The water of Eleshka River is the material which is used for the purposes of the research. For this purpose, in the experimental part of the research, were carried out analysis ofthesamples taken from Eleshka River. Samples of the water were taken in the first week of July and September.Taken samples were transported in sterile glass bottles at a temperature of ± 4 ° C in field refrigerators. The following analyses were used for the purposes of the experimental researches. The determination of ammonia and nitrite in the water, was done with spectrophotometric device Spectroqvant UV / VIS Pharo 300, according to the method 14752 Determining of the: nitrates, dissolved oxygen, is performed with UV PASTEL (SECOMAM - France)– instrument for direct readout of values with UV analyzer software and the necessary calibrations.

Results and Discussion

Circulation of nitrogen in surface waters is a chain reaction composed of several different processes of transformation of the different types of nitrogen. The main role in these processes has microorganisms (Juhna *et al.*, 2007; Beversdorf *et al.*, 2013). The results of two months of testing are presented in graphs to get a visual impression of the current state of water in Eleshka River for May and June.

Nitrogen in the form of ammonia (NH_3)

Ammonia is an important form of nitrogen that can catalyze the process of eutrophication and to facilitate the rapid growth of algae. It can be said that ammonia is an "indicator of pollution that occurred recently" (Zhao *et al.*, 2005; Dalmacija *et al*., 2011).

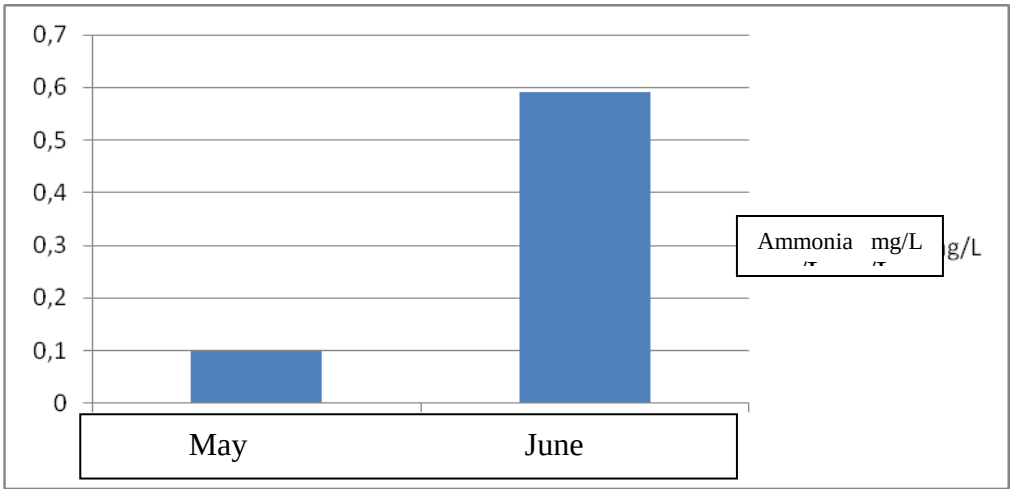

Figure 1. Concentration of ammonia in the water Eleshka River for May and June.

According to data presented in Figure 3, we see that the amount of ammonia nitrogen in the samples of water from the Eleshka River is higher in June as opposed to May. This situation is due to the increased concentration of organic matter, which comes to the river from the surrounding villages.It can be concluded that the water from Eleshka River in May and June, ranks third and fourth category of waters.It suggests that the water in May can be used for irrigation

Nitrite nitrogen

Determining the presence of nitrites in the water indicates a decrease in its quality.According to Glavan (2010), the origin of nitrites in the water may be from the biodegradableorganic matter or as a result of the activity of anaerobic bacteria that lead to the reduction of nitrates. (Djuikom *et al.*, 2006).

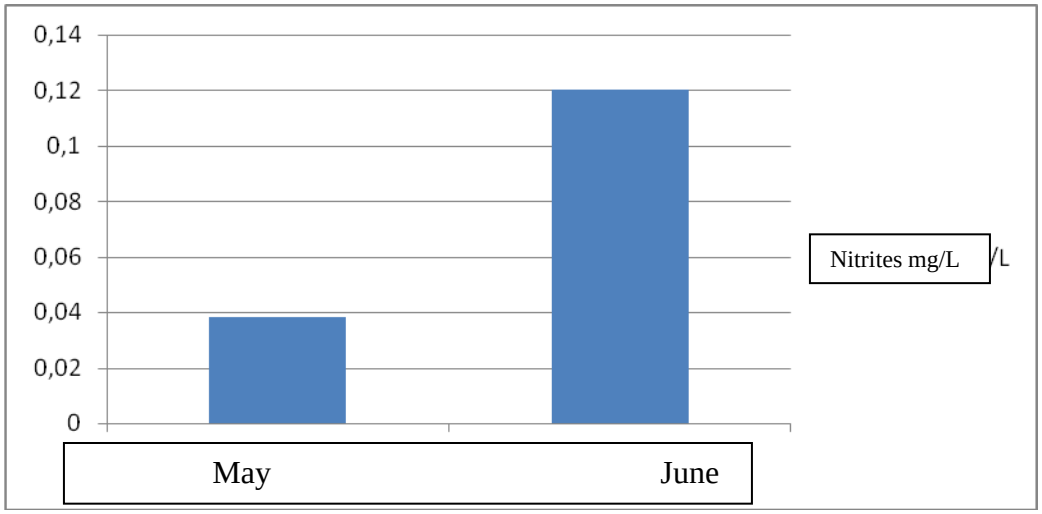

Figure 2. Concentrations of nitrite in the water of Eleshka River for May and June.

From Figure 2, we can conclude that the amount of nitrogen present which is present in the form of nitrite is higher in June as opposed to May. Ambient temperature which is typical for summer has a catalytic effect on the processes of nitrification and it is the reason why we have more intensive chemical reactions in which there is a greater amount of nitrates. Despite these monthly fluctuations we can conclude that organic nitrogen load which has Eleshka River in May and June does not exceed the maximum allowable concentrations and its water belongs to the third category.

Nitrate nitrogen ($NO_3 - NO_3 - N$)

The presence of nitrates in the water indicates a "final phase" of the degradation of organic matter. According to Dalmacija (2011), their presence in surface water originates from nitrogen fertilizers, as well as the uncontrolled discharge of waste water with organic matter and the high level of nitrates indicates that it is the final stage of degradation of organic matter (Wakida *et al.*, 2005; Zhao *et al*., 2015).

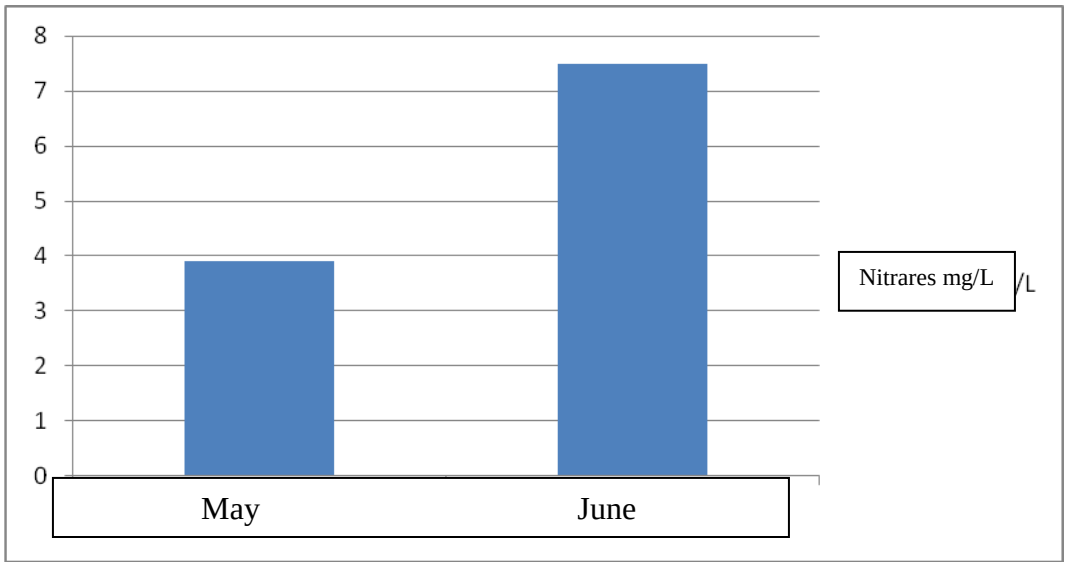

Figure 3. Concentration of nitrates in water from the Eleshka River for May and June.

From Figure 3 can be clearly seen that the amount of nitrate nitrogen, recorded in the sample of water from Eleshka River is higher in June as opposed to May. Water pollution with nitrogen compounds (of any kind) usually occurs from the decomposition of organic compounds under the influence of the relevant bacteria.We believe that the reason for the difference in the concentrations is due to the higher temperature in June as opposed to May. Also, the water level appears as a reason, namely, in summer the water level in the river is lower and it causes higher concentration of organic matter and thus higher concentration of the nitrates. Knowing the factors that influence the chemical reactions, we can conclude that the higher temperature accelerates chemical reactions (Venkatesharaju *et al.*, 2010).In terms of present organic matter for decomposition, the higher temperature accelerates the nitrification process. Although this is some increase in the content of nitrates - 7,5 mg/L in June, we can conclude that the amount of nitrates in the sample water does not exceed the limit.

Dissolved oxygen

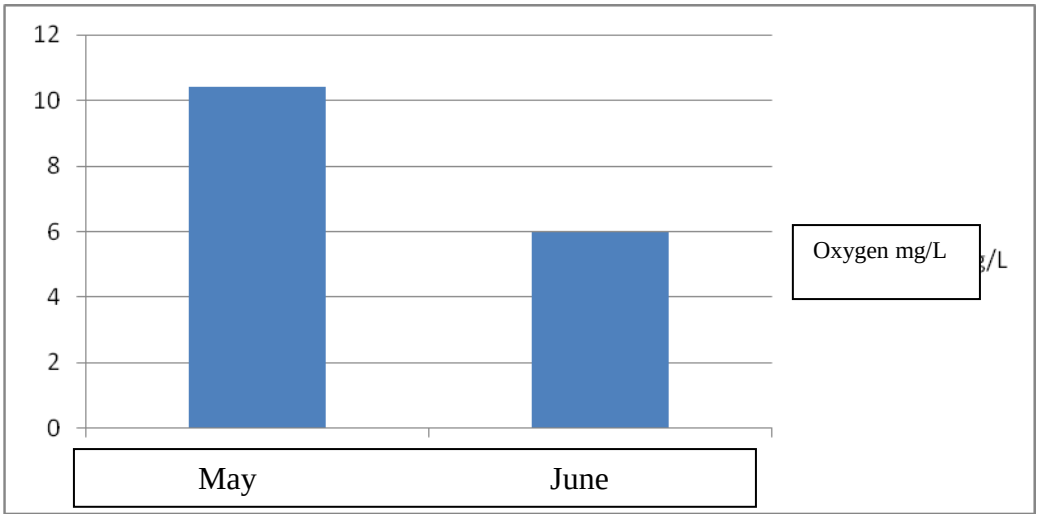

Figure 4. Concentration of dissolved oxygen in the water of the Eleshka River for May and June.

According to Figure 4, we can conclude higher content of dissolved oxygen in May compared to June.We can determine the intensity of decomposition of the organic compounds present in the water samples, are affecting inversely on the amount of dissolved oxygen in the water, ie the more increases the amount of nitrates, nitrites and ammonia, the more it reduces the amount of dissolved oxygen.

Conclusion

With sublimation of the data, we can deduce the following conclusions: The water from Eleshka River, although a mountain river which is considered with relatively clean water, however along its course dissolves part of the minerals from the surrounding villages receives certain organic load and of course pollution caused by fertilizers used in the surrounding fields.The obtained values indicate that there is no great fecal contamination (according to the content of ammonia) but that it is a water, which according to its quality and purpose belongs to the third category. This water according to the purpose can be used for irrigation.

The amount of nitrates, nitrites and ammonia is greater in June, compared to May, and it is due to the difference in temperature in these two months and reduced water levels typical for the summer period of the year. By reducing the water level of the river, the concentration of organic matter present in it is increasing. We believe that this pollution comes from Eleshka River, is affecting the water quality in the Crna River, but is not the only pollutant. We think that our data and monitoring which makes HMS Skopje, gives us a clear picture of the impact of Eleshka River on water quality in the Black River. The responsibility remains on us and our relationship to the planned use of the waters and their protection from pollution.

Abstract

The main goal of this investigation was to compare effects of different irrigation and fertilization regimes on the number of formed flowers and fruits sets in pruned pepper ("V"system). For this purpose, the field experiment with pepper (*Capsicum annum L.var.* Bela dolga)grown in an experimental plastic house in the Skopje region was conducted during the period of May to September in 2005, 2006 and 2007. Four different irrigation and fertilization regimes were performed during the investigation. Three of the treatments were irrigated with drip irrigation and drip fertigation (DF1, DF2, DF3), while the last one was irrigated with furrow irrigation and conventional application of fertilizer ($Ø_B$). From the results obtained during the threeyears of investigation, we can conclude thatdrip fertigation frequency of every 2 days (DF1) has shown the largest number of formed flowers (69.67) and fruits sets (41.67) in comparison to DF2, DF3 and $Ø_B$. The results are statistically significant at 0.5 level of probability. Also, drip fertigation frequency of every 4 days (DF2) significantly affects the number increase of formed flowers and fruits sets in comparison to DF3 and $Ø_B$.A positiveeffectof drip fertigation on the number of formed flowers and fruits sets is presented by comparison of the results from the treatments DF3 (drip fertigation scheduled by tensiometers)and $Ø_B$. Namely, the DF3treatment (with similarand sometimesa bitlongerirrigation intervalcomparedto$Ø_B$) has shown8.32% and 19.2% highernumber of formed flowers and fruits sets compared to$Ø_B$. The results are statistically significant at 0.5 level of probability

Introduction

The plants growth, biology of development and their changes that appear during the vegetation are genetic properties of each variety or population, but at the same time these properties are in direct relation with the complex external factors (Jankulovski, 1983).Bosland and Votava (2000) reported that pepperisone of themost sensitivevegetablestoexternal factors, especially to light, temperature, soil moisture and airmoisture. The pepper needs a lot of heat during whole growing period, which is connected with its native place of origin (Jankulovski, 1997; Gvozdenović *et al.*, 2004). If the temperature is below 15^oC, there are possibilities for increase of the falling of flowers (Lazić*et al.*, 2001; Gvozdenović*et al.*, 2004). Also, the flowers and fruits can fall if the temperature risesabove 35^oC (Rylski, 1986). The best pepper yields can be obtained when the air temperature during the day time is between 18-32^oC, especially in the stage of fruit formation (Bosland and Votava, 2000). Also, it is well known that pepper is the most sensitive to water shortage (drought) during the flowering and fruit formation (Candido*et al*., 2009; Bosland and

Votava, 2000). Water deficit during the period between flowering and fruit development reduced the final fruit production (Jaimez*et al*., 2000; Dalla Costa and Gianquinto, 2002; Sezen*et al*., 2006). Also, many authors indicate that cultivation practiceshave influence on pepper plant growth and biology of development. Jankulovski (1983) indicates that pepper varieties have influence on the duration of the vegetation period. Burt *et al.*, (1998) and Tanaskovik*et al*., (2015) noted similar effect as result of the irrigation and fertigation techniques. Antony and Singandhupe (2004) and Sezen*et al*., (2006) indicate influence of drip irrigation on flower and fruit development, as well as on yield production. Jovicich*et al*., (2004)and Rusevski (2005)reported influence of pruning systems on yield potential, flower and fruit development.
Irrigationof agricultural crops always had great importance for climatic conditions of the Republic of Macedonia. Results from the terrain show that surface irrigation is still a commonly used irrigation technique in vegetable production in the country, and therefore farmers have low yield potential and low water and fertilizer use efficiency. Even if drip irrigation is used by farmers, still there are problems especially related to irrigation scheduling and application of fertilizer(conventional use of fertilizers).According to Tanaskovik*et al*., (2015), the reasons for low pepper productivity (about 18 t/ha) in the country are traditional cultivation practices or just partial (separate) use of modern technologies,even though there is real possibility to combine them and improve production.
Therefore, the main objective ofthis researchwas toassess the effects of different irrigation and fertilization regimes on the number of formed flowers and fruits sets in two stem pruned pepper grownin anunheated plastic house. Furthermore, one of the goals of this study is to provide opportunities to pepper producers in the country to improve their yields by using drip fertigation practice and pepper pruning technology in their fields.

Material and methods

The field experiments were conducted with pepper crop (*Capsicum annum L.var.* Bela dolga) in an experimental plastic house located near the Faculty of Agricultural Sciences and Food in Skopje (42^{o} 00' N, 21^{o} 27' E), during the period of May to September in 2005, 2006 and 2007. The soil type of the experimental field wasFluvisol (WRB 2015). The average results of chemical and physical characteristics of the soil layer 0-60 cm are presented in Table 1.

Table 1. Chemical and physical characteristicsof the soil layer 0-60 cm

Chemical characteristics	
Reaction (pH in water)	8,04
Electrical conductivity (ECedS/m)	2,31
$CaCO_3$%	3,54
Organic matter %	0,77
Available N mg/100 g soil	2,80
AvailableP_2O_5 mg/100 g soil	13,2
AvailableK_2O mg/100 g soil	22,5
Particle size of the soil layer	
Total sand in %	62,2
Silt in %	13,0
Clay in %	24,8
Water physical properties	
Wilting point(soil moisture retention at 15 bars) in volume %	14,37
Field capacity(soil moisture retention at 0,33 bars) in volume %	34,05
Bulk density in g/cm^3	1,52

The pepper planted in our conditions with yields up to 60 t/ha needs the following amount of nutrients: N 485 kg/ha, P_2O_5 243 kg/ha and K_2O 585 kg/ha (Jankulovski, 1997; Lazić*et al.*, 2001).The application of the fertilizer for the treatments was done in two portions (before transplanting and during the growing season), which is a common practice in our country. For all treatments, the first portions of the fertilizers were applied before transplanting pepper, while the rest of the fertilizers were applied through the fertigation system for the drip fertigation treatments (Table 2) and conventional fertilization of soil for the control treatment (spread in two portions - at flowering and fruit formation). All investigated treatments received the same amount of fertilizers, but by different methods and frequency of application of water and fertilizers, which was the main idea of this study.

Table 2. Type and amount of fertilizers used during the vegetation period in drip fertigation treatments in kg/ha

Type of fertilizers	Amount of applied fertilizer	Period of application
15:15:15	318 kg/ha	before transplanting
0:52:34	375 kg/ha	drip fertigation during the vegetation
0:0:51+18S	802 kg/ha	drip fertigation during the vegetation
46:0:0	952 kg/ha	drip fertigation during the vegetation

*Remark: the same amounts and quantity of fertilizers were used for furrow irrigation treatment

A drip irrigation system with integrated compensating drippers and a discharge of 4 l/h was installed.The fertigation equipment for the drip fertigation treatments was Dosatron 16, with a plastic barrel as reservoir for concentrated fertilizer. The source of water was the water supply system for the city of Skopje. The irrigation of the experiment (treatment DF1, DF2 and $Ø_B$) was scheduled according to long-term average daily evapotranspiration of pepper in the Skopje region (Figure 1). The long-term average (LTA) crop evapotranspiration was calculated by FAO software CROPWAT using crop coefficient (K_c) and stage length adjusted for the local conditions.

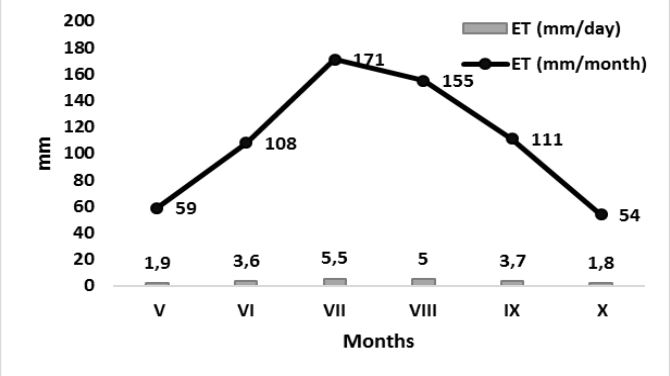

Figure 1. Long-term average daily and monthly evapotranspiration (mm) for pepper in the Skopje region calculated by FAO software CROPWAT

The irrigation scheme used in the field experiments was designed according to randomized block design for experimental purposes with four treatments in three replications. Generally, the experimental treatments were set up according to the daily evapotranspiration rate and irrigation and fertilization techniques. Therefore, the followingexperimental treatments were applied in this

field experiment: Drip fertigation according to daily evapotranspiration with application of water and fertilizer every 2 days (DF1); Drip fertigation according to daily evapotranspiration with application of water and fertilizer every 4 days (DF2); Drip fertigation scheduled with tensiometers (DF3) with recommendations undertaken by Tekinel and Kanber (2002); Furrow irrigation according to daily evapotranspiration with application of water every 7 days ($Ø_B$) and conventional fertilization. The dailyevapotranspiration of DF 1 and DF2in our study was decreased by20% (coverage coefficient) similarly to Xie*et al*., (1999).

The size of each plot (replication) was 6.6 m^2 (25 plants in 0.75 m of row spacing and 0.35 m plant spacing in the row). Each plot (replication) was designed with five rows of crop and five plants in each row. Five plants from the middle row from each plot and treatment were assumed for experimental purposes. The flowers formed on each plant were marked with colored tie and counted. The picking and counting of formed fruits(fruit sets) from the representative plants was carried out in the stage of technical-technological maturity. The ratio between the number of formed flowers and fruit sets presents the percentage of fructification.

The plant pruning started when pepper plants were at least a foot tall(mid of May). Lateral branch shoots were pruned to form a plant structure of "V" system (two main shoots).

The collected data were subjected to statistical analysis of variance and the means were compared by using the least significant difference (LSD) at the 5% level of probability ($P<0.05$) test. Also, bivariate Pearson correlation (with SPSS 17) between the number of formed flowers, number of fruits sets and yield potential was done in this study.

Results and discussion

The meteorological conditions during the research

During our investigation, the average monthly temperatures in the experimental plastic house in all three years (Figure 2) were within the optimum values recommended by many authors (Rylski, 1986; Bosland and Votava, 2000). Gvozdenović (2004) reported that lower relative air humidity followed by high temperature can affect flower and fruit falling. Except in July 2007, the average relative humidity during our investigation was close to the recommended values for pepper production in controlled environment (Jankulovski 1997; Penella*et al*., 2014).

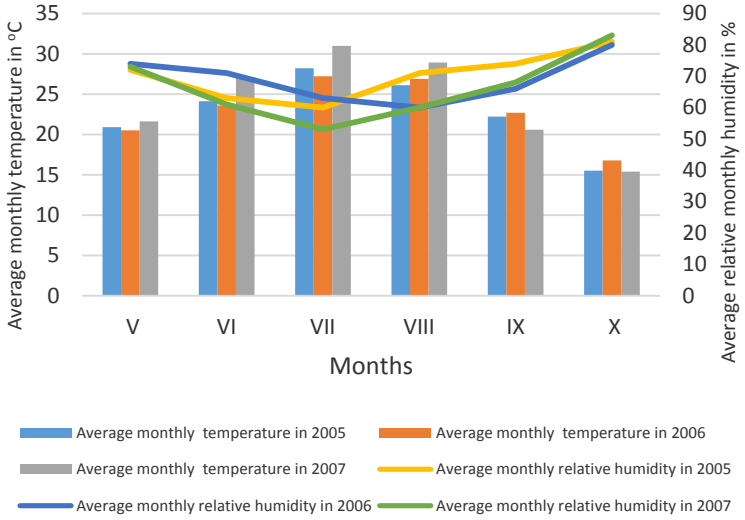

Figure 2. Monthly average air temperature and relative humidity in experimental plastic house in 2005-2007

Effects of irrigation and fertilization on the number of formed flowers, fruits sets, percentage of fructificationand yield potential

As mentioned above, all investigated treatments in the present study received the same growing conditions during the vegetation, the onlydifference was in the irrigation and fertilization techniques and frequency of water and fertilizersapplication. This approach enabled us to estimate the effects of different irrigation and fertigation regimes on the number of formed flowers and fruits sets in pruned pepper. As it can be seen from the results in Table 3, the examined treatments have noted differences according to the number of formed flowers and the number of fruits sets per plant. The largest number of formed flowers (69.67) and fruits sets (41.67) was noted in the drip fertigation treatment with 2 day frequency (DF1) with a statistical significance of 0.5 level of probability in comparison to DF2, DF3 and $Ø_B$. Then comes the DF2treatment with65.90 formed flowers and 38.50 fruits sets and statistical significance of 0.5 level of probability when compared to DF3 and $Ø_B$. Similar effects of the drip irrigation interval on the number of bell pepper fruits are presented by Sezen*et al*., (2006). A positiveeffectof drip fertigation on the number of formed flowers and fruits sets in our study is presented by comparison of the results from the treatments DF3 (drip fertigation scheduled by tensiometers)and $Ø_B$. Namely, the treatment DF3(with similarand sometimesa bitlongerirrigation intervalcomparedwith $Ø_B$) has shown8.32% and 19.2% higher number of formed flowers and fruits sets compared to$Ø_B$. The results are statistically significant at 0.5 level of probability.Antony and Singandhupe (2004) indicated that drip irrigation pepper had bigger plant height and highernumber of branches compared with surface irrigated crops. As the plant height and branches increased, new nodes for flower and fruit development appeared resulting in an increase in number of fruits and total yield. In this context, Burt *et al*.,(1998) reported that drip irrigated peppers do not experience the moisture stress that furrow irrigated peppers experience between irrigations. This seems to allow more uniform growth rates and development without periods of starting and stopping.

Table 3. Average number of formed flowers and fruit sets per plant, and percentage of fructification for the period 2005-2007

Treatments	Number of formed flowers	Number of fruits sets	Percentage of fructification	Comparison of percentage of fructification with treatment $Ø_B$
DF1	69,67[a]	41,67[a]	59,8	119,8
DF2	65,90[b]	38,50[b]	58,4	117,0
DF3	60,64[c]	33,26[c]	54,8	109,8
$Ø_B$	55,98[d]	27,91[d]	49,9	100

*Values in rows followed by the same letter are not significantly different at the 0.05 probability level

Regarding the percentage of fructification, the highest percentage was noted in the DF1 and DF2treatments. This positive effect of these two treatments is due to the higher number of formed flowers and the greater opportunity for them to be fructified, which can be connected with the proper irrigation and fertigation regime enabled through the drip irrigation system. The DF3 treatment has achieved a somewhat lower percentage of fructification when compared to DF1 and DF2 or expressed through relative values 9, i.e. 6.5% lower fructification. The highest abortion of flowers, i.e. lowest fructification of49.9%, was noted in the treatmentwith furrow irrigation with application of water every 7 days with conventional fertilization ($Ø_B$). Jankulovski (1983) noted an average fructification of 19.78% in Sweet Yellow variety up to 31.22% in

StajkovskiKavardjik. Our results for pepper fructification in furrow irrigated treatment with conventional fertilization are better than those of Jankulovski (1983), what can be result of the technology of controlled pepper growth (pruning of pepper). According to Rusevski (2005), pruned pepper has possibility for re-flowering, it means that pepper can form fruits and flowers again; even ifharvest waspreviously done from the same nodes. However, the highest percentage of abortion of flowers in the $Ø_B$treatment in our investigation may be associated with continuous water stress which is result of inadequate water and soil nutrient procurement affected by the irrigation and fertilization regime. In this context, Candido*et al*., (2009)emphasized that water deficit and reduced fertilizer availability, especially of nitrogen, are very harmful for bell pepper during the reproductive phase. Wiertz and Lenz (1987) suggested that water shortage can be more detrimental to pepper than nutrient deficiency.Therefore, water stress during flowering or fruit sets causes flower drop (Candido*et al*., 2009), lower size, number and weight of fruits (Katerji*et al.*, 1991), as well as yield losses (Jaimez*et al*., 2000; Sezen*et al*., 2006). According to Rego*et al*., (1988), suitable irrigation can increase the soil water content and also nutrient availability, which according to many authors results in better water and fertilizer use efficiency, as well as improving of yields (Burt *et al*.,1998; Cukaliev*et al*., 2008; Kafkafi and Tarchitzky 2011;Tanaskovikand Cukaliev 2014; Bar-Tal *et al*., 2015; etc). Tanaskovik*et al*., (2015) indicated that drip fertigation created better environment for initial flowering and technological maturity in pepper than furrow irrigation and conventional application of fertilizers. Also, in the present studywe have found thatirrigation and fertigation regimeaffects yield potential too (Table 4).

Table 4. Average pepper yields (t/ha) for the period 2005-2007

	DF1	DF2	DF3	$Ø_B$
Yield t/ha	71,11[a]	68,40[a]	62,61[b]	54,74[c]
Comparison with treatment $Ø_B$ in %	129,9	125,0	114,4	100

*Values in rows followed by the same letter are not significantly different at the 0.05 probability level

From the data presented in Table 4, it can be concluded that the highest average pepper yield of 71.11 t/ha has been realized in the DF1treatment, followed by the DF2treatment with 68.40 t/ha or 2.71 t/ha less yield, while the DF3 treatment showed 8.5% i.e. 5.79 t/ha less yield when compared to DF1 and DF2. Similar effects of drip fertigation intervals as ours were reported by Bar Yosef (2003). According to Agele*et al.*,(2006), the trend to increase crop yields has led to frequent fertigation and therefore the time intervals between successive fertigation events have diminished to hours or even less. Otherwise, the lowest yield of54.74 t/ha in our study was noted in the control treatment ($Ø_B$), which is result of applied irrigation and fertilization techniques. All three treatments with drip fertigation show statistically significant yield when compared to the control treatment($Ø_B$).Our results are consistent with a number of other investigations (Oğuzer*et al.*, 1991; Halitligil*et al*., 2002; Antony and Singandhupe 2004; Tanaskovic*et al*., 2005; Sezen*et al*., 2006; Tanaskovik*et al*., 2011).

Table 5. Correlation coeficients determined by bivariate Pearson analysis

	Number of irrigation application rate	Number of formed flowers	Number of fruits sets	Yield
Number of irrigation application rate	1	0,768	0,682	0,625
Number of formed flowers	0,768	1	0,869	0,755
Number of fruits sets	0,682	0,869	1	0,878
Yield	0,625	0,755	0,878	1

Furthermore, to confirm our results mentioned above, we have done correlation analysis between the number of irrigation application rate, number of formed flowers, number of fruits sets and yield potential. According to the Petz classification (1985), a significant positive correlation was found between the number of irrigation application rate, number of formed flowers, number of fruits sets and yield potential (Table 5). The achieved results in our study once again showed positive effect of the drip irrigation regime on the productive characteristics of the pepper. In this context, Candido*et al*., (2009) reported that plants subjected to periods of water shortage exhibited a significant reduction of the number of peppers and marketable yields in comparison with proper irrigated plants.DallaCosta and Gianquinto (2002), noted that yield losses in stressed pepper are always related due to reduced number of fruits.As it can be seen from the results in the Table 5, there isa strong linkage between the productive characteristics of the pepper crop. Antony and Singandhupe (2004) in their investigations established positive correlation between plant height and number of branches with pepper yield.

Conclusions

Fortwo stem pruned pepper grown in an unheated plastic house and irrigated and fertigatedwith the same amount of water and fertilizers, the drip fertigation technique provideshigher number of formed flowers and fruits sets, better percentage of fructification and higher yield compared tofurrow irrigation and conventional application of fertilizers.Generally,from the results achieved in our study, we can conclude that drip fertigation at 2 and 4 day intervals is the best option to achieve higher percentage of fructification and higher yield, as well as better farmer's income and productivity.

AGRO-CHEMICAL CHARACTERISTICS OF SOIL IN RASPBERRY-GROWING REGION OF IVANJICA (SERBIA)

Abstract

Raspberry growing in certain parts of Serbia is rapidly developing owing to cost-effectiveness of production and specific physical-chemical characteristics of the soil, making it unsuitable for other types of fruit-growing. Analysis of soil samples from existing and prospective raspberry plantations reveals its heterogenic composition, depending on sampling site and actual method of land use. Prospective raspberry-growing land areas are characterised by strong substitution acidity (pH/KCl<4.5) in 52.8% samples, with non-carbonic composition present in 88.9% of samples and an approximately equal share of medium and high content of humus and total nitrogen in the humus horizon, compared to a considerable reduction of these parameters in the sub-humus horizon. The content of accessible phosphorus is <6 mg/100 g in 41.7% of humus horizon samples, compared to 55.6% in sub-humus horizon, whereas accessible K_2O content ranged from low to medium supply required for raspberry cultivation. Soil under raspberry plantations shows presence of acidic soil reaction in the humus horizon, with 97.2% of non-carbon samples and a significant number of samples having a high content of humus and total nitrogen, as well as a high content of accessible phosphorus in the humus horizon in 77.8% of samples, as opposed to only 16.7% in soils of prospective raspberry plantations. The high content of accessible potassium was pronounced, reaching 94.4%. The presented results show that unfavourable agro-physical and agro-chemical composition of soil is compensated by high volumes of mineral and organic fertilizers, with potentially multiple impacts on environmental sustainability and productivity of raspberry plantations.

Key words: *Agro-chemical analysis, Soil reaction, Phosphorus, Potassium, Raspberry.*

Introduction

Soil is complex and dynamic system which tends to change its biological, chemical and physical characteristics when subjected to agricultural production. A number of studies indicate that intensive agricultural production causes deterioration of the soil quality. On the other hand, it is well-known that proper soil management, good agricultural practices (implying regular control of soil fertility and implementation of basic measures of fertilisation and agro-technology) can sustain the soil's productive capacity at a minimum impact on the environment (Milivojevic et al., 2012). Preventive measures, detection of risk and devising effective solutions play a vital role in protecting soil from degradation. To this end, it is recommended to conduct systematic checks of the soil fertility and contents of hazardous substances, i.e. to conduct monitoring of the soil quality (Sekulic et al. 2005). The variability of climatic conditions and incomplete agro-technical measures due to insufficient implementation of fertilisers have a significant impact on the accessibility of nitrogen in the soil, thereby frequently reducing accessibility of the plant nutrient (Bogdanovic 2009). A limiting factor in intensive farming is the soil acidity and insufficient supply of plant nutrients. Large areas of land in our country are characterised by presence of acid

soils such as lessive and pseudo-gley soils. Stevanovic et al. (1995) state that in the total area of 4.700.000 ha of cultivation areas in the territory of Central Serbia and Kosovo, over 2.800.000 ha or more than 60% are lands of acidic reaction, around 30% of which are extremely acidic. With the exception of one part of regions of Mačva, Pomoravlje and Stig, acidic soils dominate the agricultural areas of Central Serbia, as well as the largest part of the hills-and-mountains region of the country. Considering that most of cultivated plants require mildly-acidic, neutral to mildly-alkalic soil reaction, there are few plants that can endure the conditions of these soil types. Voluminous research so far has supported the conclusion that the content of mobil aluminium in these soils has increased (Dugalic et al., 2008; Djalovic et al., 2012). Narro et al. (2001) and Sumner (2004), state that the weak fertility of acid soils occurs as a result of the reduced conductivity of certain biogenic elements and compounds (P, Mo, B), as well as due to the increased presence of certain toxic elements, primarily Al. There is also a large number of authors who point that the main reason for the reduced productivity of this type of soils is its increased content of mobile Aluminium, which is toxic for most of cultivated plant species (Jelic,1996; Jelic et al., 2004; Jelic and Djalovic, 2008). Due to the reasons stated above, there is the growing need to formulate fertilisation and cultivation systems for most of the cultivated plant types, taking into consideration both the soil and climatic conditions of diverse farming areas.

The aim of the paper was to determine the agro-chemical characteristics of the soil in the region of Ivanjica Municipality and its suitability for cultivation of different types of fruits.

Material and methods

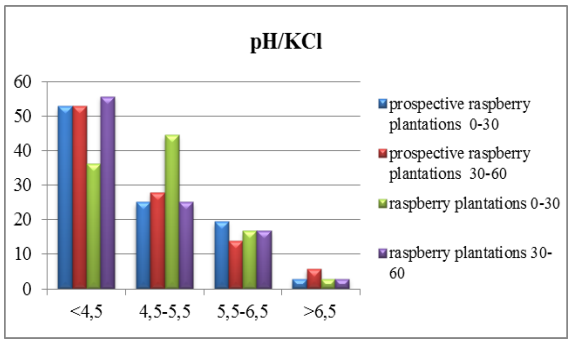
Sampling of soil was performed in August 2015 in the rural area of the Ivanjica municipality, at agricultural land under raspberry plantations, as well as potential cultivation areas (plough-fields, stubble-fields, meadows, fodder fields), collecting an equal number of samples from a total of 72 sampling localities. The samples were taken from two depth levels (0-30 cm and 30-60 cm, respectively) and the sampling plots were assigned GPS coordinates. The number of samples per local village areas was determined in proportion with the area of cultivated land and the actual level of agricultural production of the area, primarily focusing on raspberry production according to the data from the 2012 Agricultural Census. The agro-technical characteristics of the soil were determined using the following methods: pH value in H_2O and 1 MKCl-u (potentiometrically); humus (using the Kotzman method); total nitrogen (Kjehdahl method); easily accessible phosphorus and potassium (AL method), P_2O_5 (colorimetric method), K_2O (flame-photometric).

Results and discussion

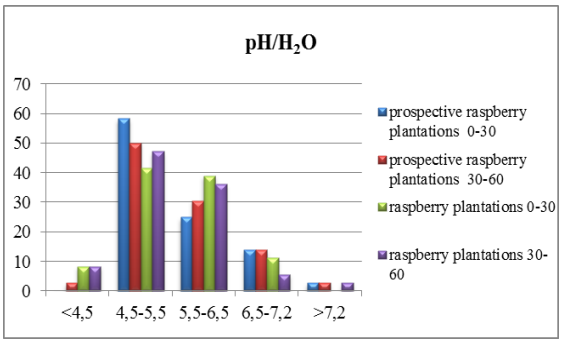
The active acidity of the soil, shown in Graph 1 at both sampling depths in cultivated areas which are not used for fruit cultivation (plough-fields, meadows, stubble-fields, fodder fields) was in the range between the strong acid reaction (50.0-58.3% of the samples) and medium acid reaction in 25-30.6% of the samples. A neutral reaction of the soil was present in only 13.9% of the samples. Areas under raspberry plantations were also mostly found to have a strong acid reaction of the soil (41.7-47.2%) of the samples, as well as a medium acid reaction in 36.1-38.9% of the samples. Samples taken in certain localities show extremely acid reaction (8.3%), and a similar trend was observed for neutral and weak alkalic reaction.

Substitution acidity of the soil, (Graph 2) in the humus (Ah) horizon (0-30 cm) of agricultural areas not used for fruit-growing was in 58% of the samples found to have a strong acidic reaction of the soil, which represents a limiting factor in a potential use of these types of soils for intensive production of most fruit types except berries. An acidic reaction was observed in 25.0-

27.8% of the samples, whereas the percentage of occurrence of a weak acid reaction was even lower (13.9-19.4%). In 36.1% of samples taken from the 0-30 cm layer of land areas under raspberry plantations, there was a strong acid reaction, whereas 44.4% of the samples showed an acid reaction. With the increase of the sampling depth in the sub-humus the acidity of the soil increases as well, so that 55.6% of the samples recorded a strong acid reaction of the soil. In addition to this, acid reaction was recorded in 25.0% of the samples, whereas the number of samples with a weak to neutral reaction in both horizons ranged between 2.8% and 16.6%. The over-excessive acidity is one of the factors reducing the overall quality of the soil and its fertility, thereby their productive capacity. The low productivity of the cultivated plants occurs due to the combination of the toxic effects (Al, Mn, Fe and H) and the insufficiencies of P, Ca, Mg, K and Zn (Milivojevic et al., 2012).

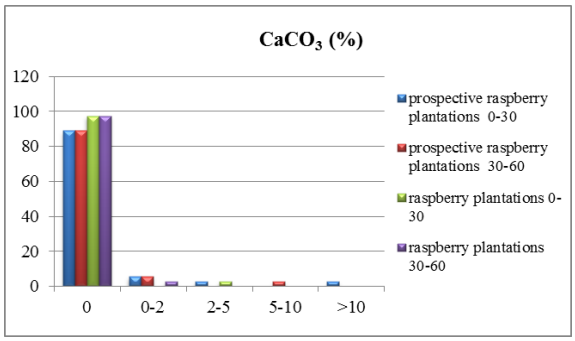


Graph 1. Active acidity of the soil (pH/H_2O)



Graph 2. Substitution acidity of the soil (pH/KCl)

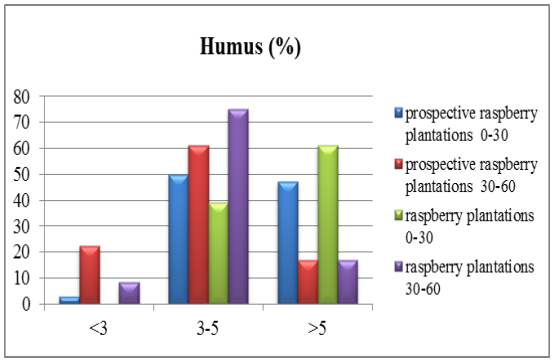
In farmland areas that are not currently used for fruit-growing, there was an 88.9% share of non-carbon, compared to 5.5% of mildly carbon soils (0-2% CaCO3). The areas under fruit plantations, 97.2% of the samples in both sampling horizons were non-carbon soils. Presence of calcium carbonate was established in certain individual localities, as a consequence of non-decomposure of the material that was applied in the calcification process.



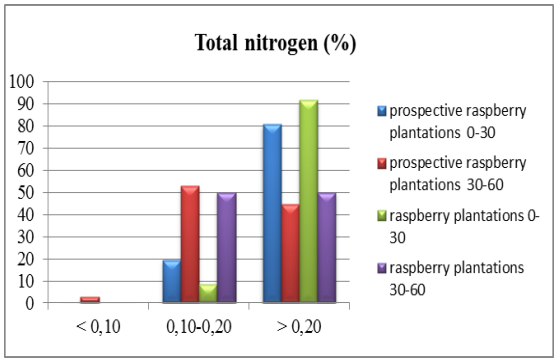
Graph 3. Content CaCO3 (%)

The humus content in the soils present in the Ivanjica municipality region (Graph 3) mostly belong to the class of humus soils (3-5% hums), as established in 50.0% of the humus horizon samples and 61.1% samples taken from the sub-humus horizon. High-humus soils are present in 47.2% of the samples taken in the humus horizon and 16.6% of the sub-humus horizon samples. A lower level of humus (< 3%) was observed in 2.8% of the samples from the humus horizon (0-30 cm) and 22.2% of the samples from the sub-humus horizon. Similar results were found in the soils under fruit plantations.

Study results shown in Graph 4 show that the soils under consideration possess a medium (0,10-0,20%) to high (>0,20%) contents of total nitrogen, depending on the depth of the soil sampling profile. The farmland areas that are not used for cultivation, there was a high nitrogen content (>0,20%) established in 80.6% of the samples of the soil and 44.4% of the sub-humus horizon samples. The content of the total nitrogen decreases with the increase of the sampling depth. In the land areas under raspberry plantations, the content of total nitrogen in the soil was higher in the humus (Ah) horizon, since 91.7% of the samples showed high nitrogen contents.



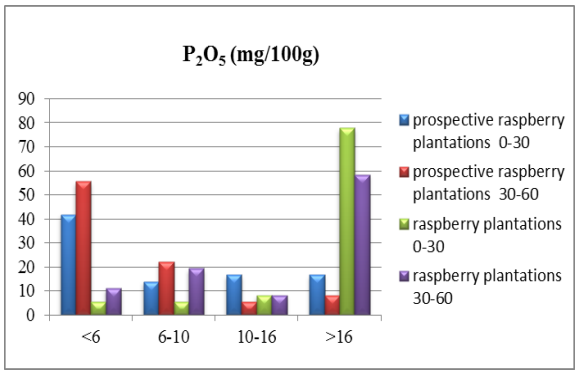
Graph 4. Content of humus (%)



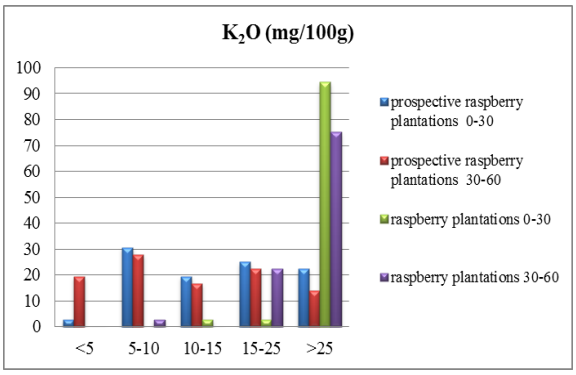
Graph 5. Content of total N (%)

Based on the border values determining the ranges of easily-accessible P_2O_5 levels in soils possessing pH <6 in 1M KCl, the highest percentage of the samples from the potential raspberry-growing land areas showed a very low content of easily accessible phosphorus (< 6 mg P_2O_5/100g of the soil). In the potential fruit-growing land, very low content of phosphorus (< 6 mg P_2O_5/100 g of the soil) was found in the humus (Ah) horizon (0-30 cm) of 41.7% of the soils samples, compared to 55.6% of the samples in the sub-humus horizon (30-60 cm). The low pH value contributed to the bonding. The low phosphorous content is mostly found in soils with acid reaction. It is well-known that accessibility of phosphorus in acid soils decreases due to its immobilisation by free Al^{3+} and Fe^{3+} ions (Debnath et al. 2000).

The soils under fruit plantations show significant differences in the content of accessible phosphorus, compared to other farmland areas where the sampling was performed. In 77.8% of the humus (Ah) horizon (0-30 cm) and 58,3% of the sub-humus horizon (30-60 cm), the content of the easily accessible phosphorus is high (>16 mg P_2O_5/100g of the soil). The optimum content of easily accessible phosphorus (10-16 mg P_2O_5/100g of the soil) was found in 8.3 % of the samples taken from both depths of the soil, whereas the other samples contained a low phosphorus content. Improper and uncontrolled use of fertilisers in excessive doses can lead to antagonism in certain elements, and can also lead to different changes in biological balance of agro-systems with an ultimate adverse impact on the quality of the yield (Wu et al. 1998, Kraus et al. 2000).



Graph 6. Content of easily accessible P_2O_5 (mg/100g of the soil)



Graph 7. Content of easily accessible K_2O (mg/100g of the soil)

The soils of farmland areas that are not currently used for fruit production were found to have a low content of easily accessible potassium (K_2O 5-10 mg/100g of the soil) in 30.6% of the samples from the humus horizon (0-30 cm) and a medium content of this element (10-15 mg/100g of the soil) in 19.4% of the samples. The optimum content of potassium (K_2O 15-25 mg/100g of the soil) was found in 25.0% of the samples from the humus horizon, whereas a high potassium content (K_2O >25 mg/100g of the soil) was present in 22.2% of the samples. With the increased depth of sampling (30-60 cm), there was a reduced presence in the class of optimum and high content values of this element, which was complemented with a higher percentage of the low to very low content class. The optimum content of the easily accessible potassium was found in 22.2% of the samples, compared to 27.8% of the samples with a low content of easily accessible potassium; the percentage of the samples within other intervals of boundary values was between 13.9% and 19.4%.

Soils under fruit plantations occupy a large share (94,4%) in the category of the samples with a high content of easily accessible potassium (K_2O >25 mg/100g of the soil), which is an indication of intensive nutrition of plants with this element. A high content of the easily accessible potassium was found in 75.0% of the samples from sub-humus (30-60 cm) horizon, compared to 22.2% of the samples with an optimum content of this element.

Conclusion

Soils of the Ivanjica raspberry-growing region are mostly characterised by highly acidic to acidic soil reaction, carbon-free in 88.9-97.0% of samples, depending on the type of sampled areas. The humus content in most of the sampling areas was in the range between 3 and 5%, with no significant differences being observed in relation to the type of the cultivated land. At the same time, the total nitrogen content was high in over 80% of the samples, with raspberry plantations soil having a higher total nitrogen content compared to other types of cultivation land. The soil of the farm-land under raspberry has a high content of easily-accessible phosphorus to over-excessive nutrition, while at the same time the soils of non-cultivated areas are extremely poor in this element. The potassium level depends on the level of nutrition, with a lower content of potassium being present in the less-cultivated areas, compared to a high content of this element generally present in 94.4% of samples taken from intensive raspberry plantations. The results show that agro-chemical characteristics of the soil in most localities do not support cultivation of most fruit types, whereas the measures for cultivation of raspberry-growing land require pre-planned implementation of melioration measures, which are not standardly used in most plantations.

Acknowledgements

This study was funded by the Ministry of Agriculture and Environmental Protection of the Republic of Serbia, under the project entitled 'Agro-physical and Agro-chemical Characteristics of the Soils of West Serbia (Moravičko-Kolubarski Region) with a Recommendation for their Use in Growing Different Types of Fruits', partial funding was provided by the Ministry of Education and Science of the Republic of Serbia (Donation No. TP 31080).

Abstract

Soil is one of the most important natural resources and degraded due to intensive agricultural practices. Soil degredationdecreases soil fertility with decreasing soil physical, chemical and biological quality parameters. Management of physical soil quality parameters shapes the dynamic parts of soil chemical and biological quality. Basic physical soil quality indicators can be summariezed as soil texture, soil depth, infiltration, bulk density, water holding capacity, aggregate stability and penetration resistance. Recycling organic wastes in agricultural fields is important to improve soil physical parameters as a part of whole soil quality.Evaluating soil physical behaviours helps to decision for basic agricultural practice or crop patern in sustainable land management systems.

Key words: *Soil quality, physical indicators, organic waste*

Introduction

The health of our environment depends on soil, air, and water quality. As a natural resource, soilcan provide the physical support, nutrients, water, and gas exchange necessary for crop growth. The soil quality concept placed in the literature in the early 1990s (Doran and Safely, 1997; Wienhold et al., 2004). Generall definition of soil quality is‘‘the capacity of a specific kind of soil to function, with in natural or managed ecosystem boundaries, to sustain plant and animal productivity, maintain or enhance water and air quality, and support human health and habitation’’ (Karlen et al., 1997).

Soil quality has an intrinsic part covering a soil's inherent capacity for crop growth, and a dynamic part influenced by the manager. Natural or inherent soil quality, that is a function of geological materials and soil state factors or variables such as topography, parent material, mineralogy and particle size distribution, are mainly viewed as almost static and usually show little change over time. Dynamic part of soil quality generally changes in response to soil use and management (Larson and Pierce, 1994). The distinction between inherent and dynamic parts of soil quality can be characterized by the genetic (or static) pedological processes versus the kinetic (or dynamic) processes in soil (Richter 1987; Koolen 1987; Carter 1990).

The smallest set of soil properties is called as minimum data set for soil quality assesment. Indicators in minimum data set of soil quality are need to be developed for (i) integrate soil physical, chemical and/or biological properties and processes, (ii) apply under diverse field conditions, (iii) complement either existing databases or easily measurable data, and (iv) respond to land use, management practices, climate and human factors (Doran and Parkin, 1994). In this paper attributes of soil physical quality parameters and using organic wastes to improve soil physical quality in agricultural management system were reviewed.

Physical soil quality indicators

Physical indicators of soil quality are mostly related to water storage and movement, soil structure. Basic physical indicators of soil quality are soil texture, soil depth, infiltration, bulk density, water holding capacity, aggregate stability and penetration resistance (Table 1). Some physical indicators such as; texture and topsoil depth are fixed soil properties that cannot be altered, except over long time periods or sediment deposition by erosion. These soil properties influence soil use or productivity, they are inherent part of soil quality. For example, soil texture is an inherent soil property which strongly influences many soil quality indicators, like drainage and water holding capacity.

Table 1. Physical, chemical, and biological indicators for soil quality (Doran et al., 1996; Larson and Pierce, 1994; and Doran and Parkin, 1994)

Soil Physical Indicator	**Rationale for assessment**
Soil texture	Indicates how well water and chemicals are retained and transported. Provides an estimate of soil erosion and variability.
Soil depth and rooting	Indicates productivity potential.
Infiltration	Describes the potential for leaching, productivity, and erosion.
Soil bulk density	Describes soil structure, porosity, aeration and water holding capacity and permeability. It is used to correct soil analyses to volumetric basis.
Water holding capacity	Describes water retention, transport, and erosion. Available water is related with soil bulk density and organic matter.
Aggregate stability	Describe soil erodibility, capacity to store and transmit water, aeration
Penetration resistance	Describes soil strength for effective penetration by crop roots

Managing physical soil quality indicators

Many soil quality indicators interact with each other, and the value of one indicator may be influenced by one or more of the other selected parameters (Arshed and Martin, 2002). Changes in soil quality can be assessed by measuring appropriate soil quality indicators at different time intervals for a specific use in a selected agro-ecosystem. Using organic wastes is very important for improving soil physical quality in agricultural fields (Özdemir et al., 2015; Gülser et al. 2015).Candemir and Gülser (2011) studied the effects of different agricultural wastes on some soil quality indexes over two years in a clay field and a loamy sand field. They found that soil organic carbon contents were around 2% after 30 months in clay while they were generally less than 2% after 7 months in loamy sand. Candemir and Gülser (2010) found that addition of organic wastes generally decreased bulk density of the fine and coarse textured soils (Figure 1).

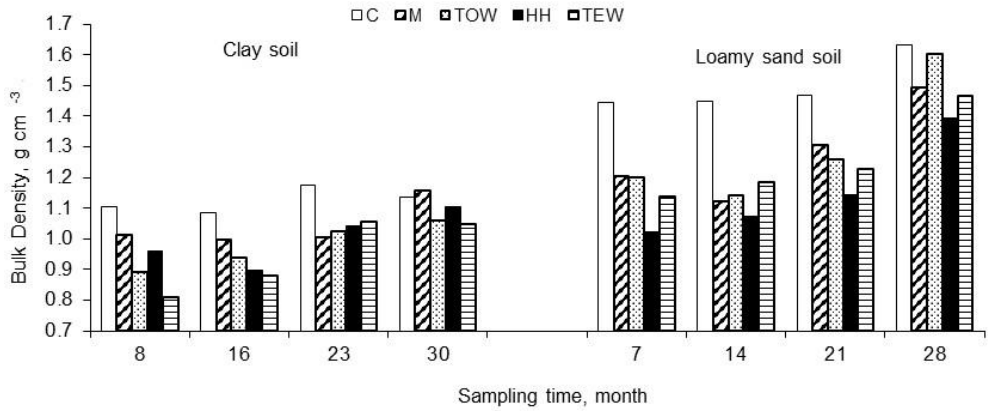

Figure 1. Effects of organic wastes on bulk density in clay and loamy sand soils (C:control; M:manure; TOW: Tobacco waste, HH: hazelnut husk, TEW:tea waste) (Candemir and Gülser 2010).

Bulk density is dependent on the densities of the soil particles (sand, silt, clay, and organic matter) and their packing arrangement. Bulk density is a dynamic property that varies with the structural condition of the soil. This condition can be altered by cultivation; trampling by animals; agricultural machinery; and climate (raindrop impact etc). Compacted soil layers have high bulk densities, restrict root growth, and inhibit the movement of air and water through the soil. Gülser and Candemir (2012) found that application of organic wastes into a clay soil increased total porosity, water holding capacity with decreasing bulk density and penetration resistance over the control treatment.

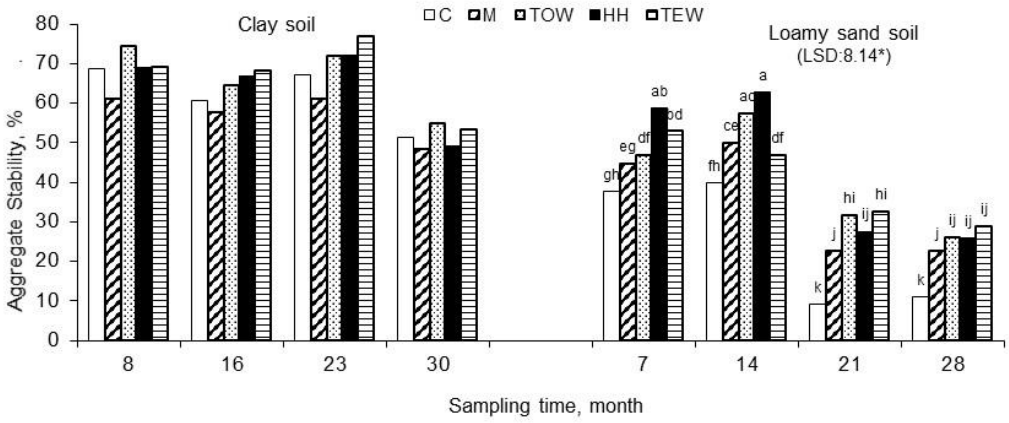

Figure 2. Effects of organic wastes on aggregate stability, in clay and loamy sand soils (C:control; M:manure; TOW: Tobacco waste, HH: hazelnut husk, TEW:tea waste) (Candemir and Gülser 2010).

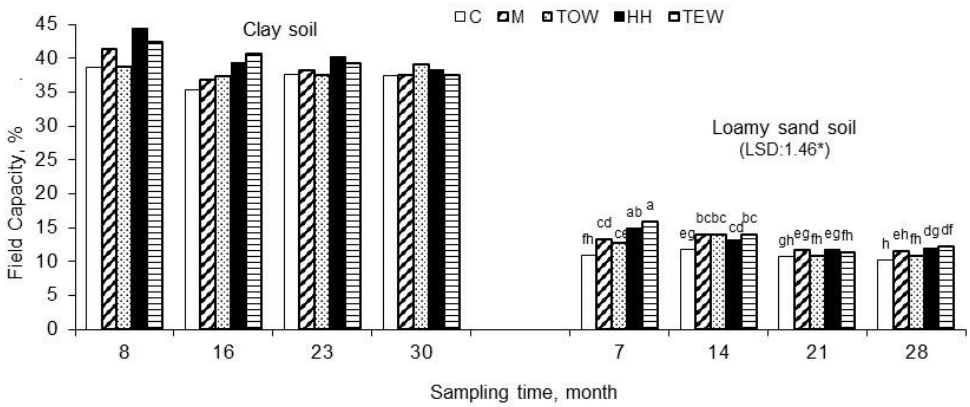

Figure 3. Effects of organic wastes on field capacity in clay and loamy sand soils (C:control; M:manure; TOW: Tobacco waste, HH: hazelnut husk, TEW:tea waste) (Candemir and Gülser 2010).

Aggregate stability is a measure of the vulnerability of soil aggregates to external destructive forces (Hillel, 1982). Candemir and Gülser (2010) reported that addition of organic wastes into fine and coarse textured soils generally increased aggregate stability (Figure 2). Aggregates improve soil quality by protecting soil organic matter entrapped in the aggregates from exposure to air and microbial decomposition, decreasing soil erodibility, improving water and air movement, improving the physical environment for root growth and improving soil organism habitat (USDA 1999).Breakdown of aggregates is the first step to crust development and surface sealing, which impedes water infiltration and increases erosion. Soil aggregation can change over a period of time, such as in a season or year. Aggregates can form, disintegrate, and reform periodically (Hillel, 1982). Organic matter applications increase aggregate stability of soils (Özdemir and Kop Durmus, 2016; Gülser et al. 2015).

An aggregated structure is generally considered best for agricultural activities. Candemir and Gülser (2010) found that addition of organic wastes generally increased field capacity of the fine and coarse textured soils (Figure 3).A good soil structure is defined as an arrangement of soil particles into stable larger units, and of the pore spaces between those units, that allows movement of water through the soil, movement of air into and out of the soil and ease of penetration by roots, and that protects the soil against erosion (Gülser, 2006).Pore size distribution is considered to be a good indicator of the soil structural condition and useful for predicting water infiltration rates, water availability to plants, soil water storage capacity, and soil aeration status (Carter et al., 1997).

In another study, Gülser et al. (2015) found that incorporating compost and hazelnut husk into clay soil at the hazelnut orchard improved soil physical properties. Compost and hazelnut husk applications increased aggregate stability by 2 and 7%, initial infiltration rate by 34 and 436%, and reduced bulk density by 20 and 33%, penetration resistance by 33 and 67% respectively ($P<0.01$), in comparison to control treatment. They concluded that hazelnut husk application was much more effective on improving the soil quality in hazelnut orchard than compost application in comparison to control treatment.

Conclusion

The assesment of soil quality is an important for defining the sensitivity of soil to damage and need to consider the sustainable management of soils. Soil quality should be defined with a reference to the function of soil because for a soil that is a good quality for one purpose may be a poorer quality for another purpose. Therefore in sustainable land management soil quality should be considered with respect to not only chemical quality indicators but also physical indicators due

to its multifunctionality because of possible change of the land management.Physical soil quality can be improved and managed in fine and coarse textured soils using agricultural wastes.

Abstract

Phosphorus (P), a dynamic property of soil is one of the absolutely required nutrients for healthy plant growth. Parent materials as well as management practices in a region significantly affect plant available phosphorus (PAP) concentration of soils. The purpose of this study was to determine the PAP concentrations of soils under five different management practices and to analyze and map the spatial distribution of PAP using geostatistical techniques. Soil samples were collected from approximately the corners of 5km*5km size grid cells within 252.000 ha land in South Eastern Region of Turkey. Total of 110 disturbed samples were taken from 0-20 cm depths, and analyzed for PAP, particle size distribution (sand, silt and clay), soil reactions (pH), electrical conductivity (EC), organic matter (OM) and calcium carbonate content. The P_2O_5 concentration ranged from 11.6- 787.9 kg ha^{-1} with a mean value of 70.9 kg ha^{-1}. The highest P_2O_5 concentration was recorded in forest soils (mean 98.9 kg ha^{-1}) and the lowest P_2O_5 (mean 39.4 kg ha^{-1}) was obtained from soils located in pastures. The highest variation (CV=155.25%) of P concentration was recorded in wheat-barley fields (rainfed) and the lowest CV (CV 61.53%) was obtained in lentil fields (rainfed). Changes in parent material, climate and management practices in the study area probably contributed to the high variation of P concentration. The semivariogram of PAP best fitted to exponential model. The range of the influence calculated for the PAP was 7020 m. The value for nugget/sill of PAP was 2.77% that indicated a strong spatial autocorrelation. High range value and low nugget/sill ratio suggest that PAP concentration of soils wassignificantly influenced by intrinsic variations such as parent material. The formation of a hole effect structure in semivariogram of PAP indicates a form of cyclicity or periodicity in parent materials of soils.

Keywords: *Spatial analyses, phosphorus, management, geostatistics, mapping*.

Introduction

Phosphorus, an important plant nutrient play a key role in many physiological and biochemical processes that increases the efficiency of agricultural production (Richards and Johnston, 2001). Therefore, PAP concentration in the soil should be at the optimum level.The variability of PAP affected by not only physical (clay content) andchemical (pH, OM, $CaCO_3$) properties of soilsbut alsofertilizer management, land use system, management practices, parent materials (Wang et al., 2009; Liu et al., 2013; Cheng et al., 2016) and environmental factors (slope, precipitation, elevation and land use) (Gao et al., 2011;Zhang et al., 2012). Besides Gao et al. (2011) reported

thatthe PAPconcentrationgradually decreased as the slope,elevation and precipitation and cultivation practices increases.Such factors lead to the heterogeneous distribution of PAP concentration (Umali et al., 2012; Roger et al., 2014). The heterogeneous supply of available P in the field causesvariability in plant growth (Corazza et al., 2003). Roger et al. (2014), reported that land use differences have significant impact on soil P reserves. The impact of land use can be evaluated by the determining soil P contents under different land uses.

Spatial variability of PAP may have significant effect on the efficiency of management practices applied. Therefore, determination of spatial variability of PAP concentration is quite important in terms of understanding the complex relationships within and between environmental factors (Liu et al., 2013). Evaluating and mapping the variability of soil properties on a regional scale require high costs, intensive labor and time. Greater variability particularly in the area to be studied results to increase the number of samples to be taken and higher costs, labor, and time (Mulla and McBratney, 2001), therefore, geostatistical methods have been developed as an alternative to existing methods. In this study, the effects of different land uses in an approximately 252.000 ha land on PAP have been investigated and mapped.

Material and Methods

Study Area

Soil samples were collected from an area of about 252.000 ha landlocated in Diyarbakir Province, Southeast Anatolia Region of Turkey (Figure 1.) Soils in study area have been formed over different parent materials. Soils in the south and south west part of the study have been formed mostly over basalt. The nort west and eastern part of the study area mostly composed of alluvium and marl(Çelik 2015). Long term total annual average rainfall of the area is 490.1 mm, and mean soil temperature is15.8°C(Anonymous, 2016).

Soil Sampling

The study area was divided into 5km*5kmsquare grids, and 250, 750 m and 1750 m sampling intervals were also sampled to analyze the variability in soilproperties occur at shorter than 5km distance. Thus, total of 110 soil sampleswith different parent materials and land uses was taken from 0-20 cm depth. Differences in parent material and land use provided a wide variabilityin physical and chemical characteristics.

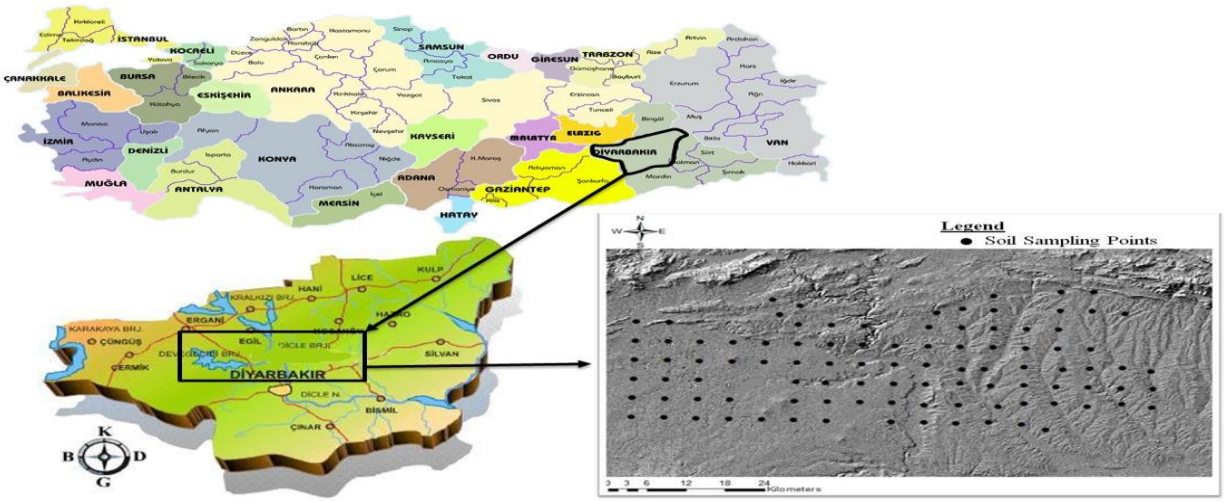

Figure 1. Study area and sampling locations

Physical and Chemical Soil Analysis:

AvaliableP was extracted using 0.5 M NaHCO3 and using the molybdenum-blue method (Olsen et al., 1954). Particle size distribution was determined by the hydrometer method in a sedimentation cylinder, using sodium hexamethaphosphate as the dispersing agent (Gee and Bauder, 1986). The soil reaction (pH) and electrical conductivity (EC) were measured in saturated paste (Rhoades, 1982). CaCO3 was determined by using calcimeter method as mentioned by Allison and Moodie (Allison and Moodie, 1965). Organic matter was determined by Walkley and Black (Nelson and Sommer, 1982).

