS than Whites, given the allele differences, and 2) what about other races? This obvious information can be immediately useful in clinical care and policy decisions. We examined this potential racial difference in the risk of hospitalized SJS and TEN using a nationwide inpatient dataset.

Methods: We used the National Inpatient Sample (NIS), a database representative of hospitalizations in the US from 2009-2011, where severe AHS (caused by uric acid metabolism drugs) patients were identified by a primary discharge diagnosis ICD-9-CM code for SJS (695.13) and TEN (695.14-15), followed by a secondary discharge diagnosis of an adverse effect caused by uric acid metabolism drugs in therapeutic use (E9447) or gout (274.x). In the context, severe AHS occurs almost exclusively related to allopurinol. We calculated race-specific hospitalization rate ratios for AHS using Whites as the reference; in-hospital mortality and length of stay were also compared. Analyses were performed using NIS sampling weights to obtain US national estimates.

Results: During 2009-2011 in the US, there were 608 patients admitted with SJS or TEN meeting our criteria. The mean age was 69 years and 47% were men. Of the 608, there was a substantial over-representation of Asians (23%) and Blacks (28%) as compared to Whites (32%) and Hispanics (5%), given their background population rates from the US census (5%, 13%, 78%, and 16%, respectively). The hospitalization rate ratios for AHS among Asians, Blacks, Hispanics, and Whites were 11.4, 5.2, 0.8, and 1.0 (referent). These ratios agreed with their *HLA-B*5801* frequencies in the US population (7.4%, 4%, 1%, and 1%, respectively). In-hospital mortality of the 608 was 13%. The mortality rate as well as the mean length of stay were higher among Asians than other races ($p=0.001$ and <0.001, respectively).

Conclusion: Our findings based on these nationally representative inpatient data indicate that race is a strong determinant of severe AHS risk: Asians (11x) > Blacks (5x) > Hispanics (1x) = Whites (1). Mortality and length of stay were worse among Asians. These data call for extra caution among Asians (and perhaps Blacks) when considering allopurinol, and support the ACR recommendation to screen for *HLA-B*5801* for high-risk Asians.

Table. Risk Estimates of Hospitalized Severe Allopurinol Hypersensitivity Syndrome by Race in the US (2009-2011)

	Age, Year (Mean ± SE)	Hospitalization Weighted N (%)	Hospitalization Rate per 100,000 persons	Hospitalization Rate Ratio	In-Hospital Death Weighted N (%)	Mean Length of Stay (SE)
RACE						
White	71 ± 2	197 (32)	0.027	1.00 (ref)	33 (17)	12.2 ± 2.1
Black	67 ± 2	171 (28)	0.141	5.2 (4.2 to 6.4)	*	9.4 ± 1.8
Hispanic	72 ± 2	31 (5)	0.020	0.8 (0.5 to 1.1)	*	6.2 ± 1.6
Asian	71 ± 2	143 (23)	0.310	11.4 (9.2 to 14.2)	29 (21)	18.5 ± 3.8
Other/Missing	65 ± 2	66 (11)	-	-	-	-

Session Date: Monday, November 9, 2015

Session Title: Metabolic and Crystal Arthropathies I: Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: No clinical trials had previously investigated the characteristics of joint damage in early gout or the benefit of instituting urate-lowering therapy (ULT) earlier in the course of the disease. The objectives of this study were to evaluate 1) the effect of febuxostat vs. placebo on joint damage after 2 years of treatment in subjects with early gout and 2) the safety of febuxostat.

Methods: Subjects with serum urate [sUA] ≥7.0 mg/dL received either febuxostat 40/80 mg or placebo for up to 2 years. Febuxostat was up titrated from 40 to 80 mg at the Month 1 visit if sUA ≥6.0 mg/dL at the Day 14 visit. Early gout was defined as having experienced ≤2 gout flares total, and only 1 flare during the previous 12 months. Joint damage was evaluated utilizing x-ray and magnetic resonance imaging (MRI). X-rays were assessed using a modified Sharp-van der Heijde (mSvdH) method validated in gout patients. MRI images were assessed using the rheumatoid arthritis MRI scoring (RAMRIS) system. For both X-ray and MRI assessments, the joint with the first gout flare was identified as the primary affected joint. Contrast-enhanced MRI images were used for scoring of synovitis. Safety assessments included adverse events (AEs), serious AEs and clinical laboratory measures.

Results: At baseline, mSvdH erosion score >0 in the primary affected joint was present in 9% of the placebo group and 14% of the febuxostat group. After 2 years of treatment, the placebo and febuxostat groups showed no differences in the changes from baseline in mSvdH erosion scores from the primary affected joint or from full hand and foot radiographs. At baseline, RAMRIS synovitis score >0 in the primary affected joint was present in 89% of the placebo group and 94% of the febuxostat group. There was a significant reduction in the RAMRIS synovitis score for the primary affected joint in the febuxostat group compared to the placebo group after 1 ($p=0.025$) and 2 ($p<0.001$) years of treatment. The RAMRIS erosion and bone edema scores showed no differences for the primary affected joint comparing febuxostat and placebo groups. The percentage of subjects with sUA levels <6.0 mg/dL was 62.8% and 5.7% after 2 years of treatment with febuxostat and placebo, respectively.

The most frequent treatment emergent adverse events (TEAE) and adjudicated major adverse cardiovascular events (MACE) are

summarized in Table 1.

Conclusion: This first clinical trial in early gout subjects demonstrated that treatment with febuxostat can achieve a significant reduction in synovitis compared to placebo. No measurable change in the affected joint erosion score was observed with and without ULT during the observation period. Febuxostat was generally well tolerated in this population of early gout subjects.

Table 1. Treatment Emergent Adverse Events (TEAE) and Major Adverse Cardiovascular Events (MACE)

	Placebo (n, %)	Febuxostat (n, %)
Total randomized	157	157
Subjects with any TEAE	115 (73.2)	115 (73.2)
Subjects with ≥1 treatment related TEAE	20 (12.7)	29 (18.5)
Most frequently reported TEAE (≥5% of subjects)[a]		
Musculoskeletal and connective tissue pain and discomfort	25 (15.9)	21 (13.4)
Joint related signs and symptoms	11 (7.0)	15 (9.6)
Liver function analyses	15 (9.6)	21 (13.4)
Skeletal and cardiac muscle analyses	11 (7.0)	9 (5.7)
Dermatitis and eczema	4 (2.5)	8 (5.1)
Headaches	11 (7.0)	5 (3.2)
Diarrhea (non-infective)	6 (3.8)	9 (5.7)
Edema	5 (3.2)	9 (5.7)
Upper respiratory tract infection	21 (13.4)	27 (17.2)
Upper respiratory tract signs and symptoms	1 (<1)	8 (5.1)
Subjects with MACE

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Metabolic and Crystal Arthropathies I: Therapeutics
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Arhalofenate is a novel Urate-Lowering Anti-Flare Therapy (ULAFT) to treat gout. It lowers serum uric acid (sUA) by blocking URAT1, a tubular UA transporter, and reduces gout flares by blocking the local release of IL-1β. The study primary objective was to evaluate the anti-flare activity of arhalofenate in gout patients in the absence of background colchicine treatment.

Methods: This was a randomized, double-blind, placebo- and active-controlled phase 2b (NCT02063997) at 54 centers. Male or female gout subjects with a sUA ≥ 7.5 mg/dL and ≤ 12 mg/dL were enrolled. Subjects experienced at least three flares during the previous year and could not have been using Urate Lowering Therapy (ULT) and colchicine two weeks before screening. Subjects were randomized 1:2:2:2:2 to placebo, arhalofenate 600 mg or 800 mg, allopurinol 300 mg or allopurinol 300 mg combined with colchicine 0.6 mg. Randomization was stratified on sUA levels and presence of tophi. Dosing was once daily, orally for 12 weeks. Flares were recorded with an electronic diary. During study, flares were treated with non-steroidal or steroidal anti-inflammatory.

Results:

A total of 239 subjects were randomized and dosed, and constitute the efficacy (mITT) and safety population. The primary outcome of efficacy comparing flare rates between the arhalofenate 800 mg to allopurinol 300 mg groups was met with a 46% improvement (p = .0056). Additional key outcomes are presented in the table:

		Placebo	Arhalofenate 600 mg	Arhalofenate 800 mg	Allopurinol 300 mg	Allopurinol 300mg + 0.6 mg COL
	N	28	53	51	54	53
Flare rate		1.13	1.04	0.66[a]	1.24	0.40
Mean % change in sUA from baseline to	Week 8	+1	-14	-20	-30	-24
	Week 12	-1	-12[b]	-16[c]	-29	-25
Discontinued for safety		1	1	1	3	5
Serious Adverse Events (SAEs)		0	0	1	3	1

[a] 46% reduction vs. allopurinol 300 mg (p = .0056) and 41% reduction vs. placebo (p= .049)

[b] p = .0021 vs.placebo

[c] p = .0059 vs. placebo

There were no SAEs related to arhalofenate. There was one SAE of a kidney stone in a patient on allopurinol 300 mg. There were no meaningful differences in the number of patients reporting Treatment Emergent AEs (TEAEs). The most frequent TEAEs were increases in creatine phosphokinase (4.6%), upper respiratory tract infections (3.8%), hypertension and headache (both 3.3%) with no relevant differences between groups. No subjects on arhalofenate who developed an abnormal serum creatinine value that was more than 1.5 times above pre-treatment values.

Conclusion:

Arhalofenate at 800 mg significantly decreases gout flares when compared to allopurinol 300 mg. There was no statistical difference in flares between arhalofenate 800 mg and allopurinol 300 mg combined with colchicine. Arhalofenate 800 mg also significantly decreased flares when compared to placebo. These results indicate that Arhalofenate has intrinsic anti-inflammatory activities clinically associated with improvement in gout flares.

Arhalofenate sUA lowering activity, while significant compared to placebo, was lower than in the allopurinol 300 mg groups.

Arhalofenate was well tolerated and appeared safe.

Arhalofenate is currently in development for the treatment of gout as a combination therapy with ULT, both to lower serum uric acid and prevent flares.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Metabolic and Crystal Arthropathies I: Therapeutics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Two randomized, double-blind, placebo-controlled Phase III clinical trials showed that lesinurad (200 or 400 mg) when added to allopurinol (200-900 mg) significantly increased the proportion of gout patients achieving the serum uric acid (sUA) target of <6.0 mg/dL by Month 6, representing an approximate 2-fold increase with lesinurad 200 mg compared with allopurinol alone. Lesinurad was generally well tolerated, particularly at the 200 mg dose, where the safety profile was comparable to allopurinol alone, with the exception of a higher incidence in predominately reversible serum creatinine (sCr) elevations. As renal impairment and gout frequently coexist, the objective of the current pooled analysis was to explore efficacy and safety endpoints in gout patients based on baseline renal function.

Methods: Patient data were combined from 2 Phase III clinical studies examining the efficacy and safety of lesinurad, a selective uric acid reabsorption inhibitor (SURI), in combination with standard of care allopurinol (200-900 mg) (CLEAR 1 [NCT01510158], CLEAR 2 [NCT01493531]). In current analyses, patients were analyzed by baseline renal function using estimated creatinine clearance (eCrCl; Cockcroft-Gault formula using ideal body weight): <60, <90, and ≥90 mL/min.

Results: In total, 1208 patients were included in the analyses. Demographic characteristics, including age, gender, race, weight, and BMI, were broadly similar between patient groups stratified by baseline renal function. Efficacy, assessed by the proportions of patients with sUA <6.0 mg/dL at 6 and 12 months, was consistently greater (P<0.05) for both lesinurad doses (200 mg and 400 mg) than placebo in all groups assessed by baseline renal function (Table). There were no consistent differences in TEAE rates in patients based on baseline renal function (Table). sCr elevations occurred at higher rates in the lesinurad groups (particularly the 400 mg dose) versus placebo, without evident differences when analyzed by baseline renal function.

Conclusion: These combined analyses from 2 Phase III studies indicate that lesinurad in combination with allopurinol provides consistent, significant efficacy across all renal function groups. Safety findings were consistent between treatment groups across

all renal function categories.

Table: Efficacy and safety endpoints in CLEAR 1 and CLEAR 2 combined: stratification by baseline eCrCl <60, <90, and ≥90 mL/min

SESSION INFORMATION

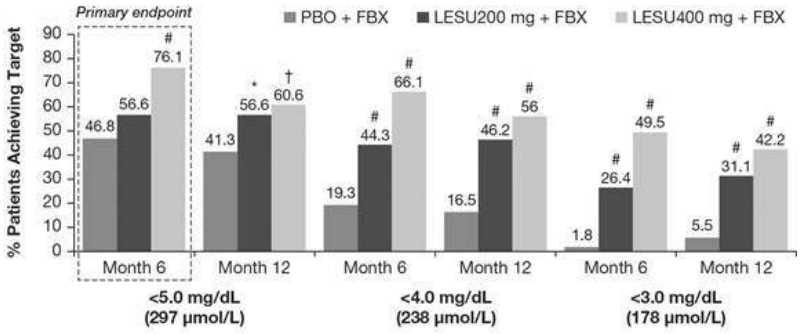
Session Date: Monday, November 9, 2015
Session Title: Metabolic and Crystal Arthropathies I: Therapeutics
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Lesinurad (LESU; RDEA594) is a selective uric acid reabsorption inhibitor (SURI) being investigated for the treatment of gout in combination with a xanthine oxidase inhibitor. The CRYSTAL study is a multinational, randomized, double-blind, placebo-controlled, Phase III clinical trial of LESU in combination with febuxostat (FBX) to determine efficacy and safety of combination therapy compared with FBX monotherapy in patients with tophaceous gout (NCT01510769).

Methods: Patients with gout, aged 18–85 yrs, with serum uric acid (sUA) ≥8 mg/dL (≥6 mg/dL on urate lowering therapy) and ≥1 tophus were given FBX 80 mg qd for 3 weeks before randomization to LESU (200 mg or 400 mg oral, qd) in combination with FBX or placebo (PBO) + FBX. Primary endpoint was proportion of patients with sUA <5.0 mg/dL by Month 6. Secondary endpoints included proportion of patients with complete resolution of ≥1 tophus and percent reduction in tophus area by Month 12. Safety assessments included adverse events and laboratory data.

Results: Patients (N=324) were white (79.9%) and male (95.4%) with mean±SD age of 54.1±11.0 yrs and 14.7±10.9 yrs since gout diagnosis. sUA was 8.7±1.6 mg/dL at screening and 5.3±1.6 mg/dL on FBX at randomization (28% with sUA ≥6 mg/dL). More patients achieved sUA levels <6, <5 (primary endpoint), <4, and <3 mg/dL with LESU+FBX (Figure). Percentage of patients with complete resolution of ≥1 tophus by Month 12 was 21.1%, 25.5%, and 30.3% for FBX+PBO, FBX+LESU200, and FBX+LESU400, respectively. Percent decrease in tophus area by Month 12 was 55.8% and 57.9% for FBX+LESU200 and FBX+LESU400, respectively, vs 31.3% for FBX + PBO (both nominal $P<0.05$). Safety data are reported in the Table. More serum creatinine (sCr) increases were observed with LESU+FBX; most resolved by last study visit (Table). Kidney stones were lower with LESU.

Conclusion: In patients with tophaceous gout, LESU (200 or 400 mg) in combination with FBX increased the proportion of patients achieving sUA <5 mg/dL at 6 months compared with FBX alone. LESU in combination with FBX resulted in greater tophus area resolution compared with FBX alone, as well as a dose-ordered numerical increase in the proportion of subjects having complete tophi resolution. LESU was generally well tolerated, except for higher incidence of predominately reversible sCr elevations. Combination therapy with LESU+FBX may represent a future treatment option for patients with tophaceous gout on FBX who warrant additional therapy.



Nonresponder imputation. *$P<0.05$; †$P<0.01$; ‡$P<0.0001$ vs PBO + FBX; no multiplicity adjustment.

Higher Total Knee Arthroplasty Revision Rates in Black Americans: A Systematic Literature Review and Meta-Analysis

Anne R. Bass[1], Kelly McHugh[1], Kara Fields[2,3], Rie Smethurst[4], Michael Parks[5] and Susan M. Goodman[1], [1]Rheumatology, Hospital for Special Surgery, New York, NY, [2]Medicine/Rheumatology, Hospital for Special Surgery, New York, NY, [3]Biostatistics, Hospital for Special Surgery, New York, NY, [4]Education - Academic Training, Hospital for Special Surgery, New York, NY, [5]Orthopedics, Hospital for Special Surgery, New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Utilization of total knee arthroplasty (TKA) is lower among blacks than whites in the United States (U.S.), which may be due to blacks' perception of increased TKA risk. Approximately 4% of TKA require revision within five years. The purpose of this study was to determine whether U.S. blacks are at higher risk for TKA revision than U.S. whites.

Methods: A systematic review of English language articles, published during or after 2000, was performed on March 31, 2015 using Medline via PubMed, the Cochrane register and EMBASE. In addition, a hand search of unlisted journals that focus on

racial disparities was performed. Study inclusion criteria were (1) U.S. patient population, (2) TKA as the primary procedure; (3) follow up period at least 2 years; (4) reporting of revisions rates; (5) analysis of patient race as an independent predictor of revision. Two reviewers screened titles, abstracts and full text articles in a standardized manner. Meta-analysis was used to analyze the risk of revision TKA in blacks compared to whites.

Results: 4286 studies were identified and screened by title, 106 by abstract and 24 by full text. Six studies met the inclusion criteria and were qualitatively reviewed (**Table 1**). Only 4 of the 6 studies could be meta-analyzed because of overlapping study populations in 3 of them. The meta-analysis represented 451,960 TKA patients, of whom 31,568 (7.0%) underwent revision surgery and 28,772 (6.3%) were black. The risk of revision TKA was significantly higher among U.S. blacks than U.S. whites (HR 1.38; 95% CI 1.20-1.59) (**Figure 1**). Analysis of the 3 studies with overlapping study populations demonstrated discordant results as a result of adjustment versus non-adjustment for insurance status (**Figure 2**).

Conclusion: Blacks in the U.S. are at higher risk for revision TKA than whites, which may contribute to a perception of increased TKA risk among blacks. Socioeconomic status (as represented by insurance status) also contributes to revision risk and is an important confounder in analyses of race.

Intra-Operative Synovitis Predicts Worse Pain and Function 2 Years After Total Knee Arthroplasty for Osteoarthritis

Background/Purpose:

Total knee arthroplasty (TKA) is one of the most common elective orthopedic procedures in the US. However, up to 20% of patients have chronic post-operative pain. There is therefore an urgent need to identify modifiable risk factors to improve patients' outcomes. Inflammation is reversible, and has been associated with pain in knee osteoarthritis (KOA). However, whether inflammation is associated with chronic pain or other suboptimal outcomes after TKR is unknown. Therefore, this study investigated the association between pre-operative synovial inflammation and 2-year outcomes following TKA for KOA.

Methods:

We identified 33 KOA patients who underwent primary unilateral TKA and had chronic pain (WOMAC ≤60; 100 =best) at 2 years. Patients were matched 2:1 on surgeon and surgery date with TKA cases with little pain at 2 years, (WOMAC ≥70). All patients provided demographic and pre-and post-operative self-report data. Preoperative radiographs were graded by two blinded evaluators for alignment and Kellgren and Lawrence score. H+E slides of intra-operative synovial tissue were reviewed and graded for inflammation according to the validated Krenn Criteria. Prosthesis information, history of previous surgery to the index knee, post-operative steroid injection and manipulations were recorded from surgeons' and inpatient charts. Regression analyses were performed to evaluate whether pre-operative inflammation was an independent predictor of pain, function or stiffness 2 years after TKA.

Results:

Average age was 67 years, (±7.9), 65% were women and 91% were Caucasian. In a multivariate linear regression controlling for Krenn Score, post-operative steroid injection, age, MCS, PCS, pre-operative WOMAC pain and Euroqol, patients with greater inflammation (Krenn ≥3) had more pain at 2-years (WOMAC 65.01 vs. 76.14; p-value 0.03). Patients who had a steroid injection soon after TKA (based on surgeon's suspicion of tenosynovitis) were more likely to have worse 2 year WOMAC pain scores (60.3 vs. 80.9; p-value = 0.0495). Every 10 year increase in age was associated with a 6.6 unit increase in 2-year WOMAC pain score,(i.e. less pain.). Separate models showed a similar association between high Krenn score and worse 2-year function, (WOMAC Function 70.2 vs. 81.1; p-value 0.01), but no association between Krenn score and 2 year WOMAC stiffness. Neither radiographic findings nor implant type were associated with 2-year outcomes.

