(1) SUMMARY (196 words)

Phylloquinone (PhQ) or Vitamin K₁ is an essential electron carrier (A₁) in photosystem I (PSI). In the green alga *Chlamydomonas reinhardtii*, which is a model organism for photosynthesis study, a detailed characterization of the pathway is missing with only one mutant deficient for MEND that has been analyzed. We took advantage of the fact that a double reduction of plastoquinone occurs in anoxia into the A₁ site in the *mend* mutant, interrupting photosynthetic electron transfer, to isolate four new phylloquinone-deficient mutants impaired in *MENA*, *MENB*, *MENC* (*PHYLLO*) and *MENE*. Compared to wild-type and complemented strains for *MENB* and *MENE*, the four *men* mutants grow slowly in low light and are sensitive to high light. When grown in low light, they show a reduced photosynthetic electron transfer due to a specific decrease of PSI. Upon exposure to high light for a few hours, PSI becomes almost completely inactive, which leads in turn to lack of phototrophic growth. Loss of PhQ also fully prevents reactivation of photosynthesis after dark anoxia acclimation. *In silico* analyses allowed us to propose a PhQ biosynthesis pathway in *Chlamydomonas* that involves eleven enzymatic steps from chorismate located in the chloroplast and in the peroxisome.

(2) SIGNIFICANCE STATEMENT (25 words)

Chlamydomonas phylloquinone-deficient mutants impaired in *MENA*, -B, -C, and -E activities are light-sensitive, primarily affected in photosystem I, and unable to initiate photosynthesis in anoxia.

(3) INTRODUCTION (1058 words)

1
2
3
4 1
5 2 In cyanobacteria, algae and land plants, photosynthetic electron transfer is driven by two
6 3 large intrinsic protein complexes, photosystem I (PSI) and photosystem II (PSII)
7 4 embedded in the thylakoid membrane. Each PS possesses several cofactors, including
8 5 quinones (benzoquinone or naphthoquinone derivatives) required for electron transfer.
9 6 Plastoquinones (PQ) are benzoquinone derivatives (PQ) located in PSII (two binding
10 7 sites, Q_A and Q_B) and in the PQ pool. PQ is doubly reduced into plastoquinol (PQH₂) at
11 8 Q_B site and diffuses in the membrane to join PQ pool allowing then the reduction of
12 9 cytochrome *b₆f* complex (cyt *b₆f*) (Rochaix, 2002). In contrast, naphthoquinone
13 10 derivatives participate to electron transfer within PSI. PSI is composed of two core
14 11 subunits, PsaA and PsaB, containing 11 transmembrane domains and forming the
15 12 heterodimeric reaction center that coordinate cofactors required for electron transfer
16 13 (Rochaix, 2002). The primary PSI electron donor is a dimer of chlorophyll a (P₇₀₀)
17 14 located on the luminal side of the membrane. Electron transfer from P₇₀₀ to ferredoxin
18 15 occurs via chlorophyll A₀, naphthoquinone A₁ and three iron-sulfur centers [4Fe-4S]
19 16 noted F_X, F_A and F_B. Two naphthoquinones are present by P₇₀₀ and allow electron
20 17 transfer from A₀ to F_X by two branches (A and B) (Joliot and Joliot, 1999; Guergova-
21 18 Kuras et al., 2001). To date three types of 2-methyl-1,4-naphthoquinone derivatives,
22 19 also known as vitamin K, have been identified in different oxygenic photosynthetic
23 20 organisms. They share the same naphthalene nucleus but differ in the prenyl side-chain
24 21 attached in position 3: menaquinone-4 (MK-4, vitamin K₂) found in bacteria, diatoms
25 22 and red algae (Yoshida et al., 2003; Ikeda et al., 2008) has a fully unsaturated C₂₀
26 23 isoprenoid side-chain; phylloquinone (PhQ, vitamin K₁) found in most cyanobacteria,
27 24 green algae and land plants, has a phytyl side-chain (partially saturated C₂₀ prenyl)
28 25 while 5'-monohydroxyphylloquinone (OH-PhQ) is found in *Euglena gracilis* and in
29 26 some cyanobacteria like *Synechococcus elongatus* (Law et al., 1973; Omata and Murata,
30 27 1984). Some species such as the green microalga *Chlamydomonas reinhardtii* possess
31 28 two types of naphthoquinones: PhQ and OH-PhQ (Ozawa et al., 2012). In *C.*
32 29 *reinhartii*, PhQ and OH-PhQ account for 10 and 90% of the total naphthoquinone
33 30 content, respectively. Both are functional and contribute to the photosynthetic electron
34 31 transfer (Ozawa et al., 2012).

1 The conversion of chorismate to menaquinone has been characterized in details in
2 bacteria over the past decade (Meganathan, 2001; Jiang et al., 2007; Jiang et al., 2008;
3 Chen et al., 2013). Since the different types of naphthoquinones are structurally close,
4 most of the components of the phyloquinone biosynthesis pathway in the
5 cyanobacteria *Synechocystis* sp. PCC 6803 have been identified by searching the
6 cyanobacterial genome using bacterial genes as queries. In *Synechocystis*, nine
7 enzymes, characterized by reverse genetics, catalyze the same steps as those required
8 for synthesis of menaquinone: MenF (isochorismate synthase), MenD (2-succinyl-5-
9 enolpyruvyl-6-hydroxy-3-cyclohexene-1-carboxylic acid (SEPHCHC) synthase), MenH
10 (2-succinyl-6-hydroxy-2,4-cyclohexadiene-1-carboxylate (SHCHC) synthase), MenC
11 (*o*-succinylbenzoic acid synthase), MenE (*o*-succinylbenzoyl-CoA ligase), MenB (1,4-
12 dihydroxy-2-naphthoate (DHNA) synthase), Slr0204 (1,4-dihydroxy-2-naphthoate
13 (DHNA)-CoA thioesterase), MenA (DHNA phytyltransferase), and MenG
14 (methyltransferase) (Johnson et al., 2000; Johnson et al., 2001; Widhalm et al., 2009)
15 (Table 1).

16 In *Synechocystis*, inactivation of *menA*, *-B*, *-D* and *-E* genes leads to the complete
17 absence of phyloquinone, which is replaced by PQ in the A₁ site of PSI (Johnson et al.,
18 2000; Semenov et al., 2000; Johnson et al., 2001; Johnson et al., 2003). This
19 substitution leads to a delayed electron transfer from A₁⁻ to F_X because the redox
20 potential of PQ in the A₁ site is more oxidizing than native PhQ, rendering the electron
21 transfer thermodynamically unfavorable. These mutants grow slowly under low light
22 conditions and are sensitive to high light. In contrast, inactivation of *menG*, the last
23 enzyme of the phyloquinone biosynthetic pathway, results in the accumulation of
24 demethylphyloquinone which replaces PhQ in PSI (Sakuragi et al., 2002). The *menG*
25 mutant is characterized by a normal growth although electron transfer from A₁⁻ to F_X is
26 three times slower. All *Synechocystis men* mutants are characterized by a decreased
27 PSI/PSII ratio but only under high light for *menG*.

28 Mutants deficient in PhQ biosynthesis pathway have also been identified in
29 photosynthetic eukaryotes. In *Arabidopsis thaliana*, inactivation of *ABC4* (*menA*
30 homolog) leads to a significant decrease of PSII and PSI content, and PQ level is
31 reduced to 3% (Shimada et al., 2005). Mutants in *PHYLLO* gene (which encodes a
32 fusion of four eubacterial *men*-homologous regions corresponding to

1 *menF/menD/menC/menH* genes) have drastically reduced PSI levels (5-15%) with
2 nearly normal levels of PSII and accumulate 55% of PQ (Gross et al., 2006). Mutants
3 deleted for the *AAE14* gene (*menE* homolog), *ABC4* and *PHYLLLO*, exhibits a seedling-
4 lethal phenotype (Kim, 2008). In contrast, *Arabidopsis menG*-homologous deficient
5 mutant is viable because, like in *Synechocystis*, demethylphyloquinone acts as PhQ
6 substitute in PSI (Lohmann et al., 2006). Last year, it was established in *Synechocystis*
7 and *Arabidopsis* that the biosynthesis of phyloquinone has an additional step : the
8 reduction of the demethylphyloquinone ring by a type-II NADPH dehydrogenase
9 named NdbB in *Synechocystis* and NDC1 in *Arabidopsis* prior to its transmethylation
10 by MenG (Fatihi et al., 2015). *Synechocystis ndbB* and *Arabidopsis ndc1* mutants
11 display increased photosensitivity to high light like phyloquinone-deficient mutants
12 previously characterized in these organisms.