Statistical Analysis

The descriptive statistics of data (minimum, maximum, mean, standard deviation, coefficient of variation, skewness and kurtosis) was performed by SPSS, Version 22.0(Table 1:Table 2).Geostatistical analysis was performed by the ARCGIS 10.1 (Table 3). The suitability of semi-variogram model was determined by r^2 value and Residual Sum of Squares (RSS). The models with r^2 value close to 1.0 and RSS value close to 0.00 were considered to be suitable (Yang et al., 2011).

Results and Discussion

Soils in the study area have formed over different parent materials such as basal, clay stone, sand stone, gravel and marl. Majority of soils have clay texture (97% of all) and the rest had clayey loam particle size distribution. Other than forest and rangelands, wheat and barley were the dominant crops (48% of the study area), lentils (21%) and maize (9%) are the other crops widely grown in the area. The P_2O_5 concentration ranged from11.55 to 787.90 kg ha^{-1}. The coefficient of variability for soil properties were 145.05% for P_2O_5, 56.62% for organic matter (OM), 54.44% for sand, 37.63% for silt and 36.62% for electrical conductivity (EC), respectively. The pH had the lowest variability in the study area (Table 1). The P_2O_5 had very high variability within all land uses and the highest variability was obtained in wheat and barley fields (Table 2).

Webster (2001) indicated that skewness value of a soil data can be accepted as an indication of distribution tendency. If skewness value is ≤ 0.5 the data does not require a transformation, if skewness value is > 0.5 and ≤ 1.0 square root transformation is applied and if skewness is >1.0 log transformation is used to bring the distribution of data to the normal distribution. The skewness value (4.71) of PAP indicated that PAP does not have a normal distribution. The PAP data was log transformed prior to the statistical and geostatistical analyses.

Table 1. Descriptive statistics for physical and chemical characteristics of soils studied at 0-20 cm depth (N=110)

		Minimum	Maximum	Mean	S. Deviation	CV	Skew.	Kurt.
Clay	%	32.70	82.70	63.14	12.21	19.34	-0.59	-0.64
Sand		2.30	47.30	17.91	9.75	54.44	0.77	-0.12
Silt		7.50	47.50	18.95	7.13	37.63	1.62	3.54
$CaCO_3$		1.02	49.28	5.25	7.58	144.40	3.50	14.56
OM		0.68	8.90	2.12	1.20	56.62	2.88	11.41
pH		6.76	8.19	7.59	0.31	4.11	-0.86	0.20
EC	dS m^{-1}	0.37	1.97	0.83	0.30	36.32	1.77	3.55
P_2O_5	kg ha^{-1}	11.55	787.90	70.90	102.84	145.05	4.71	27.46

The lowest PAP concentration was in pasture land (Table 2). The pastures in the region have mostly been severely degraded due to the intensive grazing.Ozgoz et al. (2013) also reported that

PAP concentration of pastures(27.09 mg/kg) was almost half (56.50 mg/kg) of the adjacent cultivated field.

The model created for PAP concentration and the related parameters have been shown in Table 3. The best fitted model of PAP was exponential. Exponential model exhibits linear increase from the origin and indicates a higher level of short-range variability. The PAP is one of the well-known dynamic properties which is strongly affected by changes in management practices. The management practices applied by the different land users in the study area contributed to the short range variability shown in exponential model represented.

Spatial dependence is widely used to express the variability of soil properties in space. If spatial dependence value is ≤ 25% the attribute is considered strongly dependent, if the value is between 25% to 75% the attribute is considered as moderately dependent and if the value is higher than 75% the attributed is considered to have low spatial dependency (Trangmar et al. 1985; Yang et al., 2011).

Table 2. Descriptive statistics of phosphorus (kg $P_2O_5 ha^{-1}$)concentrations under different land uses

Use Land	Minimum	Maximum	Mean	S. Deviation	CV	Skew.	Kurt.	N
Wheat/Barley	10.30	787.90	70.42	115.20	163.59	5.08	30.33	53
Lentil	16.00	102.80	45.50	28.00	61.54	0.70	-0.80	24
Corn	19.40	251.60	77.10	72.00	93.39	1.81	3.46	10
Pasture	11.60	159.00	39.40	40.30	102.28	2.48	6.94	13
Forest	13.30	234.90	98.90	91.40	92.42	0.68	-1.56	10

Pearson correlation showedthat P_2O_5 was significantly and positively correlated with both OM and EC while negatively correlated with clay content (Table 3).

Table 3. Correlation analysis among soil properties

	Clay	Sand	Silt	CaCO3	OM	pH	EC
Sand	-0.81**						
Silt	-0.59**	0.00					
CaCO3	-0.46**	0.20*	0.50**				
OM	-0.22*	0.07	0.28**	0.02			
pH	-0.16	0.17	0,03	0.30**	-0.02		
EC	0.14	-0.02	-0.21*	-0.10	-0.10	0.03	
P_2O_5	-0.23*	0.17	0.16	0.17	0.50**	0.04	0.22*

**Correlation is significant at the 0.01 level *Correlation is significant at the 0.05 level

The model revealed that the range value of PAP concentration is 7020 m and PAP has a strong spatial dependency. Wang et al. (2009) reported PAP concentration with a moderate spatial dependence and a range value of 3141 m. They indicated that spatial dependence of PAP has strongly been influenced by particle size distribution, mineralogical composition, soil forming processes, fertilization and soil tillage practices. The changes of slope, direction and management practices (different land use choices, soil tillage, irrigation and fertilization methods) in short distances lead to have a 7020 m range value. The similarity between samples have been significantly decreased after this distance. The model indicated a hole effect in PAP concentration. The structure of hole effect in many case is related to the existence of periodicity or reoccurrence due to the spatial feature of geological material in the region (Pyrcz et al. 2003).

Table 4 - Fitted semivariogram models and spatial characteristics of PAP

	Model	Co	Co+C	A (m)	SD (Co/(Co+C))*100	R^2	RSS
P_2O_5	Exponential	0.025	0.90	7020	2.77	0.96	0.0087

Co: nugget effect; Co+C: structural variance; A: range (m); RSS: residual sums of squares; SD: spatial dependence (%); R^2 correlation coefficient

The maps obtained for PAP concentration clearly showed that the PAP concentration in most part of the study area is lower than the threshold value for plant production (Figure 2). However, PAP concentration was much higher than the need of healthy plant growth in certain regions.

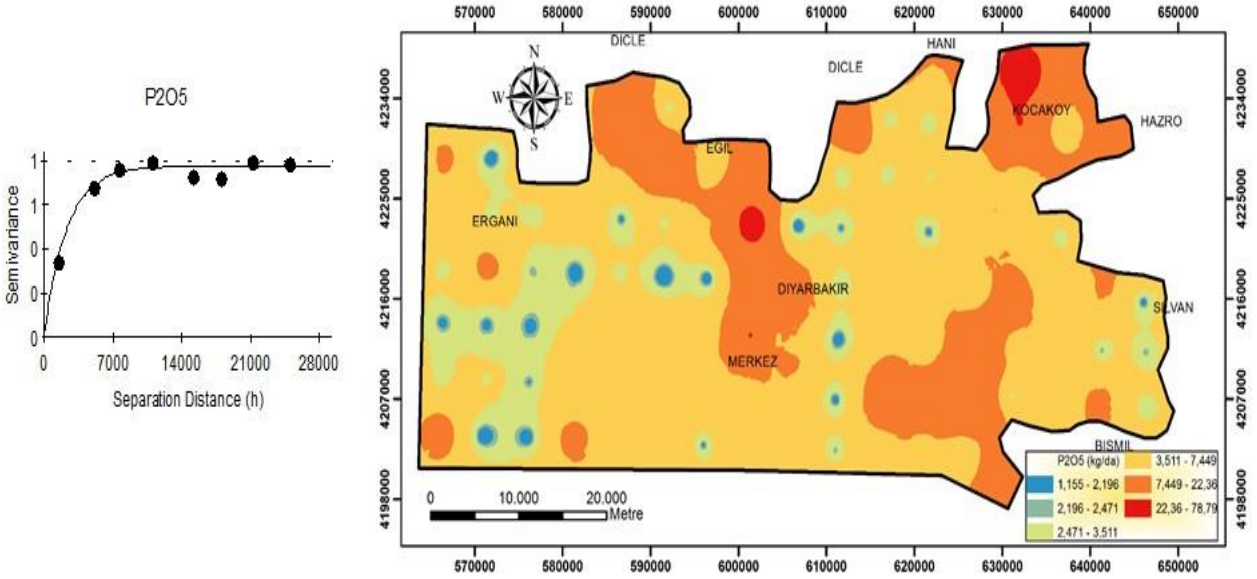

Figure 2. Spatial distribution of P_2O_5concentration in study area

Conclusions

The results of this study revealed that variation in land use had significant contribution to the spatial structure of PAP. The difference in management practices among farmers particularly for wheat, barley and maize fields resulted to such high spatial variability. The use of fertilizer mainly depends on the financial status of farmers not to any kind of soils test. This results to variable rate of fertilizer use for even adjacent fields.

Abstract

Several factors affect the availability of phosphorus (P) concentration in soils. Understanding the factors affecting the soil P content is essential to appropriate use of P sources in agricultural production. This study was aimed to identify the factors important for the plant available P concentration of naturally formed saline alkaline soils and map the spatial distribution of P concentration. Soil samples were collected from 0-30 and 30-60 cm depths by field sampling in a 400m×400m grid. Total of 202 locations were sampled from 2650 ha land. Plant available P (PAP) concentration, soil texture (clay, silt and sand contents), calcium carbonate content, organic matter, soil pH, electrical conductivity, exchangeable Ca, Mg, Na and K, exchangeable sodium percentage and sodium adsorption ratio of soil samples were determined. The PAP concentration in 0-30 cm depth ranged from 2.98 to 89.72 mg kg^{-1} with an average value of 28.52 mg kg^{-1}. The PAP concentration of 30-60 cm soil depth was between 1.72 and 83.04 mg kg^{-1} with a mean value of 35.91 mg kg^{-1}. The correlation analyses revealed that available P had a significant negative relationship between clay, calcium carbonate and exchangeable Ca and Mg contents, whereas the P had significant positive correlation between sand and exchangeable K contents of soils. Relatively high clay (mean 52.4%) and low organic matter content (1.87%) of soils increased the P fixation and lowered the availability. In addition to this, high and pH and calcium carbonate content might have induced to the formation of tricalcium and trimagnesium phosphates which significantly reduce the availability of phosphorus. In such cases, plants will have difficulty to utilize the soil P and show the signs of P deficiency. Thus, spatial distribution maps of plant nutritions such as P are important to locate and alleviate the problems encountered in arid regions.

Introduction

Soil salinity and sodicity of agricultural fields in arid and semi-arid regions pose an important constrain on plant productivity (Wang et al., 2015).In addition to the threats of salinity and high sodium concentration, reduction of phosphorus (P) availability and plant uptake in such environment worsen the problem of plant growth (Elgharably, 2011). Precipitation, transformation and fixation of P by soluble salts lower the P concentration in soil solution. Navarro et al. (2001) pointed to the low level of P flux through xylem under saline condition.

Soil pH, organic matter (Schneider and Haderlein 2016), the amount of clay size particles and the type of clay minerals, concentration of certain cations and anions (Elgharably, 2008), exchangeable sodium percentage (Parfitt, 1978), calcium carbonate content (Leytem and Mikkelsen 2005), hydroxides of Al^{+3} and Fe^{+3} (Bhattacharyya et al., 2015) have significant impact on availability of P in saline soils. The concentration of PAP in calcareous soils is

controlled by calcium phosphates in solid form. The P in soil solution can react with calcium (Ca) and magnesium (Mg) ions and form less soluble Ca and Mg-phosphates. Under this circumstances, plants cannot use the P in soil and may suffer severe P deficiency(Leytem and Mikkelsen 2005; Mahmood et al., 2013).

Abundance of factors affecting the concentration of plant-available phosphorus leads to have a very high variability even in a single field (Umali et al., 2012) which requires site-specific fertilization recommendations (Roger et al., 2014). Thus, determining the factors affecting the availability of P in a single field or a larger scale terrain is important to sustain the agricultural productivity. Geostatistical techniques have been widely used to model and map spatial distribution of soil properties. Roger et al (2014) showed that land use plays a significant role in soil P distribution.The purpose of this study was to assess the impact of several soil properties on PAP in saline and sodic soils.

Material and Methods

Study Area

Study area (2.650 ha) is situated in Emen Plain of Central Anatolian Plateau. The annual long term (1971-2000) average precipitation is 322.4 mm and mean air temperature is 11.7 ºC. Soil temperature regime is mesic (mean value of 13.5 ºC) and soil moisture regime is aridic (Soil Survey Staff, 1999). The dominant plant species were halophytes.

Soil Sampling

The study area was divided into 400m*400m square grids, and soil samples from 152 points of 0-30 cm and 30-60 cm depths were collected. Fifty more soil samples with 5, 20, 50, 125 and 300 m sampling intervals were also sampled to analyse the variability in soil properties occur at shorter than 400m distance.Thus, 202soil samples have been collected (Figure 1).

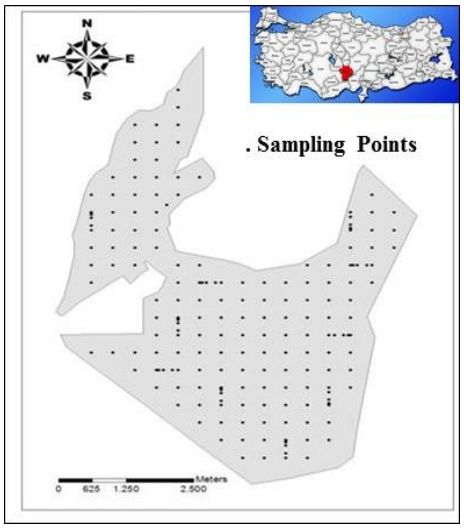

Figure 1. Study area and sampling locations

Physical and Chemical Soil Analysis:

Available P was a method described by Olsen et al. (1954). Particle size distribution was determined by the hydrometer method (Gee and Bauder, 1986). Exchangeable Na, K, Ca and Mg were determined with a method described by Thomas(1982). The exchangeable sodium percentage (ESP) was determined from the concentration of exchangeable cations using Equation 1 (U.S. Salinity Lab. Staff, 1954). The soil reaction (pH) and electrical conductivity (EC) were measured in saturated paste (Rhoades, 1982). Calcium carbonate was determined by using calcimeter method as mentioned by Allison and Moodie (Allison and Moodie, 1965). Organic matter was determined by Walkley and Black (Nelson and Sommer, 1982). Sodium adsorption ratio (SAR) was calculated from the concentration of Na, Ca and Mg concentrations extracted from saturated pastes (U.S. Salinity Lab. Staff, 1954).

$$ESP\ (\%) = \frac{\text{Exchangeable Na}}{\text{CEC}} * 100 \qquad (1)$$

$$SAR = \frac{[Na^{+}]}{\sqrt{\frac{[Ca^{++}]+[Mg^{++}]}{2}}} \qquad (2)$$

Statistical Analyses

The descriptive statistics and correlation testwere performed by SPSS, Version 22.0. Geostatistical analysis was performed by ARCGIS 10.1. The suitability of semi-variogram models was determined by r^2 value and Residual Sum of Squares (RSS). The models with r^2 value close to 1.0 and RSS close to 0.00 were considered to be suitable (Yang et al., 2011).

Results and Discussion

Soils in study area have been formed over salt rich marine and volcanic sediments. Soils were found on flat slope, mostly poor in organic matter, high in calcium carbonate, salt and exchangeable sodium (Table 1).

Table 1. Descriptive statistics soil properties for 0-30cm and 30-60 cm depths (N=202)

		Depth (cm)	Minimum	Maximum	Mean	Std.Dev.	CV	Skewness	Kurtosis

The PAP concentrations of surface soils ranged from 2.98 and 89.72 mg/kg with a mean value of 15.43 p mg/kg. The PAP concentrations of subsurface soils were between 1.72 and 83.02 mg/kg with a mean of 35.91 mg/kg (Table 1). The CV values in both depths indicated high variability (54.10% and 57.70%) that probably resulted from the high variability ofclay, sand, silt and $CaCO_3$ contents, EC, SAR and ESP values andexchangeable Ca, Na, Mg and K concentrations. Barros et al., (2005) investigated the effects of clay content on inorganic P cycle and reported a quite high relationship (r^2 =0.99) between clay content and P sorption of soils.

The relationships between the PAP concentration of soils and other soil properties have been evaluated by correlation test (Table 2). Significant negative correlations (P<0.01) indicated that the PAP concentration in surface soils is low where clay, $CaCO_3$, exchangeable Ca and Mg concentrations are high. In subsurface soils, the PAP concentration had significant negative correlations (P<0.01) with $CaCO_3$, OM, exchangeable Ca and Mg concentrations (Table 2). The PAP concentration in subsurface soils was high and significantly affected by salinity parameters of EC, exchangeable Na, SAR and ESP. The results revealed that the PAP concentration is high in saline and sodic conditions. The findings of Curtin et al. (1993) support the results of this

study. They claimed that excess Na^{+} in saline and sodic conditions replaces Ca^{+2}, Mg^{+2}, and Al^{+3} at the exchange sites. Increased negative charges promotes desorption of P components(HPO_4^- and $H_2PO_4^-$). In contrast, Khoshgoftarmanesh and Nourbakhsh (2009) found less available P in saline soils due to the increased bicarbonate extractable P.

Table 2. The results of ccorrelationtest among soil properties

	Depth (cm)	**Clay**	**Sand**	**Silt**	**CaCO3**	**OM**	**pH**	**EC**	**Ca**	**K**	**Mg**	**Na**	**ESP**	**SAR**

* Correlation is important at 5% level of significance, ** Correlation is important at 1.0% level of significance.

The parameters of best fitted semivariogram model for PAP concentrations were presented in Table 3. The best fitted model of PAP was exponential for both depths. Exponential model exhibits linear increase from the origin and indicates a higher level of short-range variability.

Table 3 - Fitted semivariogram models and spatial characteristics of PAP

	Depth (cm)	Model	Co	Co+C	A (m)	SD (Co/(Co+C))*100	R^2	RSS
PAP	0-30	Exponential	0.001	1.71	354	0.06	0.85	0.0437
	30-60	Exponential	0.32	3.50	339	9.14	0.75	0.33

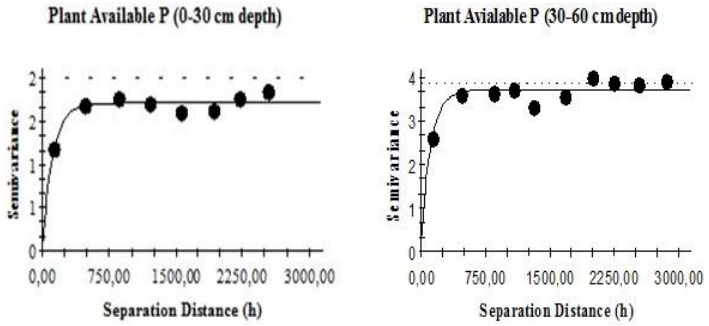

Figure 2. Experimental semivariograms of plant availablephosphorus with fitted models

The lowest PAP concentration was found in central part of the study area where $CaCO_3$ content was almost 40% and OM content was ranging from 0.5 to1.0% (Figure 2). Negative correlations between PAP concentration and $CaCO_3$comply with the distribution maps. The P species in alkaline soils with high exchangeable Ca and Mg concentrationsprobably have formed less soluble $CaPO_4$and $MgPO_4$(Lindsay et al., 1989).

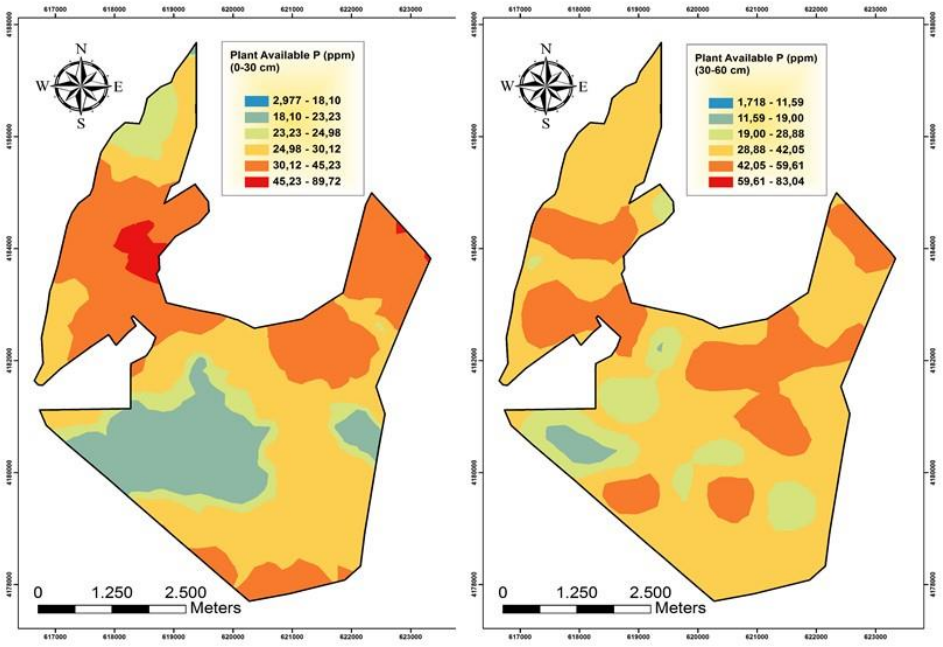

Figure 3. Spatial distribution of plant available phosphorus in 0-30 cm and 30-60 cm depths

Conclusion

The results indicated that the spatial structure of PAP in saline and sodic environment has been markedly affected by salinity/sodicity parameters (EC, exchangeable Na, SAR and ESP), clay, $CaCO_3$ and exchangeable Ca and Mg contents. Spatial maps are useful to locate the distribution of concentrations in a particular area of interest. This allows to locate the areas need to be precisely managed to correct the deficiency. Controlling the factors affecting the availability of a plant nutrient is also important in precision agriculture.

Abstract

Salinization is one of the most important limiting problems of plant growth in Turkey as it is in all over the World. Salinity differs from other soil characteristics in terms of spatial distribution structure and has mainly patchy distribution. Therefore, better management of salinity can only be achieved by mapping the salinity of soils. The purpose of this study was to determine the most acceptable method to estimate the values of attributes related to soil salinity in Çerikli Irrigation Planning Area located in central Turkey. The coverage area of study area is 14.924,00 ha. Disturbed soil samples were collected from 0-30 cm, 30-60 cm and 60-90 cm depths of 110 sampling locations. Soil samples were analyzed for soil pH, electrical conductivity (EC), sodium adsorption ratio and water extractable Ca, Mg, Na and K concentrations. The estimation performance of deterministic (Radial Basic Functions(RBF) and Inverse Distance Weighting(IDW)) and Stochastic (Ordinary Kriging, Simple Kriging and Universal Kriging) interpolation methods have been compared for the predication of soil salinity in the project area. Salinity /EC) in 0-30 cm depth ranged from 0.65 and 67.1 dS/m with a mean value of 8.90 dS/m, in 30-60 cm depth EC ranged from 0.86 dS/m and 79.9 dS/m, and in 60-90 cm depth EC ranged from 1.07 dS/m and 98.80 dS/m. The root mean square error (RMSE) of the methods was used to compare and determine the best method. The mean absolute error (MAE) value was used in case of having the same RMSE value. The RBF-ST provided the accurate results for the EC of 0-30 cm and 30-60 cm depths and the RBF-IM was the most appropriate method for 60-90 cm depth. The results obtained are helpful for making effective decisions for protection of soils and sustainability of agriculture. This study is a good example for mapping soil properties by geostatistical methods.

Keywords:*Salinity, Geostatistics, Deterministic, Stochastic, Mapping, Monitoring*

Introduction

Soils may become saline under arid or semi-arid conditions in poor natural drainage conditions. The application of waters containing salts, weathering of primary and secondary minerals containing components of salts, decomposition of organic matter and fluctuating water table may lead to the accumulation of soluble salts in soil profile. Type of soil, climate and agricultural practices determine the rate of salinization in a region (Juan et al., 2011). Unsustainable water management practices at the farm-level cause to raise of groundwater and contributes to salt accumulation, particularly in irrigated fields of arid and semi-arid regions of Turkey (Gunal et al., 2015).

Soil properties in general vary in space and time due to the inherent (parent material, topography, climate, vegetation and time) and dynamic (management practices such as fertilization, irrigation, soil tillage etc.) factors. It is not practical to measure or record the characteristics of soils in every location in an area of interest. Theory in geostatistics addresses to the spatial variability of an individual variable. (Goovaerts, 1997).Geostatistical interpolation techniques can potentially be used to understand the progress in soil salinization. Determining the spatial patterns of salinization in a region helps also predicting areas that may be at high risk and need to be monitored.

Various geostatistical techniques are used widely for prediction of spatial variations of the soil. Kriging is a useful tool of geostatistical techniques. Under certain stationary assumptions, the kriging refers to at least square linear predictor that requires covariance parameters and the functional form for the mean of the underlying random function. Robinson and Metternicht (2006) compared the accuracy of ordinary kriging (OK), lognormal ordinary kriging (LOK), inverse distance weighting (IDW) and splines for interpolating pH, electric conductivity and organic matter. The results indicated that pH in the topsoil was estimated better with OK and LOK performed the best results when applied to ECe in the topsoil. The IDW method provided the greatest accuracy for the interpolation of subsoil pH and for interpolating the soil organic matter spline interpolation method had the highest accuracy. Wang et al. (2016) showed that the estimation precision of IDW method was superior to that of OK. However, the differences obtained between the accuracy in predictions were not significant. In this study; deterministic (Radial Basic Functions (RBF) and Inverse Distance Weighting (IDW)) and Stochastic (Ordinary Kriging, Simple Kriging and Universal Kriging) interpolation techniques have been tested to model and map the parameters associated to the soil salinity.

Material and Methods

The study area is located in the central Anatolia in Turkey. Total area sampled is 14.924,00 ha and irrigated land within the study area is 12.306,00 ha. Soil sampling started from 8 km east of Yerkoy town (Yozgat province) and continue along Delice stream untill the junction of Kizilirmak River.

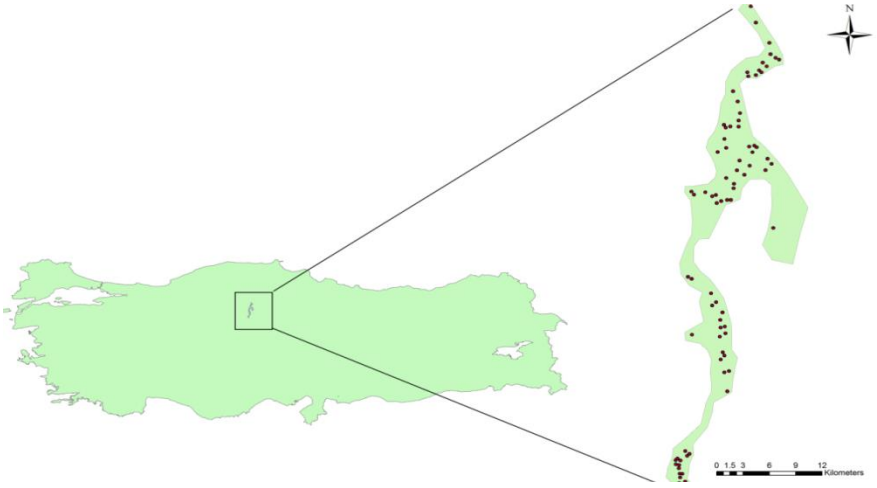

Figure 1. Study area and sampling locations

Soil Sampling and Analyses

Disturbed soil samples were collected from 110 points of 0-30 cm, 30-60 cm, 60-90 cm and 90-120 cm depths. In order to determine the spatial distribution of salinity and related soil attributes, soil samples were analyzed for soil pHand electrical conductivity(Rhoades, 1982), exchangeable cations and exchangeable sodium percentage, cation exchange capacity (Thomas, 1982) and particle size distribution (Bouyoucos, 1962).

Geostatistical Analyses

Five different interpolation techniques have been compared to model and map the parameters associated to the soil salinity. The techniques used were deterministic (Radial Basic Functions (RBF) and IDW) and Stochastic (OK, Simple Kriging (SK) and Universal Kriging (UK)). The interpolating value of a point is highly influenced the nearby points in deterministic techniques and farther points have less influence. However, the kriging techniques assume the data comes from a stationary stochastic process and rely on the notion of autocorrelation(Webster and Oliver, 2001). The IDW procedure is more simple and fact while kriging provides best linear unbiased estimates (Eldeiry and Garcia, 2011).

Prior to the preparation of spatial distribution maps, the best fitted geostatistical model for each parameter has been conducted and model parameters have been recorded. Cross validation was used to compare these methods by statistical parameters of root mean squared error (RMSE) and mean absolute error (MAE). The calculation of the parameters of RMSE and MAE is described by equations 1 and 2.

$$RMSE = \sqrt{\frac{\sum(z_{i^*} - z_i)^2}{n}} \quad \text{(Equation 1)}$$

$$MAE = \frac{1}{n}\sum_{\mathrm{i}=1}^{n} |Z_{\mathrm{i}} - Z| \quad \text{(Equation 2)}$$

N: Number of observation points, Z_i : Estimate the value of i points Z_{i^*} : Average values of observation

The MAE and RMSE are similar to each other, though the sensivity of MAE is lower to large estimate errors. The MAE is preferred for small or limited data sets. The RMSE indicates the absolute fit of the model to the data, how close the observed data points are to the model's predicted values. The lower value of RMSE indicates a better model fit (Eldeiry and Garcia, 2011).

Results and Discussion

The main statistical parameters for the soil properties are given in Table 1. The EC values in 0-30 cm of the study area vary from non saline 0.65 dS/m to very strongly 67.1 dS/m. Salinity levels of soils increased with increased depth. The EC ranged from 0.86 dS/m to 79.9 dS/m in 30-60 cm, from 1.07 dS/m to 98.8 dS/m in 60-90 cm. The CV values indicated very high variation of EC values within study area.

Table Descriptive statistics of soil properties

Depth/Attribute		Unit	Min.	Max.	Mean	Std.Dev.	Coe Var	Skewness	Kurtosis	Distribution
0-30 cm	EC	dS/m	0.65	67.1	8.90	14.27	160.34	2.53	8.72	Log normal
	pH		7.5	9.0	8.14	0.275	3.38	0.17	3.24	Normal
	ESP	%	1.43	25.42	7.31	4.07	55.68	1.39	6.40	Log normal
30-60 cm	EC	dS/m	0.86	79.9	11.00	16.43	149.36	2.44	8.37	Log normal
	pH		7.47	8.96	8.23	0.32	3.89	0.11	2.64	Normal
	ESP	%	2.0	25.36	8.73	4.74	54.30	1.02	3.86	Log normal
60-90 cm	EC	dS/m	1.07	98.80	12.06	16.24	134.66	3.02	13.49	Log normal
	pH		6.30	9.30	8.24	0.40	4.85	-0.86	8.63	Normal
	ESP	%	1.82	28.57	8.99	4.84	53.84	1.28	5.16	Log normal
90-120 cm	EC	dS/m	0.99	54.50	13.20	12.76	96.67	1.86	5.76	Log normal
	pH		7.55	9.31	8.26	0.31	3.75	1.14	5.20	Normal
	ESP	%	1.22	26.22	9.00	4.93	54.78	1.27	4.92	Log normal

The RMSE values for EC ranged from 13.827 to 20.348 and MAE values from 8.007 to 10.852. The RMSE values were used to determine the best method. The results showed that sub-functions of IDW, RBF and kriging methods were different from each other. When all methods compared, the RBF-ST method gave the most accurate results in 0-30 cm and 30-60 cm depths. The RBF-IM method was acceptable for 60-90 cm and IDW-1 method for 90-120 cm (Table 2).

and MAE from 3.430 to 4.142. The lowest RMSE value was 4.567 and obtained or RBF-CRS and RBF-ST methods. In this case, the method with a lower MAE value was accepted as the best method to map the spatial distribution of ESP of 60-90 cm. The RBF-CRS method had lower MAE value, and used to prepare the spatial distribution of ESP map (Figure 3).

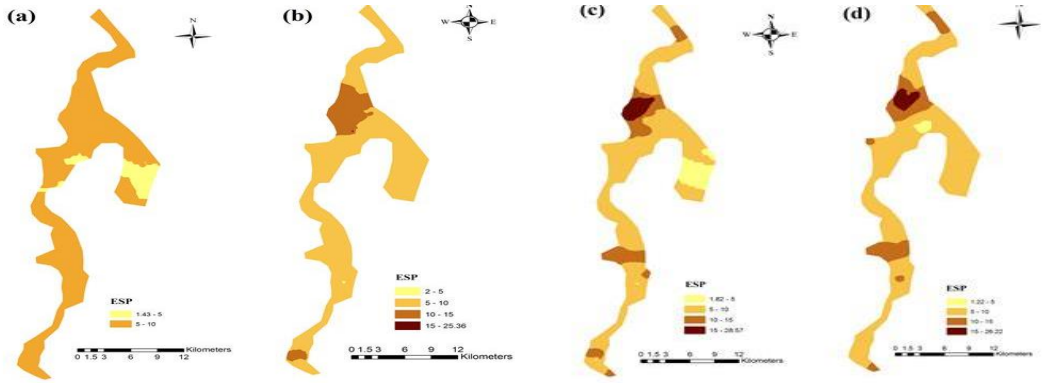

Figure 3. Spatial distribution of ESP values in (a) 0-30 cm (b) 30-60 cm) (c) 60-90 cm (d) 90-120 cm

The best methods of soil pH were RBF-IM, SK, RBF-CRS and IDW-1 for 0-30cm, 30-60cm, 60-90cm and 90-120cm depths, respectively (Table 4). The pH values of soils were at highest level in the middle of the study area (Figure 4).

Conclusions

The study presented the results of a study to evaluate some interpolation techniques for mapping spatial distribution of soil salinity, pH and sodium adsorption ratio in central Anatolia of Turkey.The inappropriate and excessive irrigation without an adequate drainage system, irrigation water quality, a rising water table, climate, local topography and farming practices are the major causes of salinity in the study area.

The results of present study demonstrated that precision of spatial distribution maps can be increased with the use of alternative geostatistcal methods. The nature of data has significant effect to determine the best method of interpolation.

Abstract

The intensive agricultural production around the area of Karavasta Lagoon in Albania and the discharge of Semani and Shkumbini Rivers in vicinity to it could affect the environmental quality of the wetland and its ability to sustain the living organisms. This paper aims to estimate the quality of water and sediments of the Karavasta Lagoon, through measuring the physicochemical parameters and the presence of heavy metals. Samples of surface water and bottom sediments have been collected in different specific points in the Lagoon in the spring season of 2013 and have been analyzed for their concentration of heavy metals such as Pb, Cr, Cu, Cd, and Hg. The results show high levels of Cr pollution, followed by Cu and Pb and highlight the need for further monitoring of the physicochemical parameters. The application of Enrichment Factor (EF) suggests that Cr originates from the alluvium brought by Shkumbini River that flows through ultramafic areas in Albania rich in this metal, whereas Cu and Pb come from the agricultural drainage channels, urban effluents and tributaries.

Introduction

The quality of lagoon water changes with seasons and geographical areas, even when there is no evident pollution (Abdo MH, 2005) Besides its importance as a natural heritage, Karavasta Lagoon is threatened by several factors. Increase in population, human activities, industries and agriculture around the coastal environment are greatly affecting the neutrality of the water system (Chauvelon P, 2004). Lagoon pollution has been increasingly significant over the recent years and this has been found to contribute significantly to environmental problems (Abowei JFN 2010). Due to intensive agricultural activities in the surrounding area of lagoon, the soils could be subjected to non-point pollution as for relevance to Lagoon environments (Abdo MH, 2005). Karavasta is subject to different factors that would damage its biodiversity and eco-touristic values such as: eutrophication, (Chauvelon P, 2004) urban pollution, illegal constructions, illegal hunting and fishing, weak participation of local communities in decision-making etc. Shkumbini River was strongly impacted by the Metallurgic Complex of Elbasan: about 30 to 35 million m^3 $year^{-1}$ of liquid waste with a high content of toxic compounds were discharged directly into the river, and about 300,000 tones $year^{-1}$ of solid waste were disposed on its riverbanks (Chauvelon P, (2004). Even if Divjaka urban area is not drained to the lagoon, part of its polluting load discharging from Terbufi Canal may reach the lagoon because its plume is directed mainly southward and close to the coast during spring and summer. In this context, the concentration of heavy metals in the lagoon water stand important at first for measuring the state of pollution of Karavasta Lagoon, and secondly it contributes on designing and implementing scientifically sound based conservation policies and actions. The heavy metals released in the water, eventually

are accumulated in the sediments (Abulude FO, Fapohunda OO, Awanlenhen 2006). Therefore, sediment analyses enable the assessment of the "Chemical Status" of transitional and coastal waters. The occurrence of elevated levels of trace metals especially in sediments can be a good indication of man induced pollution and high levels of heavy metals can often be attributed to anthropogenic influences, rather than natural enrichment of the sediment from geological weathering (Christophoridis A, Stamatis N, and Orfanidis S, 2007). Sediments integrate contaminants over time and are in constant flux with the overlying water column (Lord DA, Thompson GA, 1988). The analysis of heavy metals in the sediments permits detection of pollutants that may be either absent or in low concentrations in the water column (Binning K, Baird D, 2001). Their distribution in coastal sediments provides a record of the spatial and temporal history of pollution in a particular region or ecosystem (Addo MA, 2002). The traces of metal content in the sediment could affect the water quality, the bio-assimilation and bio-accumulation of metals in aquatic organisms, resulting in potential long-term implications on human health and ecosystem in general (Bani A, Imeri A, Echevarria G, Pavlova D, Reeves RD, Morel JL, and Sulçe S, 2013).

In the last years, the levels of the heavy metals the around the Karavasta Lagoon have increased due to human activities. Thus, the exact measuring of heavy metals in aquatic environments is important to control their pollution levels (Bani A, Imeri A, Echevarria G, Pavlova D, Reeves RD, Morel JL, and Sulçe S, 2013).

The main objective of this study is to measure the level of heavy metal contamination in the water, sediment ad vegetation of the Karavasta Lagoon in Albania.

Material and Methods

Study area

Karavasta lagoon lies within the Mediterranean Climatic Zone, Central Sub-zone. The average rainfall is 950 – 1200mm during 85 – 100 days of the year, being one of the lowest levels in Albania. Two thirds of this occurs in November to March, with peaks in October and November (Cullaj A, Hasko A, Miho A, Schanz F, Brandl H, Bachofen R, 2005). The winter is mild, with January the coldest month of the year (average temperature 8.5°C). Days of temperature under 0°C are very rare. The mean annual temperature is 19.8°C. The temperature remains > 10°C up to about 9 months (Cullaj A, Hasko A, Miho A, Schanz F, Brandl H, Bachofen R, 2005). The wind has two main directions southeast during autumn and winter and northwest during spring and summer. The average wind speed varies 2.5 m/s to 3.3 m/s.

Sampling

Water samples were collected at eight sites in the Karavasta Lagoon on December 2013 and July 2014. The sampling sites were strategically selected to see the impact of all potential contamination sources. Sampling station 1 was at Dajlan Center (N: 40° 55' 507"and E: 19° 28' 264") 200 m from the quay where fish is processed in order to see the influence of such activity; sampling station 2 was among "Grykederdhje 3" and Bedat village (N: 40° 54' 287" and E: 19° 27' 489"); sampling station 3 in front of Bedat village, closed to Lena channel (N: 40° 53' 451" and E: 19° 28' 247"); sampling station 4 was closed to Mucias village (N: 40° 54' 164"and E:19° 30' 255"); sampling station 5 closed to the villages of Kamenice and Gur (N:40° 55' 421"and E: 19° 31' 396"); sampling station 6 is set in a distance of 100m from Kryekuq channel, at the pumping station (N:40° 55' 242"and E:19° 30' 562"); sampling station 7 at Kryekuq outlet (N:40°

55' 421" and E:19° 31' 396"), and the last one sampling station(8) at drainage outlet of Zharnec village (N: 40° 56' 421"and E: 19° 31' 68").
Water sampling 'Ruttner' is used for the sampling of the lagoon water. The water samples for the physico-chemical analysis were taken from the surface of the lagoon (50 cm under the surface) at each sampling location using 1.5 liters polyvinyl bottles and labeled according to the sampling sites. The samples for the trace metal analysis were acidified to pH <2 using 10% analytical grade HNO3. This was to keep the metals in dissolved state and to prevent bacteria action on them.
The samples were placed in refrigerator boxes (+4 °C) and transported to the laboratory of Faculty of Science, University of Tirana within a day.

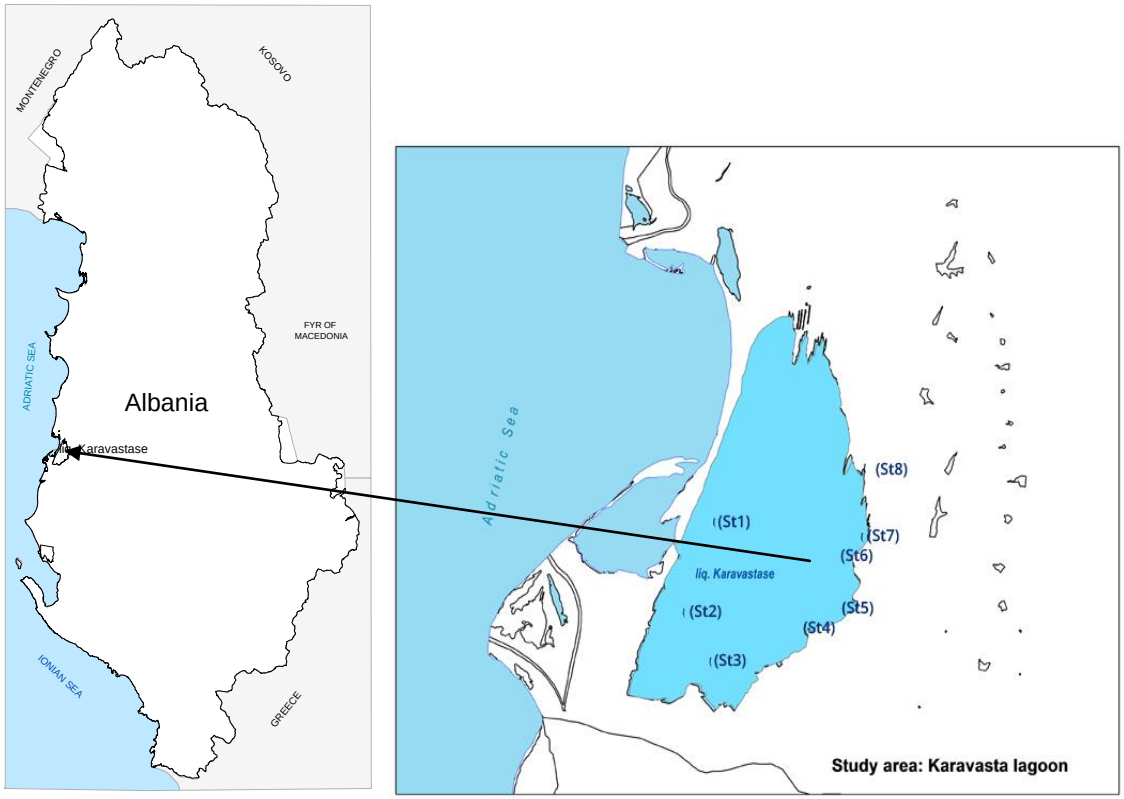

Fig 1 - Map of the location of the study area (Karavasta Lagoon)

Heavy metals analyses

To determine the level of heavy metals in the lagoon's water (Cd, Cr, Cu, Pb, Hg) was used the EPA Method No. 1637. The water samples were treated with nitric acid to reach pH = 2. A volume of 100 ml of sample was put in a 400 ml volume chemical cup and treated with 3 ml of concentrated nitric acid. In addition, the chemical cup was heated without reaching the boiling level in order to evaporate until reaching the 20 ml volume. Then 3 ml of concentrated nitric acid is added again, covering crystal glasses and heating temperature is regulated, so that an acid reflux can be created until the complete digestion of the sample. The samples then evaporated until they almost dried up and were left to cool down. After cooling, nitric acid 1:1 is added and the samples heated until complete dissolution of any residue or precipitation. Samples were centrifuged to remove any insoluble residue and then diluted up to 25 ml volume. The concentration of metals in this fraction was calculated by the method calibration curve and

converted to lagoon water (ppb) concentration according to the formula: $C_m = C_{l.kal.} \frac{25}{100}$. Metals in solution were determined directly by Graphite Furnace AAS.

Results and Discussion

Heavy metals in the water samples of Karavasta lagoon.

We have analyzed the heavy metal values concentration on the lagoon water to know the effects all factors that may have influenced the status of heavy metals in the lagoon (Table 1). The average level of Cu in the water samples ranged from 13.5 to 24.1μg L^{-1}depending of the season of the sampling. The highest average concentration value of copper in the water for both seasons was measured in sampling stations 3, 7 and 8 affected by contribution of Lena and Zharrnec channel that pass along agricultural fields of these village, that were regularly treated with copper-based pesticides. Cu levels in Karavasta lagoon were higher than surface water of Butrinti Lagoon (Topi T, Bani A, Sulce S, 2012) due to the intensive agriculture activities in the field around the Karavasta Lagoon, but close to the standards of EU (Table 1), so it should be monitored. Cd values on the water of Karavasta vary according to the sampling stations and seasonsbut Cdvalues in the lagoon water was under the allowed standards (<1 μg L^{-1}) (Table 1). The average level of Pb in the lagoon's water ranged from 0.72 to 4.95 μg L-1 in December and from 0.33 to 2.9μg L-1in July while highest value of Pb on the water surface was measured in December and in the sampling stations 1 and 8 respectively influenced by fishing activities and Zharnec channel. Pb value in water lagoon was smaller than the referenced standards (EU-2008 -7.2 μg L^{-1}). Results of this study told that Pb values have to be monitored because Pb it is an accumulative poison toxic for living organisms.

The average value of Cr in sampling sample of water in Karavasta lagoon ranged depending of sampling stations but had not big differences between seasons. (Table 1) told us that the average values and in some stations Cr values were higher than the required values from EU standards. In the sampling stations 3, the concentration of Cr in the water of lagoon results to be about twice higher than the EU standard values, whereas in the 4 and 8 stations the values were higher than those of EU standards influenced by alluvium brought by Shkumbini river which passes through areas rich in Cr (Albanian ultramafic sites) (Table1)

Vegetation evaluation in Karavasta lagoon

High levels of productivity and biomass of the species *Zoostera nolti*, Floristic impoverishment of these plant associations. Floristically dominant associations are very poor and often like a mono-dominant plant community. Disappear of species with narrow ecological amplitude, and their replacement by mono-dominant association or species with wide ecological amplitude. Species spreader in lagoon *Zoostera nolti, Ruppia cirrhosa (Figure.2/3/4)* belongs to the group of wide ecological amplitude. This is shown in the Table.2 through the twelve selected sampling stations.

Flora and vegetation around the lagoon

We have identified approximately 112 plants, which belong to 38 families. This is a considerable resource, if we take in consideration this small extent of the undertaken studied area. Based on the Red book and new electronic variant (2006) we identified 10 species as Rare and threatened plants, mainly of sandy dunes, as well as on aluvional forests, costal wetlands *Pancratium maritimum* L., *Matthiola tricuspidata* (L.)R.Br., *Quercus ilex* L., *Ammophila arenaria* L., *Hypericum perforatum* L., *Origanum vulgare* L., *Lotus cytisoides* L., *Colchicum autumnale* L., *Stachys maritima* Gouan, *Quercus robur.*

Conclusions

Results of this study show that the distribution of heavy metals in the water of the lagoon varies depending on the season and sampling stations. The elements Cu, Pb in some stations are found to be close to the allow able values by the EU standards and represent a potential contamination risk. The average values of Cr in water of Karavasta lagoon in both seasons were higher than the European standards. This can be explained by the flow of Shkumbini River, which runs in ultramafic areas of the country, (Topi T, Bani A, Sulce S, 2012) or passes through the metallurgical site. Considering this study for the state of heavy metals in the lagoon of Karavasta, as a conclusion it could be said that continuous monitoring has to be carried out in order to prevent its pollution.

Based on the Red book and new electronic variant (2006) we identified 10 species as Rare and threatened plants, mainly of sandy dunes, as well as on aluvional forests, costal wetlands *Pancratium maritimum* L., *Matthiola tricuspidata* (L.)R.Br., *Quercus ilex* L., *Ammophila arenaria* L., *Hypericum perforatum* L., *Origanum vulgare* L., *Lotus cytisoides* L., *Colchicum autumnale* L., *Stachys maritima* Gouan, *Quercus robur* L. We have identified approximately 112 plants, which belong to 38 families. This is a considerable resource, if we take in consideration this small extent of the undertaken studied area.

Abstract

Bees have been part of culture and human heritage for millenniums. Yet these useful insects seem increasingly affected by diseases and parasites. Repeated use of synthetic chemical compounds leaves harmful residues in wax and honey. In fact, the use of biological control agents (BACs) is encouraged. In this context, the present work studied the effect of two local bacterial strains of the genus Bacillus on honeybees Apis mellifera intermissa. Initially we conducted a macroscopic, biochemical, physiological and physicochemical characterization of the two bacterial strains isolated in 2011, from soil in two regions from Algeria (a coastal area and the Sahara Desert). Study of abiotic characteristics of the two bacterial strains showed that growth is better at a temperature between 32 ° C and 45 ° C and pH between 6 and 8. Afterwards, we focused our study on the effect of these bacteria on mortality, feeding activity and production of wax. Hence, the study of the effect on mortality shows a low rate of mortality among bees treated with the two bacterial isolates; whereas the feeding activity demonstrates no effect on the consumption of syrup and pollen. Furthermore, the production of the wax slightly increased in some individuals treated with different concentrations of bacterial strains. Finally, it would be very advantageous for further study on these bacteria about their effects on other biological parameters of the bee.

Keywords: *honeybees, bacteria, mortality, feeding activity, wax.*

Introduction

Pollinators are a key component of global biodiversity, providing vital ecosystem services to crops and wild plants (Le Conte &Navajas, 2008). Among the main pollinators, Bees are a vital component in ecological networks and provide significant socialand economic benefits to humans through crop pollination and maintaining the character of the landscape (Breeze *et al*., 2012). Honey, pollen, royal jelly, propolis and wax are main products which directly benefit humans (Leven *et al.,* 2005). There are several popular races of honey bees raised in Africa. Among the most famous, *Apis mellifera intermissa* (Tellian bee) (Fayet, 2013).

Despite their importance, both to people and the natural environment, unsustainable agriculture, diseases and habitat degradation have placed significant pressures on many species of bees, causing widespread declines (Breeze *et al.*, 2012). Several causes can explain managed honeybee losses, among them, infestations by organisms ranging from arthropod pests such as ectoparasitic mite *Varroa* that feeds their hemolymph (Leven *et al.*, 2005).

Moreover, repeated use over several years of synthetic chemical compounds to treat these bee enemies and the intentional exposure of honey bees to pesticides used in agriculture have resulted in residues in hive products, especially beeswax and honey (Leven *et al*., 2005).In order to protect honey bees from pesticide poisoning, actually, more than 100 bacteria have been

identified as arthropod pathogens among which *Bacillus thuringiensis* and *Bacillus sphaericus* have received most attention as microbial control agents (Abrol, 2013).
So, the aim of present study is to determine the effects of two strains of *Bacillus sphaericus*, isolated from desert (strain Bss) and coastline (strain Bsn) of Algeria, on honey bee "*Apis mellifera intermissa*". This work is a following of the research works focused on evaluating insecticidal activity of the two bacteria selected against crop pests (MohandKaci &Doumandji-Mitiche, 2011, Oulebsir-Mohandkaci *et al.*, 2015).

Material and methods

Biological material

The study was performed on the local honeybee "*Apis mellifera intermissa*". This strain is derived from apiary of laboratory of Valorisation and Conservation of Biological Resources at the University M'hamed Bougara of Boumerdes (Algeria).
The bees were reared in cages wooden bread (10.5cm x 10.5cm x 7.5cm) placed in incubator at 34 ° C. Feeding of bees consists of a syrup (50% water and 50% sugar), water and pollen mixed with honey and crafted in boule.
Also, we have used 2 strains of *Bacillus sphaericus* isolated from soil in two regions from Algeria ; Boumerdes (a coastal area that has mild winters, warm spring and summers whose heat is not excessive. soil is clay-loam with a pH of 7.5.) and Adrar (located in the Sahara Desert and receives extremely rare rains, characterized by cold winters, hot summers, cold nights and warm days with a sandy texture soil, low organic matter content with low water holding capacity and subjected to a salinisation limiting its productivity). For long-term preservation, isolates were stored at -20°C in 30% glycerol.
Belonging of bacteria isolated to *Bacillus sphaericus* species is confirmed by identification tests, namely: the microscopic appearance rod-shaped, with a Gram and catalase positive, it is spore-forming bacteria, with a positive response to tests nitrate, urease, casein hydrolysis, mobilit-mannitol, acid and gas on glucose, and anaerobiosis. As against the tests of starch hydrolysis, gelatine liquefaction and indole gave negative results (Guiraud, 2003).
We assigned codes to the strains used according to initial namely Bsn for *B. sphaericus* (north strain)and Bss for *B. sphaericus* (south strain).

Methods

Study of abiotic characteristics of the two bacterial strains

Growth and survival of bacteria is greatly influenced by the physicochemical nature of the environment. In this part we studied the effect of three physiochemical parameters which are: temperature, pH and salinity. 5 temperatures were chosen for this study: 0 ° C, 8 ° C, 32 ° C, 45 ° C and 60 ° C. The pH chosen are: 3, 4.5, 6, 7, 8 and 9.5. For salinity, 6 different NaCl concentrations were tested: 0 mm, 100 mM, 300 mM, 500 mM, 1000mm and 1500mm.
Study of bacterial growth in different temperatures took place on nutrient agar. The results are reflected in the growth or not of bacterial culture. However for pH and salinity, the study of bacterial growth took place on nutrient broth. Reading the results is done by measuring the optical density at 620 nm after incubation.

Study of the Effect of the bacterial strains of honeybees

- Sporulation and spore production: For this, the *Bacillus sphaericus* isolates are cultured, as described by Abbas (2014). Indeed, Bacterial cultures were sub-cultured on nutrient agar for 48 h at 32 ° C. Some bacterial colony were taken and placed into an Eppendorf tube with 1.5ml of

saline solution. The suspension was centrifuged at 4000 rcf for 15 min at 4 ° C, a small pellet was visible at the bottom of the tube. The liquid was removed, and the pellet was nerve recovery and added with 500 µl of saline solution, after this, it was realizedheating for10 minutes at 100 ° C and we subjected to preculture a heat shock for 2 to 3 minutes by ice water. After centrifugation at 4000 rcf for 15 min at 4 ° C, the supernatant was recovered.

- Bioassay of entomopathogenic bacterial strains against honeybees: vegetative cells and spores are used for treating bees. For the calculation of bacterial concentrations, the number of inoculum cells was evaluated from the number of colonies that grew on the culture medium. Assuming that each colony is derived from a single cell, the concentration of bacteria per 1 ml of solution is expressed as " colony-forming unit (CFU or cfu).

3 doses were used: D1 = 2 x 10^7cfu / ml, D2 = 10^6 cfu / ml and D3 = 3 x 10^5cfu / ml.

For the treatment of bees, bread small cages were used, each consisting of 20 bees and put in an incubator at 34 ° C. Controls were fed with sugar syrup supplemented with 400 µl of saline solution, pollen and water. Moreover, in the treated bees, the sugar syrup was added with 400 ml of each bacterial concentration for 24 hours. After this the treated syrup is replaced by another non-treated syrup.24 hours after treatment, the daily counting of mortality occurred. The resulting mortality rates were corrected by the formula of Abbot (1925). Consumption of syrup and pollen was evaluated as well as the production of the wax.

Statistical analysis

Experiments were repeated thrice. Dose-related changes in the mortality rates were checked to normality of data distribution. One-way analysis of variance (ANOVA at5% significant level) and test tucky were used to compare means statistical analysis (XL software. 2009 STAT).

Results and discussion

Abiotic Factors Influencing In Vitro Growth of the bacterial strains

The Effect of Temperature on Growth of bacteria

The effect of temperature on the growth rate was studied in *B.sphaericus* between 0 and 60 degrees C cultivated in solid medium. After incubation, no growth was observed at 0° C, 8 ° C and 60 ° C. Against at 45 ° C the number of colonies obtained is high, at 32 ° C, bacterial growth is better.

Table 1: Growth of the two strains of *B. sphaericus* (Bsn and Bss) at different temperatures

Strain / temperature	0°C	10°C	32°C	45°C	60°C
Bsn	-	-	++	+	-
Bss	-	-	++	+	-

- : absence, + : presence

Bacteria are more tolerant of environmental conditions than other organisms. However, each species has its own characteristic and particular range of values in which it grows and reproduces best. The growth of both strains of *B.sphaericus* (Bss and Bdn), is possible only between 32 ° C and 45 ° C.

According to Cuq (2007), mesophilic bacteria have an optimum growth of 37 ° C, the minimum temperature for growth is between 10 and 20 ° C and the maximum temperature is 45 ° C. The optimum of temperature of grows of bacteria *Bacillus sphaericus* is 28-35 ° C (Brossard *et al*.,

2008). Indeed; the heat causes an increase in rate of metabolic reactions and growth rate, causing denaturation of microbial compounds (Guiraud, 2003).

The Effect of pH and Salt on Growth of bacteria

Each species of microbe has its own characteristic range of pH values in which it grows and reproduces best, The results obtained (figure 1) show that the two bacteria (Bsn and Bss) grow best around neutral pH values (7.0), but Bss thrive in basic conditions (pH 8) and can tolerate a high pH. However, Even though they can live in alkaline environments, its internal pH is much closer to neutral values, this can be explained by the fact that this strain was isolated from soil of the Adrar region located in desert of Algeria which is characterized by basic soils.

However, the results of salt effects in bacterial growth show that both two bacteria (Bsn and Bss) can grow without salt but can also tolerate small amounts of salt in their growth medium. Optimal growth is obtained in the absence of salt, but in the presence of salt they will grow, just at a lower rate.

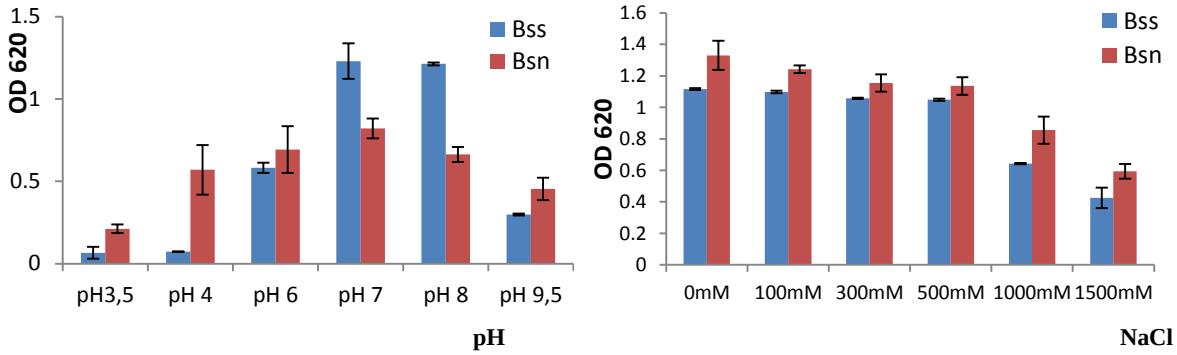

Figure 1: growth of the two strains of *B. sphaericus* (Bsn and Bss) at different pH* and Salt concentrations**

***Analysis of variance show that there is a highly significant difference in the Bsn strain (F = 0.001) and very highly significant for the strain Bss (F = 0.0001).

**ANOVA indicates a very highly significant difference between the growth rates of the two bacteria depending on the salinity for Bsn strain (F = 0.0001) and a significant difference in the Bss strain (F = 0.030)

Bacteria are sensitive to the hydrogen ion concentration they find in their environment. Large proteins, such as enzymes, are affected by pH. According to Brossard *et al* (2008), the genus *Bacillus* cultivates at temperature of at (12-45 ° C) and pH (6-8.5).

Most bacteria can grow on media whose pH varies from 4.5 to 9 but the more one deviates from the optimum pH range (6.5 to 7.5) more growth is slow (Nicolas and Daniel, 2007). This confirms our results.

Bacteria are continually adapting to changes in their environment. The majority of bacteria living in a pH around neutrality (6-7), but there are bacteria that produce acid by fermentation, for example, supporting pH 4-5 (Favet, 2013).Similarly, Euzéby (2007), shows that the optimum pH for the genus *Bacillus* is between 6.8 and 7.5, but these bacteria can resist up at a minimum pH of 5.6 and pH of 9.4 to 10.0.

Therefore, the effect to which salt concentration causes changes in bacterial growth depends on the osmotic balance required for such growth. Some bacteria require an astonishingly high level of salt to begin growth, whereas others would be immediately killed in high levels of salt.

Lambin& German (1969) note that most bacteria except those that live in marine waters, grow in the presence of low concentrations of salts.
Bacteria, except Mycoplasmatales, are less sensitive to osmotic pressure variations as they are protected by their cell membran. However, some marine species are adapted to environments containing about 35 g NaCl per liter (Euzéby, 2007).

Effect of the two bacterial strains of honeybees
Mortality Assessment
The results obtained after treatment with vegetative cells and spores of Bsn (Figure 2) indicate that the corrected mortality rate is very low, they reach a maximum of 2.69%, 1.68%, 3.03% for doses D1, D2 and D3 after 10 days, for vegetative cells and 2.02% for D1 and D2 and 2.35% for the dose D3 for spores.

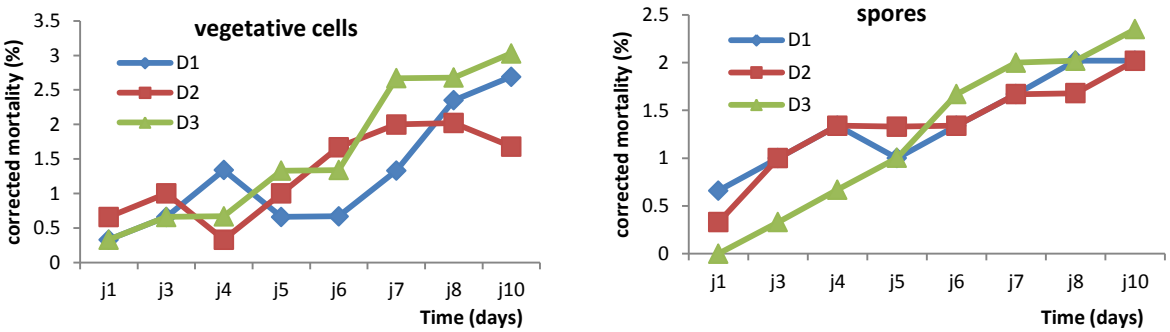

Figure 2: Corrected bee mortality after treatment with the strain Bsn((D1 = 2 x 10^7cfu / ml, D2 = 10^6 cfu / ml and D3 = 3 x 10^5cfu / ml)
(No significant effect was observed by analyzing the variance in mortality rates obtained in control bees and treated by the vegetative cells and spores of both strains (F = 0.1)).

The results obtained after treatment with vegetative cells and spores of Bss (Figure 3) show that the daily bee mortality increased after the treatment application, but not exceeding2.35% for D1 to 3.03% D2 and D3 to 2.02% for vegetative cells and 2.69%, 2.5% and 1.34% for D1, D2 and D3 for spores. Consequently, this mortality obtained is not due only to treatment but it may depend on other factors such as: The life span of worker bee, his diet composed only by syrup, water and pollen, its society lifestyle and the experimental conditions.

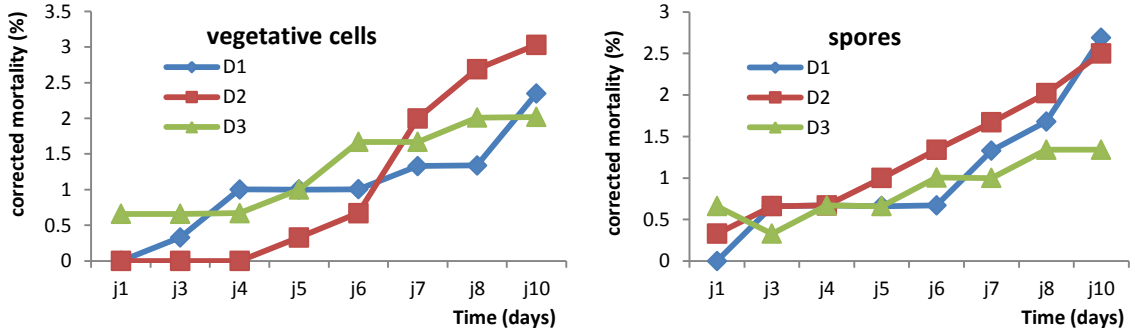

Figure 3 : Corrected bee mortality after treatment with the strain Bss(D1 = 2 x 10^7cfu / ml, D2 = 10^6 cfu / ml and D3 = 3 x 10^5cfu / ml)
(According to the test of analysis of variance, a non-significant change in mortality rate was noted in the treated bees vegetative cells and spores of Bss compared with controls (F = 0.052)).

The research has not ceased to exploit family of Bacillaceae which contains the most promising species in the control of arthropod disease vectors. Among biological insecticides, the most effective and promising in the field, the spore-forming bacterium *Bacillus sphaericus* which targets aquatic larvae of mosquito and blackfly. (Charles & Nicolas, 1986).

When mosquito-larvicidal *B. sphaericus* strain SSII-1 cultures were fed to newly emerged adult honey bees and to bee colonies, no effect was found on the longevity of newly emerged bees nor on the brood production of colonies (Davidson, 1977). These results are in agreement with ours which are also, in agreement with those obtained when treating bees with two Bt commercial formulation containing the same kurstaki strain (Malone *et al*., 2001); similarly, Mommaerts *et al*.(2010) concluded that no effect on mortality of bumblebees could be attributed to an oral Bt kurstaki treatment. Therefore, Bt var kustaki (4D1) when ingested, are reported to have an effect on honey bee physiology and immunity (Evans & Lopez, 2004).