Conclusion:

Increased synovial inflammation at the time of surgery predicts worse WOMAC pain and function 2 years after TKA. This is a potentially modifiable risk factor which could be a target for future interventional trials.

Session Title: Orthopedics, Low Back Pain and Rehabilitation
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Pain in the distal upper limb (elbow, forearm, wrist or hand) is common, yet the best approach to management is unclear. While the etiological and prognostic factors are similar to other pain conditions, such as low back pain, management approaches differ greatly. Bed rest is no longer advocated for back pain, although patients with arm pain are often advised to rest and to avoid 'harmful' activities, while awaiting physiotherapy. This advice is without an evidence base.

We hypothesized a) that advice to remain active and maintain usual activities while awaiting physiotherapy, would be superior to advice to rest the arm; and b) that fast-track physiotherapy would be superior to normal (waiting list) physiotherapy.

Methods:

Multi-center randomized controlled trial (ISRCTN79085082). Patients with distal upper limb pain were identified from 14 out-patient physiotherapy departments across the UK. A telephone screening and pre-trial physical assessment confirmed eligibility and collected baseline information. Participants were randomized to either:

* Advice to remain active, or

* Advice to rest the arm

while awaiting physiotherapy, or

* Immediate physiotherapy,

using a mixed randomization/minimization algorithm to maintain treatment balance in terms of treatment center, gender, laterality (dominant, non-dominant, or bilateral problem), a broad categorization of diagnosis (elbow versus wrist/hand problem), and baseline arm function. Outcome was measured at 26 weeks using the modified DASH (Disabilities of the Arm, Shoulder and Hand) questionnaire which asks people to rate difficulty in performing eleven pre-specified activities over the past week, because

of pain in their distal upper limb. This was scored as 0 (no disability) versus >=1 (some disability). **Results** , from an intention-to-treat analysis, are presented as odds ratios (95% confidence intervals) for the probability of recovery.

Results:

539 patients were randomized evenly between the three groups (179, 182 and 178, respectively). Participants had a mean age of 49yrs (SD 13.6); 54.5% were female; and 87.6% were right handed. Approximately an equal number of patients reported pain in their elbow, wrist/hand, or both; and pain was most common in the dominant side (45.5%), or bilateral (24.7%). 435 participants (81%) provided follow-up data at 26 weeks.

32.1% of patients who received advice to rest were free of disability at 26 weeks, compared to 45.2% of those who received advice to remain active. Thus, advice to rest was associated with a decrease in the likelihood of recovery (odds ratio: 0.54; 95%CI: 0.32-0.90). There was no difference in recovery between those receiving immediate physiotherapy (35.8%) versus delayed (38.6%).

Conclusion:

We have shown, among patients referred to physiotherapy with distal upper limb pain, that advice to remain active is associated with a superior long-term outcome, compared with advice to rest the arm, but our results do not support the provision of 'fast-track' physiotherapy for such patients. These findings call into question current advice and provide evidence that the no-bed-rest management approaches now common in back pain perhaps have parallels in other regional musculoskeletal pain conditions.

Session Title: Orthopedics, Low Back Pain and Rehabilitation

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Low back pain (LBP) causes enormous financial and disability burden worldwide, and therapeutic options have limited efficacy. This burden could be potentially reduced by gaining an understanding of the predictors of LBP in order to optimize preventive strategies. As having previous episodes of LBP are predictive of future recurrences, understanding the risk factors associated with

LBP in early adulthood are particularly important. There is evidence that women are more likely to suffer from LBP and utilise health care to a greater extent in comparison to men, and there is a paucity of data examining predictors of LBP, such as weight and physical activity, in young women. The aim of this study was to identify whether modifiable risk factors, weight and physical activity, were predictive of low back pain in young adult women.

Methods:

Participants took part in a large population-based cohort study, the Australian Longitudinal Study of Women's Health. Community dwelling women born between 1973 and 1978 were randomly selected from the national health insurance scheme database, which includes most permanent residents of Australia. Women were recruited nationally with intentional oversampling from rural and remote areas. Women completed questionnaires three-yearly between 2000 and 2012. In year 2000, 9,688 women completed the questionnaire and 83% completed follow up questionnaires 12 years later. Self-reported data on back pain, weight, height, age, education status, physical activity, and depression were collected at each of the five surveys.

Results:

In this cohort of women at baseline, median age was 24.6 years and 41% had self-reported back pain in the last 12 months. Women reporting back pain were more likely to seek help (38.2% vs. 3.4%, $p<0.001$) and be unemployed (19.7% vs. 15.7%, $p<0.001$) compared with those without back pain. Inadequate physical activity and depression were independent predictors of back pain over the following 12 years (both $p<0.001$), after adjusting for age, weight, height and education status. For every 5kg higher weight at baseline, there was a 5% (95% CI 1.04 - 1.06) increased risk of back pain over the next 12 years. Higher weight at each survey also predicted subsequent back pain risk three years later, with the adverse effects of weight being present at all levels of physical activity.

Conclusion:

Back pain is common in community-based young adult women. Higher weight, inadequate levels of physical activity and depression were all independent predictors of back pain over the following decade. Furthermore, the adverse effects of weight on back pain were not mitigated by physical activity. Our findings highlight the role of both weight gain and physical inactivity in back pain among young adult women and suggest potential opportunities for future prevention.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Chronic low back pain (cLBP) is a significant public health problem. Establishing treatment guidelines has been difficult due to heterogeneity of research data. Little is known about medication use for cLBP in the community.

Methods: We used data from the back pain survey, administered to a representative sample of US adults aged 20-69 (N = 5103)

during the 2009-2010 cycle of the National Health and Nutrition Examination Survey (NHANES). Participants who reported pain in the area between the lower posterior margin of the ribcage and the horizontal gluteal fold at the time of survey with a history of pain lasting almost every day for at least 3 months were classified as having cLBP (N = 700). Data on prescription medications was collected by a trained interviewer, verified with medication bottles when available, and recorded into an electronic database. We used Lexicon Plus® categories to search for the commonly prescribed medications for chronic pain: acetaminophen, NSAIDs, narcotic analgesics (including tramadol), other neurologics (gabapentin, pregabalin), topical analgesics, skeletal muscle relaxants, antidepressants, anxiolytics. Chi-square tests, analysis of variance and adjusted logistic regression models were used for comparisons.

Results: 68.6% of US adults with cLBP aged 20-69 were taking at least one prescription medication in the past 30 days. 18.8% were using narcotic analgesics, 9.9% acetaminophen (including in combination with narcotics), 9.7% NSAIDs, 8.5% muscle relaxants, 6.9% gabapentin or pregabalin. COX2 inhibitors and topical lidocaine preparations were rarely used, 0.5% each. The prevalence of antidepressant and anxiolytic use was 20.2% and 8.5% respectively. The median number of days on the current prescription was 1009 for antidepressants (IQR 316-1945), 750 for anxiolytics (IQR 162-1845), 702 for narcotics (IQR 314-1770), 682 for muscle relaxants (IQR 258-1688), 534 for gabapentin or pregabalin (IQR 224-1611), and 522 for NSAIDs (IQR 155-1924).

Conclusion: Despite recommendations to limit the use of narcotics in chronic pain and reports of increasing incidence of deaths due to narcotic overdose, narcotic analgesics along with antidepressants were the most prevalent prescription pain medications with extended duration of use in community-based US adults with chronic low back pain.

Disclosure: A. Shmagel, None; **R. Foley**, None.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: According to different guidelines, the presence of neurological symptoms in patients with lower back pain (LBP) is a validated indication for more complex imaging studies, including lumbar spine magnetic resonance imaging (MRI). This could help in confirming clinical diagnosis and eventually establishing a treatment plan. We aimed to study the findings and clinical impact of lumbar spine MRI indicated for patients with LBP complicated by neurologic symptoms in our center.

Methods: We retrospectively analyzed 436 consecutive lumbar spine MRI studies between 2010 and 2013.Our variables of interest were: age, source of the MRI request (general practitioners -GPs- or specialists), “positive” MRI findings (MRI confirming any kind of neurologic compression), correlation between described history and MRI findings, aetiology of neurological compression (osteoarthritis or discal degenerative disease) and finally, the clinical impact on treatment (considered positive for invasive treatment such as steroid injections or surgery versus negative for non-invasive treatment or clinical therapy).

Results: We selected 355 MRIs indicated for LBP with lower limb neurologic symptoms. Patients’ mean age was 52,3 ± 14,1

years, 44.9% female. Most MRI requests, 231(70%), came from GPs. The majority of described neurologic symptoms were sensitive 318 (89,3%). Contrary to our expectations, the rate of normal MRIs was significantly higher in MRIs indicated for motor than sensory symptoms: 15.8% vs 5.7%, respectively (p=0.032). We found normal MRI (with no neurological compressions) in 156 (43.9%) of patients. Among the 199 (56.1%) positive MRIs, there was a dissonance between history and MRI findings in 22 (11,1%) patients. Adding normal MRI studies (156) and MRI with neurologic compressions but without clinical concordance (22) : 178/355 (50,1%) of MRI were negative for clinical relevant neurologic compressions**.** The likelihood of asking for a positive MRI didn't differ between GPs and specialists (p=0,84). Only 87 patients (24,4%) had any invasive procedure, 46 (12,9%) had steroid injections and 41 (11,5%) had surgery. Patients whom MRI was prescribed by a specialist instead of a GP had a significantly higher rate of having an invasive procedure: 37.3% vs 18.6%, respectively (p<0.001).

Conclusion: In this retrospective cohort, half of MRI studies indicated for LBP with supposed neurologic symptoms were negative. In patients with positive MRIs, just one fourth had any kind of invasive procedure. Lumbar spine MRI studies are probably being overused in our center. We hypothesize potential misinterpretation of lower back pain with leg irradiation as true neurologic radicular symptoms. Moreover, even true radicular pain often resolves with non-invasive treatment. MRI studies should be reserved for refractory cases or those presenting major motor symptoms needing a more invasive treatment such as spinal injections or surgery.

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Pregnancy in patients with SLE is associated with increased risk of maternal and fetal complications. Studies in experimental models and humans suggest that complement activation contributes to fetal loss, preeclampsia and growth restriction. In a case control longitudinal study of pregnancy from PROMISSE (**P**redictors of p**R**egnancy **O**utcome: Bio**M**arkers **I**n antiphospholipid antibody **S**yndrome and **S**ystemic **L**upus **E**rythematosus), we investigated whether circulating levels of maternal complement C3 and its degradation product iC3b would vary during pregnancy and would be associated with adverse pregnancy outcomes (APO) in SLE patients.

Methods: The PROMISSE Study enrolled pregnant women with ≥4 ACR SLE criteria and/or aPL antibodies and healthy pregnant controls (HC). Patients were considered aPL positive if aCL and/or antiβ2GP1 were ≥40 IU IgG or IgM and/or LA was positive in ≥2 determinations with at least once during pregnancy. Exclusion criteria were multi-fetal pregnancy, prednisone >20 mg/d, proteinuria >1 gm/24hr, and creatinine >1.2 mg/dL. APOs were defined as fetal death, neonatal death, preterm delivery <36 wks due to preeclampsia or placental insufficiency, and/or growth restriction <5th %ile. Fifty four SLE patients (18 with APO and 36 without) and 40 HCs were included in this study. C3 and iC3b were measured once per trimester in serial samples from maternal plasma using investigational lateral flow assays (Kypha, Inc. St. Louis, MO). Data were log transformed and analyzed (GraphPad Prism 6).

Results: Compared with HC, patients with SLE had lower C3, higher iC3b levels, and elevated iC3b/C3 ratios throughout pregnancy (Fig. 1, ****p<0.0001, p<0.001***, Tukey's post-hoc ++). Although neither C3 nor iC3b early in pregnancy predicted

APO (Fig. 1b), C3 levels were lower in the 3rd trimester in SLE with late APOs (n=13) compared with uncomplicated SLE and HC pregnancies (n=41) (Fig. 1b. ANOVA: F=9.213, P<0.001, Tukey's post-hoc). In the subset of aPL-positive SLE patients (n=13), elevated iC3b/C3 ratios were associated with APOs (n=5) (Fig. 2, ANOVA: F=19.48, ****p<0.0001, p<0.001***, Tukey's post-hoc ++).

Conclusion: During pregnancy, patients with SLE show evidence of complement activation and consumption. Lack of an increase in circulating C3 as pregnancy proceeds is associated with late APOs. If this is confirmed in larger populations accurate and rapid measurements of C3 and iC3b point of care assays may prove valuable in the management of SLE pregnancies.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with increased risk of adverse pregnancy outcomes (APO), including preeclampsia and intrauterine growth restriction. While significant placental pathology is expected in patients with preeclampsia, less is known about how lupus disease activity during pregnancy affects the placenta. Here, we describe a lupus population in which disease control was generally excellent during pregnancy, and in which only 30% of the pregnancies were complicated by preeclampsia. In addition to standard pathologic review, we also specifically quantified neutrophils and neutrophil extracellular traps (NETs) given their recognized association with preeclampsia in the general population, as well as endothelial damage in SLE.

Methods: Preeclampsia, SLE, and healthy placentas were scored for typical histologic features including inflammation, hemorrhage, and infarction. Neutrophils were quantified with the aid of immunohistochemical staining for the granular protein myeloperoxidase. NETs were identified by extracellular myeloperoxidase staining in the setting of decondensed nuclei. Nonparametric analysis was used to evaluate differences in netting and intact neutrophils between groups. Logistic regression was used to identify associations between histology and neutrophils.

Results: Placentas from 11 preeclampsia, 4 SLE+preeclampsia, 10 SLE pregnancies (no preeclampsia), and 10 healthy/control pregnancies were evaluated. Lupus disease activity during pregnancy was low in all but one patient. Surprisingly, as compared to controls, significantly more NETs were found infiltrating *not just*preeclampsia (p=0.0003) and SLE+preeclampsia (p=0.0345) placental intervillous spaces, but also all 10 of the SLE non-preeclampsia cases (p=0.0019). The ratio of NETs to total neutrophils was also increased in all three groups (p=0.0015, p=0.0345, p=0.0019, respectively, as compared to controls). The presence of NETs was further associated with striking histologic abnormalities including severe vasculitis with fibrinoid necrosis (p=0.02286), acute and chronic hemorrhage (p=0.02116), and laminar decidual necrosis (p=0.03458) in all groups. In summary, the placentas of clinically-stable SLE pregnancies were markedly inflamed and essentially indistinguishable from preeclampsia placentas.

Conclusion: Preeclampsia, SLE+preeclampsia, and clinically-stable SLE pregnancies were all associated with significantly higher numbers of intervillous NETs, and greater ratios of netting to total neutrophils as compared to controls. This was true not just for preeclampsia placentas, but also for placentas of lupus patients whose disease activity was low during pregnancy (and who did not have clinical preeclampsia). In summary, these data suggest lupus and preeclampsia pregnancies may share common pathogenesis that is elaborated in lupus despite clinically quiescent disease. Future studies of lupus pregnancies are required to elucidate mechanisms of this abnormal placentation, as it may have implications for both APOs and long-term outcomes of children born to mothers with SLE.

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Women with anti-Ro face a spectrum of fetal consequences when pregnant, from complete wellbeing to death from cardiac neonatal lupus (cardiac NL). Transplacental passage of anti-Ro can result in transient bradycardia, first degree or advanced block, cardiomyopathy and/or death. A cardiac NL severity score was generated to identify demographic and clinical factors associated with morbidity, and serve as a predictor for long term outcomes.

Methods: The severity score (Table 1) was based on reported mortality risk factors, such as lower fetal heart rates (which

require earlier pacemaker) and extranodal disease. The score was calculated for anti-Ro positive pregnancies in the Research Registry for Neonatal Lupus. Pregnancies antedating affected children were excluded as anti-Ro could not be verified. The severity score was evaluated in univariate analysis with cord blood biomarkers related to inflammation/fibrosis: CRP (n=108), NT proBNP (n=118), Matrix Metalloproteinase 2 (MMP2) (n=63), and uPA/uPAR/plasminogen (n=49). Clinical correlates were evaluated in 779 pregnancies from 464 mothers, including race and maternal use of hydroxychloroquine (HCQ) and fluorinated steroids (FS). The score was also evaluated in relation to long term outcomes in affected children based on postnatal echocardiogram (n=150, mean age 11.7±9.3 y).

Results: Severity score positively associated with cord CRP (Regression coefficient (RC) 2.18, p=0.02), NT proBNP (RC 2.79, p=0.002), MMP2 (RC 1.01, p=0.01), uPA (RC 33.7, p<0.001), uPAR (RC 3.72, p<0.001) and plasminogen (RC 1.01, p=0.01). Mean score in fetuses exposed vs unexposed to HCQ was 2.8±6.9 vs 5.6±6.9 (p<0.001). Severity score was higher in black (7.9±8.4) vs other races (4.9±6.6) (p=0.017). Limiting the analysis to cardiac NL pregnancies, the score in HCQ exposed vs unexposed fetuses was 12.5±6.5 (n=17) vs 10.5±6.3 (n=328) (p=0.32). Histologic evaluation of an autopsy from a 19 week HCQ exposed fetus electively terminated with complete block did not reveal HCQ associated vacuolar changes in myocytes. Severity score was not different in cardiac NL cases exposed (10.9±6.2, n=181) and unexposed (10.1±6.2, n=162) to FS (p=0.26). The score was higher in those with abnormal ventricular function on long term evaluation (10.2±4.0 vs 7.7±3.7) (p=0.002).

Conclusion: This novel cardiac NL severity score can be utilized in pregnancy counseling both as an outcome measure associated with disease risk factors, and as a predictor of future morbidity. Cord blood biomarkers of inflammation/fibrosis positively associate with the score. HCQ use during anti-Ro exposed pregnancies associate with decreased severity score, consistent with its proposed role as a preventative measure. However in affected cases, HCQ and FS do not associate with severity. The association of severity score with long term ventricular function promotes its use for counseling and medical monitoring in cardiac NL cases.

Table 1: Severity Scores for Potential Outcomes in anti-SSA/Ro Exposed Fetuses

Unaffected	0
Sinus Bradycardia (transient)	1
1st Degree AV Block	2
Advanced AV Block, No PPM at 6 months	5
Advanced AV Block, PPM placed by 6 months	6
Advanced AV Block, PPM placed by 1 week	8
1 Extranodal Manifestation	14
>1 Extranodal Manifestation	16
Death	20

Advanced AV Block = 2nd or 3rd degree heart block; PPM = permanent pacemaker; Extranodal Manifestation = endocardial fibroelastosis, dilated cardiomyopathy or hydrops fetalis

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Dilated cardiomyopathy (DCM) is a well-known complication of cardiac neonatal lupus syndrome and is associated with a high mortality rate. Its risk factors are unclear.

Methods: We analyzed the occurrence of postnatal DCM (neonatal or of late-onset) among children with a high degree congenital heart block (CHB) included in the French registry of cardiac neonatal lupus (from 1976 to 2014). The presence of postnatal DCM was defined by left ventricular systolic dysfunction with left ventricle ejection fraction <45% requiring treatment or by death related to end-stage heart failure. All mothers were anti-SSA antibodies positive.

Results:

187 children with CHB were born alive. During a median follow-up of 7 years [birth to 36 years], 35 (18.8%, one missing data) had a DCM, and 22 (11.8%) died.

DCM could be categorized in 2 different subgroups: neonatal DCM (n=13, diagnosed before day 28 of life) or late-onset DCM (n=22, diagnosed at a median age of 15.2 months [3.6 months-22.8 years]). On univariate analysis, factors associated with neonatal DCM were maternal treatment with hydroxychloroquine, *in utero* cardiomegaly and DCM, and hydrops. By contrast, factors associated with late-onset DCM were non-European origin and significant *in utero* valvulopathy. In multivariate analysis, the only factor associated with neonatal DCM was *in utero* DCM (p=0.0001; HR 15.99 [95%CI: 3.93-65.01]), whereas the only factor associated with late-onset DCM was non-white race origin (p=0.0147; HR 3.65 [95%CI: 1.28-10.0]).