13
14 In the green alga *C. reinhardtii*, which is a model organism for the study of the
15 photosynthetic machinery (Hippler et al., 1998), characterization of PhQ biosynthetic
16 pathway is still partial. Up to now, only one mutant, deficient for MEND protein was
17 characterized (Lefebvre-Legendre et al., 2007). Inactivation of *MEND* in *C. reinhardtii*,
18 like in *Synechocystis* sp. PCC 6803 (Johnson et al., 2003), leads to the complete loss of
19 PhQ and its replacement by PQ in PSI. However, accumulation of PSI is not affected in
20 this mutant and the absence of PhQ rather causes a decrease in the size of the
21 plastoquinone pool and of synthesis of PSII subunits.

22 The phenotype of the only mutant isolated in *C. reinhardtii* is thus neither closed to the
23 one described in cyanobacteria neither to the one of land plants. This observation
24 prompted us to isolate new mutants of the phyloquinone biosynthetic pathway in *C.*
25 *reinhardtii*. In anoxia, a double reduction of PQ into PQH₂ in the A₁ site occurs in the
26 *mend* mutant interrupting photosynthetic electron transfer (Lefebvre-Legendre et al.,
27 2007; McConnell et al., 2011). In this work, we took advantage of this photosynthetic
28 deficiency in anoxia to isolate four new *Chlamydomonas* mutants affected in one of the
29 enzymatic steps of phyloquinone biosynthesis pathway (MENA, MENB, MENC and
30 MENE).

31
32

(4) RESULTS (2298 words)

A peculiar chlorophyll induction curve is specific for identification of phylloquinone-deficient mutants

In *C. reinhardtii* genomic database (v5.5 on Phytozome), nine sequences corresponding to nine of the ten enzymatic steps required for phylloquinone biosynthesis pathway in cyanobacteria and land plants were found (Table 1). Genomic sequences coding for MENF, MEND, MENC and MENH enzymatic domains are located in a single ORF, named *PHYLLO* by similarity to gene organization in *Arabidopsis thaliana* (Gross et al., 2006), and likely coding for a tetramodular enzyme. We did not find any homolog to the DHNA-CoA thioesterase performing the seventh step of the pathway in cyanobacteria and land plants but a putative candidate (TEH4) is suggested (see discussion).

To isolate new strains deficient in phylloquinone biosynthesis in *C. reinhardtii*, we screened 13,250 hygromycin-resistant (Hyg^R) transformants and 3,500 paromomycin-resistant (Par^R) transformants by an *in vivo* chlorophyll fluorescence imaging screening protocol. The screening procedure is based on the observation that a double reduction of PQ in PQH_2 into the A_1 site occurs in a *mend* mutant in anoxia interrupting photosynthetic electron transfer (McConnell et al., 2011). We thus recorded chlorophyll fluorescence induction curves of transformants after prolonged dark anoxic incubation. As previously described (Godaux et al., 2013), for dark anoxic acclimated wild-type cells, F_0 is close to F_M which indicated that the PSII acceptor pool (Q_a , PQ) is largely reduced. Upon illumination, the fluorescence yield reaches a maximal transient value in a few ms and then it decreases to a steady-state value after ~ 1 s. The value of the photosystem II efficiency (Φ_{PSII}), determined after 3 s of illumination by addition of a saturating pulse reached 0.5 (Figure 1a). Conversely, the electron transfer was blocked from the very beginning of illumination in *mend* mutant and Φ_{PSII} after 3 s of illumination is null (Figure 1a). We isolated here five Hyg^R (AL2, AO1, AO2, AS1, AS2) and two Paro^R mutants (24.1, 25.1) with a similar chlorophyll fluorescence induction curve to *mend* (Figure 1b). In contrast, the behaviour of these mutants is

1 almost identical to wild type in control conditions (oxic) (Figure 1c). This suggested
2 that these mutants were specifically impaired in phylloquinone biosynthesis.

3
4 To determine whether the fluorescence phenotype of these mutants was linked to the
5 antibiotic-resistance cassette, a genetic cross between each mutant of mating-type plus
6 (mt^+) was performed with wild-type strain of the opposite mating type (mt^-) and
7 phenotype of the meiotic progeny was analyzed (Table S1). For four mutants (AO1,
8 AS1, AS2 and 25.1) all meiotic products that were resistant to antibiotic also showed
9 mutant fluorescence phenotype, while all meiotic products that were sensitive to the
10 presence of antibiotics behaved like wild type. In addition, around half of the meiotic
11 progeny was resistant to antibiotics in each of the four crosses. This suggested that a
12 unique functional cassette was linked to the phenotype of each individual mutant. In
13 contrast, the presence of four classes of meiotic products in the progeny of AL2, AO2,
14 and 24.1 indicated that the fluorescence phenotype was not directly linked to the
15 insertion of the cassettes. As a consequence, these mutants (AL2, AO2 and 24.1) were
16 discarded. To confirm that only one cassette was inserted in the genome of AO1, AS1,
17 AS2 and 25.1 mutants, DNA gel-blot analysis was carried out on the four tagged mutant
18 strains with specific probes against *APHVII* (for AO1, AS1 and AS2 mutants) and
19 *APHVIII* (for 25.1 mutant) cassettes. As only one fragment was revealed after
20 hybridization, we concluded that each mutant contained a single copy of the resistance
21 cassette in its nuclear genome (Figure 2a). To determine genomic DNA sequences
22 flanking the insertion cassette for each individual mutant, we performed thermal
23 asymmetric interlaced (TAIL) PCR and the resulting PCR products were sequenced
24 (Figure S1). A detailed description of this analysis is given in Appendix S1 and
25 summarized in Figure 2b. In brief, the four mutants are all affected in one of the genes
26 of the putative phylloquinone biosynthetic pathway in *Chlamydomonas*: *MENA* (AS2,
27 *mena* mutant), *MENB* (AS1, *menb* mutant), *PHYLLO* (AO1, *menc* mutant) and *MENE*
28 (25.1, *mene* mutant).

29
30 We then aimed at obtaining complemented strains as an additional proof of phenotype.
31 To this end, we amplified *MENB* (4,865 bp) and *MENE* (4,177 bp) genes and their
32 flanking regions (Figure S2). We could not however amplify *MENA* (3,136 bp).

1 Concerning *PHYLLO* (15.7 kb), we did not try to amplify the corresponding gene
2 because it was too long to be amplified by PCR. *menb* cells and *mene* cells were then
3 co-transformed using the appropriate selection marker (*APHVIII* and *APHVII*,
4 respectively) and the PCR product containing *MENB* or *MENE* gene, respectively.
5 Transformants were selected on medium containing both hygromycin and paromomycin
6 and co-transformants which have incorporated and expressed the second marker (either
7 *MENB* or *MENE*) were selected on the basis of their restored wild-type fluorescence
8 pattern after acclimation to dark anoxic conditions (Figure S3). One complemented co-
9 transformant was selected for each strain, and called *menbR* and *meneR*, respectively.