The effect on the consumption of syrup and pollen

Syrup consumption

It appears from the results of the consumption of syrup by bees treated by the vegetative cells and spores of the BSN strain (Figure 4) and the Bss strain (Figure 5), that the syrup consumption in the first day is very important and it decreases over time in the control and treated with different concentrations. syrup consumption in controls and in treated bees is almost identical

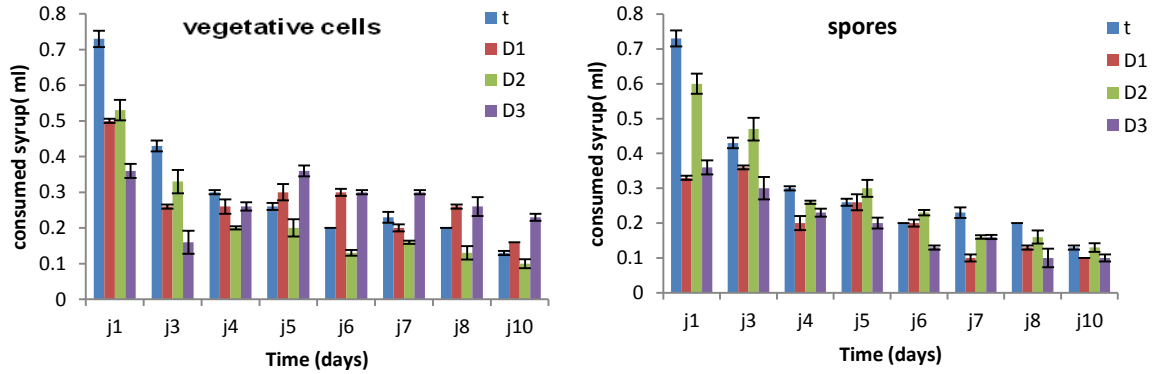

Figure 4: Syrup consumption in honeybee treated with vegetative cells and spores of Bsn

(According to the results of the analysis of variance, moderately similar values (not significant) were recorded for the syrup consumption in bees treated by vegetative cells (F = 0.388) and spores (F = 0.054) and Tukey test showed a non-significant difference between combinations)

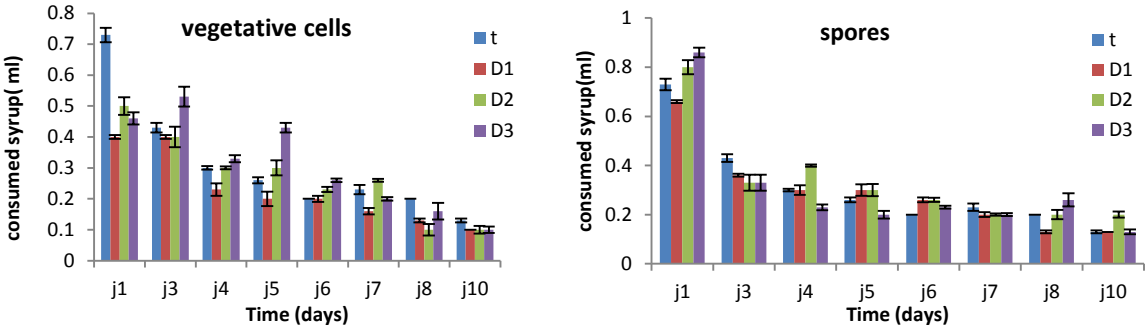

Figure 5 : Syrup consumption in honey bee treated with vegetative cells and spores of Bss

(The variance analysis results indicate a non-significant difference for vegetative cells (Pr = 0.327) and spores of Bss (Pr = 0.348), and the test tukey confirms, with no significant difference between the combinations)

Pollen consumption

The results of the consumption of pollen by bees treated by the vegetative cells and spores of Bsn strain (Figure 6) and Bss strain (Figure 7) show that the consumption of pollen during the first days, is important in cages of bees treated and control, however, in the last days, the amount of pollen consumed decreased at both lots; processed and control.

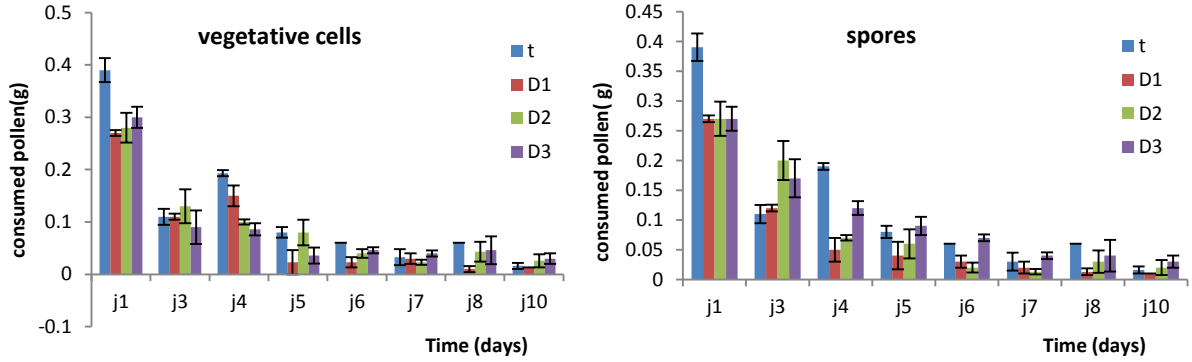

Figure 6: the pollen consumption in honey bee treated with vegetative cells and spores of Bsn
(Analysis of variance and the test tucky reveled a non-significant difference for pollen consumption by control and treated by the vegetative cells of Bsn (F = 0.740))

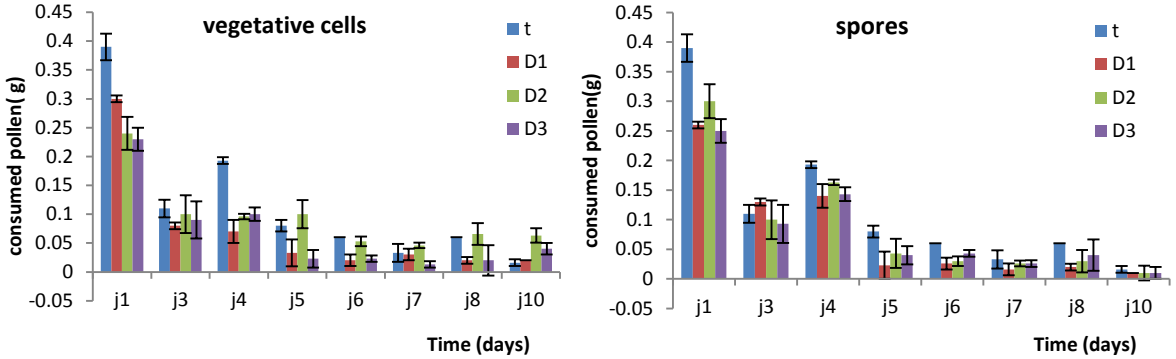

Figure 7: the syrup consumption in honey bee treated with vegetative cells and spores of Bss
(ANOVA and tucky indicate a non-significant difference for pollen consumption in control bees and bees treated by the vegetative cells (F = 0.323) and spores of Bss (F = 0.635)).

During the first days the quantity of syrup consumption is high, it is mainly used for the energy expenditure of the bee, depending on their activity and the development of internal organs. During the last days, the reduction in the syrup and water consumption may be due to reduced nutritional needs.

It is the same for pollen, during the first days, the bees need a large amount since it is considered as a source of protein that is involved in the development of hypopharyngeal glands of young bees and their fat body (Soudek , 1927).

Young bees also need pollen proteins for the formation of internal organs such as the nurturing gland and flight muscles. Imdorf *et al*. (1987) found that young bees consume pollen in abundance during the first days after emergence. During the last days, there is a pollen consumption decrease which is due to the absence of brood, which is a factor that stimulates the development of hypopharyngeal glands by pheromones (Mohammedi *et al*., 1996).

The effect on wax production

the results of the production of wax by the bees 10 days after treatment vegetative cells and spores of Bsn (Figure 8), show that the production of wax is slightly elevated in the treated small cages with 3 doses compared to controls, by against in treated by spores of the bacterium, this increase is found only in treated by D1. For bees processed by vegetative cells of Bss (Figure 9), the production of the wax is almost the same as compared with controls; however in bees processed by spores of the bacterium, there is an increase of the production of the wax compared to control

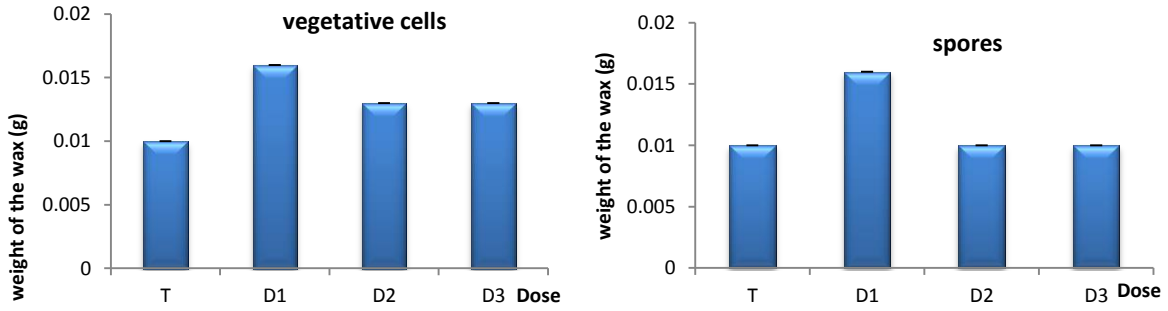

Figure 8 :wax production by *Apis mellifera*, processed by vegetative cells and spores of Bsn

(A non-significant difference was demonstrated by the test of variance analysis and Tukey's test for wax production in control bees and bee processed by vegetative cells (F = 0.222) and spores (F = 0.083))

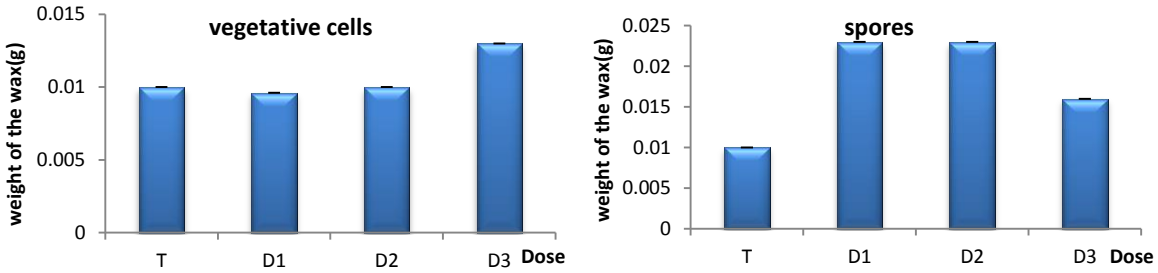

Figure 9 :wax production by *Apis mellifera*, processed by vegetative cells and spores of Bss

(Two treatment groups and the control group gave similar mean values (F = 0.188 for vegetative cells) and (F = 0.308 for spores)).

After treating bees with the two strains of bacteria, it was noted that there is a production of wax in all cages of control and treated individuals which shows that the wax glands develop normally, and they are not affected by entomopathogenic used, against (Whiffler &Hepburn, 1991; Ledoux *et al*., 2001) have found a decrease in production of the wax.

Conclusion

Bees are an essential functional group both in the natural world and to human societies, providing a broad range of benefits which would be costly to achieve in their absence.

The study of physicochemical characterization of the two strains of *Bacillus sphaericus* (Bsn and Bss), showed that growth is better at a temperature between 32 ° C and 45 ° C and pH between 6 and 8, and that these bacteria tolerate relatively high levels of NaCl but the degree of tolerance to various factors is greater for Bss.

Studies of the potential of biological control of the two strains of *Bacillus sphaericus* (Bsn and Bss) against crop pests showed no adverse effect on the honeybee. Application of bacterial

suspensions at various concentrations (2 x 10^7cfu / ml, 10^6 cfu / ml and 3 x 10^5cfu / ml), on the newly Emerged workers of *Apis mellifera intermissa* Showed a low mortality rate. The Lack of significant differences Between control groups and the treated groups whatsoever with vegetative cells or spores, confirms their no-involvement in the mortality variability obtained in the honey samples tested and That this variability is Rather related to other factors. Also, feeding activity study demonstrates no effect on consumption syrup and pollen. Moreover, the wax production increased slightly in some individuals treated versus controls.

To complete this research study, it would be very advantageous for further study on these bacteria about their ecological and toxicological impacted and also to study their effects on other biological parameters of the bee among others the wax glands to understand the cause of the increase in the amount of wax produced in the treated bees.

Abstract

Production of methyl ester cotton seed oil has been accomplished from transesterification process in between cottonseed oil and methanol in the presence of potassium hydroxide (KOH). In this study, the transesterification process was standardized by applying the response surface methodology (RSM) with Box Benhken design for three variables. A quadratic polynomial second order equation was employed to investigate the operating conditions of transesterification to obtain a high conversion of biodiesel as well its kinematic viscosity as a function of methanol/oil molar ratio, catalyst concentration and reaction temperature.The process parameters such as molar ratio, catalyst concentration and reaction temperature were standardized to reduce its kinematic viscosity with maximum possible yield of methyl ester of cottonseed oil. It is recommended that cottonseed oil reacted with 6.9:1 molar ratio and 1.19 percent KOH at 57^0C reaction temperature for reaction time of 1h and then settled for 24h to get 98.31 percent yield with 4.85 cSt kinematic viscosity.

Keywords:*Biodiesel, transesterification, yield, cottonseed oil.*

Introduction

Renewable fuels, made from biomass, have enormous potential and can meet many times the present world energy demand. Biomass can be used for energy in several ways; one of these is the conversion into liquid or gaseous fuels such as ethanol and biodiesel. Biodiesel is a type of bio-fuel which is the mono alkyl ester of long chain fatty acid derived from renewable feed stock. Bio-fuels seek to supplement conventional energy resources for meeting rapidly increasing requirement of transportation fuels and meeting energy needs of India's vast rural population by use of non-food feed stocks and as a result to reduce dependence on import of fossil fuels. Biodiesel can be produced from renewable sources such as vegetable oil, animal fat and used cooking oil.

Furthermore, biodiesel contribution to the greenhouse effect is insignificant, since carbon dioxide emitted during combustion is recycled in the photosynthesis process occurring in the plants used as raw materials for biodiesel production **(**Narayan, 1992).

In the cotton-planted areas, cottonseed oil is a by-product of cotton and seldom used as cooking oil, it is possible to use cottonseed oil as an emergency auxiliary or endemic fuel of diesel engine. (Recepet al., 2001).The world cottonseed oil production is 44.99 MMT out of that India produces 12.9 MMT oil during 2014-15 (USDA, 2015)

Transesterification of triglycerides (the main compounds in vegetable oil and animal fat) with alcohol using a base catalyst is the most common commercial method of biodiesel production. Transesterification involves various phase transitions: it changes from an initial two phage mixture of oil and alcohol to another biphasic system of glycerol and biodiesel-rich phases via a

pseudo single emulsion phage. The optimum ratio of methanol to oil depends on the nature of catalysts and feed stocks. The overall reaction is shown in Figure 1**.**

Materials and Methods

Materials

Refined cottonseed oil, supplied by Manik Industries, methanol (purity 99.8%) and potassium hydroxide (purity 87.0%) were used as reactants for the transesterification experiments. The refined oil was used to reduce two stage acid- base treatments for the biodiesel production.

Composition and acid value of refined cottonseed oil

The refined cottonseed oil was composed of four types of fatty acid triglycerides, including palmitic acid triglyceride (28.33 wt.%), stearic acid triglyceride (0.89 wt.%), oleic acid triglyceride (13.27 wt.%), and linoleic acid triglyceride (57.51 wt.%). It had the following characteristic: iodine value 114 mg I2/100 g, acid value 0.6 mg KOH/g, saponification value 199 mg KOH/g. The molecular weight of the cottonseed oil can be calculated from its saponification and acid values, and was 848.3. (Shu et al., 2009). The FFA content of cottonseed oil was found to be less than 0.1% therefore this oil can be used directly for base catalyzedransesterification reaction. The maximum percentage of FFA content allowed is 1%.

Procedure

In order to standardize the process parameters as shown in Table 1, three levels of molar ratios (5:1, 6:1 and 7:1), three levels of catalyst (KOH) concentration (0.5; 1.0 and 1.5 percent) and three levels of reaction temperature (55, 60 and 65^0C) were selected and coded as +1, 0 and -1in RSM. The esterification was done at different molar ratios in order to obtain maximum recovery of ester with lowest possible kinematic viscosity by preliminary experiments. Esterification was carried out at selected molar ratio at different levels of catalyst concentration for 60 minute at different reaction temperature in shaking water bath and then allowed to settle for 24 h for separation of lighter ester layer at the top and heavy glycerol layer at the bottom .Total 17 ester samples were selected to study the effect of molar ratio by applying the response surface methodology (Table 1), catalyst concentration and reaction temperature on ester recovery.

Results and Discussion

Effect of independent variables on yield of methyl ester of cottonseed oil

Esterification process of cottonseed oil was carried out at different molar ratio, catalyst concentration and reaction temperature using response surface methodology. Yield of methyl ester of cottonseed oil was ranged from 85.45 to 98.40% of over entire experimental conditions. It is evident (Table 1) maximum yield was observed at Experiment No. 11 having processing condition of molar ratio 7:1 (X1=1), catalyst concentration 1% (X_2=0)and temperature 55^0C (X_3=-1). Minimum was at Experiment No. 16, molar ratio5:1(X_1=-1),catalyst concentration 1% (X_2=0) and temperature 55^oC (X_3=-1). For both experiment, the reaction time and settling time was 1h and 24h respectively which was indicating that the mathematical model cover more than 97.0% of the total variations and lack of fit is insignificant; therefore, quadratic polynomial equation is adequate in describing yield of methyl ester of cottonseed oil.Eqn. 1 shows the full order regression model for yield of methyl ester of cottonseed oil.

**maximum value, * minimum value

The predicted model is given below

$$Y = 96.37 + 2.13 X_1 - 0.75 X_2 + 0.85X_3 + 0.42 X_1 X_2 - 4.06 X_1 X_3 - 1.52 X_2 X_3 - 1.31 X_1^2 + 1.01 X_2^2 - 2.22 X_3^2. \quad ..(1)$$

Where,

Y = Yield of methyl ester of cottonseed oil, %

X_1 =Molar ratio, Methanol: Oil

X_2 = Catalyst concentration, % wt. of oil

X_3 =Temperature, ^oC

Effect of independent variable on kinematic viscosity of obtained ester

Kinematic viscosity of methyl ester of cottonseed oil was attended by esterification process at different selected parameters using response surface methodology. Kinematic viscosity ranged from 4.78 to 5.39cSt of over entire experimental conditions. It is evident (Table 1) minimum kinematic viscosity was observed at Experiment No.6 having processing condition of molar ratio 6:1 (X_1=0), catalyst concentration 1% (X_2=0) and temperature 60^{o}C (X_3=0). Maximum was at Experiment No. 3, molar ratio 5:1(X_1=-1), catalyst concentration 0.5% (X_2=-1) and temperature 60^{o}C (X_3=0). For both experiment, the reaction time and settling time was 1h and 24h respectively.

The kinematic viscosity of methyl ester of cottonseed oil the quadratic polynomial second order equation model (2)was fitted and shows the full order regression model for kinematic viscosity of methyl ester of cottonseed oil. The value of R^2 for the regression model that was 0.9465 indicating that the mathematical model was adequate to cover more than 94.0% of the total

variations.The lack of fit was non- significant so model can be used to navigate the design; therefore, quadratic polynomial equation model was adequate in describing kinematic viscosity.
The predicted model is given below

$$Vk = 4.84 - 0.12\ X_1 - 0.13\ X_2 + 0.016\ X_3 - 0.017\ X_1 X_2 + 0.013\ X_1 X_3 - 0.045\ X_2 X_3 + 0.11\ X_1^2 + 0.21\ X_2^2 + 0.042\ X_3^2 \quad \ldots(2)$$

Where,

Vk = Kinematic Viscosity, cSt

Graphical analysis of yield

From Fig. 1 toFig.2 it was observed that yieldof methyl ester of cottonseed oilincreased (85.45 to 98.40%) with increase in molar ratio (X_1) from -1.00 (5:1) to 1.00 (7:1) at optimum values of catalyst concentration (X_2= 0.38) and temperature (X_3= -0.54).

Figures represent the 3D plot between molar ratio, catalyst concentration and temperature for yield. Response surface contours for yield of methyl ester of cottonseed oil as a function of molar ratio. It indicated that the yield of methyl ester of cottonseed oil increased with increase in molar ratio (from X_1= -1 to +1) but lower temperature (55^0C) gradual decreases in yield of methyl ester of cottonseed oil was observed as temperature increased. The effect of temperature (X_3) and catalyst concentration (X_2) have exhibited that yield of methyl ester of cottonseed oil goes increasing as catalyst concentration increased (from X_1= -1 to +1) at higher temperature (65^0C). Whereas with decrease in temperature X_3= -1 (55^0C) to +1 (65^0C) it goes increases at optimum level of molar ratio (X_2= 0.9). At lower temperature (55 ^{0}C) yield of methyl ester of cottonseed oil was initial gradual decreases and then drastically increased.

This could be attributed to the fact that yield increased due to increase in molar ratio with oil and decrease in the yield of methyl ester of cottonseed oil at higher temperature (65^0C) might be due to evaporation of methanol in tranesterification process. A similar yield increase trend was observed by Fan *et al.* (2011) for crude cottonseed oil. Patani*et al.* (2013)was found that the cottonseed oil gave a yield conversion of 98% in base catalyzed process. Rashid *et al.* (2009) reported the yield of methyl ester of cottonseed oil was 96.9% while Joshi (2011) found 98.5% using Novozym-435 as a catalyst.

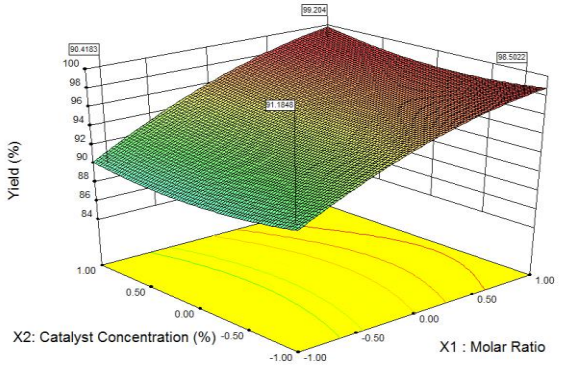

Fig 1 Response Surface Plot of Yield (%) BetweenCatalyst Concentration and Molar Ratio

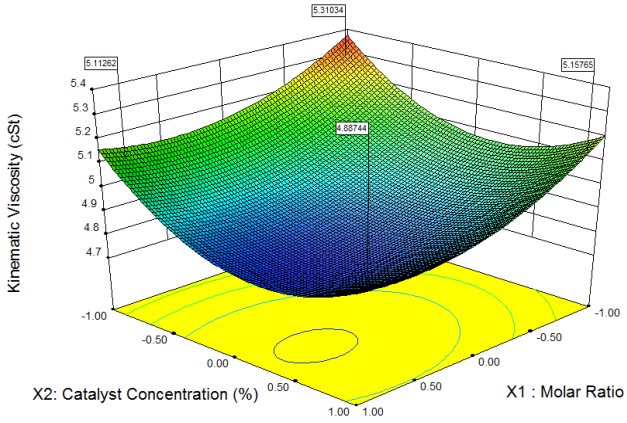

Fig 2 Response Surface Plot of Kinematic Viscosity (cSt) BetweenCatalyst Concentration and Molar Ratio

Response surface contours forgraphical analysis of kinematic viscosity shown in Fig.4. It was observed from figures that the kinematic viscosity of methyl ester of cottonseed oil decreased with increase in molar ratio (X_1) at optimum values of catalyst concentration (X_2) and temperature(X_3).Prescribed figures represent the response surface curve of kinematic viscosity as a function of molar ratio (X_1), catalyst concentration (X_2) and temperature (X_3). It seems that the increase in catalyst concentration from-1 (0.5%) to 1 (1.5%) there was gradual decrease and then increase in kinematic viscosity of methyl ester. The kinematic viscosity decreased from 5.39 to 4.78 cSt as the molar ratio increased (X_1) from -1 (5:1) to 1 (7:1) at optimum values of catalyst concentration (X_2= 0.38) and temperature (X_3= -0.54). The kinematic viscosity decreased with increase in amount of catalyst concentration from X_2= -1 to +1 at optimum level of molar ratio (X_1=0.9) while gradual decrease and then increases with increase in temperature X_3= -1 (55^{o}C) to +1 (65^{o}C). This could be attributed to the fact that kinematic viscosity decreased due to increase in molar ratio and catalyst as well. The increase in molar ratio during transesterification is associated with reduction of kinematic viscosity of methyl ester of cottonseed oil. Higher kinematic viscosity at lower catalyst concentration may be due to at low catalyst content is not efficient to perform tranesterification as a result on kinematic viscosity. Decrease in kinematic viscosity with increase in molar ratio may be due to sufficient amount of methanol present in tranesterification process to complete reaction.

Optimization of process parameters for methyl ester of cottonseed oil yield

Goal set as per the response and for independent variable shown in Table 1. Lower limit (-1) showsthe lowest value and upper limit (1) shows the highest value selected for parameters in transesterification process. The aim of this study was not only to increase the yield but also to decrease the kinematic viscosity of methyl ester of cottonseed oil. For get closer to goal the variables was set in range and results in coded and actual are depicted in Table.2.

The RSM analyses from Table3 demonstrated that the predicted optimum values of yield and kinematic viscosity of methyl ester of cottonseed oil was 98.40% and 4.81cSt at the molar ratio of methanol to cottonseed oil of 6.9:1, catalyst concentration of 1.19 wt.% and reaction temperature 57^{o}C of below theboiling point of methanol respectively as shown in Table 4.2. Reaction time of 1h andsettling time was 24h fixed. In order to test the validity and accuracy of the prediction model, experiments were carried out under the RSM optimized conditions and the actual conversion rate was 98.31 % and kinematic viscosity was 4.85 cSt. Hence, the prediction models were valid.

Table2. Goal Set for Optimization Process

Name	**Goal**	**Lower Limit**	**Upper Limit**
X_1:Molar Ratio	is in range	-1	1
X_2:Catalyst Concentration	is in range	-1	1
X_3:Temperature	is in range	-1	1
Yield	maximize	85.45	98.40
Kinematic Viscosity	minimize	4.78	5.39

Because of lesser acid value in the refined could increase the conversion rate of ester, applied under the RSM optimized conditions. Therefore, the higher ratios of alcohol to oil would be allowed to obtain higher conversion rate of ester.

Table 3. Optimization of Independent Variables

Name	Molar ratio (X_1)	Catalyst Concentration (X_2), %	Temperature (X_3), ^{0}C	Yield (%)	Kinematic Viscosity (cSt)
Coded	0.9	0.38	-0.54	98.40	4.81
Actual	6.9	1.19	57	98.31	4.85

Conclusions

RSM was successfully applied to assess the effects of multiple variables, including the alcohol/oil molar ratio, catalyst concentration and temperature for the production of biodiesel from the refined cottonseed oil. The yield of methyl ester of cottonseed oil was significantly affected by process parameters namely molar ratio, catalyst concentration and reaction temperature in transterification. The maximum obtained yield of methyl ester of cottonseed oil from cottonseed oil 98.31 per cent at minimum kinematic viscosity 4.85 cSt was likely with following standardize parameters optimized by RSM for transterification reaction. The experimental results suggested the optimal condition as the follows: molar ratio of methanol with oil 6.9:1, catalyst concentration (KOH) 1.19%, reaction time 60 min., reaction temperature 57 ^{o}C, settling time 24h.

Abstract

Yokes and harnesses are the means of attaching the animals to the implements for deriving the power. These days' yokes are developed by using locally available woods in hilly regions of Uttarakhand state (India) like Haldu and Tun etc. It is important to develop and use alternate bio-material to replace wood effectively. Hence, a study on composite material has been undertaken to develop yokes. The resin, cellulose, glass wool, jute net and silica were used in different ratio to prepare composite material for this study. On the basis of this study, the compressive strength, tensile strength and flexural strength of composite material and wood yoke were found 169 and 111.5 N/mm2, 26 and 22.1 N/mm2 and 44 and 13 N/mm2 respectively. The yoke of composite material having resin 87% w/w, silica 10% w/w, 16 numbers of jute net plies 2.5% w/w and 5 numbers of glass wool plies 1.75% w/w is suitable for sustaining the momentary force of 30% force equivalent to body weight of bullock and sufficient to carry out all the agriculture operations those are being performed by animals. The cost of composite material yoke was Rs.325 which is cheaper than the traditional yoke.

Keyword: composite material, resin, silica

Introduction

The population of draft animals in India has reduced from 72 million in 1971-72 to 55.88 million in 2007-08. The major types of draft animals and their population in India is estimated about 55.88 millions out of which Bullock are 49.70, buffalo are 4.27, camel are 0.52, pony are 0.14, horse are 0.47, mithun are 0.26, yak are 0.08, donkey are 0.44 millions. Where as the population of draft animal in Uttarakhand is estimated about 7,11,472 in 2012 out of which bullocks are 6,43,335 buffaloes are 33,467 horses and tattu are 14,632, khachchar are 19,307, donkey are 580 and yakes are 151(19^{th} Livestock census) . In hill region of Uttarakhand only bullocks are used for agricultural draft purpose where as in tarai bhabhar area the buffaloes as well as bullocks are used as draft animal. In hill, khachchar, donkey, yakes are generally used for transportation purpose

Yokes and harnesses are the means of attaching the animals to the implements for deriving the power. There are many types of yokes and harnesses depending on the tradition of the farmers, the type of animal used, the number of animals used and the type of work to be done. The attachment consists of a yoke or a harness (which receives the power directly from the animal) and the linkage which receives the power from the yoke or harness and transfers it to the implement. These days' yokes are developed by using locally available woods in hilly regions of Uttarakhand like Haldu and Tun etc. About 0.7 millions bullocks are being used as draft animals in Uttarakhand. If 60% (approx.) of total population of bullocks is being used as to carry out different agricultural operations in pair, it means 0.21 million (approx.) wooden yokes are required to perform different agricultural operations. If average volume of wood to make a single yoke is 6500 cc (130cm X 10cm X 5cm), then 1360 m^3 of wood is required to fulfill the total demand of Uttarakhand. The life of a yoke is about 3-5 years depending upon

the wood material and type of use. This shows that 628 tons of wood would be required every 3-5 years. Composite is a material formed with two or more components, combined as a macroscopic structural unit with one component as continuous matrix, and other as fillers or reinforcements (Gowda *et al*., 1999**)**. It provides high strength and stiffness as well as resistance to flexural and breaking under the applied stress. Interface bonding between the fillers and the matrix is the key to transfer the stress from the matrix into the fillers across the interface.

Therefore, keeping above points in view, it is important to develop and use alternate bio-material to replace wood effectively. Hence, a study on composite material has been undertaken to develop yokes.

Material and Methods

The material will be used in casting of composite material, and measurement techniques for physical and chemical properties are discussed below.

Material used in moulding

The main material used in moulding were resin, hardener and reinforcing element

Moulding and casting technique

The resin, cellulose and silica were mixed in desired ratio by using mechanical stirrer at room temperature. When proper mixing was completed, the hardener was aided in the mixture. Due to addition of hardener, a high viscous solution was obtained, which was remixed manually. The mould was made by using MS sheet as per requirement. Before pouring the mixture of resin, silica, hardener etc into the mould, a thin layer of lubricating material (grease) is applied on the inner surface of mould to avoid the contact between mould surface and composite material. Then after reinforce material will be placed into the mould along with solution of resin, silica and hardener. This process was repeated until it reaches to the recommended ply rating. This whole process was carried out at room temperature. The moulding process was adopted for development of yoke of composite material of the following dimensions and constituents of different models of yoke are given in table 1.

The dimensions of moulded yoke are as follows:

Length = 700 mm, Width = 45 mm, Thickness = 25 mm

Therefore, Net volume of casting = 700 x 45 x 25 = 7875 mm^3 = 7900 mm^3 (approx)

Table 1 Constituent of different model yokes

Type of treatment	Constituent						
	Jute net Number of plies	Glass wool Number of plies	Wire mesh	Silica (%)	Volume of model (ml)	Resin volume (95%of total)	Hardener volume (ml) (2% of resin)
T_1	12	4	….	4	790	750	15
T_2	12	4	….	10	790	750	15
T_3	12	4	….	16	790	750	15
T_4	16	5	….	10	790	750	15
T_5	12	4	3	10	790	750	15

Test Procedure

Though there are number of mechanical tests, which are necessary to determine the suitability of a material but the flexural strength test have been performed in the present investigation to optimize the design yoke.

Flexural strength test

Flexural strength are used to determine the ultimate load bearing capacity, flexural strength, yield point, yield strength and other properties. In the present investigation tests are conducted as per ISO test procedure for determination of flexural strength only. The tests are conducted on 100 kN servo hydraulic UTM machine (Model 2008, ADMET make.) All tests are conducted at room temperature.

Results and Discussion

Effect on Mechanical Properties of Yoke

Effect of silica percentage and the number of plies variations had been taken into account then different tests had been conducted on the different models (T_1, T_2, T_3, T_4, T_5 and T_6).

Flexural strength

The Flexural strength of models T_1, T_2, T_3 and T_6 were found 41, 32, 26, 13 N/mm^2 respectively as shown in table 2. It is also clear from the table that the value of Flexural strength for T_1, T_2, T_3 are 3 times, 2.5 times and 2 times higher than T_6. It is also clear from the table 2 that less silica percentage provided more flexural strength to the model T_1 having 4% of silica and it became more flexible moreover more silica percentage made model T_2 more stiffed, resulted as reduction in flexural strength. Whereas introducing 10% silica into model T_2 provided almost 2.5 times strength as compared to model T_6, thereby model T_2 emerged as more suitable model as compared to all.

Table 2. Effect of silica percentage on flexural strength of yokes

Types of treatment	Effective span length (mm)	Width (mm)	Thickness (mm)	Load (kN)	Flexural strength (N/mm^2)
T_1	150	43	25	5	40
	150	44	25	5	41
	150	45	25	5	41
	Avg				**41**
T_2	150	45	25	4	30
	150	45	25	4	32
	150	46	25	4	33
	Avg				**32**
T_3	150	43	25	3	27
	150	44	25	3	26
	150	45	26	3	24
	Avg				**26**
T_6	150	87	45	10	13
	150	88	45	10	13
	150	90	45	10	13
	Avg				**13**

After optimizing the silica up to 10%, tests were performed for analyzing the effect of ply on flexural strength with intention behind increasing more strength. The flexural strength of models T_2, T_4, T_5 and T_6 were found 32, 44, 37 and 13 N/mm^2 respectively at 10% silica as shown in table 3. It is also clear from the table3 that the value of flexural strength for T_2, T_4, T_5 are 2.5 times, 3.4 times and 2.8 times higher than T_6. From the table, it is evident that more plies impart more strength to the model however T_5 has been made up of taking wire mesh together with cellulose material, it is observed that strength is not increased considerably as compared to the yoke of more plies i.e. T_4. In addition, it was increasing undesired weight of the yoke.

Table 3. Effect of number and type of plies on flexural strength at 10% of silica

Types of treatment	Effective span length (mm)	Width (mm)	Thickness (mm)	Load (kN)	Flexural strength (N/mm^2)

Dimension of Yoke

A yoke that is capable of supporting the expected draft force of 6860 N (if an animal utilizes 100% force equivalent to body weight of it overcome the draft) should have dimensions determined by using the ultimate flexural strength of the composite material yoke. The treatment T_4 was selected for the design of yoke and which had the ultimate flexural strength of 44 N/mm^2 and a density of 1210 kg/m^3 will thus be treated as simply supported beam on which load (draft force) is acted at the centre of the beam. The beam is supported at the end by same loads to overcome the load acting at the centre of the beam.

Considering the bullocks' working allowance, size of bullocks and existing yoke dimensions, the designed span length is taken 1100 mm (neck-to-neck distance) and with a thickness (d), half of the width (b) of the yoke (considering the dimensions of pant hill yoke). These two dimensional parameters are the most critical to the designed yoke (Devnni, 1981).

For the simply supported beam, flexural strength-Where,

σ = flexural strength of the beam, N/mm^2

P = Load or draft force in Newton, L = Span (length) of yoke beam, mm

b = Width of yoke beam, mm, d = thickness of yoke beam, mm

$$\sigma = \frac{3 P L}{2 b d^2}$$

In practice, a bullock can generate only force equivalent to10% of its body weight in sustainable condition. However, bullock can develop 30% momentary force equivalent to its body weight. On this basis, Pant hill yoke was developed for sustaining 30% force equivalent to bullock's body weight. Hence the new composite yoke is designed for sustaining force equivalent to 30% of bullock's body weight.

It is evident from the table 4, the dimensions of the designed yoke are 1280 x71 x 36 mm and mass are 3.90 kg, whereas the wooden yoke has dimensions and mass of 1280 x 106 x 53 mm, and 4.88 kg respectively a force equivalent to 30% of body weight of bullock.

Table 4 Dimensions and mass of the designed yoke at force equivalent to 30 % of body weight of bullock

S.No.	Type of yoke	Strength (N/mm^2)	Length (mm)	Width (mm)	Thickness (mm)	Mass (kg)
1.	Designed (T4)	44	1280	71	36	3.90
2.	Wooden (T6)	13	1280	106	53	4.88

From table 4, it is evident that composite yoke is lighter and stronger than the wooden (Tun) yoke. On the basis of above all studies, it is recommended that newly designed yoke of composite material (T_4) with using resin (87% w/w), silica (10% w/w), 16 numbers of jute net plies (2.5% w/w), 5 numbers of glass wool plies (1.75% w/w) is suitable for sustaining the momentary force of equivalent to 30% of body weight of bullock. However Pant hill yoke having dimensions of 1280 x 90 x 43 mm is less than calculated value of dimensions at force equivalent to 30% of body weight of bullock.

Conclusion

On the basis of above study, it is recommended that the dimensions and mass are 1280 x71 x 36 mm and 3.9 kg at 30% force equivalent to body weight of bullock. The yoke of composite material (T4) having resin 87% w/w, silica 10% w/w, 16 numbers of jute net plies 2.5% w/w and 5 numbers of glass wool plies 1.75% w/w is suitable for sustaining the momentary force of 30% force equivalent to body weight of bullock. However Pant hill yoke having dimensions of 1280 x 90 x 43 mm is less than calculated value of dimensions of wooden (tun) yoke at 30% force of body weight of bullock. The designed yoke has the flexural strength of 44 N/mm2. These figures are more than sufficient to carry out all the agriculture operations those are being performed by animals. It cost is estimated Rs.325 which is cheaper than the traditional yoke.

Abstract

This paper deals with the development of Resource Conservation Machine for Sugarcane Cultivation. It is reported that poor yield of sugarcane is because of weed can range from 15 to 75 % depending upon field conditions. The initial 90 to 120 days are very critical for poor yield of sugarcane because of weeds. Therefore, these days are very important for weed management to ensure higher yield. In case of sugarcane crop although various type of machinery has been developed, however there is a need of resource conservation machine for better productivity by weeds incorporation and mulching operation.. The developed machine consists of a frame of 2440 mm length and 510 mm wide, the square pipe selected for frame is of 5 mm size. The tines which are 6 in numbers are attached at the front side and blades of trapezoidal shape with rounded corners were attached at the rear side of the frame. The length of blade is 650 mm and thickness is 5 mm. the blades were attached with the help of L shaped legs which were clamped to the frame. The adjustable clamps help to adjust the depth of blades during the operation. The main objective of this study is to find mathematically the thickness of the blade used at the rear end of the machine. The machine is able to perform the intercultural and mulching operation efficiently without damaging the sugarcane crop. Hence it very useful for the growth of sugarcane and saves money, time and resource conservation as compared to manual and other intercultural methods.

Key words: *Resource conservation, Sugarcane, Intercultural operation, Weeding, Mulching.*

Introduction

Sugarcane is one of the most important cash crops in India. It is cultivated in an area of about 4 million ha, with production of 75 tonnes/ha (The Hindu, Survey of Indian agriculture 2013). The total production of sugarcane has been increasingly steadily from 230 million tonnes in 1993-94 to 300 million tonnes in 2013-14. Sugar availability in the country has been about 18.5 million tonnes (The Hindu, Survey of Indian Agriculture). The energy consumption in production of sugarcane is the highest as compared to many other crops such as wheat, maize, paddy etc. Sugarcane production is labour intensive cultivation. It required about 3300 man-hours for different agricultural operations (Yadav and Chaudhary, 2000). Considering the present trend of availability of labour for sugarcane production, it has been experienced that use of modern machinery is inevitable. Use of machinery helps in labour savings ensures timeliness of operations, reduces drudgery, helps in improving quality of work, reduces cost of operation and ensures effective utilization of resources. In case of sugarcane crop although machinery has been developed, however the machines or implements has not been available for the intercultural operations up to the desired level. Thus there is a considerable mechanization gap, especially in the area of sugarcane, intercultural operation. Weed control is most critical early in the season. Two to three months after planting, the appropriate weed management must proceed; otherwise the yield reduction could be reduced up to fifty percent (Suwannarak, 1983). Weed can reduce sugarcane yields by competing for moisture, nutrients,

and Sunlight during the growing season. (D. C. Odero, 2009).Weeds also utilizes a part of nutrition and water resulting in decrease in sugar content. Heavy weed infestations can also interfere with sugarcane harvest by adding unnecessary harvesting expenses (D. C. Odero, 2009). The optimum chemical management for weed control in sugarcane required 2-3 applications per crop by using the herbicide, however the type of herbicide selection depends on type of weed and there are limited kinds of herbicide appropriate for sugarcane (Suwanarak, 1999). Ideally mechanical weed control should get preference over herbicidal control in sugarcane. At the present mechanical weeding is still in limited use. The optimum tool for control weed should be able to uproot the weeds and break the soil after operation. The present study is based on design and development of a machine for the better productivity with the objective of design and development of suitable machine for Sugarcane intercultural operation

Materials and Methods

The methodology which will be adopted for design and development of resource conservation machine for sugarcane cultivation, the procedure followed for testing of design the prototype is discussed in this section. The machine was designed and developed at Farm Machinery and Power Engineering Department of Govind Ballabh Pant University of Agriculture and Technology, Pantnagar, Uttarakhand, India.

Design and fabrication of the machine

A resource conservation technology for sugarcane cultivation was designed and fabricated in the Department of Farm Machinery and Power Engineering Department of Govind Ballabh Pant University of Agriculture and Technology, Pantnagar, Uttarakhand, India. The main parts of the machine are frame, spring loaded reversible tines, trapezoidal blade and hitching system.

Description of the resource conservation machine for sugarcane

The developed machine comprises of a rectangular frame, six spring loaded reversible tines, two legs to hold the blades, two trapezoidal blades and hitch system. The machine consists of a rectangular frame made by square pipe. Six reversible tines are attached at the front part of the machine and two trapezoidal blades are fixed exactly behind the tines. The blades are welded to the frame with the help of L shaped shank. The detailed information regarding the machine has been described in Fig. 1 and 2.

The rectangular frame consisted of two beams of hollow square section. The size of frame was 2440 x 510 x 60 mm. Number of holes were provided in the frame so that the tine spacing can be adjusted. Six cultivator tines were mounted at the front of the frame at 700mm apart from each row and 230mm part from each other with the help of nut and bolts. It was assumed as the draft force experienced by all the six tines is of similar magnitude therefore. The cross section of the beam was designed for the maximum force Fig. 3.

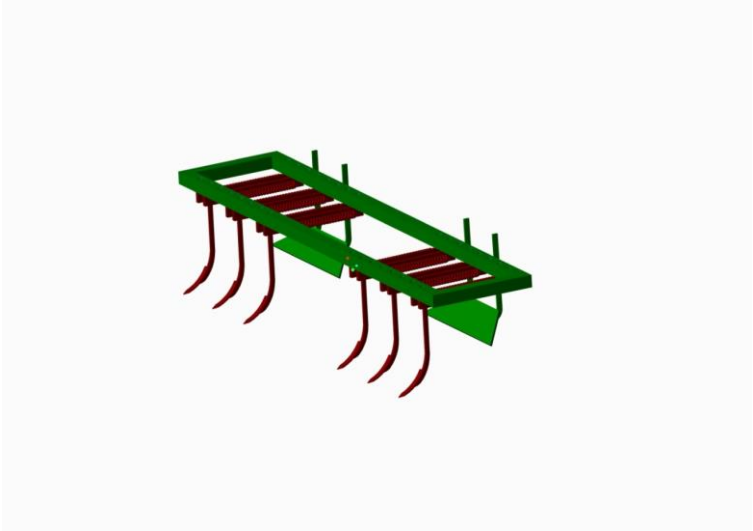

Fig. 1 The Overview of the Machine

Fig. 2 Overview of the developed Machine with hitching system

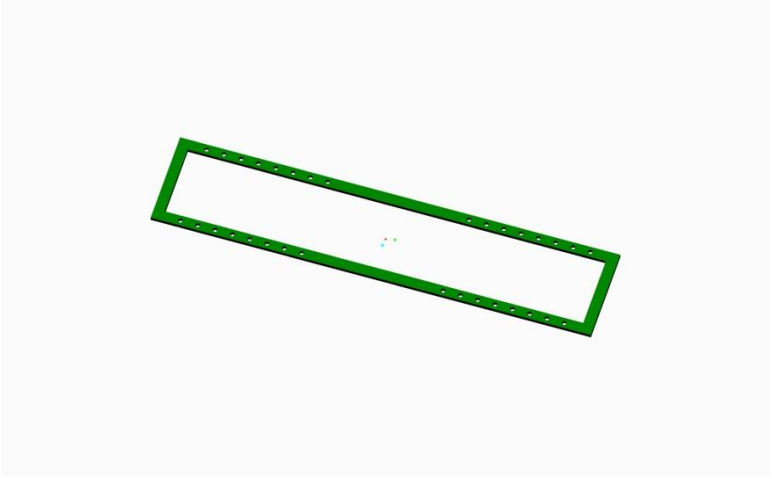

Fig. 3 Frame of the Developed Machine

The shank was designed and fabricated from flat 50×5 mm wide flat. Four shanks were designed and welded at the bottom of blade of identical size to hold the blades attached at the rear side of the frame. In each blade two shanks were welded for holding it. The two shanks

were 350mm apart from each other. Six sets of holes were drilled in each leg at 38 mm apart from each other. By these number of holes the height of the blade can be adjusted Fig.4.

Fig. 4 Shank used in the Machine

Two blades of trapezoidal shape were designed and fabricated from flat of 5mm thick plate .The base length of the trapezoidal blade is 650 mm and height of 170 mm as shown in Fig. 5. The two blades were attached exactly behind the tines attached at the front part of the frame. The distance between the two blades is 700 mm.

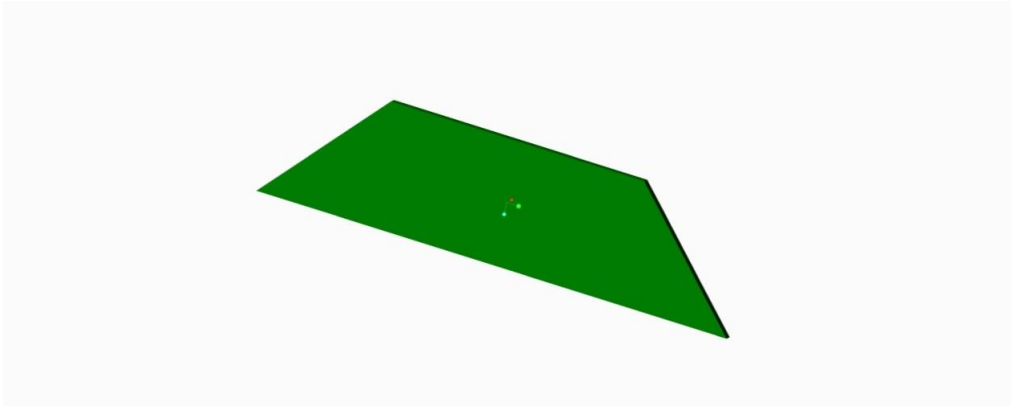

Fig. 5 Trapezoidal blade of the Developed Machine

The angular section is considered as best for clamping legs with the beam. Four 'U' shape clamp of size 50x70x14 mm has been provided for each leg to hold it properly with beam with the help of nuts and bolts. The upper angle section becomes the compression member and the bottom section becomes the tension member while working together as a conjugate device.

The hitching system of the developed machine is subjected to normal loads; therefore, the hitch point was made by welding two mild steel flats with the beam at a spacing of 284 mm from the centre of beam. The size of these mild steel flat was kept 730 x 50 x 16 mm with 28 mm diameter holes drilled at 77.5 mm from the front end to connect the upper hitch plates and hitch pins together. The lower hitch point span was kept as 685 mm which was selected as per the recommendation of BIS-4468 – 1997 for second category hitch as shown in Fig.6. A hitching system was made from mild steel flats of 100 mm (width) x 12 mm (thickness) was mounted vertically with the help of nuts and bolts with hitching flats to obtain a mast height of 610 mm which is in conformation with BIS-4468 – 1997. In order to distribute load from the front beam to the entire frame and for better balancing of the planter, the top link point

was supported at the rear beam with the help of 715 mm long mild steel flats of 60 mm (width) x 15 mm (thickness).

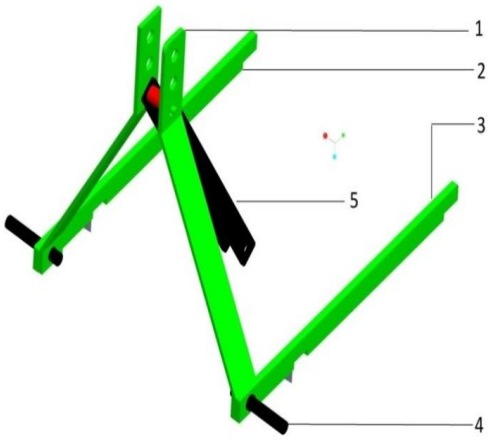

Fig. 6 Hitch system used for the Developed Machine

Where,

S. No.	Components
1	Hitch Plate
2	Supporting plate
3	Supporting end
4	Hitch Pin
5	Top Link

Intercultural operation requires weeding and loosening of the soil by shovel attached to the shank of the reversible tine. The length of the tine is 520 mm as shown below in Fig.7. Results of field investigation on optimum soil moisture content, bulk density, shovel size and depth of tines penetrated formed the design selection for the selection of shovel. Shovel not only pulverizes the soil, it uproots the weeds in between the two rows of planed sugarcane. A suitable shovel was selected having width of 50 mm and length 150 mm and shovel is fitted on lower end of the shank at 220 with nut and bolt. A rigid tine, hinged to the frame and loaded with helical spring so that it swings back when an obstacle is encountered. A curved steel furrow opener with both ends pointed is attached to the lower end of the tine.

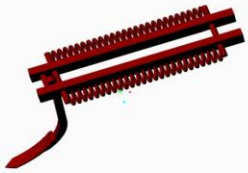

Fig. 7 Spring loaded Reversible tine used in the Developed Machine

Draft requirement of the developed machine

The maximum depth of operation of reversible tines (z) was 170 mm. Hence, for the reversible tine working at 170 mm depth and having 50 mm tine width, the aspect ratio z/w = 2.22.

Taking unit draft of soil as 0.55 kg/cm^2

Total draft per tine = depth (cm) x width (cm) x unit draft (kg/cm2) of soil ...

= 17 x 6x 0.55

= 56.1 Kg

= 46.75 x 9.81 N

= 550.34 N

= 0.550kN

Draft for six reversible tines = 0.550 x 6

= 3.30 kN

Results and Discussion

Two blades of trapezoidal shape with rounded corners were designed and fabricated from flat of 5mm thick plate. The base length of the trapezoidal blade is 650 mm and height of 170 mm as shown in Fig.2. The two blades were attached exactly behind the tines attached at the front part of the frame. The distance between the two blades is again 700 mm.

Area of blade = $\frac{1}{2} \times b \times h$

Where, b = base of blade

h = height of blade

Area = $\frac{1}{2} \times 650 \times 170$

= 55250 mm^2

The blade were attached at an angle of 17^0 from the horizontal.

The yield strength of mild steel is 248×10^6 N/mm^2

The average draft is 1089 kgf

Draft = 1089 kgf

= 1089×9.81

= 10.6×10^3 N

Draft on each blade = 5.3×10^3 N

Component of draft perpendicular to the blade, knowing the angle of blade is 17^0

= $5.3. \times 10^3 \times \cos 73^0$

$$\frac{\sigma}{FOS} = \frac{Draft\ on\ each\ blade}{Length \times thickness}$$

$$\frac{2.48 \times 10^6}{5} = \frac{5.3 \times 10^6 \times .73}{3.5\,t \times 10^{-3}}$$

t = 0.004 m

= 4 mm

So for the designed machine we can take blade of thickness above than 4 mm.

Hence we selected a blade of thickness 5 mm which is easily available in local market.

The results obtained are summarized below.

- It was observed by the initial trial of the developed machine that no plants injury was recorded and the machine worked satisfactorily.
- The calculated thickness of blade was 4 mm. So, any value above than 4 mm can be used for blade thickness. We took the blade thickness 5 mm as it was easily available in the local market.

Conclusions

The machine was able to perform the intercultural and mulching operation efficiently without damaging the sugarcane crop. Hence it is very useful for growth of sugarcane and saves money, time and resource conservation as compared to manual and other intercultural methods. The developed machine comprises of a rectangular frame (2440 x 510 x 60 mm), six spring loaded reversible tines, two legs to hold the blades, two trapezoidal blades with 5 mm thickness and hitch system. There was no plant injuries of sugarcane crop recorded in the initial trials. Thus the developed Resource conservation machine for sugarcane worked satisfactorily and recommended for resource conservation in crop cultivation.

Abstract

With the recent developments on internet and communication technology, IoT (Internet of Things) applications are being common in agriculture. ZigBee is an IEEE 802.15.4-based specification for a suite of high-level communication protocols used to create personal area networks with small, low-power digital radios. A ZigBee network can be created as Star, Tree, Cluster Tree and Mesh topologies. These topologies make ZigBee networks suitable for agricultural applications. With low power consumption and encrypted data transfer, ZigBee networks are also suitable for IoT applications. In this study; a system which collects data from bee hives via ZigBee network is designed. Solar powered under-hive units measure weight, temperature and relative humidity of hives and send all data to network coordinator with communicating one another. Designed system is a low-power, low-cost field data acquisition system which can be used in any agricultural application. Remote control over ZigBee networks are also possible to use in agricultural fields and farm management. With fuzzy logic, autonomous smart farms can be developed.

Keywords: *Internet of things, ZigBee, Bee hive, Wireless Sensor Networks.*

Introduction

With the recent developments in wireless technology, Wireless Sensor Networks (WSN) are being widely used. A Wireless Sensor Network can be used in a remote environmental monitoring application. This is enabled by smaller, cheaper, intelligent and low-power sensor nodes. These sensor nodes communicate via wireless networks with one another (Yick et al., 2008) within an algorithm. Wireless Sensor Networks (WSN) consist of embedded sensing, computing, and communication devices, and are a key technology of the Internet of Things (IoT) concept. WSN have found many applications, including healthcare, environmental monitoring and medicine (Boyle et al., 2011 and Sardini and Serpelloni, 2011). A wireless sensor network is an integration of sensors, microcontrollers, radio frequency (RF) transceivers and power sources (Wang et al., 2006).

There are different wireless standards and devices which are used in wireless sensor networks. Among them, the standards for wireless LAN, IEEE 802.11b ("WiFi") and wireless PAN, IEEE 802.115.1 ("Bluetooth") and IEEE 802.15.4 (ZigBee), are more widely for measurement and automation applications (Wang et al., 2006). ZigBee is established by the ZigBee Alliance that is supported by more than 70 members. ZigBee is known for its security, reliability, low power consumption and simple network configuration. Table 1 compares these three wireless standards that are most suitable for wireless sensor network.

Table 1. Comparison between wireless LAN, Bluetooth and Zigbee

Feature	**WiFi (IEEE 802.11b)**	**Bluetooth (IEEE 802.15.1)**	**ZigBee (IEEE 802.15.4)**
Radio	DSSS[a]	FHSS[b]	DSSS
Data rate	11 Mbps	1 Mbps	250 kbps
Nodes per master	32	7	64 000
Slave enumeration latency	Up to 3 s	Up to 10 s	30 ms
Data type	Video, audio, graphics, pictures, files	Audio, graphics, pictures, files	Small data packet

[b] FHSS, Frequency Hopping Spread Spectrum
*Source: Wang et al., 2006

The wireless standards also address the network issues for wireless sensors. Three types of networks: star network, hybrid network and mesh network, have been developed and standardized. The Bluetooth technology uses star network type, which is composed of piconets and scatternets. Each piconet connects one master node with up to seven slave nodes, whereas each scatternet connects multiple piconets, to form an ad hoc network. The ZigBee technology uses hybrid star network type, which uses multiple master nodes with routing capabilities to connect slave nodes, which have no routing capability (Sensicast, 2004).
The most efficient networking technology uses peer-to-peer, mesh networks, which allow all the nodes in the network to have the routing capability. Mesh networks allow autonomous nodes to self-assemble into the network. It also allows sensor information to propagate across the network with a high reliability and over an extended range. In addition, it allows time synchronization and low power consumption for the “listeners” in the network and, thus, extending the battery life (Wang et al., 2006).
This paper focuses on smart beehives which are using ZigBee-based wireless sensor network. In the paper, a beehive tracking unit is designed.

Material and Methods

A unit is designed and used under every hive and has a sensor pole that sticks into the hive. This unit has load cells on four corners, a temperature and humidity sensor, a microcontroller, a battery and a ZigBee module (Figure 1, Figure 2). 20 Wp rated solar panels are used at the top of hives as power source.

Working frequency	2.4 GHz ISM
TX current	40 mA @ 3.3 V
RX current	40 mA @ 3.3 V
Range	120 m
TX power	2 mW (+3 dBm)
RX sensitivity	-95 dBm
Network topology	Mesh, Star, Cluster Tree

An example of network between hives and ZigBee Coordinator is shown in Figure 7.

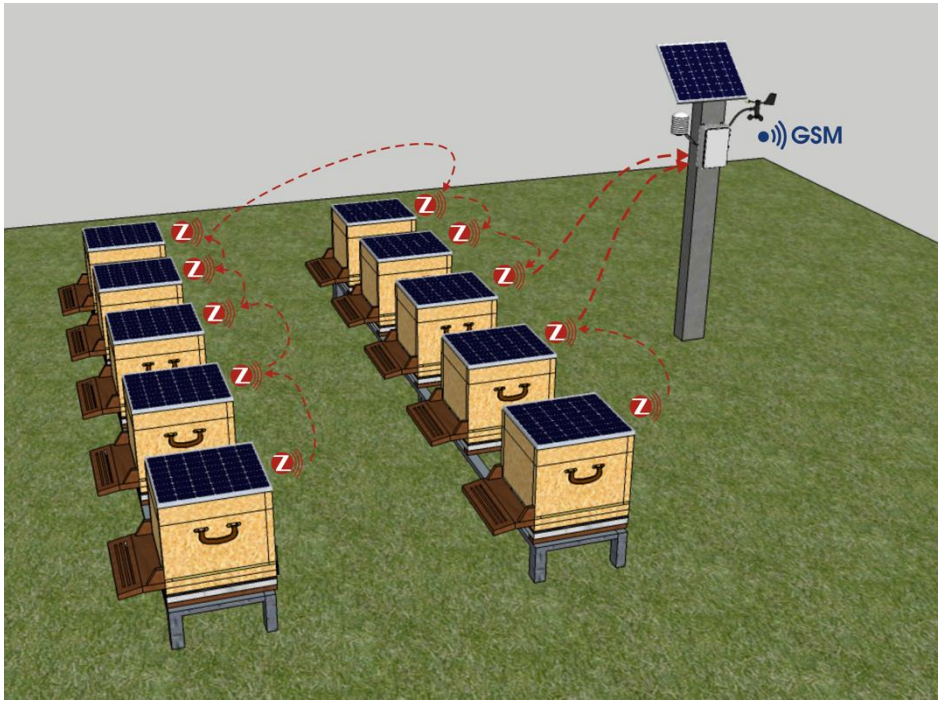

Figure 7. Network between beehives and ZigBee Coordinator

Zigbee Coordinator and Weather Module

A stationary unit is designed to collect data from beehives' network and sends to the remote server with weather data via GPRS connection. GPRS connection is provided by SIM900 GSM GPRS module. This unit is powered by a 50 Wp rated solar panel and this unit works as a ZigBee Coordinator.

Weather data such as temperature, relative humidity, wind speed, wind direction, rain, air pressure, and light is measured.

Data Collection and Analysis

A WEB server with php and MySQL database installed is used during experiments. Data is collected with a php page using GET function and saved into MySQL database (Pierce and Elliott, 2008). Time variable is added to data collected during saving process.

Data analysis is made with a php script. Daily weight change is calculated using the data from the previous day, for the same time because weight can dramatically change any time due to bee population and water amount inside the hive (Meikle and Holst, 2014).

Results and Discussion

With the system developed in this paper, hive data can be collected during both production and sleep states of honeybees, including daily weight change. Meteorological data is also collected by the main network coordinator and all data is sent to a webserver via GPRS connection.
Hourly energy consumption is calculated as in Table 4 considering sleep times.

Table 4. Power consumption of design system.

Arduino UNO	80 mWh
Load cells	0 mWh
SHT75	5 mWh
ZigBee Module	20 mWh
TOTAL	**105 mWh**

Daily weight change gives an information about how much honey is produced. Temperature, and relative humidity gives information about colony condition. If there are sudden changes in these parameters, beekeeper should be warned about the condition of bee colony.
A screenshot from the developed website is seen in Figure 8. Icons show temperature, wind speed & direction, air pressure, light intensity, average weight change, rain condition, system events and battery, location and communication status in order.

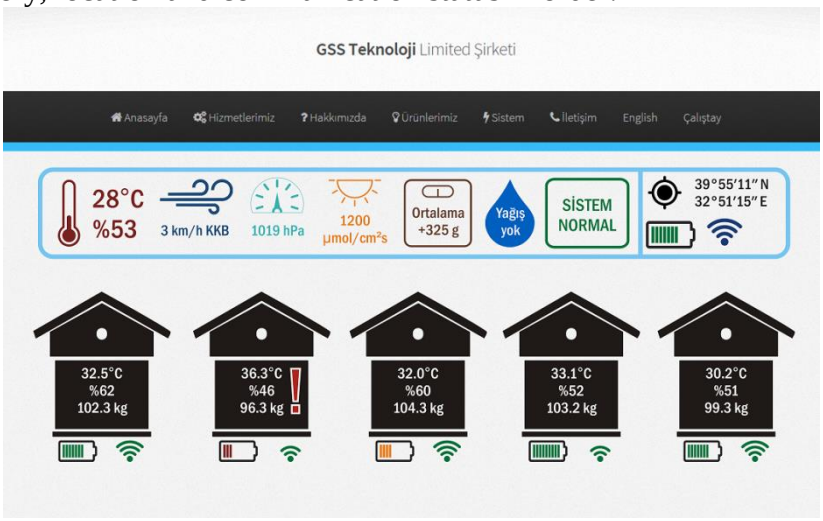

Figure 8. Website screenshot

When clicked on a hive, website shows detailed information. A screenshot from a particular hive is shown in Figure 9.

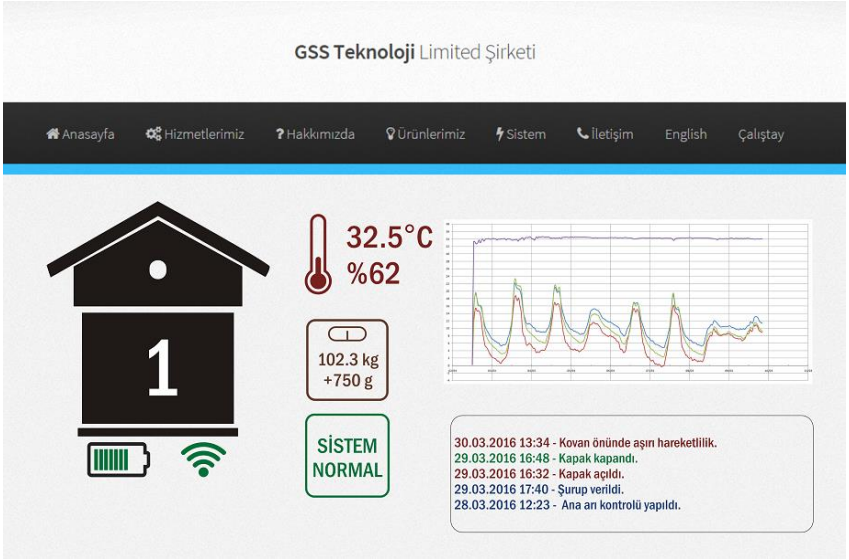

Figure 9. Single hive detailed view from the website

Conclusions

Due to its low power consumption, simplicity, extendibility and Mesh network topology, ZigBee networks can be used in solar-powered field data acquisition systems. ZigBee is suitable to use in Wireless Sensor Networks for agricultural applications. ZigBee can be used for both data acquisition and control network. With using fuzzy logic, autonomous systems such as smart farms can be designed.

As designed system work on solar power, low-power devices and internal power management are important. There have to be sleep times for microcontroller and ZigBee module to reduce power consumption and make time to energy harvesting.

A COMPARATIVE ANALYSIS OF THE EXTERIOR IN LOCAL GOAT BREEDS FROM SOUTHWEST BULGARIA

Atanas VUCHKOV, Doytcho DIMOV

Department of Animal Science. Agricultural University – Plovdiv, Bulgaria. Corresponding autor: a_vu@abv.bg

Abstract

In the last 15 -20 years there has been a higher interest in the skins of the Kalofer longhaired goats, used for making mummer's costumes, typical for Southwest Bulgaria. As a result, very valuable animals from this indigenous goat breed were brought from its tipycal habitat (Kalofer region); some of them were killed for their skin, and others left for breeding, mainly in Southwest Bulgaria (Blagoevgrad region). This region(Blagoevgrad region) , however, is a natural habitat of another local breed – the Bulgarian Screw-horned long-haired goat. Coexistence and breeding in purebred status of these two indigenous goat breeds, requires clearly distinguished breed types of both of them. For this purpose, we traced typical specimens, whith a clearly expressed breed type of Kalofer long-haired and Bulgarian screw-horned goats, reared in herds in Southwest Bulgaria. Full exterior measurements of 100 goats (50 of each breed) and 40 bucks (20 of each breed) were made. The Kalofer long-haired goat is larger than the Bulgarian Screw-horned long-haired goat - the height at the withers in the females, was - 70.76 cm and 66.9 cm, respectively. The height at the withers in the bucks was - 82.2 cm and 73.4 cm, respectively. The differences expressed a high degree of probability. The Bulgarian Screw-horned goat has a light stretched format (bucks′ stretchabillity index was 106.3), while the Kalofer long-haired goat has a square format (bucks′ stretchabillity index was 100.3). The Kalofer long-haired goat has more massive bones (index for the development of bones was 12.99) than the Bulgarian Srew-horned goat (index for the development of bones - 12.12). The differences expressed a high degree of probability.

Key words: *Goat breeding, Autohthonous breeds, local goat breeds, exterior measurements, exterior indices*

Introduction

The local goat breeds in Bulgaria are poorly investigated and fully detailed data about their exterior and productive qualities are scarce. A number of authors who studied local goats in the past described them as low-productive and of heterogeneous exterior. The investigations were initiated mainly because of the opportunity for crossbreeding with highly productive introduced breeds (Kadijski 1958, Balevska and Tjankov 1981, Solomonov, Kadijski and Lazarov 1984, Tjankov et al. 1996, Krastanov, 2003). In most of the papers the different local goat populations are mentioned under the collective term autochthonous goats. However, surviving populations are still to be found in some regions of the country, possessing characteristic and steadily transferred exterior traits. That fact calls for their separate study and description. (Vuchkov et all. 2011). The local Kalofer long-haired goat breed is threatened with extinction. Typical mountain breed. Natural area of the breed are the southern slopes of the Central Stara Planina mountain, near the town of Kalofer (Sedefchev et all.2011; Vuchkov et all 2011). In the last 15 -20 years there has been a higher interest in the skins of the Kalofer longhaired goats, used for making mummer's costumes, typical for Southwest Bulgaria. As a result, very valuable animals from this indigenous goat breed were brought from its tipycal habitat (Kalofer region); some of them were killed for their skin, and others left for breeding, mainly in Southwest Bulgaria (Blagoevgrad region). This region(Blagoevgrad region) , however, is a natural habitat of another local breed – the

Bulgarian Screw-horned long-haired goat (Sedefchev et all. 2011; Vuchkov and Dimov 2012). Coexistence and breeding in purebred status of these two indigenous goat breeds, requires clearly distinguished breed types of both of them. For this purpose, we traced typical specimens, whith a clearly expressed breed type of Kalofer long-haired and Bulgarian screw-horned goats, reared in herds in Southwest Bulgaria.