Twenty-two (11.8%) children died: 8 in the neonatal period and 14 after the first month of life and one child with DCM had a successful heart transplantation at 2.5 years of age. Neonatal deaths were always related to DCM and occurred during the first days of life despite intensive care and the placement of pacemaker in 2 out of 8 cases. The 14 later deaths occurred at a median time of 10 days after the diagnosis of DCM [0-58months]. Eleven (79%) of those deaths were the result of DCM.

The probability of survival at 10 years of age for a neonate with CHB was 87.1%: 23.1% in the presence of neonatal DCM, 53.9% for those who developed a late-onset DCM requiring treatment versus 98.6% in those without DCM. Prenatal fluorinated steroid (p=0.27; HR 1.65 [95%CI: 0.63-4.25]) did not prevent the development of late-onset DCM.

Conclusion:

The presence of in utero DCM carries a high risk of neonatal DCM. No classical risk factors were associated with late-onset DCM. The mortality associated with DCM (either neonatal or of late-onset) was high. Maternal treatment with fluorinated steroid did not prevent the development of late-onset DCM.

Racial Disparities in Lupus Pregnancy

Megan E. B. Clowse[1] and Chad Grotegut[2], [1]Rheumatology & Immunology, Duke University, Durham, NC, [2]Obstetrics & Gynecology, Duke University, Durham, NC

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Both lupus and pregnancy have significant racial disparities, with black women experiencing higher rates of complication compared to other race and ethnic groups. No large studies have focused on the impact of race/ethnicity on pregnancy outcomes among women with lupus.

Methods: Using the Nationwide Inpatient Sample (NIS) for years 2008-2010, pregnancy delivery discharges were identified and pregnancy outcomes were compared for women with lupus by maternal race/ethnicity. Women with lupus were identified using ICD-9 code 710.0. Adjusted odds ratios were calculated for various pregnancy outcomes comparing black or Hispanic women with lupus to white women with lupus.

Results: Between 2008 and 2010, there were 13,553 delivery discharges to women with lupus and 12,510,565 delivery discharges to women without lupus. Pregnant white women with lupus were, on average, 2 years older than pregnant black and Hispanic women with lupus (see Table). The cost for delivery among women with lupus was $2000-5000 higher for Hispanic and black women compared to white women. The rate of chronic hypertension was high in lupus pregnancies, but highest among black women (19.4%, OR 2.89) and Hispanic women (11.0%, OR 1.48) compared to white women (7.7%). Chronic renal failure was uncommon in pregnancy, but noted in 3.7% of black lupus pregnancies (OR 3.47). Thrombophilia, including antiphospholipid syndrome, was only noted in 4.9-6.7% of pregnancies and the rates were not different between white, black, and Hispanic lupus pregnancies.

The rate of pregnancy complication was high among lupus pregnancies. Over 40% of pregnancies to mothers of all races delivered via cesarean. Preterm labor occurred in 14-25% of pregnancies. Preeclampsia occurred in almost 20% of black and Hispanic pregnancies. After adjustment for predictors of pregnancy outcomes and racial differences in non-lupus pregnancy, black and Hispanic women with lupus had higher odds of acute renal failure, pneumonia, need for transfusion, preeclampsia, preterm labor and fetal growth restriction than white women with lupus.

Conclusion: Black and Hispanic women with lupus have disproportionately poor pregnancy outcomes compared to white women with lupus. These disparities are larger than expected in the general population. While this study is not designed to determine causation, we postulate that increased levels of lupus activity and damage among black and Hispanic women may be in part to blame. Additional sources of disparity may include differences in access to quality care and prescribed medications. This study suggests that identifying the key causes for these differences and targeting interventions to the women of greatest need is an essential next-step.

Table: The rates of medical and obstetric complications for white, black, and Hispanic women with lupus. The p-values are derived from multivariate logistic regression model that included variables that impact pregnancy outcome, including age, insurance status, thrombophilia, anemia, thrombocytopenia, drug use, alcohol use, tobacco use, chronic hypertension, chronic renal failure, diabetes, thyroid disorders, asthma, history of MI, multiple gestation, mode of delivery, and placenta previa.

	Systemic Lupus Erythematosus			p-value	p-value
	White n=5755	Black n=2762	Hispanic n=2088	Black vs. White	Hispanic vs. White
Maternal age, yrs	30.3 ± 12.5	28.3 ± 13.4	28.0 ± 13.6	p<0.0001	p<0.0001
Total charges, $	$12,289	$14,649	$17,453	p<0.0001	p<0.0001
Medical Complications in Pregnancy:					
Acute renal failure n (%)	16 (0.28%)	51 (1.8%)	49 (2.3%)	3.60 (1.91, 6.75) <0.0001	11.41 (6.05, 21.51) <0.0001
Pneumonia	15 (0.26%)	36 (1.3%)	28 (1.3%)	3.24 (1.76, 5.94) <0.0001	4.81 (2.60, 9.25) <0.0001

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Autoimmune diseases (AID) have familial aggregation and frequently share a common genetic predisposition. Only few small uncontrolled studies have evaluated the risk of AID in SLE offspring, with inconsistent results. In a large population-based study, we aimed to determine if children born to mothers with SLE have an increased risk of rheumatic and non-rheumatic AID compared to children born to mothers without SLE.

Methods: The "Offspring of SLE mothers Registry (OSLER)" includes all women who had ≥1 hospitalization for delivery after SLE diagnosis, identified through Quebec's universal healthcare databases (1989-2009). OSLER also includes a randomly selected control group of women, matched at least 4: 1 for age and year of delivery, who did not have a diagnosis of SLE prior to or at the time of delivery. We identified children born live to SLE mothers and their matched controls, and ascertained rheumatic (i.e. juvenile idiopathic arthritis, SLE, systemic sclerosis, Sjögren's disease, inflammatory myositis, systemic vasculitis) and non-rheumatic (i.e. type 1 diabetes, inflammatory bowel disease, psoriasis, celiac disease, autoimmune thyroid disease, myasthenia gravis, multiple sclerosis) AID based on ≥1 hospitalization or ≥2 physician visits with a relevant diagnostic code, at least 2 months apart but within 24 months. The study interval spanned from birth to the first of the following: event of interest, age 18, death, or end of study. We performed multivariate analyses to adjust for maternal age, education, and ethnicity, as well as calendar year of birth and sex of the child.

Results: 509 women with SLE had 719 children, while 5824 matched controls had 8493 children. Mean follow-up was 9.1 (SD 5.8) years. Compared to controls, children born to mothers with SLE had similar records of rheumatic diagnoses [0.14% (95% CI 0.01, 0.90) vs 0.19% (95% CI 0.11, 0.32)]. However, there was a trend towards more non-rheumatic AID in offspring of mothers with SLE versus controls [1.11% (95% CI 0.52, 2.27) vs 0.48% (95% CI 0.35, 0.66)]. The most frequently observed non-rheumatic AID were Crohn's disease (0.56% in SLE offspring, versus 0.19% in control children) and type 1 diabetes (0.42% in SLE offspring, versus 0.22% in control children).

In multivariate analyses, children born to mother with SLE had a substantially increased risk of non-rheumatic AID compared to controls (OR 2.62, 95% CI 1.10, 6.24), while results were inconclusive for the risk of rheumatic AID (OR 0.78, 95% CI 0.10, 5.92).

Conclusion: Our novel data suggest that, compared to children from the general population, children born to women with SLE have an increased risk of non-rheumatic AID. Our effect estimate for the risk of rheumatic AID is inconclusive. Further study of these children, throughout late childhood, adolescence, and adulthood, would be additionally enlightening.

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects III - Cardiovascular Disease and RA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk for cardiovascular disease (CVD) compared to the general population, both due to classical and novel risk factors. It remains unclear whether primary prevention strategies for CVD are effective in high grade inflammatory conditions such as RA and there are no previous, CVD outcome statin trials in patients with RA. TRACE RA was designed to assess whether atorvastatin 40mg daily is superior to placebo for the primary prevention of CVD events in patients with RA.

Methods: Prospective, randomised, double-blind, placebo-controlled, UK multicentre trial in RA patients aged >50 years or RA duration >10 years; without known atherosclerotic disease, diabetes, myopathy; not taking statins. All patients were given lifestyle advice. Primary endpoint: a composite of CVD death, non-fatal myocardial infarction, cerebrovascular accident (excl. haemorrhagic stroke), transient ischaemic attack, revascularisation. Secondary endpoints included safety outcomes and lipid changes. The trial was designed to have 80% power at $p<0.05$ to detect a 32% risk reduction with atorvastatin based on 1.8% annual event rate, using intention to treat analysis. Cox regression stratified by centre, Fisher's exact test, Mann-Whitney test or Kendall's tau-b were used for analysis, as appropriate.

Results: Trial duration: August 2007-December 2012. 2986 patients from 102 centres were randomised and followed for a median of 2.53 years (IQR 1.94-3.50), providing 7,908 patient-years of follow-up. Atorvastatin and placebo groups did not differ at baseline for age, sex, weight, BMI, RA duration, activity, severity and seropositivity, blood pressure, lipid and glucose levels, family history of CVD or diabetes. Current smoking was higher in the atorvastatin group (18.4% vs 14.5%, $p=0.019$) and there were also significant differences in NSAID use, ethnicity and EQ5D. Reduction in LDL-c levels was significantly greater in the atorvastatin group compared to placebo (-1.07 vs - 0.14 mmol/l, $p<0.001$); the magnitude of LDL-c reduction reflected reported compliance. In the atorvastatin group 24 patients had a CVD event, compared to 36 in the placebo (hazard ratio 0.66, 95% confidence interval 0.39-1.11, $p=0.119$). After adjustment for baseline differences, compliance and non-study statin use, hazard ratio was 0.54 (0.30-0.99), $p=0.045$. Number and type of any reported adverse events were similar: 294(19.7%) in the atorvastatin and 292(19.5%) in the placebo group, $p=0.927$. Due to a lower (0.76% pa) than anticipated event rate, the trial was terminated early.

Conclusion: Treatment with Atorvastatin 40mg daily resulted in significantly greater reduction of LDL-c compared to placebo. The 34% (unadjusted) risk reduction for a major CVD event compared to placebo, although not statistically significant due to early termination of the trial, is in line with the Cholesterol Treatment Trialists' Collaboration meta-analysis of the effect of statins in other populations. Statin therapy was safe in patients with RA.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects III - Cardiovascular Disease and RA
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Several recent studies have identified RA patients with very low levels of circulating total and low density lipoprotein cholesterol (LDL-C) to be at particularly high risk for cardiovascular disease (CVD) events. However, it is unknown whether coronary atherosclerosis is higher than expected among those with low lipid levels.

Methods: Data were pooled from 4 U.S. cohorts of RA patients and a compatible cohort of non-RA controls who all underwent similar assessments of serum lipids and coronary atherosclerosis [cardiac computed tomography scanning with coronary arterial calcium (CAC) calculated using the Agatston method]. Patients with prior known CVD were excluded. CAC scores according to strata of serum lipids were compared between the RA and control groups using multivariable (MV) linear regression, adjusting for pertinent confounders. The lowest stratum of LDL-C was defined at<76 mg/dL. Analyses were repeated excluding lipid lowering medication (LLM) users.

Results: A total of 629 RA patients and 1,073 non-RA controls were studied. Adjusting for unbalanced demographics, on average, the RA group had significantly lower BMI and waist circumference, higher systolic and diastolic blood pressures, more NSAID use and less use of aspirin. Smoking, diabetes, and HDL-C were similar between the groups. Mean total cholesterol did not differ for RA vs. control (193 vs 194 mg/dL, respectively; p=0.73); however, mean LDL-C was lower in the RA group (114 vs. 118 mg/dL; p=0.031). A higher proportion of RA patients had LDL-C<76 mg/dL (13 vs 8%; p=0.004), even when excluding LLM users (11 vs 7%; p=0.023). Adjusting for demographics, moderate/severe CAC (i.e. CAC≥100 units) was observed in 30% of the RA group compared with only 18% of controls (p<0.001).

In controls, the lowest average adjusted CAC scores were observed in those with a LDL-C<76 mg/dL. In contrast, average CAC scores were nearly 9-fold higher for RA patients in the same LDL stratum (p=0.002; Panel A). Absolute differences between the groups were diminished after excluding LLM users; however, RA patients with the lowest and highest LDL-C levels still had significantly higher CAC compared with controls. Similar relationships were observed for strata of total cholesterol. RA patients with LDL-C<76 mg/dL and not taking LLM were less likely to be RF positive and more likely to be prescribed hydroxychloroquine compared with those with higher LDL-C. They did not differ on disease duration, disease activity measures, or treatment with other DMARDs or prednisone.

Conclusion: These data suggest that RA patients with very low LDL-C may be candidates for heightened CVD screening and prevention

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects III - Cardiovascular Disease and RA
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Accelerated atherosclerosis in rheumatoid arthritis (RA) is well established but the role of insulin resistance in RA pts without diabetes or metabolic syndrome remains to be determined. Therefore, the aim of our study was to investigate the prevalence of insulin resistance in RA pts with normal glycoregulation and its association with carotid intima-media thickness (IMT) and therapy exposure.

Methods: Our study population included 90 RA pts (age 52.4±9.9 yrs, 86.7% females, disease duration 9 yrs, range 4-13). We determined body mass index (BMI), waist circumference (WC), blood pressure, smoking habits, and disease activity score (mDAS28-SE). IMT was measured bilaterally, at common carotid (CCA), bifurcation (BF), and internal carotid arteries (CI). All pts were treated with disease modifying antirheumatic drugs, 65.6% were on steroids (<10 mg/day), and 27.8% were on biological therapy. IR was calculated using the updated-computer Homeostasis Model Assessment (HOMA2-IR), based on fasting plasma glucose and serum specific insulin concentrations (measured by ELISA). Insulin resistance was defined as HOMA2-IR>1.

Results: Insulin resistance was detected in 74.4% of pts with median value of 1.4 (range 1.0-2.3). Pts with insulin resistance compared to those without this condition had increased IMT (mm) at all levels of carotid arteries. CCA_{max}: 0.841±0.144 vs. 0.762±0.105 (p=0.018); CCA_{mean} 0.740±0.129 vs. 0.653±0.097, p=0.004; BF_{max}: 1.059±0.169 vs. 0.920±0.124, p=0.001; BF_{mean}: 0.908±0.141 vs. 0.782±0.126, p=0.000; CI_{max}: 0.678±0.085 vs. 0.620±0.121, p=0.014; CI_{mean}: 0.599±0.077 vs. 0.553±0.091, p=0.020. Both groups were comparable regarding RA duration and anti-inflammatory treatment including glycocorticoids. In multivariate logistic regression adjusted for age, BMI, WC, and triglycerides we found that statistical significance disappeared for CCA and CI but stil persisted for BF (e.g. for age BF_{max} β coef. 4.479, p=0.030; BF_{mean}: β coef. 6.516, p=0.017). In univariant regression analysis, we revealed predictive value of logHOMA2-IR for IMT BF_{max}: β coef. 0.253, p=0.001; BF_{mean}: β coef. 0.178, p= 0.006; CI_{max}: β coef 0.097 p=0.026; while for other levels statistical significance was borderline (for CI_{mean} and CCA_{mean}p=0.052, and for CCAmax p=0.064). On the other hand we found significant association of logHOMA2-IR with disease activity: DAS28 β coef 0.034, p=0.037.

Conclusion: RA pts with insulin resistance had significantly increased carotid IMT at all evaluated levels. Significant difference persisted for carotid BF even after adjustment for well known risk factors for atherosclerosis. Significant association of insulin resistance and disease activity may indicate the important role of RA itself in the interplay of IR and atherosclerosis.

Treatment-na•ve, early rheumatoid arthritis patients demonstrate abnormalities of vascular and myocardial function on cardiac MRI

B Erhayiem, A McDiarmid, PP Swoboda, A Kidambi, DP Ripley, TA Musa, LE Dobson, P Garg, S Horton, R Dumitru, J Andrews, JP Greenwood, P Emery, S Plein, MH Buch

Background/Purpose:Cardiac studies of patients with rheumatoid arthritis (RA) have demonstrated abnormalities in left ventricular (LV) remodelling that is associated with development of heart failure and cardiovascular morbidity/mortality. No studies have evaluated changes in LV myocardial and vascular function in treatment-na•ve early RA (ERA). We evaluated whether patients with treatment-na•ve ERA demonstrate myocardial and vascular changes on cardiac MRI (CMR) compared with matched controls.

Methods: Eighty ERA patients (ACR/EULAR classification criteria) without CVD history underwent 3.0T CMR at a dedicated cardiology-CMR unit. Patient eligibility: symptoms for less than 1 year, DMARD treatment-na•ve, minimum disease activity score (DAS28) ³ 3.2. Thirty healthy controls were matched by age, sex and blood pressure. CMR protocol determined aortic distensibility (AD), LV dimensions, ventricular performance, strain analysis and extracellular volume (ECV; associated with diffuse myocardial fibrosis).

Results: Patients in ERA and control groups were of similar mean(SD) age [49.4(13.08) and 50(15) respectively, p=0.67] and systolic BP [123(16) and 120(13) respectively, p=0.43]. Median(IQR) ESR, CRP and mean(SD) DAS28 were 31(31)mm/hr, 8(23)mg/L and 5.6(1.5) respectively. 66(85%) and 59(76%) patients were ACPA and RF positive respectively. 17(21%) and 4913%) were current smokers in the ERA and control groups respectively.

Table 1 details CMR parameters. Aortic distensibility was significantly reduced in ERA patients compared to controls (median ±IQR, 3.3±2.15 $10^{-3}mmHg^{-1}$ versus 4.7±2.0 $10^{-3}mmHg^{-1}$, $p<0.001$). Other measures of arterial stiffness showed similar significant differences. Significant change in LV geometry was observed with lower LVmass index in the ERA group compared with controls. Significantly greater ECV and lower T1 were also recorded in the ERA group. Evidence for overt inflammation/fibrosis was seen in 6 patients with areas of focal non-ischaemic patterns of LGE.

Conclusion: This is a first CMR study on treatment-naive ERA patients that demonstrates abnormalities in vascular function, myocardial tissue composition and LV geometry; associated with poorer outcomes. These observations highlight presence of CV risk at the earliest stages of RA. Further investigation will determine the natural history including whether effective therapy can modulate these abnormalities.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects III - Cardiovascular Disease and RA
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Subjects with rheumatoid arthritis (RA) are at a higher risk of developing cardiovascular (CV) disease which is the leading cause of death in subjects with RA. In the general population, there is unequivocal evidence supporting ASA as secondary prophylaxis for CV events, but its efficacy as primary prevention has been questioned. There is currently no consensus regarding use of ASA as primary prophylaxis and it is necessary to identify if its use is justified in particular risk profile groups. We performed a case-crossover study in RA subjects, to evaluate if a protective association exists between ASA use and myocardial infarction (MI).

Methods:

THIN, a population-based UK database, containing data provided from general practitioners was used. We included records

between 1/1/1995 and 9/30/2013. In the UK persons over age 60 get free ASA by prescription and 75% of use is by prescription. Subjects >60 years with RA, defined as one RA read code and one DMARD code within a year, constituted our study population. We excluded all subjects with history of MI, angina prior to study initiation or a coronary artery procedure (stent/coronary artery bypass graft) prior to the index date. To be included subjects had to have an incident MI/angina or a fatal MI. Each subject contributed two observations: a “case observation” and a “control observation”. For "case observations”, the index date was the MI/angina date. For "control observations”, the control date was 90 days prior to the index date. An individual was considered exposed if he/she used ASA within 7 days prior to the index date/control date. In addition, we examined effect of ASA use within 15 and zero days prior to the event. A conditional logistic regression was performed adjusting for drugs that are potential confounders (antiaggregants-anticoagulants, antihypertensives, NSAIDS, lipid-lowering drugs, glucocorticoids, nitrates). A sensitivity analysis was performed looking at males. As a secondary outcome we looked at MI and fatal MI.

Results:

We identified 705 RA patients who experienced incident MI/angina during the study period. The characteristics of the study subjects are described in Table 1. During the case period 192 subjects were exposed to ASA and during the control period 156 subjects were exposed, with 96 discordant exposure statuses within a subject in the two observation periods. There was no significant association between ASA use and CV events after adjusting for potential confounders (1.20 (0.73, 1.96)). When analysis was restricted to men, we again found no association was present (adjusted OR 1.12 (0.49, 2.52)). Findings were similar when considering MI as our outcome and when restricting exposure to 15 and zero days prior to the index date.

Conclusion:

This study suggests ASA is not effective in RA as primary prophylaxis.

