The interleukin-6 (IL-6) cytokine superfamily (i.e. IL-6, IL-12, and IL-23) plays a major role in the modulation of inflammatory and regulatory pathways during graft versus host disease (GVHD). IL-27, a recently discovered member of this family, is a heterodimeric cytokine that is composed of the p28 and EB13 subunits and signals through a heterodimeric receptor composed of WSX-1 and gp130. Notably, IL-6 also uses gp130 as a signaling component which biologically links IL-27 and IL-6. IL-27 has been shown to have opposing proinflammatory and immunoregulatory effects, but its role in GVHD is not well understood. To define the functional significance of IL-27, lethally irradiated Balb/c (H-2\(^b\)) mice were transplanted with C57BL/6J (H-2\(^b\)) BM and spleen cells, and then treated with an anti-IL-27p28-specific antibody on days 0 and +6. p28 antibody-treated animals had significantly improved weight recovery and overall survival (47\% versus 0\% survival at day 60, p=0.002), as well as reduced numbers of proinflammatory CD4\(^+\) and CD8\(^+\) IFN-\(\gamma\) T cells in GVHD target organs, when compared to isotype control antibody-treated mice. A similar outcome was observed in an MHC-matched, minor antigen disparate model (B6→Balb.B), indicating that this was not a strain-specific phenomenon. Given the similarities between IL-6 and IL-27, we examined whether blockade of IL-27 promoted regulatory T cell (Treg) reconstitution as has been observed with inhibition of IL-6 signaling. Recipients transplanted with BM grafts from B6 Foxp3\(^{EGFP}\) reporter animals and treated with p28 antibody had a significant increase in the number of CD4\(^+\) nTregs, CD4\(^+\) iTregs and CD8\(^+\) iTregs in GVHD target organs, indicating that blockade of IL-27 augmented global Treg reconstitution. In fact, inhibition of IL-27 was more effective at augmenting Treg reconstitution than comparable antibody blockade of IL-6. To further elucidate the role of IL-27, we employed transgenic IL-27\(^{−/−}\) and IL-27R\(^{−/−}\) animals to dissect the relevant contributions of donor and recipient populations. Paradoxically, we observed that transplantation with IL-27\(^{−/−}\) donor grafts exacerbated GVHD mortality and augmented accumulation of proinflammatory T cells, whereas transplantation of recipient IL-27\(^{−/−}\) mice with wild type grafts had no effect on transplant outcomes. This discordance between antibody-based and genetic studies was unexpected and led us to consider whether there were steady state alterations in T cells from IL-27\(^{−/−}\) animals that biased these cells towards a proinflammatory phenotype. To that end, we observed that naive CD8\(^+\) T cells from IL-27\(^{−/−}\) mice had greater IFN-\(\gamma\) production than wild type cells after in vitro polyclonal stimulation and CD4\(^+\) nTregs from these animals had diminished expression of CXCR3 which is critical for Treg trafficking into inflamed tissue sites. Thus, the lack of endogenous IL-27 resulted in intrinsic immune dysregulation which led to an exacerbation of GVHD after transfer of these T cells into recipients. To resolve this paradox, we employed IL-27R\(^{−/−}\) (WSX-1\(^{−/−}\)) mice and demonstrated that mice transplanted with IL-27R\(^{−/−}\) grafts had enhanced weight recovery and survival providing confirmation that blockade of IL-27 signaling reduced GVHD. In addition, using IL-27R\(^{−/−}\) Foxp3\(^{EGFP}\) reporter mice, we observed increased frequencies and numbers of CD4\(^+\) and CD8\(^+\) Foxp3\(^+\) T cells in mice reconstituted with IL-27R\(^{−/−}\) grafts, confirming results observed with p28 antibody blockade. Since IL-10 is a mechanism by which CD4\(^+\) Tregs suppress GVHD and IL-27 has been shown to enhance T cell-derived IL-10 secretion in nontransplant models, we examined whether IL-27 blockade adversely affected IL-10 production by Tregs. Recipients transplanted with marrow grafts from IL-10.BifFoxp3\(^{EGFP}\) dual reporter animals and treated with p28 antibody had a significant reduction in the frequency of IL-10-producing conventional CD4\(^+\) and CD8\(^+\) T cells in GVHD target organs. Notably, however, there was no difference in the frequency of CD4\(^+\) Foxp3\(^+\) IL-10\(^+\) T cells, indicating that blockade of IL-27 signaling preferentially affected conventional T cells and had no adverse effect on CD4\(^+\) Foxp3\(^+\) T cell-derived IL-10 production. In summary, these studies demonstrate that blockade of IL-27 signaling potently augments Treg reconstitution leading to a reduction in the severity of GVHD and may therefore represent a novel strategy to reduce mortality from this disease in man.