The aim of this study was to perform exterior measurements of typical specimens of local goat breeds reared in Southwest Bulgaria - Kalofer long-haired goat (KLg) and Bulgarian Screw-horned long-haired goat (BSg), and to perform a comparative analysis of the exterior features of both breeds. To achieve that aim the following tasks were set:

- to trace purebred specimens with expressed breed type, reared in flocks of Southwest Bulgaria;
- carry out thorough body measurements of fully grown-up bucks and does;
- to calculate some exterior indices in goats and bucks;
- to establish accuracy in the differences in the values of the exterior parameters in both breeds;

Material and methods

For this study were selected 50 goats and 20 bucks of both breeds with clearly expressed breed type in the autumn of 2014 year,. It was formed sample of 100 goats and 40 bucks, reared in 6 herds in the mountainous regions of Southwest Bulgaria. Goats are kept under similar conditions - traditional pastural technology, with additional feeding of concentrated fodder and meadow hay in winter. In order to perform the body measurements the following tools were used: cane of Lidtin, compasses of Wilckens and a measuring band. The results are processed statistical variation.

Results and discussion

The results shows that the Kalofer Long-haired goats (KLg) are relatively higher at the withers, than the Bulgarian Srew-horned goats (BSg) - 70.76 cm and 66.9 cm respectively. The differences expessed a high degree of probability (Tabl.1.). In comparison with some dairy breeds, the Kalofer Long-haired and has a lower height at withers. According to data from the Ylmaz et all. (2016), the average requirements for Saanen goat height at withers is 73.94 cm, but the height varies from 62.0 cm to 85.0 cm. The height at withers in Shami (a Damascus goat raised in Egypt) females is 69.2 cm and in bucks – 83.1 cm (Helal, 2009). Similar results obtained and Mason (1996) in Valais goats. When compared with the height at withers (68.8 cm) established by earlier authors in other local goats in Bulgaria (Kadijski, 1958; Balevska and Tjankov, 1971) it is clear that the Kalofer Long-haired goats have higher figures for that feature. The measurements of the height at rump and compared with the height at the withers of both breeds, it is clear that Kalofer Long-haired goats (KLg) has higher height at rump, while in the Bulgarian Screw-horned goat (BSg), the height at rump is almost equal to the height at the withers (figs.2,3.). The differences expressed a high degree of probability. It is noteworthy that the KLg has proven broader and deeper chest than the BSg. The coat of the both breeds is long and straight. The quality of the hair while is different - in the BSg hair is dry, harder and slightly wavy. The hair in the KLg is softer and with silky shine.

We recognize the significant superiority of the KLg on the sign length of the hair. The average values of the length of the hair at the rump was 29.06 cm, and the length of the hair at the withers was 24.34 cm. In the BSg values of these signs are with considerably lower values, respectively - 23.44 cm and 17.06 cm. The differences expressed a high degree of probability. The bucks of both breeds has significantly longer hair in compared with the goats (table 2.). The differences between males of both breeds in the signs length hair at the withers, and at the croup expressed a high degree of probability. A clear difference can be seen in the exterior feature shin-bone girth in the bucks (fig.3). The bucks form KLg breed has markedly more massive bones, than the bucks from BSg breed. The shin-bone girth in the bucks from KLg breed was 11.42 cm. In the bucks from BVg breed was 9.55 cm. The difference was demonstrated with a high degree of probability.

Our results from exterior measurements of the head in both breeds shows that the KLg has broader and longer head, than BSg (Tabl.3,4). The width of the head in KLg was 13.56 cm, and lenght - 19.97 cm. The width of the head in the BSg was 12.76 cm, and the length is 18.32 cm. The differences are proven with a high degree of probability.

Fig.1. Heads of the Kalofer long-haired goats (KLg) and Bulgarian Screw-horned longhaired goats (BSg) – does.

Fig.2. Does from the Kalofer Long-haired (KLg) and Bulgarian Screw-horned long-haired (BSg) breeds

Fig.3. Bucks from from the Kalofer Long-haired (KLg) and Bulgarian Screw-horned long-haired (BSg) breeds

Head in BSgt is revatively smaller, triangular in shape, and slightly concave profile. The ears in KLg are large and dropping (fig.1.). The length of the ear was 16.2 cm, width - 7.2 cm. The ears in BSg is a shorter and protruding. The length of the ear was 14.0 cm, width - 6.06 cm width. The differences expressed a high degree of probability.

Conclusions

Coexistence and breeding in purebred status of these two indigenous goat breeds, requires clearly distinguished breed types of both of them. The Kalofer long-haired goat is larger than the Bulgarian Screw-horned long-haired goat - the height at the withers in the females, was - 70.76 cm and 66.9 cm, respectively. The height at the withers in the bucks was - 82.2 cm and 73.4 cm, respectively. The differences expressed a high degree of probability.

The Bulgarian Screw-horned goat has a light stretched format (buck′s stretchabillity index was 106.3), while the Kalofer long-haired goat has a square format (bucks′ stretchabillity index was 100.3). The Kalofer long-haired goat has proven more massive bones (index for the development of the bones was 12.99) than the Bulgarian Srew-horned goat (index for the development of bones - 12.12). The differences expressed a high degree of probability.

Kalofer long-haired goat has broader and longer head. The width of the head in the Kalofer goats was 13.56 cm, and lenght - 19.97 cm. The width of the head in the Bulgarian Srew-horned goat was 12.76 cm, and the length was 18.32 cm. The differences expressed a high degree of probability.

The Kalofer long-haired goats has large and dropping ears. The length of the ears was 16.2 cm, width - 7.2 cm. The Bulgarian Screw-horned goat has a shorter and protruding ears. The length of the ears was 14.0 cm, width - 6.06 cm. The differences expressed a high degree of probability.

ROLE OF INFORMATION AND COMMUNICATION TECHNOLOGIES IN INNOVATION OF LIVESTOCK SYSTEMS AND TERRITORY PROMOTION. A CASE STUDY OF CALABRIA REGION, ITALY

Adriano CIANI[1]*, Annalisa GAMBARDELLA[2]

[1]Perugia University, Perugia, Italy
[2]Freelancer, Italy
*Corresponding author: adriano.ciani@unipg.it

Abstract

A big theme at the centre of the global debate but also national one is the environmental issue also linked to intensification of agricultural-livestock production systems. The intensification trend appears to be closely related to the strong demographic and economic growth verified worldwide in recent years. According to forecasts, in 2050 population will reach 9 billion people; taking into account that today records a total of 859 million people living in a state of food insecurity, it obviously increases the demand for animal protein.The methodology of the paper is an empirical approach. By the theoretical framework of the livestock innovative systems and the strategy of valorisation of the internal area the authors produce a concrete possible project to implement at the level of the Calabria Region.The research, ultimately promoting Livestock Innovative Systems, engages in a consistent manner the Strategic Plan for the internal areas of the Calabria Region. Therefore, it aims to strengthen the potential of this region, stemming in particular from the great variability and diversity that characterizes the Region and that can be a great competitive advantage. This paper points out finally that such action must be pursued through the introduction of all possible innovations concerning the production process and the marketing and promotion, as well as services for productive activities, to the world of work and society. The authors conclude that all of this is possible to achieve with a massive introduction of ICT.

Keywords: *Livestock Management, Sustainable Development, Promotion of Territory, ICT, Local Food Chain*

Introduction

The current economic model, based on the strong industrialization of the production systems and thus on the indiscriminate exploitation of resources, brought heavy environmental and social impacts.Animal husbandry, as stated in the FAO report "The State of Food and Agriculture"(FAO,2010), is one of the sectors of the agricultural economy that records the fastest growth. The cattle also represents 40% of the total value of agricultural production and provides livelihood and food security to over a billion people. Worldwide, it provides 15% of total food energy and 25% of dietary protein The world economy is anyway directed towards increasingly greater production and thus at growing consumption of animal products. In response to the growing demand for animal products has widespread the intensive farming system, able to ensure greater production in a shorter time frame. However this turns out to be a major contributor to the many environmental changes that in recent decades are being recorded both locally and globally.(IPPC-UNEP, 2014) New strategies are therefore needed so that the livestock sector can meet the growing demand for animal products and at the same time contribute to the food security to the poverty reduction, environmental sustainability and human health. More specifically, in the livestock sector, innovative approaches should be based on controlled ecological cycles, in which the animal plays a key role, thanks to its physiological mechanisms that allow it to increase the value of biomass. (*CREA*

EXPO,2015).The livestock sector is one of the most representative activity of the inner and central areas. The latter are patterned by the presence of important environmental resources and valuable agricultural products characterized, by high typicality and appreciation from the market. The most important characteristics of these products come from the link between the territory vocationality and production techniques. It follows that the foodstuff of these areas becomes cultural heritage and local identity element. In this way it's important try to implement innovative project characterized by the strictly linkage between tradition and innovation

Literature on issue

Agriculture and rural areas thus play a crucial role as they are located to perform new functions in society, in a multi-functional operating environment that integrates the strictly agricultural/productive activities "in" the territory to the conduct of business "for" territory, from tourism and recreation and landscape to cultural, educational and social(OECD, 2007). However, rural areas are still deeply marked by the loss of traditions, the resources and uses linked to the cultivation of the land; the need to protect nature and maintain biological diversity in specific areas is critical to the ecological balance, as well as, hand in hand, the need to preserve and pass on country "knowledge and tastes" is essential for the survival and development of rural areas. In fact the Community agri-food products stand out in terms of quality because of the differences and the territorial and historical identities, which make them "attractive" for the consumer(Ciani 2015).Agriculture is a fundamental defense of the territory, a bulwark for the protection of collective goods, territories and rural landscapes, and to preserve the historical memory. The erosion of this heritage entails, however, the loss of cultural identity and farming skills handed down from generation to generation that threatens the very rural economies. (*Giuca, 2013*).Digital technological innovations and network, and their progressive integration into the world of production, processing and consumption of food, both at a macro level (production and distribution) and at micro-system level (end user enjoyment) are of fundamental importance. Globally, digital technologies are particularly contributing to network individual entities, causing major socio-cultural, political, technological and environmental changes toward the IV Industrial Revolution (*Schwab, 2016*),The Age of Sustainable Development (*Sachs, 2015*), and the implementation of Circular Economy. (*Webster, 2015)*It changes the consumer's relationship with the manufacturers and distributors, but also with his body, his senses and space. The user is transformed from mere spectator to active information manufacturer: change the processes of knowledge and the means of communication that put users in relation with each other. This is confirmed also in the light of a recent article of "Seed and Cheep" (*Cinquemani, 2016*) which shows that the ten future trends of agribusiness innovation are represented by:

- ***Precision agriculture;***
- ***Controlled environment agriculture;***
- ***3D Printers;***
- ***Nutraceuticals;***
- ***Traceability;***
- ***Packaging;***
- ***Precision nutrition;***
- ***Smart kitchen and precision cooking;***
- ***Sharing economy;***
- ***E-Commerce.***

ICTs have repeatedly demonstrated their potential to combat poverty in developing countries. In many cases, there are experienced benefits in the form of increased income; better health care;

better education and training; access to job opportunities; commitment to public services; contacts with family and friends; business development opportunities(*Ciani ,2012*); increased agricultural productivity, and so on. " (*Meena and Singh, 2013*).Among the various advantages offered by the introduction of innovations in agriculture that figure coming from agriculture precision, the use of ICT platforms and processes to promote communication, information exchange and networking among a large number of individuals, organizations and businesses, from monitoring of land use models. Environmental databases can be used to monitor the status of various indicators and impacts for sustainable environmental management and environmental protection. The connection of these roles unleashes the potential that ICT offers to address environmental issues with a high degree of accuracy and timeliness. Public investment in ICT applications will be particularly important in coping with the unpredictability of climate change. (*Hall and Dorai, 2010*)The change of course is necessary to achieve a sustainable type of development, therefore, requires the transformation of the patterns of production and consumption, supported by a radical technological transformation. The technology will have to go against real changes, so as to become more efficient. The main challenges to start the transition to a green economy include the improvement of use of these technologies, their adaptation to local and sector-specific requirements, extending applications to reduce costs and providing incentives and mechanisms to facilitate their spreading. These challenges require a long-term vision, political will, additional investment and coordination of actions at the global and local level. (*Vos and Alacorn, 2016*)These issues are closely related to the concept of circular economy, based primarily on the conservation value of materials and energy used in products for durability and minimizing waste and excessive use of resources. It is an economy where the waste of a production and consumption process circulate as a new entry in the same or a different process.(Fig 1and 2).

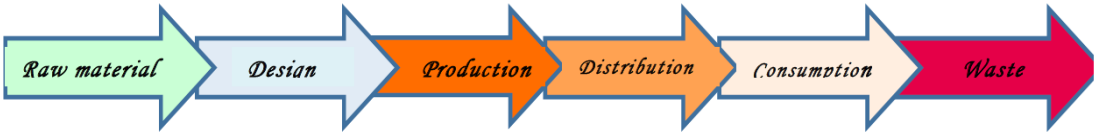

Fig 1-Theoretical linear economy scheme
Source:Our Elaboration

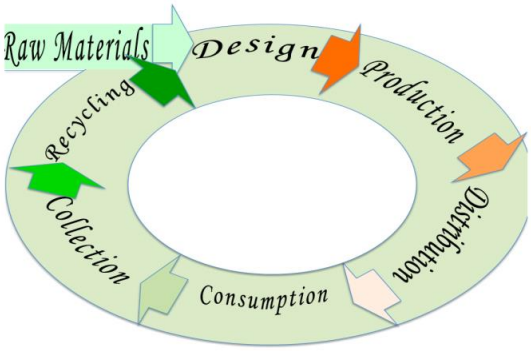

Fig 2- Theoretical circular economy scheme
Source:Our Elaboration

The circular economy can foster competitiveness, innovation, a high level of protection for man and the environment, and bring important economic benefits, thus contributing to the growth and creation of jobs. It can also provide more durable and innovative products that provide consumers with cost savings and increased quality of life. The development of innovative solutions and new markets also need to be supported as key elements of circular economy. Research and innovation should be encouraged in order to effectively take these opportunities forward. (*E.U., 2015*).In this regard, in July 2014, the European Commission has adopted a circular: "Economy Package" including a Communication entitled "Towards a circular economy: a zero waste program for Europe", accompanied by communications

related to sustainable construction, green jobs, and a legislative proposal for the revision of waste legislation.

Objectives,Materials and Methods and Survey Proposal

Objectives

This paper aims to contribute to outline the possible virtuous combination of a highly innovative and sustainable future of the livestock and the exploitation of the Inner Areas of a region highly representative as is the context of Calabria in the context of National and European reference.

The work has as its reference point the Calabria Region, which has a significant variability for animal husbandry and agriculture, thanks to the typical geographical and productive characteristics of the pastures, and still today allows farmers to maintain traditional techniques of production and processing of foodstuffs, especially for those of animal origin. Faced with this potential another objective of the research is to try to turn the weaknesses of the inland areas into strengths, through triggering the existing strong innovative mechanisms, namely through the implementation of the strategy called "*Tradi-Ovation*". This is to create a "*New Renaissance*" of these internal areas and to stimulate sustainable land management and the strengthening of circular economy, in line with the sustainable development strategy of "Sustainable Development Goals 2030", to promote and raise the quality of life.

Materials

The first part of this paper is devoted to a bibliographical study, linked to the role of ICT in the livestock sector and the enhancement of rural areas, in line with the Sustainable Development Goal's 2015-2030. Subsequently a possible in the Region of the sector's recovery program has been outlined with the aim of achieving the implementation of plans and projects enhancement of Inner Areas.

Methods

The method is highly empirical, since the design of the relaunch of the Calabrian livestock program was based on in-depth study of the role of innovation in territorial development. It was developed a spatial analysis of the Inner Areas of the Calabria region and a study of the livestock sector of the territory through the collection of data from recent research projects and studies. Also it was carried out research designed to detect the current territorial situation from the point of view of innovation in the field of agro-livestock and based on these data it was possible to identify an innovative plan that suits real and current necessitated the territory through an approach based on the concept of local growth of type "Bottom-up".

Survey and Proposal

The theme of the development of the inner areas of the Calabrian territory is particularly relevant. The Internal Areas of Calabria, which constitute a large part of the territory, are central to the provision of ecosystem goods and services for the food chain and for the production of energy from renewable sources. However, a substantial proportion of these areas has suffered, over the decades, a gradual process of marginalization. The internal areas of Calabria are characterized by a great and unique variety of natural habitats. Agriculture is the main activity associating also a clear environmental advantage of climate, spread of agriculture and extensive animal husbandry.

Results and Discussion

Everything what has been mentioned above, requires a real effort expected among within the other European Digital Agenda (*Barroso, 2009*) which provides for 2020 to reach 80% of the

population with broadband. Through this innovative infrastructure, that should cover in particular the rural areas it is possible to imagine that an innovative livestock is able to support the great visionary project of a sustainable combination of Smart Cities, Smart Lands and Smart Communities. This offers great chances to take part in the great project of the Sustainable Development Goals 2015-2030 to reach a sustainability measurement approach no longer with the GDP-Gross Domestic Product but through GNH-Gross National Happiness. It is essentially to achieve a goal in which the territory with the approach M2M (machine to machine) is able to communicate with the users in various ways in real time.This approach allows the creation of a new urban-rural relationship, in order to facilitate collective business initiatives, encounter between supply and demand, the development of creative ideas, the protection and defense of the environment and landscape, the stimulus to the emergence of new entrepreneurship in the integration between agricultural activities and maintenance of the territory, the development of a new welfare in urban margins, social and educational farms, low cost tourism, urban forestation to improve the local environment and contribute to action against global climate change (Kyoto Protocol). In this context, this paper tends to make the internal areas of the territories that express the full production potential and supply of related services mainly to tourist use niche. This road will increase the chances of reaching an exaltation of multifunctionality "breeder" of the companies that operate there.A strategic plan for the Internal Areas of Calabria Region must necessarily have an integrated vision that seeks to strengthen the potential of this diversity and variability typical of the area, which the tradition of good practices grafts all possible innovations relating to both the production process and storage, marketing and promotion, as well as services for productive activities, to the world of work and society. It is important, next to a sustainable land management, the widespread introduction of technological innovations at the service of the productive activity and of all the Information and Communication Technology systems, serving the same basic production activities, as well as the activities related to livestock sector and services aimed at the promotion, enhancement and enjoyment of the landscape. For the livestock sector can be highlighted the PLF (*Precision Livestock Farming)*, the use of drones and smart and self-milking systems.

Figure 3 Podolica breeding - Sila

Figure 1 Geographic Information System

The first guarantees a better control and monitoring of animals through the use of sensors placed on the animal, which send data of a different kind (environmental and animal) and the breeder who receives them can easily control every single item. The purpose of these technical tools is not to replace, but to act as a support to the figure of the breeder (*Fontana and Guarino, 2015*).

The drones are configured as put into effect tool to provide satellite images, in this case for rearing, improving the company's control, and the continuous monitoring of the animals.

Another innovative technology that can be applied to farm is that of the open source GIS tools and GIS-MCDA (Geographic Information System - based on - Multi-Criteria Decision Analysis) for a territorial analysis(*ERSA, 2012*). It is aimed at collecting geographic

information systems, research, representation and analysis of spatial data. Such a system can ensure the optimal use of *pasture land by the livestock farms, through forecasting models* able to simulate the behavior of components of pastoral systems in order to rationalize their use. This may be an interesting contribution to the development of the territories in particular for those marginal

Conclusions

This study wanted to provide opportunities for enhancement of the Inner Areas through the re-launch of an innovative and sustainable animal husbandry. This was done taking into account the potential benefits offered by the region, from local breeds and by the professionalism of the local operatorsThe analysis of the existing livestock production showed a variation of the same and an extraordinary force that significantly transmits the sensations of colors, smells, tastes, sounds and even passions and love for the players' attachment to their land. The international reference framework (Sustainable Development Goals 2015-2030) as well as European, Italian and regional ones enabled us to identify on the existing, in a concrete way the confirmation of the hypothesis of the work, which can activate the re-launch of the Internal Areas of Calabria through sustainable and innovative livestock projects. Moreover, the presence of pastureland and transhumance provided in innovative animal husbandry, have had and still have special importance in the context of landscape and biodiversity conservation. They have contributed and contribute to shaping, in time, unique landscaped areas, management models and invaluable know-how and can contribute to the maintenance of plant species and animal breeds that would otherwise be destined for disappearance. This allows to restrict the genetic erosion and cooperate in the development and conservation of biodiversity. All these aspects are going to be important opportunities, especially for Inner Areas, turning weaknesses into strengths of social and economic development of the same. This can happen, considering the current situation, strongly since the beginning of the Industrial Revolution IV, related to the consolidation of circular economy. This is to create a path of modernization, keeping the traditions "*Tradi-Ovation*", that raises the level of professionalism, human capital and quality of life with highly sustainable and characters and with high representativeness of the role of man garrison on the territory The experience of the project has the character of *repeatability, traceability* and *transferability* and represents a way of further *transformation of the weaknesses* into *strengths* of the rural areas of each country including Bosnja –Herzegovina and an innovative *interlocking possible sustainable management and promotion of the territory.*

Abstract

The study was conducted to determine some egg traits of white and bronze turkeys (*Meleagris gallopavo*) reared in a free-range system. A total of 144 female turkeys (72 white and 72 bronze) were used for this study. The turkeys between 32 and 55 weeks of age were used. For measuring egg production and mortality of turkeys, egg weight, shape index, shell weight and shell thickness. In both genotypes, egg production was decreased by age. Moreover, the white turkeys were more vulnerable to free-range conditions in terms of legs problems and consequent liability. The white turkeys laid heavier eggs than the bronze ones (88.7 g vs 80.27, $P<0.05$). All determined egg parameters were different in the white turkeys compared to those in the bronze turkeys. Furthermore, as animals were getting older, egg weight of both white and bronze turkeys were increased. However, their shell weight and thickness were decreased by age. To conclude, the bronze turkeys showed better performance and egg quality traits compared to the white turkeys.

Keywords: *Egg, free-range, genotype, Turkey.*

Introduction

Egg production of turkeys has been studied in lower extend since only sixty-ninety eggs are obtained from turkey hens in one ovulation season. The weights of turkey eggs have been reported to be affected by age and season. In this case, the quality properties for turkey eggs have become important (Nestor et al., 1995).

Housing conditions can affect production traits as affected animal welfare (Tuyttens et al., 2008; Taskin et al., 2014). The regulations relating to the welfare of farm animals are usually applied on a voluntary basis (Petek, 2012). Poultry are kept usually on cages and small floored areas. All production data have been produced from intensive housing conditions. In particular, recent tendencies on poultry production have been semi-intensive, extensive, free-range and ecological farming. The products obtained from alternative systems are more natural, healthy and produced in accordance with accepted that animal welfare, but expensive (Sarıca and Yamak, 2010).

Unlike white turkeys, bronze turkeys are usually black in color, feathers covering the whole body are bright like bronze. This breed is no longer a pure origin in any country, including America, our country is also still producing hybrids with this breed (Camci and Sarica, 1991; Cevher and Turkyilmaz, 1999; Turkoglu at al., 2005).

Turkey is mostly used in the production of semi-intensive and extensive farm but found insufficient in terms of development and reproductive characteristics are needed in the development of these characteristics bronze turkeys. Maurice et al. (1990) did not detect a decrease in body weight in different farming conditions.

When animals are kept in closed areas, they are affected negatively. Naturally illumination and ventilated system in free-range system improve animal welfare and health. Free-range systems outside the shelter, there is a wide area and can take advantage of the sunlight can exhibit natural behavior of animals. Free range system allow animal dust bathing outside. This

opportunity may affect production and live weight (Turkoglu and Sarıca, 2009; Thiele at al., 2008).

With increasing the egg weight, egg shell thickness, the percentage of the total and thick albumen, the ratio of the total, thick and thin albumen to the yolk was elevated, whereas the proportions of the egg shell vs. the whole egg, the percentage of the yolk and the yolk index are reduced in turkeys (Bachev et al., 1970).

Isidahomen et al. (2014) studied egg traits of Local, Exotic and Crossbred turkeys. They found egg weights of 65.85±0.87, 76.10±1.71 and 70.98±0.92, respectively. Egg length, egg width, shell weight, shell thickness were determined as 5.85±0.09, 6.27±0.16 and 6.09±0.09 cm; 4.04±0.05, 4.32±0.07 and 4.14±0.06 cm; 6.20±0.09, 7.35±0.10 and 6.55±0.15 g; 0.34±0.00, 0.36±0.00 and 0.36±0.00 respective to genotype and parameters.

As give above, the studies on turkey have been quite old. Also, there has been no studies regarding the egg traits of turkey hens in free range condition. Therefore, in this study, two strains of turkeys were compared with respect to egg production traits and live weight changes in free range conditions.

Material and Methods

This study was conducted in Free Range Poultry Unit of Agriculture Faculty of Ahi Evran University, Kirsehir (Turkey). One hundred forty four females were used 72 of them was for white, 72 of them was for bronze turkeys. Bird density was 2 birds/m^2 indoors and 0.66 birds/m^2 outdoors. Feed and water were provided *ad libitum* inside the houses only. The pens (indoors) were 2.0 × 6.00 m in size and bedded with fresh wood shavings. They were daily observed for mortality and any abnormalities. Both genotype of the animals, in the first eight weeks, the diet having 28% crude protein and 2800 kcal ME / kg were fed on. Ambient temperature was 32±1°C throughout the first week and progressively <21°C by third week and the relative humidity was well kept in just about 60-70%. 23, 20 and 16 h of light were provided to 7, 12 and 17 weeks of age, correspondingly in the housing. In the upcoming period, the diet having 21% crude protein and 3100 kcal ME / kg were offered. After 17 weeks, a diet including 16% crude protein and 2800 kcal ME / kg were given. All hens were provided feed and water *ad libitum*. All diets were formulated to include sufficient nutrient levels as suggested by the NRC (1994). During experimental period, were divided to tree replications each included 24 females, totally 72 animals for each genotype.

Animals 2x6x2 m (height x length x width) in a closed area and also they can come and go freely from sunrise to sunset again 2x18x2 m (height x length x width) were reared in an open field. In open areas, land is used in its natural state. In this study, round type plastic feeders and drinkers were used. In order to determine egg production, wooden nesting boxes were used. Each box was replaced for three hens.

The birds were fed and reared under uniform conditions. At the age of between 32 and 55 weeks, 30 eggs produced by each line were taken for examination of the following morphological traits: average egg weight (AEW) and egg shell weight (SW) with a precision of 0.01 g. Egg length and egg width of the egg were measured with electronic digital caliper sensitive to 0.01 mm. The shape index was determined according to the formula Shape Index (SI) = [egg width / egg length] × 100 (Anderson et al., 2004). The shell thickness (ST) was determined according to Monira et al. (2003).

All data collected were subjected to Analysis of Variance in a general linear model (GLM) of the Statistical Analysis System Institute (SAS, 1999). Significant differences were computed using Duncan multiple range test (Gomez and Gomez, 1984) to determine the significance of specific classes. Also, linear regression analysis were conducted between weeks and each of egg traits egg weight, shape index, shell thickness and shell weight.

Results and Discussion

According to present results, genotype significantly affected egg weight and some egg traits. Similarly, egg weight variations in different genotypes were reported (Chatterjee et al., 2007). Egg shape index (SI) were affected by genotype significantly ($P<0.05$). The white turkey showed higher values in SI than that of bronze turkey. Shell weight was significantly ($P<0.05$) affected by genotype. The egg shell weights were significantly higher in white turkey than that of bronze turkey. Shell thickness varied significantly ($P<0.05$) between genotypes. The shells of white turkey eggs were thicker than that of bronze hens.

Body weight and egg weight of poultry was positively associated (Shanawany, 1987). The average weight of eggs determined as 80.27 g and 88.7 g in bronze and white hens respectively. This value is similar to values reported by different researchers of turkey eggs (Christensen and Nestor, 1994; Christensen et al., 1996; Anandh et al., 2012).

According to a study of Anandh et al. (2012), there were three turkey mean shape index values 76.10±0.21, 75.00±0.31 and 75±0.13, respectively, and turkey egg weight groups were significantly different did not in terms of egg shape index. The present results regarding shape index are consistent with this value.

For both genotypes, the egg production (HHEP) and the live weights of turkey hens decreased by aging as seen in Figure 1.

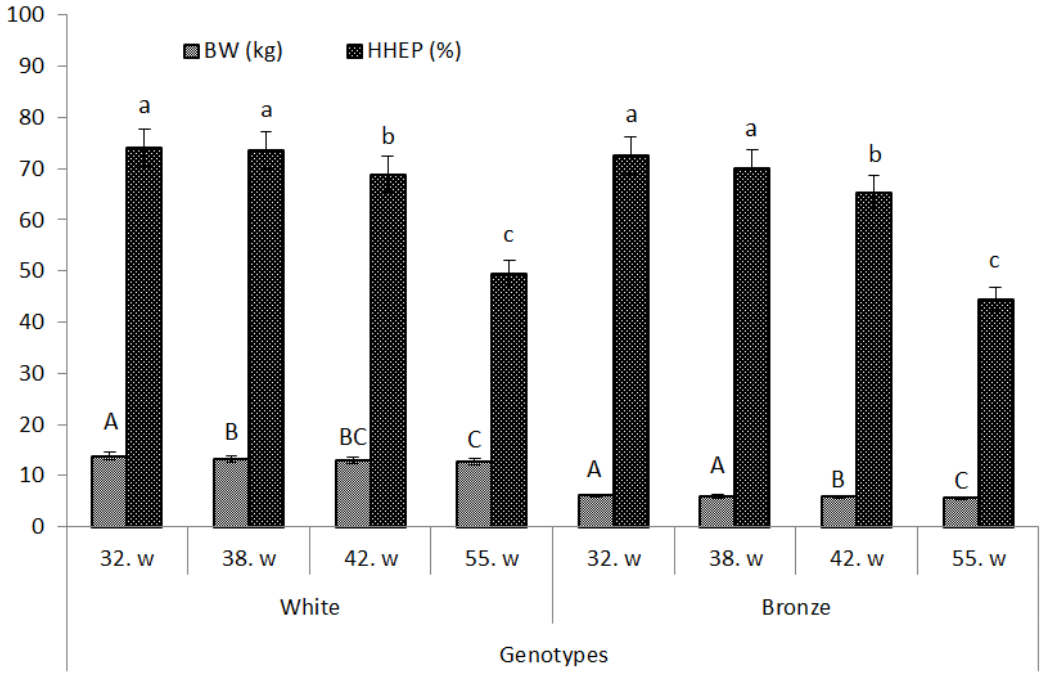

Figure 1. Bodyweight and egg production of female turkey egg production period. BW (Bodyweight, kg); HHEP (Hen housed egg production, %), * $P<0.05$; the average difference between groups with different letters are statistically significant

In both genotypes, the average egg weight was increased by age. However, the other egg traits decreased by age as given in Figure 2. Between these parameters and the ages of turkey hens, the higher regression coefficients were obtained.

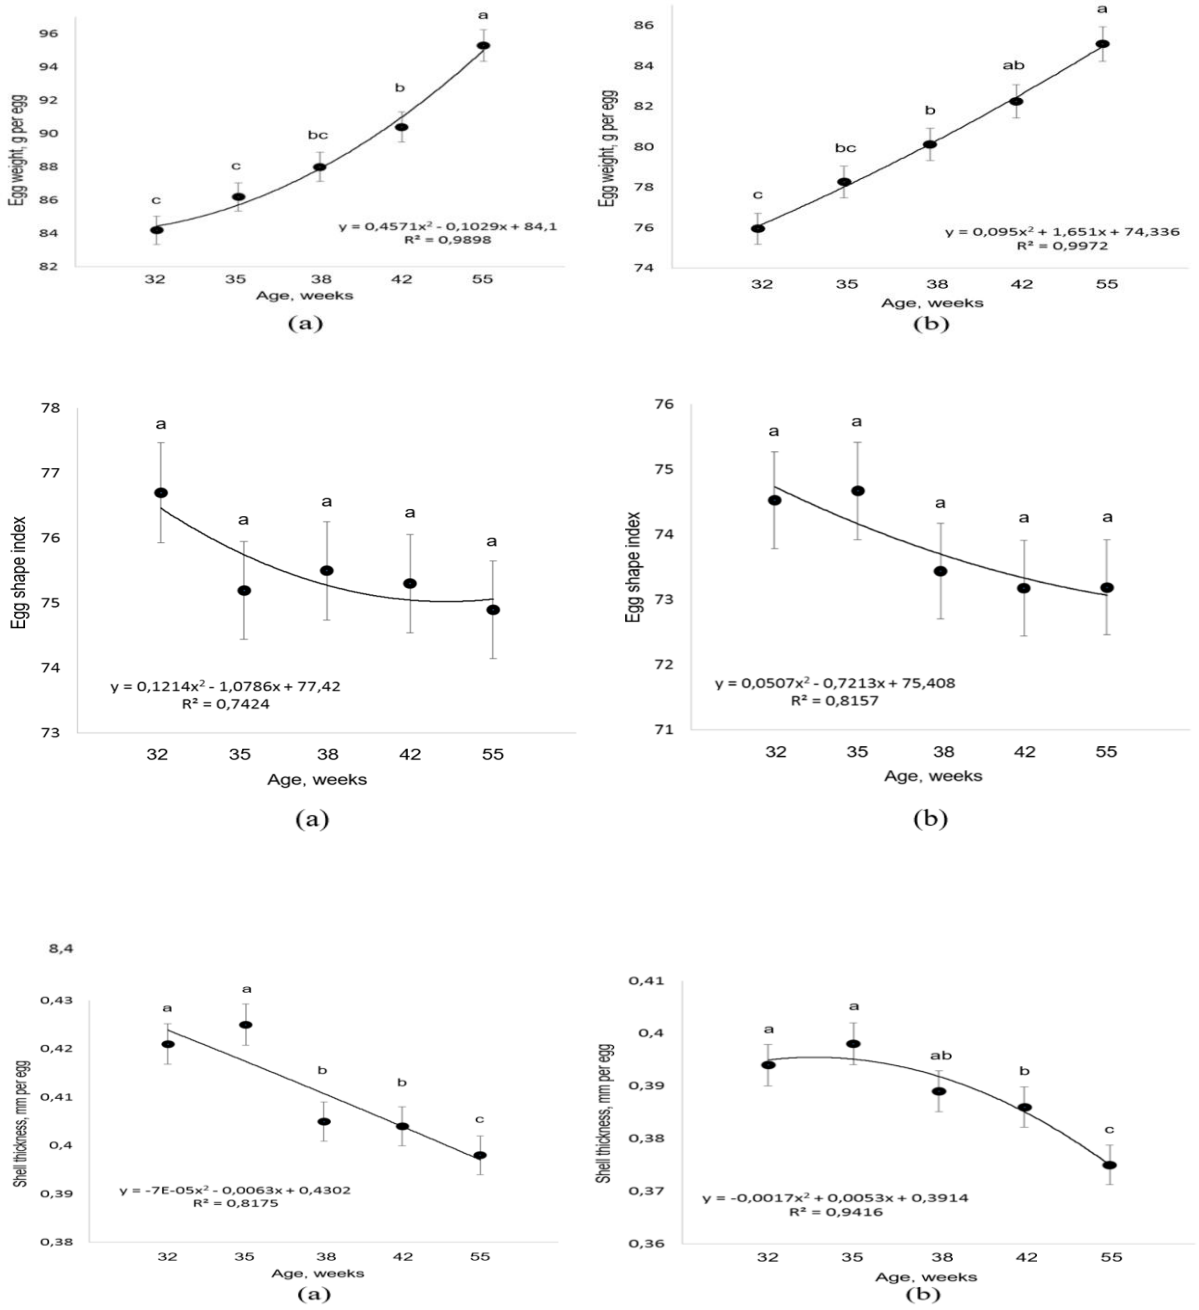

Figure 2. Distribution of egg traits in white (a) and bronze (b) turkeys (n=30). The average difference between groups with different letters are statistically significant.

Conclusion

When bronze and white turkey hens were getting older they produced heavier eggs with losing their qualities in free range housing system. To conclude, the bronze turkeys showed better performance and egg quality traits compared to the white turkeys in free range system.

IDENTIFICATION AND PHENOTYPIC CHARACTERIZATION OF FIVE LOCAL CATTLE OF BUSHA TYPE FARMED IN ALBANIA AND KOSOVO

Naim REXHAJ[1]*, Lumturi PAPA[1], Kristaq KUME[2]

[1]Agriculture University of Tirana, Albania
[2]National Coordinator of FarmAnimal Genetic Resources, Albania
Corresponding author: lumturipapa@yahoo.com

Abstract

Busha autochthonous cattle are spread out mainly in the borders between Albania and Kosovo and Kosovo and Macedonia. It is classified in the group of short horn breeds. Most of Busha population is found in remote mountainous areas, and it is well adapted to extensive farming system. Five local populations of Busha cattle type are identified until now in Kosovo and Albania. Their number per farm, rearing system, morphology andmorphometrical measurements was registered according to Food and Agriculture Organization guidelines (2012). Albanian populations are characterized by small body size, big head, broad forehead, medium size ears with a lot of hairs inside inward back, and short horns. The data from previous study shows that average milk yield is 300-400 kg per cow and in some cases up to 60-700 kg. Lactation length is 4-5 months. These caws in Kosovo are bigger in body size, comparable in frontal width, shaped and longer horns and ears.The average milk production is 1500-1800 kg per lactation. Lactation length is 240-280 days. Discriminate analysis was used to elaborate morphometric measures. Based on data collected until now three groups are formed with distinguished distances: the first group, Back Rjoll herd of Albania; second group Dragosh herd located in Gjakove, Kosovo and third group Zherger herd of Gjilani, Kososvo. These are preliminary results because the number of measured animals was limited. Increase in the number of monitored animals for population will improve the prediction accuracy of genetic distances between them, as bases for breeding program for their in situ conservation.

Key words: *Busha cattle, morphometric measurement, local differentiation.*

Introduction

The Busha Cattle exists in the Balkans since Neolithic times. It is adapted to harsh environmental conditions and spread out with numerous strains, but in small fragmented relict populations throughout the Balkans. Actually these trans-boundary breed are in high danger of extinction.

Two types of local cattle are found in Albania and Kosovo:Illyrian Dwarf Cattle and Busha Cattle, both of Brachucerous type (Kume et al., 2013; Bytuqi et al., 2013). In lack of a wild ancestor, the local cattle breeds represent a genetic resource (Medugarac et al., 2009). Therefore study of these breeds is with interest to animal genetic diversity and further development. Based on the information gathered up to now the local breeds of cattle in Albania and Kosovo are still present in remote areas. They have not been crossed with exotic breeds because of geographic isolation and harsh conditions. The rural development of mountain region will be based mainly on traditional system. The local breeds of animals are the most suitablefor this system and a strong supporting factor for the production of local food and the development of agro tourism in these areas. Small herds of local cattle on family farms will help to protect the natural environment and landscapes that are very attractive for tourism development. Small-scale production units and farmers interested in keeping the

locally adapted cattle to produce local foods is important in both conservation of the breed and rural development to increase the economic diversification and finally to enhance the quality of life for local people (LPP et al., 2010)

In the FAO-EFABIS database, actual data about Busha Cattle are rare. Busha cattle, shows a very high polymorphism. Genetic distance investigations showed, that unselected Busha breeds exhibit a very high degree of diversity within an identified cluster of Brachycerous cattle. Conservation of this genetic diversity is challenging, because these animalsare in small rapidly declining subpopulations. Due to lack of information and data, it is difficult to run sustainable conservation programmers.

Consequently, to compile a sustainable breeding strategy, as one of the most important document for compiling and implementation a national or cross border (Albania and Kosovo) conservation program, collection of above information is needed: (I) data about the current status of Busha Cattle in both two countries , (ii) information regarding specific products of Busha cattle and their marketing (iii) services like working power and grazing for nature protection purposes.

Therefore, the study was undertaken to identify and characterize the phenotype of localcattle population of bush type in Albania and Kosovo.

Materials and methods.

Description of the study area.

The study areas were: Back Rjoll village in Velipoja commune of Scuteri region, Albania; Gjilan, ZhergerDragash, Gjakoveregions of Kosovo. The sampled areas in Kosovo were well defined in eastand west of the country.

Data collection

The study was conducted from May to December 2015. The number of cattle's sampled for phenotypic characterization was 53 of which 45 were females and 8 were males. Regions-wise 14, 5, 24, 3, 7 cattle's were sampled from BackRrjoll, Dragash, Gjakove, Gjilan and Zherger.

Linear body measurement including body length, heart girth, pelvic width, ear length, horn length, frontal width, were taken using measuring tape while wither height was measured using a 1.5 m ruler. The measures were done in adult animals only. The linear body measurement vere done according to FAO guidelines 2012

Data analyses

The means of morphometric variables were done for animals not divided by sex.Quantitative traits for body measurements were used to calculate correlation coefficient of Pirsonsed (r). Discriminate analyses model was used to evaluate the level of local differentiation of cattle populations. .

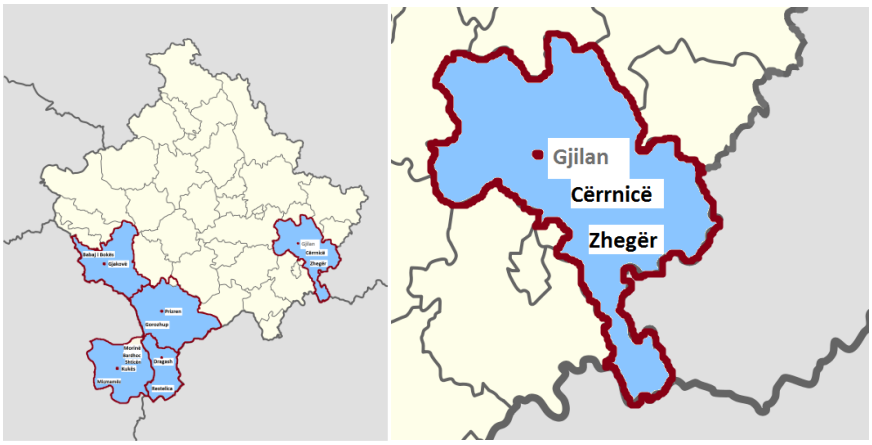

Figure 1. Map of the study area.

Results and discussion

Characterization of quantitative traits.

The average values and standard deviations of body measurements for both sexes in different regions of Albania and Kosovo are presented in Table 1.

Table 1 Average values of quantitative traits.

Population	Back Rrjoll	Dragash	Gjakove	Gjilan	Zherger	Total
Number of animals	14	5	24	3	7	53
Traits	Avergae ±SD					
Frontal width	19.5 ±1.605	19.4±0.89	19.79±0.77	19.67±0.57	19.43±1.39	19.62±1.11
Horn length	16.75 ±5.80	17.4±1.51	19.67 ±1.27	17.333±2.51	18.43±2.37	18.39±3.44
Budy length	113.5±8.83	117.2±3.11	117.83±2.078	115.67±1.15	126.862.96	117.69±6.30
Ear lenth	15.86±1.09	16.6±1.14	17.5±1.063	16.33±1.15	16.43±0.78	16.77±1.23

The data shows that Albanian population represented in this study by Back Rjoll herd is characterized by small body size, big head, broad forehead, medium size ears inside inward back, and short horns. These caws in Kosovo are bigger in body size, comparable in frontal width, shaped and longer hornsand ears. These differences in body measures are reflected in milk production. Previous studies conducted in Albania and Kosovo (Kume et al 2013; Bytyqi et al. 2013) show that respected average milk yield in Albanian populations is 300-400 kg per cow and in some cases up to 60-700 kg. Lactation length is 4-5 months. The average milk production of Kosovo populations is 1500-1800 kg per lactation. Lactation length is 240-280 days.

Correlations coefficients of Pirson that serve to evaluate stochastic relationship between analyzed quantitative traitsare presented in table Nr. 2.

Table 2. Correlations coefficients of Pirson

Gjilan village is excluded because of small number of animals monitored. So four classifying functions corresponding to each region are presented in above table.Using two first discriminatefunctions the distribution of all cows from four regions isdescribed in Figure Nr. 2.

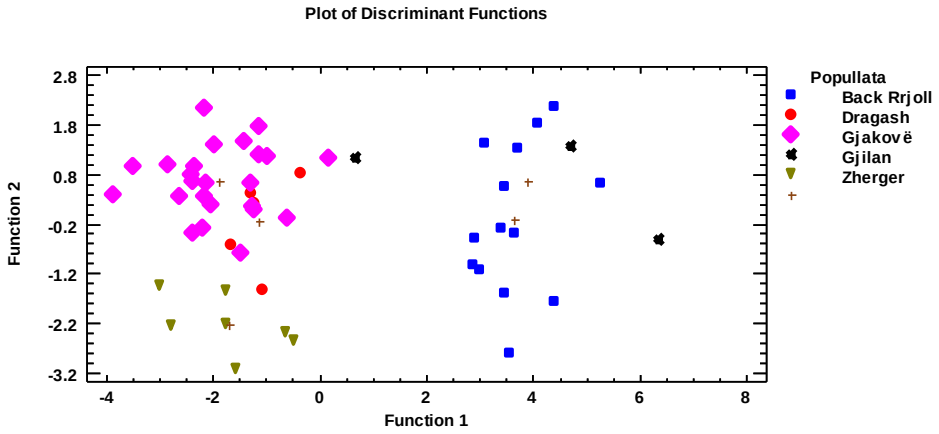

Fig.Nr. 2 The distribution of subpopulations of Busha type cattle.

Three distinguished groups are formed with cows belonging to different populations: In the first group is Back Rrjoll population; the second group is the population of Drag ash, Gjakova; the third group is the population of Zherger. The population of Gjilan that has only three animals is not considered.

Referring to the geographical position to which these populations belong, we note that there are similarities between the distances of cattle populations estimatedusing morphometrikindicators and geographical distance between regions. Consequently the hypothesis it may rise is that in the case of Bushacows, the process of evolution of the morphometrictraits and selection have been associated with the presence of isolation in distance, which as a rule is main conditions that affect the establishing of isolated genetic

niches. Obviously such a hypothesis needs further verification. More animals must be included in the study to have more reliable results.

Conclusions

The obtained results are preliminary because the populations number and their size are limited. Involving more animals per population could increase the prediction accuracy of genetig distribution between them.Enriching of data with DNA polymorphism analysis to specify the genetic variability between populations would be a strong base to design the in situ conservation program of local cattle of Busha type both in Albania and Kosovo.

Abstract

With the aim to investigate the presence of parasites in the gastrointestinal tract of Ohrid belvica (*Salmo ohridanus*, Steindachner, 1892), investigations were conducted on individuals captured in vegetative and reproductive development period of Ohrid belvica, on three localities of Ohrid Lake (located between southwestern Macedonia and eastern Albania): Kalista, Kaneo and Elesec, on depth from 45 to 70 m. Tests were performed on a total of 60 samples with average body mass from 90 to 100 g and average total body length from 217 to 225 mm. It has been established the presence of the following parasites in the gut content of fish: *Cyathocephalus truncatus* (Class Cestoda), *Pseudocapillaria salvelini* and *Salmonema ephemeridarum* (Class Nematoda). *Cyathocephalus truncatus* was present on the locality Kalista, in both stages of the development of Ohrid belvica, and on the locality Elesec only in the reproductive stage. *Pseudocapillaria salvelini* was registered in the samples from locality Kalista and Kaneo in both stages of the development of Ohrid belvica. *Salmonema ephemeridarum* was found in the vegetative stage of Ohrid belvica only in locality Elesec. The presence of parasites was higher during the reproductive phase of development of the Ohrid belvica, i.e during the winter, unlike during the vegetative phase, actually autumn. The highest proportion (100% of the tested fish) of tapeworm *Cyathocephalus truncatus* was found during the reproductive phase of the individuals from the locality Kalista.

Keywords: Lake Ohrid, Salmo ohridanus, intestinal parasites

Introductıon

Ohrid Lake (located between southwestern Macedonia and eastern Albania) is a rare natural phenomenon of tectonic origin, one of the oldest oligotrophic lakes in the world and represents a complex ecological system, where its wildlife takes a special place. According to its geomorphological and biological values it represents a single entity in which there is a preserved part of the old tertiary world, with numerous archaic forms, such as relics and endemics.

Ohrid belvica (*Salmo ohridanus*, Steindachner, 1892) as one of the representatives of "living fossils" represents tertiary relict and endemic trout species belonging to macrostom salmonids and lives only in Ohrid Lake. It is a small endemic trout which represents expressively a lake and depth type of fish. It feeds mainly on zooplankton, and benthic fauna elements.

Primarily investigations of the parasitofauna of Ohrid belvica were carried out by Šinžar (quoted by Blaželković Dimovska, 2013), who found *Cyatocephalus truncatus* among 2% of examined belvica (*Salmo ohridanus* Steindachner, 1892). Hristivski et al. (1999) were found that the most likely, Ohrid belvica was infected with Cyathocephalus truncatus. Blaželković Dimovska et al. (2013) established the following parasites in the intestines of Ohrid belvica: *Nicolla testiobliqua* (Class Trematoda), *Eubothrium salvelini* (Class Cestoda),

Metechinorhynchus truttae, *Metechinorhycchus salmonis*, *Acanthocephalus anguillae* and *Pomphorhycchus bosniacus* (Class Acanthocephala), of which the most common was *Metechinorhynchus truttae* (12.66%). Ohrid belvica is an insufficiently investigated fish. That was the reason for this investigation.

Material and methods

Investigations were conducted on fish species of Ohrid belvica (*Salmo ohridanus*, Steindachner, 1892). The samples were captured in the reproductive phase of development of Ohrid belvica, i.e during the winter, the season of natural reproduction of belvica, when most individuals in the population of belvica participate in the natural breeding – spawning and the period of vegetative phase or autumn, on three localities of Ohrid Lake: Kalista, Kaneo and Elesec, on depth from 45 to 70 m. Tests were performed on 10 samples of each locality and each phase of development or a total of 60 fish.

For the purposes of examination (analyzing) the intestinal parasites of Ohrid belvica it has been performed carefully extracting the digestive tract of the fish after cutting the esophagus and rectum. Then, dissection of the digestive tract was performed and with a spatula gut content was removed. Gut content was fixed in 4% formaldehyde and subsequently determination of the components in the gut content was performed, with stereo-zoom microscope SMC 4 and digital color video camera SONY SSC-DC 54AP, using computer software Metric in the laboratory at the Hydrobiological Institute in Ohrid. Parasites were isolated from the gut content and put into a Petri dishes after which followed procedure of their determination.

The determination of the parasites found was according to: Moravec et al. (1991) and Moravec (1994, 2004).

Results and discussion

The participation of parasites in the digestive tract of the fish during the vegetative and reproductive phase of development of the Ohrid belvica on three localities of Ohrid Lake (Kalista, Kaneo and Elesec) is shown in Table 1.

Table 1. The findings of parasites in the digestive tract of Ohrid belvica in vegetative and reproductive stages of development (n=10)

Taxon	Vegetative stage		Reproductive stage	
	No. of infected fish	% of infected fish	No. of infected fish	% of infected fish
KALISTA				
Cestoda				
Cyathocephalus truncatus	3	30	10	100
Nematoda				
Pseudocapillaria salvelini	2	20	3	30
KANEO				
Nematoda				
Pseudocapillaria salvelini	2	20	6	60
ELESEC				
Cestoda				
Cyathocephalus truncatus	0	0	7	70
Nematoda				
Salmonema ephemeridarum	4	40	0	0

The investigation of the guts of Ohrid belvica showed some presence of parasites in the digestive tract. There were found representatives of the groups Cestoda and Nematoda (Tab.

1). From the group Cestoda it was recorded endoparasite *Cyathocephalus truncatus* (Fig. 1) at the locality Kalista, in both phases of the development of Ohrid belvica, and on the locality Elesec only in the reproductive stage. This parasite was not found in the digestive tract of the samples from the locality Kaneo. The presence of endoparasite *Cyathocephalus truncatus* in the intestines of Ohrid belvica was found by other authors (Šinžar, 1956; Hristovski, 1983; Stojanovski, 1997; Hristovski et al., 1999). *Cyathocephalus truncatus* is widespread in Europe, Asia and North America, in the fish of the families Salmonidae, Thymallidae, Esocidae and others (Čanković et al., 1968).

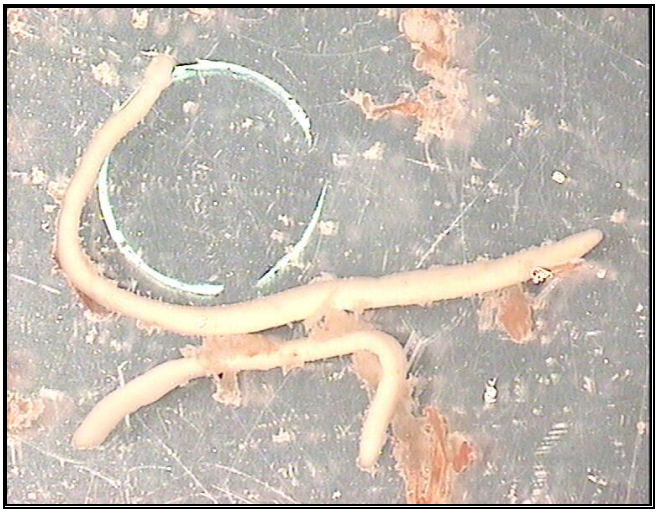

Figure 1. *Cyathocephalus truncatus*

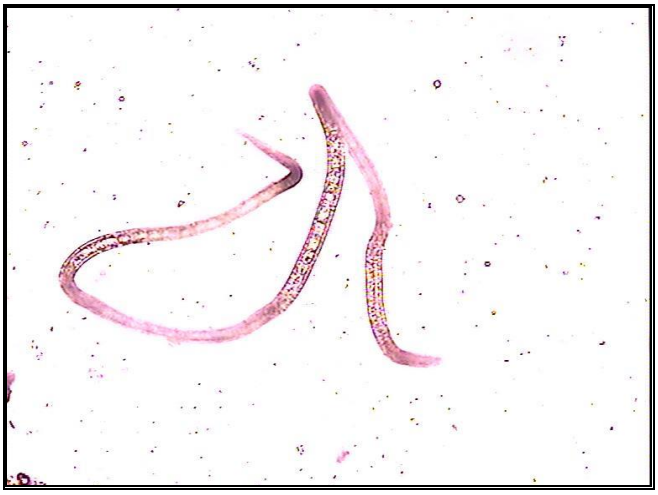

Figure 2. *Pseudocapillaria salvelini*

Figure 3. *Salmonema ephemeridarum*

In the digestive tract of Ohrid belvica was found the presence of two nematode among individuals collected from all three investigated localities. The first was *Pseudocapillaria salvelini* (Polyansky, 1952) from the family Capillariidae (Fig. 2), the only capillarid known from the intestine of European salmonids. It was registered in samples from Kalista and Kaneo localities in both phases of the development of Ohrid belvica (Tab. 1). *Pseudocapillaria salvelini* is a holarctic species widespread in palearctic Eurasia and North America, where it occurs in many species of various salmonids (Salvelinus, Salmo, Brachymystax, Hucho, Stenodus, Oncorhynchus, Thymallus). It was also found in the countries of the former Yugoslavia (Bosnia and Herzegovina, Montenegro) (Moravec, 1994). We could not find evidence that this parasite has been found so far in the digestive tract of Ohrid belvica.

Second isolated nematode was *Salmonema ephemeridarum* (Linstow, 1872) (Fig. 3), with synonymous *Cystidicoloides tenuissima* (Zeder, 1800). It was found in the digestive tract of the samplaes in the vegetative stage from locality Elesec. This parasite in Ohrid belvica for the first time was registered in 1999 (Hristovski et al. 1999). It is a parasite in the digestive tract of holarctic salmonid fish species (Moravec, 1994, 2008; Poulin, 2007).

Varying degree of infection of Ohrid belvca with parasites in the different localities and stages of development was probably due to the different population densities of the Ohrid belvica population and the presence of the intermediate hosts. In larger grouping of fish, the number of parasites present in the digestive tract is greater and vice versa. Lake-dwelling salmonid fish species are known to host several food-transmitted parasites (Kristoffersen, 1993; Knudsen and Klemetsen, 1994; Curtis, 1995; Curtis et al., 1995; Knudsen et al., 1997), some of them having amphipods (*Gammarus lacustris*, *Gammarus pulex*) as their intermediate host (Knudsen, 1995; Amundsen et al., 2003; Atrashkevich et al., 2005; Franceschi et al., 2007).

Conclusion

Based on the research (analysis, investigations) of the intestinal contents of Ohrid belvica (*Salmo ohridanus*, Steindachner, 1892) from three different localities of the Ohrid Lake (Kalista, Kaneo and Elesec) during the vegetative and reproductive stage, it might be concluded that in the gut contents were present the following parasites: *Cyathocephalus truncatus* (Class Cestoda), *Pseudocapillaria salvelini* and *Salmonema ephemeridarum* (Class Nematoda).

Cyathocephalus truncatus was present on the locality Kalista, in both stages of the development of Ohrid belvica, and on the locality Elesec only in the reproductive stage. *Pseudocapillaria salvelini* was registered in the samples from locality Kalista and Kaneo in

both stages of the development of Ohrid belvica. *Salmonema ephemeridarum* was found in the vegetative stage of Ohrid belvica only in locality Elesec.

The presence of parasites was higher during the reproductive phase of development of the Ohrid belvica, i.e during the winter, the season of natural reproduction of belvica, when most individuals in the population of belvica participate in the natural breeding - spawning, unlike the period of vegetative phase or autumn.

RED CLOVER QUALITY AFFECTED BY CULTIVAR, CUT AND STAGE OF GROWTH

Jordan MARKOVIĆ*, Tanja VASIĆ, Mirjana PETROVIĆ, Dragoslav ĐOKIĆ, Zoran LUGIĆ, Dragan TERZIĆ, Bora DINIĆ

Institute for Forage Crops d.o.o. Globoder, Kruševac, Serbia
*Corresponding author: jordan.markovic@ikbks.com

Abstract

Forage quality is affected by many independent factors including maturity, crop species, harvest and storage, environment, soil fertility and variety. Generally, red clover varieties differ in quality according to ploidy level and earliness. This paper provides measurements of the chemical composition of the red clover (a diploid – K 39 and a tetraploid – K 32 cultivar) in different development stages from the first to the third crop production cycle during the second year of growth in the field of Institute for forage crops, city ofKruševac (Serbia). The experiment was designed as three factorial trials: a – cultivar, b – cut and c – stage of development by randomized block system in three replicates. The diploid cultivar of red clover, K 39, had higher content of CP (Crude Protein), NDF (Neutral Detergent Fiber) and ADF (Acid Detergent Fiber) than tetraploid cultivar, K 32, but lower DDM (Digestibility Dry Matter), DMI (Dry Matter Intake) and RFV (Relative Feed Value). The highest content of CP was observed in the third cut (195.5 g kg^{-1} DM), whereas the highest content of NDF and ADF was in the first cut (512.1 g kg^{-1} and 377.5 g kg^{-1} DM, respectively). The results of this investigation indicated that DDM, DMI and RFV declined with advancing maturity, whereas content of NDF and ADF increased. All factors of investigation showed a significant statistical influence on investigated quality parameters. The achieved results show that red clover quality was the best in the third production cycle.

Keywords: *red clover, forage quality, Relative Feed Value*

Introduction

The quality of red clover forage depends primarly on the stage of development and environmental conditions. Taylor and Quesenberry (1996) claimed that the content of crude protein and *in vitro* dry matter digestibility are the two most reliable quality characteristics. Their value decreases with age, as a result of a decreasing portion of leaves in relation to stems and the process of lignification, which are typical for all perennial legumes. The decline in digestibility after budding is associated with increased contents of lignin and structural polysacharides. Nutritive values of forage crops can be changed among cultivars, ecotypes and genotypes within a plant species for animal nutrition. Differences in quality properties of forage crops within a species have been shown by Job (1996) in eight red clover cultivars, Broderick et al (2004) in 113 red clover cultivars, Yolcu et al (2008) in 12 alfalfa cultivars and Yolcu et al (2009) in 25 red clover genotypes. The tetraploid red clover is characterised by a higher content of protein, WSC (Water Soluble Carbohydrates), potassium and phosphorus and by a lower content of fiber than diploid red clover (Bieniaszewski and Fordonski 1996).

The main objective of this work was to assess the chemical composition and the relative feed value of tetraploid and diploid red clover in different development stages from the first to the third crop production cycle during the second year of growth in Central Serbia.

Materials and methods

The experiment was carried out in the experimental field of Institute for forage crops, city of Kruševac (43º34'58"N, 21º19'35"E), Serbia (2012). The study area was situated at altitude of 166 m above sea level in Central Serbia. The mean annual temperature and the total precipitation for the region are 11.3º C and 636 mm, respectively.

The study was designed in a three factorial arrangement (A-cultivar, B-cut and C-stage of growth) of a randomized complete block with three replications. Three stages of growth of red clover *cv* K-32 (tetraploid cultivar) and *cv* K-39 (diploid cultivar) were examined in the first, second and the third cut during the second year of vegetation. The first stage was cut at the full bud stage, another one when plants were at the begining of flowering and the third stage of growt was cut when plants were around 50-60% of flowering. The dates of Crude Protein (CP), Neutral Detergent Fiber (NDF), Acid Detergent Fiber (ADF), Digestibility Dry Matter (DDM), Dry Matter Intake (DMI) and Relative Feed Value (RFV) were determined in the result of analyze or calculate. Crude protein (CP = N × 6.25) was measured by Kjeldahl-N analysis on a Kjeltec 1030N autotitrator (AOAC 984.13, 1990). NDF and ADF were determined as filter residue weights after boiling forage samples for 1 h in beakers either in neutral detergent solution or in acid detergent solution, according Van Soest et al. (1991). DDM, DMI and RFV were calculated according to the following equations adapted from common formulas for forages (Schroeder, 1994):

DDM % = 88.9 – (0.779 × ADF, %)
DMI = 120 / NDF, %
RFV = (DDM, % × DMI, %) / 1.29

Data were processed by the analysis of variance in a randomized block design as three factorial trial. Effects were considered different based on significant ($p < 0.01$) F ratio.

Results and discussion

The variety differences in the contents of CP, NDF and ADF are presented in the Table 1. Our results showed significant variety differences between evaluated forage quality parameters. Following the mean values of CP content diploid cultivar of red clover (182.3 g kg^{-1} DM) featured higher CP content than tetraploid cultivar of red clover (178.1 g kg^{-1}), but this variety contained higher content of NDF and ADF.

Chemical composition of red clover differed in CP, NDF and ADF content ($p < 0.01$) between cuts. The highest content of CP was found in cut III (195.9 g kg^{-1} DM) and the lowest in cut I (160.4 g kg^{-1} DM). Despite the CP content, the level of cell wall components (NDF and ADF) was the highest in cut I (512.1 g kg^{-1} DM and 377.5 g kg^{-1} DM, respectively). The content of NDF found in cut II and III did not differ ($p > 0.05$).

Stage of plant development at the cutting had a significant effect ($p < 0.01$). The highest CP content was detected at the beginning of flowering (188.6 g kg^{-1} DM), and the lowest when plants were around 50-60% of flowering (169.5 g kg^{-1} DM). The analysis of mean values of NDF and ADF shows that the highest content of NDF and ADF was detected at the third development stage (483.1 g kg^{-1} DM and 370.9 g kg^{-1} DM, respectively), whereas the lowest content of cell wall components was at the first stage of plant development (Tab. 1).

The interactions cultivar × cut, cultivar × stage of growth and cut × stage of growth were also significant for crude protein content and content of cell wall components – NDF and ADF.

A_1 – K 32, tetraploid cultivar of red clover; A_2 – K 39, diploid cultivar of red clober; B_1 – cut I; B_2 – cut II; B_3 – cut III; C_1 – first stage, full bud; C_2 – second stage, begining of flowering; C_3 – third stage – 50-60% of flowering; Different letters denote significantly different means ($p< 0.01$)

The differences between cultivars in DDM, DMI and RFV were observed in this investigation. Tetraploid red clover cultivar, K 32, had higher DDM (630.5 g kg^{-1} DM), DMI (2.59% BW) and RFV (127.4) than diploid red clover, K 39 (602.3 g kg^{-1} DM, 2.49% BW and 117.0, respectively).

The cut was an important source of variability for DDM, DMI and RFV in this investigation. The evaluated forage quality parameters were the highest in the second cut, and the lowest in the first cut (Table 2).

Forage quality declines with advancing maturity. Significant differences were determined among forage stages of growth in terms of DDM, DMI and RFV for animal feeding (Table 2). The highest DDM ratio was found at the first stage of plant development (626.9 g kg^{-1} DM), and the lowest at the third stage of plant development (600.0 g kg^{-1} DM). Maturity of harvest also influences forage consumption by animals ($p< 0.01$). This is because NDF is more difficult to digest than the non-fiber components of forage. The RFV of red clover hay harvested at different maturity stages ranged from 125.8 to 116.8 ($p< 0.01$).

A_1 – K 32, tetraploid cultivar of red clover; A_2 – K 39, diploid cultivar of red clober; B_1 – cut I; B_2 – cut II; B_3 – cut III; C_1 – first stage, full bud; C_2 – second stage, begining of flowering; C_3 – third stage – 50-60% of flowering; Different letters denote significantly different means ($p< 0.01$)

The results for DDM, DMI and RFV obtained in this investigation are lower than values reported by Marković et al. (2011) and Stallings et al. (2005). The decrease in DDM, DMI and RFV are possibly associated with increased NDF and ADF contents (Wilson et al, 1991), and increased lignification and decreased leaf:stem ratio (Hides et al., 1983) as the plant matures.

The NDF is used to predict DMI, and is negatively correlated with DMI, which means that when NDF is high the quality and DMI are low (Horrocks and Vallentine, 1999). The RFV is an index that is used to predict the intake and energy value of the forages and it is derived

from the DDM and DMI. Forage with the RFV value > 151 is considered prime (Horrocks and Vallentine, 1999). In the present experiment, the RFV value was lower than 151, which agrees with the other quality characteristics (NDF, ADF, DDM and DMI).

Adequate fiber levels are needed in the rumen to promote a healthy population of cellulolytic species important to maintain normal lipid metabolism and milk fat levels, and to enhance microbial protein output to the lower digestive tract (Van Soest et al., 1991). Need to harvest aerly to increase crude protein concentration may sacrifice forage yield and provide insufficient fiber concentration.

Forage producers have special interst in quality improvements to partially offset the decline in nutritive value associated with advancing maturity of the crop when harvest is delayed. Some farmers harvest second growth early to obtain higher protein and lower fiber concentrations during mid-summer when quality values are often lowest of the three harvest.

Conclusions

On the basis of the knowledge about different nutritive values of diploid and tetraploid red clover varieties we compared the assessed varieties also in this respect. From our results we may deduce that diploid cultivar (K-39) can also produce high quality forage. The choice of the harvesting moment is important insuring the forage quality and quantity. Relative Feed Value might be a relevant indicator supporting the decisions of cutting management. It is observable that the relationship between RFV and CP content is inverse, which complicates the choice of the optimal harvest moment. The most adequate decision of cutting might be in the begining of flowering, when even the RFV is fast decreasing, the crude protein content is substantially increasing.