Session Title: Rheumatoid Arthritis - Clinical Aspects III - Cardiovascular Disease and RA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid arthritis (RA) patients have an increased cardiovascular (CV) risk. Current algorithms generally underestimate the risk in these patients [1]. In a meta-analysis, we have recently shown that younger RA patients bare the highest excess risk as compared to age-matched counterparts from the general population [2]. *Objective:* To investigate whether gender and age are contributing to the misclassification of CV risk in RA patients, when current risk algorithms developed for the general population are used.

Methods: Prospectively collected data on cardiovascular risk factors and incident events from the Nijmegen inception cohort were analyzed, with up to 10 years follow-up [1]. Original as well as the EULAR modified (M_) SCORE algorithms were used to calculate the CV risk. Patients were stratified in deciles according to increasing risk and Hosmer-Lemeshow test was used to check concordance between observed and predicted risk, in subgroups based on gender and age.

Results: 863 prospectively followed RA patients were included in the analysis, 566 females and 297 males. During the first 10 years of follow-up 128 incident cardiovascular events had been recorded. In the whole group there was evidence of discrepancy between the predicted and observed CV risk (H-L test $p<0.003$) when the SCORE algorithm was applied. This mismatch was also present in the female subgroup (H-L test $p<0.001$), but it was less pronounced in males (H-L test $p=0.09$). Among the group of women who developed an event 40% had a predicted risk lower than 10% (corresponding to the low-risk group), whereas this was just 14 % in the RA males. When analyzing sub groups based on age, the H-L test p-values were: <55 years $p<0.001$, between 55 – 65 years $p=0.93$ and >65 years $p=0.96$. The discrepancy between observed and predicted CV events in the youngest RA patients consisted mainly of underestimation of the CV risk (5.3% predicted vs. 8.0% observed). Similar results were obtained when the M_SCORE was applied.

Conclusion: We report here in prospectively followed RA patients that CV risk is especially underestimated in women and younger patients. This suggests that modifying the weight for female gender and/or younger age in currently used CV risk algorithms might improve their predictive value in RA, contributing to better CV risk management in this group of patients.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Synovial fluid pH is decreased in patients with rheumatoid arthritis (RA); however, the underlying mechanisms are unclear. Here, we examined the mechanism by which synovial fluid pH is regulated and explore the therapeutic strategy by manipulating this mechanism.

Methods: The pH and lactate concentration in synovial fluid from RA and osteoarthritis (OA) patients were determined. Cultured synovial fibroblasts (SFs) from the inflamed joints of patients with RA (RASFs) were examined for the expression of ion transporters that regulate intracellular and extracellular pH. The ion transporter up-regulated in RASF lines was then suppressed in RASFs by small interfering RNA (siRNA) and the effect of transfection on viability and proliferation was investigated. Finally, we examined the therapeutic effect of electro-transfer of *MCT4*-specific siRNA into the articular synovium of collagen-induced arthritis (CIA) mice.

Results: The synovial fluid from RA patients had significantly lower pH ($p < 0.01$) and higher lactate values ($p < 0.05$), respectively, than the synovial fluid from OA patients (Figure 1A). Synovial fluid pH correlated inversely with both the patient disease activity score (DAS)-28 CRP ($r = -0.51$, $p < 0.05$, Figure 1B) and synovial fluid lactate levels ($r = -0.71$, $p < 0.01$, Figure 1C). RASFs exhibited up-regulated transcription of monocarboxylate transporter (*MCT*) 4 mRNA. MCT4 exports intracellular lactate into the extracellular space. RASFs had significantly higher MCT4 protein levels than osteoarthritis synovial fibroblasts. Knockdown of *MCT4* induced RASF apoptosis (Figure 2), thereby inhibiting their proliferation. Moreover, electro-transfer of *MCT4*-specific siRNA into the articular synovium of CIA mice significantly reduced the severity of arthritis ($p < 0.05$, Figure 3).

Conclusion: RA activity correlated with decreased synovial fluid pH. This may be due to increased MCT4 expression in RASFs.

Silencing MCT4 induced apoptosis in RASFs and reduced the severity of CIA, suggesting that MCT4 is a potential therapeutic target for inflammatory arthritis.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid arthritis (RA) fibroblast-like synoviocytes (FLS) promote disease pathogenesis by aggressively invading the joint extracellular matrix. The focal adhesion kinase (FAK) signaling pathway is emerging as a contributor to the anomalous behavior of FLS in this disease. Because the receptor protein tyrosine phosphatase α (RPTPα), encoded by the *PTPRA* gene, is a key promoter of FAK signaling, we investigated whether RPTPα mediates FLS aggressiveness and joint damage.

Methods: Through RPTPα knockdown with cell-permeable morpholino antisense oligonucleotides, we assessed RA FLS gene expression in response to tumor necrosis factor (TNF) and interleukin 1β (IL-1β) by quantitative PCR, invasion in transwell assays in response to platelet-derived growth factor (PDGF), and activation of signaling pathways by Western blotting of FLS lysates. Arthritis development was examined in mice lacking *Ptpra* using the K/BxN passive serum transfer model. The contribution of radiosensitive and radioresistant cells to disease was evaluated by reciprocal bone-marrow transplantation. Pharmacological inhibition of RPTPα activity was achieved using a novel cell-permeable peptide.

Results: We found that RPTPα was enriched in the RA synovial lining and expressed in RA FLS. Upon RPTPα knockdown, PDGF-induced invasion of RA FLS was decreased by 49±8% ($p<0.0001$, Mann-Whitney test). RPTPα knockdown in RA FLS also decreased TNF-induced expression of C-X-C motif chemokine 10 (*CXCL10*) and matrix metalloproteinase 13 (*MMP13*) by >80% ($p<0.001$, Mann-Whitney test), and decreased IL-1β-induced production of *IL6*, *MMP3* and *MMP13* by ≥50% ($p<0.0001$, Mann-Whitney test). These phenotypes correlated with >3-fold increase in phosphorylation of SRC on inhibitory Y527 and decreased phosphorylation of FAK on stimulatory Y397. Treatment of RA FLS with inhibitors of SRC and FAK mimicked the effect of RPTPα knockdown. *Ptpra*-deficient mice were protected from arthritis development (58±3% decrease in area under the curve [AUC] of ankle swelling, $p<0.0001$, paired t-test), which we confirmed to be due to radioresistant cells. Importantly, pharmacological inhibition of RPTPα activity decreased TNF-induced expression of *CXCL10* in RA FLS by 65±16% and reduced arthritis in mice (32±1% decrease in AUC of ankle swelling, $p<0.05$, paired t-test).

Conclusion: These data suggest that RPTPα mediates pro-inflammatory and pro-invasive signaling in RA FLS by regulating phosphorylation of SRC and FAK. We also find that knockdown or pharmacological inhibition of RPTPα significantly ameliorates arthritis in an FLS-dependent model of RA, suggesting that inhibition of RPTPα could be a novel therapeutic strategy to target the aggressiveness of FLS in RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To examine the relationship between synovial hypoxia, cellular bioenergetics and mitochondrial dysfunction with synovial inflammation.

Methods: Primary RASFC were cultured with 3% hypoxia, DMOG (stabilizes HIF1α) or lactic acid. Reactive oxygen species (ROS), mitochondrial membrane potential (MMP) and mitochondrial mass (MM) were quantified using fluorescent probes, RASFC invasion by Transwell Matrigel™ chambers, and VEGF, bFGF by ELISA. Alterations in the synovial mitochondrial genome were assessed by Random Mutation Capture assay. RASFC metabolism was assessed by the XF24 Flux analyser (Seahorse) which quantifies real-time aerobic and anaerobic bioenergetic profiles. To examine if altered metabolism is also observed *in vivo*, 44 patients with active inflammatory arthritis underwent arthroscopy, clinical assessment and synovial tissue oxygen (tpO_2) measurements. Synovial microscopic levels of glycolysis and oxidative phosphorylation (GAPDH, PKM2, GLUT1, ATP), inflammation (CD3, CD68) and angiogenesis (FactorVIII/αSMA) were quantified by immunohistology. A subgroup of patients underwent contiguous MRI and PET/CT imaging. Finally we examined the effect by blocking glycolysis using a small molecule, 3-(3-pyridinyl)-1-(4-pyridinyl)-2-propen-1-one (3PO) (which blocks PFKFB3) in RASFC, human microvascular endothelial cells (HMVEC) and RA synovial explant cultures. Migration, angiogenesis, HIF1α activation and pro-inflammatory mediators were assessed using specific functional assays, western blot and ELISA.

Results: In RASFC, hypoxia induced increased mitochondrial DNA mutations, MM, MMP, ROS and invasion but inhibited ATP indicating altered cellular energy metabolism (all $p<0.01$). Hypoxia increased the rate of glycolysis with concomitant attenuation of mitochondrial respiration ($p<0.01$), decreased basal and maximal respiration ($p<0.01$) with a simultaneous induction in glycolytic cell activity ($p<0.001$). Hypoxia inhibited RASFC glucose secretion ($p<0.05$) and increased lactate levels ($p<0.05$). Lactic acid in turn, induced RASFC invasion and secretion of bFGF and VEGF. Elevated RASFC glycolysis was concurrent with *in vivo* assessments, with synovial expression of GAPDH, PKM2 and GLUT1 significantly higher in patients with tpO2 levels *in vivo*<20mmHg (all $p<0.05$), in contrast to ATP which was significantly lower ($p<0.05$). Glycolytic marker expression also correlated with increased macroscopic/microscopic vascularity and synovitis (all $p<0.05$). PET/MRI hybrid images demonstrated close association between metabolic turnover and site of inflammation with tpO2 levels *in vivo*. Finally 3PO significantly inhibited RASFC migration, HIF1α activation, angiogenesis and secretion of IL-6, IL-8, MCP-1 and ICAM-1 (all $p<0.05$).

Conclusion: Hypoxia alters cellular bioenergetics by down-regulating mitochondrial respiration and promoting a switch to glycolysis in the inflamed joint. This may enable synovial cells to generate sufficient ATP to support enhanced synovial proliferation, angiogenesis and pannus formation. Blockade of glycolysis may represent a potential therapeutic strategy for RA and other autoimmune diseases.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Recently, it was shown that extracellular vesicles (EV) convey microRNAs (miR) from platelets to endothelial cells[1]and regulate recipient cell gene expression. Interaction of synovial monocyte (MC)/macrophages with synovial fibroblasts (SF) is a key step to the inflammatory process in rheumatoid arthritis (RA). We hypothesised that MC/macrophage regulate SF behavior by delivering specific microRNA via EVs.

Methods: Characterization of EVs from human $CD14^+$MCs and THP-1 cells was performed using scanning electron microscopy (SEM, n=3), nanosight trafficking analysis (NTA, n=3-7); and flow cytometry (n>4) with predefined sized beads for gating. smallRNA sequencing was performed on macrophages (n=4) and RASFs (n=4) as well as on macrophage-derived EVs (n=4). Macrophages were differentiated by culturing peripheral blood (PB) $CD14^+$MCs from RA patients with M-CSF and either stimulated with LPS or not. In addition, matched RA PB and synovial fluid $CD14^+$ (n=8), PB $CD14^+$ from RA DMARD responders (n=16), DMARD non-responders (n=22), Biologic resistant (n=41), and age-matched healthy controls (n=21) were isolated and used for validation. (Pre-)miR-223 expression and copy number was quantified in cells or tissues via TLDA, qPCR & in situ hybridisation with specific primers and probes. Targeted pathways were identified using prediction algorithms (TargetScanHuman6.2). Transfer of miR-223 from MCs to SFs was determined by fluorescence microscopy, direct cell co-culture and FACS, as well as transwell co-culture. RASF Proliferation assays and IL-6 ELISAs served as read-out.

Results: SEM & NTA revealed a mean size of EVs from MCs & THP-1 cells of about 250nm (range 50-800nm). EV production was induced in myeloid cells by LPS ($p<0.05$). SmallRNA sequencing revealed high levels of miR-223 in macrophages as opposed to a lack of its expression in RASF. miR-223 levels were significantly higher in PB $CD14^+$ cells of DMARD responders compared to DMARD non-responders and Biologic resistant RA patients ($p<0.05$ and $p<0.01$). miR-223 levels in $CD14^+$ cells showed significant positive correlations to CDAI and SDAI. miR-223 was downregulated in synovial fluid MCs compared to matched PB controls ($p< 0.01$) and its expression was down-regulated in MCs/macrophages upon LPS stimulation. In contrast, EVs derived from LPS stimulated THP-1 cells contained higher levels of miR-223 suggesting stimulation driven packing of miR-223 into EVs. If co-cultured with MCs for 3d, RASF acquire miR-223 expression, but not pre-miR-223 to a significant extent (n=6, $C_t$values <30) confirming transfer of mature miR-223 between cells. Prediction algorithms identified FBXW7, a ubiquitin ligase targeting cyclin E, as a candidate target for miR-223 in RASF. Co-culture of RASF with THP-1-derived EV increased RASF proliferation (n=3, $p<0.05$). miR-223 transfection (25nM & 50nM) itself led to an increase of RASF proliferation after 72 and 96h (n=6-8, $p<0.01$ for all).

Conclusion: miR-223 transfer from MCs/macrophages to SFs by EVs during initial or chronic phases of synovial inflammation could promote SF proliferation and represent a novel intercellular mechanism underlying the pathogenesis of rheumatoid arthritis.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Synovial fibroblasts play crucial roles in the pathogenesis of rheumatoid arthritis (RA). They expand as part of the pannus, mediate degradation of cartilage, amplify inflammation, and contribute to osteoclastogenesis. Considering these diverse roles of synovial fibroblasts, we hypothesized that synovial fibroblasts may consist of several subsets with distinct functions, contrary to the common view of fibroblasts as a homogeneous population. Here we sought to identify fibroblast subsets and to characterize subpopulations important in the pathology of RA.

Methods: Synovial cells were isolated by enzymatic digestion from surgical specimens from osteoarthritis (OA) and RA patients. Flow cytometry was used to separate freshly isolated fibroblasts into subpopulations based on the expression of several mesenchymal cell markers. In our initial analysis, nine fibroblast subpopulations were collected by cell sorting and subjected to further analysis by Affymetrix GeneChip Human Gene 2.0 ST microarray. To validate results, we applied low-input RNA-sequencing and single cell RNA-sequencing to independent samples. The functions of these fibroblast subsets were examined by several in vitro assays including the response to TNF stimulation and co-culture with macrophages.

Results: Freshly isolated synovial fibroblasts were divided into several subpopulations based on the expression patterns of fibroblast markers including podoplanin, cadherin11, CD90, CD34, and CD146. The analysis of gene expression microarray data revealed 2,986 genes with significant (1% FDR) variation across fibroblast subpopulations. An independent sample of RA donors, from different joints than the original samples, and assayed via RNA-seq, showed consistent variation of these genes across fibroblast subpopulations. Pathways enriched with this variation included extracellular matrix disassembly (P=7.51e-11) and the TNF signaling pathway (P=1.96e-6). We defined distinct functional cell populations by population-specific expression of genes with well-studied functions. For example, CD34+, CD90+, cadherin11+ cells highly expressed IL-6, CCL2 and CXCL12. CD34-, CD90+, cadherin11+ cells highly expressed TNFSF11. CD34-, CD90- cells highly expressed IL-8, CXCL1, MMP-1 and MMP-3. Differential expression of several genes that mediate distinct fibroblast functions was confirmed at the protein level after culturing cells in the presence or absence of TNF. Functionally, CD34+, CD90+, cadherin11+ cells skewed macrophages into anti-inflammatory phenotype. CD34-, CD90+, cadherin11+ cells promoted osteoclastogenesis. In RA synovial tissue, the proportion of CD34-, CD90+, cadherin11+ cells was increased compared to that in OA.

Conclusion: 1) Synovial fibroblasts are composed of several subsets that are distinct in surface phenotype, transcriptional programs, and functional effects on other cell types. 2) The heterogeneity of fibroblasts and the selective expansion of particular subsets are relevant to understanding RA pathology.

Critical Role of Fibroblast-like Synoviocytes Glycolytic Metabolism in Rheumatoid Arthritis

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Glucose metabolism is altered not only in tumor cell growth but also in immune cells on activation. However, little is known about glucose metabolism in fibroblast-like synoviocytes (FLS). We recently showed that a glycolysis inhibitor suppressed the aggressive behavior of cultured RA FLS, including proliferation, cytokine secretion and cell migration. Here, we further evaluated changes in glucose metabolism in both RA synovium and RA FLS and its role in inflammation and joint damage.

Methods: The glucose metabolism profile of synovium was determined by ^{1}H-MRS. Analysis of FLS oxygen consumption/extracellular acidification was determined by Seahorse technology. Effect of inflammatory mediators on the glycolytic rate in FLS was determined by Seahorse after LPS and PDGF stimulation. Glucose metabolism related gene expression was determined by qPCR. The increase of glycolysis in a murine model was determined using IRDye®800CW 2-DG, a fluorescent optical imaging agent that assesses glucose uptake, and by FACS. For arthritis experiments, the glycolysis inhibitor bromopyruvate (BrPa; 5mg/kg) was injected daily i.p. at the peak of arthritis in two murine models, passive K/BxN model (from day 5) and collagen induced arthritis (from day 35).

Results: Compared to osteoarthritis (OA), RA FLS had a higher baseline glycolytic rate, a decreased mitochondrial respiration and increased extracellular acidification after LPS stimulation. Intracellular lactate was also higher in RA synovium and several metabolites related to glucose metabolism correlated with lactate levels, suggesting higher glucose metabolism in RA synovium samples. Glucose transporter 1 (GLUT1) expression correlated with FLS baseline functions and her expression increased after LPS and PDGF stimulation. In a mouse model of inflammatory arthritis, we observed an increase of glucose uptake in arthritic joints and an increase of glucose uptake and glycolytic gene expression in the CD45-PDPN+ stromal cell compartment. Glycolytic inhibition by BrPa administered in vivo significantly decreased arthritis severity in both animal models.

Conclusion: Targeting metabolic dysfunction offers a novel approach of understanding the mechanisms of disease and potential new treatments. Glycolytic inhibition may directly modulate synoviocyte-mediated inflammatory functions and could be an

effective treatment strategy for arthritis.

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy IV: Safety of Targeted Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Duvelisib is a potent, oral, dual inhibitor of phosphoinositide-3-kinase (PI3K)-δ,γ being developed for hematologic malignancies, and was also explored in early phase studies in inflammatory diseases. PI3K-δ,γ isoforms are necessary for adaptive and innate immunity and have significant, non-overlapping roles in immune cell signaling. **Results** from several preclinical arthritis models and the inhibition of basophil activation in a healthy subject study supported duvelisib dosing between 0.5 and 5 mg twice daily (BID) in this study. The objective of this phase 2 study was to determine the safety and efficacy of duvelisib at 0.5, 1, and 5 mg BID in adults with moderate-to-severe RA while receiving background MTX.

Methods: Adults with active RA (≥ 5 swollen and tender joints, and CRP > 7 mg/L [1.4 x ULN]) on stable background MTX were randomized to 12 weeks of double-blinded treatment with placebo or duvelisib (0.5, 1, or 5 mg BID). The primary endpoint was the proportion of subjects who achieve an ACR20 at Week 12. Immunophenotyping analysis of B- and T-cell subtypes and pharmacokinetics (PK) and safety were also assessed.

Results: Of 322 subjects enrolled, 274 completed 12 weeks of treatment. Most subjects were female (83.2%) and white (93.5%). Median age was 54.5 (21-71) years. Median time since diagnosis of RA was 78.2 (4.1-522) months; 73% of subjects had Class II RA. Mean duration of MTX prior to study entry was 54.7 (±52.1) months. The primary endpoint (ACR20 at Week 12) was not met for any of the doses of duvelisib tested in this study (Table). Although statistically significant improvements in some secondary endpoints were noted, there were no large, consistent or dose-related improvements over placebo. For example, the DAS28-CRP mean changes from baseline were greater with 0.5 and 5 mg BID than placebo after 12 weeks, but with small absolute differences (Table). Duvelisib appeared to be generally well tolerated: overall, the majority of adverse events (AEs) were Grade 1 or 2 and reversible. The most frequent AEs more common in duvelisib than placebo during treatment were anemia, elevated ALT/AST, lymphopenia, nausea, nasopharyngitis, and headache. Treatment discontinuations of 6 patients on duvelisib 5 mg BID and 1 placebo patient were required per protocol; these patients, with normal baseline ALT/AST, had reversible elevations > 3 x ULN, with no significant elevation in bilirubin. A statistically significant, but small increase from baseline in mean absolute counts of peripheral blood B-cells and T-cells (CD4+ and CD8+) at week 2 was observed at 5 mg BID.