11 **Absence of phyloquinone in the *men* mutant strains**

13 To determine the impact of *mena*, *menb*, *menc* and *mene* mutations on phyloquinone
14 abundance, pigments were extracted from lyophilized cells and analysed by UPLC-MS.
15 The elution profile of the *men* mutant cell extracts was compared with those of wild-
16 type and complemented cell extracts. Because about 90% of the total amount of
17 naphthoquinones in *C. reinhardtii* is present as OH-PhQ (Ozawa et al., 2012), we
18 decided to focus on the detection of this form. OH-PhQ whose determined m/z values of
19 non-adduct form and Na⁺ adduct form are respectively 467.35 and 489.33, was detected
20 as a single peak at 8.06 min of the chromatogram of wild-type and complemented cell
21 extracts. This peak was missing in the *men* mutant cell extracts (Figure 3) indicating
22 loss of OH-PhQ.

24 **Light response of phyloquinone-deficient mutants**

26 Since the previously isolated *Chlamydomonas mend* mutant is light sensitive (Lefebvre-
27 Legendre et al., 2007), we analyzed the growth of *mena*, *menb*, *menc*, *mend* and *mene*
28 mutant strains in the presence (TAP medium) or in the absence (TMP medium) of
29 acetate. We emphasized on comparing growth at low and high light intensities for
30 mutant and control strains. After 3 days of illumination, all mutants grew more slowly
31 than wild-type and complemented strains, whatever the medium and the light conditions
32 used (Figure 4). At day 7, this delayed growth is not observed anymore on acetate

1 medium (TAP) in the dark and under low light ($25 \mu\text{mol photons m}^{-2} \text{s}^{-1}$) but is still
2 visible in the other conditions, *e. g.* under higher light (125 and $300 \mu\text{mol photons m}^{-2} \text{s}^{-1}$)
3 ¹) in the presence (TAP) or in the absence (TMP) of acetate in the medium. In addition,
4 it has been shown that growth of *mend* could be partially restored by addition of
5 exogenous phylloquinone at high light intensities (Lefebvre-Legendre et al., 2007). This
6 was also the case for *menb*, *menc* and *mene* mutants, suggesting that the three mutants
7 are auxotrophic for PhQ. In contrast, the addition of exogenous PhQ had no effect on
8 the growth of *mena* mutant (Figure 4).

10 **Reorganization of the photosynthetic apparatus in the absence of phylloquinone**

12 In order to investigate the impact of the lack of phylloquinone on photosynthesis, we
13 first determined the content of active PSI and PSII in mutant and control strains by a
14 spectroscopic approach based on the magnitude of the electrochromic shift (ECS)
15 induced by a charge separation (Bailleul et al., 2010). We observed a decrease of 30-
16 40% of active PSI centers in all mutant strains (Figure 5a). This decrease in active PSI
17 content was further confirmed by assessing the relative concentration of P_{700} by redox
18 difference spectroscopy (Figure S4) and by immunoblotting on western blot against
19 PsaA protein (Figure 5c). Similarly, in line with previous immunoblotting experiments
20 against PSII core proteins D1 and D2 (Lefebvre-Legendre et al., 2007), the amount of
21 active PSII (Figure 5a) and core antenna subunit Cp43 (Figure 5c) was very low in the
22 *mend* mutant. Conversely, no decline in PSII centers was observed in the four *men*
23 mutants identified in this work (Figure 5a and Figure 5c).

25 To gain information on excitation energy distribution between PSI and PSII, we also
26 recorded 77K fluorescence emission spectra of whole *C. reinhardtii* cells. Excitation in
27 the Chlorophyll Soret band produces PSII and PSI fluorescence bands at 685 and 715
28 nm, respectively, each band resulting from fluorescence emission of different forms of
29 PS-LHC supercomplexes [*e.g.* ranging from 708 to 715 nm in the case of PSI (Drop et
30 al., 2011)]. In *men* mutant cells frozen to 77 K under the white low light used for
31 growth, the relative amplitude of 715 nm peak was larger than in wild-type and
32 complemented strains (Figure 5g). This result suggests a relative increase in PSI

1 antenna size in *men* mutant cells due to (i) a larger light-harvesting complexes I (LHCI)
2 or (ii) an association of LHCII to PSI (*i.e.* a transition to state II due to a more reduced
3 state of the plastoquinone (PQ) pool (Wollman, 2001). To test these hypotheses, we
4 treated the cells with DCMU to inhibit PSII and to reoxidize the PQ pool in the light,
5 thus allowing association of LHCII back to PSII (*i.e.* transition to state 1) (Cardol et al.,
6 2003). In wild-type and complemented strains, this treatment leads to a full transition to
7 state 1, detected as a decrease of the relative amplitude of the 715 nm band. In contrast,
8 DCMU-treated *men* cells still show a higher emission at 715nm relative to 685 nm. To
9 confirm this result, we measured PSI antenna size at state I using ECS (Bailleul et al.,
10 2010; Takahashi et al., 2013). The initial slope of the ECS changes measured in
11 continuous light and in the presence of DCMU (to inhibit PSII) can be used to probe the
12 absorption cross-section of PSI because it is proportional to the light intensity (Figure
13 S5a). An increase in PSI antenna size was observed in all *men* mutants compared to
14 controls strains (20-50 % increase) (Figure 5h). In parallel, PSII antenna size was
15 estimated from mid-rise values of the chlorophyll fluorescence transients measured in
16 continuous light and in the presence of DCMU at state 1 (Figure S5b). PSII antenna size
17 remained unchanged, at the exception of *mend* (70 % increase) (Figure 5h).

18
19 We finally explored the impact of the imbalance in PSI/PSII stoichiometry and antenna
20 size of *men* mutants on the relative electron transfer rate at PSII level ($rETR_{II}$). When
21 cultivated in low light, *men* mutants exhibited a significant decrease of $rETR_{II}$ compared
22 to wild-type and complemented strains (Figure 5e). A decrease of ~ 30% is observed for
23 *mena* and *menb* mutants and of ~ 60% for *menc*, *mend* and *mene* mutants.

24
25 So far all spectroscopic experiments were carried out on algae grown under low light. In
26 these conditions, *men* mutants are still able to grow (Figure 4) even if a decrease in the
27 number of active PSI centers limits the photosynthetic electron flow. In contrast mutants
28 are unable to grow under high light. We thus assumed the existence of additional
29 deleterious effects on the photosynthetic chain in algal cells under high light. To test
30 this hypothesis, wild-type and mutants cells were grown in low light (25 $\mu\text{mol photons}$
31 $\text{m}^{-2} \text{s}^{-1}$) and then transferred for four hours at high light intensity (400 $\mu\text{mol photons}$
32 $\text{m}^{-2} \text{s}^{-1}$). After 4 hours in high light, the content of active PSI centers remained relatively

1 constant in WT and complemented strains, but it progressively decreased over time in
2 *mena*, *menb*, *menc* and *mene* to less than 10% of controls and in *mend* by half (Figure
3 5b and S6). Conversely, the amount of active PSII centers already fell at a steady level
4 after one hour in high light in control strains (40-60% decrease) and *men* mutants (70-
5 80% decrease) (Figures 5b and S6), indicating a more pronounced PSII photoinhibition
6 in all *men* strains. Consistently, rETR_{II} was drastically reduced in all *men* strains after
7 four hours under high light (~ 20% of the wild-type) (Figure 5f).

8 To determine whether the decrease in the number of active PS is associated with a
9 decrease in the total amount of PS per cell, or a loss of activity of PS centers present
10 after exposure to high light (4 hours), the amount of core subunit PsaA (PSI) and core
11 antenna subunit Cp43 (PSII) were compared to the amount of cytochrome *f*
12 (cytochrome *b₆f* complex) by immunodetection on western blot on total cell extracts
13 (Figure 5d). PsaA content was lower in all *men* mutants but this decrease was not
14 especially more pronounced in comparison to the decrease in the amount of PsaA
15 observed for low light-adapted *men* mutant cells. We concluded that the decrease of
16 rETR_{II} in *men* mutant exposed to high light is thus due to a specific PSI photoinhibition.