Abstract

Aim of study was to examine the impact of thawing temperature on motility parameters of bull's sperms after thawing. A total of 120 commercial doses of deep-frozen bull's semen, originated from three Simmental bulls, were examined. Semen was thawed at 38°C for 30 seconds (n=60 doses, 20 from each bull) or at 50°C for 15 seconds (n=60 doses, 20 from each bull). Motility parameters of sperms (Curvilinear Velocity, VCL, μm/s; Straight Line Velocity, VSL, μm/s; Average Path Velocity, VAP, μm/s, Amplitude of Lateral Head Displacement, μm) were determined as an average for 20 thawed doses of each bull on each of two thawing temperatures, by using Computer Assisted Sperm Analysis (CASA) program in NIS Elements software. All sperm motility parameters in all three bulls were significantly higher at higher thawing temperature (VCL 59.99±0.11, 58.96±0.13 and 56.87±0.16 vs. 52.89±0.14, 52.66±0.13 and 51.99±0.17 μm/s, $p<0.001$; VSL 52.58±0.11, 49.32±0.12 and 43.33±0.15 vs. 43.28±0.14, 42.13±0.14 and 40.69±0.16 μm/s, $p<0.001$; VAP 53.96±0.11, 51.00±0.12 and 45.37±0.14 vs. 44.85±0.14, 43.78±0.13 and 42.72±0.16 μm/s, $p<0.001$; ALH 4.07±0.02, 3.90±0.02 and 4.12±0.03 vs. 3.70±0.02, 3.77±0.02 and 3.51±0.02 μm, $p<0.001$, respectively). Our results indicate positive impact of higher thawing temperature on bull sperm motility parameters, as an indicators of their fertilisation ability.

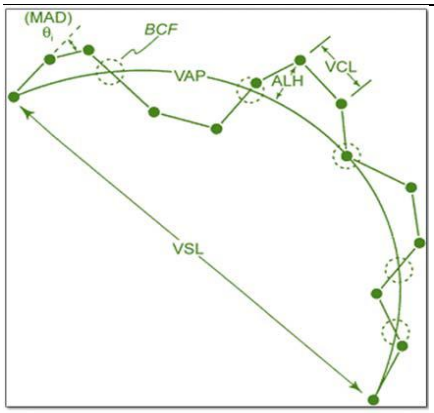
Keywords: *bull's sperm, thawing temperature, motility.*

Introduction

Semen analysis and prediction of its fertility potential is key aim of each andrological investigation (Nikolovski et al., 2014). Older methods of semen analyzing are based on semiquantitative visual assessment (Miljković, 1998), and such results are subjective and depends on the evaluator's experience. In order to eliminate that problem, automated systems for the evaluation of semen were developed, from photocytometers for sperm counting to software programs which can count sperms and analyze parameters of their motility, too. One of the currently most popular system for semen evaluation is CASA (Computer Assisted Sperm Analysis) system (Mortimer, 1990). This system consists of phase-contrast microscope with a camera and computer software for the analysis of video recordings. The use of phase-contrast lens makes possible to identify sperm as bright particles on a dark background field, and to digitalize the image of each individual sperm. Recording is performed during a period determined by the software, which makes high number of shots per time unit, in order to track the movement of sperm and reconstruct its trajectory.

CASA system is configured to monitor the actual trajectory of sperm, which should move progressively forward and rotating around its axis at the same time. Based on the images, the software determines the kinetic parameters of sperm movement, such as speed on curvilinear path (Curvilinear Velocity, VCL), average speed (Average Path Velocity, VAP), speed of linear movement (Straight Line Velocity, VSL) and the amplitude of movement sperm head

relative to its direction (Amplitude of Lateral Head Displacement, ALH), as shown in Figure 1.



Parameter	Description
Straight Line Velocity, VSL (μm/sec)	Total gain of space by the sperm head per unit time
Average Path Velocity, VAP (μm/sec)	Average track distance of sperm head per unit time
Curvilinear Velocity, VCL (μm/sec)	Total distance travelled by the sperm head per unit time
Lateral Amplitude of Head Displacement, ALH (μm)	Width of the sperm head movement

Figure 1. Kinetic parameters of sperm motility in CASA system (modified according to Mortimer, 1990, Mortimer and Maxwell, 2004, Nikolovski et al., 2014).

Sperm motility parameters determined by CASA system are good indicator and predictor of their fertilisation ability (Del Olmo et al., 2013), more precise than sperm count and overall percent of progressive motility. There are many studies that use this system as a precise tool to determine effect of different thawing protocols, extenders or additives to insemination doses and other factors that can influence sperm motility parameters. Assuming that, the aim of this study was to examine the impact of thawing temperature on motility parameters of bull's semen after thawing, assessed by CASA system.

Material and methods

The study included a total of 120 commercial insemination doses of semen, originating from three Simmental bulls (Indurein, Strellas, Polian, 40 doses for each of bulls). Bulls were housed in standard conditions of commercial reprocenter and fed in accordance with the norms for a given breed. In order to avoid the impact of the various terms of ejaculate taking on the parameters of semen quality, all doses from each bull originated from the same ejaculate. Doses of semen were taken during January 2014 from the commercial center for artificial insemination (AD Veterinary Cattle Breeding Center Banja Luka). Their thawing and analysis of quality parameters were carried out in the Laboratory of Genetics and Reproduction, Faculty of Agriculture, University of Banja Luka (Entity of Republic of Srpska, Bosnia and Herzegovina). Half of the selected insemination doses of each bull (n=20) were thawed by using standard procedure (at 38°C for 30 seconds), while the remainder (n=20) was thawed at a temperature of 50°C for 15 seconds.

After thawing, the parameters of sperm motility were determinedfor each dose, by using a computer program for sperm analysis (Computer Assisted Sperm Analysis, CASA, NIS Elements software). The following parameters were determined: velocity of straight line movement (Straight Line Velocity - VSL, μm/s), velocity of curvilinear movement (Curvilinear Velocity - VCL, μm/s), velocity of average movement (Average Path Velocity - VAP, μm/s) and the deviation from the average trajectory of movement (Amplitude of Lateral Head Displacement - ALH, μm).

The influence of different temperature treatments on sperm motility parameters was tested by combined factorial analysis of variance and Pearsons χ^2 test, with software package SPSS 22 (IBM 2013).

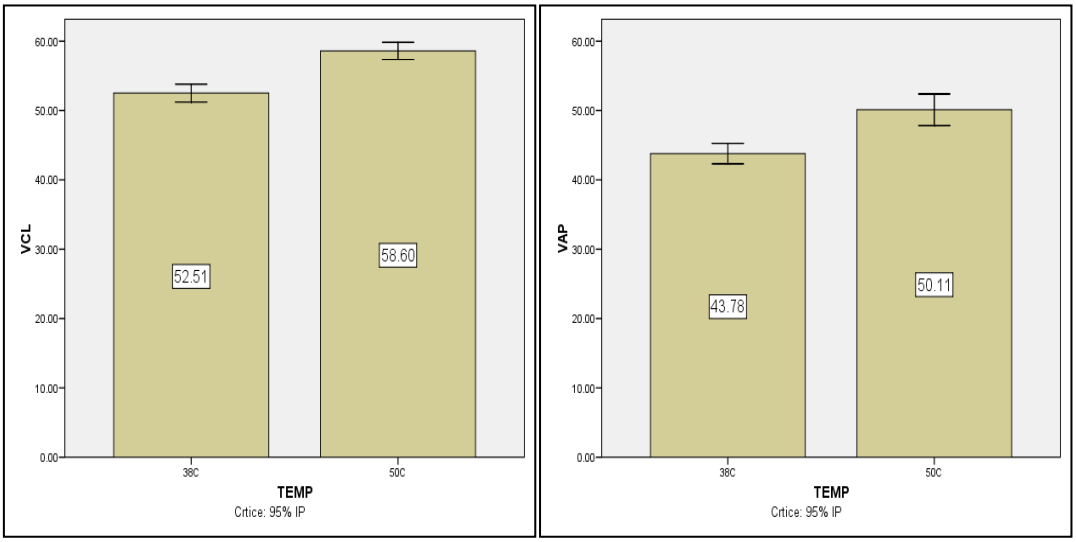
Results and discussion

Sperm motility parameters for insemination doses thawed at different temperatures are shown in Table 1.

Table 1. Sperm motility parameters for insemination doses thawed at different temperatures (M±SE)

Bull	t (°C)	n	Parameter			
			VCL	VAP	VSL	ALH
			µm/s	µm/s	µm/s	µm
Indurein	38	10 408	52,89±0,14	44,85±0,14	43,28±0,14	3,70±0,02
	50	15 971	59,99±0,11	53,96±0,11	52,58±0,11	4,07±0,02
Polian	38	12 684	52,66±0,13	43,78±0,13	42,13±0,14	3,77±0,02
	50	13 972	58,96±0,13	51,00±0,12	49,32±0,12	3,90±0,02
Strellas	38	11 533	51,99±0,17	42,72±0,16	40,69±0,16	3,51±0,02
	50	10 392	56,87±0,16	45,37±0,14	43,33±0,15	4,12±0,03

The values of all parameters determined were higher after thawing at a higher temperature in all three bulls. Average values of all examined parameters of sperm motility were significantly higher after thawing at 50°C compared to thawing at 38°C (VCL 58,60 vs. 52,51 µm/s, F=52,696, p<0,00; VAP 50,11 vs. 43,78 µm/s, F=43,675, p<0,00; VSL 48,41 vs. 42,03 µm/s,F=43,266, p<0,00; ALH 4,02 vs. 3,66 µm, F=17,337, p<0,00), as shown in Figure 2.



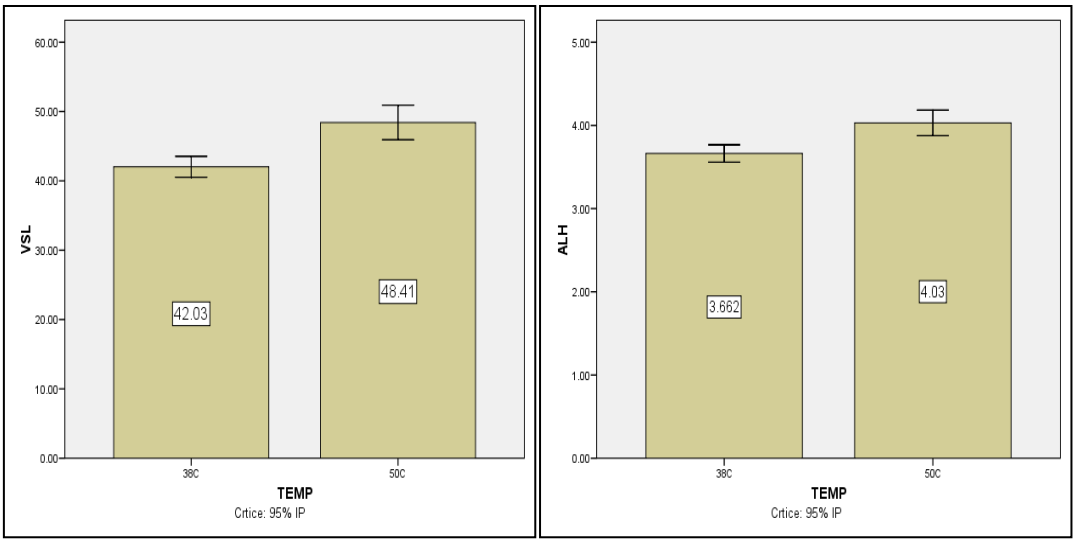


Figure 2. Average values of examined parameters of sperm motility after thawing at different temperatures

The results of the sperm motility parameters obtained with one CASA system can not be realibly compared with the results obtained in other laboratories, given the specificity of each version of the CASA system, as well as the characteristics of semen, such as sperm concentration, extender used, breed and individual studs' characteristics, and experimental protocols used. Najjar et al (2013), pointed to individual bull's characteristics as a factor that influences the values of the sperm motility parameters. These authors examined semen samples from four different bulls, and found significant differences in the obtained values (70, 75, 89 and 59 µm/s forVCL; 83, 86, 109 and 70 µm/s forVAP; 132, 138, 187 and 116 µm/s for VSL). The influence of breed on the values of the sperm motility parameters was examined by Sarastina et al. (2012). These authors found different values of these parameters, depending to breed (from 105,30 to 121,04 µm/s for VCL; from 62,31 do 73,19 µm/s for VAP; from 47,43 to 61,60 µm/s for VSL; from 3,85 to 4,59 µm for ALH). Sariozkan et al. (2010) examined the influence of diluent (Bioxcell, Optidyl, Tris) and breed (Holstein and Brown Swiss) on the sperm motility parameters after thawing at 37°C for 20 seconds. Values of sperm motility parameters in Holstein bulls, according to these authors, depended on the diluent type, and were 208, 218 and 241 µm/s for VCL, 102, 117 and 123 µm/s for VAP, 65.9, 84.8 and 79.9 µm/s for VSL, and 8.20, 9.44 and 9.82 µm for ALH. In the Brown-Swiss bulls values of these parameters were 210, 219 and 213 µm/s for VCL, 108, 115 and 122 µm/s for VAP, 94.6, 85.9 and 87.0 µm/s for VSL and 8.01, 9.29 and 7.82 µm for ALH. Values found by these authors are higher compared to our results, which is most likely due to different experimental protocols and characteristics of CASA system used. The values of the sperm motility parameters similar to those found in this study were reported by Šimoník et al. (2013), who thawed bull's semen at 37°C for 30 seconds and found values of 54.1 µm/s for VAP and 43,7 µm/s for VSL.

Conclusion

Results of this study indicate a generally favorable impact of higher thawing temperatures on sperm motility parameters. According to our results, it can be expected that faster moving of sperms after thawing at higher temperatures can increase fertilization rate, because the traveling time of sperms to fallopian tube should be shortened. On the other hand, the assumption is that faster and more intensely sperm moving after thawing at a higher temperature can lead to faster consuming of limited energy reserves of sperms, and limit their

vitality in female genital organs. Therefore, further research related to the effect of thawing temperature on sperm motility parameters in order to assess their fertilisation ability should be supplemented by examining the survival time and vitality of sperms after thawing at different temperatures.

Abstract

Goats one of the most important domestic livestock species and can adapt to extreme climatic and mountain conditions. Goat breeding is the livelihood especially for small farmers living in harsh condition in Turkey like developing countries. DNA technologies have been used extensively in livestock production like in many fields. DNA technologies are used improving of the quality and quantity of economically important traits (reproduction, meat, milk yields etc.) with selection. Genetic polymorphisms are playing an increasingly important role as genetic markers in many fields of animal breeding. β-lactoglobulin (β-LG) is one important protein related to milk quality in different ruminant species. Digestion with *Sac*II restriction enzyme of exon 7 the β-LG gene reveals three different genotypes (AA-S_2S_2, AB-S_1S_2 and BB-S_1S_1) associated with milk quality and yield in goat breeds. Polymorphism in β -LG gene can be use for milk yield and quality in Marker Assisted Selection. In this study, β -LG gene polymorphism was investigated by using PCR-RFLP methods. In total 70 samples were used from four populations reared in different regions of Antalya province from Turkey. The amplified products were observed as 426 bp size at exon 7 in β-LG gene. These PCR products were digested with *Sac*II restriction enzyme. As a result of PCR-RFLP analysis, frequencies of A and B alleles in β-LG gene were 0.545 and 0.455 respectively, while genotypic frequencies for AA, AB and BB were 0.285, 0.529 and 0.186 respectively.

Keywords: β-lactoglobulin, PCR-RFLP, Polymorphism, Hair Goat, Turkey

Introduction

Goats are usually raised under harsh environmental conditions and have a unique ability to take advantage of marginal areas (Gama and Bressana, 2011). Goats are one of important ruminant species in Turkey like developing countries. Goat breeding is the livelihood especially for small farmers living in harsh condition. According to TUIK (2015) data, there are about 10 million head goats in Turkey of which consist of 98% hair goats and 2% Angora goats (Anonymous, 2016a). Antalya is the largest second province of Turkey made goat breeding with presence of nearly 630.000 head goats. Hair goats are grown for primarily meat and milk later hair and leather. (Anonymous, 2016b).

β-lactoglobulin is one of two major important protein related to milk quality in different ruminant species (Kumar *et al.,* 2006; Lekerpes *et al.,* 2014). β-LG is the first milk protein shown different variants (A and B) in cows by Aschaffenburg and Drewry (1955). Since then, different variants has been shown in farm animals on molecular level. The relationship of between different variants of the β-LG gene with milk yield, composition and cheesemaking traits has been reported in various ruminant species (Rachagani *et al.,* 2006; Kumar *et al.,* 2006; Ramos *et al.,* 2009).

Two new variants have been detected for the goat-lactoglobulin gene at the genomic level by Pena *et al.,* (2000). The two polymorphisms are located on exon 7 of the gene. First

polymorphism is occurred a single nucleotide substitution in position +4601 of gene and can be detected with Polymerase Chain Reaction-Restriction Fragment Length Polymorphism (PCR-RFLP) using *Sac*II restriction enzyme. The other polymorphism is a 10 bp long insertion at position +4641 of gene and can be determined by capillary electrophoresis of amplified PCR products. Also Kumar *et al.,* (2006) reported that two alleles having an effect on 90-day milk production in goats and can be detected by SDS-page electrophoresis.
The aim of this study was to investigate β -LG gene polymorphism of raised Hair goats in Antalya province from Turkey by using PCR-RFLP methods.

Materials and methods

Totally 70 blood samples were randomly collected from four hair goat populations reared in different regions of Antalya in February 2016. Blood samples were taken (approximately 5 ml) from the jugular vein, using sample tubes containing K3-EDTA. The blood samples were kept at -20 ºC until the isolation of total DNA. Genomic DNA from blood samples was made using method by Miller *et al.,* (1988). DNA quality and quantity were analyzed on agarose gel and measured by spectrophotometric methods. After isolation of DNA it was adjusted 50µl/ml using bidistilled water H_2O for the PCR procedure.
Polymerase Chain Reaction-Restriction Fragment Length (PCR-RFLP) was performed for detection of polymorphism on β-LG gene from exon 7 to 3' flanking region. PCR amplification was performed by using forward 5'-CGG GAG CCT TGG CCC TCT GG-3' and reverse 5'-CCT TTG TCG AGT TTG GGT GT-3' primers. The amplification protocol was carried out as follow; initial denaturation at 94 ºC for 5 min, followed by 35 cycles consisting of denaturation at 94 ºC for 30 sec, annealing 65 ºC 40 sec, extension at 72 ºC for 30 sec and final extension at 72 ºC for 5 min. The PCR reaction was performed in a 50 µl reaction mixture containing; 50 ng/µl genomic DNA, 5 µl 10 X PCR buffer (containing $(NH_4)_2SO_4$, pH: 8.8), 2.5 mM $MgCl_2$, 2.5 mM dNTP mix, 1.0 U Taq DNA Polymerase (Fermantase) and 0.5 µM of each primer. PCR products resolved by electrophoresis on 1.5 % agarose gel at 100 V for 45 min.
10 µl PCR products were digested with SacII restriction enzyme (10 U- Fermantase) to determined β-LG A and B alleles overnight at 37 ºC. The digestion products were separated on 3% agarose gel.
Allelic frequencies were obtained by direct counting in examined samples (Nei, 1987).

Results and Discussion

After DNA extraction (Figure 1), exon 7 of goat B-Lactoglobulin gene was successfully amplified by PCR process. A result of the PCR process obtained 426 bp size single band (Figure 2) in all samples. According to method proposed by Pena et al (2000) at single nucleotide substitution in position +4601 of exon 7 on β-LG gene, the digestion of these 426 bp size PCR poducts with SacII restriction enzyme revealed three genotypes. These genotypes were shown as AA (S_2S_2 - undigested single band; size 426 bp), AB (S_1S_2 - three bands; sizes 426, 349 and 77 bp) and BB (S_1S_1-two band; sizes 349 and 77 bp) (Figure 3).

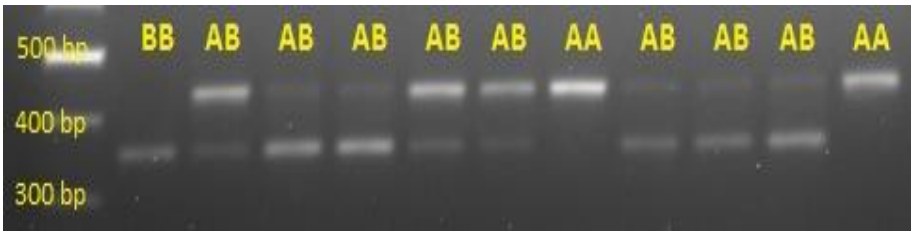

Figure 3 Image of genotypes exon 7 of caprine β-Lactoglobulin gene after digestion with *Sac*II restriction enzyme of PCR products

β-Lactoglobulin and other milk protens (e.g. α_{s1}, α_{s2}, β, k-caseins) are associated with milk production, milk composition and chesemaking traits. In β-LG gene eight variants in cattle, three variants in ovine (A, B, C), two variants (A or S_2, B or S_1) in goat have been reported in various studies. (Piınzenberg and Erhardt, 1999; Pena *et al.*, 2000; Kumar *et al.*, 2006; Rachagani *et al.*, 2006; Moioli *et al.*, 2007). β-LG AA genotype had higher milk yield than the β-LG AB genotype showed by Kumar et al (2006) in Barbari and Jamunapari goats. Similar finding were obtained in 5 Indian goat breeds by Prakash *et al.*, (2002). These genes can be use as candidate gene for marker assisted selection in goats.

In this study, frequencies of A and B alleles in β-LG gene were 0.545 and 0.455 respectively, while genotypic frequencies for AA, AB and BB were 0.285, 0.529 and 0.186 respectively. The present study frequency of A allele was found higher reported by Elmacı *et al.*, (2009) and by Korkmaz Agaoglu *et al.*, (2012) in Hair goat (0.33, 0.42) respectively. In contrast to these studies, frequency of A allele lower than reported by Yüksel and Akyüz (2014) in Hair goat (0.81). Kumar *et al.*, (2006) reported that frequency of A allele ranging from 0.47-1 in thirteen goat breeds, Lekerpes *et al.*, (2014) reported as 0.23 and 0.13 in Samburu and Narok goat respectively. The frequency of AA genotype (0.245) identified in this study is higher than reported by Elmacı *et al.*, (2009) and Korkmaz Agaoglu *et al.*, (2012) AA genotype frequencies (0.11, 0.13 respectively) in Hair goat. These finding suggest may be used Hair goats reared in Antalya province to improve milk yield and cheesemaking traits in other regions of Turkey.

Conclusions

Nowadays DNA technologies have been used extensively in livestock production like in many fields. DNA technologies are used in the conservation of animal genetic resources, phylogenetic analysis, improving of the quality and quantity of economically important traits (reproduction, meat, milk yields etc.) with selection and gene mapping studies. Genetic polymorphisms are playing an increasingly important role as genetic markers in many fields of animal breeding. In this study, polymorphism in β -LG gene showed reared Hair goats in Antalya province from Turkey. Polymorphism in β-LG gene can be use for milk yield and quality in Marker Assisted Selection. However, the use of multiple genes is more suitable for

Marker Assisted Selection. Therefore, it is necessary to study polymorphisms other genes related to milk yield and quality in goats. Similar researches should be done again with further samples in β-LG and other milk proteins genes.

TOLERANCE OF HONEY BEES ON COMMON JUNIPER (*Juniperus communis*) AND SCOTS PINE (*Pinus silvestris*) ESSENTIAL OILS

Nebojša NEDIĆ[1*], Miroslav KOSTIĆ[2], Tatjana MARKOVIĆ[2], Kazimir MATOVIĆ[3], Miša MARKOVIĆ[1]

Abstract

The need to provide welfare of bees in alternative systems of the fight against pests without application of chemicals influenced our investigation of application of different substances of natural origin on the honey bees. In order to perceive the common juniper (*Juniperus communis*) and scots pine (*Pinus silvestris*) essential oils of honey bee tolerance and contact residual toxicity was examined in the laboratory conditions. The chemical composition of the oils was determined by standard GC and GC/MC methods. Different doses of the essential oils dissolved in acetone (10 – 40 µl/Petri dish) were applied in Petri dishes and left to dry for 20 minute at a room temperature. Following this period of time, ten honey bees were added in each Petri dish in four replications and maintained in controlled conditions. Survival of examined honey bees was recorded two times, after 24 h and 48 h. The most prominent toxic effect on the examined honey bees was observed with application of 24 µl/Petri dish of common juniper oil and with dose of 15 µl/Petri dish of scots pine oil. Recorded biological activities of the oils tested in different doses, revealed the opportunity to proceed with further investigation by selecting the most appropriate variants for further investigation on both, honey bee and honey bee mite *Varroa destructor*.

Keywords: *Apis mellifera, essential oils, residual contact toxicity.*

Introduction

Honey bees (*Apis mellifera* L.) is exposed to the impact of many pests and diseases; significant loss of bee colonies around the world has been reported since 2006 (Le Conte *et al*., 2010). As one of the main causes of the syndrome, a colony collapse disorder is an ectoparasite *Varroa destructor*. It causes a great damage to the bees, since it significantly weakens the colony, and it is a vector of numerous viruses (Mond *et al*., 2011). If during the year the bee colonies are not treated by acaricides against the mites, they use to die (Ruffinengo *et al*., 2014). For *Varroa* control, several methods were developed and the most commonly used are chemical ones. Their negative effects include the emergence of resistant mites and cumulative deposition of harmful metabolites of their synthetic constituents in the wax, which further migrate into the honey and other bee products (Martel *et al*., 2007). Consumers consider bee products, primarily the honey, as a healthy and safe food, thus, the occurrence of residues in the bee products creates a negative impression and great doubt in their quality. Therefore, in the fight against *Varroa destructor* the solution require testing and application of so-called "green pesticides", which are mainly based on essential oils or organic acids (Cole *et al*., 2008). The complex structure of essential oils and a very low tolerance of the honey bee to their application in laboratory testing, makes difficult to discover effective oil that would be harmless to the bee and efficient against the mites (Nedić *et al*., 2012).

The aim of the initial phase of our research was to examine in the laboratory conditions the honeybee's tolerance to contact residual toxicity of commercial juniper and scots pine essential oils.

Material and Methods

The juniper oil (*Juniperus communis*) and scots pine oil (*Pinus silvestris*), used in this experiment, were purchased as commercial samples from "Elmar d.o.o.", city of Trebinje, Republic of Srpska (Bosnia and Herzegovina). Analytical gas chromatography (GC-FID) was performed on the GC HP-5890 Series II apparatus, equipped with autosampler (ALS), split-splitless injector, attached to HP-5 fused silica capillary column (25 mm × 0.32 mm, 0.52 μm film thickness) and fitted to flame-ionization detector (FID). Identification of individual essential oils' constituents were accomplished by comparison of their mass spectra with those from available MS libraries (NIST/Wiley) and by comparison of their experimentally determined retention indices (calibrated AMDIS) with data from the literature (Adams, 2001).
Testing of bees tolerance to contact residual toxicity of essential oils, was conducted in Petri dishes, in four replications, under controlled laboratory conditions (T= 30° C; Relative humidity = 60%). Different essential oils' doses dissolved in acetone (0.1–10 μL/Petri dish) were applied in Petri dishes (11 cm in diameter) and left to dry for 20 minute at a room temperature, and then the dishes was supplemented with 10 newly emerged adult bees (0 to 3 days old). The bees were fed with 3 g of candy and watered with water from a plastic micro tube (1.5 mL). Acetone was used as control. Survival of bees in each Petri dish was recorded twice, after 24 h and 48 h. The obtained results were processed by Analysis of variance (LSD test at the significance level of 5 and 1%). Probit analysis was used to calculate the contact residual toxicity of the essential oils for adult bee at LD_{30}, LD_{50} and LD_{95} after 24 and 48 hours.

Results and Discussion

Results of GC-FID and GC/MS analysis of commercial juniper (*Juniperus communis*) and scots pine (*Pinus silvestris*) essential oils are presented in Table 1.

Composition of commercial essential oil depends on the variety used for its production (Marković, 2011). The most dominant components of juniper oil used in this experiment were α-pinene, myrcene, limonene, *cis–cis*-geranyl linalool and *trans*-caryophyllene, which together accounted 81.2% for the entire oil, while in the oil of scots pine the most dominant constituents were α-pinene and limonene, and they accounted for 91.5% of this oil (Table 1).
Results of residual contact toxicity observed 24 h and 48 h following the application of different doses of juniper oil, and results of Probit analysis are presented in Tables 2 and 3, respectively.

Table 5. Probit analysis for residual contact toxicity on bee adults caused by application of the *Pinus sylvestris* essential oil

Time	Intercept (a)	Slope (b) (± SE)	LD_{30} (95% CI*)	LD_{50} (95% CI)	LD_{95} (95% CI)
After 24h	-3.30	5.61(±0.67)	24.29 (21.91-26.25)	30.12 (27.97-32.81)	59.19 (49.70-79.97)
After 48h	-3.00	5.81(±0.59)	19.38 (17.14-21.15)	23.85 (21.96-25.65)	45.79 (40.30-55.71)

*CI (Confidence interval)

After the first 24 h, the doses of *J. communis* oil ranging from 20 to 30 ml / Petri dish had no statistically significant effect on the honey bee mortality (Table 2). The highest two oil doses, 36 and 40 ml / Petri dish caused mortality of approximately 7 and 7.5 bees / petri dish, respectively, and their differences were statistically highly significant from the remaining doses of this oil. With increasing oil concentration, the oil became toxic to the bees.

The scots pine essential oil applied at doses of 27, 30, 32, 36 and 40 ml / Petri dish showed pronounced toxicity in comparison to other tested doses, and the average numbers of dead individuals per replication were 4.75, 5.75, 6, 6.75 and 6, respectively (Table 4).

In observation of residual contact toxicity made after 48 hours, the toxic effects of the two tested oils applied was more pronounced comparing to the effects of these two oils expressed after 24 hours (Tables 2 and 4). The scots pine oil applied in doses 30, 32, 36 and 40 µL/Petri dish expressed significant toxicity to the bees; the average numbers of dead adult bees per replication were 3.75, 4.5, 7 and 7.75, respectively (Table 2). The scots pine oil applied in doses 24, 27, 30, 32, 36 and 40 µL/Petri dish expressed the average numbers of dead adult bees per replication of 4.75, 7, 7.25, 7.75, 8 and 9, respectively (Table 4).

Great challenge in the application of essential oils in controlling bee pests is to find the oil which is non-toxic to the host (the honeybee). On the other hand, the insecticidal activity of the oils can vary even if it is originating from the same source. The reasons for this is a great variability of oil chemical composition depending on many factors (the age of the plant, plant organs or tissues used for the oil extraction, type of distillation), as well as due to the type and age of the treated organism (Sampson *et al*., 2005).

Genda et al. (2010) examined the impact of *Eucaliptus globulus* essential oils from different geographic regions of Argentina against honey bee diseases. The content of dominant oil components, eucalyptol and α-pinene, differed and depended on the investigated regions; when treated with 5 uL / cage, the bee mortality after 48 h of treatment with oil from Conlara and Mar del Plata was 8% and 0%, respectively.

Kraus *et al*. (1994) tested a number of different essential oils and came to conclusion that none of them increased the bee mortality when applied at concentrations of 0.1% and 1%, while at the concentration of 10% they always did.

Lindberg *et al*. (2000) have recommended criterion for selection of appropriate chemical for Varroa control; it is supposed to kill more than 70% of mites and less than 30% of bees. If we adhere to this recommendation, the most appropriate calculated doses of the *J. communis* essential oil for the effects observed after 24 and 48 hours, according to our experiment would be 28.19 and 27.75 ml / Petri dish, respectively (Table 3), while in the case of *P. sylvestris*, the best oil doses would be 24.29 and 19:38 uL /Petri dish, respectively (Table 5). The pine oil compared to juniper oil in our experiment showed greater toxicity for the bees.

Conclusion

The emergence of resistance among *Varroa* mites due to application of synthetic chemical agents in its control, as well as the presence of residues in the wax and other bee products, imposed the need to introduce an integrated system to combat organisms that are harmful to the bees.

The oil of *J. communis* applied in doses ranging from 27 to 40 μL caused contact residual toxicity to the bees at an unacceptable level.

The *P. sylvestris* oil applied at doses ranging from 24 to 40 μL expressed toxic effects which caused an unacceptable level of the bee mortality.

Further research will be focused on application of *J. communis* and *P. sylvestris* essential oils at doses below 27.75 uL and 19.38 uL, respectively, and their effects on both, the bees and the mite *Varroa destructor,* will be carefully investigated.

Abstract

The main aim of this article is to present the Polish eggs market after accession to the European Union (EU) in the context of foreign trade in eggs products. In the last decade, there has been an increase in the positive trade balance for eggs products and slow processes of concentration of eggs production in Poland. The increase in exports was possible by substantially reducing domestic consumption, which contributed to the improvement of Polish self-sufficiency in the production of eggs. In addition, in the first years after joining the EU, Polish eggs possessed a price advantage on the EU market, and in subsequent years the average prices of Polish eggs were close to average EU prices of eggs. In the analyzed period, Poland was a net exporter of the eggs products. This article is valuable not only to the eggs producers, processing industry of eggs, and customers, but also to the Polish economic policy. The study used a comparative analysis in time and an analysis of the structure of exports and imports of egg products, with particular emphasis on the commodity structure of exports and imports of eggs products. The article includes an analysis of the geographical structure of exports and imports of egg products. The study covers the period 2006-2015. The data comes mainly from the Polish Ministry of Finance and the Central Statistical Office.

Keywords: *eggs market, foreign trade in eggs, Poland, hen-laying*

Introduction

Due to difficulty of transporting poultry eggs in shells, they are not a commonly exported item. The level of egg consumption around the world is very diverse, e.g. in 2005, egg consumption per capita amounted to 320 units in China, 45 eggs in Pakistan, and 11.2 units in Nigeria (Kornakowski, 2007).

The cost of egg production in the EU is higher than in other important producer countries (Ukraine, USA, Argentina, and India) (van Horne, 2014). According to P. van Horne, those countries pose no threat to the EU shell egg market due to import duties and the difficulty of maintaining appropriate quality in long-distance transport (van Horne, 2014).

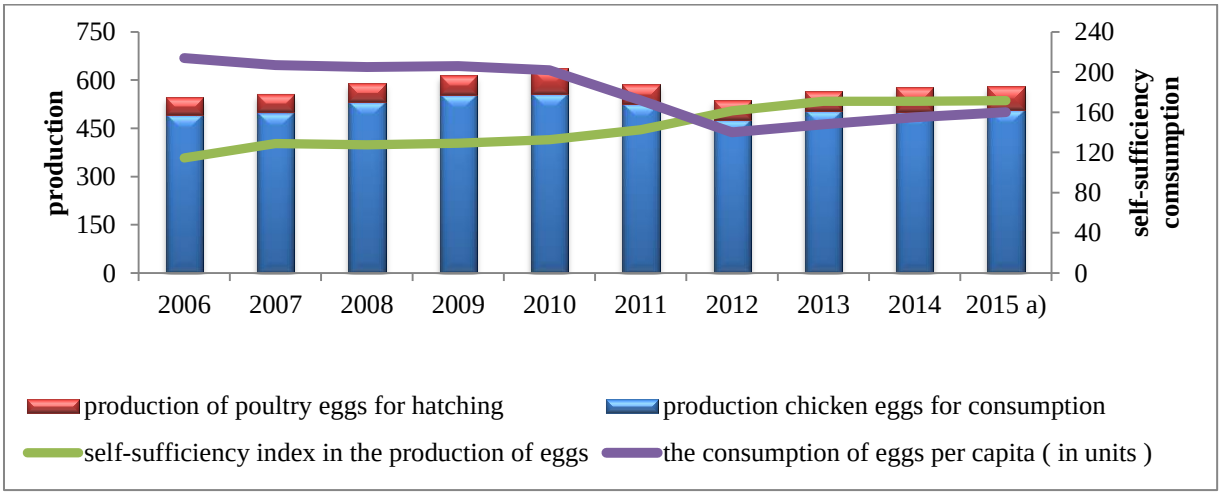
A decisive majority of research results related to the Polish egg market concerns egg consumption, prices (Świetlik, 2013; Świetlik, 2012a; Świetlik, 2012b, Świetlik 2008) and production (Kapusta, 2014). The studies related to foreign trade primarily provide analysis of trade in eggs (Czyżewski and Danilczuk, 2008) and certain egg products. Moreover, research on geographic directions of foreign trade in eggs and egg products is conducted by the Institute of Agricultural and Food Economics. The principal goal of research by the Institute is to assess short-term changes to the Polish egg market. The results are published each year (IERIGŻ-PIB, MRiRW, ARR, 2006-2015). None the studies in question provide an analysis of the scale of Polish foreign trade in hatching eggs or egg albumins.

Material and Methods

The research uses data from the Central Statistical Office of Poland (GUS) concerning production of eggs for consumption and hatching and the data from the Ministry of Finance concerning foreign trade in egg products, i.e. albumins, hatching eggs, eggs not in shell, egg yolks and eggs in shell. Data concerning foreign trade in 2015 is preliminary data. The research utilises comparative analysis over time and exports and imports structure analysis. The research covers primarily the 2006-2015 period. Deviations from the temporal scope resulted mainly from the unavailability to credible/reliable statistical data or the impossibility to present the structure of the phenomenon.

Results and Discussion

Egg production is an important branch of animal production in Poland. Compared to 2006, increased by about 6% in 2015, which was facilitated by the export demand (Fig. 1). This increase in production was a resultant of the increase in production of eggs for consumption by 3% and increase in hatching eggs production by 32%. Poland produces mainly chicken eggs for consumption, the production of hatching eggs concerns mainly chicken, duck's, goose's and turkey eggs. Production of eggs grew in 2007-2010 and in 2013-2015, while in 2011-2012 a decrease, which resulted from the necessity to withdraw conventional cages from the battery cage system. Producers had 12 years for implementing EU requirements in this regard. (Dybowski, 2013). This led to an increase in cost and thus a decrease in profitability of egg production (Krawczyk, Sokołowicz, 2008). The percentage of eggs for consumption in total production ranged from 87% to 91%, and the percentage of hatching eggs from 9% to 13%. In 2014, the percentage of chicken eggs for consumption in market oriented animal production increased by 1.5 percentage point compared to 2006 to reach 9.7% in 2014 (GUS b, 2009, GUS b, 2015).



a) estimation

Figure 1. Production of eggs in Poland (in the thousand of tonnes), polish self-sufficiency index in the production of eggs for consumption (in %), the consumption of chicken eggs per capita (in units).

Source: own study on the base: data from Main Statistical Office (GUS) follow by:[(Dybowski 2011, p. 18), (Dybowski 2015, p. 28)], (GUS c, 2007, p. 96), (GUS c, 2010, p. 77) (GUS c, 2015), (Świetlik 2015, p. 37)

In the period in question, eggs were one of the foodstuff groups whose price increased the most, which resulted in a drop in their consumption and growth in consumption of other products that are source of animal protein (Pasińska, 2015). According to household budget studies concerning that period, the decrease in egg consumption was the highest in the case of

self-employed persons' households (to 120 eggs per person in 2015), and the level of egg consumption was the highest in the case of farmers' and pensioners' household, which was related to those two groups' self-supply capability (data from GUS, Pasińska 2015). In 2006, the retail price of hen eggs for consumption was PLN 0.34 per item, in the year when the production of eggs for consumption was the lowest (2012) – PLN 0.60, and in 2015 – PLN 0.51. A significant growth in retail price of eggs in 2012 was accompanied by the least egg consumption per capita in the studied period (140 chicken eggs per capita) (data from GUS, GUS c, 2015). The slowdown of price in the following years (2013-2015) resulted in a growth in consumption (to about 160 eggs per capita - estimation) (Świetlik, 2015). In the period in question, the downward trend in egg consumption contributed to the improvement to self-sufficiency in domestic egg production.

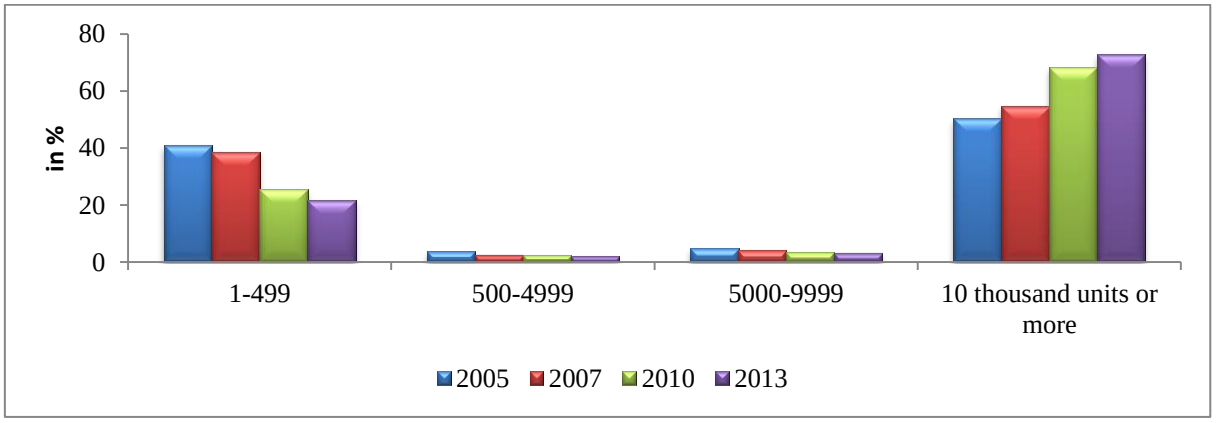


Figure 2. Structure of laying hens stock according to the breeding scale (in %).
Source: own work based on the: (GUS a, 2006 p. 198), (GUS a, 2008 p.188), (GUS a, 2012 p. 232), (GUS a, 2014, p. 124)

Slow concentration of laying hen rearing and breeding can be observed in Poland (Fig 2). This is reflected by the decreasing number of farms that produce eggs for hatching and consumption and the increase in percentage of the domestic chicken stock in chicken flocks of 10,000 laying hens or more units. In 2013 the number of laying hen rearing and breeding farms decreased by about 55% (to 516,000 farms in 2013) compared to 2005 (GUS a, 2006), (GUS a, 2014). At the same time, the proportion of laying hens in flocks of 10,000 or more rose from 50.3% in 2005 to 72.8% in 2013. This increase occurred primarily at the expense of the percentage of laying hens in small flocks of 1-499 from 41.0% in 2005 to 21.7% in 2013. (GUS a, 2006), (GUS a 2014).

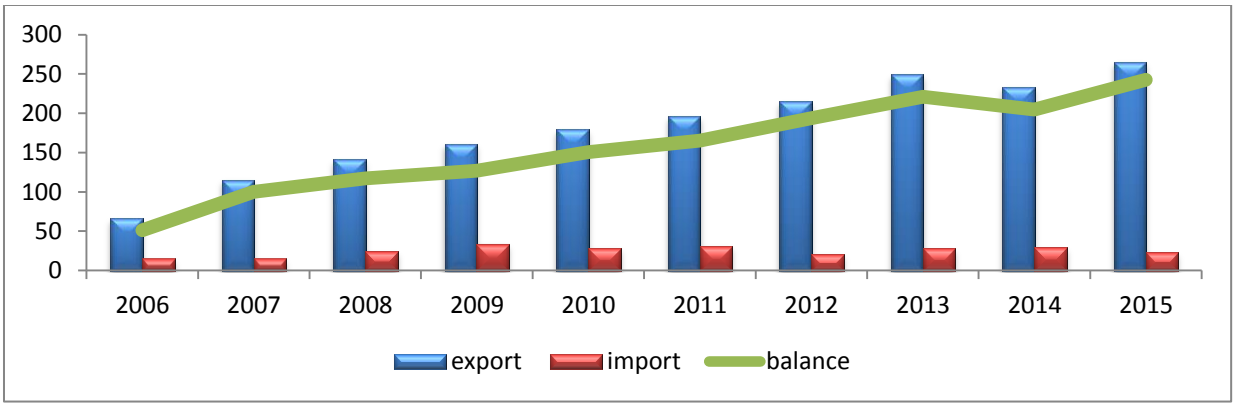

Figure 3. Foreign trade of egg products (in thous. tonnes).
Source: Own calculations based on data from the Ministry of Finance.

In 2006-2015, there was an upward trend in the Polish foreign egg trade turnover (Fig 3). In the relative perspective, the average annual rate of eggs products export growth amounted to about 17%. Egg product exports increased over four times, from 66,000 tonnes to 265,000 in 2015, and the simultaneous about 1.5 times increase in imports from 15,000 tonnes to 23,000 tonnes made Poland the net poultry product exporter in the entire period in question. The increase in egg product exports was possible due to a significant drop in domestic egg consumption.
In the studied period, egg product imports grew over 1.5 times in terms of quantity, and nearly 2.0 times in terms of value, to nearly EUR 50 million (see Fig. 2). The imports were low, particularly compared to Polish poultry product exports. The lower volume dynamics in imports than currency inflows resulted, among other things, from the increase in transaction prices. In spite of the dominant upward trend in egg product imports in the studied period, there were some drops (in 2010, 2012, and 2015). The average imports to Poland in 2006-2015 grew by 5% each year.

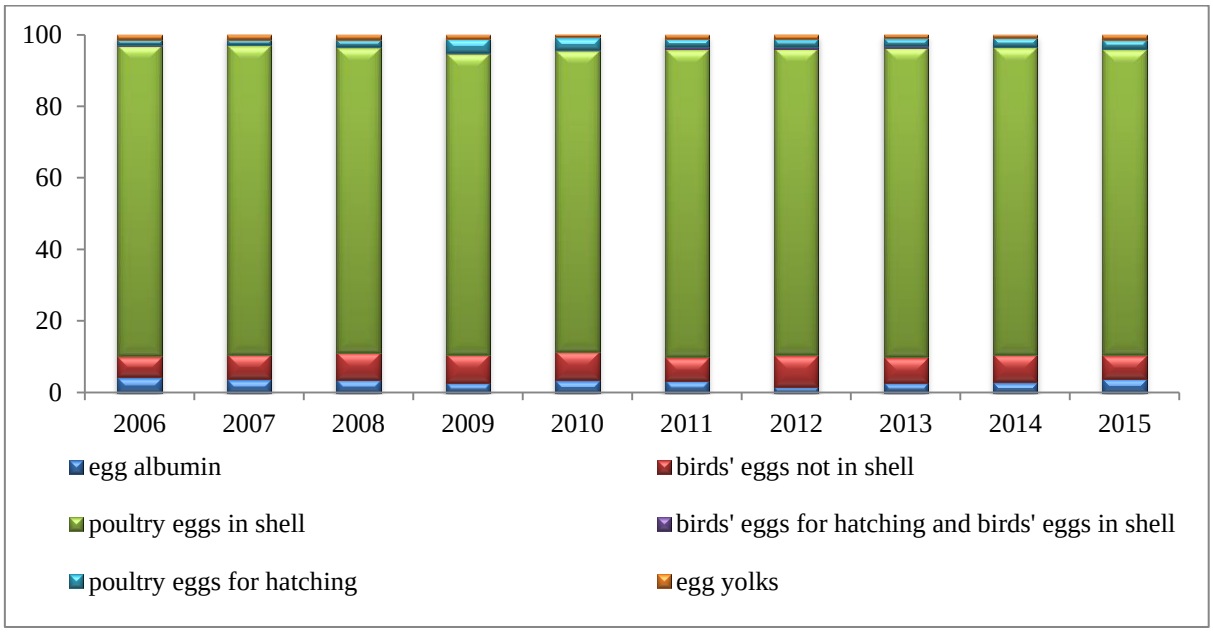

Figure 4. The structure of exports of egg products in the period of 2006-2015 (%).
Source: own work based on data of the Ministry of Finance.

In 2006-2015, the commodity structure of exports was diverse. It was dominated by shell eggs for consumption (over 84%) (Fig. 4). In the year of the Polish accession to the EU, Polish eggs for consumption gained a competitive advantage because their price was about 14% lower than the average EU price for this product range. In the studied period, however, the average L and M class egg prices were lower than the EU average only in 2006, 2007, 2009, 2011, and 2014 (about 2%-3%), while in the remaining part of the period, they were higher (about 1%-9%) (European Commission, 2016). Poland exported shell eggs primarily to the EU countries. The main buyers of Polish shell eggs were: Germany, Netherlands, Italy, Czech Republic, Romania, and Slovakia. In the studied period, the L and M class egg prices in some main buyer countries were significantly higher than in Poland, i.e. in Italy (from 32% to 72%) and Denmark (6%-58%). In 2006-2015, the differences between the average poultry egg (in shell) export prices and import prices were varied, but it were not more than 0.10 EUR / kg. Other groups of products constituted a relatively low percentage of exports: egg albumins – 2% to 4%, egg yolks – about 1%, bird eggs not in shell – 6% to 9%, shelled and hatching eggs of birds – nearly 0% to 1%, poultry hatching eggs – 2% to 4%. In the entire studied period import prices of hatching eggs were higher than the export prices. The highest proportion of exports from Poland in various categories:

- poultry eggs in shells had chicken eggs since 2012,[2]
- albumins – egg albumin, fit for human consumption (excluding dried {for example in sheets, flakes, crystals, powder}),
- bird eggs, not in shell – birds' eggs, not in shell, fresh, cooked by steaming or by boiling in water, moulded, frozen or otherwise preserved, whether or not containing added sugar or other sweetening matter, suitable for human consumption (excluding dried and egg yolks),
- hatching eggs – chicken eggs since 2012,[3]
- yolks – egg yolks, liquid, suitable for human consumption, whether or not containing added sugar or other sweetening matter.

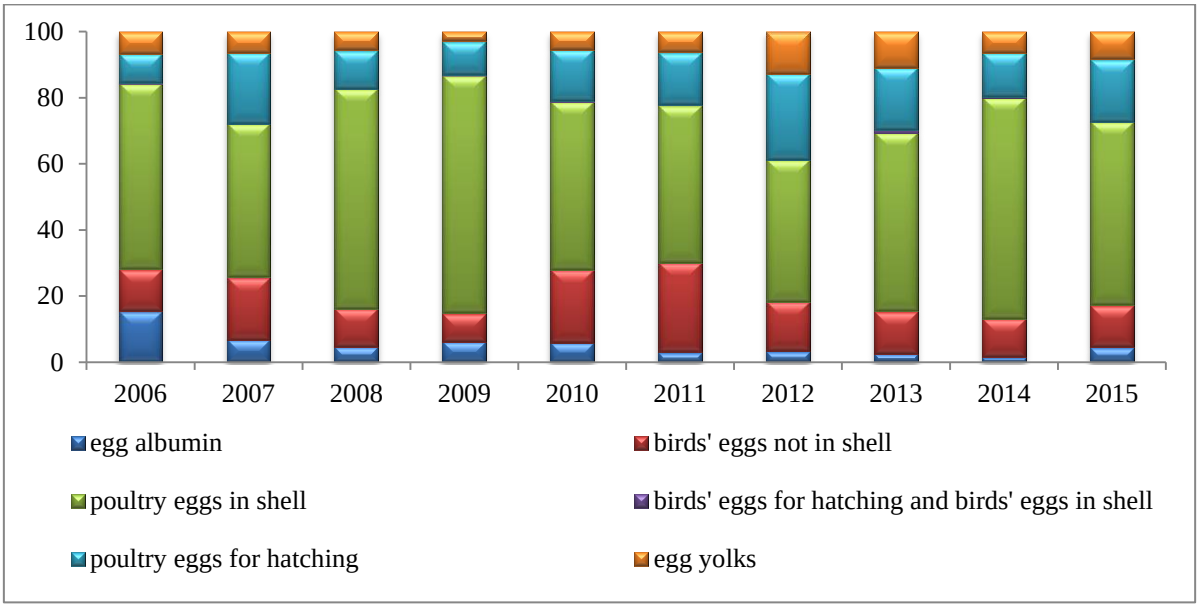

Figure 5. Imports structure of egg products in the period 2006-2015 (%).
Source: own work on the basis of data of the Ministry of Finance.

The commodity structure of Polish egg product imports was diverse and changed (Fig. 5). In the period in question, the most popular product range were shelled poultry eggs (over 42% share). The proportion of albumins dropped from 15% in 2006 to 5% in 2015, the proportion of poultry eggs in shells - from 56% to 55%, the percentage of poultry eggs for hatching grew from 9% to 19%, yolks - from 7% to 8%, the proportion of bird eggs not in shell stayed the same - 13%, and the percentage of birds' eggs for hatching and in shell - nearly 0%. The highest proportion of import to Poland in various categories:

- poultry eggs in shells had chicken eggs since 2012,
- albumin – egg albumin, fit for human consumption (excluding dried {for example in sheets, flakes, crystals, powder}),
- bird eggs, not in shell – birds' eggs, not in shell, fresh, cooked by steaming or by boiling in water, moulded, frozen or otherwise preserved, whether or not containing

[2] In the years 2006-2011 there was a lack in the Common Customs Tariff Code concerning exclusively chicken eggs, then the CN code 04070030 was used, which included all kinds of poultry eggs in shell – excluding for hatching (including chicken eggs and other species of poultry eggs) .

[3] In years 2006-2011 lacked code concerning exclusively chicken eggs for hatching in the Common Customs Tariff, then the CN code: 04070019 was applied. This code included hatching eggs of all domestic species apart from goose's and turkey eggs.

added sugar or other sweetening matter, suitable for human consumption (excluding dried and egg yolks),

- hatching eggs – chicken eggs since 2012,
- yolks – egg yolks, liquid, suitable for human consumption, whether or not containing added sugar or other sweetening matter.

Table 1. The balance of foreign trade turnover egg products.

Source: own work on the basis of data of the Ministry of Finance.

In 2006-2015 Poland was a net exporter of egg albumins, bird eggs not in shell, poultry eggs in shells, and birds' eggs for hatching and in shell (apart from 2014 in the case of this product range) (table 1). In 2006-2007 and 2011, the poultry hatching egg trade balance was negative both in terms of quantity and value, and it was positive in 2014 and 2015, and the quantitative balance was positive and the balance in terms of value was negative in 2008-2010, and 2013, which was most probably related to export of cheaper product ranges and import of the more expensive ones.

Source: own work on the basis of data of the Ministry of Finance.

In the studied period, the primary buyers of various product groups exported from Poland, except hatching eggs in 2006 and 2007, were EU countries (tab. 2). In 2006-2015, Poland imported egg products mainly from the EU.

Conclusions

Currently Poland is self-sufficient in production of eggs for consumption. Poland's accession to the EU contributed to the improvement in egg product trade balance simultaneously resulting in a change to its structure. It may be considered a success of the Polish egg sector, particularly if we take account of the fact that EU was self-sufficient in egg production (European Commission, 2015). The upward trend in export of eggs for consumption was facilitated by the price advantage in the early years following the accession, and in subsequent years the avian influenza affecting laying hens in certain countries, and the good quality of Polish egg products.

In the period in question, Poland was a net exporter of most egg product groups. Dynamic change to the course of trade was accompanied by: the downward trend in domestic egg consumption, quite advanced concentration in laying hen rearing and breeding, and variability of egg production profitability. Factors that may contribute to an increase in export of Polish egg products include: price advantage of Polish egg products on the global market and diversification of export destinations.

Polish eggs for consumption do not have a price advantage on the EU market, so it seems necessary to continuously monitor competitors' activity and cost of egg production, particularly due to the fact that this sector depends on the sales to foreign markets, so measures aimed at higher level of integration of egg producers in Poland may be considered. Such measures may help the sector lower the cost of egg production and face the competition, particularly the EU and CIS countries.

It is predicted that the exports of eggs for consumptions will stay at a relatively high level for a few years provided that there are no market disruptions (e.g. avian influenza). What is more, vertical and horizontal integration will still take place in the sector.

Abstract

To assess the protective efficiency of immunization against secondary alveolar echinococcosis, with an antigen from Echinococcus multilocularis protoscolexes in combination with Roncoleukin® - recombinant interleukin-2 (rIL-2) immunostimulation, an assay was carried out on 48 white outbred mice. These were divided into four groups of twelve mice each. The antigen was isolated from the metabolism products of Echinococcus multilocularis protoscolexes, cultured in RPMI–1640 medium enriched with 6% fetal bovine serum in a CO_2 incubator. The mice were immunized via two subcutaneous injections, administered with a ten day. The formulations consisted of antigen protein (60 μg) and/or rIL-2 (180 IU/per mouse) in 0.2 ml of sterile 0.9% NaCl per injection. The group 1 were treated with the Roncoleukin®; the group 2 - Roncoleukin® and antigen formulation. The group 3 received the antigen and the group 4 were the control, receiving 0.2 ml of sterile 0.9% NaCl. After a 20 day regimen, the groups were inoculated with a dose of 750 ± 50 units of Echinococcus multilocularis protoscolexes per mouse. After 90 days of incubation, the mice were euthanized and dissected for evaluation. The maximum protection was obtained in mice immunized with the combination of antigen and Roncoleukin® (83,3%). The protective effect in the group immunized by protoscolex antigen was 66,7%; in the group treated with Roncoleukin® was 58,3%. In conclusion, the use of immunostimulation in combination with specific antigens for the immunoprophylaxis against experimental alveolar echinococcosis has a synergistic effect.

Keywords: *Echinococcus multilocularis, immunomodulatory, antigen protective effect.*

Introduction

Alveolar hydatid disease (AHD), is a parasitic zoonosis resulting from Echinococcus multilocularis, tapeworm that belongs to the class Cestoda, family Taeniidae. AHD is found worldwide, mostly in northern latitudes in central Europe, Russia, China, Central Asia, Japan, and North America. The life cycle of these parasitic tapeworm requires two mammalian hosts. First - definitive host, such as foxes and dogs (and other canids) in which the adult or strobilar phase develops in the small intestine, and second - intermediate host, in which the alveolar stage develops in different organs in the body by tumor-like or cyst-like metacestode. The larval stage of Echinococcus multilocularis causes alveolar echinococcosis, the serious helminthozoonosis with a high mortality in patients with late treatment (Wilson, 1995). Alveolar echinococcosis is a serious disease has a significantly high fatality rate.

The therapy of this disease represents an important problem. Scientific research for effective means of protection against this deadly disease is conducted throughout the world. E.multilocularis induces parasite-specific cellular and humoral immune response in intermediate host (Gottstein and Hemphill, 1997). Cell-mediated immune response depending

on interaction of macrophages and T lymphocytes is regarded as protective against E. multilocularis infection (Reimann and Kaufmann, 1997). Also, in the scientific literature there are sufficient data on the effectiveness of various adjuvant agents such as Freund's adjuvant, aluminum hydroxide, BCG vaccine and others. These drugs are used in vaccines against parasitic infections, including larval hydatid disease (Li *et al.*, 2007; Dang *et al.*, 2012; Tuerxun *et al.*, 2013). There is a lot of references about strengthening the body's resistance to helminth infection by the application of non-specific immune stimulating agents (Berezhko *et al.*, 2004; Rudneva *et al.*, 2014; Smolencev *et al.*,2011). Application of immunomodulatory substances could improve host immune status during E. multilocularis infection and limit the growth of the parasite (Dvorožňáková, 2015). The combination of specific and non-specific stimulation means provides natural resistance and increased immunoreactivity to specific antigens E.multilocularis (Rudneva *et al.*, 2005).

In our study, we focused on the study of immunoprophylaxis activity of immunomodulatory preparation Roncoleukin® - recombinant interleukin-2 (rIL-2) in complex excretory-secretory antigen of protoscolex cells of Echinococcus multilocularis in enhancing of the host antiparasite defence in alveolar echinococcosis. Also we evaluated the protective effect immunostimulant Roncoleukin® in experimental secondary alveolar echinococcosis of albino outbred mice.

Material and methods

To assess the protective efficiency of immunization against secondary alveolar echinococcosis, with an antigen from Echinococcus multilocularis protoscolexes in combination with Roncoleukin ®, an assay was carried out on 48 white outbred mice, males, weighing 20–25 g. These were divided into four groups of twelve mice each. Mice were kept under a 12-h light/dark regime at room temperature (21±3°C) and 50–60% relative humidity on a commercial diet and water. The experimental protocols complied with the current Russian ethics law.

E. multilocularis metacestodes (an Asian genotype circulating in the Central region of Russia; strain provided by Department of immunodiagnostic and cellular technology, All-Russian research institute of fundamental and applied parasitology of animals and plants of name K.I. Scriabina, Moscow, Russia) was obtained from the wild foxes (Vulpes vulpes) (Andreyanov *et al*., 2015) and was passaged in our laboratory by intraperitoneal injection of laboratory albino outbred rats Rattus norvegicus.

Parasite cysts were isolated 6 months post infection (p.i.) and cut into pieces in sterile 0.9% NaCl with antibiotics, 8 μg/100 ml Gentamycinum (Paneco-ltd, Russia), and passed through a nylons mesh using apertures ranging №033. Protoscolexes obtained after the last filtration were subjected to grinding and homogenization. Primary cell cultures were obtained by gentle hand-homogenization and passed through nylons cell mesh using apertures ranging from 220 to 50 μm.

The antigen was isolated from the metabolism products of Echinococcus multilocularis protoscolexes cells, cultured in RPMI 1640 medium (Sigma-Aldrich, Germany) enriched with 6% fetal bovine serum. Culturing cells were performed in 6-well culture plates placed in a Heraeus CO2 incubator under conditions of high humidity, temperature of 37 °C and a CO2 level of 5% [12].

Roncoleukin ® - recombinant interleukin-2 (rIL-2) - is a structural and functional analogue of endogenous human interleukin-2.

The efficacy of immunoprophylaxis was evaluated by the cyst development in infected mice. E.multilocularis cysts were isolated from sacrificed mice and parasite cysts were weighed and proved pathogenicity of metacestodes by a biological test on other mice.

The mice were immunized via two subcutaneous injections, administered with a ten day interval between them. The formulations consisted of antigen protein (60 µg) and/or Roncoleukin® (180 IU/per mouse) in 0.2 ml of sterile 0.9% NaCl per injection.
The group 1 mice were treated with the Roncoleukin® formulation only. The group 2 mice were treated with the Roncoleukin® and antigen formulation. The group 3 mice received the antigen formulation only and the group 4 mice were the control, receiving only 0.2 ml of sterile 0.9% NaCl. After a 20 day regimen, the groups were inoculated with a dose of 750 ± 50 units of E.multilocularis protoscolexes per mouse.
After 90 days of incubation, the mice were euthanized and dissected for evaluation.

Results and discussion

Evaluation of the data of the experiment shows that all drugs used to stimulate the body's defensive response of mice against E.multilocularis with varying degrees of protective effect.

Data of the experiment are presented in Table 1.

Table 1. Representative data for calculation evaluation the protective efficiency of immunization against secondary alveolar echinococcosis with Roncoleukin® immunostimulation in combination an antigen from Echinococcus multilocularis protoscoleces

Group	*n*	*infected animals*	*percent of uninfected animals*
1	12	5	*58,3%*
2	12	4	*66,7%*
3	12	2	*83,3%*
4	12	12	*0 %*

The above table shows that the maximum protection against the Echinococcus multilocularis infection from total number of animals was obtained in mice immunized with the combination of antigen and Roncoleukin® (83,3 %). Only two mouse in this group (16,7%) showed singular metacestodes in the liver, with no infective egg elements. This was proved by a biological test on other mice.
The mice immunized with the protoscolex antigen only showed a protective effect of 66,7% In 4 mice from this group (33,3%), metacestodes with diameters of up to two mm were found but there were no egg elements. The protective effect in the group treated with Roncoleukin® only was less than 58,3%. The majority of mice infected in this group (41,7%) showed fertile parasite metacestodes. The protective effect in the group treated with sterile 0.9% NaCl was 0%. All mice were infected in this group (100%), showed fertile parasite metacestodes
Research results presented below graphically.

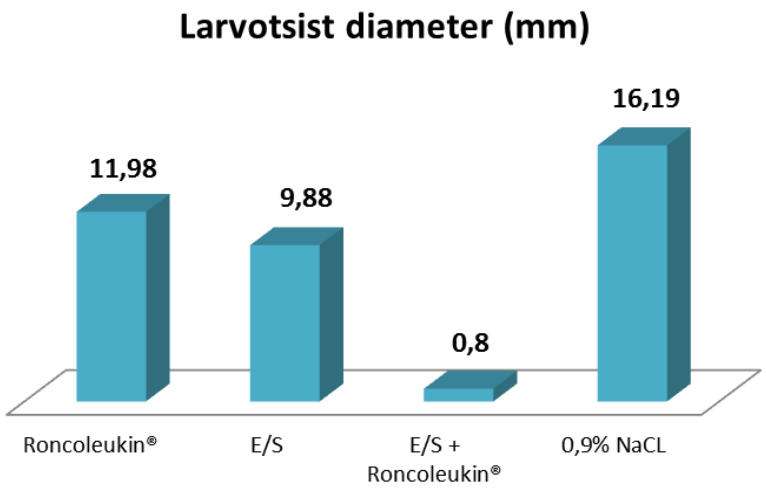

Fig. 1 Diameter of cysts found in infected mice

Figure 1 shows the results of measurements parasite cysts size in millimeters.
We can see that the largest diameter metacestodes was found in control group. In the first group of mice metacestod's diameter was 1,35 times less than in control group. Metatsetod's diameter in the second and the third group of mice was 1,64 and 20,24 times less than in the control group, respectively.

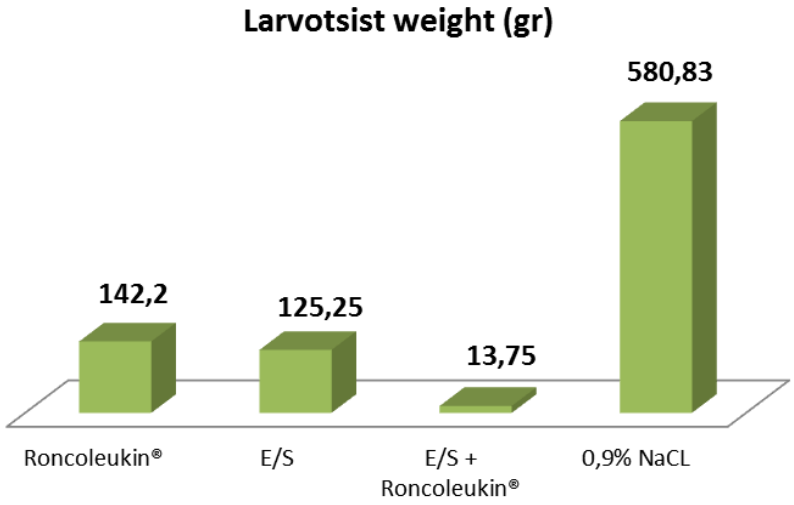

Fig. 2 Cysts weight cysts found in infected mice

The above figure 2 presents the results of measurements of total cysts weight in grams found in infected mice. We can see that the maximum weight of cysts achieved was in control group. Cysts weight in the first group was 4,08 times lower than in the control group. A light weight cysts observed. In the second group weight of cyst was lower, and in the third group was the lowest, and42,24 times less than in the control group.
However, only weight and size don't give a complete picture of the protective protection products. The presence of pathogenic elements in secondary cysts that can cause infestation in the secondary - intermediate hosts is one of the most important factors in evaluating the

protective effect of complex immunization formulations. Infective material obtained in the course of the experiment from the experimental mice we studied by bioassay in other laboratory mice.