Table: ACR20 and DAS28-CRP at Week 12

	Treatment Group (patients)			
	Placebo	**0.5 mg BID**	**1 mg BID**	**5 mg BID**
	(n=80)	**(n=81)**	**(n=80)**	**(n=81)**
ACR20, n (%)	37 (46.3%)	42 (51.9%)	36 (45.0%)	35 (43.2%)
DAS28-CRP, LS mean change from baseline (SE)	-1.28 (0.148)	-1.66 (0.147)	-1.36 (0.144)	-1.68 (0.161)

Conclusion: The findings from this study indicated that in subjects with RA on background MTX duvelisib administered at 0.5, 1, and 5 mg BID had no added benefit over placebo. No new safety signals associated with duvelisib therapy were identified.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy IV: Safety of Targeted Therapies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

XmAb®5871 is a humanized Fc engineered monoclonal antibody that binds to the B cell restricted surface antigen CD19 and has enhanced Fc binding to the inhibitory Fcγ receptor IIb (FcγRIIb). Co-ligation of CD19 and FcγRIIb by XmAb5871 has been demonstrated to reversibly down-regulate B cell activity. XmAb5871 is in development for the treatment of B cell mediated autoimmune disorders. The primary objective of this study was to determine the safety, tolerability, PK, PD and immunogenicity profile of XmAb5871 in patients with active RA on stable non-biologic DMARD therapy. A secondary objective (Part B) was to evaluate the effect of XmAb5871 on RA disease response at Day 85 as measured by changes in DAS28-CRP.

Methods:

This multi-center, randomized, placebo-controlled, double-blinded, clinical study was conducted in patients with active RA despite DMARD therapy. All patients fulfilled ACR criteria for RA. Patients received 6 IV infusions of XmAb5871 or placebo (Pbo) on an every 14 day schedule. In Part A, 30 RA patients were randomized to Pbo or XmAb5871 in 4 consecutive dose cohorts of 0.3, 1, 3, or 10 mg/kg. After completion of Part A, 27 patients with active disease were enrolled in an extension cohort, Part B, to receive either 10 mg/kg XmAb5871 or Pbo in a 2:1 ratio. Disease efficacy assessments occurred 2 weeks after the 6thinfusion on Day 85.

Results: A total of 57 patients were randomized; 40 patients received at least 1 dose of XmAb5871. Peripheral B cell count decreased ~40% from baseline after the 1st dose in all XmAb5871 cohorts and did not decrease further with subsequent doses. XmAb5871 was generally well tolerated, with 2 SAEs in the XmAb5871 group (infusion-related reaction, venous thrombosis). The most common treatment-related adverse events in the XmAb5871 group were nausea, vomiting or diarrhea that occurred only during the 1st infusion in 25% of patients. Two subjects experienced infusion reactions with hypotension (both at 10 mg/kg) and were discontinued. The nature and severity of these infusion reactions were consistent with those reported for other monoclonal antibody therapies. In Part B, 15 XmAb5871-treated and 8 Pbo-treated patients were evaluable for disease activity assessment at Day 85. More subjects treated with XmAb5871 (10 mg/kg) achieved DAS28-CRP low disease or remission at Day 85 than did the Pbo treated subjects. Similar trends were seen with other disease assessments. Median ACR Hybrid scores over time were consistently greater in XmAb5871-treated patients than in Pbo-treated patients.

Conclusion:

XmAb5871 administered over 12 weeks was found to be generally well tolerated. Although the trial was not powered to show a significant difference in efficacy results between XmAb5871 and Pbo, sufficient efficacy trends were seen to warrant continued clinical development of XmAb5871 in autoimmune diseases.

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy IV: Safety of Targeted Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

The association between TNF inhibitors (TNFis) and vasculitis-like events, possibly secondary to induction of autoantibodies, has been well reported. However, the incidence, drug-specific differences and factors associated have been poorly characterised. The aims of this study were to (i) compare the drug specific risk of vasculitis-like events in TNFi treated RA patients to those receiving non-biologic (nb)DMARDs and (ii) assess factors associated with the event.

Methods:

The British Society for Rheumatology Biologics Register for RA (BSRBR-RA) is a prospective cohort study assessing the safety of biologics. This analysis included two cohorts recruited between 2001-2014: (i) patients starting first TNFi (adalimumab, etanercept, infliximab, certolizumab) (ii) biologic-naïve comparison cohort receiving nbDMARDs. To calculate drug-specific risk biologic-naïve patients at baseline on first TNFi only were included. Additional information from consultants was sought for events. Patients with baseline systemic vasculitis were excluded. The risk of an event was compared between the two cohorts using Cox proportional-hazard models, adjusted using deciles of propensity scores (PD). Events were attributed to TNFi therapy if they occurred within 90 days of being on drug. Follow-up was censored at first event, switching to another biologic, death, last returned clinical follow-up or 30/11/2014, whichever came first. A sensitivity analysis was performed excluding patients who had a possible secondary vasculitis cause (e.g. infection), on other medications associated with vasculitis-like events or known baseline nailfold vasculitis.

Results:

There were 94 incident cases: 14 in 3640 nbDMARD patients and 80 in 12,385 first TNFi-treated subjects, with 19,681 and 49,678 patient years of follow up generating crude incidence rates of 7/10,000 and 16/10,000 person years respectively (Table). After adjusting for PD, the hazard ratio of vasculitis-like events in patients on TNFi vs. nbDMARD was 1.03 (95% CI 0.51-2.09). Drug specific hazard ratios were highest in the etanercept and infliximab patients, however following adjustment was not significant (Table). Factors associated with lower rates included baseline MTX use (HR 0.8, 95% CI 0.74-0.88), SSZ (HR 0.58, 95% CI 0.51-0.66) or LEF (HR 0.66, 95% CI 0.54-0.77). Other variables associated with the outcome included male gender (HR 1.49, 95% CI 1.01-2.21), baseline DAS28 score (HR 1.42, 95% CI 1.20-1.68), disease duration (HR 1.02, 95% CI 1.01-1.04 per year), RF+ status (HR 1.79 (95% CI 1.16-2.75) and baseline HAQ (HR 1.63, 95% CI 1.18-2.26).

Table. Patient characteristics and risk of first vasculitis-like event on first drug

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy IV: Safety of Targeted Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Immune incompetence may lower host surveillance against incipient tumours. Conversely, immune therapies have emerged as a promising therapeutic approach to cancer. Malignancies thus constitute an important aspect of the safety of biologics as used in Rheumatology, including agents targeting TNF, CD20, CTLA-4, and IL6. Previous reports concerning TNF inhibitors (TNFi) and risk of malignancies have mostly been reassuring. The risk of malignancies among RA patients treated with non-TNFi biologics is less well-known.

Methods:

Through linkages of Swedish national and population-based registers we assembled three cohorts of patients with RA initiating a first ever treatment of: 1) rituximab, 2) abatacept, 3) tocilizumab, 4) any TNFi, and 5) a cohort initiating a second TNFi. Also, 6) a biologics-naïve RA cohort was assembled, and 7) a general population comparator cohort, matched 1:10 on the biologics-naïve RA cohort. Through linkage with the Cancer Register information on cancer events were gathered. Outcomes were defined as first solid invasive malignancy, first hematologic malignancy, first invasive squamous cell skin cancer, and first solid or hematologic malignancy, all defined as first during follow-up. Patients were followed from treatment start until death, emigration, outcome or end of follow up. Crude incidences, as well as age and sex standardized incidences were calculated for outcomes from 2006 through 2012. Hazard ratios were calculated using Cox-regression, adjusted for age and sex.

Results:

Adjusted for age and sex, there were no statistically significant differences, for any of the outcomes, between initiators of non-TNFi biologics and initiators of a first or second TNFi, although small number of events precluded formal comparisons in some of the analyses.

Conclusion: The overall risk of malignancies among RA patients initiating rituximab, abatacept, or tocilizumab in clinical practice does not differ substantially from that of RA patients initiating a first or second TNF inhibitor, though risks for specific cancer sites or with longer latency cannot be excluded.

Table. Number of persons, events, crude incidence, standardized incidence, average follow-up time and hazard ratios for the different outcomes under study.

Outcome definition	Cohort	Number of persons at risk	Number of events	Crude incidence per 100,000 pys	Incidence rate standardized to the non-tnfi bio cohorts (by age and sex)	Mean follow-up, years	HR (adjusted for age and sex)

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy IV: Safety of Targeted Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Interferon-γ release assays (IGRAs) offer the possibility of an improved method to detect TB infections in pts with autoimmune disorders. Compare results of an IGRA vs standard TST as a screening tool for latent TB infection (LTBI) in the Golimumab [GLM] PURSUIT Ulcerative Colitis (UC) program versus GLM SC Rheumatology (RA, PsA, AS) program[1].

Methods: In both programs, pts were screened for LTBI using standard TST and IGRA to assess eligibility in the following studies: PURSUIT-SC and PURSUIT-IV; GO-BEFORE, GO-FORWARD, GO-AFTER, GO-REVEAL, and GO-RAISE, resp. Any pt with a newly identified positive finding for TB in whom there was no evidence of active TB was permitted to enter provided appropriate treatment for LTBI was initiated before or at the time of first dose of drug. TST was performed by the Mantoux method, using 5TUs of PPD standard or 2TU of PPD RT-23. TST was deemed positive for LTBI according to local country guidelines for an immunosuppressed host or, in the absence of local guidelines, according to an induration ≥5mm. The IGRA used to screen for LTBI was QuantiFERON-TB Gold In-Tube test. Overall IGRA and TST results were assessed. Prior BCG vaccination and con meds(ie corticosteroids and/or immunomodulators) on outcome was also assessed.

Results: In GLM PURSUIT, 1283 pts and in GLM Rheumatology 2282 pts had both IGRA and TST screening prior to GLM treatment. Both programs were global; differences were PURSUIT included S. Africa and the Rheum program included Asia. In the PURSUIT and Rheum programs, agreement between the TST and IGRA results, measured by the kappa coefficient, was 0.135 (95% CI, 0.050-0.220; p=0.028) and 0.22 (95% CI, 0.157-0.279; p=0.021), resp. Overall, in PURSUIT, 501(39.0%) of 1283 pts

had previously received BCG vaccine; among this vaccinated group, the rate of positivity for LTBI by TST was 10.4% vs 5.0% for IGRA positivity. In the Rheum program, 781 (34.2%) of 2282 pts had previously received BCG vaccine; within this vaccinated group, the rate of positivity for LTBI by TST was 15.2% vs 9.1% for IGRA positivity. PURSUIT pts who had not received the BCG vaccine, the rate of positivity by TST was 1.9% vs 2.8 % for IGRA positivity compared with 5.0% vs 5.8%, resp, in the Rheum program. When IGRA was repeated in PURSUIT pts whose results were initially indeterminate, the majority of pts(67.0%) were IGRA negative on repeat whereas the number of pts whose results were positive was 5.3%; IGRA remained indeterminate for 27.7%. Similar results were seen in the Rheum program (74% IGRA negative, 2.7% positive, and 23.2% remained indeterminate). Concomitant corticosteroid and/or immunomodulator use did not appear to have an impact on results.

Conclusion: Results of this comparison suggest IGRA provides greater specificity and possibly greater sensitivity than TST, and performs similarly in UC and Rheum populations.

Results from the GLM PURSUIT UC and GLM Rheumatology Programs		
Screening test results	PURSUIT UC	Rheumatology SC Program
IGRA/TST		
IGRA +	48/1283 (3.7%)	160/2282 (7.0%)
TST +	15/48 (31.3%)	59/160 (36.9%)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy IV: Safety of Targeted Therapies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). In Phase 3 (P3) studies, tofacitinib demonstrated safety and efficacy at 5 and 10 mg BID when used as monotherapy or with conventional synthetic (cs) DMARDs (csDMARDs). Here, we examine the safety profile of tofacitinib 5 mg BID as monotherapy and combination therapy in the P3 RA program.

Methods: Safety data for tofacitinib were obtained from six double-blind P3 studies of 6–24 months duration and stratified by whether tofacitinib was administered as monotherapy (NCT00814307, ORAL Solo; NCT01039688, ORAL Start) or with csDMARDs (NCT00960440, ORAL Step; NCT00847613, ORAL Scan; NCT00856544, ORAL Sync; and NCT00853385, ORAL Standard). Patients (pts) in ORAL Start were methotrexate (MTX)-naïve while pts in all other studies had an inadequate response to cs or biologic DMARDs. Endpoints included: serious adverse events (SAEs), discontinuations due to adverse events (AEs), serious infection events (SIEs), opportunistic infections, herpes zoster (HZ), malignancies, major adverse cardiovascular events, gastrointestinal perforations, all-cause mortality, and laboratory safety data.

Results: Tofacitinib 5 mg BID was administered as monotherapy in 616 pts (243 from ORAL Solo and 373 from ORAL Start, mean age 51.1 years [yrs], mean RA duration 4.9 yrs, 49.8% received glucocorticoids [GC]) and combination therapy in 973 pts (mean age 53.4 yrs, mean RA duration 8.9 yrs, 57.8% received GC). Incidence rates (IRs) for SAEs, discontinuations due to AEs, SIEs and HZ were generally lower in pts receiving tofacitinib monotherapy vs combination therapy. A similar trend was observed when pts were stratified by GC use; however confidence intervals were wide and overlapping for some outcomes (Table 1). IRs for SIEs and HZ were greater for pts who received GC compared with those who did not irrespective of whether tofacitinib was given as monotherapy or in combination. Similar proportions of pts in the monotherapy and combination therapy groups had confirmed laboratory decreases in hemoglobin, neutrophil and lymphocyte counts, and increases in liver enzymes and serum creatinine (Table 2).

Conclusion: In this analysis, IRs for SAEs, discontinuations due to AEs, SIEs, and HZ were lower in the tofacitinib 5 mg BID monotherapy group vs the combination therapy group; however, IRs should be interpreted with caution as the data are from controlled studies of limited duration and MTX-naïve pts with shorter disease duration were included in the monotherapy group only.

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment:Treatment of PsA and SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: IL-23 is essential for the differentiation and maintenance of Th17 cells in psoriasis and psoriatic arthritis (PsA). We assessed the efficacy and safety of the humanized IgG1 monoclonal antibody BI 655066, which selectively inhibits IL-23p19, compared with ustekinumab, an IL-12/23 inhibitor, in patients with moderate-to-severe plaque psoriasis with and without concurrent PsA.

Methods: In this Phase 2 study (NCT02054481; 1311.02), 166 patients were randomly assigned (1:1:1:1 ratio) to receive subcutaneous injections of one of three dosage regimens of BI 655066 (18 mg single dose at Week 0; 90 or 180 mg at Weeks 0, 4, and 16), or ustekinumab (45 or 90 mg, based on weight, at Weeks 0, 4, and 16). Skin lesions were assessed using the Psoriasis Area and Severity Index (PASI) with the primary endpoint of PASI 90 (90% improvement in PASI score from baseline) at Week 12. Pain was assessed by visual analog scale (pain-VAS [0–100 mm]) at baseline (Week 0) and at Weeks 4, 12, and 24 in patients who had concurrent PsA. In this interim analysis, all patients had completed the Week 24 visit.

Results: The primary endpoint of PASI 90 response at Week 12 was achieved by 32.6% (14/43), 73.2% (30/41), and 81.0% (34/42) of BI 655066 patients in the 18, 90, and 180 mg groups, respectively, and 40.0% (16/40) of ustekinumab patients. A two-sided Cochran-Mantel-Haenszel test of PASI 90 response at Week 12 between the 18, 90, and 180 mg groups of BI 655066, and ustekinumab, gave p-values of 0.4337, 0.0013, and <0.0001, respectively. Among the 46 (27.7%) patients with PsA (either previously diagnosed by rheumatologist [n=13] or suspected by investigator [n=33]), median decreases from baseline in pain-VAS at Week 24 were 7.6%, 80.0%, and 86.5%, respectively, for the BI 655066 18, 90, and 180 mg dose groups, compared with 77.6% for ustekinumab. The criterion of >50% decrease in pain-VAS (defined post hoc) at Week 24 was achieved in 16.7% (1/6), 81.8% (9/11), and 90.9% (10/11) of patients in BI 655066 18, 90, and 180 mg dose groups, respectively, compared with 57.1% (8/14) for ustekinumab. In the BI 655066 90 and 180 mg dose arms the reductions in pain-VAS score were observed as early as 4 weeks, and were highest at 24 weeks (Figure 1). AEs were similar between treatment arms and there was no dose response relationship for any AE. Seven patients reported serious AEs (four in the 18 mg and two in the 90 mg BI 655066 arms and one in the ustekinumab arm); all were considered unrelated to study medication.

Conclusion: Selective blockade of IL-23p19 with BI 655066, in the 90 mg and 180 mg arms, were associated with PASI responses superior to ustekinumab in patients with moderate-to-severe plaque psoriasis. Treatment with BI 655066 or ustekinumab was associated with numeric improvement in pain-VAS in patients with diagnosed or suspected PsA. Further studies are needed to assess long-term efficacy and safety of BI 655066 in both psoriasis and PsA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment:Treatment of PsA and SpA

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease associated with psoriasis, peripheral arthritis, enthesitis, dactylitis, and spondylitis. PsA has a significant negative impact on patients' quality of life, physical function, and work productivity. Ixekizumab is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL-17A, currently under investigation for the treatment of PsA.

Methods: In this phase 3 trial, 417 biologic disease-modifying antirheumatic drug (bDMARD)-naive patients with active PsA were randomized to receive up to 24 weeks of placebo (N=106); adalimumab 40 mg once every 2 weeks (Q2W; N=101) (active control); or ixekizumab 80 mg every 4 weeks (Q4W; N=107) or Q2W (N=103) following a 160 mg starting dose at Week 0. Patient Reported Outcomes (PROs) included, but were not limited to, Health Assessment Questionnaire – Disability Index (HAQ-DI), Short Form-36 Health Survey Physical Component Score (SF-36 PCS), European Quality of Life 5 Dimensions Visual Analog Scale (EQ-5D VAS), and Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP), and were analyzed using the intent-to-treat population. Continuous PRO data were evaluated using a mixed-effects model for repeated measures. The model included data up to Week 24 for all patients except inadequate responders (IRs) for whom data after Week 16 were excluded. Categorical PRO data were compared using a logistic regression model; missing values were imputed with the non-responder imputation method, treating IRs as non-responders.

Results: Across treatment groups, baseline demographics and clinical characteristics were generally similar; population mean baseline scores for HAQ-DI, SF-36 PCS, and EQ-5D VAS were 1.17, 33.63, and 55.4, respectively, indicating reduced physical function and quality of life. Mean baseline scores for the individual components of the WPAI-SHP assessment were 8.6 for Absenteeism, 36.6 for Presenteeism, 38.9 for Work Productivity, and 47.0 for Activity Impairment. At Week 12, patients treated with either ixekizumab 80 mg Q4W or Q2W reported significantly greater improvements compared to placebo in HAQ-DI, SF-36, EQ-5D VAS, and WPAI-SHP (all components, except Absenteeism); improvements were maintained through Week 24 for all treatment groups (Table). Additionally at Weeks 12 and 24, the percentage of patients with a baseline HAQ-DI score ≥0.35 achieving minimally clinically important difference (MCID) for HAQ-DI (improvement from baseline in HAQ-DI ≥0.35) was significantly greater in both ixekizumab treatment arms compared to placebo (Table).

Conclusion: In bDMARD-naive patients with active PsA, ixekizumab significantly improved quality of life, physical function and work productivity.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment:Treatment of PsA and SpA
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: There remains an unmet need for additional treatment options for patients (pts) with psoriatic arthritis (PsA) who have had an inadequate response to or intolerance of anti-tumor necrosis factor (anti-TNF) therapy. Secukinumab, a human anti–IL-17A monoclonal antibody, demonstrated significant efficacy in the randomized, double-blind, placebo (PBO)-controlled phase 3 FUTURE 2 study (NCT01752634).[1]Here, we present the 52-week (wk) efficacy and safety of secukinumab by anti-TNF history in pts enrolled in this study.