17
18 It is to note that *mend* mutant behaves slightly differently. Its PSII content is much
19 lower in low light (Figures 5a and 5c), which is in agreement with its original
20 description (Lefebvre-Legendre et al., 2007). Upon exposure to high light, this reduced
21 PSII content might limit electron flow to PSI which translates into a lower PSI
22 photoinhibition compared to other *men* mutants (Figure 5b). In principle both *menc* and
23 *mend* mutants should be affected in the whole *PHYLLLO* locus and thus should behave
24 exactly the same. As a matter of proof, a RT-PCR experiment indicated that the mRNA
25 segment corresponding to MENC-MENH domain is absent in *mend* mutant, as in *menc*
26 mutant (Figure S7). We tried to determine if a secondary mutation could be responsible
27 of the partly rescued phenotype of *mend* but unfortunately it was impossible to cross
28 *mend* with our wild-type reference strains. We postulate that *mend* mutant (Lefebvre-
29 Legendre et al., 2007) has been subject to adaptations that led to the observed decrease
30 in PSII content and consequently to a lower PSI photoinhibition (Figures 5a, 5b and
31 S6), and a better growth (Figure 4).

6 **Phylloquinone biosynthesis pathway might comprise eleven enzymatic steps**
7 **located in the chloroplast and in the peroxisome**

9 *C. reinhardtii* genomic data (Table 1) indicate that the biosynthesis pathway of
10 phylloquinone (PhQ) from chorismate comprises homologs for nine of the ten
11 consecutive enzymatic steps involved in PhQ biosynthesis in *Synechocystis sp.* PCC
12 6803 and in *Arabidopsis thaliana* (Fatihi et al., 2015). We did not find any obvious
13 homolog of the cyanobacterial and plant DHNA-CoA thioesterase nor in
14 *Chlamydomonas* neither in other green algae (e.g. *Chlorella vulgaris* C-169, *Chlorella*
15 *sp.* NC64A, *Volvox carteri*). It is to note that the plant and cyanobacteria DHNA-CoA
16 thioesterases are not encoded by homologous genes, the plant version originating from a
17 horizontal gene transfer with a bacterial species (Widhalm et al., 2012). Altogether, this
18 suggests that another thioesterase might operate in PhQ biosynthesis pathway of green
19 algae. Among the large family of thioesterases in *Chlamydomonas reinhardtii*, TEH4
20 (Cre07.g323150) is a possible candidate because it possesses the hot-dog domain
21 typical of DHNA-CoA thioesterase (Furt et al., 2013), a putative binding site for Co-
22 enzyme A, and a peroxisomal targeting sequence (PTS) (see below for further
23 discussion). In flowering plants, genetic approaches identified the *PHYLLO* locus
24 which codes for a multienzyme composed of four fused eubacterial *men*-homologous
25 modules corresponding to MenF/MenD/MenC/MenH proteins, respectively (Gross et
26 al., 2006). Homology searches revealed the existence of cluster *PHYLLO* orthologues in
27 green algae, mosses, diatoms and red algae (Gross et al., 2006). The C-terminal region
28 bearing the chorismate binding site is absent from *PHYLLO* MENF module in
29 *Arabidopsis*, and isochorismate synthase (ICS) activity is performed by *ICS1* and *ICS2*
30 gene products (Gross et al., 2006; Garcion et al., 2008). *PHYLLO* then catalyzes
31 consecutive reactions (MEND, C, and H) that lead to the synthesis of *o*-
32 succinylbenzoate (Gross et al., 2006). In contrast to *Arabidopsis* *PHYLLO* protein, *C.*

1
2
3
4 1 *reinhardtii* nuclear genome likely encodes a PHYLLLO tetramodular enzyme that would
5 2 exhibit a full MENF chorismate binding domain that might be functional (Figure 2b and
6 3 S8). Accordingly, we thus assume that our *Chlamydomonas* mutants are impaired in the
7 4 fourth (MENC), the fifth (MENE), the sixth (MENB), and the eighth (MENA)
8 5 enzymatic steps of PhQ biosynthesis (Figure 7). The previously characterized *mend*
9 6 mutant (Lefebvre-Legendre et al., 2007) would be impaired in the second step. Even if
10 7 the existence of a tetramodular PHYLLLO enzyme remains to be demonstrated beyond
11 8 genomic evidences, it is however reasonable to consider at this stage that *menc* and
12 9 *mend* mutants are impaired in the function of the whole PHYLLLO multienzyme (*i.e.*
13 10 including MENF and MENH activities).

14 11 Ultimately, four steps remain to be characterized by genetic approaches in
15 12 *Chlamydomonas*: the step 7 is the putative DHNA-CoA thioesterase TEH4; the step 9
16 13 would be performed by the type II NADPH dehydrogenase NDA5 which is the
17 14 homolog of *Arabidopsis* NDC1 and *Synechocystis* NdbB (Desplats et al., 2009); step 10
18 15 is probably performed by the MENG homolog, and an ultimate additional step (step 11)
19 16 of hydroxylation of PhQ to OH-PhQ, specific to some microalgae like *Chlamydomonas*
20 17 *reinhardtii* and *Euglena gracilis* (Ziegler et al., 1989; Ozawa et al., 2012) remains also
21 18 to be elucidated. In this regard, two Cytochrome P450-dependent PhQ hydroxylase have
22 19 been recently identified (CYP4F2 and CYP4F11) in human (Edson et al., 2013). A
23 20 putative homolog (CYP25, Cre08.g373100) is present in *Chlamydomonas* (Figure S9)
24 21 and could fulfill the role.

25 22
26 23 Localisation of the phylloquinone biosynthesis pathway in *Chlamydomonas* is also
27 24 unknown. Mainly originating from the cyanobacterial ancestor, most of the proteins
28 25 involved in biosynthesis of PhQ in *Arabidopsis* are located in chloroplast (Shimada et
29 26 al., 2005; Gross et al., 2006; Lohmann et al., 2006; Garcion et al., 2008; Kim, 2008).
30 27 MenE/AAE14 has however a dual localization in chloroplast and peroxisome (Kim,
31 28 2008; Babujee et al., 2010), while MenB/NS and DHNA-CoA thioesterases are targeted
32 29 to the peroxisome (Reumann et al., 2007; Babujee et al., 2010) (Widhalm et al., 2012).
33 30 Here we took advantage of the recent identification of PTS motifs in *C. reinhardtii*,
34 31 which are similar to *Arabidopsis* PTS (Lauersen et al., 2016), to identify three PTS
35 32 sequences among *Chlamydomonas* peptide sequences discussed in this work : a PTS1

1 (SRL) in MENE and TEH4 C-terminal parts (position 732-734 and 201-203,
2 respectively), and a PTS2 in MENB N-terminal part (RLqvlslnHL at position 7-15). This
3 suggests that in *Chlamydomonas* like in *Arabidopsis*, this part of the biosynthetic
4 pathway also occurs in the peroxisome but this hypothesis remains to be confirmed by
5 subcellular localisation experiments. Altogether, our results suggest that localization of
6 the steps involved in PhQ biosynthesis pathway in *Chlamydomonas* (Figure 7) might be
7 very similar to the one previously described in land plants (Fatihi et al., 2015), and that
8 there is no alternative route for PhQ synthesis in *Chlamydomonas*. We thus propose that
9 chorismate is converted into *o*-succinylbenzoate by the first four enzymatic steps
10 (PHYLLO) in the chloroplast. Then, *o*-succinylbenzoate would be exported to the
11 peroxisome where the succinyl chain would be activated by ligation with CoA and
12 cyclised to yield 1,4-dihydroxy-2-naphthoyl(DHNA)-CoA. After DHNA-CoA hydrolysis
13 by an unknown thioesterase possibly located in the peroxisome, the naphthoquinone
14 ring would be conjugated to a phtyl chain. At last, demethylphyloquinone precursor
15 would be reduced in demethylphyloquinol form, methylated into PhQ, and
16 hydroxylated into OH-PhQ in the chloroplast (Figure 7).