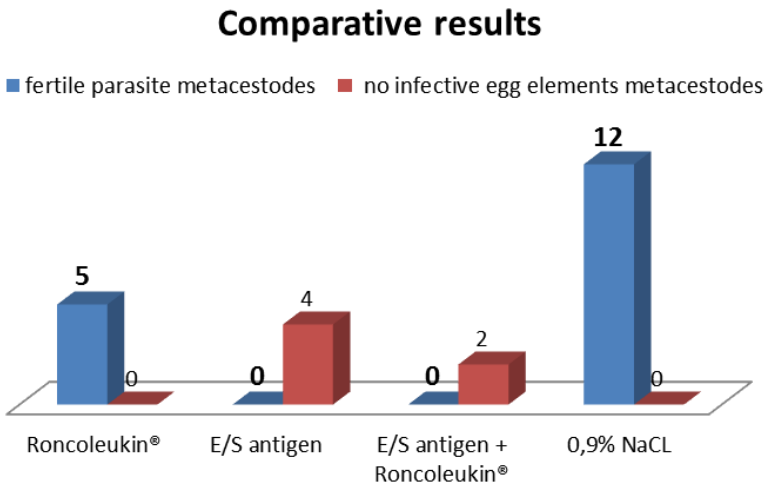

Fig. 3 Comparative results between the presence of mature pathogens and non-invasive elements in metatsestodes in secondary experimental echinococcosis.

Figure 3 presents results of the comparison between the presence of invasive pathogens and undeveloped elements in metatsestods in the secondary echinococcosis. There are significant differences between metatsestodes with no infective egg elements and fertile parasite metacestodes. The greatest positive influence of immunoprophylaxis was found in third group, where only two mouse developed singular metacestodes in the liver, which didn't contain infective egg elements. The use of the E-S antigen had a positive effect too. The number of animals having developed cysts was higher in this group than in the third group, but these metatsestods were small and didn't contain the invasive elements. Application of Roncoleukin® decreased number of metatsestods in the first group of mice, but all the elements were fertile and invasive the highest number of mature cysts was found in control group. All mice in this group were infected, all developed fertile parasite metacestodes.

Conclusion

Our experiment showed that the use of immunostimulators in combination with specific antigens for the immunoprophylaxis against secondary alveolar echinococcosis has a synergistic effect on the treatment. Thus, in all the experiments it was clearly demonstrated the advantage of the drug complex comprising the specific antigen and immunostimulating agents, to achieve the best protective effect.

Our data are actually not inconsistent with the results of other researchers which have used various immunomodulating and adjuvant agents. That enhance the immunogenicity of antigens as a means of increase potentiation animal body defense mechanisms against helminthiasis.

Acknowledgments

We thank Dr. V.K. Berezhko for her help in our work in all time. We wish to thank Dr Sinisa Berjan and Dr. Noureddin Driouech for providing valuable comments and corrections on the manuscript. We also want to express our gratitude Rudnev family to provide support for the

publication of this work, and participation in the 7th International Symposium Agrosym 2016. As well as the staff of the Federal State Budget Institution "All-Russian Scientific Research Institute of Fundamental and Applied Parasitology of Animals and Plants named after K.I. Abstract

Due to many reasons, the number of goats has decreased in nearly 20 years in Turkey. However, economic and geographical conditions are very suitable for effective goat breeding in Turkey. The 17.3% of Turkey's goat population is raised in the Southeastern Anatolia Region (SAR). The bred of goat in the Southeastern Anatolia Region is hair goat and a small number of mohair goat. Goat breeding business are usually located on mountainous and rugged terrain. The coat color of hair goats is mostly black. Goat breeding is usually conducted in tandem with sheep raising, while there are some albeit few farmers which only breed goats. The milking is performed almost entirely by hand. Kilis goat, originated in Southeastern Anatolian, are the major dairy breeds which have an important role in the regional economy. The purpose of this study was to determine the present situation of goat breeding in the Southeastern Anatolian Region of Turkey. It is thought that the results of this research will form important database for future research about development of goat breeding in the Southeastern Anatolia.

Keywords: *Turkey, Southeastern Anatolia, Goat, Production trait*

Introduction

According the 2013 data, the number of goat, amount of goat milk and goat meat are 1 006 785 725 heads, 18 422 372 tonnes and 5 417 407 tonnes in the World. In the World, Turkey is the 20th in the number of goat (10 347 159 heads), the 9th in the amount of goat milk (415 743 tonnes) and the 11th in the goat meat production (56 480 tonnes). (FAO, 2013).

The Southeastern Anatolia Region comprises 9.5% of the area of Turkey, while 10.7% of the population live in this area. The Southeastern Anatolia Region (SAR) includes the Adiyaman, Batman, Diyarbakir, Gaziantep, Kilis, Mardin, Siirt Sanliurfa, and Sirnak provinces.

Goat breeders constitute one of the lowest income groups in Turkey. Goat breeding in the SAR is dependent on pasture and nature conditions. Therefore goat breeders live on a nomadic and semi-nomadic basis. The dependence on nature of breeders particularly on mountainous areas is of much greater significance. Goat breeders living in regions with unfavorable environmental conditions make their living on limited income (Picak, 2007; Kaymakci, 2006; Ertugrul, 2001; Sireli, 2012).

The number of goat in Turkey has decreased nearly 50% between 1991 and 2009, down to 5.1 million heads. The number of goat in the SAR has registered a higher rate than the Turkey average, decreasing by 57% during the same period. One of the important causes of the decrease in the number of goat in the area is the extraordinary events that are experienced in the region. With the contribution of the Ministry of Food, Agriculture and Animal Husbandry had implemented in 2005, the goat population in Turkey has increased after 2009 and risen to 10.4 million heads in 2015. Approximately 23% of Turkey's goat population lives in the SAR (Anonymous, 2015a).

In this study, the current status of goat breeders in the SAR and the manner of utilization of the products obtained from goats was presented, and suggestions were made for developing potential.

The goat populations and products in Southeastern Anatolia Region of Turkey

Goat breeding in the SAR is usually based on pasture and partially on stubble grazing, and is generally concentrated on the level of small - scale farming business, extensively and on mostly mountainous and rugged terrain (Özcan, 1984). Small-scale farmers which take advantage of pastures (79%) usually utilize shared village pastures (69%). Changes have also been observed in goat breeding systems over recent years. It is seen that the nomadic animal husbandry is not found in goat breeders in the SAR provinces and that the transhumance livestock is 15-24% and that the settled farms rearing goat is 75% (Tekel, 2012).

Male goat addition occurs during September-October in the region. The fertilization occurs in the form of free mounting and male goats are not supplied with extra feed. The number of female goat per male is adjusted to 15-20 heads (Arac and Daskiran, 2010). Small-scale farmers usually obtained their shepherd requirements from family members. Owners of large herds employ shepherds from outside. Births occur during the months of February and March. The lactation period is 6-7 months, and the milk yield during lactation is around 450-500 kg. The age of weaning for kids are 2.5-3.0 months. Kids are weaned at around 2.5-3 months and pasture - based feeding is applied. (Arac and Daskiran, 2010). One of the local breeds in Turkey is Kilis breed. Their total number is estimated to be around 60000 heads. The goats are known with high milk yield. Lactation milk yields of Kilis goat are 200-300 kg in lactation periods of 190-230 days (Güzeler et al., 2010). Sales of kid, milk, and dairy products are the income of the farmers.

Examining the quantities of the goat products hair and angora wool, a total of 9.3 million heads of goat were sheared Turkey wide in 2015, generating 5569 tonnes hair and 325 tonnes angora wool were obtained from goats. The number of sheared animals in the SAR is 2.1 million heads and the quantity of hair obtained is 1151 tonnes, which accounts for 20.7% of total production. The yield of hair and angora wool per goat has been calculated as 596 g, 1.71 kg, and 540 g and 1.42 g for Turkey and the SAR, respectively. Approximately 2 million goat leather are produced nationwide in Turkey (Anonymous, 2015a).

The goat populations in Turkey and the SAR are shown in Table 1. The total goat population in the SAR is 2.4 million heads, and a large majority -98.5%- of which is made up of hair goat and the rest (1.5%) are Colored Mohair Goats.

The number of milked goat and amount of milk produced in Turkey and the SAR are shown in Table 2. While the number of milked goat rapidly decreased until 2009, it has increased by 41-250% between 2010 and 2015, reaching 2.6 - 4.6 million heads. The total milk production in Turkey is 18.7 million tonnes. Goat milk acounts for 2.6% (481 000 tonnes) of total milk. 24.1% of the obtained goat milk (116 000 tonnes) is produced in the SAR.

The number of slaughtered goat and amount of meat produced in Turkey and the SAR are shown in Table 3. Turkish Statistical Institute (TUIK) data for the number of slaughtered goats and goat production covers the years 2007-2009. No information is available for later years. While the number of slaughtered goat rapidly decreased until 2009, it increased by 201-330% between 2010 and 2015, reaching 1.22 - 2 million heads (Table 3). Meat production also increased by 197-291% between 2010-2015 and reached 23-34 thousand tonnes. The total red meat production in Turkey is 1.15 million tonnes. Goat meat accounts for 3.0% of the total red meat production in Turkey. 2.0% of the total goat meat obtained is produced in the SAR.

Conclusion

Hair goat and a small number of angora goats are bred in the SAR . Goat breeding business are usually located on mountainous and rugged terrain. The color of hair goats is mostly black, while brown hair goats can also be encountered. Goat breeding is usually conducted in tandem with sheep raising, while there are some albeit few small - scale farmers which only breed goats. The milking is performed almost entirely by hand.

For goat breeding to develop in the region, animal husbandry farmers should be supported first. Measures should be taken against animal diseases, and the use of high quality roughage and concentrate feed should be supported. Organizations of breeders should be provided. Joint strategies and forward-looking projections should be created by public organizations and institutions serving in the region's provinces, and the needed significance should be given to goat breeding, in order to utilize the available goat potential of the region.

Abstract

The purpose of the study was to analyze the economic efficiency of dairy farms in Kosovo. This was a descriptive and quantitative survey and the target population was the dairy farmers registered with the Kosovo Paying Agency. The random sampling technique was used to select the respondents (n=138). Two methods of data analysis were used, namely; descriptive statistics, and gross margin analysis. The annual farm income, the cost of milk production, and the problems faced by the farms were studied. Data on milk production, farm expenses and returns, use of milking machine, artificial insemination, fodder production, and feed bought in the market for each farm were recorded during 2015. The milk cost ranged from 0,166 to 0,696 euro cents/kg and milk price ranged from 0,220 to 0,600 euro cents/kg. About 12 percent of the farms are selling the milk directly to the market getting a higher price than selling to processors. In variable cost, feed took the highest share by 69,2 percent. The Gross Margin per Cow, for all the farms monitored, have positive values: 76.1 Euro/cow for the GMpC milk+meat and 4.17 Euro/cow for the GMpC milk. However 35,5% of the farms have negative values for the GMpC milk+meat while 12,3% of the farms have negative values for GMpC milk. This is one of the reasons, emphasized by MAFRD, that the analysis of the competitiveness of agriculture of Kosovo shows that currently only a small share of farms can compete in the regional market, EU and international level.

Key words: *dairy farm, gross margin, farm income, income per cow, medium and large sized farms.*

Introduction

Kosovo continues to be a predominantly rural economy with 12 percent of GDP generated by agriculture, which is also the largest employing sector, accounting for approximately 35% of total employment (World Bank, 2011; IPA, 2013; Qeveria, 2013).

Agriculture still remains subsistence-oriented due to a very small average size of farms, on average, the farm size is 3.2 ha agricultural land (including common land/pasture) and about 3.9 cattle (about 2 milking cows). Most of the farms are mixed ones and only 1-2 percent of agricultural land is used by commercial farms, more than 10 ha/farm (MAFRD, 2014).

According to Agriculture Census in Kosovo, there are 130,775 agricultural farms, which are breeding 261,689 cattle (51 percent of which milking cows). It is estimated that today there are about 91,200 livestock farms in Kosovo (ASK, 2015).

According to the MAFRD (2014), farms with more than 5 milking cows, which are consider commercial farms, during 2014 were 5,472 (7.8 percent of the dairy farms), These farms are the main suppliers to the dairy processing industry with a total of about 62 million liters of milk per year, or about 18 percent of the milk produced in the country (AAD, 2015; MAFRD, 2015; and authors' calculation). The rest is used for feeding calves, for own consumption, sold as raw milk or white cheese on the various local unregulated (green) markets (Nushi & Selimi, 2009; Nushi, 2010; Bytyqi et al., 2014).

Direct payments for dairy cows started in 2009 and were given to farmers that owned at least 5 ears tagged dairy cows and registered in Identification and Registration system (I&R system). In 2013, direct payments for dairy cows were distributed to 5,075 farmers with a total of 42,119 heads and the amount was 50 Euro/cow (MAFRD, 2014).

In Kosovo, very few studies are conducted on the milk production profitability; therefore the present study was undertaken to evaluate the gross margin of medium and large dairy farms. According to Delgado et al. (2003) larger producers may survive with low unit profit because of the large volume of business; in fact, such producers may deliberately push unit profit to low levels to squeeze out smaller producers from the market. Returns in dairy farming are deeply determined by variable cost and production cost and the correlations existing between farm size, milk yield, variable cost, total cost and milk price are important to be studied and keep under control by farmers (Dhuyvetter, 2010).

The findings of this study are important because they reveal some information to help dairy farmers and all stakeholders in the dairy industry to try and improve economic inefficiency.

Methods and Materials

This study was conducted to collect farm data pertaining to revenue and expenses on medium and large sized[1] dairy farms and make an economic analysis based on gross margin. In brief, the gross margin is the total income minus the total expenses (variable cost). Variable cost includes the cost of: feed (from farm fodder production and feed bought in the market), labor (from family member and hired labor), veterinary service, water, electricity, transportation, and miscellaneous.

The random sampling techniques were used to select the respondents. One hundred-thirty-eight dairy farms were monitored and interviewed in the seven regions of Kosovo.

***Data collection*:** A structured questionnaire was used for collection of all information related to dairy farming. According to the questionnaire the following data were recorded:

- Income and expenses: (i) Milk yield per cow; (ii) Milk production per farm; (iii) Quantity and price of milk sold; (iv) Quantity and price of meat sold (live body weight); (v) Expenses for the fodder production; (vi) Expenses for the animal feed bought in the market; (vii) Expenses for veterinary service and cow's insemination; (viii) Expenses for fuel, electricity, water, trips, lease on the land, and the land tax; (ix) estimated cost of labor needed per year. (x) Incomes per Farm from sales of milk and meat (IpF milk+meat); (xi) Incomes per Farm from sales of milk (IpF milk); (xii) Gross Margin per Cow from sales of milk and meat (GMpC milk+meat); (xiii) Gross Margin per Cow from sales of milk (GMpC milk).

***Data analysis*:** For data analysis was developed a model in Microsoft Excel program, while the statistical data processing was done with Statgraphics Centurion XVI.

[1] In Kosovo, the dairy farms are breeding one to 50 cows and does not exist any definition of small, medium and large farms. The authors for the data comparison have called the farms breeding 5-10 cows as medium sized farms and those breeding 11-50 cows as large sized farms.

Results and discussions

Data on number of cattle and cows per farm, milk yield, IpF milk + meat, IpF milk, Gross Margin per Cow (GMpC milk+meat and GMpC milk), and milk cost**,** are summarized in Table 1, as shown below:

Table 1: Technical data

Number of heads	No of Farms	No of cattle per farm	No of Cows per farm (average)	Milk yield (liter)	IpF (milk + meat) Euro	IpF (milk) Euro	Variable cost per farm	GMpC (milk + meat) Euro	GMpC (milk) Euro	Milk cost (Euro/ kg)
5-10 cows (small size farms)	68	12,54	7,25	3166	8168	7799	8486.4	-45.2	-96.4	0,369
11-50 cows (medium size farms)	70	37,85	20,93	3932	29974	28086	24992.7	193.93	101.83	0,298
Total	138	25,38	14,19	3555	19228	18089	16859	76.1	4.17	0,333

Source: Data from the farm visits and interviews.

The milk yield of large sized farms (ranged from 2000 to 6238 kg/cow) is 24.2 percent higher than the medium sized farms (ranged from 1633 to 5742 kg/cow). The milk cost of medium farms is 23.8 percent higher than large farms. About 12 percent of the farms in both medium and large sized are selling the milk directly to the market and getting the highest price of 0.50-0.60 euro cents/kg.

In variable cost, feed took the highest share by 69.2 percent, ranged from 66.4 percent for the medium farms to 71.8 percent of the large farms, because the large farms are spending more on concentrate feed as the milk yield is higher compared with medium farms.

The returns of the dairy farms came from the sale of milk and meat. The highest share of total returns for all categories of farms came from the sale of milk (93.7-95.5%) and sale of calves (4.5-6.3%).

The GMpC milk+meat and GMpC milk have negative values for the medium sized farms -45.2 Euro/cow and -96,4 Euro/cow, respectively, while the large farms have positive value (193.93 Euro/cow and 101.83 Euro/cow, respectively). However, for the all farms monitored, the values are positive 76.1 Euro/cow for the GMpC milk+meat and 4.17 Euro/cow for the GMpC milk. According to MAFRD (2015b) analysis of competitiveness of agriculture of Kosovo shows that currently only a small share of farms can compete in the regional market, EU and international level.

The IpF milk+meat in the large sized farms are 267 percent more than the medium ones (29974 Euro vs. 8168 Euro) while the IpF milk of large farms is 260 percent more than the medium farms (28086 Euro vs. 7799 Euro). These significant differences are coming as the result of the number of cows, milk yield, the price of milk and meat sold, that in most of the cases are higher at large sized farms compare with medium sized ones. The IpF milk+meat, IpF milk, GMpC milk+meat and GMpC milk are several times higher at large farms compared with medium ones because most of the medium farms are losing money from milk production, as the cost of production is very high. With respect to dairy, some studies have found a negative relationship between expenditures for purchase feed per cow and measures of financial profitability **(**Gloy et al, 2001). A higher milk yield requires a higher production cost, an aspect that farmers should take into consideration and handle in the most efficient way (Popescu, 2014).

Statgraphics Centurion XVI was used for statistical data processing, comparing medium and large farms for: IpF milk+meat vs. Number of cows/year; IpF milk vs. Number of cows/year; and Milk Cost (cent/Euro) vs. Milk Yield, and results are shown below:

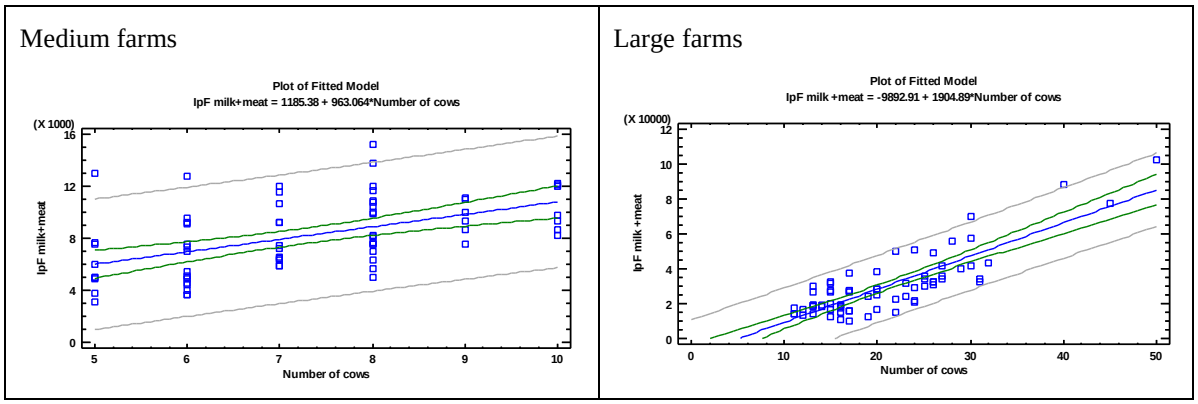

Fig. 1: Medium and Large farms IpF milk+meat vs. Number of cows/year

For the medium farms: IpF milk+meat = 1185.38 + 963.064*Number of cows. The correlation coefficient equals 0.51032, indicating a moderately strong relationship between the variables.

For the large farms : IpF milk +meat = -9892.91 + 1904.89*Number of cows. The correlation coefficient equals 0.840564, indicating a moderately strong relationship between the variables. Since the P-value in the ANOVA table is less than 0.05, for both groups of farms, there is a statistically significant relationship between IpF milk+meat and Number of cows at the 95.0% confidence level.

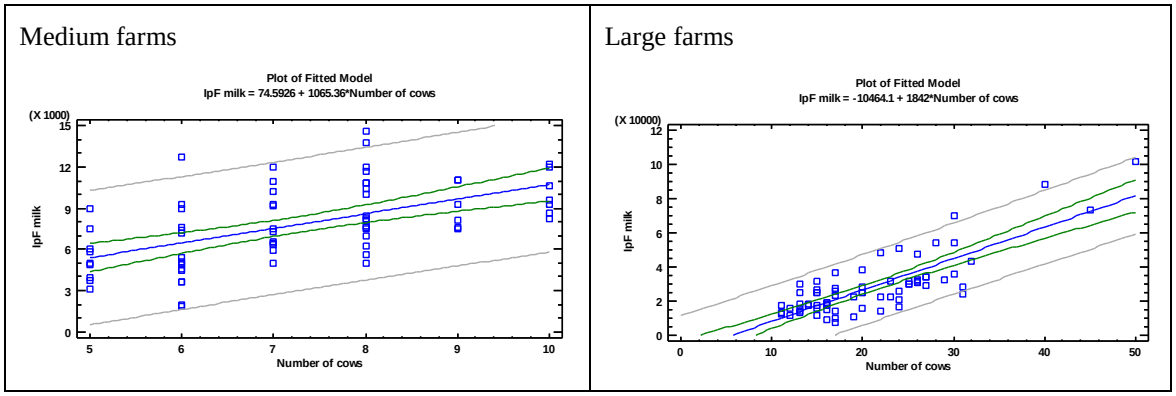

Fig. 2: Medium and Large farms IpF milk vs. Number of cows/year

Medium farms IpF milk = 74.5926 + 1065.36*Number of cows. The correlation coefficient equals 0.559758, indicating a moderately strong relationship between the variables.

Large farms: IpF milk = -10464.1 + 1842*Number of cows. The correlation coefficient equals 0.815097, indicating a moderately strong relationship between the variables. Since the P-value in the ANOVA table is less than 0.05, for both groups of farms, there is a statistically significant relationship between IpF milk and Number of Cows at the 95.0% confidence level.

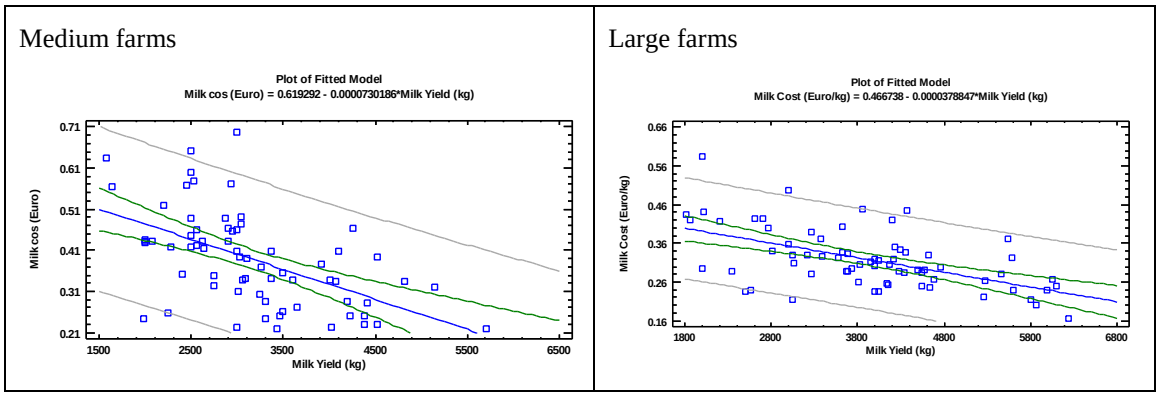

Fig 3. Medium and Large farm Milk Cost (euro cents/kg) vs. Milk Yield (kg)

Medium Farms : Milk cost (euro cents/kg) = 0.619292 - 0.0000730186*Milk Yield (kg). The correlation coefficient equals -0.545522, indicating a negative moderately strong relationship between the variables.

Large farms: Milk Cost (euro cents/kg) = 0.466738 - 0.0000378847*Milk Yield (kg). The correlation coefficient equals -0.557623, indicating a negative moderately strong relationship between the variables. Since the P-value in the ANOVA table is less than 0.05, for both groups of farms, there is a statistically significant relationship between Milk Cost (euro cents/kg) and Milk Yield at the 95.0% confidence level.

These data of our study show that large sized farms had better results than the medium sized farms for milk yield, production cost, incomes per farm, incomes per cow, and gross margin per cow.

Conclusion

The economic results of our study are much better for large sized farms than for medium sized farms such as milk yield (24.2 % higher); milk cost (23.8% less); better access to artificial facilities (62.9 percent vs 55.9 percent) and milking machine (88.6 vs 55.9). The GMpC milk+meat and GMpC milk have negative values for the medium sized farms -45.2 Euro/cow and -96,4 Euro/cow, respectively, while the large farms have positive value (193.93 Euro/cow and 101.83 Euro/cow respectively). The IpF milk+meat and IpF milk in the large sized farms are 267% and 260%, respectively, more than the medium ones. The farm inefficiency decreased as farm size increased, it means that there is ample scope to raise farm profitability by improving economic efficiency and minimizing the profit loss.

In our opinion, maybe the farmers are satisfied with their situation because they are supported from MAFRD with direct payments of 50 Euro/cows. In addition, they have profited from other crops of their farms (cereals and/or vegetables) and they do not understand that they are losing money from milk production.

As the medium sized farms have negative incomes for the milk production is a must for extension service to train farmers to keep the financial record separate for milk, and other crops. Developing a better understanding of the factors that influence dairy farm profitability is potentially important to many parties. Farm managers should be able to use this knowledge to improve their operations and increase profitability. Extension educators and other firms that interact with farmers can use the results to assist farmers in improving the profitability and long-term viability of their operations. The results may also serve to guide extension programming as topics are prioritized for educational emphasis.

Abstract

The nervature of honey bee wings is constructed from chitine and its function is to support and strengthen the honeybee wings. The linear distances and angles that are formed by branching wing nervature are considered to be very accurate taxonomic parameters and are extensively researched through morphometric studies. The aim of this study was to determine the variability within and between honeybee colonies of morphometric parameters of the angles between the nerves on the hind right wing. Three angles were measured on prepared hind right wings (W1, W2 and W3). The study included 20 honeybee colonies from apiary of the Institute for forage crops (Serbia) and the measurements were done on 50 individual honeybees per colony. Each individual honeybee colony presents individual population due to its isolation and different genetic heritage in relation to other colonies. Using descriptive and ANOVA statistics it was determined that there was variability between colonies, meaning that there was clearly distinguished homogenous groups. Considering angles W1 and W3 two homogenous groups were distinguished, while the angle W2 showed the existence of three homogenous groups. The intrapopulation variability was relatively, where the angle W3 had the highest average coefficient of variance.

Key words: *honeybee, variability, angles, morphometry*

Introduction

Serbia as a country has excellent conditions for development of beekeeping because it is characterized by variable relief, favorable climate and abundant honey bee pasture. For the intensive development of beekeeping it is necessary to provide adequate biological material that will be the basis for the development of both the individual apiaries and beekeeping as a whole (Mladenovic and Mirjanić, 2003). In order to precisely determine the differences between races, ecotypes and populations of honey bees in the selection programs the biometric methods are used. Biometrics is a method that can detect differences within taxa. This method is very powerful for identification of honey bee species and subspecies (Francoy et al., 2006). The first biometric characteristics that were studied (size and color) led to the fact that what is now considered that a good biometric characteristics should include a number of different morphological parameters. In addition to morphometric characteristics (tongue length, length and width of the wings and tarsus, size of abdominal rings, etc.). DuPraw (1965) introduces the measurement of eleven angles on the front right wing (A4, B4, D7 E9 G18, J10, J16, K19, L13 , N23 and O26). Later he introduced the measurement and for three angles of hind right wing (W1, W2 and W3). Considering carniolan honey bee, Rutner (1988) points out that, by precise morphometric studies, several ecotypes can be recognized within this race. Elements of external morphology of carniolan honey bee from Serbia were studied by Krunić (1967), Stojanović (1992), Plužnjikov (1994), Georgijev (2000), Stevanović

(2002), Jevtić (2007), Mladenović i Simeonova (2010), Nedić et al., (2011), Jevtić et al., (2015), etc. In these studies it was found that there is considerable variation in almost all observed morphometric characteristics of honey bees from this region. Variation of certain characteristics is so high that it differentiated certain populations (local populations - ecotypes) compared to colonies from near or further surroundings.
Given that most of the previous studies mainly consider only angles of the front wing, in this paper the priority was given to angles of the hind right wing. The objective of this study was to determine the variability of wing angles in nervature of hind wing.

Material and methods

In this study, the bees from 20 colonies from the apiary of Institute for forage crops in Kruševac were analyzed. The experiment was conducted during 2014. These companies were previously collected from 6 different sites from all over Serbia: Bečej (Banat), Pešter, Kopaonik, Tupižnica near Negotin, Kraljevo and Kruševac. These colonies were situated on the same apiary for several years and were subjected to selection with free queen bee reproduction. Fifty honey bees were sampled from each colony. After sampling, bees were kept in 96% ethyl alcohol and stored in a refrigerator at a temperature of -4°C until measurement.
Following angles of chitinous nervature of hind right wing were measured: W1, W2 and W3. Morphometric measurements of angles were performed by standard method by Ruttner et al., (1978). Temporary isolated anatomical preparations were first scanned under a resolution of 9600 dpi and then processed using computer software Motic Images Plus 2.0.
After measurement, values of descriptive statistics for all parameters were determined: average value, extremes, standard deviation and coefficients of variation. In addition, the analysis of variance was performed for the studied angles.

Results and discussion

Based on the results (Table 1) it can be seen that the angle W1 had an average value of 132.48° and that it also had the highest standard deviation and variation interval. However, the values of this angle had the lowest coefficient of variation (1.07%). Other observed angle (W2) had an average value of 71.05° and had lower deviation and variation interval and higher coefficient of variation compared to the previous one. The angle W3 had an average value of 28,03°. This angle had the highest coefficient of variation (4.11%), while the standard deviation was the same as in the previous one. In studies by Mladenović and Simeonova (2010) very similar values for angles W1 and W2 were determined. A significant difference in their results appears for the angle W3 which value is lower and the average is 26.23°. In their research, there are significant variations between colonies which are taken from different locations, and between colonies from the same locality. The average value of the coefficient of variation for them ranged from 3.4% (W1) to 6.4 (W2 and W3). In similar studies on bees from South Serbia (Bosilegrad, Surdulica and Vladičin Han) the average value of the angle W1 was 134.77º, 72.80º in angle W2 and 26.43º in angle W3 (Mladenović and Simeonova, 2010), with even higher coefficients of variation (CV = 5.2 to 8.0%). While Nedić (2009), in his research, stated the following values: W1 = 132.871º, W2 = 70.821º, W3 = 26.034º. These results are very similar to our research, but also show that there are considerable differences in sizes of the hind wing angles. This may indicate to the belonging to different races or eco-types of honey bees as was stated in the researches of Abou-Shaara and Al-Ghamdi (2012).

Table 1. Average values for angles (º), standard deviation, coefficient of variation (CV%), extremes (min, max) and interval of variation (IV)

Parameter	W1	W2	W3
Average	132.48	71.05	28.03
Standard deviation	1.42	1.15	1.15
CV	1.07	1.62	4.11
Min	130.01	69.00	26.03
Max	135.00	73.00	29.98
IV	4.99	4.00	3.95

By testing the values for the angle W1, it was found that there were two homogeneous groups of colonies (Table 2). The colony number 15 had the lowest value for this angle 132.14 º and differed significantly from other colonies. The colony number 14 (132.70º) and number 10 (132.72º) had the highest values for angles and were also significantly different from other colonies. Other colonies were not significantly different. By comparing the values of the angle W2 it has been found that there were three homogeneous groups of colonies. The lowest value for this angle was determined in colonies 7, 14, 10 and 15 (70.87º to 70.90º).

Companies that belong to the same group do not differ between themselves but are different when compared to other groups. Considering the angle W3, two homogenous groups are also separated. The lowest value was measured in the colony number 6 (27.63º).

The highest value for this parameter was found in the colony number 12 (28.23º). When analyzing all three observed angles it can be seen that the colonies that had the maximum and minimum values for one of the angles do not have high values for the other two angles. Colony that had the lowest or the highest value for one angle had a completely average values for the other two angles.

Table 2. T-test for angles of the hind wing of the observed colonies

Angles					
W1		W2		W3	
Colony	Average	Colony	Average	Colony	Average
15	132.14^{a}	7	70.87^{a}	6	27.63^{a}
20	132.22^{ab}	14	70.88^{a}	14	27.91^{ab}
11	132.30^{ab}	10	70.89^{a}	7	27.93^{ab}
8	132.35^{ab}	15	70.90^{a}	4	27.95^{ab}

2	132.39^{ab}	8	70.95^{ab}	13	27.96^{ab}
7	132.44^{ab}	4	70.96^{ab}	3	27.99^{ab}
5	132.44^{ab}	3	70.97^{abc}	19	28.00^{ab}
13	132.46^{ab}	9	70.97^{abc}	5	28.03^{ab}
17	132.49^{ab}	20	70.98^{abc}	15	28.05^{ab}
16	132.50^{ab}	19	70.99^{abc}	18	28.06^{ab}
18	132.53^{ab}	6	71.01^{abc}	10	28.06^{ab}
9	132.53^{ab}	1	71.01^{abc}	8	28.06^{ab}
3	132.53^{ab}	11	71.04^{abc}	16	28.10^{b}
12	132.61^{ab}	17	71.12^{abc}	11	28.12^{b}
6	132.61^{ab}	5	71.12^{abc}	2	28.13^{b}
1	132.63^{ab}	13	71.25^{abc}	20	28.17^{b}
4	132.66^{ab}	2	71.30^{abc}	9	28.17^{b}
14	132.70^{b}	18	71.36^{bc}	1	28.20^{b}
10	132.72^{b}	16	71.42^{c}	12	28.23^{b}

Conclusion

Based on the measurements of angles performed on the 50 individual honey bees from 20 colonies from the Institute for forage crops, the following conclusions can be derived:

- The average value of the angle W1 = 132.48 º, angle W2 = 71.05 º and for angle W3 = 28,03º.
- The maximum variance and standard deviation were determined for the angle W1, and the highest coefficient of variation was in the angle W3 (4.11%).
- Analysis of variance in single-factor experiment showed that the differences between the values of angles was significantly affected by the colony from which the bees were sampled.
- By testing the obtained differences it was found that in the angles W1 and W3 two homogeneous groups of colonies were distinguished, and in the angle W2 3 homogeneous groups of colonies were distinguished.

UTILIZATION OF ENZYMES IN NON RUMINANT'S ANIMAL NUTRITION, AS A BIOTECHNOLOGY FOR REDUCING POSPHORUS IN ANIMAL MANURE

Rezana PENGU[1], Etleva DELIA[2], Edmond HALA[2]

[1]Faculty of Agriculture, F. S. Noli University Korce, Albania

Abstract

One of the important reasons of soil and water pollution in Albania is the agricultural techniques and animal manures. Soil and water are compounding parts of agriculture and face the risks of presenting pollution problems of environmental equilibrium change. Nevertheless the agriculture is always in front of difficulties from the influence of agronomic techniques and the animal wastes. Excessive animal manure and fertilizer inputs do cause various environmental problems, related to the accumulation and elevated leaching, runoff of nutrients (N and P) and heavy metal to ground water and surface water. This is particularly true in areas where animal production has been geographically concentrated. The P-excretion on the pigs and poultry faeces is potential source for soil and water pollution, due to his high level on the subsoil water and destruction of the ecosystem. Interest in phytase for non-ruminant animals take place in regions, where soil and groundwater pollution due to animal wastes is a serious problem and phosphorus is a major concern. The aim of this study was to test the effects of the microbial phytase (*Aspergillus niger*, NATUPHOS) 750 FTU/kg on the increase of P availability and animal performance, as well as in the reducing of environmental pollution. The microbial phytase preparation (*Aspergillus niger*, was supplemented to a basal ration 750 FTU/kg feed and the effects on P digestibility and animal performance have been well documented. The P-excretion was reduced by 20-25%.

Key-words: *Livestock development, Environment, Water and soil pollution, Animal manure, Enzymes.*

Introduction

It's important to evidence that Albania is a mountainous country and only 16% of its territory is located at elevations of less than 100 m a.s.l. The agricultural land is distributed as follows: 43,3% in the plan or flat areas, 34% in the hilly zones and the remaining, 22,7% in the mountainous region. Albania continues the reforms and developed good institutional and regulatory capacities for managing environmental issues. (Borici et al, 2005)

The roles of the public and private sectors need to be considerer according the pollution intensity (solid pollution, the potential collapse of water, water contamination from agricultural or industrial pollutants, energy inefficiency, and threats to natural resources.

Groundwater contamination by nitrate-nitrogen and eutrophication of surface waters by phosphorus originating from land application of fertilizers and animal manure are well documented in some most populated areas like, Durres, suburb of Tirana, Lushnja, Fier etc.

Nonpoint source nutrient pollution of ground water and surface water by agriculture is a major, longstanding environmental issue in the United States (Sims, 2005).

As comprehensive nutrient management planning has become more widespread in the U.S., it has become increasingly apparent that the primary causative factor for nonpoint nutrient pollution in many regions is nutrient imbalance. Nutrient surpluses, usually due to imports of

feed and fertilizer far in excess of exports in crops and animal products, lead to the buildup on nutrients in soils and increase the likelihood of poorly timed applications of manures.
It is now widely accepted that a fundamental tenet of agro-environmental policy must be restoring nutrient balance on farms, especially those referred to as" Concentrated Animal Feeding Operations" (CAFO-s). To achieve nutrient balance on farms or in watersheds requires a number of political, social, economic and logistic challenges (Sims, 2005).

Case Study-Durrës.

Durrës is one of the biggest cities in Albania. Also, there are the most concentrated poultry, pig farms and industries in this area. There are nearly: 1 million broiler chickens, 16.000 cattle and swine industry. Population in this area is nearly 200,000 habitants and arable surface: 16. 000 ha.

Table 1. The average quantity of organic fertilizer belongs to the species in Albania (Piu and Locher, 2001).

Species	Live weight (kg)	The quantity (ton)/year
Cow	300	7
	400	8
	500	10
Sow with piglets in maternity	200	2
Pigs	100	1.2
Piglets	30	0.9
Chicken	2	0.07
Sheep	40	0.6
Goat	30	0.4
Horse	500	6

Table 2. N and P amended in the cultivated soils with manure (Sulce and Veizaj, 2006)

	Number of livestock	Annual manure production (in 000/tons)	N (tons)	P (tons)
Cattle	32 000	170 (35% moisture)	1300	380
Chicken	977 000	70 (60% moisture)	1200	300
Pigs	4 000	4 (45% moisture)	150	25
Sheeps/goats	40 000	20	600	100
Total			3250	805

Animal nutrition and Environmental problems.

As a result of growing concern about the environment, intensification of animal production in many European countries is considered as potential source of air pollution and threat to soil and drinking water quality. (Eeckhout and De Paepe, 1994).

Cereals composition

Nutritive ration of non ruminant animals (pigs and poultry) contains 90% cereals seed (corn, wheat, barley, rye, and oat). The majority of "P" in cereal grains is organically bound as phytic acid or phytate. This form of P is nutritionally unavailable to non-ruminant animals due to the lack of phytase in their digestive tract. Indeed, plant phytate is the major form of plant phosphorus and phytate phosphorus itself has low availability (Kirby and Nelson, 1988).

The P-excretion on the pigs and poultry faeces is potential source for soil and water pollution, due to his high level on the subsoil water and destruction of the ecosystem. In such situation the solution is utilization of phytase on pigs and poultry nutritive rations.

Material and Methods

Forty piglets (Large White x Landras) of four litters were transferred after weaning to flat-decks and allocated to 2 groups (A and B) with 20 animals, respectively. Two piglets from different litters (1 male and 1 female), with the same body weight were housed in every box (experimental unit). The control group (A) was feed with a balanced diet, containing mono calcium phosphate. The experimental group (B) was feed with low level of P, without inorganic phosphorus. All the phosphorus in this group originates from soybean meal. This group was supplemented with NATUPHOS phytase 750 FTU/kg feed. Ambient room temperature was maintained at 25^0C for three first weeks and lowered by 1^0C for each week thereafter. The photoperiod was controlled to provide 12 hour of light and 12 hour of dark in the stall. The ventilation also was provided to ensure good air quality. The basal diet mainly contained maize and soybean meal and the nutrient contents met or exceeded nutrient requirements recommended by (NRC, 1998). The diets were offered ad-libitum and animals (group A and B) had free access to water during experiment period.

Results and Discussions

Table 4. Efficacy of supplemented phytase in low phosphorus diet for piglets.

Parameters		Control group	Experimental group
Production	n[1]	X±SE	X±SE
Initial BW,kg	20	12.2 ± 0.90	12.6 ± 0.48
Final BW,kg		23.2 ± 1.06	24.5 ± 0.96
DWG,g		369 ± 10.0	396 ± 7.33
FCR		2.44 ± 0.11	2.43 ± 0.10

The supplementation of microbial phytase preparation (*Aspergillus niger*, NATUPHOS) 750 FTU/kg feed was reduced the N and P-excretion. The P-excretion was reduced by 20-25%, provided that pig's diets can be supplemented with an economical and efficacious level of phytase that will allow all of the supplemental inorganic P to be removed from the diet (Cromwell and Coffey, 1991).

With the industrial production of phytase, application of this enzyme to pig's diet to increase P availability and improve animal performance, as well as reducing environmental pollution has gained widespread attention. The beneficial effects of supplementary phytases on P digestibility and animal performance have been well documented (Rao et al., 1999, Ravindran et al., 1999). The efficacy of any enzyme preparation depends not only on the type, inclusion rate and level of activity present, but also on the ability of the enzyme to maintain its activity in the different conditions encountered through the gastrointestinal tract and the conditions used for the pre-treatment of a feedstuff or diet.

Conclusions

Agricultural techniques and animal rest is a serious problem for soil and water pollution, especially in the areas with a big concentration of livestock farms. An original solution is the utilization of microbial phytase on the nutritive rations of non ruminant animals. Nowadays, phytase supplementation is considered as a good way to reduce phosphorus excretion in non ruminant animals.

The inorganic phosphates in faeces, harmful for the environment, were reduced by 25-30%. This new technology offer substantial benefits to swine production by reducing the potential for environmental problems associated with excess N and P excretion. Supported by these conclusions, some of the best known companies of swine production in our country have actually included this technology in the everyday practice of the pig's diet.

TOTAL BILIRUBIN CONCENTRATION AND AST ACTIVITY IN SERUM OF SIMMENTAL COWS IN DIFFERENT GEOGRAPHIC REGIONS OF BOSNIA AND HERZEGOVINA

Jelena NIKITOVIC[1*], Tatjana PANDUREVIC[2], Marko LAZIC[3]

[1]University of Banja Luka, Genetic Resources Institute, Banja Luka, Republic of Srpska, Bosnia and Herzegovina

Abstract

The objective of this study was to evaluate serum bilirubin concentration and AST activity in Simmental cows in two different geographic regions (Lijevce Polje lowlands and high altitude Nevesinje). A total of 42 healthy cows, 21 per farm, were tested. Cows were allocated to three groups viz. late pregnant or dry cows (7 animals), cows in the first days post-calving (7 animals), and cows in the second to third month of lactation (7 animals). The study was conducted during the autumn-winter period (2008) and repeated during spring (2009) involving the same cows. Blood samples were collected for analysis by puncture of the coccygeal vein (vena coccigea) using sterile needles into sterile single-use vacuette blood collection tubes without an anticoagulant. After 24 hour storage at room temperature, serum was separated, deep-frozen, and transported within 48 days to the laboratory for further biochemical assays. Blood (serum) bilirubin concentration was within the physiological range in all experimental cows in both locations. The results related to AST activity showed a slight increase above the physiological limit in all groups of cows, with late pregnant cows (Nevesinje location, winter period) exhibiting significantly higher values.

Key words: *Concentration, Serum, Geographic area, Bilirubin, AST*

Introduction

The importance of assays for the determination of serum biochemical parameters in high-yielding dairy cows and the interpretation of their levels as the supporting evidence for identifying some diseases have been explained in detail by many authors who have addressed this issue for many years (Brugere-Picoux and Brugere, 1987; Lotthammer, 1991; Klinkon et al., 2007; Radojicic et al., 2001; Radojicic et al., 2007; Radojicic, 2008; Samanc et al., 2004). Some researchers have focused on analyzing hepatographic data such as glucose, urea, albumin and bilirubin levels and AST activity, which can serve as indicators of both nutritional and metabolic equilibrium and the functional status of the liver (Kasagic, 2005; Radojicic et al., 2007).

The determination of AST activity as an important indicator of the hepatic status in cows showed stable physiological values of AST activity in the blood serum of older cows after peroral administration of propylene glycol via feed (as an energy precursor, but also as a hepatoprotective) seven days prepartum and seven days postpartum (Kasagic, 2005).

Table 1. Physiological values of bilirubin and AST in the blood of high-yielding dairy cows (according to different authors)

Author	Bilirubin (mmol/l)	AST(U/l)
Kaneko (1989)	2.0-8.0	Up to 60
Blood (1994)	0.1-9.0	80
Lotthammer (1991)	1.0-5.7	80
Radojicic et al. (2007)	0.1-8.0	80

Material and Methods

The research was conducted on two dairy farms. Twenty-one animals aged 3-5 years were selected from each farm and allocated to three groups: late pregnant or dry cows, cows in the first days post-calving and lactating cows, each consisting of 7 animals. The experiment was conducted during the autumn-winter period of 2008 and repeated on the same animals in spring 2009 when many of them belonged to different categories of dairy cattle. The Livac Agricultural Cooperative operating the dairy farm covers about 2.5 ha of land. The cooperative runs its own production of breeding young stock. The high-altitude Nevesinje farm estate employs a closed housing system.

Blood samples were collected for analysis by puncture of the coccygeal vein (vena coccigea) using sterile needles into sterile single-use vacuette blood collection tubes without an anticoagulant. After 24 hour storage at room temperature, serum was separated, deep-frozen and transported within 48 hours to the laboratory for further biochemical assays.

Serum analyses were performed at the accredited Laboratory of Hematology and Biochemistry, Hexalab Institute, Belgrade, Serbia, using a modern spectrophotometer and commonly used standardized reagents, with values calibrated for veterinary use.

The data obtained were statistically analyzed using a factorial analysis of variance and LSD test. Comparisons were made across production statuses and locations. The statistical analysis of the results was performed using the Prisma Pad 4.00 statistics package and MS Excel.

Results and Discussion

Data showing mean values and the factorial analysis of variance are presented in the tables below.

Table 2. Serum parameters across locations and production statuses – comparison I

Location	Production status	$\overline{X}$ for Bilirubin	$\overline{X}$ for AST
Lijevce	Late pregnant	3.04	74.00
	Lactation II/III	1.50	97.58
Nevesinje	Late pregnant	2.50	112.57
	Lactation II/III	1.01	69.31

Parameter	F_{exp}			$LSD_{0,05}$
	Location	Production status	Interaction (Location × Production Status)	Interaction (Location × Production Status)

Bilirubin	1.66	14.35**	0.01	
AST	0.22	0.82	9.43	31.76

*Source: Authors' original data

A statistically highly significant difference was observed in blood bilirubin concentration depending on the production status regardless of location.
The interaction shows a highly significant difference in blood AST concentration in late pregnant cows and cows in the second/third month of lactation in the two locations.

Table 3. Serum parameters across locations and production statuses – comparison II

Location	Production status	$\overline{X}$ for Bilirubin	$\overline{X}$ for AST
Lijevce	Late pregnant	5.56	94.57
	Lactation II/III	1.41	96.14
Nevesinje	Late pregnant	4.26	90.57
	Lactation II/III	1.36	72.86

Parameter	F_{exp}		
	Location	Production status	Interaction (Location × Production Status)
Bilirubin	0.75	20.12**	0.63
AST	5.09**	1.78	2.54

*Source: Authors' original data

A statistically highly significant difference was observed in blood bilirubin concentration depending on the production status regardless of location.
The difference in blood AST concentration was statistically highly significant depending on the location, regardless of the production status.

Table 4. Serum parameters across locations and production statuses – comparison III

Location	Production status	$\overline{X}$ for Bilirubin	$\overline{X}$ for AST
Lijevce	Late pregnant	2.56	72.14
	Lactation II/III	1.24	94.86
Nevesinje	Late pregnant	2.84	77.86
	Lactation II/III	1.42	80.49

Parameter	F_{exp}		
	Location	Production status	Interaction (Location × Production Status)
Bilirubin	1.02	35.98**	0.06
AST	0.37	3.21	2.01

*Source: Authors' original data

Blood bilirubin concentration showed a highly significant difference depending on the production status regardless of location.

Bilirubin, the main coloring matter of the bile, is a breakdown product of hemoglobin in the liver, more precisely the hepatocytes. Total bilirubin includes direct and indirect bilirubin i.e. conjugated and unconjugated bilirubin. Both forms of bilirubin can be separately measured in the serum, but total bilirubin is used for the analysis of the functional ability of the liver. Elevated levels of serum bilirubin imply three aspects of hepatocyte decay, the most important and common being the so-called hepatocellular icterus (icterus hepatocelulare). The production of bilirubin itself comes from the catabolism of hemoglobin or microsomatic cytochromes. Bilirubin is produced in the reticuloendothelial system, spleen, Kupffer cells and bone marrow. There are two forms: conjugated (direct) and unconjugated (indirect) bilirubin. Unconjugated bilirubin is lipid soluble, toxic and bound to plasma albumin. Conjugated bilirubin is insoluble and excreted from the body by the kidneys i.e. in the urine.

The liver can process bilirubin concentrations that are manifold higher than the physiological concentration without expending conjugation mechanisms, and only extremely high blood bilirubin concentrations lead to elevated levels of unconjugated bilirubin in the blood. However, in hepatic or hepatocellular jaundice, the damaged hepatocytes are unable to process all the produced bilirubin, and even the processed bilirubin flows back into the bloodstream, leading to elevations in both conjugated and unconjugated bilirubin in the blood. In obstructive jaundice, for instance, the amount of conjugated bilirubin in the blood is directly dependent on the degree of obstruction of the bile ducts.

Bilirubin levels should be assessed as soon after blood sampling as possible. Serum must not be exposed to sunlight. It is not affected by the anticoagulant used.

Samanc et al. (1993) found that serum bilirubin level in older cows was 14.3 µmol/l on average. However, in first-calvers, the value was lower i.e. 6.59 µmol/l on average in early puerperium, and significantly higher than in the last stage of pregnancy, when it was 4.85 µmol/l (Samanc et al., 1993). Djokovic (1989) proved that there is a correlation between fatty liver and elevated blood bilirubin level in ketotic cows compared to healthy cows (x=6,79:5,80 µmol/l). Radojicic et al. (2001) reported an average bilirubin value of more than 8 µmol/l in ketotic cows, which is in agreement with the values reported by Kaneko (1989) and Blood (1994) which can be as high as 9 µmol/l for the upper physiological limit.

Aspartat aminotransferase or AST is not the key enzyme which can on its own serve as an indicator of hepatocyte status or as the so-called biomarker of liver status, but it plays an important role when correlated with increased bilirubin and urea levels and decreased albumin concentration (Brugere-Picoux and Brugere, 1987; Radojicic, 2008). Changes in its amount and activity occur in cases of myopathies, damage and injury to the skeletal striated muscle, heart and liver. Also, these values are increased in hepatopathies, but are compared along with other parameters. For example, in hepatitis, AST values are increased, whereas a more moderate increase is observed in chronic liver cirrhosis. In organophosphate poisoning, toxic liver injury results in the release of high transaminase levels i.e. the increase in serum transaminase activity. Although quite disparate AST values have been reported, the increase of over 80 U/L in cattle and up to 120 U/L in sheep is deemed physiological in a number of studies (Kaneko, 1989; Blood, 1994; Lotthammer, 1991; Brugere-Picoux and Brugere, 1987; Radojicic et al., 2007; Radojicic, 2008).

Conclusions

Aspartat aminotransferase or AST is not the key enzyme which can on its own serve as an indicator of hepatocyte status or as the so-called biomarker of liver status, but its activity when correlated with bilirubin, urea and albumin plays an important role in evaluating the

functional activity of the liver (Brugere-Picoux and Brugere, 1987; Radojicic, 2008). Changes in its amount and activity occur in cases of myopathies, damage and injury to the skeletal striated muscle, heart and liver. Also, these values are increased in hepatopathies, but are compared along with other parameters. Although quite disparate AST values have been reported, the increase of over 80 U/L in cattle and up to 120 U/L in sheep is deemed physiological in a number of studies (Kaneko, 1989; Blood, 1994; Lotthammer, 1991; Brugere-Picoux and Brugere, 1987; Radojicic et al., 2007; Radojicic, 2008). In this study, there was a slight increase in AST activity above the physiological limit in all groups of cows, with late pregnant cows (Nevesinje location, winter period) exhibiting significantly higher values i.e. x=112.57.

In many studies, total bilirubin level in the blood serum is considered the most important indicator of liver status and, even, the key biomarker. Also, many authors have studied the importance of changes in the peripartum period i.e. the correlation between bilirubin level and the degree of liver cell damage (Lothammer, 1991; Samanc et al., 1993; Djokovic, 1989; Kovacevic, 2000; Radojicic et al., 2001). These results are supported by the present findings, as the presence of bilirubinemia in this study was within the physiological range in all experimental cows in both locations.

Abstract

Goat is one of the species widespread raised among the domestic animals. Goats are raised in many different environments almost everywhere in the world. It is important to have knowledge relating to goat and other livestock behavior to ensure better health care, nutrition and environment conditions. Knowledge and interpretation of animal behaviour will also enable a rise in yield levels. The rise will provide income to farmers and protein to consumers. The position of the animal in the social hierarchy also affects productivity. In this sense, an animal can be assumed to be unproductive due to being lower in the social hierarchy. Knowledge of animal behavior is important for safety and for decreasing the stress on both the producer and the animal. In this way, animal from being excluded from breeding stock, it may be incorporation again.

In this review, the aim was to reveal the various types of goat behavior in order to perform the raising of goat farming easily and improve yield.

Keywords: *Goat, Behavior patterns*

Introduction

Living organisms live in harmony with their environment. Organisms' reaction to the changes around them, and the behavious exhibited when living organsms encounter each other are subjects that should be studied.

Ethology (the science of behaviour): It is the branch of science which studies the behaviour of living organisms in their natural environments.

Stimulus: Physical, chemical, and biological changes that occur in the internal or external environment and can cause a reaction in the living organism.

Reaction: The response given by effector organs to stimuli. Behaviour is a result of stimuli and reactions.

Behaviour: It is the whole of activities which the organism brings about in response to stimuli received from the internal and external environment. Behaviour helps the living organism find a mate, water, food, and shelter or avoid unfavorable environmental conditions (enemies, scarcity, fire, flood, etc.). Behaviour can be studied in thee groups which are inherent behaviour, learned behaviour, and social behaviour (Anonymous, 2016).

Knowledge about animal behaviour is important for raising the productivity of domesticated species that are cultivated as well as for optimizing the welfare of animals. Behaviour is a very important criterion in evaluating animal welfare (Akcapinar and Ozbeyaz, 1999; Unal, 2004; Yakan et al., 2007). The position of the animal in the social hierarchy is known to have an influence in their productivity. In this sense, an animal can be assumed to be unproductive due to being lower in the social hierarchy. In order to prevent these animals from being excluded from breeding stock, it would be beneficial to consider the ranking in social hierarchy as an environmental factor in breeding programs. Variations are observed in the nature and levels of aggressive behaviour observed in animals. Studies on animal

temperament are required which study aggressive behaviour of animals on an individual basis, in order to determine these variations in breeding efforts (Tolu and Savas, 2006).
In this review was undertaken to be compiled some behaviour characteristic of goats (Grazing and watering, modes of social, sexual, parturition and maternal, abnormal sexual behaviours).

Factors which influence animal behaviour

Genetics: Genetics plays an important role in animal behaviour. Many behaviours of animals of genetically similar species are similar.
Environment: Some environmental factors which influence animal behaviour are:

- Periods of high and low environmental temperature
- Day length (photoperiod) is influential in the goat entering the mating season.
- The availability of feed - The amount and type of available coarse feed influences grazing models.
- Social grouping - The size of the social group, the age of its members and the sex of animals influences behaviour.
- Behaviour of humands - Animals usually respond with a docile reaction to kind treatment and a combative one to harsh treament by their caretakers.

Domestication: The selection of brood animals with economically significant characteristics for the sake of profitable production has caused these species to exhibit different behaviour than their ancestors. Today, most farm animals live in more comfortable environmental conditions that are controlled by humans.

Physiology: Nervous and endocrine systems play an important role in animal behaviour. The nervous system receives, processes, and stores information received from external stimuli. The endocrine system creates important influences on behaviour via hormones.

Sensory systems: Animals receive information ceated by the stimuli received via their visual, auditory, olfactory, taste, and tactile senses. The capacities of these systems for receiving and processing information varies among species. Generally, information received from multiple sensory systems are used to generate an appropriate response.

Modes of behaviour in goats

1. Grazing and watering behaviour: Daily feed ingestion activities in goats comprise 1/3 of all activities. Although goats ingest feed more rapidly than sheep, their grazing period takes longer than sheep. The reason for this is that they are excessively selective and mobile while grazing (Ngwa et al., 2000). Since front incisors in goats have a higher outward inclination, they can gnaw tree barks and trunks. They detach grass with the aid of their tongues and front incisors, and complete their grazing behaviour by shredding them between their teeth (Yakan et al, 2007).
Goats conduct their watering behaviour in the form of sucking. As is the case in all animals, water requirement in goats varies according to the variety and condition of feed, and lactation and pregnancy status. Water intake in goats increased at increased environmental temperature, and during periods such as during pregnancy and lactation (Haenleinet et al., 1992). Goats mostly graze at lower and flat places, but they also like to roam and graze at steep hillsides and rocky inclines. They are also capable of treading 14-15 km a day at the pasture. Goats can take advantage of low quality pastures, maquis and bushes. They can stand on their rear legs and eat the sprouts, buds, and leaves on the branches of leaves (Schwartz, 1981). There are many factors which influence the grazing period. These are respectively: climate conditions, the quality of the pasture where the animals graze, live weight, race, size of herd, age, health condition, the condition of the goat's hair cover and the parasite status, and many other factors. During periods where air temperatures increase, goats deliberately decrease their intake of feed to compensate for heat stress. They tend to graze more during early morning

and late evening during warm seasons (Yakan et al., 2007). Furthermore, the central and peripheral nervous systems as well as hormones are also known to have an influence on the grazing behaviour of goats (Hafez and Hafez, 2000). Since adult goats are better able to distinguish the weeds to which they are accustomed, and that are nourishing they can obtain them in a shorter period of time than young goats. There are also variations between races with respect to grazing period. For instance, goats that are bred for angora yields graze for longer periods as compared to milk goats (Quick and Dehority, 1986; Hoste et al., 2001).
Goats display selective behaviour toward their favorite plants while grazing at the pasture. The taste and smell of plants plays an important role in their selection. Another factor which is influential in the selection of feeds at pasture is the nutrient and toxic content of plants. During studies, goats have been observed to have a higher preference for plants with high nutritious content. Physiological conditions such as lactation and pregnancy are also influential in goats' feed preferences (Wittenberger, 1981; Hoste et al., 2001). Pregnancy and lactation have been reported to increase the total daily time of feeding, the frequency of feeding, the total daily time of rumination, and the frequency of rumination (Wittenberger, 1981).

2. Modes of social behaviour in goats:

2.1. Hierarchical behaviour: Goats are animals with herd instincts. Their relationships with other individuals within the heard leads to the formation of a hierarchical structure among them. This condition which we call social hierarchy allows them to live together. Factors such as temperament, live weight, and the presence of horns play an influential role in the social hierarchy amongst goats. Especially the presence of horns has a significant place in determining the individual's place within the herd. Animals that are placed high in the hierarchy fully exhibit, grazing, resting, mating, and general activity behaviour (Lickliter, 1984; Shackleton and Shank, 1984; Craig, 1986).

2.2. Agonistic (combative) behaviour: Agonistic behaviour in goats are behaviours such as attacking, escape, threatening, and defense. The reason for these behaviours in goats is the instinct to protect both themselves and their food sources (Mc Glone, 1986). Agonistic behaviour is observed to be 50% higher in males. The most important cause of this is the fact that females have no horns or weak horns(Unal and Akcapinar, 1994). Agonistic behaviour modes in goats are observed mostly in the form of attacking, threatening, and submission. Knowledge of these behaviours is important for breeding and handling of animals (Shackleton and Shank, 1984; Barroso et al., 2000; Yakan et al., 2007).

2.2.1. Threatening behaviour: As the number of living creatures in a population rises, competition for food, living space, and mate increases. Competition leads to theemergence of social hierarchy among animals which make up the group. The individual which proves its superiority has the chance to meet its vital needs before others. These individuals exhibit symbolic threatening behaviour. Animals which are dominant within the herd try to have their superiority recognized by other animals through certain sounds and motions to express their intent to the other animal (Anonymous, 2016).

2.2.2. Attacking behaviour: It is perhaps the most important of agonistic behaviours. Environmental factors have a fairly high influence in the emergence of these behaviours. We could list herd size and physical amenities (shelter, feed, area for water etc.) among these factors. For instance increased herd size can increase attacking behaviour since it will limit food, water, and shelter areas (Unal and Akcapinar, 1994; Yakan et al., 2007). Attacking behaviour also increase with sexual maturity. These behaviours mostly manifest in the form of head-butting (Craig, 1986; Barroso et al., 2000; Yakan et al., 2007).

2.2.3. Submissive Behaviour: This mode of behaviour mostly manifests in the form of accepting defeat following threatening and aggressive behaviour (Yakan et al., 2007).

3. Sexual behaviour in goats: In goats, these can be listed as courting, estrus, mating, and pregnancy-related behaviour. Factors such as sex, race, feeding, and day length are important in terms of behavioural differences. For instance in bucks this activity emerges most during periods when day length shortens (Hafez and Hafez, 2000; Imwalle and Katz 2004).
Female goats in their mating season secrete some chemicals called pheromones from their urine and vaginal secretions in order to increase the interest of the opposite sex. Male goats which detect this pheromone extend their head upwards, back their upper lip, which is called the Flehmen movement. In some cases male goats cause an erection in their penis and urinate toward their front legs, and can secrete pheromones from their own body by smelling this urine kokmasıdır (Delgadillo and Malpaux, 1996; Hafez and Hafez, 2000; Imwalle and Katz, 2004).
3.1. Estrus behaviour in goats: Goats which approach rutting or are already rutting exhibit a marked decrease in their feed consumption and milk production. They are quite mobile during this period, constantly moving their tail while bleating and seek male goats within the herd. They constantly pounce on other goats and allow other goats to pounce on them. When they meet with the buck, they let him pounce on them. Buck on the other hand secrete odors to attract goats in rut. During this period bucks are aggressive and display a constant wish for mounting. They also sniff and lick the vaginal section of the goat and make grunting sounds. They kick the sides of the goat with their front legs (Chemineau 1983; Cupps, 1991).
3.2. Buck goat effect: Buck that had been isolated from the goat herd for a long time (4-6 weeks) prior to the addition of male goats are observed to influence the reproductive mechanisms of goats upon being re-introduced into the herd through pheromones they secrete from their skin and around their eyes, and female goats are similarly observed to influence buck through some pheromones in their vaginal secretions and urine (Hafez and Hafez, 2000; Martin, 2001; Ungerfeld, 2003).
3.3. Courting behaviour in goats: Courting behaviour is of great importance for successful mating in goats. These behaviours include the male goat sniffing the rutting female's perineal region; and hitting the goat's flank with front legs and making noises in the meantime. Female goats respond to these behaviours by urinating and by moving forward. The male goat on the other hand sniffs the urine, sometimes licks it and shakes his head from side to side while making the Flehmen movement. Courting behaviours that are rarely seen in female goats is to sidle up to the male, trying to hide under his chest, and leaning her body along the male goat's flank (Imwalle and Katz, 2004; Yakan et al., 2007).
3.4. Mating behaviours in goats: The male goat pounces the goat which he had found to be in rut, and exhibits the mounting behaviour by grasping it firmly from its buttocks. Mating is achieved through repetitive pushing motions to the rear of the goat. Ejaculation occurs after the mounting movement and the male goat unmounts from the goat and concludes the mating (Kilgour and Dalton, 1984).

4. Parturition and maternal behaviour in goats: The behaviour of during birth period can be studied under three headings. They are prenatal, during the birth and postnatal behavior (Lickliter, 1984; Kilgour and Dalton, 1984; Craig, 1986; Haenlein, et al, 1992). Major behaviours observed in goats before birth are a decrease in the desire to feed, keeping the male goat away, slower movements, and frequent urination (Kaymakci, 2013). Also moving away from other goats (76%), discomfort and frequent changes in position (72%), frequent bleating (57%), chasing away or head-butting animals in its proximity, and aggressive behaviour can also be observed (42%) (Yakan et al., 2007). Behaviour during the birth itself are the following; the period between the onset of uterine contractions in the goat and the expulsion of the kid are defined as birth, and occur over a period of approximately three hours

without help in a standing or prone position (Cupps, 1991; Hafez and Hafez, 2000; Kaymakci, 2002; Yakan et al., 2007) .

Postnatal behaviour and the relationship between the mother goat and kid are behaviours that begin immediately after birth. Maternal bonding begin with birth and end with the weaning period. Age, number of births, the kid's need for nutrition, race, birth type, and stimulus by the kid (warmth, sucking, moving) are influential on mothering behaviour. The mother goat immediately beginning to lick her kid and allowing the kid to suckle herself are the first indications of mothering behaviour (Unal and Akcapinar,1994; Kaymakci, 2002).

5. Abnormal sexual behaviours in goats

5.1. Homosexuality: Homosexuality is a behaviour that is observed among domesticated sexually mature male mammals and manifests in the form of mutual mounting behaviour. Isolation of male animals from female promotes homosexual behaviour. When males in this condition are once again introduced to females heterosexuality emerges again (Kaymakci, 2002).

5.2. *High sexual activity*: High sexual activity is more than normal numbers of mounting, mating, and ejaculation by male mammals (Kaymakci, 2002).

5.3. Low sexual activity: Low sexual activity is less than normal numbers of mounting, mating, and ejaculation by male mammals. This condition is always observed in the form of an absence of desire to mount or mate.

5.4. Masturbation: Masturbation is erection or ejaculation of male mammals on their own (Kaymakci, 2002).

Conclusion

Goat breeding is an animal husbandry activity that has economical significance. Goats are the most important farm animals which can consume many foods that are hard to digest, converting them to animal production. Furthermore, goat is also an indispensable source of income with its ability to adapt to highly varied geographical regions and climate conditions. Knowledge and interpretation of animal behaviour will also enable a rise in yield levels. The increasing number of studies on the behavior of goats and informing to farmers, it will be rendered more profitable and attractive in goat breeding.

In conclusion, it should be known of goats behavior patterns for economically goat breeding . In this way, animal products will be increased. This increase will provide income to farmers and protein to consumers.