Methods: Pts were randomized to receive subcutaneous (s.c.) secukinumab 300 mg, 150 mg, or 75 mg, or placebo (PBO) at baseline, Wks 1, 2, 3, and 4, and then every 4 wks (q4wk) from Wk 8. At Wk 16, PBO-treated pts were re-randomized to receive secukinumab 300 mg or 150 mg s.c. q4wk from Wk 16 or 24, depending upon clinical response. Randomization was stratified by anti-TNF history: anti–TNF-naïve, or inadequate response/intolerance to not more than 3 anti-TNF agents (anti–TNF-IR). The primary endpoint was ACR20 response at Wk 24. Secondary endpoints were PASI 75/90, DAS28-CRP, SF-36 PCS, HAQ-DI, ACR 50, dactylitis, and enthesitis. ACR70 was an exploratory endpoint. Analyses used non-responder imputation (binary variables) and mixed-effect model repeated measures (continuous variables) through Wk 52. Analysis of primary and secondary endpoints stratified by anti-TNF history was pre-specified.

Results: Of the 397 pts enrolled in FUTURE 2, 65% were anti–TNF-naïve and 35% were anti–TNF-IR. At Wk 24, ACR 20/50/70 and PASI 75/90 responses were higher with secukinumab versus PBO in both anti–TNF-naïve and anti–TNF-IR pts (Table). Improvements with secukinumab versus PBO at Wk 24 were also observed for other secondary endpoints in both anti–TNF-naïve and anti–TNF-IR pts. Response rates were generally higher amongst anti–TNF-naïve pts versus anti–TNF-IR pts. The greatest improvements in the anti–TNF-IR group were generally observed with secukinumab 300 mg. Clinical responses to secukinumab were sustained or continued to improve through 52 wks of therapy in both anti–TNF-naïve and anti–TNF-IR pts (Table).

Conclusion: Secukinumab provided sustained improvements in the signs and symptoms of PsA in both anti–TNF-naïve and anti–TNF-IR pts.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment:Treatment of PsA and SpA
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Classic DMARDs are not routinely prescribed for axial spondyloarthritis (SpA). Recent studies have found that concomitant therapy with methotrexate (MTX) reduced immunogenicity of TNF inhibitors (TNFi). However the effect of sulfasalazine (SSZ) on the development of anti-drug antibodies (ADA) has not been properly studied. We investigated the effect of MTX or SSZ on ADA development in a cohort of SpA patients treated with Infliximab (Ifx) or Adalimumab (Ada).

Methods: SpA patients were enrolled from two prospective observational cohorts, Spain (n=122) and The Netherlands (n=85). Out of 208 SpA patients treated with Ifx or Ada we included 152 patients; 41(26.9%) with Ifx and 111(73%) with Ada, who had drug and ADA levels measured during the first year of TNFi therapy. Concomitant DMARD use was assessed at baseline.

Disease activity was measured at baseline, 6 months and 1 year by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Low disease activity (LDA) was defined as BASDAI<4 with normal CRP and clinical improvement as ΔBASDAI>2. Serum drug levels were measured by ELISA and ADA levels were measured by ELISA(Spain) and ABT(The Netherlands) and samples were collected just before drug administration.

We performed the last observation carried forward analysis to include patients who dropped-out before one year.

Results: The demographic and clinical characteristics of the 152 SpA patients are shown in table1. ADA were detected in 26(17%) SpA patients: 5(19%) treated with Ifx and 21(81%) with Ada. Only 3 patients with ADA were treated with DMARS concomitantly, specifically with SSZ.

The majority of ADA appeared at 6 months: 17 (65%) patients and 9 (35%) developed ADA at 1 year. SpA patients treated with TNFi in monotherapy developed more frequently ADA than patients treated concomitantly with DMARDs: 23(26%) vs 3(4.7%), p=0.004. Patients treated with TNFi in combination with MTX or SSZ developed ADA less frequently than patients treated in monotherapy: 23(26%) vs 0(0%), p=0.02; 23(26%) vs 3(8%), p=0.03, respectively). However we did not find significant differences in ADA development when we compared SpA patients treated with MTX vs SSZ: 0(0%) vs 3(8%), p=0.54, respectively.

Most patients with ADA did not reach LDA during the first year of treatment: 9(38%) ADA positive patients vs 70(62%) ADA negative patients, p=0.04. ΔBASDAI was higher in ADA negative patients (Mdn, IQR): 2.2, 0.9-4 in ADA negative patients vs 1.1, 0.5-2.8 in ADA positive patients, p=0.03

Conclusion: In our cohorts of SpA patients treated with Ifx or Ada the concomitant use of DMARDs (MTX or SSZ) is associated with a lower development of ADA, which suggests a protective role of DMARDs to prevent immunogenicity and, hence, to prevent a secondary failure of the biological treatment.

Table 1: Clinical and demographic characteristics of patients grouped by presence of anti-drug antibodies (ADA).

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment:Treatment of PsA and SpA
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: In the Phase 3, randomized, double-blind, placebo (PBO)-controlled, FUTURE 1 study (NCT01392326), the anti–interleukin-17A monoclonal antibody secukinumab provided rapid and significant improvements in key clinical domains of psoriatic arthritis (PsA), including signs and symptoms, joint structural damage, physical function and quality of life.[1] Here, we present the long-term efficacy and safety of secukinumab in patients (pts) enrolled in FUTURE 1 and treated for up to 104 weeks (wks).

Methods: A total of 606 adults with active PsA were randomized to receive secukinumab or PBO. Secukinumab pts received a 10 mg/kg i.v. loading dose at baseline (BL), Wks 2 and 4, and then either 150 mg s.c. (IV→150 mg) or 75 mg s.c. (IV→75 mg) every 4 wks from Wk 8. PBO was given on the same dosing schedule. At Wk 16, PBO-treated pts were re-randomized to receive secukinumab 150 or 75 mg s.c. from either Wk 16 or Wk 24, based on clinical response. Assessments of clinical efficacy at Wk 104 included: ACR 20/50/70; PASI 75/90; DAS28-CRP; SF-36 PCS; HAQ-DI; mTSS. Efficacy variables are presented from those pts originally randomized to secukinumab. Wk 104 data are as observed.

Results: 476 pts (78.5%) completed 104 wks of study (167 [82.7%] pts in the IV→150 mg group and 155 [76.7%] in the IV→75 mg group). At Wk 104, ACR 20/50/70 response rates were 73.9/46.4/28.1% with IV→150 mg and 68.8/35.5/22.5% with IV→75 mg (observed data). Sustained clinical improvements with secukinumab through Wk 104 were observed across several other clinically important domains of PsA (Table). Responses were sustained through Wk 104 in pts naïve to anti-TNF therapy and in those with an inadequate response or intolerance to these agents (anti-TNF-IR). ACR20 response rates (observed data) at Wk 104 in anti-TNF-naïve pts were 80.0% and 72.9% with IV→150 mg and IV→75 mg, respectively; corresponding rates in anti-TNF-IR pts were 55.3% and 54.8%. Between BL and Wk 104, 84.6% of x-ray completers in the IV→150 mg group and 83.9% in the IV→75 mg group, had no radiographic disease progression (≤0.5 change in mTSS). Over the entire study period (mean exposure to secukinumab of 627.1 days) the type, incidence and severity of AEs was consistent with that reported previously. Infections and infestations were the most common AE observed with secukinumab (67.9 per 100 pt-years). No cases of TB were reported. Malignant or unspecified tumors were reported at a rate of 0.3 per 100-pt years. Major adverse cardiac event rates with secukinumab were 0.7 per 100 pt-years. No suicides were recorded in secukinumab-treated patients.

Conclusion: Secukinumab provided sustained improvements in signs and symptoms and multiple clinical domains of active PsA in pts who completed 2 years of therapy. Secukinumab was well tolerated with a safety profile consistent with that previously reported.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment:Treatment of PsA and SpA
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Tumour Necrosis Factor alpha inhibitors (TNFi) have proven to be effective in the treatment of with spondyloarthropaties. There is rationale to support that in patients who have achieved disease remission while on treatment with TNFi, a lower dose than that used to induce remission may suffice to maintain the disease inactive in the long term. Dose reduction schedules are empirically used in routine clinical practice, but up to now such practice is not based on evidence from clinical trials. With the hypothesis that reduced doses are non inferior to full doses in terms of maintenance of response and safety profile, and with the aim to generate evidence to guide clinical practice, a prospective, multicentre randomised open-label study with non-inferiority objective was jointly sponsored by the Spanish Societies of Clinical Pharmacology and Rheumatology.

Methods: A total of 126 patients with axial non-psoriatic spondyloarthritis that had been treated with TNFi for a minimum of 12 weeks and had achieved a sustained clinical remission (BASDI $\leq$ 2, no clinical arthritis or enthesitis and normal CRP) during additional 8 weeks or more were randomized (1:1) to continue with the full dose treatment (Control, C) or a reduced dose maintenance treatment according to a standardized protocol (Experimental, E) in 22 Spanish sites. The main study endpoint was the proportion of patients who after 1 year qualified for Acceptable Therapeutic Goal (ATG) (BASDAI, physician global assessment and patient and nocturnal axial pain VAS, all <4). The non-inferiority design assumed 87% of ATG in the control group and a lower limit for the 95%CI of the adjusted difference between treatments of 17% for the per protocol (PP) population. The proportion of patients with Ideal Therapeutic Goal (BASDAI, patient and physician global assessment, all < 2) was a key secondary endpoint. Other endpoints included ASAS Disease Activity Score, BASFI, and Quality of Life Questionnaire scores. Safety issues with special focus on infectious adverse events were also evaluated. Patients were visited every 8 weeks, following the recommendations of the Spanish Rheumatology Society. Patients were followed a minimum of 56 weeks or until treatment discontinuation. The study was registered with EudraCT: 2011-005871-18.

Results: Baseline characteristics are described in table 1. In the PP population 48 (82.8%) patients in the reduced arm and 47 (85.5%) patients in the full dose were on ATG at one year assessment, with adjusted difference (95%CI) of -2.5%(-16.6 to 11.7%), thus meeting the primary non inferiority study objective. The proportion of infectious events were 17.2% in E and 25.5% in C groups (NS).

Table 1. Study results

Baseline characteristics	*Control* *n=55*	*Experimental* *n=58*	*Total* *n=113*

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Early stages of systemic sclerosis (SSc) are characterized by inflammatory skin infiltrates mainly composed of activated T cells. Cytotoxic T-lymphocyte associated molecule-4 (CTLA-4) is a key regulator of T cell activation and preliminary data have suggested that it might contribute to SSc. Our aim was to investigate the efficacy of the CTLA-4-Ig abatacept, an inhibitor of T cell activation, in reducing skin fibrosis in complementary mouse models of SSc.

Methods: We first evaluated the antifibrotic properties of abatacept in the mouse model of bleomycin-induced dermal fibrosis. To assess whether abatacept might prevent the development of dermal fibrosis, mice received in parallel subcutaneous injections of bleomycin and intraperitoneal (i.p) injections of abatacept or purified human IgG1 at a dose of 100 mg every other day for three weeks. To assess whether abatacept might induce the regression of established dermal fibrosis, mice were challenged with bleomycin for 6 weeks and received i.p injections of 100 mg of abatacept or control IgG1 every other day during the last 3 weeks. Then, we investigated abatacept in the tight skin (Tsk-1) mice. Tsk-1 mice received i.p injections of 100 mg of abatacept or control IgG1 every other day for 5 weeks. Infiltrating T cells, B cells and monocytes were quantified in lesional skin by immunohistochemistry for CD3, CD22 and CD68. Inflammatory cytokines were measured in lesional skin by flow cytometry.

Results: Treatment with abatacept prevented the induction of bleomycin-induced dermal fibrosis: dermal thickness was significantly reduced by 48±5% in mice treated with abatacept compared to mice receiving the control IgG1 ($p=0.03$). Consistent with decreased dermal thickness, hydroxyproline content and myofibroblast counts were reduced upon treatment with abatacept by 63±4% ($p=0.02$) and 41±6% ($p=0.04$) respectively, compared to mice receiving the control antibody. In this model, treatment with abatacept led to decreased T cell, B cell and monocyte infiltration in the lesional skin. Upon bleomycin injections, skin IL-6 and IL-10 levels were significantly reduced upon abatacept treatment.

Abatacept also induced the regression of established bleomycin-induced dermal fibrosis: dermal thickness, hydroxyproline content and myofibroblast counts were reduced by 15±2% ($p<0.01$), 16±3% ($p<0.01$) and 33±5% ($p=0.01$) respectively, compared to mice receiving control antibody. Abatacept demonstrated no efficacy in Tsk-1 mice.

Conclusion: Using complementary mouse models of SSc, we demonstrate that abatacept can prevent and induce the regression of inflammation-driven experimental dermal fibrosis. Antifibrotic effects of abatacept are mediated in the bleomycin mouse model by the reduction of T cell, B cell and monocyte infiltration into lesional skin, and by the decreased of IL-6 and IL-10 skin levels. Translation to human disease is now required, and targeting early and inflammatory stages of SSc sounds the most appropriate. This strategy is currently under investigation in a phase-3 clinical trial assessing the efficacy of abatacept to improve skin involvement in patients with early diffuse SSc.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic sclerosis (SSc) is a progressive, debilitating disease with limited treatment options. IL-6 has been implicated in disease pathogenesis. Tocilizumab (TCZ), an IL-6Rα inhibitor, was evaluated in the 2-year faSScinate study, a randomized, double-blind, placebo-controlled trial. At week 24 (primary end point), favorable trends in skin score for TCZ were detected though the primary skin score end point was not met. In addition, smaller declines in FVC were observed in the TCZ-treated patients.

Methods: Eighty-seven patients with active SSc were randomly assigned 1:1 to subcutaneous TCZ 162 mg or placebo (PBO) weekly for 48 weeks. The primary end point was mean change in modified Rodnan skin score from baseline at week 24. Gene expression analysis was performed on skin biopsy samples collected at baseline and week 24. First, genomewide expression analysis was conducted on all available biopsy samples and on biopsy samples of age- and sex-matched healthy volunteers (HVs) using custom Agilent 60-mer microarray (Epistem, Manchester, UK). Based on these data, 86 genes representing fibrosis, IFN, and myeloid pathways were selected for more quantitative gene expression analysis using nCounter technology (NanoString Technologies, Seattle, WA, USA). CCL18 serum levels were determined using an IMPACT-based immunoassay (Roche Diagnostics, Penzberg, Germany).

Results: Of the 86 genes selected for follow-up expression analysis, 75 were, on average, significantly overexpressed in SSc patients compared with HVs. Analysis of genes significantly downregulated after TCZ treatment and stable or increased with PBO identified a subset of 14 genes highly enriched for myeloid-associated genes, including genes associated with M2 macrophages (Table 1). All 14 genes were overexpressed in SSc patients compared with HVs. No effect of TCZ on the fibrosis and IFN pathways was detected. Serum levels of the M2 macrophage chemokine CCL18 revealed a rapid and sustained decrease from elevated levels in the TCZ group to close to levels in healthy controls but not in PBO controls.

Table 1. Relative Change in Expression Between Baseline and Week 24 in the TCZ and PBO Groups

Gene	ΔPBO, %	ΔTCZ, %	*p*	Gene	ΔPBO, %	ΔTCZ, %	*p*
*C1QB**	0.1	–42.3	0.0004	*IFI16*	–1.3	–16.2	0.0142
*CCL18**	–20.8	–58.3	0.0086	*MS4A4A**	–2.1	–30.9	0.0168
*CD14**	–3.2	–37.6	0.0002	*MSR1**	11.7	–29.9	0.0032
*CD163**	–4.7	–28.0	0.0410	*NNMT*	4.8	–27.1	0.0026
*FCGR1B**	20.4	–20.0	0.0007	*SOCS3*	3.4	–27.9	0.0157
*FCGR3B**	–3.6	–41.9	0.0018	*TLR7**	18.7	–21.5	0.0292
*FPR1**	22.4	–35.4	0.0040	*VSIG4**	0.2	–27.5	0.0248

p values were calculated using the fit least square model in JMP (SAS Institute Inc., Cary, NC, USA) of the change in expression levels between baseline and week 24 in the TCZ and PBO groups, corrected for baseline expression value.
*Myeloid-associated gene.

Conclusion: The effect of TCZ on myeloid-associated genes may reflect inhibition and/or depletion of skin-infiltrating macrophages. In addition, the effect of TCZ on CCL18 (RNA and protein), CD163, MS4A4A, and MSR1 suggests a specific inhibitory effect of TCZ on M2 macrophages, which are known to promote fibrosis and inflammation. These findings represent a potential novel mode of action for TCZ in SSc, which will be further investigated in the upcoming phase 3 study of TCZ in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Long noncoding RNAs (LncRNAs) are emerging as a novel class of noncoding transcripts involved in the regulation of gene expression. So far, for only few of them the function has been elucidated therefore their role in disease is poorly understood.

Methods: Here we aimed to identify candidate lncRNAs in systemic sclerosis (SSc) and investigate their function, particularly in relation to the TGFβ pathway and the development of the myofibroblast phenotype. RNA Sequencing Ilumina HiSeq2000 was performed in healthy control (HC) and SSc skin biopsies. Human skin fibroblasts were isolated from biopsies of SSc patients and HC; human pulmonary smooth muscle cells were purchased from Lonza. Cells were treated with 10 ng/ml TGFβ. TGFβR1 inhibitors (SD208 and SB431542) and siRNA against SMAD3 and SMAD4 were used to investigate TGFβ driven gene expression. LncRNA H19X was silenced in skin fibroblasts using locked nucleic acid antisense oligonucleotides (LNA GapmeRs), followed by qPCR analyses, immunofluorescence staining and Sircol assay. The expression of H19X was also measured in tissue samples of liver and lung fibrosis.

Results: RNA sequencing showed a significant upregulation of the lncRNA H19X in SSc versus HC skin biopsies. Importantly, the upregulation of H19X was not limited to SSc skin, but present also in the tissues from liver and lung fibrosis, indicating a broader role of H19X in fibrotic diseases. While there was no difference in the basal expression of H19X between SSc and HC cultured dermal fibroblasts, H19X was strongly and consistently induced by TGFβ. Induction of H19X by TGFβ was not limited to skin fibroblasts, but evident also in other cell types relevant for SSc, e.g. pulmonary vascular smooth muscle cells. Time curve analysis revealed that the upregulation of H19X by TGFβ was strongest after 6h reaching 12.8±0.7 induction; and dose curve analysis showed a steady increase of H19X over physiologically relevant TGFβ concentrations. These effects were TGFβR1 dependent as shown by the inhibition experiments with the chemical inhibitors SD208 and SB431542. Moreover, the upregulation of H19X by TGFβ was significantly impaired by silencing of SMAD3 and SMAD4, further pointing to a role of the canonical TGFβ pathway in H19X induction. Knockdown of H19X in skin fibroblasts led to a strong down-regulation of pro-fibrotic genes COL1A1, fibronectin and αSMA mRNAs. Immunofluorescence staining showed reduced αSMA and stress fibers formation in H19X silenced dermal fibroblasts indicating an involvement of H19X in the development of a myofibroblast phenotype. Furthermore, Sircol assay revealed a decrease of total collagen secretion upon H19X knockdown confirming the pro-fibrotic

effects of H19X.

Conclusion: This is the first study reporting changes in long-non coding RNAs in SSc and across fibrotic diseases. It opens new perspectives in studying the pathogenesis of fibrotic diseases by this novel class of regulatory, non-coding RNAs.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Nintedanib is a tyrosine kinase inhibitor that inhibits PDGF-, FGFR-, VEGFR-receptors and Src kinases. Nintedanib has recently been approved for the treatment of idiopathic pulmonary fibrosis (IPF). The aim of this study was to analyze the effects of nintedanib on fibrotic and vascular manifestations in preclinical models of systemic sclerosis (SSc) and to provide a scientific rationale for clinical trials in SSc.

Methods: The effects of nintedanib on migration, proliferation, myofibroblast differentiation and release of extracellular matrix were investigated by MTT- and scratch assays, stress fiber staining, qPCR and SirCol assays. The effects of nintedanib were evaluated in bleomycin-induced skin fibrosis, in murine sclerodermatous cGvHD, in Tsk-1 mice and in Fra2-tg mice.