17 18 **Lack of phyloquinone primarily affects PSI activity**

19
20 Phyloquinone (or Vitamin K₁) is an essential electron carrier in PSI. As previously
21 demonstrated in *Chlamydomonas* and *Synechocystis*, plastoquinone (PQ) might replace
22 the missing phyloquinone in the A₁ site of PSI, rendering the electron transfer from A₁⁻
23 to F_X thermodynamically unfavourable (Semenov et al., 2000; Lefebvre-Legendre et al.,
24 2007; McConnell et al., 2011). In this work, we identified and characterized four new *C.*
25 *reinhardtii* nuclear insertion mutants deficient for 5'-monohydroxyphyloquinone (OH-
26 PhQ), the predominant form of naphthoquinone in this species (Ozawa et al., 2012). All
27 *Chlamydomonas men* mutants [including *mend* previously characterized (Lefebvre-
28 Legendre et al., 2007)] can grow photoautotrophically under moderate light (25 μmol
29 photons m⁻² s⁻¹) but are high light-sensitive. *Arabidopsis abc4* (MENA), *phyllo*
30 (PHYLLO MENDCH), *aae14* (MENE) and double knockout *ics1/ics2* (MENF) mutants
31 are also characterized by loss of phototrophy and seedling lethal phenotype even in low
32 light but it is not known if missing PhQ is replaced by PQ in this species (Shimada et

1 al., 2005; Gross et al., 2006; Garcion et al., 2008; Kim, 2008). The *Arabidopsis* MENG
2 and NDC1 mutants are the sole viable PhQ-deficient mutants in plants (Lohmann et al.,
3 2006; Fatihi et al., 2015). *Synechocystis* and *Arabidopsis meng* and *ndc1* mutants
4 accumulate demethylphyloquinone which replaces PhQ and allows less efficient PSI-
5 mediated electron transfer (Lohmann et al., 2006; Fatihi et al., 2015). Addition of
6 vitamin K₁ in the medium allows to partially restore the growth of *Chlamydomonas men*
7 mutants in high light, at the exception of *mena* (Figure 4). Although we cannot exclude
8 the possibility that the inability of *Chlamydomonas mena* mutant to recover in the
9 presence of vitamin K₁ is due to the partial deletion in the *HEL22* gene (coding for a
10 DNA helicase RecQ), the fact that *Synechocystis mena* mutant is also unable to grow on
11 medium supplemented with several naphthoquinone analogs (Johnson et al., 2001)
12 rather suggests that MENA activity might be critical in the assimilation of exogenous
13 phyloquinone. In this respect, it was demonstrated that *Mycobacterium tuberculosis*
14 treated with a MenA inhibitor could not be rescued completely at high concentrations of
15 exogenous vitamin K₂ (Kurosu and Begari, 2010). We thus hypothesize that the phytyl
16 tail of exogenous PhQ is altered during its assimilation by the cells and that MENA is
17 required to replace the altered phytyl chain. Although this activity has not been yet
18 demonstrated in photosynthetic organisms, the human MenA homolog (UBIAD1) has
19 both side-chain cleavage and prenylation activities (Nakagawa et al., 2010).

20
21 In *Chlamydomonas*, the main consequence of PhQ loss in *menc* (*phyllo*), *mene*, *menb*,
22 and *mena* mutants on the organization of the photosynthetic electron transfer chain is a
23 decrease in the amount of functional PSI. This is consistent with the reduced PSI
24 amount in *Synechocystis* mutants (Johnson et al., 2000; Sakuragi et al., 2002; Johnson et
25 al., 2003). Replacement of PhQ by PQ leads to a reduced rate of electron transfer from
26 A₁ to F_X (Lefebvre-Legendre et al., 2007; McConnell et al., 2011). In this respect, the
27 specific increase in PSI antenna size in *men* mutants could represent a compensation
28 mechanism linked to the decrease in the amount of active PSI centers. It was previously
29 shown that polypeptides of PSI light harvesting complex (LHCA) accumulate at
30 different levels and, it was suggested that flexibility in LHCA composition would allow
31 adaptation of PSI antenna configuration to the prevailing environmental conditions
32 (Stauber et al., 2009). PSII efficiency and maximum electron rate are however

1 diminished proportionally to PSI decrease in *Chlamydomonas men* mutants and these
2 effects are exacerbated at higher light intensity where additional effects are observed like
3 PSII photoinhibition. Such PSII photoinhibition under high light has been also
4 observed in *Arabidopsis meng* mutant (Lohmann et al., 2006). In high light, PSI activity
5 in *men* mutants is obviously limited from acceptor side, a situation which has been
6 described to lead to PSI photoinhibition and destruction in many studies (Munekage et
7 al., 2002; Sommer et al., 2003; Tikkanen et al., 2015). Additionally, the redox state of
8 the PQ pool is more reduced in high light and PQH₂ might occupy PS1 A₁ site in *men*
9 mutant, as previously proposed in dark-anoxic conditions (McConnell et al., 2011). This
10 might in turn further limit electron transfer and promote photoinhibition.

12 **Critical role of phylloquinone in photosynthetic electron transfer in anoxia**

14 The four *men* mutants isolated and described in this work were identified by an *in vivo*
15 chlorophyll fluorescence imaging screen based on photosynthetic induction curves
16 following transition from dark anoxia to light (Godaux et al., 2013). This *in vivo*
17 chlorophyll fluorescence screen was originally used to detect mutants impaired in H₂
18 photoproduction (Godaux et al., 2013), a process that enables algae to initiate their
19 photosynthetic electron transport chain after anoxic incubation when electron acceptor
20 availability is scarce (Ghysels et al., 2013; Godaux et al., 2013; Clowez et al., 2015).
21 The fluorescence transient observed for hydrogenase-deficient *hyd-2* mutant cells upon
22 the first second of illumination in anoxia (Figure 6a) (Godaux et al., 2013) reflects the
23 reduction phase of PSI acceptors (oxidized ferredoxin and NADP⁺). Conversely, the
24 lack of chlorophyll fluorescence changes for *men* mutant in anoxia probably indicates
25 the absence of electron transfer between P700⁺ and ferredoxin. This is in agreement
26 with the proposal that PQH₂ replaces PhQ in the A₁ site of PSI in anoxia and prevents
27 photosynthetic electron transfer in *mend* mutant (McConnell et al., 2011). As a result,
28 long term reactivation (>5 min) of PSII electron transfer in anoxia, which relies on both
29 PSI-dependant hydrogenase activity and PGRL1-dependant PSI cyclic electron flow in
30 *Chlamydomonas* wild-type cells (Godaux et al., 2015), is fully compromised in *men*
31 mutant (Figure 6b). PhQ loss thus severely impairs electron transfer in anoxia in our
32 *men* mutants, as it was already shown in *mend* mutant (Lefebvre-Legendre et al., 2007;

1
2
3
4 1 McConnell et al., 2011). Overall these results indicate that the presence of PhQ as PSI
5 2 A₁ cofactor is critical in photosynthetic organisms that encounter O₂-deprived
6 3 conditions on a regular basis.
7
8
9 4
10 5

6 (6) EXPERIMENTAL PROCEDURES (1274 words)

8 **Strains and growth conditions**

9
10 The 4A⁺ (*mt*⁺) and 2' (*mt*⁻) wild-type strains used for transformation and genetic
11 crosses, respectively, derive from 137c reference wild-type strain. The *mend* mutant
12 (Lefebvre-Legendre et al., 2007) was provided by Kevin Redding (Arizona State
13 University, United States). *C. reinhardtii* strains were grown in Tris-acetate-phosphate
14 (TAP) medium (Harris et al., 1989) at 25°C under continuous white light (25 μmol
15 photons m⁻² s⁻¹), either on solid (1.5% agar) or liquid medium.
16