Abstract

Pigs and poultry diets are primarily on cereals, legumes and oilseed products. About two-thirds of phosphorus (P) in these feedstuffs occur as phytates (mio-inositol hekxakisphosphate, InsP6), the salts of phytic acid. Phytate P in plants is a mixed calcium-magnesium-potassium salt of phytic acid that is present as chelate and solubility is very low. Phosphorus in this form is poorly digestible/available for simple-stomached animals. The aim of this study was to test the effects of the microbial phytase (NATUPHOS) on the performance parameters and faecal excretion phosphorus of piglets. The microbial phytase preparation (*Aspergillus niger*, NATUPHOS) was supplemented to a basal ration 750 FTU/kg feed and the effects on growth performance of weaned piglets were studied. The supplementation of microbial phytase improved slightly daily weight gain, feed conversion ratio and increases the digestibility and bioavailability of phosphorus from phytate, reduces the amount of inorganic phosphorus needed to maximize growth and bone mineralization and markedly reduces fecal excretion of phosphorus. Overall a positive effect of the microbial phytase on performance parameters was observed. The P-excretion in the faeces was reduced by 20%.

Keywords: *Faeces, Microbial phytase, P-reduction, Performance parameters, Piglets.*

Introduction

Excessive animal manure and fertilizer inputs do cause various environmental problems, including the accumulation and elevated leaching and runoff of nutrients (N and P) and heavy metal to ground water and surface water (de Vries et al, 2005). Groundwater contamination by nitrate-nitrogen and eutrophication of surface waters by phosphorus originating from land application of fertilizers and animal manure are well documented in some most populated areas like, Durres, suburb of Tirana, Lushnja (Borici et al, 2005), (Sulce and Veizaj, 2006).

Animal nutrition and Environmental problems.

As a result of growing concern about the environment, intensification of animal production in many European countries is considered as potential source of air pollution and threat to soil and drinking water quality, (Eeckhout and de Paepe, 1994).

Nutritive ration of non ruminant animals (pigs and poultry) contains 90% cereals seed (corn, wheat, barley, rye, and oat). The majority of "P" in cereal grains is organically bound as phytic acid or phytate. This form of P is nutritionally unavailable to non-ruminant animals due to the lack of phytase in their digestive tract. The P-excretion on the pigs and poultry feces is potential source for soil and water pollution, due to his high level on the subsoil water and destruction of the ecosystem. In such situation the solution is utilization of phytase on the nutritive ration of pigs and poultry.

Sometimes the farmers in my country have distributed the animal manure in everywhere, because there is not government law, which not allows this distribution. In such situation the

government has no control on the quantity of phosphorus and nitrogen in the arable soil and ground water. Actually in Albania, the problems of soil and water pollutions are very important (Lushaj and Suljoti, 2005) (Bregasi and Veizaj, 2007).
Some of the pigs and poultry farms in Albania are in the suburb of the cities, but some others are near the living center, like as in Tirana, Durres, Vlore, Shkoder etc. The fecal excretion only by the poultry farms in Albania are nearly 41450 T per year.
Interest in phytase for non ruminant animals take place in regions, where soil and groundwater pollution due to animal wastes is a serious problem and phosphorus is a major concern. Indeed, plant phytate is the major form of plant phosphorus (Kirby and Nelson, 1988) and phytate phosphorus itself has low availability. For this reason swine and poultry diets must be supplemented with highly available, inorganic sources of P to meet their P requirements.
Studies in the early 1990s at Kentucky and Michigan showed that feeding pigs a low-P, corn-soy diet supplemented with phytase from a mutant strain of *Aspergillus niger* improved the bioavailability of P. At about the same time, research in the Netherlands also demonstrated the efficacy of phytase produced by recombinant *Aspergillus niger* in studies with pigs and chicks. In November, 1995 a commercial source of recombinant-produced phytase (Natuphos) was approved for use in the USA. Since then, other sources and forms of phytase have been developed and evaluated. From 1992 to 2001, 82 papers involving phytase were published in Poultry Science (N=55) and the Journal of Animal Science (N=27) with 48 of these published in the last 4 years. The studies clearly show that phytase increases the digestibility and bioavailability of P from phytate, reduces the amount of inorganic P needed to maximize growth and bone mineralization, and markedly reduces fecal excretion of P. Phytase seems to increase the bioavailability of Ca, Z, and other divalent cations that otherwise bind to phytate. Some studies suggest that phytase may improve ideal digestibility of amino acids slightly, but other studies have not shown this response. This new technology offer substantial benefits to swine and poultry production by reducing the potential for environmental problems associated with excess P excretion.

Material and Methods

Thirty six piglets (Large White x Landras) of four litters were transferred to flat-decks and allocated to 2 groups (A and B) with 18 animals (9 male and 9 female), respectively. Two piglets from different litters (1 male and 1 female), with the same body weight were housed in every box (experimental unit). The litter origin was taken into account, avoiding that piglets from the same litter were allocated in the same treatment. There were nine replications per control group and nine also per treated group. The control group (A) was feed with a balanced diet, containing mono calcium phosphate. The experimental group (B) was feed with low level of phosphorus, without inorganic phosphorus. All the phosphorus in this group originates from soybean meal. This group was supplemented with NATUPHOS phytase 750 FTU/kg feed.
Ambient room temperature was maintained at 24^0C for three first weeks and lowered by 1^0C for each week thereafter. The ventilation also was provided to ensure good air quality. The basal diet mainly contained maize and soybean meal and the nutrient contents met or exceeded nutrient requirements recommended by NRC. The diets were offered ad-libitum and animals had free access to water.

Table 1. The calculated nutrient concentration of diet.

Nutrient concentration (g/kg feed)		
	Control group (A)	**Experimental group (B)**
ME (MJ/kg)	12.75	12.80
Crude protein	190.1	191.1
Crude fibre	38.4	38.1
Calcium	6.90	6.45
Phosphorus	6.0	4.2
Lysine	2.1	1.9
Metionine+Cystine	6.4	6.5

During six weeks experimental period Body Weight (BW), Daily Weight Gain (DWG) and Feed Conversion Ratio (FCR, kg feed/kg Body Weight Gain were measured weekly. Data are presented as arithmetic means with standard deviation of the mean (Mean ± SD). One-way analysis of variance and Student's *t*-test ($P<0.05$) were performed to test the differences between two groups.

Results and Discussion

Feeding phytase NATUPHOS was slightly improved the production parameters respectively: Final Body Weight (FBW) by 1.76% and Daily Weight Gain (DWG) by 1.4%, compare with control group.

Table 2. The effect of phytase on production parameters.

Parameters		**Control group**	**Experimental group**
Production	n[1]	X ± SD	X ± SD
-Initial BW, kg	18	8.1 ± 1.01	8.3 ± 1.07
-FBW 6th week [2]		22.6 ± 2.10	23.0 ± 2.33
DWG, g [3]		345.2 ± 23	350 ± 27
FCR [4]		1.90 ± 0.48	1.83 ± 0.31

[1] Number of animals, (18 piglets/ every group, at the beginning of the experiment)
[2] FBW at the end of the trial.
[3]DWG for whole experimental period.
[4]FCR for whole experimental period.

Feed Conversion Ratio (FCR) was reduced (-3.8%) to compare with control group, but the differences were not significant. The phosphorus excretion was reduced by 20%, provided that pig's diets can be supplemented with an economical and efficacious level of phytase that will allow all of the supplemental inorganic phosphorus to be removed from the diet.

The effect of microbial phytase use as a partial replacer of the bi calcium phosphate in the layers and weaned piglets, aiming a better utilization of the phytic phosphorus and decrease of the environment pollution was documented by (Piu et al, 2008). Utilization of microbial phytase (Natuphos) on the nutritive ration of weaned piglets (28 days old), was accompanied with improved performance parameters. In the experimental group, treated with Natuphos (750 FTU/kg), the excreted phosphorus amount in the dropping is decreased by 6,8%, while the excreted nitrogen amount is decreased by 5,2%. So, there is a positive output towards the minimizing of the environmental pollution with non degradable Phosphorus and Nitrogen.

In general, the performance potential and the specialization in production (e.g. pregnant sows, lactating sows, growing pigs) may have a considerable influence on the efficiency of a

phyatse supplementation. Thus (Jongbloed et al, 1993) reported that the greatest effect of microbial phytase was on lactating sows and least on breeding sows in early gestation, whereas the reaction of piglets and growing pigs were in the middle range.
(Cromwell and Coffey, 1991) concluded that a 50% reduction of excreted phosphorus would mean that 100.000 fewer tons of phosphorus would be excreted into the environment annually in the United States (Fodor and Szabo, 2005). Obviously, this could have a major impact and would be especially significant in countries, where livestock production is restricted because of environment pollution (Sims, 2005)

Conclusions

Concerns about pollution of environment with P from intensive livestock production facilities has led to diet modifications to reduce the amount of P excreted, such as supplementing diets only to required phosphorus levels and adding microbial phytase. Effectiveness of supplemental microbial phytases for swine in improving phytate phosphorus bioavailability and reducing manure phosphorus excretion has been demonstrated by many researcher groups around the world. Our study demonstrated that the use of phytase reduced the amount of phosphorus excreted and improved the production parameters.

Abstract

The aim of the study was to evaluate the influence of claw disorders on claw conformation by computer image analysis. The occurrence of claw disorders, as interdigital dermatitis and heel erosion, digital dermatitis and separately sole ulcer were observed. The measurements of lateral right claw (n=127) after functional trimming were evaluated. Computer image analysis in NIS Elements and the statistical analysis in SAS were performed. Following average values of claw conformation were found: claw angle 54.22 °, claw length 8.11 cm, heel index 4.15 cm, claw height 6.97 cm, diagonal 13.17 cm, claw width 5.26 cm, total area 42.86 cm^2 and functional area 27.87 cm^2. Analysed group of cows consisted of 9 cows affected by interdigital dermatitis and heel erosion, 11 by digital dermatitis and 12 by sole ulcer. Healthy cows had statistical significantly ($P<0.05$) larger total area and functional area than cows affected by digital dermatitis, but high statistical significantly ($P<0.01$) smaller total area than cows affected by sole ulcer. The highest positive correlations were found in claw length to claw height and of total area to functional area. Study has proved that the photometry of the claw can be successfully implemented into dairy management, with results significantly reflecting impact of disorders on claw formation.

Keywords: *photometry, claw disorder, claw conformation.*

Introduction

Claw disorders and lameness in dairy cattle are an increasing problem of the modern dairy industry (Van der Tol et al., 2004).The impact of the lameness is that reduce milk production (Bicalho and Oikonomou, 2013), disrupt animal welfare (Bicalho et al., 2009, Vermunt, 2007), cause economic losses (Warnick et al., 2001) and reduce productive efficiency and increase culling rates (Bicalho and Oikonomou, 2013). DeFrain et al. (2013) reported that infectious lesionsof the foot skin and soft tissues as digital dermatitis (DD) and foot rot predominate in early lactation and during cooler months of the year, and non-infectious lesions as white line disease, sole ulcer (SU) and toe ulcer predominate during the 3 months following summer heat stress and their distribution follows a typical lactation curve. Baird et al. (2009) reported the associations of genetic, environmental and infectious factors with claw pathologies in dairy cows. Šárová et al. (2011) reported that farm managers underestimated the level of lameness. The economic value of claw disorder incidence was -26.73€ per case per cow and year as found Krupová et al. (2016).

The goal of preventive trimming is to promote natural loading by increasing the weight-bearing contact area of the claws and improving the balance between the medial and lateral claw as reported Van der Tol et al. (2004). Leach et al. (2012) reported the high effectivity of regular claw trimming as prevention to claw disorders and lameness.

Polák (2005) reported that photometry is objective, noninvasive method, which works on principle of computer image analysis. The use of the digital image analysis to determination of the body measurements and live weight of Holstein cows reported Tasdemiret al. (2011).

The aim of the study was to evaluate the influence of claw disorders on claw conformation by computer image analysis.

Material and Methods

Into the study, 127 Holstein dairy cows from university farm (SUA Nitra) were included. Cows were free stall housed. During the functional trimming the occurrence of claw disorders as interdigital dermatitis and heel erosion (IDHE), digital dermatitis (DD) and separately sole ulcer (SU) were observed. Claw disorders were evaluated as 0 (absence) or 1 (presence). Digital images of lateral right claw (n=127) from the bottom and right side with ruler by digital camera Olympus SP-600 UZ after functional trimming were made. Computer image analysis in NIS Elements 3.0 was performed. Claw measurements as claw angle, claw length, heel index, claw height, diagonal and claw width according to the methodology of Vermunt and Greenough (1995) were made. The statistical analysis and the evaluation of differences between groups with t-test in SAS (version 9.2, SAS Institute Inc., Cary, NC) were performed.

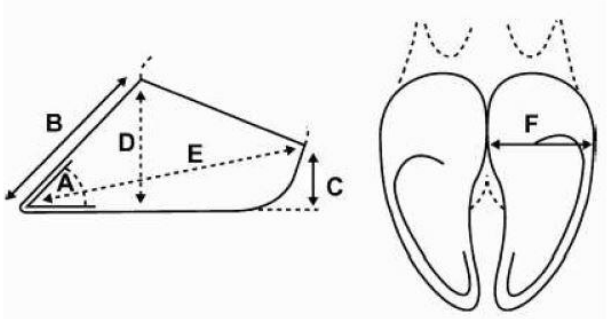

Figure 1 Claw measurements (Vermunt and Greenough, 1995)
A- claw angle, B- claw length, C- heel index, D- claw height, E-diagonal, F- claw width

Results and Discussion

In total, 127 lateral right claws of Holstein cows after functional trimming were evaluated. Analysed group of cows consisted of 9 cows affected by IDHE (the frequency 7.09 %), 11 by DD (8.66 %) and 12 by SU (9.45 %). DeFrain et al. (2013) reported that only 31.17 % of cows out of 17 confinement dairies (mainly from USA) had any lesions. 27.83 % were affected by DD and 13.29 % by SU. In Slovakia, Kasarda et al. (2015b) reported that the occurrence of IDHE, DD and SU was almost 16 % for each one.

Following average values of claw measurement were observed: claw angle 54.22 °, claw length 8.11 cm, heel index 4.15 cm, claw height 6.97 cm, diagonal 13.17 cm, claw width 5.26 cm. The size of total claw area was 42.86 cm^2 and the size of functional claw area was 27.87 cm^2. The results are in accordance with Kasarda et al. (2015a), who reported the size of total area 41.76 $cm^2$and the size of functional claw area 28.98 cm^2.

Width of claw was 4.91 cm and in present study it was 5.26 cm. Cows affected by IDHE had by 1.34 mm significantly ($P<0.05$) longer diagonal than healthy cows. On the other hand, cows affected by DD had significantly ($P<0.05$) smaller values of claw height, diagonal, claw width, total area, functional area and high significantly ($P<0.01$) smaller values of heel index than healthy cows. Gomez et al. (2015) found significant differences between healthy and DD affected heifers in claw angle, heel index, depth of the interdigital space, level of interdigital hygiene and incidence of heel horn erosion. Cows housed on concrete flooring had shorter claw length and higher claw angle as cows on rubber- matted flooring (Kremer et al., 2007).

Observed cows affected by SU had high significantly ($P<0.01$) larger total area than healthy cows.

Table 1 Estimated phenotypic correlations between claw measurements

	A	B	C	D	E	F	Total Area	Functional Area

Functional Area	-0.2309 0.009	0.13537 0.1292	0.01204 0.8932	0.09597 0.2831	0.27465 0.0018	0.44626 <.0001	0.67441 <.0001	1

A- claw angle, B- claw length, C- heel index, D- claw height, E-diagonal, F- claw width

In this study the highest positive correlations were found in claw height to claw length and of total area to functional area. In both, correlations were highly significant ($P<0.01$).The highest negative correlation was between claw angle and claw width ($P>0.05$). Similar results found Riecka et al. (2008), who reported the highest positive correlations of claw height to claw length and of diagonal to heel index. Both were highly significant ($P<0.01$). DeFrain et al. (2013) found that digital dermatitis and foot rot were greatest in the first 60 days in milk and differed across lactation number. Baird et al. (2009) found in first and second lactations the higher total lesion scores between 71 and 150 days in milk. Almost half of problems recorded were before 180 days in milk, indicating the need to focus on factors known to cause lameness between dry period and mid-lactation (DeFrain et al., 2013). The significant claw conformation changes occurred in heifers affected by DD before lameness symptoms were detected (Gomez et al., 2015). Bicalho and Oikonomou (2013) highlighted the importance of prevention of the disease through improved management and housing.

Conclusion

As confirmed in previous studies, claw disorder incidence has high economic impact on dairy cow's profitability. Within high intensity farming conditions all tools providing up to date and accurate information's essential for the successful farm management. Use of photometry in evaluation of claw formation after functional trimming and evaluation of effect of claw disorders on claw proportions were studied. Study has proved that the photometry of the claw can be successfully implemented into dairy management, with results significantly reflecting impact of disorders on claw formation. Further implementation of photometry is foreseen as tool for data collection as part of the precision livestock farming management.

Abstract

In this study, the term "a national scientific paper" refers to an article published in a national journal belonging to category M50. In addition to the categorization for the purpose of quantification of scientific and research results, scientific papers are classified according to the Universal Decimal Classification (UDC) scheme and system. In the UDC, animal husbandry and breeding in general are placed under agriculture and related sciences and techniques. Given the above, the aim of this study was to quantitatively show scientific interests in the field of animal husbandry and breeding in general at the national level, based on the categorization of journals and classification of scientific papers. M51, M52 and M53 national journals and UDC codes assigned to published articles were used for the analysis. All national journals dedicated to scientific research that meet the requirements of bibliometric analysis were covered. Within these journals, all articles published in the past few years (from 2009. to 2014.) and containing UDC codes beginning with 636 were analyzed. Apart from the fact that UDC is an important scheme and a highly flexible classification system based on which national catalogues and national bibliographies are being organized, the results of this study can be used in creating new and more complex scientific questions arising from current and future problems. Overall, despite the fact that scientific interest in animal husbandry and breeding in general is focused on economically important animal species, the results of the present study may stimulate future research into neglected areas.

Keywords: *categorization, comparison, livestock rearing, UDC.*

Introduction

Given the concept of science and scientific work as the result of creator's mental activity, classification of scientific interest can be helpful principally to scientists in the earliest period of their creativity. The fact that plant production is the primary determinant of the character of livestock production places special emphasis on the importance of classifying scientific interest in this branch of agriculture.

The preparation of scientific research generally has seven stages, as follows: general introduction to the problem and its setting, collection of scientific materials on the subject being studied, coordination and interpretation of scientific data, hypothesis and the choice of working hypotheses, proving the working hypothesis, drawing conclusions and making recommendations, description of results (Spasic and Milosevic, 2011). Research plan includes the following elements: object of research, funds required for the implementation of research,

research directions, executors of the plan, as well as other important elements for the success of the research team (Veljovic, 2001).

In Serbia there are several publishers of scientific journals of different quality ranks in the field of animal husbandry as a branch of agricultural production. Journal categorization results are published annually on the Ministry of Education, Science and Technological Development website (MPNTR, 2009a, 2010, 2011, 2012, 2013, 2014). The final decision on the categorization of journals that are published in Serbia is passed by the Minister upon proposal of the scientific committee inside the Ministry in charge of research activities (KoBSON, 2001). Category (type) of work may be suggested by reviewers and members of the editorial board or section editors, but the responsibility for categorization shall be borne exclusively by the editor-in-chief (MPNTR, 2009*b*). In order to improve the quality of periodic publishing, the Ministry has passed the Act on Editing Scientific Journals (KoBSON, 2001). Articles in journals are classified into the following categories: scientific articles (original scientific article, review article, short or preliminary communication, scientific critique or controversy and review) and technical articles (technical paper, informative contribution, review) (MPNTR, 2009*b*). National journals are categorized as follows: scientific journals (category M53), journals of national importance (category M52) and leading journals of national importance (category M51) (Official Gazette of the RS, 2016). However, despite the different analyses and reports, little has been said about scientific interest in agricultural science, and even less about its neglected subfields.

Given the above, the aim of this study was to quantitatively show scientific interests in the field of animal husbandry and breeding in general at the national level, based on the categorization of journals and classification of scientific papers.

Materials and Methods

According to the UDC, animal husbandry and breeding in general are placed under agriculture and related sciences and techniques. Animal husbandry and breeding in general are further divided into: domestic equines (636.1), large ruminants (636.2), small ruminants (636.3), pigs (636.4), poultry (636.5), birds (except poultry and game) bred or kept by humans (636.6) dogs (636.7), cats (636.8) and other animals kept by humans (636.9) (*UDC Summary, 2009*). In addition to these divisions, animal husbandry includes the subdivision of special auxiliary subdivision for animal husbandry (636.01/.09). M_{51}, M_{52} and M_{53} national journals and UDC codes assigned to published articles were used for the analysis. All national journals dedicated to scientific research that meet the requirements of bibliometric analysis were covered. Categorization of domestic scientific journals (M50) in biotechnology and agro-industry is available on the Ministry of Education, Science and Technological Development website (MPNTR, 2009a, 2010, 2011, 2012, 2013, 2014) for the period 2009-2014. Given that no journal categorization proposal for 2015 has been published, the analysis presented includes articles published during the abovementioned period. Within these journals, all articles published in the past few years (from 2009. to 2014.) and containing UDC codes beginning with 636 were analyzed. The results of the research were analyzed using ANOVA (Maletic, 2005; Stankovic *et al*., 1990; Spasic *et al*. 2006), as well as their percentage.

Results and Discussion

Based on the annual number of published papers, the results presented in Table 1 show that scientific interest in the field of animal husbandry and animal breeding in general is highest in 2009, followed by 2014. The results for the analyzed period indicate that in 2012 somewhat fewer articles were published at the national level in the field of animal husbandry and animal breeding in general. However, it should be noted that some of the leading journals of national significance (category M51) were verified by a special decision for 2012 (category M24),

based on which they were categorized among journals of international importance in this year (MPNTR, 2009a, 2010, 2011, 2012, 2013, 2014).
Given the results (see Table 1), the difference in UDC classification across years was statistically significant ($F_{(8,45)}$ =15.01, $p \leq 0.01$), which indicates significant differences between scientific interest in animal husbandry and animal breeding in general in the period 2009–2014. However, differences in UDC codes between published articles and journals were statistically non-significant (F_{exp}, $p > 0.05$).

Table 1. ANOVA and percentage values of published articles and journals according to UDC classification and categorization during the period 2009–2014.

Item	Animal husbandry and breeding in general (UDC: 636)								
	636.1	636.2	636.3	636.4	636.5	636.6	636.7	636.8	636.9
Category	$F_{(8,18)}$ =2.25, $p > 0.05$								
M51	47.62	55.93	77.78	64.20	67.09	-	42.86	50.00	83.33
M52	33.33	32.20	15.87	29.63	16.46	-	52.38	50.00	0.00

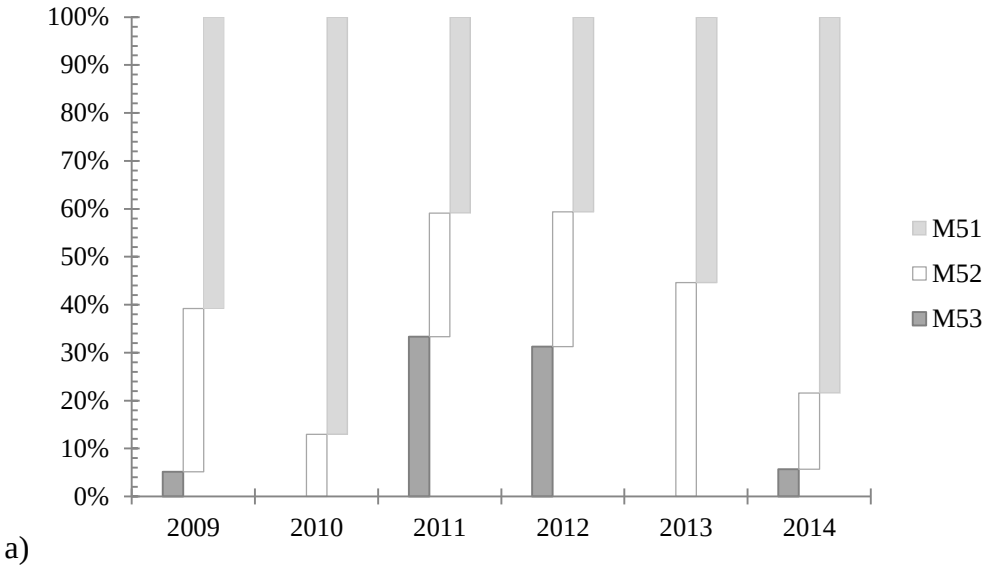
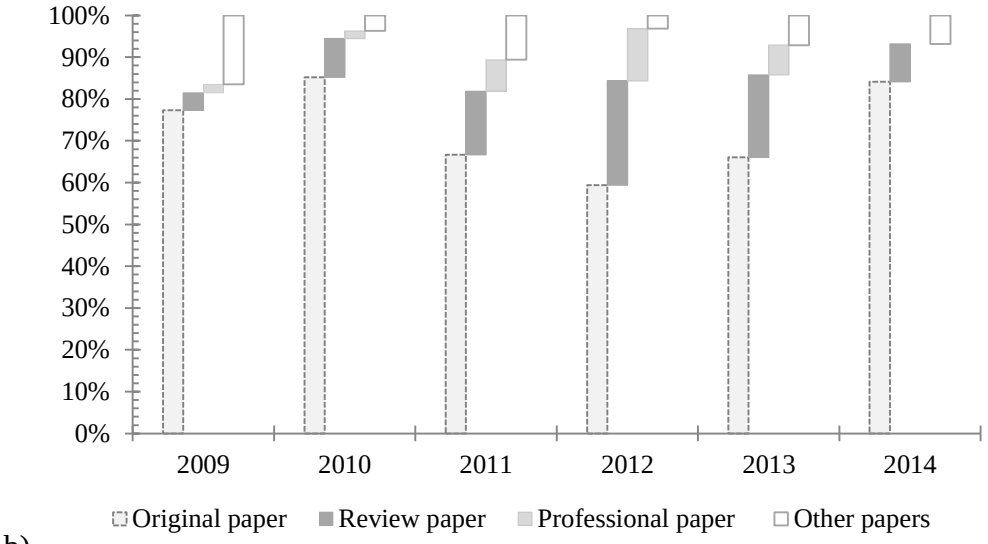
Professional	4.76	5.08	1.59	6.17	1.27	-	0.00	50.00	0.00
Another	23.81	11.86	6.35	4.94	5.06	-	14.29	50.00	0.00
Total, %	100	100	100	100	100	-	100	100	100
Years	$F_{(8,45)}$ =15.01, $p \leq 0.01$								
2009.	19.05	27.12	22.22	19.75	30.38	-	23.81	25.00	16.67
2010.	14.29	18.64	14.29	9.88	10.13	-	14.29	0.00	16.67
2011.	28.57	15.25	14.29	17.28	22.78	-	4.76	0.00	0.00
2012.	4.76	5.93	4.76	11.11	8.86	-	14.29	25.00	16.67
2013.	9.52	16.95	11.11	14.81	13.92	-	14.29	25.00	0.00
2014.	23.81	16.10	33.33	27.16	13.92	-	28.57	25.00	50.00
Total, %	100	100	100	100	100	-	100	100	100
Percentage	5.34 %	30.03 %	16.03 %	20.61 %	20.10 %	-	5.34 %	1.02 %	1.53 %

A desirable and acceptable scientific paper always involves good preparation, research and drawing conclusions, with quality primarily being affected by acquired skills and innovative capacity of researchers. Despite the fact that experienced researchers characteristically show scientific interest in particular disciplines, the results obtained, inter alia, can focus scientific research on neglected animal species and research priorities (see Table 1).
Based on available and analyzed UDC codes in the field of animal husbandry and animal breeding in general, it can be concluded that scientific interest in the period 2009–2014 was focused primarily on large ruminants (30.03%), followed by pigs (20.61%), poultry (20.10%) and small ruminants (16.03%) (see Table 1). Other animal species are not and/or are considerably less dealt with in published articles in the field of animal husbandry and animal breeding in general. Moreover, contemporary scientific literature on agriculture tends towards a higher level of scientific knowledge primarily in under-researched areas, but also towards information of recent date. The results presented (see Table 1 and Graph 1) show that the highest number of published articles are found in leading journals of national importance

(category M51), and that original scientific papers make the highest contribution to the contents of national scientific journals and, hence, account for the largest portion of primary scientific literature (Spasic and Milosevic, 2011).
Results on percentage change as regards national categorization for journals and articles published during 2009–2014 are presented in Graph 1.



a)



b)

Graph 1. Percentage change in national categorization for scientific journals (a) and published articles (b) during the period 2009–2014

Furthermore, in the field of animal husbandry and animal breeding in general, there are some published articles whose UDC code consists only of 636 (Aleksic *et al*., 2009; Nikiton, 2009; Petrovic *et al*., 2013; Pusic *et al*., 2011; Umetsu *et al*., 2011). There are also papers in the field of animal husbandry and animal breeding in general which addressed different species of animals (Bojkovski *et al*., 2011; Lilic *et al*., 2009; Radulovic *et al*., 2013).
In addition to scientific interest and nature of the research project, potential research teams should be formed in accordance with both the topical area under study and the approach taken. Scientific engagement both in the laboratory and in the field, and computer-related

activities should be specifically determined. In addition to experience in planning, conducting and reporting on research work, properly defined activities of potential team members can lead to the development of advanced skills in a particular field of science, especially when it comes to long-term agricultural experiments.

Conclusion

In the field of animal husbandry and breeding of animals in general, each livestock species has a role to play; however, based on the available national and analyzed articles in recent years, research interests are primarily focused on economically important animal species, especially large ruminants, followed by pigs, poultry and small ruminants. The obtained results, inter alia, indicate that differences in UDC classifications across study years are statistically significant, suggesting significant differences between scientific interest in animal husbandry and animal breeding in general in the period 2009–2014. Also, it should be emphasized that the highest number of published articles are found in leading journals of national significance, and that original scientific papers make up the largest portion of the contents of national scientific journals. Given that the focus of scientific interest can primarily be helpful for scientific workers in the earliest period of their creativity, attention in further analyses should be paid to some other parameters that indicate the value and / or impact of published articles.

Abstract

The aim of this study was to effects of the addition of 5% molasses or 0.5% urea into milk thistle on silage nutrient content, pH, lactic acid (LA), acetic acid (AA) and butyric acid (BA) concentrations and *in vitro* digestibility with Ankom Daisy II method. The addition of urea to milk thistle silage significantly ($P<0.05$) increased crude protein (CP) and ether extract (EE) content, but decreased the organic matter (OM) content compared with control. While the addition of urea to milk thistle increased acetic acid concentration of silages, molasses addition to milk thistle decreased the butyric acid concentration compared to control ($P<0.05$). The lactic acid concentrations in milk thistle silages were not affected by treatments. The quality classes of milk thistle silage with or without additives were considered as "fair-quality". *In vitro* digestibilities of CP in milk thistle silages were increased by addition of additives, but NDF digestibilty was decreased compared the control. The addition of molasses increased OM digestibility and energy value of silages compared with control ($P<0.05$). In conclusion, urea addition to milk thistle at 0.5% level improved the CP and EE content and *in vitro* OM digestibility of the silages. The addition of 5% molasses to milk thistle silages improved the *in vitro* digestibility of OM and CP content and energy values of the silages.

Keywords: *Milk thistle, silage quality, in vitro digestibility, molasses, urea.*

Introduction

Annual forage requirement of Turkey is approximately 52 million tons based on existing number of animals. Existing pasture, range amount of forage produced can be accounted for 80% (Anonymous, 2016). It is also very important to improve feeding quality of these animals. This production was provided from 25% of the grassland area, 20% of the forage cultivation, 17% of the silage, 13% of the pasture, 25% with low feed as hay and stubble. Use of silage has a great importance for requirement the high quality forage our country (Anonymous, 2016).

Silybum marianum L. Gaerth, also known as milk thistle, is a medicinal plant containing hepatoprotectant flavonolignans. The flavonolignans in *Silybum* that exhibit these medicinal properties are collectively known as silymarin. Milk thistle (*Silybum marianum* L. Gaerth) has been used for over 2000 years as a remedy for various types of liver disease and it has hepatoprotective, anti-inflammatory, cytoprotective and anti-carcinogenic effects (Manna *et al*., 1999).

Due to its hepatoprotective effects, silymarin was tested as a natural treatment in ketotic cows (Vojtíšek *et al*., 1991), in lactating dairy cows exposed to dietary aflatoxin contamination and in periparturient cows subjected to subclinical fatty liver (Tedesco *et al*., 2003, 2004a,b), in broiler exposed to dietary aflatoxin B_1 contamination (Dumari *et al*., 2014).

Basmacıoğlu-Malayoğlu *et al*. (2015) reported that milk thistle plant is possible to use as an alternative forage source in animal nutrition. But, the livestock can not directly consume the milk thistle because of their spines. Also, milk thistle is source of slowly fermentable fibre and contains high level fibrous fractions which using in ruminant feeding (Maccarana *et al.,* 2013). The most important problem in ruminant nutrition issue is the low digestibility of forages like milk thistle, which contain high amounts of fiber. To improve the digestibility, nitrogen, and easily digestible carbohydrates in milk thistle silages, molasses and urea additives are neccessary, which are proved to have positive effects, as additives on roughage forages (Yokota *et al*., 1992; Bolsen *et al*., 1996).

The objective of the current study was to evaluate the effects of the addition of 5% molasses or 0.5% urea into milk thistle on silage nutrient contents, silage quality and *in vitro* digestibility.

Materials ve Methods

Milk thistle (*Silybum marianum* L. Gaerth) was grown in the experimental site of Field Crops Department, Faculty of Agriculture, Ege University. In this trial, *Silybum marianum* L. Gaerth cv. Budakaszi (registered in Hungary) seeds obtained from Iranian Biological Resource Center were used. The experiment was set in randomized complete block design with four replications and started in 2015. Plot size was 2×3 m, inter and intra row spacing of the plants were 50 cm. Plants were harvested at the flowering stage. They were dried to approximately 40% dry matter. Silymarin content of the plants was 10.4%. The experimental treatments included: milk thistle silage with no additive (control), milk thistle silage treated with 5% molasses (control+5% molasses), milk thistle silage treated with 0.5% urea (control+0.5% urea). There were four replicates of each treatment. The milk thistle plants was ensiled in a 1 kg vacuumed nylon bag silos using a vacuum packaging machine and incubated for 60 days.

The silages were opened at the end of 60 d. The pH levels were measured immediately by a digital pH meter (HANNA HI 2211-02). The votalite fatty acids (LA, AA and BA) were determined by the Lepper method (Alçiçek and Özkan, 1996). Fleig point was calculated as described by (Kılıç, 1986).

Fleig point = 220+(2x%Dry Matter-15)–40xpH

In the silage samples prepared, dry matter (DM), organic matter (OM), crude protein (CP), ether extract (EE) and crude ash analyses were made according to Weende analyses method (Menke and Huss, 1975; DLG, 1997), acid detergent fiber (ADF) and neutral detergent fiber (NDF) analyses according to Van Soest (Goering and Van Soest, 1970). Chemical analyses were performed in duplicate.

The *in vitro* digestibility measurements were made using Ankom Daisy II method according to Damiran *et al*. (2008). *In vitro* fermentation was carried out for 48 h using the Daisy II incubator. Each incubator housed four 2-L digestion vessels. The inoculum was obtained from three rumen-cannulated lactating dairy cows that were fed 60% roughage 40% concentrated feed. Rumen fluid was collected 2 h after feed delivery into a pre-warmed thermos and strained through four layers of cheesecloth into a preheated flask. All samples were tested in triplicate. Two solutions were mixed in a 5:1 ratio, and 1.800 mL of the mixed buffer solution was added to each vessel. Vessels were placed in the incubator which was equilibrate to 39°C. The samples were weighed into the bags (triplicate per treatment) at a mass of 0.5±0.01 g per bag, sealed by an impulse bag sealer. After the incubation the filter bags were gently rinsed with cold tap water until the water ran clear and then placed in a 105°C forced-air oven to dry for 2-4 h. Feed samples were also analyzed for *in vitro* dry matter digestibility (DMD), organic matter digestibility (OMD), crude protein digestibility (CPD), neutral detergent fiber digestibility (NDFD) and acid detergent fiber digestibility (ADFD) while metabolizable energy (ME) was determined, using the OMD (NRC, 1981).

% *In vitro* digestibility= 100 – (Final bag weight –(Bag tare weight x Blank bag weight) x100
Sample weight

Digestible energy (DE, Mcal/kg) = TDN × 0.04409
ME (Mcal/kg) = DE × 0.82
Net energy lactation (NEL, Mcal/kg) = 0.0245 × TDN – 0.12

The statistical analysis of the results included one-way analysis of variance and Duncan's multiple range test, which were applied to the results using the SPSS (IBM SPSS Statistics 20.0). Probabilities of $P<0.05$ were considered statistically significant.

Results and Discussion

Data on the nutrient content, pH, volatile fatty acids and quality classify values, *in vitro* digestibility and energy value of the milk thistle silages are presented in Table 1, Table 2 and Table 3, respectively.

Table 1. Nutrient content of milk thistle silages with or without additives (DM%)

Nutrient content*	**Control**	**Control+5% Molasses**	**Control+0.5% Urea**	**SEM**	***P*-values**
DM	35.18	36.16	34.32	0.56	0.082

After 60 days of ensiling, the DM content of the silages was within the range 34.32%-36.16%. There were no significant differences between treatments regarding DM, crude ash, NDF and ADF levels (Table 1; $P>0.05$). The OM content of silages significantly decreased (-2.2%; $P<0.05$) with the addition of urea compared the control. The addition of urea significantly increased ($P<0.05$) the CP (9.29%) and EE (5.98%) contents of milk thistle silages compared with control (8.71% and 5.07%, respectively). This finding is in agreement with the findings of other researchers who reported that adding urea increases the amount of crude protein (Güney *et al.*, 2007). Similarly, Konca *et al*. (2003) and Yokota *et al.* (1992) who reported that molasses additon to sunflower silage and wilted napier grass did not change silage DM, NDF and ADF compared the control.

The changes in pH of milk thistle silage due to additives are shown in Table 2. In this research, the pH of milk thistle silage was not affected by treatments ($P>0.05$). The pH value of 5.51-5.70 obtained in this study was in agreement with 4.5-5.5 reported by Meneses *et al*.

(2007) but higher than 4.2-5.0 reported by Babayemi (2009). Similar finding was observed that urea addition to silages made of citrus peels and peanut shells and molasses addition to Italian ryegrass did not change silage pH (Hadjipanayiotou, 1988; Islam et al., 2001). Other researchers reported that adding urea and molasses or urea to the sorghum silage does increase the pH (Demirel *et al.,* 2004). According to Weinberg and Muck (1996), if forage with too high moisture content is ensiled, Clostridia fermenting lactic acid to butyric acid and amino acids to ammonia might became active, resulting in an increase in pH value and a large loss of silage dry matter.

The lactic acid contents of the silage were not affected by silage additives compared to the control (Table 2; $P>0.05$). While the acetic acid content in milk thistle silage increased ($P<0.05$) with urea addition, but the butyric acid content in milk thistle silage decreased with molasses addition. The increases in acetic acid content may be attributed to a decrease in yeasts and molds, which have the ability to assimilate organic acids. Although there are no studies in literature with milk thistle silage, in another study Singh *et al.*(1996) reported that the addition of urea to sorghum silage increases the concentration of acetic acid. In contrast to our result, Bureenok *et al.* (2012) reported that lactic acid content is very high in the Napier grass silage with additional molasses. The evaluation results showed that silages with or without additives were 'fair-quality'. Milk thistle has needle sharp spines on all parts of the plant. Therefore chopping and pressing should be done very well in the silage making process.

The OMD of the milk thistle silage treated with molasses (33.89% vs 30.31%) was higher than that of control (Table 3; $P<0.05$). There were no significant differences between the control and control+0.5% urea with respect to OMD ($P>0.05$). Also, the addition of molasses or urea to milk thistle silage significantly increased ($P<0.05$) the CPD compared the control. On the other hand, NDFD of the silage with additives were lower than control ($P<0.05$). The additives did not affect the DM and ADF digestibility of the silages (Table 3). The energy value of DE, ME and NEL value (1.42 Mcal/kg, 1.17 Mcal/kg and 0.67 Mcal/kg, respectively) the milk thistle silage treated with molasses was higher than that of control (1.27 Mcal/kg, 1.05 Mcal/kg and 0.59 Mcal/kg, respectively) ($P<0.05$). Similarly to this study, use of urea as silage additive to sorghum silage did not accelerate OMD of the silages (Güney *et al.*, 2007). In another study (Bureenok *et al*., 2012), the in *vivo* OM, CP and NDF digestibility of the Napier grass (*Pennisetum purpureum*) silage treated with molasses was higher than the silage without additives. Arbabi and Ghoorchi (2008) reported that addition the molasses to foxtail millet silage increases the ME, compared to the control group, which is the same in this research.

Conclusions

In conclusion, milk thistle silage with or without additives are fair-quality. The addition of urea to milk thistle improved the CP and EE content and CPD of the silages. The addition of molasses improved the *in vitro* digestibility of OM and CP and energy values of the silages. The addition of molasses or urea to milk thistle could be evaluated with regard to nutrient digestibility.

MOLECULAR DETECTION OF PROTOZOAN PATHOGENS IN COMMERCIAL BUMBLEBEE (*B. terrestris* L.)

Bahar ARGUN KARSLI*, Fehmi GÜREL

Faculty of Agriculture, Department of Animal Science, Akdeniz University, Antalya, Turkey
*Corresponding author: bhrargun@akdeniz.edu.tr

Abstract

Bumblebees are important pollinators of greenhouse and field crops. They are therefore reared commercially on a large scale. *Bombus terrestris* is the most reared bumble bee species for commercial pollination since 1987 and has been used outside its natural distribution area. Commercially produced *B. terrestris* colonies often have higher levels of pathogens than wild bumble bee populations. These pathogens can spread to wild bees and may lead to decline in wild bee species. The most commonly reported bumblebee protozoan pathogens are the microsporodium *Nosema bombi, Crithidia bombi* and *Apicystis bombi.* These parasites have also detrimental effects on colonization, survival and reproduction of *B. terrestris* queens. Therefore, the correct identification of *B. terrestris* parasites is very important. Nowadays, in order to identify infected bumblebees, various molecular methods have been developed to provide highly sensitive, reliable and fast results. In this study, a total of 130 *B. terrestris* queens who died in the colony initiation period after diapauses were obtained from the commercial company. DNA was extracted from bumblebee gut tissues using a modified Chelex 100 method. ITSf2/r2, Nbombi-SSU-Jf1/Jr1 and SSU-rRNA-Ff1/Rr1b primer pairs for *N. bombi*, SEF/SER, CB-ITS1-F / CB-ITS1-R primer pairs for *C. bombi* and NeoF/NeoR, ApBF1/ ApUR2 primer pairs for *A.bombi* were tested by PCR amplification, but these parasites were not detected in the examined samples. In conclusion, more samples should be investigated to detect infected bumblebees with *N. bombi, C. bombi* and *A. bombi.*

Keywords: *Bumblebee, PCR, Nosema bombi, Crithidia bombi, Apicystis bombi*

Introduction

Bumblebees are among the most important natural pollinators in northern temperate and may provide superior pollination services than the honeybees for many plant species. There are about 250 species of bumble-bees (Williams, 1998). Currently five species of bumble-bees (*Bombus terrestris, Bombus lucorum, Bombus occidentalis, Bombus ignitus* and *Bombus impatiens)* are reared commercially on a large scale mainly for greenhouse pollination in many countries (Velthuis and van Doorn, 2006). The main commercially reared species is the Eurasian *Bombus terrestris* L. Commercial rearing of bumble bee colonies for pollination services first started in the 1980s. Today, it is estimated that the current worldwide sales of commercially produced bumble bee colonies has reached over one million colonies per year and has been used as pollinator of many crops mainly in tomatoes (Banda & Paxton, 1991; Velthuis and van Doorn, 2006).

Bumblebees are also important natural pollinators for a wide range of wild plants. On the other hand in recent years, the natural abundance and diversity of bumblebee species is in decline all over the world (Goulson, 2003). This decline may lead to severe effects on natural populations of flowering plants and agricultural production (Memmott *et. al.*, 2004). There are many factors regarding the causes of bumblebees decline such as climate change, habitat fragmentation with diminished floral resources and pathogens. The most important of these factors is considered as pathogens (van Engelsdorp *et. al*., 2009; Cameron *et. al*., 2011).

Pathogens play a role in the decline of bumblebee species and can also affect the ecology and distribution of bumblebees (Schmid-Hempel, 2001; Cameron *et al*., 2011). Pathogens have also caused economic losses in commercially managed bumble bees populations. Commercially reared bumblebee colonies can function as parasite reservoirs, which can lead to the spillover of pathogens to wild bee species. They are able to interact with wild pollinators, since commercially reared bees often escape from greenhouse to wild. A recent report by the National Academy Sciences stated that, a possible cause of bumble bee declines is pathogen spillover from commercially reared bumblebee colonies. Therefore, pathogens loads of commercially reared bee colonies could be important for wild bee species.

Many methods have been developed for the diagnosis of microsporidia in hosts, including immunofluorescent staining, electron microscopy, and antigenic or biochemical analysis (Weber *et. al*., 1999). Molecular techniques, particularly involving the PCR and the based on the amplification of rRNA and rDNA gene fragments, seem to be superior because of their high specifity and sensitivity (Weiss and Vossbrinck, 1993) as well as their ability to detect all microsporidian developmental stages. Here, we used a rapid, specific and sensitive method for the detection of *N.bombi, C.bombi* and *A. bombi* in commercial reared *B. terrestris* by PCR amplification.

Bumble-bee parasites and diseases

Natural and commercially bumblebee colonies are exposed to many pathogenic internal and external parasites. The most commonly reported bumblebee protozoan pathogens are the microsporodium *Nosema bombi, Crithidia bombi* and *Apicystis.* Generally, these parasites have detrimental effects on colonization, survival and reproduction. Therefore, the accurately identification and control of bumble bee diseases and parasites are very important.

Nosema bombi Fantham and Porter 1914 is obligate, intracellular and spore forming microsporidian parasite that infects the Malpighian tubules, the ventriculus, the fat tissue and and even nerve tissues, including the brain of bumble-bees (Larsson, 2007). The effects are generally chronic, including reduction in individual reproductive rate (Otti and Schmid-Hempel, 2007, 2008), life span, and colony growth (Rutrecht and Brown, 2009).

Crithidia bombi is extracellular trypanosomatid parasites and it is a widespread parasite of bumble-bees. This parasite targets the gut and results in large numbers of parasite cells lining the wall of the midgut lumen and rectum from where cells are shed for further transmission (Schmid-Hempel, 1998). Replication of *C. bombi* in the host is rapid but the effects on individuals are usually complicated, such as decrease pollen loads carried in foraging trips, variation in foraging behavior and increase ovaries development in workers (Otterstatter and Thomson, 2006). Furthermore, on the colony level, *C. bombi* leads to decrease colony growth rate and colony fitness (Brown *et. al*., 2003).

Apicystis bombi, first discovered in Italy in 1988, *is* a neogregarine parasite and has now been recorded in nearly 20 bombus species (Lipa and Triggiani, 1992; 1996) and commercially produced bumble-bee colonies (Murray *et. al.*, 2013). The fat body of infected bumble-bees is destroyed due to the proliferation of the pathogen, and its presence correlates with high mortality in infected spring queens, preventing them from establishing colonies (Rutrecht and Brown, 2008). Therefore, the potential spread of the neogregarine *A. bombi* should be carefully monitored.

Materials and Methods

Samples

We were collected 130 bumblebee queens from commercially produced Bombus *terrestris* colonies in different nests in order to investigate the occurrence of pathogenic diseases in august 2014. Samples of queen who died in the colony initiation period after diapauses were

obtained from the commercial company. All samples were stored in 95% ethanol at -20 ºC until DNA extraction.

DNA extraction

Genomic DNA of bumblebee was extracted from infected intestinal tissues using a modified Chelex 100 method (Walsh *et. al*., 1991). All intestinal tissues of bumble-bee were put into large centrifuge tube. First, 800 µl 10% Chelex resin solution was added and completely crushed with sterile plastic types. Second, 10 µl Proteinase K (20 mg/ml) was added in each tube and vortexed. The sample was incubated at 56 ºC for 4 h, followed by 95 ºC for 15 min to denature enzymes. Samples were centrifuged (2 min, 12.000 g) and the supernatant was stored at -20 ºC until needed as DNA template in PCRs.

Primers

rRNA primers of *Nosema bombi* were designed on conserved rRNA regions of microsporidian species. *Crithidia* and *Apicystis* primers were designed from the 18S rDNA sequences. An internal amplification control was designed; different 18S rDNA sequences Apidae species. (Table 1).

Polymerase Chain Reaction (PCR)

PCR reactions were performed using a TC3000 (Techne) in 50 µl volume containing 5.0 µl of template DNA, 4 µl of 10x PCR buffer, 4 µl of $MgCI_2$, 2 µl of dNTPs, 0.2 µl of Taq polymerase and 0.25 µl of each forward and reverse primer, plus 34.3 µl of water. PCR parameters for amplification were as follows: initial DNA template denaturation at 95 ºC for 4 min, 40 cycles of denaturation at 95 ºC for 1 min, primer annealing at the primer specific temperature (Table 1) for 1 min and primer extension at 72 ºC for 1 min, followed by a final extension at 72 ºC for 5 min. Then 10 µl of the PCR products were resolved on % 1.5 agarose gels (1x TBE) and visualized by ethidium bromide staining. For each PCR experiment,

negative (water) and positive (previously identified positive sample) controls were run along with treatments.

Results and Discussion

We collected and analysed a total of 130 commercial *B. terrestris* queens in order to detect of microsporidia. Currently, many different primer pairs are available for the detection of *N. bombi, C. bombi* and *A. bombi* in host gut tissues. We tested seven different primer pairs (Table 1) but it did not happen in any amplification. The amplification occured only in the positive controls and Apidae primers.This result was mainly due to the small number of samples used in this study. Indeed, the number of samples used in previous studies was greater than 130. For example, Cordes *et al* (2012) analyzed 9909, Li *et al* (2012) 1009 and Blaker *et al* (2014) 1036 bumblebee samples. Therefore, it can be conclude that more samples should be used to analyses.

Tay *et al* (2005) characterized the entire rRNA gene of a *N. bombi* from 11 isolates in 8 different European *Bombu*s species using 9 primer pairs including ITSf2- ITSr2 and SSU rRNA Ff1-Rr1b. Li *et al* (2012) screened a large sample of workers of 27 different Bombus spp. using SSU rRNA Ff1-Rr1b primer pairs in China and found that 13 different *Bombus spp*., approximately half of the examined species, carried microsporidia. In North America, nearly 10,000 samples of 36 bumblebee species were collected and evaluated for the presence and prevalence of two *Bombus* pathogens, the *N. bombi* and *Crithidia* (Cordes *et. al.*, 2012). In this study, widely used primer sequences were tested.

PCR, qPCR and multiplex PCR based methods were developed for the specific and sensitive diagnosis of the microsprodian parasites in bumble bees. Klee *et al* (2006) conducted the first study of the specific and sensitive molecular diagnosis of *N. bombi* in bumble bees. To detect *N.bombi*, they used primer pair Nbombi-SSU-Jf1/Jr1, which amplifies partial SSU rRNA of the *N.bombi* genome. This primer pairs seems to be specific for *N.bombi.* Primer pair ITS-f2/r2 was extremely sensitive (as few as 10 spores per 100 µl homoganete**)** in the detection of *N. bombi* spores. This work is similar to the first comparative quantitative real-time PCR study of nine *Nosema spp*. primers within the framework of primer specifity and sensitivity (Erler *et. al.*, 2012). Another study was performed by multiplex PCR method. Meeus *et al* (2009) were reported the development of a multiplex PCR using two broad-range primer pairs for PCR- based protozoa detection including a universal Apidae control. In this study, SEF-SER, NeoF- NeoR and ApBF1- ApUR2 primer pairs were used for detection *C. bombi* and *A. bombi*, respectively.

Conclusion

In conclusion, PCR- based molecular methods and primers should be continuously developed and tested. Also, the screening of parasite in natural and commercial reared bumblebees should be done regularly.

Acknowledgment

NATIVE DOG BREEDS OF TURKEY

Orhan YILMAZ

Ardahan University, Vocational High School of Posof, 75500, Ardahan, Turkey.
*Corresponding author: zileliorhan@gmail.com

Abstract

This paper describes eleven such, five of which are molossers, one is a sighthound, two are scenthounds, one is watch dog and two are small Spitz types. Two of the molossers (Kangal and Akbash) have local breed societies or associations and are well known and have breed societies internationally but are not recognized by the Fédération Cynoloqique Internationale (FCI). One molosser (Kars) is registered by the Turkish Standards Institute and another (Koyun) has been recently identified. Karaman is another molosser type dog and has been identified yet. The sighthound (Tazi) is similar to other Near and Middle East greyhounds. The scenthound (Tarsus Catalburun also known in English as Fork-nose and Turkish Pointer) is little known outside Turkey but is celebrated in its home area for its skills and is finding employment as a sniffer dog for narcotics, explosives and live and dead people. The other scenthound of Turkish Chaser Dog of Zagar is the last registered dog breed by the Turkish Standards Institute. The Spitz-type (Dikkulak and Fino of Tonya) is employed mainly as a household guard dog as are two other breeds of indeterminate type. Zerdava dog is a watch dog and locally bred in northeast of Turkey.

Keywords: Working dogs, morphometry, breed societies, animal legislation, welfare

Introduction

Situated at the junction of Europe and Asia, Turkey is a geographic bridge that has been traversed by traders, travellers, treasure seekers and trespassers for thousands of years. It is thus also a cultural bridge imbued within the DNA of many civilizations. Because of such history, Turkey is a repository of a rich array of domestic livestock resources that includes animals for food, for work and for companionship. The present day inhabitants of modern Turkey arrived in the country with the expansion of the Turkic Empire out from Centra Asia in the middle of the eleventh century. They travelled with their herds and flocks and were accompanied by the guard dogs that protected these livestock and the present day inhabitants of modern Turkey arrived in the country with the expansion of the Turkic Empire out from Centra Asia in the middle of the eleventh century. They travelled with their herds and flocks and with the guard dogs that protected these animals and hunting dogs that assisted in the search for food. In the one thousand years since the Turkish arrival in Asia Minor and Thrace several dog breeds have developed. Whilst Turkish hunting dogs are analogous with those of much of Europe the "shepherd" dogs of Turkey are guard dogs bred for and trained to protect the flocks and not to control the sheep. This review is part of a series of papers that will eventually cover most species of domestic livestock in Turkey (Wilson et al 2011, Yilmaz et al 2011a, 2011b, 2012a, 2012b, 2012c, 2012d). The paper builds in part on an earlier review (Reed 1996) but provides information breed organization, registration and welfare in addition to describing and providing other information on ten identified types of which five are molossers, one is a sighthound, one is a scenthound and one is a Spitz type.

Breeds

Turkish Kangal (Karabash) Shepherd

It is believed that the Kangal, a molosser flock guard dog, is believed to have originated in Central Asia (Kirmizi 1994, Yilmaz 2007a, 2007b, Derbent and Yilmaz 2008, Yilmaz 2008) and is genetically distinct from other Turkish dogs (Altunok et al 2005). The Kangal dog has historically been associated with the town of Kangal - a district town in Sivas Province in eastern Anatolia where Akkaraman sheep production is an important activity -- but Kangal is not the original name of this breed but came into use in Turkey via discussions at the United Kingdom's Kennel Club in the 1970s (Broadhead 2003, Reed 2003). The original name of Karabash (Dikmen 1936, Tellioglu 1973, Oncul 1983) means blackhead in Turkish and derives from the black muzzle (Figure 1). The Kangal can withstand the extremes of the cold harsh climate of its homeland. Courage, faithfulness and sensitivity are the foremost characteristics of the breed. It is a fearless and capable protector of its own flock, herd and its human family with whom it forms bonds yet it is a formidable fighter against large dogs and other predators (Pugnetti 2001, Kazak and Bakir 2002, Derbent and Yilmaz 2008, Yilmaz 2008).

The Kangal has a strong, sturdy body with a black mask and muzzle and black around the ears and around eyes. The tail hangs low and has a slightly upward and forward curl (Gulec 1996, Galand 1997, Yesilyurt 1999, Kartay 2002, Yilmaz 2007a, 2007b). The true Kangal dog colour is solid dun or slightly paler shades of fawn or cream but never snow white ('boz' in Turkish) (Robinson 1989, Yilmaz 2007a, 2007b). Colour is an important breed trait and in Turkey non-standard colours or patterns are indicators of outside blood (Yilmaz 2007a, 2007b, Derbent and Yilmaz 2008, Yilmaz 2008). The dense double coat is moderately short. Average mature live weights are 47.6 kg for males and 43.5 kg for females with shoulder heights of 75.9 cm for males and 73.3 cm for females (Yilmaz 2007a).

The Kangal was registered with the Turkish Standards Institute as Notification Number 11172 in 1997 (Anon 1997b). It is supported nationally by Coban Kopegi Irki Dernegi (Kangal Dog Club of Turkey) and government and academic institutions operate kennels where Kangal dogs are bred and pedigrees are carefully maintained. Its iconic status is confirmed by its appearance on a Turkish postage stamp. Outside Turkey there is the Kangal Dogs International the breed is supported in the UK by the Kangal Dog Trust. Kangal dogs are recognized by the Kennel Club of the United Kingdom, the United Kennel Club of the USA and by the national kennel clubs of South Africa, New Zealand and Australia. The first Kangal litter was born in the United Kingdom in 1967 and purebred programmes were established in the USA in the 1980s. Kangals are bred in Germany mainly by immigrant Turkish workers and are registered as Anatolians but most are unregistered. There are Kangal clubs or breed societies in Belgium, Bulgaria, France, the Netherlands and Sweden (Yilmaz and Ertugrul 2011c, Yilmaz 2007b). In Namibia, where Kangals are used to guard sheep flocks, almost 300 Kangals have been given to farmers by the Cheetah Conservation Fund since 1994 (Anon 2010). The Turkish Kennel Club is petitioning the FCI for recognition of both the Kangal Dog and the Akbash Dog.

The Akbash (Figure 2) is another molosser that is widely used as a flock guardian dog. The origin of this ancient breed is unclear but it is believed that, as for the Kangal, it originated in Central Asia. In Turkey the breed is now mainly found in plains and mountains of Ankara, Afyon, Eskisehir and Konya Provinces which is known as the Salt Lake Plateau (Yilmaz 2007b, Yilmaz 2008).

Turkish Akbash Shepherd

Akbash translates as "white head" and the main colour is a solid milk white (Qadiri 1998, Sims 2006, Yilmaz 2006, 2007a, 2007b, Derbent and Yilmaz 2008, Yilmaz 2008). Purebred Akbash are free of pinto, skewbald and brindle markings or other indeterminate colours although a cream stripe from the ears to the rump is acceptable. Compared with the fawn coated Kangal, the Akbash has a more refined appearance with a pointed muzzle and a softer coat with medium to long. Weight and height at the shoulders are similar to or slightly less than the Kangal with a mean weight of 44.9 kg and shoulder height of 75.3 cm (Yilmaz and Ertugrul 2012a). The Akbash has a natural protective instinct and is equally as brave and faithful as the Kangal and possibly even more so in fighting with predators. Temperamentally it is calm, quiet, alert, courageous and independent. It is a very agile dog capable of jumping over obstacles as high as a man. Great stamina is coupled to great speed (Anon 1997a, Kartay 2008, Yilmaz 2008).

The Akbash was registered with the Turkish Standards Institute as Notification Number 12891 in 27.11.2002 (Anon 2002a). Akbas Coban Kopegini Koruma ve Arastirma Dernegi (AKAD) (Akbash Shepherd Dog Conservation and Research Association) is the effective breed society in Turkey. It has links with and a representative on the board of Akbash Dogs International in the USA which is the successor to the North American Akbash Dogs Club. There are also members of Akbash Dogs International in Canada and the Netherlands.

Kars (Caucasian) Shepherd

This regional breed (Figure 3), another molosser type, was first defined 1996 (Nelson and Nelson 1996). It has several alternative names including 'Killi' (shaggy) in Ardahan, Erzurum and Kars Provinces, 'Sacakli' (fringed) in Ardahan Province and 'Tuylu' (hairy) in Artvin Povince (Yilmaz 2008) and these localities are its main areas of distribution but it also extends to Igdir Province (Yilmaz 2012b).

In appearance the Kars resembles the Caucasian Ovcharka (Mountain Dog). Its coat exhibits many colours and patterns. Colours include black, reddish brown, agouti, grey, mixtures of black and brown, white, piebald and white with grey patches. White markings are very common in otherwise solid colour dogs. Also common are white forequarters, chests and neck collars. The head is usually dark. The usually long coat – there are some short-coated dogs – is important under severe winter conditions but when it is shed it gives the dog a dishevelled motley appearance. The hairs on the neck and the back of the hindquarters are long and this mane makes it appear larger from the front. The Kars is a somewhat smaller dog than either the Kangal or the Akbash with a mean weight of 44.6 kg and a mean height at the shoulder of 72.4 cm (Kirmizibayrak 2004, Yilmaz 2012b). Local anecdotes relate that a small group of Kars can cope with and even kill a smaller-sized bear. In general the Kars is a "one-man dog" but it an ideal courageous and faithful guard dog (Yilmaz 2006, 2007a, 2007b, 2008).

The Kars has a breed standard provided by the Turkish Standards Institute as Notification Number 12892 in 27.11.2002 but this seems unreliable in some respects and especially for weight (Anon 2002b).

Rize Koyun Shepherd

Newly described (Yilmaz and Ertugrul 2012b) from Rize Province on the eastern shore of the Black Sea in northeast Turkey the Rize Koyun (Figure 4) is a flock and herd guardian dog of molosser type. Koyun dogs are also present in Ordu Province to the west of Rize.

The dog is met in various colours but dark grey is the most common. Bi-coloured animals also occur. Rize Koyun dogs have a solid body structure and strong legs which make for easy traverses of the hilly areas of the Canik Mountains where they are found. The tail is normally pendent but is raised in an alert posture up. Shoulder heights of dogs are about 70 cm and

those of bitches about 1-2 cm lower. The Rize Koyun is not a pet and in addition to guardian duties it assists its human owners in giving vociferous or even physical warning of the presence of intruding people or animals (Yilmaz and Ertugrul 2012b).

Karaman Shepherd

Found mainly in Karaman, Konya and Aksaray Provinces in Central Anatolia where the herding of Akkaraman sheep is widespread the Karaman (Figure 5) is Turkey's fifth type of molosser flock guardian dog. In some respects the breed resembles the Kangal (Karabash) type but the Karaman occurs in many different coat colours. It has a sturdy body constitution and strong legs and is adapted to the harsh climate and geographic conditions of Central Anatolia (Yilmaz 2007a).

The Turkish Tazi (Figure 6) is a classic sighthound-greyhound that is generally concentrated in Konya Province in Central Anatolia and in Sanliurfa Province in Southeast Anatolia. There are smaller numbers in Igdir, Kars, Karaman, Ankara and Istanbul Provinces (Yilmaz and Ertugrul 2011a). It is asserted that the Turkish Tazi is descended from the Kirghiz Taigan and was brought to Anatolia by Turks during the Great Migration (Yilmaz 2008). It also resembles but is larger than the Saluki. The breed is historically better documented than many other Turkish breeds despite being fewer in number (Yilmaz 2007a, Yilmaz 2007b). One of Sehzades (Sultan's son) of Sultan Suleiman (King Solomon) the Magnificent in hunting with greyhounds was illustrated in a miniature dated from the 16th Century (Yilmaz 2008).

Turkish Tazi (Sighthound)

The Turkish Tazi possesses long forequarters and hindquarters, a slim body, a thin tail without hairs, a long and slender skull, a long neck, deep chest and a flexible and curved spine. Coat colour is very variable with black (35.2 per cent), being most common followed by dun (25.4 per cent), brown (12.3 per cent), tan (10.7 per cent), white (8.2 per cent) and pied (8.2 per cent). Body weights are about 18. 4 kilograms and height at shoulder about 62 cm (Yilmaz and Ertugrul 2011a.). These dogs are reared for their superior skills, mainly in wetlands in Central and South Anatolia, in hunting quail, partridge, rabbits and foxes for detecting and bringing back the prey shot [they hunt prey by running/chasing them down] (Yilmaz 2007a, Derbent and Yilmaz 2008, Yilmaz 2008). The Turkish Tazi is extremely fast (speeds of up to 65 km/hr over 1 km) it is not hyperactive (Serpell 1996, Palika 2007, Yilmaz 2008). The Tazi makes a good pet because of its loyal, mild and affectionate character and gets along well with children and other family pets including cats. The thin coat renders the Tazi susceptible to cold weather and, as with greyhounds elsewhere, most owners cover their dogs with a rug in winter (Anon 2002c, Yilmaz 2007a, Yilmaz 2008).

Tarsus Catalburun (Fork-nose)

The Catalburun (Figure 7, Figure 8) is the only recognized scenthound in Turkey. In English it is known as the Tarsus Fork-nose dog and sometimes known as the Turkish Pointer. The breed is mainly located in Icel Province in the extreme south of Asian Turkey in the Mediterranean Region (Dinçer 2006, Yilmaz 2007a, Yilmaz 2007b, Yilmaz 2008, Yilmaz and Ertugrul 2011d, Yilmaz 2012d).

The Catalburun has a fully split nose, essentially resulting in a double nose, that is quite a rare feature in dog breeds and arises from the nostrils being separated vertically by a band of skin and fur dividing the nose all the way to the upper lips. The hair is short and thee coat is of various colours, brown being the most common (52.7 per cent) followed by brown and white (23.6 per cent), black and white (14.6 per cent and black (9.1 per cent). Live weights average 21.7 kg and height at shoulders 48.5 cm (Yilmaz and Ertugrul 2012c). In the Catalburun dogs

the live weight was 21.7 kg, and height at shoulders was 48.5 cm (Yilmaz and Ertugrul 2012c). The Catalburun has a very acute sense of smell that is arguably heightened by the peculiar nose structure and is therefore particularly good at hunting by scent and indicating the prey as a pointer dog. In addition to traditional hunting the Catalburun is being increasingly used by the police as a sniffer dog for narcotics, explosives and for finding living and dead people. The dog tends to be hunted as a singleton rather than in couples or packs. Catalburun dogs are very friendly and get along well with humans in addition to other dogs but are not suitable as pets in confined spaces as they prefer lots of space (Dinçer 2006, Yilmaz 2007a, 2007b).

Dikkulak (Erect-ear)

The Turkish Dikkulak (Erect-ear) dog (Figure 9) is a typical Spitz type of small compact body size with erect ears. It is also variously known as 'dikkulak' (erect ear), 'çivikulak' (nail ear) and 'zagar'. Dikkulak dogs are raised in the same area as the Kars Dogs in Agri, Ardahan, Erzurum, Igdir and Kars Provinces. In appearance the Dikkulak resembles the Pembrokeshire Welsh Corgi (Yilmaz and Ertugrul 2011b) that is beloved of Her Majesty Elizabeth the Second, by the Grace of God of the United Kingdom of Great Britain and Northern Ireland and of Her other Realms and Territories Queen, Head of the Commonwealth, Defender of the Faith".