Results:

Nintedanib reduced the PDGF- and TGFbeta-induced proliferation and migration more effectively than selective inhibition of PDGF-, VEGF or FGF-receptors. Nintedanib dose-dependently inhibited PDGF- and TGFbeta-induced myofibroblast differentiation and collagen release. In SSc fibroblasts, nintedanib also reduced the endogenous activation and decreased the collagen release even in the absence of exogenous stimulation. Nintedanib exerted potent anti-fibrotic effects in bleomycin-induced skin fibrosis, in experimental cGvHD, in Tsk-1 and in Fra2-tg mice with dose-dependent amelioration of dermal and pulmonary fibrosis. Of note, treatment with nintedanib also inhibited vascular manifestations in Fra2-tg mice. Nintedanib reduced proliferation of vascular smooth muscle cells and prevented thickening of the vessel walls and luminal occlusion of pulmonary arteries. Of note, treatment with nintedanib also inhibited apoptosis of dermal microvascular endothelial cells and blunted the

capillary rarefication in Fra2-tg mice.

Conclusion:

Nintedanib exerts potent anti-fibrotic effects in several complementary mouse models of SSc, but also ameliorates the histological features of PAH and of microangiopathy in Fra2-tg mice. The potent effects of nintedanib on fibrosis and vascular manifestations might have direct implications for the upcoming phase III clinical trial with nintedanib in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Hedgehog signaling plays a critical role in the pathogenesis of fibrosis in Systemic sclerosis (SSc). Besides canonical hedgehog signaling with Smoothened (Smo)-dependent activation of Gli transcription factors, Gli can be activated independently of classical hedgehog ligands and receptors (so-called non-canonical pathways). The aim of the present study was to evaluate the role of non-canonical hedgehog signaling in SSc and to test the efficacy of direct Gli-inhibitors that target simultaneously canonical and non-canonical hedgehog pathways.

Methods: The Gli-inhibitor GANT-61 was used to inhibit canonical as well as non-canonical hedgehog signaling, while the Smo-inhibitor vismodegib was used to selectively target canonical hedgehog signaling. In addition, Gli2 was selectively depleted in fibroblasts using the Cre LoxP system. The effects of pharmacologic or genetic of Gli2 on TGF-β signaling were analyzed in cultured fibroblasts, in bleomycin-induced pulmonary fibrosis and in mice with overexpression of a constitutively active TGF-b receptor I (TBRI).

Results: The expression of Gli2 was transcriptionally upregulated in fibroblasts and in murine tissues by TGF-β in a Smad-independent manner. Consistent with a novel role of Gli2 as a downstream mediator of TGF-β in fibroblasts, fibroblast-specific knockout of Gli2 reduced the stimulatory effects of TGF-β on fibroblasts and ameliorated TBR-induced skin fibrosis. The Gli2 inhibitor GANT-61 also prevented the stimulatory effects of TGF-β on fibroblasts *in vitro* and *in vivo*. Treatment with GANT-61 downregulated the levels of prototypical TGF-b targeted genes, reduced the collagen release and also blocked TGF-b-induced myofibroblast differentiation. In contrast, inhibition of canonical hedgehog signaling by vismodegib did not ameliorate TGF-β-induced fibroblast activation. Furthermore, GANT-61 ameliorated experimental fibrosis of the skin more efficiently than vismodegib. In the model of TBRI-induced fibrosis, mice treated with GANT-61 showed reduced dermal thickening, lower myofibroblast counts and decreased hydroxyproline content, whereas inhibition of canonical hedgehog signaling by vismodegib had no anti-fibrotic effect. GANT-61 also exerted potent anti-fibrotic effects in the model of bleomycin-induced pulmonary fibrosis and induced regression of pre-established fibrosis. In both models, GANT-61 did not only reduce levels of the hedgehog

target genes, but also the levels of the TGF-b target genes, thus confirming inhibition of TGF-b signaling upon targeting of Gli2.

Conclusion: We characterize Gli2 as a novel intracellular mediator of the pro-fibrotic effects of TGF-b. Pharmacologic inhibition of Gli2 targets canonical as well as non-canonical hedgehog signaling and ameliorates the pro-fibrotic effects of TGF-b . The potent anti-fibrotic effects of Gli2 inhibitors on cultured fibroblasts, dermal and pulmonary fibrosis and availability of direct Gli2 inhibitors for clinical use encourage additional studies to further explore the potential of Gli2 inhibitors for the treatment of fibrosis.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Activation of sphingosine-1-phosphate (S1P) signaling has been extensively documented in various fibrotic conditions including pulmonary fibrosis. The aim of this study was to provide a molecular basis for therapeutic intervention in lung fibrosis associated with scleroderma by inhibition of S1P using a novel S1P receptor 2 antagonist, AB22. AB22 has improved pharmacokinetics over other S1P receptor antagonists such as AB1 and JTE013.

Methods: AB22 and AB1 comparative efficacy was investigated in lung fibroblasts isolated from patients with scleroderma pulmonary fibrosis and in mice with bleomycin-induced pulmonary fibrosis. Lung injury was induced in 6-8 week old female C57BL/6 mice by a single intratracheal instillation of bleomycin. AB22 (Arroyo BioSciences, LLC, USA) was administrated once daily by gavage beginning on day 1 (early treatment, anti-inflammatory effect) or on day 8 (late treatment, anti-fibrotic effect) following bleomycin instillation. Two and three weeks after bleomycin instillation mice were euthanized, and broncho-alveolar lavage fluid (BALF) and lung tissue were investigated. Multiple sections from each lung were stained with hematoxylin and eosin (H&E) or with trichrome staining for collagen and other extracellular matrix proteins. For the area analysis of fibrotic changes, a quantitative fibrotic scale (Ashcroft scale) was used. Collagen, TGFβ, connective tissue growth factor (CTGF, CCN2), and α-smooth muscle actin (SMA) were studied by immunoblotting and immunofluorescent staining.

Results:

AB22 reduced collagen and CTGF in lung fibroblasts isolated from patients with scleroderma pulmonary fibrosis and in TGFβ-stimulated control fibroblasts to a higher extent as compared with AB1 and was selected for further testing in animal model of pulmonary fibrosis. Both early and late treatment with AB22 attenuated the development of bleomycin-induced pulmonary fibrosis, increased mouse survival, and decreased histological lung inflammation and fibrosis. AB22 significantly reduced

inflammatory cells and protein concentrations in BALF and diminished collagen, TGFβ, CTGF, and α-SMA expression in mice with bleomycin-induced lung fibrosis, whereas it had no effect on basal levels of these proteins.

Conclusion:

We conclude that inhibition of S1P receptor 2 using the oral antagonist AB22 restrains profibrotic events in lung fibroblasts and has marked anti-inflammatory and anti-fibrotic effects in a bleomycin model of lung injury. Inhibition of S1P signaling by AB22 may serve as a potential novel therapeutic avenue for the treatment of pulmonary fibrosis associated with scleroderma and other fibrosing diseases.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: This study aimed to 1) catalogue damage in a longitudinal cohort of patients with giant cell arteritis (GCA) and 2) evaluate predictors of damage in GCA.

Methods: Patients with GCA enrolled in a prospective, multicenter, longitudinal study were included. Periodic assessment included a standardized protocol with the Vasculitis Damage Index (VDI) and the Large-Vessel Vasculitis Index of Damage (LVVID). Univariate analyses were used to evaluate predictors of any damage at last follow-up and accrual of new damage during follow-up.

Results: The study included 204 patients with GCA: 156 women (76%); mean age at diagnosis = 71.3±8.3 years; median (25^{th}, 75^{th} quartiles) time from diagnosis to entry in the cohort was 3.7 (1.0, 16.5) months. Mean (±SD) duration of follow-up for the cohort was 3.5 (±1.9) years.

At least 1 damage item was present on VDI in 54% of patients at baseline and 79% at last follow-up. For LVVID, at least 1 damage item was present in 60% at baseline and 82% at last follow-up. At least 1 damage item was recorded in 46/114 (40%) of patients diagnosed ≤180 days prior to study entry on VDI compared to 64/87 (74%) with disease duration >180 days ($p<0.0001$).

Similarly, 55/116 (47%) of patients diagnosed ≤180 days prior to study entry had at least 1 item by LVVID compared to 68/87 (78%) with disease duration >180 days (p<0.0001).

At last follow-up, at least 1 *new* item of damage was noted in 55% patients on VDI and 60% on LVVID. The median number of new damage items accrued was 1 (0-8) on VDI and 1 (0-8) on LVVID. The majority of the new damage items were cataracts (40%), hypertension (20%), osteoporosis (20%), new limb claudication/arterial occlusion/infarction (29%) and damage requiring vascular intervention (angioplasty, stent, bypass, 9%). Organ systems with damage at baseline and last follow-up are in the **Table.**

Only disease duration was associated with presence of any damage item at last follow-up (OR 1.22; 95% CI l 1.04, 1.44). Age at diagnosis, sex, any relapse, number of relapses, highest Birmingham Vasculitis Activity Score (BVAS) or highest Physician Global Assessment (PGA) were not associated with presence of damage.

Predictors of accrual of *new* damage were evaluated in 94 patients with newly-diagnosed GCA (enrolled within 90 days of GCA diagnosis) with mean (±SD) duration of follow-up 3.1 (±1.7) years. Age, sex, any relapse, number of relapses, highest BVAS, or highest PGA were not associated with new damage during follow-up.

Conclusion: Damage from vasculitis or its treatment is present in 40-50% of patients with GCA within 6 months of diagnosis, and, in >75% during follow-up. Most of the new damage accrued during follow-up is treatment-associated; however, significant disease-associated damage, especially from peripheral arterial manifestations also occurs. These results emphasize the cumulative burden of disease associated with GCA even after initial diagnosis and treatment.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Relapses in patients with giant cell arteritis (GCA) are common and often lead to higher cumulative use of glucocorticoids. This study aims to evaluate the relapse characteristics and glucocorticoid use among a large single-institution cohort of patients with biopsy-proven GCA.

Methods: A retrospective review was performed to identify all patients with biopsy-proven GCA from January 1998 to December 2013. Demographic, clinical, laboratory and treatment data at baseline and subsequent follow visits were collected. Relapse was defined as recurrence of clinical manifestations compatible with spectrum of GCA and/or increase in inflammatory markers (ESR/CRP), not otherwise explainable, which required reintroduction or increased dose of glucocorticoid therapy. Comparisons between relapse groups were performed using Chi-square and Kruskal-Wallis tests. Time to daily dose of <5 mg and 0 mg of prednisone as well as glucocorticoid-associated adverse events were assessed using Kaplan-Meier methods. Patients with initial oral prednisone dose of >40 mg and ≤40 mg were compared using Cox models.

Results: The cohort included 286 patients with biopsy-proven GCA (213 females and 73 males, mean [±SD] age 75.0 [±7.6] years) with a mean (±SD) followup of 6.0 (±3.9) years. During followup 213 patients (75%) had one or more relapses. In patients experiencing a relapse, 50% of relapses occurred during the first year, 68% during the first two years and 79% during the first five years of follow up. The median relapse rate observed was 0.4 [Interquartile range (IQR) 0.21, 0.64] relapses per year. We further evaluated patients in three groups; no relapse, low relapse rate (<0.5 relapses/yr), and high relapse rate (≥ 0.5 relapses/yr). A higher proportion of patients with hypertension (p=0.007), diabetes (p=0.04) and prior history of venous thrombosis (p=0.04) were present in the ≥0.5 relapse/yr group compared to the no relapse and <0.5 relapse/yr groups.

Twenty-two patients (8%) received pulse dose steroids at diagnosis. Of the remaining 264 patients, 155 (59%) initially received >40 mg and 109 (41%) ≤40 mg of daily oral prednisone. Comparing patients treated with an initial oral prednisone dose of >40mg/day with patients receiving ≤40mg/day, the mean (±SD) prednisone dose was higher at the following intervals: one year [7.4 (±2.3) g vs. 5.8 (±2.1) g; p<0.001], during the first two years [9.6 (±3.5) g vs. 7.7 (±2.7) g; p=0.01] and total follow up duration [10.0 (±4.9) g vs. 8.2 (±5.2) g; p=0.03]. Patients started on >40 mg/day reached <5 mg/day [HR 1.46 (1.09, 1.96); p=0.01] and 0 mg [HR 1.56 (1.09, 2.23); p=0.02] earlier than those started on ≤40 mg/day. Time to first relapse based on initial oral prednisone dose did not differ [HR 1.18 (0.88, 1.57); p=0.27].No difference in glucocorticoid-associated adverse events was seen between the two groups.

Conclusion: In our biopsy-proven GCA cohort, female sex, hypertension, diabetes and history of venous thrombosis were associated with increased risk of relapse. An initial prednisone dose of >40mg/day led to earlier steroid discontinuation without increase in glucocorticoid-associated adverse events.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Data from mostly small cohorts consistently suggest that a diagnosis of giant cell arteritis (GCA) does not substantially affect survival but GCA- and GCA treatment-related morbidity may result in specific patterns of causes of death. Large databases of death certificates allow for studying patterns of mortality associated with specific medical conditions and determining changes over time in the extent to which they contribute to mortality.

Methods: We obtained data from multiple-cause mortality files compiled by the French Epidemiological Center for the Medical Causes of Death (CépiDC) for 1980–2011. GCA cases were defined as decedents ≥55 years old with International Classification of Diseases (ICD) codes 446.5 (ICD-9) or M31.6 (ICD-10) listed as the underlying or contributory cause of death. We calculated annual death rates (using national census data as a denominator) and average ages at death for GCA and for the general French population; time trends were analyzed by linear regression. To investigate the relation between deaths associated with GCA due to other medical disorders, we calculated standardized mortality odds ratios (SMORs) for 16 conditions frequently listed as causes of death in the general population or with a known association with GCA morbidity or mortality. SMORs were computed from more detailed data from the death certificates from 2000 to 2011, in which GCA was listed as a contributory cause of death.

Results: Among the 14,927,440 death records compiled over the 32-year period for decedents ≥55 years old, 15,020 listed a diagnosis of GCA. Females accounted for 68% of GCA cases and 51% of general-population death records. GCA death rates increased from 1980 to 2000 (P<0.001) and decreased thereafter (P<0.001). Mean age at death for GCA patients was 83.6 years as compared with 79.6 years for the general population (≥55 years old); mean age at death from 1980 to 2011 increased by 6.4 years for patients with GCA (P<0.001) and by 3.2 years for the general population (P<0.001). From the analyses of 4,427 death certificates from 2000 to 2011, as compared with the general population (≥55 years old), GCA decedent certificates more often listed “arterial aneurysms/dissections” (SMOR: 2.42, 95% CI: 1.86–3.11), “hypertensive disease” (SMOR: 1.92, 95% CI: 1.64–2.23) or “infections (excluding pneumonia)” (SMOR: 1.77, 95% CI: 1.50–2.08) as the underlying cause of death but less often “malignant neoplasms (excluding blood cancers)” (SMOR: 0.46, 95% CI: 0.41–0.52).

Conclusion: The higher age at death with GCA as compared with the general population further supports that life expectancy is not decreased by GCA. The secular trends of increasing age at the time of death and the recent decline in GCA-associated death rates may reflect improved survival among GCA cases and/or a change in the epidemiological characteristics of GCA. Patients with GCA are at increased risk of dying from large-vessel disease and treatment-related co-morbidities, including cardiovascular disease and infection.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Vasculitis II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: While many manifestations of TA improve quickly after starting glucocorticoid therapy, vascular inflammation appears to persist. To obtain more information about the duration of the histolopathologic changes after initiating glucocorticoids, we prospectively obtained second temporal artery biopsies in patients who had been treated for periods up to one year after first diagnostic biopsy. The study was approved by Mayo Clinic institutional IRB.

Methods: 231 patients were seen at the Mayo Clinical for suspected TA and had temporal artery biopsies (TAB) (2004-2010). In 89 (39%) TA was diagnosed. 40 of the 89 agreed to have a second TAB randomly assigned to 3, 6, 9, or 12 months after the first. The initial TAB was performed on the side clinically most suggestive of TA. The second was performed on the opposite side. Histories and physical exams were performed prior to the biopsies. After biopsy oral glucocorticoid therapy was given at a median initial dose of 60 mg/day (range 30-80/day) for one month and then reduced gradually by approximately 10% of the daily dose per 2 weeks as tolerated according to the patients' symptoms and findings. Histopathologic findings were retrospectively evaluated (in a blinded fashion) and documented by a cardiovascular pathologist (JJM).

Results: The cohort contained 28 women and the median age at diagnosis was 77 years (range 57-89). Manifestations at diagnosis were typical of TA and were similar among the four groups. Overall 26 had jaw claudication, 15 PMR, and 6 ischemic optic neuropathy (AION). Median hemoglobin for the 40 was 11.9 g/dl (range 9.3-14.1) and median ESR was 74 mm/hr (range 16-149). Second TAB still showed vasculitis in 7/10 at 3 mo., 9/12 at 6 mo, 4/9 at 9 mo, and 4/9 at 12 mo, at which time median prednisone doses were, respectively, 25.0 mg/d, 9 mg/d, 10 mg/d, and 4.5 mg/d. Overall those with a positive second TAB did not have a greater number of symptoms at diagnosis. However, all 6 pts with AION at diagnosis had vasculitis on second TAB (2 at 3 mo, 2 at 6 mo, 1 at 9 mo, and 1 at 12 mo. Of those with a positive second TAB at 3 mo, 2 had headaches, 1 jaw claudication, and 1 scalp tenderness. At 6 mo, 1 had headache and PMR, and at 9 and 12 mos, only 1 patient had headache. No patient developed any new manifestations of TA after therapy was started and no biopsy complications were observed. Giant cells were present on the initial biopsy in 22 of the 40 cases. Of those, 2 of 6 were still present at 3 mo, 6 of 8 were present at 6 mo, and none were found at 9 or 12 mos. Additionally, giant cells were found on three follow up biopsies that were not present on the first biopsy, 1 at 3 mo, 1 at 6 mo, 1 at 9 mo. Medial fibrosis was observed in 13 initial biopsies and 24 secondary biopsies with 6/10 at 3 mo, 9/12 at 6 mo, 5/9 at 9 mo, and 4/9 at 12 mo.

Conclusion: In a population of patients with TA treated with glucocorticoids, few reversible manifestations persisted after initiation of therapy, however, vasculitis continued in a diminishing number at 12 month follow-up. Medial fibrosis appears to correlate with chronicity of TA but is not always observed. Giant cells may persist up to 6 months after initial biopsy but are rarely seen after that point.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Vasculitis II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Giant cell arteritis (GCA) is a relatively common form of primary systemic vasculitis which if untreated can lead to permanent sight loss. It is a medical emergency, requiring urgent treatment and investigation. We compared the value of ultrasound, as an alternative diagnostic test to temporal artery biopsy, which is typically negative in 10-30% of true cases. Our objective was to compare the effectiveness and cost effectiveness of ultrasound with biopsy in the diagnosis of patients with suspected GCA.

Methods:

We undertook a prospective multicentre cohort study of temporal artery biopsy compared to ultrasound of temporal and axillary arteries for diagnosis of newly suspected GCA. Sonographers received training and examined 10 healthy subjects and 1 patient with active GCA before participating in the study. We recruited patients referred to secondary care with suspected new onset of GCA. The main outcome measures were sensitivity, specificity and cost-effectiveness using a reference diagnosis derived from the final clinical diagnosis, American College of Rheumatology classification criteria for GCA and expert review. Cost-effectiveness analysis compared treatment costs, the impact of steroid toxicity in false-positives and the impact of GCA complications in false-negatives for the two tests and different testing strategies in combination with clinical judgement.

Results: We recruited 430 patients with suspected GCA from 20 centres between 2010 and 2013. We included 381 patients in the primary analysis (median age 71.1 years; 72% female) and 257 (67%) were given a reference diagnosis of GCA. The sensitivity of biopsy was 39% (95% CI 33-46%), significantly lower than previously published series and inferior to ultrasound (54%, 95% CI 48-60%); the specificity of biopsy was superior to ultrasound (100% vs 81%) compared to the gold standard defined by final diagnosis which included the results of the biopsy. Combining ultrasound with clinical judgement (sensitivity 93%, specificity 77%) was more cost-effective than biopsy with clinical judgement (sensitivity 91%, specificity 81%); incremental net monetary benefit was £493 (€546, US$703) per suspected case. A strategy of ultrasound for all suspected cases followed by biopsy in medium- and high-risk patients with a negative ultrasound was slightly more cost-effective (sensitivity 95%, specificity 77%, incremental net monetary benefit £498 [€552, US$710] per suspected case).