17 **Insertional mutagenesis and fluorescence screening procedure**

18
19 4A⁺ cells were electroporated with 10 μg of DNA carrier and 250 ng of hygromycin B
20 (*APHVII*) or paromomycin (*APHVIII*) resistance cassettes as previously described
21 (Shimogawara et al., 1998). *APHVII* and *APHVIII* cassettes were amplified by PCR
22 from pHyg3 (Berthold et al., 2002) or pSL18 (Depège et al., 2003) plasmids,
23 respectively, as described in (Barbieri et al., 2011) using primers pairs APH7-F/APH7-
24 R for *APHVII* and APH8-F/APH8-R for *APHVIII* (Table S2). Transformants were
25 selected on TAP agar medium containing 25 μg/ml of hygromycin B or paromomycin
26 in the light. After incubation of 5 to 10 days under light, transformants were screened
27 directly on transformation plates according to a published procedure (Godaux et al.,
28 2013) where anoxia is reached by incubation in anoxic bags (Anaerocult P, Merck).
29

30 **DNA extraction, PCR amplifications, and TAIL-PCR**

31

1 Total DNA was extracted using the procedure of (Newman et al., 1990). PCR
2 amplifications were performed according standard protocols using Taq polymerase
3 (Promega) or KAPA HIFI DNA polymerase (KAPA Biosystems,
4 <http://www.kapabiosystems.com>) in case of amplification of *MENB* and *MENE* genes
5 using primers menB-F3/menB-R1 and menE-F3/menE-R, respectively (Table S2).

6 Amplification of insertion-linked sequence by thermal asymmetric interlaced (TAIL)-
7 PCR was performed as described previously (Dent et al., 2005) using AD1, AD2 (Liu et
8 al., 1995), RMD227 and RMD228 (Dent et al., 2005) as non-specific primers. For
9 *APHVII*, the specific primers for primary, secondary and tertiary reactions were
10 respectively APH7-R3, APH7-R4, and APH7-R5 at the 5' and HygTerm1, HygTerm2,
11 and HygTerm3 at the 3' end of the coding sequence of the cassette (Table S2). For
12 *APHVIII*, the specific primers for primary, secondary and tertiary reactions were
13 respectively ParoTermB, ParoTermC/1, and ParoTerm2 at the 3' end of the coding
14 sequence of the cassette (Table S2). PCR products were sequenced by Beckman Coulter
15 Genomics and aligned to the *Chlamydomonas* genome sequence database (v5.5 on
16 Phytozome v11.0).

18 Genetic analyses

20 Genetic crosses were performed as described in (Duby and Matagne, 1999). Zygotes
21 were matured for 3 to 4 days under continuous light on nitrogen-free minimal agar
22 plates. After maturation, blocks of agar carrying 50-100 zygotes were transferred to
23 fresh TAP agar plates and exposed to chloroform vapours during 30 s. Germination was
24 induced by exposure to light and nitrogen restoration. After 10 days of culture, 150-300
25 meiotic clones were randomly sampled and linkage analysis between resistance cassette
26 and photosynthetic deficiency was determined using the protocol described previously
27 (Godaux et al., 2013).

29 DNA gel blot analysis

31 Total DNA from wild-type and mutants cells were digested with *StuI* and *PstI*
32 restriction enzymes (Thermo Scientific, Fast digest) which do not cut into *APHVII* or

1 *APHVIII* cassettes. DNA was separated on agarose gel, blotted to Hybond-N
2 membranes (Amersham) and hybridized using digoxigenin-labeled probes (Duby and
3 Matagne, 1999). Probes used to detect *APHVII* and *APHVIII* cassette were amplified by
4 PCR with primers HygTail2 and APH7-R2 and pAPH-8F and pAPH-8R (Table S2)
5 using Dig-11 dUTP, according to the procedure recommended by the manufacturer
6 (Roche).

7 8 **Spectroscopy**

9
10 For all experiments, cells grown in low light ($25 \mu\text{mol photons m}^{-2} \text{s}^{-1}$), were harvested
11 during exponential growth phase ($3\text{-}5 \times 10^6$ cells/ml) and concentrated to a
12 concentration of $10 \mu\text{g chlorophyll/ml}$ in fresh TAP medium.

13 *In vivo* chlorophyll fluorescence measurements were performed at room temperature
14 using a fluorescence spectrophotometer (JTS-10, Biologic) or a fluorescence imaging
15 setup (Speedzen-2, BEAMBIO). Actinic light was provided by light sources peaking at
16 640 nm and 520 nm, respectively. The effective photochemical yield of PSII (ΦPSII)
17 was calculated as $(F_m' - F_s)/F_m'$, where F_s is the fluorescence level excited by actinic
18 light (I_{lum}), and F_m' is the maximum fluorescence emission level induced by a 150-ms
19 superimposed pulse of saturating light ($> 3500 \mu\text{mol photons m}^{-2} \text{s}^{-1}$). The relative
20 electron transfer rate is obtained as $\text{rETR}_{\text{II}} = \Phi\text{PSII} \times I_{\text{lum}}$ (Genty et al., 1989).

21 Fluorescence emission spectra at 77K were recorded using a homebuilt
22 spectrophotometer, based on a detecting diode array (AVS-USB 200; Ocean Optics).
23 The excitation wavelength was provided by a LED source peaking at 440 nm. Cells
24 were treated to induce state transitions before freezing in liquid nitrogen. PSII inhibitor
25 DCMU ($20 \mu\text{M}$) was added for 20 min in the light used to promote state I.

26 The ratio between active PSI and PSII centers was estimated as previously described
27 (Godaux et al., 2015) on cells adapted to dark for 30 min. Briefly, the amplitude of the
28 fast phase (<1 ms) of the ECS signal (at 520–546 nm) after illumination with a single-
29 turnover laser flash was monitored with a JTS-10 spectrophotometer (Biologic, France).

30 The contribution of PSII was calculated from the decrease in the ECS amplitude after
31 the flash upon the addition of the PSII inhibitors DCMU ($20 \mu\text{M}$) and hydroxylamine (1
32 mM), whereas the contribution of PSI corresponded to the amplitude of the ECS that

1 was insensitive to these inhibitors. PSI relative content was also assessed by measuring
2 P_{700} absorption changes with a probing light peaking at 705 nm (6 nm full width at half
3 maximum). In order to remove unspecific contributions to the signal at 705 nm,
4 absorption changes measured at 740 nm (10 nm full width at half maximum) were
5 subtracted. To fully reduce P_{700} , actinic light was provided by LED light sources (~ 1000
6 $\mu\text{mol photons m}^{-2} \text{ s}^{-1}$) peaking at 640 nm in the presence of DCMU (20 μM) and
7 hydroxylamine (1 mM).

8 Functional PSI antenna size was measured as the photon absorption rates of PSI ($\text{s}^{-1} \text{PS}^{-1}$)
9 by recording the initial rate of ECS at the onset of actinic light in the presence of PSII
10 inhibitors DCMU (20 μM) and hydroxylamine (1mM) (Roberty et al., 2014). The slope
11 was then normalized on ECS values corresponding to one charge separation per PSI.

13 **Western blot analysis**

15 The cell pellet corresponding to 1.5 ml of cell culture was suspended in extraction
16 buffer (SDS 10%, glycerol 10%, 0.1 M DTT, 0.06 M Tris pH 6.8) to a final
17 concentration of 1 $\mu\text{g protein}/\mu\text{l}$ and incubated for 5 min at 100°C. Samples (5 μg) were
18 then loaded in 10% SDS acrylamide gel and electroblotted according to standard
19 protocols onto PVDF membranes (Amersham GE Healthcare, Buckinghamshire,
20 England). Detection was performed using a Chemiluminescence Western blotting kit
21 (Roche, Basel, Switzerland) with anti-rabbit peroxidase conjugated antibodies.
22 Commercial rabbit antibodies (Agrisera) against PsaA (1:10,000), PsbC (1:30,000), and
23 Cytochrome *f* (1:10,000) were used.