Conclusion:

We evaluated the role of ultrasound compared to biopsy as diagnostic tests in patients with suspected giant cell arteritis. We demonstrated that as primary investigation of suspected GCA, ultrasound can improve sensitivity but not specificity, when compared to biopsy. A diagnosis of GCA requires clinical assessment, based on the history and examination of the patient; a

combined strategy of scanning all patients followed by biopsy of scan negative cases provides an effective and cost effective method to evaluate patients with a medium to high index of suspicion of GCA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Vasculitis II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Giant cell arteritis (GCA) requires treatment with high dose corticosteroids. Many patients require chronic steroid therapy with associated significant side effects. There is a lack of proven alternative therapies. Interleukin 12 (IL12) and interleukin 23 (IL23) drive Th1 and Th17 responses respectively which are central to the pathogenesis of GCA. The aim of this study was to evaluate the efficacy and safety of ustekinumab, an IL12/IL23 inhibitor in GCA.

Methods:

We performed a prospective open label study of ustekinumab in patients with refractory GCA. Ustekinumab was administered subcutaneously at a dose of 90mg at week 1 and week 4 followed by every 12 weeks. All patients met the 1990 ACR classification criteria for GCA. Patients underwent standardized clinical assessments. Disease activity was based on a combination of clinical assessment, acute phase reactants (ESR, CRP) and available imaging studies. Descriptive statistics were reported as median and interquartile range (IQR) or number (n) and percentages as appropriate, Wilcoxon Signed Rank test was used to compare between group differences. Statistical significance was set at $p<0.05$. All patients gave written informed consent and the study was approved by the ethics committee of St. Vincent's University Hospital.

Results:

12 patients commenced ustekinumab having failed to taper corticosteroid monotherapy and a median of 1 other immunosuppressive agent, with a median (IQR) of 3 (2, 5) prior relapses of GCA. 83% had experienced significant corticosteroid

side effects. Full demographic and clinical details are shown in Table 1. Median (IQR) duration of ustekinumab treatment at last follow-up was 8 (5, 11) months, 3 patients required an increase in dosing interval to 8-weekly. Median (IQR) steroid dose decreased significantly from 23mg (15, 33) to 5mg (3, 8) (p=0.003). No patient experienced a relapse of GCA during ustekinumab treatment. Efficacy outcomes are detailed in Table 2. 5 adverse events were recorded, 1 UTI, 1 LRTI, 1 hair loss, 1 parasthesia, and 1 dental abscess. 3 patients discontinued ustekinumab due to adverse events or personal preference, 2 subsequently had a relapse of GCA.

Conclusion:

Ustekinumab permitted a significant reduction in steroid dose and of other immunosuppressants in patients with refractory GCA. The efficacy of ustekinumab in GCA warrants further investigation in a randomized controlled trial.

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Understanding the associations between education and health status among Hispanics with arthritis and/or joint pain is crucial in adapting existing arthritis interventions for this minority population. Nationwide, 35.3% of Hispanics lack a high school diploma, (compared with 8.3% of non-Hispanic whites), indicating a need to assess the differences in health status among higher and lower educated Hispanics. The purpose of this study was to examine associations between education and health status in Hispanics with self-reported joint pain.

Methods: Adult Hispanic participants (n=285) were recruited from North Carolina clinics, churches, and a Mexican consulate for a 6 week pre-post evaluation of a self-directed walking program. Participants were recruited if they self-reported arthritis and/or joint pain and were physically inactive. Descriptive characteristics of the population include means and frequencies according to high school (HS) education level (<HS diploma or ≥HS diploma). Multi-level logistic regression models were used to explore associations between education and health status measures at baseline. All models were adjusted for gender, age, obesity, marital status and country of origin with study site adjusted for as a random effect.

Results: We found that 44% of participants had less than a high school education. These participants were significantly more likely to be born in Mexico (80.7%), be unmarried (14.4%), and speak only Spanish (95.0%) compared with more educated participants (Table 1). Participants lacking a high school diploma were also significantly more likely to have higher levels of fatigue (OR=1.68; 95% CI=1.01-2.80) and stiffness (OR=1.69; 95% CI=1.01-2.82), and poor general health (OR=3.11; 95% CI=1.78-5.42) (Table 2). Although failing to reach statistical significance in multivariable regression models, less educated participants also had a higher frequency of comorbidities, including heart disease, circulation problems, and diabetes. They were also more likely to have multiple chronic comorbid conditions

Conclusion: Compared to their more educated counterparts, Hispanics who self-reported arthritis and/or joint pain and were less educated had more severe joint symptoms and poorer general health. In addition, the lower educated group also showed higher rates of comorbidity and were more likely to have multiple comorbidities, which might account for some of the disparity in health status. These findings may help inform the selection and adaptation of arthritis interventions for Hispanics.

Table 1. Baseline characteristics of according to education

Baseline Characteristic	**Total Cohort**	**Education <HS**	**Education ≥HS**	**P-value[μ]**

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Osteoarthritis (OA) is the most common form of arthritis and affects nearly 30 million Americans. Chronic pain is the major symptom in OA and patients often also live with other comorbidities, most notably insomnia and depression. Female sex has been shown to be an important risk factor for development of OA but few studies have examined its association with other comorbidities in persons with OA. The purpose of this study was to examine associations between sex and pain, insomnia and depression in older adults with OA. We hypothesized that the strength of any sex-related association would be increased with increasing numbers of comorbidities.

Methods:

8,057 participants aged 60+ with an electronic medical record OA diagnosis were mailed a screening questionnaire which asked about their pain, sleep disturbance, and depressive symptoms. Pain intensity, persistence, and interference were assessed by the Graded Chronic Pain Scale (GCPS). Insomnia severity was measured by the Insomnia Severity Index (ISI), and daytime dysfunction related to sleep was assessed by asking if participants had residual problems related to trouble sleeping, such as tiredness or poor concentration. Depression was measured by the Patient Health Questionnaire depression scale (PHQ-8). Cut points were determined based on upper tertiles of each comorbidity severity (GCPS $\geq$ 2, ISI $\geq$ 10, daytime dysfunction $\geq$ 4, and PHQ $\geq$ 6) to ensure equivalent comparisons. The Charlson Comorbidity Index was calculated from medical records of participants who had granted research access. Logistic regression analysis was conducted to examine the associations between sex and OA comorbidities.

Results:

3,321 participants completed the questionnaire. Overall, they were older (Mean = 72 yrs) and highly educated, with 81.6% completing at least community college. The majority were female (66.6%) and about 80% had one or more daytime problems related to trouble sleeping. The top four problems were trouble concentrating (13.8%), memory problems (13.7%), tiredness (12.5%), and upset stomach (11.3%). Females had a higher odds ratio of having pain and insomnia simultaneously than males (OR = 1.66, 95% CI = 1.37, 2.02), controlling for age, education, and comorbidity index. Similarly, females tended to have higher rates of pain with depression than males (OR = 1.63, 95% CI = 1.35, 1.99), and higher rates of comorbid insomnia and depression (OR = 1.57, 95% CI = 1.30, 1.88). As predicted, the association with sex appeared to be the strongest when considering the presence of the three comorbidities together (OR = 1.73, 95% CI = 1.40, 2.15), although the strength of association was similar. Females also had a higher odds ratio of daytime dysfunction related to sleep than males (OR = 1.59, 95% CI = 1.35, 1.87).

Conclusion:

Sex differences are associated with comorbid pain, insomnia, and depression in older adults with OA. Specifically, females are more likely to suffer these comorbid symptoms compared to males. In addition, the strength of this association increases with increasing comorbidity.

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose : Growing evidence suggests that the prevalence and incidence of knee OA is rising, partially due to increasing life expectancy and the growing obesity epidemic. The most commonly cited estimate of the burden of symptomatic knee OA in the US is 9.3 million individuals. This figure was derived using 2005 population estimates and is based on a prevalence estimate from a large cohort study of a predominantly white population from the 1980s. We sought to provide a contemporary estimate of the burden of knee OA in the US, taking into consideration racial/ethnic differences in obesity rates, age-

specific population size, and mortality rates. **Methods:** We used published prevalence rates of symptomatic knee OA derived from the National Health Interview Survey (2007-08) (NHIS), stratified by age, sex, race/ethnicity, and obesity status. We adjusted for self-reported OA diagnosis using positive predictive values of self-reported knee OA from the literature, and also derived the proportions of individuals with advanced (Kellgren-Lawrence grade 3 or 4), symptomatic knee OA using the validated Osteoarthritis Policy Model. We calculated the burden as the number of persons diagnosed with symptomatic knee OA by combining the stratified prevalence rates from NHIS with corresponding obesity rates from the National Health and Nutrition Examination Survey (2011-12) and population estimates from the Census Bureau (2012) among adults older than 25 years. **Results:** We estimated the overall prevalence of symptomatic knee OA as 15.6 million, with advanced knee OA comprising 8.9 million of those individuals (Table). Adults under 45 years old represented nearly 1.7 million cases of symptomatic knee OA and 0.7 million cases of advanced, symptomatic knee OA. The proportion of symptomatic knee OA cases classified as advanced among these younger persons was greater among males (36%–40%) than among females (28%–35%). Among individuals between 45 and 65 years of age, nearly 7 million have symptomatic knee OA, including 2 million racial/ethnic minorities. Prevalence was higher among females than males across all strata, and among women over 65 years of age, one in five were estimated to have symptomatic knee OA, with two-thirds of those having advanced disease. The prevalence of knee OA was greater among younger Hispanic and non-Hispanic Black women compared to non-Hispanic White women. **Conclusion:** Using contemporary national data on population size, obesity and OA prevalence, we estimated that 15.6 million persons in the US are living with symptomatic knee OA. This estimate is 68% higher than the prior estimate of 9.3 million. The majority of individuals with symptomatic knee OA are at an advanced stage of the disease. Policymakers should expect healthcare utilization for knee OA, particularly total knee replacement, to increase further in upcoming decades.

Table. Number of individuals (in thousands) with symptomatic and advanced (Kellgren-Lawrence grade 3 or 4), symptomatic knee osteoarthritis in the United States.

Age	Race/Ethnicity	Sex	Population	Symptomatic Knee OA Prevalence	Advanced, Symptomatic Knee OA Prevalence

Awareness and Reasons for Lack of Post-Fracture Osteoporosis Therapy: A Survey of Post-Menopausal Women

Denise Boudreau[1], Onchee Yu[1], Akhila Balasubramanian[2], Jane Grafton[1], Heidi Wirtz[3], Andreas Grauer[3], D. Barry Crittenden[3] and Delia Scholes[1], [1]Group Health Research Institute, Seattle, WA, [2]Center for Observational Research, Amgen, Inc., Thousand Oaks, CA, [3]Amgen Inc., Thousand Oaks, CA

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health
Session Type: ACR/ARHP Combined Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Osteoporotic fractures cause patient morbidity and increase risk for future fracture. Effective drug therapies for osteoporosis (OP) are available, yet only a minority of women receives osteoporosis pharmacotherapy (OP-Rx) post-fracture. Reasons for lack of post-fracture OP-Rx are not well understood. We undertook the first large scale survey of women with recent osteoporotic fractures to characterize their beliefs about OP and their physician interactions, and to understand the factors associated with lack of post-fracture OP-Rx.

Methods: A survey was mailed to 985 women, aged >55 years with an osteoporotic fracture in 2013-2014, who were enrollees of Group Health Cooperative, a large Northwest health plan. Receipt of OP-Rx in the 6 months post-fracture was determined from automated pharmacy data. The associations between factors of interest and non-receipt of post-fracture OP-Rx were assessed using age-adjusted modified Poisson regression with a robust sandwich estimator.

Results: 634 women returned the survey (73% response rate, excluding 119 ineligibles); mean age was 75 years (SD 11.1) and 77% were white. Primary fracture sites were distal forearm (31%), hip (27%), spine (14%), and humerus (18%). 84% of women did not receive OP-Rx within 6 months post fracture. Even among the 11% of women who were on OP-Rx prior to fracture, 40% did not continue therapy following the fracture. Only 20% of all respondents believed that OP-Rx reduces risk of fracture. Women who were not concerned about OP or future fractures, did not think OP caused their fracture, did not think OP-Rx was effective in reducing fractures, or did not believe a fracture put them at risk for future fracture were at increased risk for non-receipt of OP-Rx (Table). Similarly, women who did not discuss OP management or fracture prevention with their physicians, and whose primary source of information on OP was the media or family and friends rather than their medical providers were also at higher risk for not receiving OP-Rx.

Conclusion: The majority of women who suffered an OP fracture did not receive OP-Rx in the 6 months post-fracture. This study suggests that patient education about OP, the risk for future fracture after an initial fracture, and the potential benefits of therapy – through physician input or potentially other reliable sources – may help reverse the substantial under-treatment of women post-fracture.

Table. Association between patient perspectives and interactions with medical providers on non-receipt of osteoporosis pharmacotherapy (OP-Rx) within 6 months of osteoporotic fracture			
		Relative Risk[1]	**95% CI**
Patient self-reported perspectives and beliefs on osteoporosis and fracture			
Concerned about their future risk of fractures	Not at all vs. very/somewhat	1.13	1.05-1.21
Concerned about osteoporosis	Not at all vs. very/somewhat	1.21	1.14-1.28
Believe a fracture puts them at risk for future fractures	No vs. yes	1.17	1.09-1.25
Believe osteoporosis caused their fracture	No vs. yes	1.31	1.15-1.48
Believe OP-Rx reduces risk of fracture	No vs. yes	1.22	1.09-1.36
Believe harms of OP-Rx outweigh benefits	Yes vs. no	1.06	0.98-1.14
Interactions with medical providers on osteoporosis and fractures			
Primary source of information on osteoporosis	Media vs. medical provider Family/friends vs. medical provider	1.13 1.20	1.05-1.21 1.11-1.30
PCP aware of fracture	No vs. yes	1.08	1.00-1.17
Told had osteoporosis by provider	No vs. yes	1.25	1.16-1.36
Provider recommendation to prevent fractures and/or manage osteoporosis	OP-Rx Other (e.g. supplements, diet) No recommendation	(ref) 1.89 1.85	1.61-2.21 1.57-2.19
Contact with PCP post fracture	No vs. yes	1.03	0.92-1.15
Discussed preventing fractures	No vs. yes	1.13	1.04-1.24
Discussed managing osteoporosis	No vs. yes	1.38	1.23-1.54
Osteoporosis was among top 3 topics discussed at PCP visits	No vs. yes	1.34	1.21-1.49

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:Rheumatoid arthritis (RA) is a known cause of work productivity loss. The goal within rheumatology today is to diagnose RA as soon as possible, to allow for early and aggressive treatment aiming for remission and sustained levels of daily activities. The objective of the current study was to assess work participation in an early, untreated RA cohort, and assess if work productivity differed across groups of patients according to disease activity.

Methods: Consecutive RA patients who fulfilled the 2010 ACR/EULAR classification criteria were recruited between October 2010 and April 2013. All patients had symptom duration <2 years from first swollen joint, and were disease modifying anti-rheumatic drug (DMARD) na•ve with indication for DMARD treatment at time of inclusion. The data collection included clinical examination, patient reported outcome measures (e.g. Work Productivity and Activity Impairment Questionnaire, WPAI) and laboratory assessment. We used data from WPAI and additional information on work participation to assess absenteeism (work time missed), presenteeism (impairment while at work) and overall work productivity loss (absenteeism plus presenteeism) due to RA. We then compared work participation across disease activity groups by Mann-Whitney U-test or chi-square test as appropriate.

Results: A total of 233 patients were included with median (25^{th} percentile, 75^{th} percentile) age 53.9 (41.7, 62.5) years, median disease duration from first swollen joint 5.7 (2.8, 10.2) months, 61.8 % female gender and 82.0% anti-citrullinated protein antibody (ACPA) positivity. 176 patients (75.5%) reported current employment (**Table**). Patients not reporting employment were retired (49.1%), on disability pension (19.3%) or unemployed for other reasons (31.6%). Although employed patients overall had limited absenteeism and moderate work productivity loss, patients with high disease activity had higher levels of absenteeism (median 71.4% vs 0.0%, p-value<0.001), presenteeism (40.0% vs. 10.0%, p-value < 0.01) and had impaired overall work productivity (85.7% vs. 50.0%, p-value <0.001) compared to patients in low disease activity (**Table**). There were no significant differences between groups with regards to age, gender, ACPA positivity and disease duration.

	All patients (n=233)	Low disease activity (n=33)	Moderate disease activity (n=103)	High disease activity (n=85)

Presenteeism %*	30.0 (10.0, 50.0)	10.0 (0.0, 40.0)	30.0 (10.0, 40.0)	**40.0 (20.0, 60.0)#**
Overall work impairment due to RA %*	50 (20.0, 100.0)	27.7 (0.0, 50.0)	40.0 (20.0, 70.0)	**85.7 (50.0, 100.0)¤**
# p-value <0.05 when compared to patients in low disease activity ¤ p-value<0.001 *Median (25th percentile, 75th percentile) Disease activity groups were defined according to disease activity score (DAS): low disease activity = DAS 1.6-2.4, moderate disease activity = DAS 2.4-3.7, high disease activity = DAS>3.7.				

Conclusion: Newly diagnosed DMARD-na•ve RA patients on average had low levels of absenteeism, but about half the patients had work impairment due to either absenteeism or presenteeism. Patients with high disease activity had higher levels of absenteeism, presenteeism and overall work impairment than patients with low disease activity. The data suggest that the 2010 ACR/EULAR classification criteria might capture RA patients with short symptom duration before significant loss of work productivity, but that even in this group many patients have already experienced work impairment due to their disease.

Session Title: ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

Session Type: ACR/ARHP Combined Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

The Outcome Measures in Rheumatology (OMERACT) Initiative has suggested an analysis of the occurrence of benefit and harm in trials simultaneously, at the individual patient level can enhance trial reports. We applied this method in a recent trial dataset.

Methods:

OMERACT suggests creating 3 levels of benefit and harm, and expressing each patient's outcome as a pair of values for benefit and harm. **Results** for the groups are summarized in 3x3 contingency tables. In addition, outcome of patients at the extremes can be labeled as 'unqualified success', resp. 'unmitigated failure'. The 48-week data of the recent 'RA Comparison of Active Therapies' (RACAT) study were re-analyzed according to this framework.

Three levels of harm were defined as 1) no adverse events (none), 2) at least one adverse event (AE), and 3) at least one serious adverse event or withdrawal from the trial due to an adverse event (SAE). The three levels of benefit were defined using both ACR and the EULAR response criteria. Under ACR criteria, the three levels of benefit were defined as 1) less than 20% improvement (none), 2) 20% or 50% improvement (moderate), and 3) 70% improvement or greater (good). Unqualified success was defined as achieving a good response without AE; unmitigated failure as no response with SAE. Chi-square tests assessed the association between benefit and harm, or exact tests where appropriate.

Results:

The trial compared addition of sulfasalazine and hydroxychloroquine or etanercept to methotrexate (MTX) in RA patients with inadequate response. Of the 353 randomized patients, 309 were followed to study completion at 48 weeks and were eligible for analysis. Of those, 226 (73%) experienced adverse events and 46 (15%) experienced serious adverse events.

Under the ACR criteria, 3% patients experienced an unqualified success, while 9% experienced an unmitigated failure. For the 154 patients randomized to triple therapy, the rates were 3 resp. 9% (Table); for the 155 MTX + etanercept the rates were 3 resp. 8% (Table).

Under EULAR criteria, 6% patients experienced an unqualified success while 4% experienced an unmitigated failure. For the triple therapy patients the rates were 4 resp 4%; for the MTX + etanercept patients the rates were 6 resp. 4%.

Benefit by both EULAR and ACR response distributions were significantly associated with the three levels of harm (p=0.008 and p=0.01, respectively): frequency of AE and SAE increased as response decreased. There we no significant differences in associations across treatment groups (p=0.83 and p=0.44 by EULAR and ACR criteria, respectively).

Conclusion:

This is the first study to suggest that in trials the occurrence of harm increases as benefit decreases.

Benefit – ACR Response (%)

Harm (%)	Triple Therapy (n=154) Good	Mod.	None		MTX+Etanercept (n=155) Good	Mod.	None	
None	3	4	3	10	3	8	3	14
AE	14	31	30	74	22	27	23	72
SAE	2	5	9	16	1	4	8	14
	19	40	42		26	39	34