25 **Pigment analyses**

27 Pigments were extracted from whole cells in 90% (v/v) methanol, and debris were
28 removed by centrifugation at 10,000 x g. Chlorophyll a + b concentration was
29 determined with a λ 20 spectrophotometer (Perkin Elmer). Pigments and quinones were
30 extracted from lyophilized cells with N,N-dimethylformamide (DMF) (Furuya et al.,
31 1998). The resulting extracts were applied to an Acquity UPLC BEH C18 column (1.7
32 μm , 2.1 mm x 150 mm, Waters) at 40°C and were separated at a flow rate of 0.3 ml/min

1 using an UPLC (Acquity UPLC I-Class system, Waters) coupled with tandem mass
2 spectrometry (Q Exactive, Thermo Scientific). The elution liquid gradient was
3 generated as the following steps using solvent A (formic acid : water = 0.1 : 99.9) and
4 solvent B (methanol): 0-5 min, 15%A/85%B to 5%A/95%B, hold to 9 min; 9-10 min,
5 5%A/95%B to 100%B, hold to 11.5 min; 11.5-12 min, 100%B to 15%A/85%B. The
6 injection volume was 1 μ l. Mass spectroscopy measurements were performed in a
7 positive mode ESI.

10 (7) ACCESSION NUMBERS (7 words)

12 Accession numbers are listed in Table 1.

15 (8) ACKNOWLEDGMENTS (121 words)

17 We thank K. E. Redding for providing the *mend* strain of *C. reinhardtii*, the laboratory
18 of K. K. Niyogi for providing 4A⁺ wild-type strain, G. Eppe & A. Marée for their
19 technical help in UPLC-MS analyses, Y. Takahashi for advices on PhQ extraction
20 method, E. Perez for her help in the identification of putative PTS, F. Franck for assay
21 of PhQ analysis by HPLC, and M. Radoux for expert technical assistance. P.C

^aE-values from BLAST analysis with *Arabidopsis* protein sequences against *Chlamydomonas* genome (version 5.5).

^bNo homolog has been found in *C. reinhardtii* genomic database for the DHNA-CoA thioesterase described in *Synechocystis* and *Arabidopsis*. TEH4 is a putative candidate (see discussion for further details).

^cThe penultimate reduction step of PhQ biosynthesis has not yet been demonstrated in menaquinone biosynthesis in bacteria.

(12) FIGURES LEGENDS (809 words)

Figure 1: Chlorophyll fluorescence induction curves of wild-type and mutant strains.

Chlorophyll fluorescence induction curves upon illumination at $\sim 110 \mu\text{mol photons } (\lambda = 520 \text{ nm}) \text{ m}^{-2} \text{ s}^{-1}$ of *C. reinhardtii* wild type, *mend* mutant, and mutant strains identified in this work after acclimation to dark anoxic (>12 h) (a-b) and oxic conditions (c). Arrows indicate when the saturating light pulse was given.

Figure 2: Molecular characterization of the mutants.

(a) DNA-blot analysis of wild-type and mutant strains. For AO1, AS1 and AS2, DNA-blot was hybridized with dig-labelled *APHVII* probe while for 25.1 DNA-blot was hybridized with *APHVIII* dig-labelled probe. (b) Organization and structure of the *MENA*, *MENB*, *MENE*, and *PHYLLO* genes as shown in *C. reinhardtii* genome version 5.5 available at <http://phytozome.org> (black boxes, exons; black lines, introns; grey boxes, 5' and 3' UTRs; *men*-homologous regions, black pointer), and localization of the antibiotic resistance cassette (diagonally hatched arrows, *APHVII*; vertically hatched arrows, *APHVII*; white arrows, pieces of non-functional cassette).

1 mM) - poisoned cells (Figure S5a). PSII antenna size estimated from chlorophyll fluorescence transients in DCMU (20 μ M) - poisoned cells (Figure S5b). (g-h) Wild-type values were normalized to 1 and all values are the average of three independent experiments.

Figure 6: Reactivation of photosynthesis after dark anoxia acclimation.

(a) Chlorophyll fluorescence induction curves upon illumination at $\sim 110 \mu\text{mol photons } (\lambda = 520 \text{ nm}) \text{ m}^{-2} \text{ s}^{-1}$ of *C. reinhardtii* wild-type, hydrogenase-deficient (*hydg-2*), *menb* mutant and *menbR* complemented strains after acclimation to dark anoxic (220 min). (b) Evolution of PSII quantum yield (ΦPSII) following a shift from dark anoxia to light ($250 \mu\text{mol photons } \text{m}^{-2} \text{ s}^{-1}$) of *C. reinhardtii* wild-type, hydrogenase-deficient (*hydg-2*), *menb* mutant and *menbR* complemented strains.

Figure 7: Phylloquinone biosynthetic pathway in *Chlamydomonas reinhardtii*.

The gene products encoding each step in *Chlamydomonas* are indicated. The PHYLLO protein contains catalytic domains corresponding to MenF, MenD, MenH and MenC of the menaquinone pathway. MENE, MENB, and TEH4 possess peroxisome targeting sequences suggesting a compartmentalized phylloquinone biosynthesis pathway similar to that of land plants (see text for details). Solid black boxes indicate that mutants have been characterized, dotted black boxes specify putative *men* proteins and grey arrows designate uncharacterized membrane trafficking steps (see text for details). MenF, isochorismate synthase; MenD, SEPHCHC synthase; MenH, SHCHC synthase; MenC, OSB synthase; MenE, OSB-CoA ligase; MenB, DHNA synthase; MenA, DHNA phytyltransferase; TEH4, DHNAT, putative DHNA-CoA thioesterase; Nda5, demethylphylloquinone oxidoreductase; MenG, demethylphylloquinone methyltransferase. SEPHCHC, 2-succinyl-5-enolpyruvyl-6-hydroxy-3-cyclohexene-1-carboxylic acid; SHCHC, 2-succinyl-6-hydroxy-2,4-cyclohexadiene-1-carboxylic acid.; OSB, o-succinylbenzoic acid; DHNA, 1,4-dihydroxy-2-naphtoate, CYP25, putative phylloquinone hydroxylase.

Figure 2: Molecular characterization of the mutants.

(a) DNA-blot analysis of wild-type and mutant strains. For AO1, AS1 and AS2, DNA-blot was hybridized with dig-labelled APHVII probe while for 25.1 DNA-blot was hybridized with APHVIII dig-labelled probe. (b) Organization and structure of the MENA, MENB, MENE, and PHYLLLO genes as shown in *C. reinhardtii* genome version 5.5 available at <http://phytozome.org> (black boxes, exons; black lines, introns; grey boxes, 5' and 3' UTRs; men-homologous regions, black pointer), and localization of the antibiotic resistance cassette (diagonally hatched arrows, APHVII; vertically hatched arrows, APHVIII; white arrows, pieces of non-functional cassette).

Appendix S1: Detailed description of TAIL-PCR analysis.

TAIL-PCR products were obtained at the 3' end of the resistance cassette for AO1, AS1 and 25.1 mutants and at both ends for AS2 mutant. In AO1 mutant, the PCR sequence contains 273 bp of the 3' end of *APHVII* and 459 bp of *PHYLLO* gene (Cre16.g659050, 15,756 bp) (Figure S1), allowing us to localize the 3' end of the cassette at position 11,716 of *PHYLLO* gene in MENC catalytic domain (Figure 2b). In AS1 mutant, the TAIL-PCR product contains 101 bp of the 3' end of the *APHVII* cassette and 693 bp of the *MENB* gene (Cre02.g114250, 5,066 bp) (Figure S1), allowing us to localize the 3' end of the cassette at position 422 of *MENB* gene (Figure 2b). In AS2 mutant, the sequence of the TAIL-PCR products (Figure S1) allowed us to localize the 5' end of *APHVII* at position 186 in *MENA* gene (Cre04.g219787, 3,136 bp) and the 3' of *APHVII* at position 14,251 in the neighbouring gene coding for *HEL22* DNA helicase RecQ (Cre04.g219750, 14,531 bp). The cassette insertion caused a deletion of 514 bp in AS2 genome (279 bp of *HEL22*, 49 bp of intergenic sequence and 186 bp of *MENA*). Additional PCR analysis showed a piece of non-functional cassette (597 bp) upstream of the 5' end of *APHVII* functional cassette in AS2 (Figure 2b). Finally, in 25.1 mutant, the PCR sequence contains 259 bp of the 3' end of *APHVIII* and 535 bp of *MENE* (Cre01.g030900, 3,986 bp) (Figure S1), allowing us to localize the 3' end of the cassette at position 548 of *MENE* gene. Additional PCR analysis showed a piece of non-functional cassette (477 bp) upstream of the 5' end of *APHVIII* functional cassette in 25.1 (Figure 2b).

Supplemental Figure S1: TAIL-PCR product sequences.

Supplemental Figure S2: Amplification of *MENB* and *MENE* genes and their flanking regions. (a) *MENB* gene PCR product (4,865 bp) amplified by *menB-F3*/*menB-R1* primers covers the *MENB* gene from 467 bp upstream of the ATG codon to the STOP codon. (b) *MENE* gene PCR product (4,177 bp) amplified by *menE-F3*/*menE-R* primers covers the *MENE* gene from 403 bp upstream of the ATG codon to 174 bp after the STOP codon.

Figure S2
117x49mm (300 x 300 DPI)

Supplemental Figure S3: Chlorophyll fluorescence induction curves of wild-type and complemented strains. Chlorophyll fluorescence induction curves upon illumination at $\sim 110 \mu\text{mol photons } (\lambda = 520 \text{ nm}) \text{ m}^{-2} \text{ s}^{-1}$ of *C. reinhardtii* wild-type and complemented strains (*menbR*, *meneR*) after acclimation to dark anoxic conditions ($>12 \text{ h}$). Arrows indicate the time when the saturating light pulse was given.

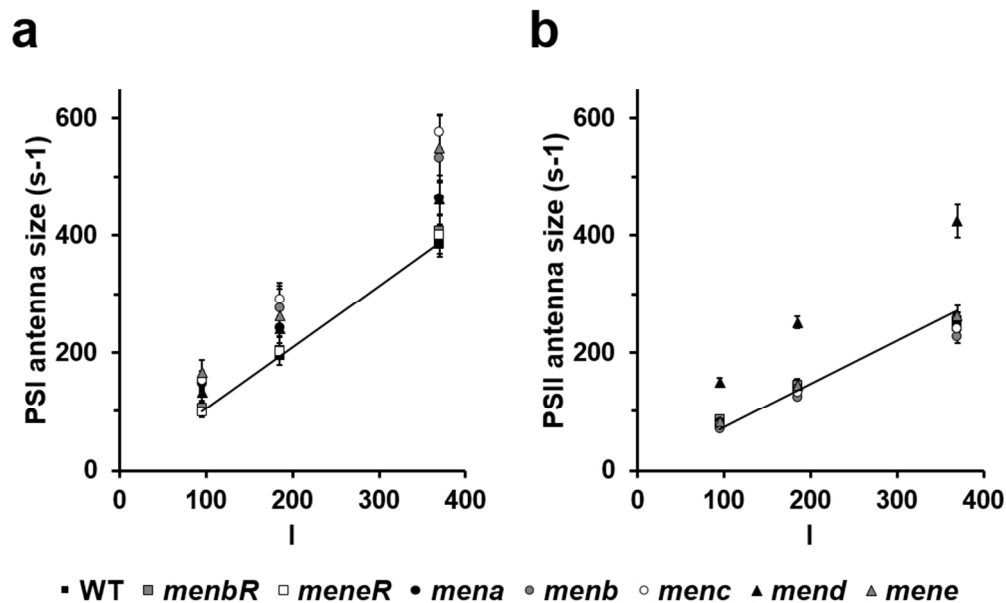

Figure S3
34x29mm (300 x 300 DPI)

Supplemental Figure S4: PSI relative content.

PSI relative content (wild-type value normalized to 1) determined from the maximum absorption changes at 705-740 nm between dark acclimated cells (P700 oxidized) and cells exposed to saturating light in the presence of DCMU (20 μ M) (P700 reduced). Values are the average of three independent experiments.

Figure S4
45x47mm (300 x 300 DPI)

Supplemental Figure S5: Determination of PSI and PSII antenna size in wild-type, complemented and men mutant strains.

(a) PSI antenna size estimated from ECS absorbance transients (520-546 nm) in DCMU (20 μ M) + hydroxylamine (1 mM) - poisoned cells as a function of light intensity. The initial rate of this signal is proportional to the antenna size of PSI (s-1). (b) PSII antenna size estimated from chlorophyll fluorescence transients in DCMU (20 μ M) - poisoned cells as a function of light intensity. The mid-rise time of this signal is proportional to the antenna size of PSII (s-1). Values are the average of three independent experiments. Values reported in Figure 5g are the values of the slopes, normalized on the value of the slope for wild type.

Figure S5
85x54mm (300 x 300 DPI)

Supplemental Figure S6: PSI and PSII content in control and mutant strains. ECS measurements (520-546 nm) on cells grown in low light and then transferred for four hours at high light intensity (HL, 400 $\mu\text{mol photons m}^{-2} \text{s}^{-1}$). Active PSI center content of wild-type cells adapted to darkness was normalized to 1. Values are the average of three independent experiments.

Figure S6
79x81mm (300 x 300 DPI)

Supplemental Figure S7: RT-PCR analysis of *menc* and *mend* mutants.

Upper, RT-PCR analysis using primers binding PHYLLLO (size: 330 bp) and β -tubulin (size: 666 bp) cDNAs. PCRs were performed on samples without nucleic acid (-, negative control); on DNA (+, positive control), on cDNA and on RNA treated with Dnase (negative control). Lower, organization and structure of *Chlamydomonas* alpha-tubulin and PHYLLLO genes. Exons are indicated by black boxes. The positions of the PHYLLLO-F2 and PHYLLLO-R2 primers (Table S2) used to produce and amplify PHYLLLO cDNA are indicated. Analyses were performed according to standard protocols using M-MLV Reverse Transcriptase (Promega). P1Tub and P2Tub (Table S2) were used to produce and amplify alpha-tubulin cDNA.

Figure S2

93x82mm (300 x 300 DPI)

Supplemental Figure S8: Sequence alignment of PHYLLO protein from *C. reinhardtii* (CrPHYLLO) and *A. thaliana* (AtPHYLLO) with *E. coli* MenF, MenD, MenC and MenH proteins (EcMenF, -D, -C, -H).

The PHYLLO locus found in plants and algae comprises the four Men modules responsible for the first four enzymatic steps of menaquinone biosynthesis in bacteria. In *A. thaliana*, the C-terminal chorismate binding domain is truncated from the PHYLLO MenF module unlike *C. reinhardtii* in which MenF structural integrity was maintained. The protein sequences were aligned using Clustal Omega and BoxShade.

Table S1: Cosegregation analysis of the antibiotic resistance cassette with the fluorescence phenotype.

Fluorescence phenotype ^a	Mutant		Wild type	
Antibiotic resistance ^b	+	-	+	-
Strains	% of meiotic clones ^c			
AL2	10.1	13.7	6.5	69.7
AO1	48.3	0	0	51.7
AO2	0.5	2.8	1.1	95.6
AS1	40.5	0	0	59.4
AS2	50.5	0	0	49.5
24.1	41.9	12.5	36.8	8.8
25.1	51.5	0	0	48.5

^aThe fluorescence phenotype in anoxia was determined as described for Figure 1. ^bAntibiotic resistance: + and – indicate resistance or sensitivity to hygromycin (AL2, AO1, AO2, AS1, AS2) or paromomycin (24.1, 25.1), respectively. ^cResults are expressed as a percentage of independent meiotic clones (150-300 clones analyzed for each cross).