The coat colour is variable with some 29.5 per cent being white, 23.0 per cent black, 19.7 per cent brown and white, 18.0 per cent brown and 9.8 per cent tan. Live weight averages 10.6 kg with the height at the shoulder being 27.8 cm (Yilmaz and Ertugrul 2011b). Spitz types were originally bred as cattle dogs but in Turkey the Dikkulak is used as a small size watch dog. Although incapable of attacking or restraining intruders they bark loudly to alert their owners of unwarranted intrusion. In its watchdog role the Dikkulak is either tethered or allowed to run loose in an enclosure area (Yilmaz 2008).

Turk Izci Kopegi Zagar (Turkish Chaser Dog fo Zagar)

Zagar (Figure 10) is also called as Kopay, Kopoy, Tavsanci (Hare hunter), Izsüren (Chaser), Cakir. It is bred by Yoruk people in region of Thrace and provinces of Bursa, Manisa, Izmir, Aydin, Denizli, Mugla and Afyon. This dog is especially used for hare hunting. Coat colour is generally black or brown. It is a smart, loyal and energetic dog breed. It is resistance against bad management and feeding. Height at withers is about 52.2 cm for male and 48.8 cm for female. Live weight is 19.5 kg for male and 17.6 kg for female (Anon 2012).

Zerdava (Kapi)

The Zerdava (Figure 11) is bred in provinces of Trabzon and it's around (pers. observ.). There is lack of information about Zerdava's history. Some owners claim that this breed originally came from Georgia. It was bred in province of Artvin, and later than it was spreaded to other provinces of Giresun, Rize and Trabzon (pers. commun.). The Zerdava has a unique colour pattern. The base colour is dark or liver brown but the chest, legs and point of tail are white with small dark spots. The white-coloured and spotted area around the neck is called 'peskir' (can be translated in English as hand towel) and the small dark spots themselves are known as 'pul' (stamp pattern). The eyes are yellowish-brown rather than brown. Shoulder height averages 51.2 cm (Yilmaz 2012c). The Zerdava was originally a hunting dog for smaller prey and vermin such as wild pig, foxes and jackals but its principal role in the twenty-first century is as a watch dog. The dog is brave, energetic and agile dogs and according to Zerdava owners they will pursue a lure for several days.

Zedava dogs are themselves hunted by wolves which may account in part for declining numbers in recent several years (pers. commun.).

Fino of Tonya (Kobi)

There is lack of information about history of Fino of Tonya (Figure 12), but some owners claim that origin of this dog came from Ukraine by sailors (pers. commun.). Actually Fino of Tonya closely resembles to spitz type dogs such as German White Spitz, Japanese Spitz, and Volpino Italiano. White is the only colour of this dog. The shoulder height is about 31.1 cm, height at rump 30.1 cm, and weight is about 9.7 kg. Mainly kept as a vociferous watch dog and suspicious of intruders it is nevertheless playful, energetic and friendly to children (Yilmaz 2012a).

Conclusin

The Kangal and the Akbash are the two major dog breeds of Turkey. Not only are they widespread in the country but also elsewhere in the world where they continue to be used as guard dogs in addition to their new role as "fashion accessories". None of the other breeds is widespread within Turkey and they are generally little known outside the country. Turkish dog owners complain that local breeds are in constant decline and this anecdotal evidence is supported by the records of the Turkish Dog Federation in which only two of 21 member associations are of native breeds. The Turkish Dog Federation is, however, providing support to nascent groups of owners who wish to promote local breeds. Three breeds of dogs have been registered with the Turkish Standards Institute but in general there is little Government (at either national or regional level) support for dog breeding although support is provided for other domestic animal species through its "In Vitro Conservation and Preliminary Molecular identification of some Turkish Domestic Animal Genetic Resources (TURKHAYGEN-I)" (Arat 2011). There are possibilities that an extension of TUKHAYGEN into a second phase will include some dog breeds but most support will need to come from the private sector as breeders groups and as individuals. As household incomes in Turkey are likely to rise in the future and aspirations for a more "modern" lifestyle increase the prognosis for important cultural and genetic resource that is the dog is not too negative.

Abstract

Honey bee (Apis mellifera L.) provides honey and honey products which contribute to a healthy diet to human. Honey bees are common live social insects which are called as colony. They provide 85% of pollination among whole pollination of the World. From this side honey bees are crucial for maintaining of nature life. Anatolia which is Asian part of Turkey is one of the most important bee husbandry centre which is origin of several bee breeds. Those breeds are Anatolian Bee (Apis mellifera anatolica Maa, 1953) which is the most common breed, Caucasian Bee (Apis mellifera caucasia Gorbachew, 1916), Armenian Bee (Apis mellifera armenica Skorikov, 1929), Persian Bee (Apis mellifera meda Skorikov, 1929), and Macedonian Bee (Apis mellifera macedonia Ruttner, 1988). In this review morphology, biology, colony structure and social life of honey bees which live in Turkey were summarized.

Key words: *Apis mellifera anatoliaca*, native breed, genetic resource, genetics, morphology.

Introduction

Anatolia which is Asian part of Turkey is one of the most important bee husbandry centre in the World and it is origin of Anatolian Bee (Apis mellifera anatolica Maa, 1953) and Caucasian Bee (Apis mellifera caucasia Gorbachew, 1916) (Guler, 2009). Common Honey Bee (*Apis mellifera*) (Table 1) is also domesticated B.C. 5.000 in Central Anaolia (Arslangundogdu, 2011). Turkey has a great advantage of beekeeping potential because of available natural conditions, proper climate and rich flora. Especially beekeping is available between April and September in the most part of Turkey (Sirali, 2002). In the long history, human used numerous kinds of insects for them such as honey bees. Turkey is like a bridge between Asia and Europe. Hence Turkey includes various kinds of climate, habitat and geographical conditions which is origin of numerous kinds of vegetable and animal species.

Table 1. Scientific classification of the honey bee (Akbay 1982).

Phyluym	*Artropoda*
Class	*Insecta/Hexapoda*
Ordo	*Hymenoptera*
Subordo	*Apocrita*
Super Family	*Apoidea*
Family	*Apidae*
Genus	*Apis*
Species	*A. mellifera L. 1758*

(Nalbantoğlu, 2009). Honey bees contributed to plants to give more yield. For example the benefit obtained from the pollination of flowers is 6-10 times more than the benefit obtained from honey harvest (Kansu 1994, Arslangundogdu 2011). There is a reciprocal indispensable

relationship between plants and bees which plants need bees for pollination, on the other hand bees need pollination for feeding (Yuce 2011). Aim of this paper is to review honey bee biology in Turkey under perpective of genetics, morphology, biology, and pathology.

Genetics

Among honeybees there are variation about Mitochondrial DNA which provides to be determined different breed groups. The first group is called as Western (or 'W'). Western and northern European populations are in this group such as *A. m. mellifera* and *A. m. iberiensis*. The second group can be called as Eastern (or 'C') and southeastern European plus northern and eastern Mediterrenean populations are in this group such as *A. m. carnica, A. m. ligustica, A. m. caucasia,* and *A. m. anatoliaca*. North and south of the Sahara populations in Africa consist of the group African (or 'A'). *A. m. capensis, A. m. intermissa, A. m. litorea, A. m. monticola, A. m. sahariensis,* and *A. m. scutellata* are in the group 'A'. The last group was discoverd recenlty and called as Middle Eastern (or 'M'). *A. m. syriaca* is in this group 'M' (Smith 2002, Kence 2006). In a study six enzyme systems were studied to investigate the genetic variability in honeybee populations in Turkey. 10 morphometric characters were also measured to determine the extent of morphometric variation. Out of six enzyme systems, four were found to be polymorphic with 16 allozymes. In thepopulations the average heterozygosity was calculated as 0.072 ± 0.007. Morphometric and electrophoretic variables were equally effective in discriminating honeybee populations. Anatolian and European honeybees were separated on the first axis, and Anatolian honeybees were further separated along a second canonical axis. The observation of rare alleles in isoenzymes, detection of high genetic diversity and the presence of four known subspecies supported the argument that Anatolia had been a genetic center for honeybee populations in the Near East (Kandemir et al. 2000). In a research study the Central Anatolian honeybees (*A. mellifera L.*) were electrophoretically examined at six enzyme loci. Although four loci were polymorphic (Est-3, Pgm, Hk, and Mdh) and two loci were found to be monomorphic (Pgi and Me). Genotypic frequencies of enzymes agreed Hardy-Weinberg expectations. Low levels of genetic variability were detected. Heterozygosity was calculated as 0.033 ± 0.005. Gene frequencies gained for Pgm, Est, Hk and Mdh were compared with those of the studies carried out in other countries, especially in neighboring countries (Kandemir and Kence 1995).

Morphology and Biology

Enzyme polymorphism was investigated in honey bees which were collected from four different Anatolian regions. Three enzyme systems were analyzed and results showed that malatedehydrogenase and malic enyzme systems were monomorphic in all populations, but Esterase enzyme system was found to be polymorphic only in West Anatolia (Asal et al. 1995). In a study general protein (P-3) system was searched in 15 honey bee (*A. mellifera L.*) colonies from 3 different localities. Horizontal starch gel electrophoresis was performed on dark-eyed pupae (13-19 days old) using Poulik's (1) discontinuous buffer system. The frequencies of P-3F allele in three apiaries were 0.658, 0.333 and 0.442 (Yildiz and Asal 1996).

Some ecotypes and crossbreeds were investigated in Beypazari and Tokat regions. According to results the following means were gainend: 6.62±0.008 mm for proboscis length, 0.36±0.002 mm for length of cover hair on tergite 5, 9.15±0.014 mm for wing length and 3.13±0.007 mm for the width, 4.38±0.004 mm for width of tergite 4, 4.40±0.114 pigmentation on tergite, 2.12±0.028 for cubital index, 34,21 for forewing index and 56.47 for metatarsal index (Karacaoglu and Firatli 1998). In a field study a total of 42 honey bee colonies collected from 5 apiaries at 4 different localities in the Central Anatolia and breeder stock of Turkish Development Foundation (Turkiye Kalkinma Vakfi) was searched to define some

morphologic traits in ecotype of Central Anatolia and breed of Caucasian Bees. As a result 32 morphological characteristics were determined for the Central Anatolian ecotypes (*A. m. anatoliaca*) obtained from Kirsehir, Beypazari, Cankiri and Eskisehir and for the Caucasian breed (*A. m. caucasica*). In additional 25 workers from each colony of Central Anatolian ecotypes and Caucasian race constituted two distinct groups. The Central Anatolian ecotypes formed an intermingled cluster when individual bee values were considered whereas colony averages made possible the discrimination of the regional population into corresponding ecotypes. According to analyses results the 57.62 % of the individual bees and 97.62 % of the colonies were included in their own groups. In conclusion, it was clearl that Central Anatolia with its natural advantages preserved some original honey bee populations despite the extensive use of replacement queen bees and migratory beekeeping (Gencer and Firatli 1999).
A field study was conducted to define some morphological characters of some important honeybee (*A. mellifera L.*) races and ecotypes in Turkey. Samples were collected from six different regions of Central Anatolia Region (Beypazarı), North Eastern Anatolia Region (Posof), Marmara Region (Gokceada), Thrace Region (Saray), Aegean Region (Fethiye) and Mediterranean Region (Erdemli). 41 morphological characters were measured and twenty one morphological characters were evaluated in this research. There were not any variation between genotypes regarding length of tibia, length of metatarsus, length of 6^{th} sternit, metatarsal, sternum index, length of fore wing (longitudinal), width of fore wing (transversal), cubital vein distance a, cubital vein distance b, angles of wing venation A4, B4, D7, E9, G12, J10, J16, K19, N23 and O26, pigmentation of tergite 2, 3, 4 and scutellum. In additional there were significant variation between genotypes in terms of other 16 characters. It was also found that there were not any variation between genotypes regarding forewing weight, wing venations B4, E9, J10 and N23. However, there were significant variations between genotypes as for 16 characters. The results showed that some genotypes have differentiation characters regarding their morphological structure (Guler and Kaftanoglu 1999[a,b]).

Table 6. Diseases and harmful creatures of honey bees (Akbay 1982, Tuncer and Yesilbag 2009, Celik et al. 2013, Demir and Eseceli 2013, Anon 2014).

Bacterial diseases	1. American foulbrood (Amerikan Yavru Curuklugu) 2. European foulbrood (Avrupa Yavru Curuklugu)
Fungal diseases	1. Chalkbrood (Kirec Hastaligi) 2. Stonebrood (Tas Hastaligi)
Viral diseases	1. *Chronic Paralysis Virus* (Kronik Ari Felci Virusu) 2. *Acud Bee Paralysis Virus* (Akut Ari Felci Virusu) 3. *Israeli Acud Bee Paralysis Virus* (Israil Akut Ari Felci Virusu) 4. *Kashmir Acud Bee Paralysis Virus* (Kasmir Akut Ari Felci Virusu) 5. *Black Queen Cell Virus* (Siyah Kralice Hucre Virusu) 6. *Cloudy Wing Virus* (Bulanik Kanat Virusu) 7. *Sacbrood Virus* (Tulum/Torba Hastaligi) 8. *Deformed Wing Virus* (Deforme Kanat Virusu) 9. *Kakugo Virus* (Kakugo Virusu) 10. *Varroa Destructor Virus 1* (Varroa Virusu) 11. *Invertebrate Iridescent Virus* (Salkim Hastaligi) 12. *Tobacco Ringspot Virus* (Tutun Halkali Leke Virusu)
Pests and parasites	1. Varroa (Varoa) 2. Acarine (Tracheal) mites (Akar) 3. Nosema (Nozema) 4. Small hive beetle (Kucuk Kovan Bocegi) 5. Wax moths (Petek Guvesi)

	6. *Tropilaelaps* (Ari Biti) 7. Others: Ant (karinca), wasp (esek arisi), bear (ayi), mouse/rat (fare/sican), bird (kus), spider (oruncek), frog (kurbaga), hedgehog (kirpi)

A field study was conducted to investigate the morphological characteristics and moreover to identify the honeybee (*A. mellifera L*.) genotypes in the Artvin and Ardahan regions of the northeastern Anatolia Region. A total of 84 worker bee experimental samples was collected from 8 apiaries in different locations. For every sample 20 workers were used and 19 morphological characteristics were measured biometrically. The samples used were collected from 3 regions of Ardahan (Ardahan-Center, Posof-Yenikoy and Posof-Sungulu) and from 5 different regions of Artvin province (Hamurlu, Kasikci, Borcka-Camili, Savsat-Kocabey and Muratli). As a result there was no variation between bees from different areas in T4 and cubital vein length a on the front wing. Although seven discriminant functions were analysed, the first three functions accounted for 84.1% of the total variation. The 24 samples taken from Artvin Borcka-Camili and 10 samples from Ardahan-Center and 10 samples from Ardahan Posof-Yenikoy were completely classified into their real groups. The those samples were distinguished from other groups and formed a distinct group. On the other hand the same samples overlapped in the Hamurlu, Kasikci, Savsat-Kocabey and Muratli populations (Guler et al. 2002).

Pathology

Adequate nutrition supports the development of healthy honey bee colonies. Larvas are strongly affected by shortages of nutrient. Larval starvation, alone or in combination with other stressors, can weaken colonies (Akbay 1982, Brodschneider and Crailsheim 2010). In Turkey there is sudden loss of bees since 2006 by agreeing the other world countries which threatens beekeeping of Turkey (Giray et al. 2010, Demir and Eseceli 2013). In the near past 600.000 of 2.500.000 bee colonies of USA died suddenly. The same ratio was about 30% in Turkey and 60% in Spain and Poland. About 5 million bee colonies died just in two days in Croatia. Bee colonies die also in Canada, Australia, Greece, Switzerland, Italy, Germany, and Portugal (Celik et al. 2013). Among all bee diseases (Table 6), viral diseases are the mostly responsible of the bee diseases in Turkey, but there are not enough information and research about viral bee diseases in Turkey (Akbay 1982, Kurt 2005, Tuncer and Yesilbag 2009). In a study foulbrood diseases were investigated about 153 colonies from different places of Bursa province. According to results there were no evidence about American or European foulbrood diseases (Borum et al. 2010).

Conclusions

Anatolia have had a significant role on evolotion of most spicies. Because of having various climate conditions, having jeological structure that changes according to different geographic regions and being a naturel bridge among Africa, Europe and Asia (Kence 2006). Even if the nature is very generous, using the naturel sources depends on some genetic factors of the colony. Positive correlation between qalified breed features and honey yield can not be ignored. Queen's ovulation rate, worker bees' collecting nectar, polen, propolis efficiency and fry rearing ability, colony's tend of swarming, having resistance to illnesses and parasites, defensive behaviors are some important qualified breed featutes. Honey bees have adapted to local climate conditions and flora while evolving. Man have used this adaptation as economical opportunity. As a result of existing honey bee colonies for tens of thousands years at Anatolia, it's known that they have adaptated to the local ecological conditions and have had differentiation. The most productive ecotype for a specific region is also the honey bees

that well adaptated that region. Honey bee have evoluated for thousands years in our country and have adaptated the regions thus a lot of breeds and ecotype have been occured. To maintanence ecological balance honey bees that adaptated the regional flora, microorganisms, bee enemies and climate conditions to be conserved. Honey bee subspecies and ecotypes have to be improved in their region and variation of honey bee genetics have to be conserved to use by farmers for now and future.

Abstract

In recent years, the use of agro-industrial by-products in animal nutrition has been successfully adopted as a strategy for reducing feeding costs and also coping with a need for recycling of waste material that is costly to be disposed of. Agro-industrial by-products are cheap and widely available in Mediterranean countries, and suitable for sheep and goat nutrition. Many of these alternative feed resources contain secondary compounds, such as tannins. For instance, tannin-containing feeds could cause effects on meat and milk quality, when consumed in large quantities by animals (Vasta et al., 2008).The objective of this study was to contribute to the characterization of nutritional potential of some agro-industrial by-products informally used in Mediterranean countries for ruminant feeding. The species selected were: *Vitis vinífera* (vine plant), *Ipomea batata(*sweet potato*), Musa acuminata* (banana by-products), *Cucúrbita pepo* (pumpkin), *Solanum lycopersicum* (tomato plant) and *Olea europaea* (*olive* plant). Crude protein (CP) ranged from 10% on banana by-products to 21% on *Cucúrbita pepo* leaves, whereas neutral detergent fiber (NDF) ranged between 26.5% on *Cucúrbita pepo* and 58% on banana leaves. Condensed tannins ranged from 0.10% on banana by-products to 1.2% on olive plant, and total phenols ranged from 0.50% on banana by-products and 7.3% on olive plants. The organic matter digestibility (OMD) ranged from 43% banana by-products to 85% on *Cucúrbita pepo*. Current results show that some agro-industrial by-products have potential to be used in the ruminant feeding system, supplementing the existing diets.

Keywords: *Vitis, Ipomea, Musa, Cucúrbita, Solanum.*

Introduction

The use of agro-industrial by-products in animal nutrition has been successfully adopted as a strategy to reduce feeding costs and also to cope with the need to recycle waste material which is costly to dispose of. Moreover when the use of cereals and soybean in animal's diets creates a competitive conflict with human nutrition's and is expensive. Further the future of arid and semiarid regions depends on the development of sustainable agricultural systems and on the cultivation of appropriate crops that must cope successfully with water shortage, high temperature, and poor soil fertility (Nefzaoui, and Ben Salem, 2002).Thus the development of innovative mixed-farming systems that reconnect livestock and crop production on various territorial scales, can reduce the negative impacts of agriculture on the environment, produce valuable ecosystem services and achieve acceptable economic efficiency for farming enterprises. Mixed-farming systems with unconventional starch sources increase the possibilities of better recycling of nutrients within systems, limiting recourse to the purchase of increasingly expensive inputs and safeguarding the biodiversity of agricultural ecosystems. Some agro-industrial by-products (*e.g.* olive cake, tomato forages, banana by–products…), can be successfully used as supplements in small ruminant diets, without compromising animal performance. In several studies, olive cake (Martin Garcia et al., 2003), banana by-

products (Pieltain et al., 1998-1999) or tomato (Ventura et al., 2009) have been successfully used as supplements for small ruminant diets. *Ipomea batatas* (sweet potato) forage is mainly a source of protein and contains about 15-30% CP in the DM, but the forage quality depends on the proportion of leaves and stems, thus stems containing much less protein than the leaves (Le Van, 2004). Unlike legume forages, it does not contain notable quantities of ant nutritional factors. Olive leaves *(Olea europae)* are suitable forage for ruminants as a bulky feed in maintenance and low-production systems. They are rich in long fiber and require nitrogen and phosphorus supplementation. *Cucurbita pepo* (Pumpkin) was found to have potential as a ruminant feed with a ME value of 16.9 MJ/DM and a crude protein higher than those of beet pulp (Enishi et al., 2004).

Most species are widely distributed in the world exist numerous crops. Some of them cultivated mainly in Mediterranean climates (*Vitis vinífera* (vine plant), *Olea europae* (olive plant), *Cucúrbita pepo* (pumpkin), *Solanum lycopersicum* (tomato plant) *or* in the tropical and subtropical areas *as Ipomea batatas* (sweet potato) and *Musa acuminata* (banana by-products). However, some of these alternative feed resources contain secondary compounds, such as condensed tannins that, when present in high concentrations in the diet, can negatively affect feed intake, animal productivity or even affect the quality of the products (eg. milk, meat…) Vasta et al., (2008).

Materials and methods

The species used in this study were *Vitis vinífera* (vine plant), *Ipomea batata* (sweet potato), *Musa acuminata* (banana by-products), *Cucúrbita pepo* (pumpkin), *Solanum lycopersicum* (tomato plant) and Olea europaea (olive plant) from different localities in Gran Canary (Latitude 27º 55´ 45´´; Longitude 15º 23´ 20´´). The original plants were randomly selected from crops which have been harvested for human feed for farmers and recycling residues of plants for feed animals and crops cultivated on the Cabildo's Experimental Farm in Gran Canary. Samples were collected from the basal, medium and apical parts of several representative plants, at the same time during the spring season, when all forages are in similar and optimum phenologic stage for forage production. Fresh samples were weighed, cut and dried at 60 ◦C to about 90 g/kg dry matter (DM). They were then ground to pass a 1mm screen prior to duplicate chemical analyses. Dry matter, ash and crude protein (CP) were determined according to standard methods as described in AOAC (2000) (methods 930.15, 942.05, and 976.05, respectively). Ash-free neutral detergent fibre (NDFom) was determined using sodium sulfite in the ND according to Van Soest et al. (1991). The acid detergent fibre (ADF) and acid detergent lignin (ADL) were determined following the procedure of Van Soest *et al.* (1991).Condensed tannin (TC) analysis and total phenolic content (PC) were performed by the vanillin-HCL method of Burns (1963) and the technique of Makkar, H. and Al. (1993) respectively; *In vitro* dry matter digestibility (DMD) and organic matter digestibility (OMD) was determined according to the two stage pepsin-cellulase method (Pepcel) (Aufrere, 1982). Based on digestible OM, digestible energy (DE, MJ/kg DM) content of the species was estimated as 0.0185 × digestible OM (NRC, 1988). To assess the content of nutrients according to the type of plant, an analysis model of variance with a factor of variation (ANOVA-1) was used (SAS, 2000).

Results and discussion

However, little information is available on the effects of some of these agro-industrial by-product, there are resources that can be used as feedstuff in this semi-arid conditions, which provides the necessary nutrients to improve the nutritional status of the animals, some of them have been selected and analyzed in this study to compare nutritive value among them; The objective of this study was to assess the nutritive value of some unconventional feed (agro-industrial by-products), species which could used to feeding animals, specially taking into account their profiles on phenolic compounds and condensed tannins for select properly the species and the variety of the by-products for animal nutrition.

The chemical composition of the species used is shown in Table 1. The dry matter (DM) content of the species was 130–506 g/kg fresh forage.There was a great difference in the DM content of the original raw materials, been higher on *Vitis vinífera* and olive plant sources. In practice, this fact could make a difference in the manipulation and conservation in favor of this species. However, it will depend on local availability of the other species as well as the high market price of cereals, oleaginous products and forages as occur in the Canary Islands (Spain). Moreover taking account the high number of small farms of goats and sheep for cheese production, encourage continued work on the rational and more intensive use of such local feed resources for concentrate and diet formulation at small scales. Pieltain et al., 1998-1999 reported similar results of chemical composition on banana by-products while Ventura et al., 2009 found high crude protein (CP) and organic matter digestibility (OMD) on tomato by-products.

Table1. Chemical composition on conventional and unconventional feed (g/kg DM)

SPECIES	DM	OM	CP	NDF	ADF	ADL	ASH	PT	TC
Vitis vinifera	506	840	131	421	311	130	83	2.10	0.50
Ipomea batata	130	756	173	367	256	84	157	0.80	0.10
Musa acuminata	177	776	100	580	387	105	140	0.50	0.10
Curcubita pepo	140	872	214	265	183	35	162	0.85	0.12
Solanum lycopesicum	209	747	153	466	335	60	162	0.70	0.10
Olive plant	501	884	87	399	278	164	61	7.30	1.20

(DM) dry matter; (OM) organic matter; (CP) Crude protein ;(NDF) Neutral detergent fibre; (ADF) acid detergent fibre; (ADL) acid detergent lignin; (ASH) ash in g/kgDM. (PT) Total Phenols (% of tannins as tannic acid equivalent), (TC)Condensed Tannins content (% of tannins as catechin equivalent),

CP content ranged from 87 to 214 g/kg DM.The CP contents of *Cucúrbita pepo* were greater than the respective values found in the other species and it was lower in the olive plants. Although similar results of chemical composition were described by Alibes and Tisserand, 1990 and Gomez Cabrera, 2009 for *Cucúrbita pepo* and Olive forages respectively, the OM digestibility reported by them it was lower in both species. On the other hand similar results of chemical composition are reported on AFZ, 2011; URZ,2009 for *Ipomea batatas* while condensed tannins contents (6.2 g /Kg DM tannins as catechin equivalent) were quite high than our values.

Condensed tannins contents (TC) ranged from 0.10% to 1.2% of tannins as catechin equivalent, and total phenols contents (PT) ranged from 0.5% to 7.3 % of tannins as tannic acid equivalent. Both TC and PT contents were higher in the olive plant while, but an exception of *Vitis vinífera* no differences occurred for the rest of species in the condensed tannins contents. Nevertheless just in case of concentrations greater than 50 g/kg DM, tannins can decrease food intake (Barry et al., 1983) and this should limits the use of feedstuffs even though they may have high protein content. For instance, tannin-containing feeds cause adverse effects on meat and milk fatty acid composition, depending on the amounts of

condensed tannins ingested by the animals, while meat color is evidently paler when condensed tannins are present in the diet (Vasta et al., 2008).

Table 2. Dry matter digestibility (DMD), organic matter digestibility (DMD), digestible organic matter (DOM) in g/kg DM and estimate digestible energy (DE) in MJ/kg DM.

SPECIES	DMD	OMD	DOM	DE
Vitis vinifera	0.56	0.53	445	8.2
Ipomea batata	0.81	0.77	588	10.8
Musa acuminata	0.56	0.43	339	6.2
Curcubita pepo	0.87	0.85	740	13.7
Solanum lycopesicum	0.71	0.65	490	9.0
Olive plant	0.67	0.65	580	10.7

The *In vitro* organic matter digestibility (IVOMD) (Table 2) ranged from 0.430 (Banana plant) to 0.850 in the *Cucúrbita pepo*, were it was the higher value. Moreover IVOMD was similar among tomato plant and olive plant.

Finally, based on IVOMD, digestible energy of the different species was estimated to range from 6.2 to 13.7 MJ DE/kg DM. It was lower in the banana by-products and higher in *Cucúrbita pepo*. ED was similar among *Ipomea batata* and olive plant. Estimated DE of the species analyzed was similar to unconventional starch sources and forage legumes shrubs such as *Bituminaria* varieties, *Medicago arborea* or tagasaste reported by Ventura et al. (2002; 2004; 2009). Moreover DE content of all species analyzed was higher and in the range (6.9-9.2 MJ DE/kg DM) estimated by INRA (1988) for cereals, legumes straws and medium quality alfalfa hay.

Current results support the thesis that, some alternative local feedstuffs have potential to be used in ruminant feeding systems strategies.

Conclusion

The value of forages as supplements is mainly depending on their capacity to provide essential nutrients to the rumen microbial population and/or critical nutrients (anti-nutritive factors) to meet the host animal requirements, thus increasing or reducing the efficiency of feed utilization (Elliot and McMenimen, 1987). In this study we can see that there are many differences in chemical composition, in the condensed tannins and in the total phenols contents within the different species analyzed. Condensed tannins and total phenols contents were low in the different species analyzed a exception of total phenols contents in the Olea europaea (olive plant) were it was quite high and medium PT content on Vitis vinifera. Although, more research should be done on the relation between the quantity of total phenols and tannins and the possible toxic effects on animals or the reduction on voluntary dry matter intake, palatability and productive effect on meat and milk.

Based on CP, IVOMD and digestible energy results, all the species analyzed are within the range estimated by INRA (1988) for cereals, legumes straws and medium quality alfalfa hay. Current results support the thesis that, these alternative local feedstuffs have potential to be used in ruminant feeding systems strategies, although diets supplemented with agro-industrial by-products should be carefully formulated, in order to guarantee small ruminants their nutritional requirements and to avoid the presence of anti-nutritional factors on the rations, nevertheless more research is needed to see productive responses on animals feeding these agro-industrial by-products.

Acknowledgments

The authors acknowledge the technical team of INRA for their assistance, and the laboratory technicians of the CIRAD for their help in samples analyses.

METHOD OF MOVING HIVES WHEN PREPARING HONEYBEE COLONIES FOR ACACIA FLOW

Duška SLIJEPAC*, Dejan POPOVIĆ

Faculty of Agriculture, University of Banja Luka, Republic of Srpska, Bosnia and Herzegovina
*Corresponding author: sljepac.duska@yahoo.com

Abstract

The acacia is the most significant honey plant on the territory of the Republic of Srpska (RS). From the very beginning, honeybee colonies have been good at using acacia flow in the best possible way. The objective of this paper is to examine the influence of moving hives as an important method in preparing honeybee colonies for acacia flow, in order to increase the total yield of honey in an apiary and at the same time to use good productive queen bees to a greater extent. The research was made in an experimental apiary of the Faculty of Agriculture in Banja Luka in April, May and July 2010. Twelve (12) hives were chosen for the research and divided in strong, medium and weak honeybee colonies. Strength of a honeybee colony was determined by the number of bees in a beehive and the percentage of surface area related to honey, pollen, bee nests as well as how many hive frames were occupied. As a condition for maximal readiness of honeybee colonies for the following acacia flow, colonies were fed with sugar syrup in the period from 6thApril 2010 to 10thMay 2010. During the experiment, the weather favoured the growth of the honeybee colonies. Based on the results, it can be concluded that the method of moving hives leads to an increase in the surface area of honey, pollen and bee nests, while the honeybee colonies remain strong. The number of scout bees in the colonies increased when additional colonies were added by the method of moving hives, which also increased productive results in the apiary. This practice is not very often used in the RS but it is very efficient and can be used all year long.

Key words: *acacia flow, honeybee colony, yield, moving hives*

Introduction

On the territory of the RS the beekeeping industry has been present for a long time. However, the number of beekeepers decreased in this area because young people today are not interested in this industry. There are 50 beekeeping associations with 130 000 hives registered in the RS (MAFW, 2010). The registered beekeepers in the RS produce 2 400 tons of honey per year if optimum conditions for collecting honey are satisfied (SORS, 2010). The false acacia is the most important honey plant on the territory of the Republic of Srpska. The false acacia is a deciduous tree originated in North America (Maceljski et al., 2001). The white flowers with strong fragrance hanging in loose clusters are congregated together. The flowers usually bloom from the beginning of May to the end of June, 40 to 45 days after the first signs of bud movement (Klašnja et al., 2011). An altitude, a type and a sunny area under the false acacia are crucial to the beginning of blossoming process. Consequently, two or even three false acacia flows can be used in one season, significantly increasing the yield of honey (Slijepac, 2015). The false acacia flowers secrete the strongest nectar at temperatures from 2°C to 25°C, when there is no wind, only morning dew and the temperature above 16°C. Daily bearing of this flow can be up to 15 kg of nectar and the total yield of one flow can be 70 kg honey per hive. Beekeepers should insist on preserving the available area under the false acacia and planting new trees. The false acacia is very sensitive to late spring frosts and sometimes the buds completely freeze, so that the flowering lack in some locations (Umeljić,

1999). Heavy rains in late autumn, heavy snowfalls in winter and enough sunny days in spring are conditions required for good honey (Vraštanović, 2013). From the very beginning honeybee colonies have to be good and strong at using acacia flow in the best possible way. All preparations have to be completed promptly in order to achieve that objective. If the phenological calendar states that the false acacia trees flower in an area on 10thMay, the bees hatched from the eggs laid by the queen between 15thMarch and 25thApril are going to participate in that flow (Zečević, 2011). At the end of winter and at the beginning of spring, daily temperatures begin to increase and the bees begin with their daily contact in the area, and thus the conditions are satisfied for the first inspection of honeybee colonies in detail. From that time, the total activity of bees and beekeepers has begun (Umeljić, 2010). The first spring flow starts with hazel flowers in February (Svatok, 2004). The equalization of bee colonies is made in April and May. If a beekeeper doesn't replace old combs before winter, then spring is the right time for replacing them (Belčić et al., 1989). In this period, space for expanding brood is created by demareeing (replacing honey supers) and the method of moving hives (replacing hives) is the most important method in preparing bees for flow in order to increase the yield of honey in an apiary.

Materials and methods

The research was carried out in an experimental apiary of the Faculty of Agriculture, the University of Banja Luka (RS, Bosnia and Herzegovina). Out of the total number of bee colonies 12 hives of the different strength were selected. The apiary was sheltered from the wind, surrounded by a fence and the hive entrances were faced south – south-east. The bee colonies in the experimental apiary were placed in LR - hives. During the research out of the total number of bee colonies 12 hives were selected and divided into strong, medium and weak bee colonies. The bee colony strength was determined by the number of bees in a hive and the percentage of surface area related to honey, pollen and bee nests, calculated in (dm^2), as well as how many hive frames were occupied. The experiment was carried out in six inspections at the intervals of ten days. The research was carried out in April, May and June 2010. During the first inspection based on the surface of honey, pollen and bee nests, the equalization of the bee colonies was made in each group. All colonies were fed with sugar syrup prepared in the ratio of water to sugar (2:1) in order to instigate the queen for higher productivity, as a condition for maximal readiness of honeybee colonies for the following false acacia pasture in the period from 6thApril 2010 to 10thMay. The honeybee colonies were fed with 0.25 L of sugar syrup, fifteen times at the intervals of every second evening. Old and deformed honeycombs were taken away from the hives and replaced by comb foundations in order to reach the optimum readiness of honeybee colonies for the main flow and to satisfy the conditions favoured the entry of pollen, honey and development of brood. The method of moving was made within three groups according to which honeybee colonies divided into strong, medium and weak i.e. the replacement of hives between groups (strong with medium, strong with weak, medium with strong, medium with weak, weak with strong and weak with medium). When conducting research, the weather conditions prevailing in the area of Banja Luka (HSRS, 2010) favoured the spring development of bee colonies. The average temperatures in 2010 were 12C ° in April, 16.5C °in May and 20.4C °in June. The relative humidity was 71% in April, 72% in May and 75% in June. There were three sunny days in April, one sunny day in May and five sunny days in June. There were 17 rainy days in April, 18 rainy days in May and 14 rainy days in June.

Results and discussion

Based on the achieved results described in the table 1, it can be concluded that the number of scout bees decreased in bee colonies which were moved in medium and weak groups, and consequently the surface area of honey changed of (0.70 dm²). The result was higher compared to the unmoved honeybee colonies where the average value of the difference on the surface of honey was (-7.91 dm²). Those changes occurred because scout bees decreased, and therefore the surface of bee nests decreased as well as nurse bees changed their activity from processing pollen to processing honey.

Table 1. Surface area of honey expressed in dm²; Group – strong bee colonies

No. hive	Position of colonies	Initial state (dm²)	Final state (dm²)	Difference in value	Difference in honey surface (dm²)
3.	Unmoved	11.37	5.36	-6.01	-7.91
10.	Unmoved	20.13	10.85	-9.82	
9.	Moved	13.99	13.09	-0.90	0.70
11.	Moved	21.46	20.96	-0.50	

Based on the achieved results described in the table 2, it can be concluded that the number of scout bees decreased in bee colonies which were moved in medium groups and weak groups, and consequently the surface area of pollen changed of (-3.74 dm²) which was smaller compared to unmoved colonies where the average pollen surface was (0.20 dm²). The number of scout bees decreased in moved colonies, and therefore the input of pollen also decreased but the consumption of pollen increased due to the necessity of feeding brood nest.

Table 2. Surface area of pollen expressed in dm²; Group – strong bee colonies

No. hive	Position of colonies	Initial state (dm²)	Final state (dm²)	Difference in value	Difference in pollen surface (dm²)
3.	Unmoved	9.18	8.27	-0.91	0.20
10.	Unmoved	0.86	2.17	+1.31	
9.	Moved	6.13	2.58	-3.55	-3.74
11.	Moved	11.79	7.86	-3.93	

Based on the achieved results described in the table 3, it can be concluded that the number of scout bees decreased in colonies which were moved in medium and weak groups, and consequently the surface area of brood nest changed as seen in the figure (-12.95 dm²). The result was smaller compared to unmoved colonies where the average of change related to brood nest increased as seen in the figure (11.21 dm²). The number of scout bees decreased in moved colonies, the input of pollen also decreased, and consequently the surface of brood nest decreased. Because of the fact that the surface under brood nest decreased, nurse bees changed their activity from processing pollen to processing honey.

Table 3. Surface area of pollen expressed in dm²; Group – strong bee colonies

No. hive	Position of colonies	Initial state (dm²)	Final state (dm²)	Difference in value	Difference in brood nest surface (dm²)
3.	Unmoved	22.33	30.66	+8.33	11.21
10.	Unmoved	15.76	30.66	+14.09	
9.	Moved	29.78	4.79	-24.99	-12.95
11.	Moved	17.51	16.59	-0.92	

Based on the research, it can be seen in the moving method of medium honeybee colonies that colonies moved in the strong group increased the number of scout bees but the number of scout bees decreased in the colonies moved in the weak group. As a result, the average surface of honey changed as seen in the figure of (17.73 dm²) which was higher compared to unmoved colonies as in the average surface of honey (-16.26 dm²). The number of scout bees increased during moving colonies in the strong group, but the number of scout bees decreased during moving colonies in the weak group as resulted in the change on the average surface of pollen (3.74 dm²) which was higher compared to unmoved colonies with the average of (-1.11 dm²). The number of scout bees increased during moving colonies in the strong group, but the number of scout bees decreased during moving colonies in the weak group as resulted in the change on the surface of brood nest (12.48 dm²). That was higher compared to unmoved colonies which had the average of brood nest (3.77 dm²). Moving hives led to an increase in the surface area of honey, pollen and nests but only where medium and weak colonies were moved into strong colonies. The number of scout bees increased when weak and medium colonies were installed in strong colonies, the input of pollen also increased and the queen bee was encouraged to expand brood nests.

Table 4. Surface area of honey expressed in dm²; Group - weak colonies

No. hive	Position of colonies	Initial state (dm²)	Final state (dm²)	Difference in value	Difference in honey surface (dm²)
1.	Unmoved	19.68	7.85	-11.83	-6.91
7.	Unmoved	23.87	21.87	-2.00	
6.	Moved	6.08	26.71	+20.63	5.06
5.	Moved	10.93	0.43	-10.50	

Based on the achieved results described in the table 4, it can be seen in the example of colonies which were moved in medium and strong colonies that scout bees were added as resulted in the change on the average surface of honey (5.06 dm²) which was higher compared to unmoved colonies with the average surface of honey (-6.91 dm²).

Table 5. Surface area of pollen expressed in dm²; Group - weak colonies

No. hive	Position of colonies	Initial state (dm²)	Final state (dm²)	Difference in value	Difference in pollen surface (dm²)
1.	Unmoved	6.80	6.53	-0.27	0.95
7.	Unmoved	11.79	13.96	+2.17	
6.	Moved	7.43	3.91	-3.52	-3.17
5.	Moved	10.22	7.40	-2.82	

Based on the achieved results described in the table 5, it can be seen in the example of colonies which were moved in the groups of medium and strong that scout bees were added as resulted in the change on the average surface of pollen (-3.17 dm²), which was smaller compared to unmoved colonies with the average pollen of (0.95 dm²).

Tabela 6. Surface area of brood nest expressed in dm²; Group - weak colonies

No. hive	Position of colonies	Initial state (dm²)	Final state (dm²)	Difference in value	Difference in brood nest surface (dm²)
1.	Unmoved	5.66	10.06	+4.40	1.95
7.	Unmoved	5.25	4.36	-0.89	
6.	Moved	15.33	30.67	+15.34	17.31
5.	Moved	1.30	20.58	+19.28	

Based on the achieved results described in the table 6, it can be seen that scout bees were added during moving colonies moved in the groups of medium and strong. As a result the change on the surface of brood nest (17.31 dm²) appeared which was higher compared to the unmoved colonies where the average surface of brood nest was (1.95 dm²). The number of scout bees increased by moving and the conditions were satisfied for higher input of pollen. Increasing the surface of pollen made the preconditions for expanding the surface of brood nest and its feeding.

Conclusion

Based on the results in this research, it can be concluded that bee colonies, in which scout bees were added by the method of moving, produced the higher amount of honey and pollen. Adding scout bees in colonies brought the higher amount of pollen. Therefore, the production of honey increased and the bee queen was blocked. The colonies, where scout bees were taken by the moving method, produced less honey and pollen but more brood nests. In those colonies, queen bees tried to recover the number of lost scout bees by laying a greater number of eggs and the higher amount of pollen was used to feed young bees. Based on the results during the research, it is concluded that this apitechinal procedure can be recommended in achieving better results in the yield of honey and pollen, while the bee colonies still remain strong. Apart from the main bee colonies for producing honey, apiaries need to have additional colonies which can be used to increase the number of scout bees by the method of moving which can increase the production results.

Abstract

In the past, tannins are often described to have negative effects on animals, such as feed intake depression and growth reduction, as they reduce digestibility of proteins and lower the activity of digestive enzymes. On the other hand, health enhancing properties, such as antibacterial, anti-parasitic, antioxidant, antidiarrheal and anticancerogenic were also confirmed. The effect of tannin supplementation on growth performance, carcasses and meat quality traits of fattening boars was studied. A total of 51 entire males which were divided in four groups: control group (BEK-2, 12.9 MJ ME/kg, 15 % proteins with no tannin supplement, T0, n=12), and tree groups feed with same diet supplemented with 1 % tannin Farmatan® (Tanin Sevnica d.d., Sevnica, Slovenia) supplementation (T1, n=13), 2 % tannin Farmatan® supplementation (T2, n=13) and 3 % tannin Farmatan® supplementation (T3, n=13) were studied. Boars were housed in group pens and the study was carried out respecting the Slovenian law on animal protection. Experiment started when boars reached approx. 60 kg of live weight, entered the fattening stage and received experimental diets. Increased body weight ($P < 0.002$) and daily gain ($P < 0.000$), was followed with addition of tannin supplementation. Addition of tannin supplementation increased carcass weight ($P < 0.005$) and for meat parameters, thawing ($P < 0.000$) and cooking ($P < 0.001$) loss was statistically decreased between T0 and T1, T2 and T3, whereas difference between T1 and T2 group was not noticed. Present results suggest that 3% tannin supplementation in boars diet had significant influence on body weight and daily gain, carcass and meat quality traits.

Keywords: *hydrolysable tannins; growth performance traits; carcass and meat traits; entire males*

Introduction

Tannins play a protective role in the crops defines to be eaten by herbivores (Jansman 1993). They are synthesized by a wide variety of plants and trees and several of these have been used as feeds or diet supplements. The response of ruminants and non-ruminants animals on tannins are lower feed intake, protein and dry matter digestibility's, live weight gains, milk yield and wool growth (Jansman et al. 1994a,b, Reed 1995). Tannins are known to have a astringent taste which reduces palatability and consequently negatively affect pigs voluntary feed intake and growth performance inhibits specific gastric enzymes (Murakami et al. 1992), lowers proteolytic enzymes activity in small intestine (Van Leeuwen et al. 1995), reduces protein digestibility (Smulikowska et al. 2001) and decrease the excretion of endogenous protein (Jansman et al. 1995). Potential effects of tannins were also reported from Mediterranean countries where they have extensive pork productions with a pigs diet rich in tannins, where acorns (*Quercus*) represents the main energy source (Cantos et al. 2003, Cappai et al. 2014). Also they use chestnuts (*Castanea sativa* Mill.) which are valued source of amino acids, minerals and fatty acids for free ranging pigs (Borges et al. 2008). For some

autochthonous breed such as Celta have traditional diet consist of chestnut fruit (*Castanea sativa*) lasted three months on the end of fattening period (Franco et al. 2006). Another traditional finishing system is known for Iberian pigs and it is based on grazing acorns and grass during autumn and winter (*montanera*) in the dehesa (*Quercus ilex* open woodlands) without any supplementary feed or mineral complement (Rodríguez-Estévez et al. 2011).
Some other authors, reported no effects of hydrolysable tannins on growth rate, carcass traits and meat quality with 0.2% of tannins in pig diet (Prevolnik et al. 2012). Influence of hydrolysable tannins on pigs and boars performance are scarce, resent published study from Čandek-Potokar et al. (2015) reported that diet supplemented with hydrolysable tannins with chestnut wood extract had no negative effect on growth performance for groups with 1% or 2% of added tannin, but a diet containing 3% resulted with reduced feed intake. The present study is aimed to evaluate the effects of hydrolysable tannins on growth performance, carcasses and meat quality traits on fattening boars.

Materials and Methods

The experiment was performed in commercial family farm in the eastern part of Slovenia, rexpecting the Slovenian law on animal protection (Uradni list Republike Slovenije43/2007). Total of 51 entire male pigs (boars), which were divided in four groups: control group (without tannin supplement) (T0, n=12), treatment group with 1 % addition of tannin extract Farmatan® (Tanin Sevnica d.d., Sevnica, Slovenia) in the feed (T1, n=13), treatment group with 2 % addition of tannin extract Farmatan® in the feed (T2, n=13) and treatment group with 3 % addition of tannin extract Farmatan® in the feed (T3, n=13). The experiment start when boars has reach 55 kg of live weight (126 days of ages), entered the fattening stage and received experimental diets. Diet for control group was standard feed mixture for fatteners (BEK-2, 12.9 MJ ME/kg, 15 % proteins), whereas tannin supplemented pigs received standard diet with specified amount of added tannins. When boars reach slaughter weight 126.7 ±13.3 kg (at approx. 200 days of age), experiment was ended, and boars were transported to the commercial abattoir.

Measurements of feed intake and body weight

The voluntary feed intake was recorded on group/pen basis. Boars were weighed at the beginning (at 53.0±5.3 kg live weight) and at the end of experiment (at 126.7±11.3 kg live weight) which lasted 77 days. Daily gain (individual) was calculated based on these two measurements and represents growth rate (g/day) for the experimental period. The feeding was monitored and the same quantity of feed was offered daily to all pigs.

Carcass and meat quality measurements

At slaughter line, carcass classification (lean meat content, %) was performed by the approved control organization, carcass weight was recorded and dressing percentage calculated as the percentage of carcass in relation to live weight. Samples of *longissimus dorsi* (LD) were taken at the level of last rib, for measurement od muscle and fat thickness, by the usual procedure approved in Slovenia. Basic parameters and measurements of pH were performed after 24 hours with glass electrode (MP120 Mettler-Toledo, GmbH, 8603 Schwarzenbach, Switzerland).Water holding capacity was measured using standard EZ-Drip loss method according to Christensen (2003). Thawing and cooking loos and shear force measurements were evaluated as described by Batorek et al. (2012). Minolta Chroma Meter CR-300 (Minolta Co. Ltd, Osaka, Japan) was used for colour measurements of CIE Lab colour parameters.

Statistical data processing

Data were analyzed using GLM procedures of the statistical software SAS (SAS Inc. Cary, USA). Data is presented as LS means with respective standard errors. The main effect of tannin supplement treatment was used in the statistical model for growth, carcass and meat characteristics,. GLM was used to evaluate differences among treatment groups and its traits. In case that *F*-test was significant (P<0.05) differences between treatment groups were evaluated using Tukey test.

Results and discussion

Increased body weight, daly gain and carcass weight was followed with addition of tannin supplementation (Table 1). Boars from control group had lower body and carcass weight and daly gain in comprising with 1%, 2% and 3% treatment groups (P < 0.05). The results of previously published studies from Čandek-Potokar et al. (2015), reported significantly reduced feed intake in 3% supplemented group with Farmatan, likewise in study Lee et al. (2016), reduction of feed intake with chestnut tannins, was followed. In the study Štukelj et al. (2010), 0.15% of Farmatan addition in pigs, did not improve growth performance, but also was not violated.

Table 1. The effects of diet supplemented with tannin-rich extract (Farmatan) on growth performance and carcasses traits

Traits	Treatment group				*P*
	T0 (n=12)	T1 (n=13)	T2 (n=13)	T3 (n=13)	
Body weight, kg	117.9±4.2^{a}	125.4±2.3$^{a}_{b}$	129.7±1.7^{b}	133.2±2.3^{b}	0.002
Daily gain, g/day	0.8±0.04^{a}	0.9±0.03^{b}	1.1±0.02^{b}	1.1±0.03^{b}	0.000
Carcass weight, kg	88.1±3.3^{a}	93.7±1.5^{ab}	97.2±1.5^{b}	98.8±1.6^{b}	0.005
Dressing percentage, %	74.7±0.4	74.8±0.4	74.8±0.5	74.2±0.3	0.710
Muscle thickness, mm	6.6±0.6	7.5±0.5	9.1±0.8	9.1±0.8	0.179
Fat thickness, mm	64.2±0.4	63.5±0.5	62.7±0.6	62.8±0.6	0.030

P < 0.5 statistically significant differences between the treatment groups are denoted by different superscript letters. T0 = control group; T2 = 1% supplemented tannin; T2 = 3 % supplemented tannin; T3 = 3% supplemented tannin.

Reports about influence of hydrolysable tannins as feed to fattening boars are scarce, but some reports of condensing tannins are examined.

Different addition of faba beans (FB) (hulled faba beans protein and starch concentration) 16% and 17.5% in barrows and gilts diet depress feed intake and daily gain (Gunawardena et al. 2010). Likewise condense tannins from *Acacia tortilis* (CTA) in high diet doses as pigs supplement, reduce growth performance (Khanyile et al. 2014, Ndou et al. 2015). In the diet for weaned pigs, addition of different concentration of FB (0.25, 0.5, 0.75 and 1.0 g/kg) did not affect the growth performance in trial (Emiola and Gous et al. 2011). Chemical composition of sweet chestnut such as, regions, cultivars, genetic diversity between cultivars and different concentration added in animals diet can affected growth performance (Pereira-Lorenzo et al. 2006). It is assumption, that growing pigs can have some mechanisms of neutralizing of toxic effect up to certain level (Čandek-Potokar et al. 2015). On the other side, in the study Rodríguez-Estévez et al. (2010) has been showed that, Iberian pigs were relatively resistant to a tannin-rich diet, which can be explained with the fact that proline rich proteins from salivary gland, have a good protective role.

Table 2. The effects of diet supplemented with tannin-rich extract (Farmatan) on meat quality traits

Traits	Treatment group				*P*
	T0 (n=12)	T1 (n=13)	T2 (n=13)	T3 (n=13)	
pH	5.3±0.2	5.4±0.2	5.4±0.1	5.4±0.1	0.247
Drip loss after 24h, %	9.8±0.9	8.6±0.7	9.3±0.5	9.8±0.7	0.582
Minolta L	57.8±1.4	54.2±0.7	55.1±0.6	56.8±1.5	0.076
Minolta a	7.1±0.4	7.5±0.3	7.2±0.3	7.7±0.4	0.583
Minolta b	2.6±0.3	2.5±0.2	2.5±0.3	3.2±0.5	0.445
Thawing loss, %	15.8±0.2^{ab}	13.1±0.4^{a}	14.1±0.3^{a}	18.2±0.8^{b}	0.000
Cooking loss, %	35.8±1.1^{b}	34.1±0.5^{ab}	33.4±0.3^{a}	32.2±0.5^{a}	0.001
WB shear force, N	156.6±25.3	149.4±6.1	132.7±9.3	125.3±14.4	0.313

P < 0.5 statistically significant differences between the treatment groups are denoted by different superscript letters. T0 = control group; T2 = 1% supplemented tannin; T2 = 3 % supplemented tannin; T3 = 3% supplemented tannin.

Thawing and cooking loss were significantly reduced between treatment groups. Thawing loss was statistically different between control and 1%, 2% and 3% supplemented groups, where difference between 1% and 2% supplement groups were not noticed (Table 2). Meat quality parameters Minolta a, b and shear force were not statistically different (Table 2).). In animals oxidative stress can cause the degradation of lipids and proteins as important factors that contribute to the deterioration of meat and meat products (Prevolnik et al, 2012). Tannins in pigs diet are demonstrated as potential ant-oxidative additives (Frankič and Salobir 2011), and in this trial Farmatan addition did not affect meat quality traits. Positive effects on meat tarts are reflected in reduced thawing and cooking loss % with Farmatan additions in boars diet, likewise in study Liu et al. (2012), where sweet chestnut supplementation increase cooking loss in rabbit meat.

The color of pork for human perception is linked with lightness, which is usually affected by pH and water holding capacity, whereas redness and chroma appear to be less important (Zanardi et al. 1999). In the current study, meat color parameters (L, a and b) were not affected by Farmatan supplementation, and results are in agreement with study Prevolnik et al (2012) and Liu et al. (2012).

Conclusions

Results from presented trial indicate that high concentration of hydrolysable tannins significantly improve growth performance, without effects on meat quality parameters, except for decreased thawing loss and increased cooking loss. It can be speculate that, high dosages of hydrolysable tannins had no negative effects on growth and fattening characteristics as it described in some previse studies. Future investigations (with larger number of animals) need to confirm presented results.

Abstract

The results of monitoring of rates of infection by Taenia hydatigena in domestic and wild carnivores were given. Our work revealed the widespread prevalence of the infection both in domestic and wild canids (wolves, jackals, foxes). In 2011-2015 15 domestic, 43 stray and 33 pasture dogs were examend by the method of complete helminthological autopsy. All these dogs (irrespective of their keeping conditions or economic purpose) were infected by Taenia hydatigena and the extensity of infection (EI) was very high. The highest EI was registered in stray dogs (100%) and pasture dogs (94%); in domestic dogs EI was slightly lower (73.3%). The analysis of the rate of infection by Taenia hydatigena in 27 wolves, 38 jackals and 21 foxes was carried out by a similar method. EI in these animals was 29.6; 36.8 and 23.8%, respectively. It was found that dogs aged 1 to 4 years were most susceptible to infection by Taenia hydatigena; the high EI was maintained all year round and no marked seasonal changes were observed. Nevertheless, it was possible to note a slight increase of infection rate in the fall. It was connected with a period of mass slaughter of sheep and uncontrolled feeding dogs by animal organs infected by Taenia hydatigena larvae, which aggravated epizootological situation. The obtained results allow us to conclude that concerning this helminthosis the epizootological process is developing dynamically. High rates of infection in stray dogs and pasture dogs (in presence of their intermediate hosts – sheep or other farm animals) provide not only dynamics, but also biological activity and protection of parasitic system for a long time.

Keywords: *Taenia hydatigena, domestic and wild carnivores, infection, epizootology*

Introduction

Taenia hydatigena infection in dogs is widely spread in the Russian Federation. One has recorded that 80-100% of stray dogs in the Volgograd Region are infected with *T. hydatigena* [1]. In the Rostov Region *T. hydatigena* infection extensity (EI) among stray dogs varies 60% to 80% [6] and in the Kuban the value of EI reaches 70% to 100% with intensity of infection (II) - 2-6 specimens/animal according to the data of Mitnikova O.V. One notes 100% *T. hydatigena* infection rate in herding dogs in Kalmykia [3]. There are some data on the high infection level in dogs from different sheep farms with helminths attributed to the family *Taeniidae* [5]. Taking into account such situation the purpose of our study has been to determine *T. hydatigena* infection rates among domestic and wild carnivores in the Kabardino-Balkar Republic.

Materials and Methods

T. hydatigena infection prevalence in dogs was studied based on animal's maintenance and practical application. The small intestines of domestic, stray and herding dogs (15, 43, 33 dogs respectively) were subjected to helminthological necropsy.

The infection extensity and intensity values were estimated based on the results of helminthological necropsy of small intestines followed by statistical analysis and calculation of mean values. 27 wolves, 38 jackals and 21 foxes have been examined in the same way.

Results and Discussion

Based on the results of necropsy 11 of 15 domestic dogs were infected with *T. hydatigena* what appeared to be 73,3%. The infection extensities in stray and herding dogs were 100% and 94,0% respectively. The results of those experiments revealed that dogs used in sheep husbandry in that region were infected with *T. hydatigena* practically with the equal high infection rates (73,3%-100%), what evidenced about an insignificant effect of dog maintenance on their infection rates (Table 1).

In the conditions of complete absence of scheduled dehelmintization and sanitary norms dogs infected with *T. hydatigena* and other cestodes can represent a significant epizootological danger not only for sheep but also for other farm animals.

Table 1

Comparative rates of *Taenia hydatigena* infection in domestic, stray and herding dogs

Examined dogs	**Number of necropsied dogs**	**Number of dogs infected with *Taenia hydatigena***	**Extensity of infection, %**	**Intensity of infection, specimens/animal**	**Number of eggs per *Taenia hydatigena* proglottid , specimens**
Domestic	15	11	73,3	2,80±0,50	800±20,0
Stray	43	43	100	3,40±0,27	1030±25,8
Herding	33	31	94,0	3,81±0,13	922±18,6

Based on the results of necropsy in addition to the study of *T. hydatigena* infection extensity in dogs we determined the intensity of infection, which varied 1 to 5 specimens/animal in domestic dogs as while the same indices in stray and herding dogs appeared to be 1 to 9 and 1 to 7 specimens/animal respectively. The number of eggs per one excreted proglottid was 800±20,0; 1030±25,8 and 922±18,6 eggs respectively (Table 1).

These results confirm the high biological and epizootological potential of *T. hydatigena* providing the stability of natural infection foci. In general stable maintenance of natural infection foci can be the result of sheep owner and herder sanitary incompetence as they feed all affected organs of slaughtered sheep to dogs.

As the diagnostic surveys on *T. hydatigena* prevalence in dogs are conducted irregularly and in some regions are not carried out at all, it is difficult to evaluate the epizootological situation without account of such indices as seasonal and age dynamics of infection. Therefore, we studied the seasonal and age dynamics of *T. hydatigena* infection in dogs and estimated that dogs aged 1-4 years appeared to be the most susceptible to this helminth infection. The infection extensity in dogs of that age was in the range of 79,3%-88,6%. The highest infection rate (88,6%) was recorded in puppies aged under 1 year. In dogs older than 7 years the extensity of infection did not exceed 22,7%. Nevertheless the results of epizootic monitoring revealed that in recent years the situation on *T. hydatigena* infection among dogs of all age groups had deteriorated significantly, what was indirectly confirmed by a significant rate of *T. hydatigena larvae* infection in sheep originated from different farms in that region [2].

Table 2

Taenia hydatigena infection rates in dogs depending on the age according to the results of necropsy

Dog's age	**Number of dogs examined in the period of 2011 to 2015**	**Number of dogs infected with** *T. hydatigena*	**Infection extensity, %**
Under 1 year	79	70	88,6
Under 2 years	108	93	86,1
Under 4 years	82	65	79,3
Under 6 years	29	11	37,9
Under 7 years and older	22	5	22,7

The highest rate of *T. hydatigena* infection in dogs was observed in winter and spring. During the period of 2011–2015 the level of *T. hydatigena* infection prevalence in dogs increased depending on the season: in winter – by 2,3 times; in spring – by 2,4 times; in summer – by 3,2 times; in autumn – twice respectively what characterized the epizootological process of infection as dynamically growing one with a stationary stable biological mechanism. The high level of that helminth infection in dogs was recorded practically all year round and no clear seasonality for that infection was noted. Although the characteristic epizootological feature of *T. hydatigena* infection in the region is infection of dogs in autumn when the mass slaughtering of sheep and uncontrollable feeding of internal organs of slaughtered sheep infected by larval cysts to dogs occur.

In wild carnivores the infection extensity and intensity values were relatively lower compared with dogs what was due to the smaller number of infected animal organs (sources of infection) come into their feed.

Over the whole research period (2011-2015) 27 wolves, 38 jackals and 21 foxes were subjected to helminthological necropsy. According to the results of necropsy *T. hydatigena* infection extensities in wolves, jackals and foxes were 29,6%; 36,8% and 23,8% respectively; the indices of infection intensity appeared to be 1-2; 1-3 and 1-2 specimens/animal respectively which were comparably lower than in dogs.

Table 3
Indices of *Taenia hydatigena* infection in wild carnivores

Animal species	**Number of necropsied animals**	**mber of animals infected with** *T. hydatigena*	**Extensity of infection, %**	**Mean intensity of infection, specimens/animal**	**Number of eggs per one *Taenia hydatigena* proglottid, specimens**
Wolf	27	8	29,6	1,75±0,5	1236±27,4
Jackal	38	14	36,8	2,1±0,2	1420±24,4
Fox	21	5	23,8	1,6±0,2	1183±25,7

However the number of *T. hydatigena* eggs per one proglottid was higher in wolves, jackals and foxes than in dogs (1236±27,4; 1420±24,4 and 1183±25,7 eggs respectively) what evidenced about a high biological activity and reproductive capacity of Taenia in wild carnivores (Table 3).

Conclusions

The results of monitoring revealed the wide prevalence of *T. hydatigena* infection in dogs at the territory of the Kabardino-Balkar Republic. The high extensity level of *T. hydatigena* infection (73,3%-100%) was recorded in dogs applied in sheep husbandry. In wolves, jackals and foxes infection extensities were 29,6%; 36,8% and 23,8% respectively; as while the infection intensity values appeared to be 1-2; 1-3 and 1-2 specimens/animal. In addition one noted a tendency over the last 5 years for increase of infection rates by 2,5 times. The highest rate of *T. hydatigena* infection in dogs was observed in winter and spring. However no exact seasonality of that infection in dogs had been noted as infection with *T. hydatigena* was possible all year round what characterized the epizootological process of infection as a dynamically growing with a stable stationary biological mechanism. The high rate of *T. hydatigena* infection in dogs was provided by increasing of stray dog population and absence of sanitation and hygiene education of the population.

Abstract

Nowadays, the technological progress is affecting many industries. One of them is the aquaculture industry. In this study, it is aimed to exert the significance of the human resources in the production of the fish meal and fish oil factories which is an important component of the aquaculture industry in order to be adequate both by quality and by quantity for the social necessities and based on the science and modern technologies. The population of the survey is composed of the owners of fish meal and fish oil factories operating in Turkey, professional managers and other employees in these factories. In this research, with questionnaire method, data gathering is provided. Descriptive statistical methods have been used for the purpose of determining the relationships among the variables. Regarding sex, 16% of the employees involved in research are female; employers/managers are all male. In companies, considering the question whether there is a separate department carrying out human resources activities it is found that 44% of companies have human resources department and 23% of companies perform this function through administrative department. Male employers/managers consider themselves as persons using technology in about 73%. To hire new staff in business, a priority criterion is recruitment of staff to implement technological improvements. It is assumed that the technological progress and the human resources can be used more effectively with the help of implementing theory based on information acquired from research findings. Like any other industry, the most important resource for the fisheries and aquaculture industry to stay sustainable and be in competition with the other industries, is the qualified human resources. Thus, it is suggested that the education and training of the human resources should be an event of special interest.

Keywords: *Fish meal and fish oil factories, technology, human resources management.*

Introduction

Unprecedented technological developments and changes of today affect culture of societies, life style and socio-economic situation. Working life is also reshaped the in the light of these developments.

Technology has led to extinction of some profession groups and caused emergence of some professions and jobs. In particular, professions requiring mostly physical activity have been y machines. Therefore, companies ensure competitive edge with technology and employees using technology. For this purpose, the technology and human resource management must be utilized efficiently.

In this context, reviewing the structure of traditional organizations and taking advantage of modern management techniques managers create new policies to improve efficiency and effectiveness of human resources. These activities related to human resources of companies are dealt with human resources management.

There are many relations be it direct or indirect between technological developments and human resource management practices. With impact of technological developments

sometimes it may be necessary to make radical changes in human resources function (Küçükköseleci, 2009).

To get most effective benefits from human resources, primarily it is necessary to make a rational human resources planning in organization (Ekinci, 2008). While making this planning technological advances should be used in recruiting and employment process and this planning activity should be at a level that can provide a competitive advantage against other companies. In addition, it is necessary to organize training activities for existing employees and new employees participating to company in order to follow developments in modern business world and in the sector and to improve their qualifications. Necessary works should be performed for employees to use knowledge they gained in trainings and to interpret results of these trainings.

In this study, the technological developments in the aquaculture industry and its impact on human resources activities aimed to reveal the importance of these activities.

Material and Methods

The research population is formed of owners of fish flour and oil factories in Turkey, professional managers and other employees. Survey data collection method has been adopted.

At the time of the survey (in July 2014), it has been found 15 factories in the Ministrys list. There weren't active two of them. The questionnaire was conducted with other factories of employers / professional managers (15 people) and employees (43 people) .

In the study, employers / professional managers and employees to different questionnaires were administered. Employer / professional manager applied to questionnaire consists of 38 questions.The first 8 questions include demographic factors.

Employee questionnaire consists of 29 questions. The first 8 questions include demographic factors.

The reliability of questionnaires were tested. The data gathered was tested with SPSS 21 ve Minitab 16 Pocket Programmes. Descriptive statistical methods were used in determination of relationship of variables with each other.

Results and Discussion

Questionnaire was applied to employees, employers/managers separately.

l male and 16% of employees were women. When education status was investigated; 6% of employers/managers had primary education and 40% had university graduates and there is no employer/manager without education. 2% of employees don’t have education, 28% have primary school and 51% have secondary school and 7% have undergraduate and 12% have university education. 50% undergraduates were aquaculture engineer.

Age distribution of employers/managers was as 33% 26-35 years, 7% 36-45 years, 40% 46-55 years, and 20% 56 years and above. 11% of employees are 18-25 years, 40%, 26-35 years, 35% 36-45 years, 12% 46- 55 years and 2% 56 and above.

In companies, considering the question whether there is a separate department carrying out human resources activities it is found that 44% of companies have human resources department and 23% of companies perform this function through administrative department.

It is determined that in recruitment advices of acquaintances were effective primarily (31%), secondly Work and Employment Authority (24%) was effective. On the other hand, it was found that no support was obtained from human resources consulting companies (Table 1).

Keklik (2007) in her research on SMEs; the usage of internet was found out to be the least preferred method of canditate selection.

İrez (2009), has identified the impact of technological developments to provide human resources and selection process. benefit from the technology level of the survey respondents is not related to the sectors in which they apply. In addition, respondents have been found to be

a meaningful difference between age and job applicants in the to benefit from technology levels.

Table 1. Resources used by companies in recruitment

Resources	*%*
Listing and announcements	20
Human resources consulting companies	-
Internet	10
Turkey Work and Employment Authority	24
Professional institutions and education institutions	5
Advices of acquaintances	31
Other	10

*Source: Author's elaboration based on the questionnaire survey results.

While 22% of employers/managers specified that they didn't make any change in recruitment and selection strategies, 30% specified that spread of new technology was effective in determining personnel selection and recruitment strategy.
Despite all these, when employers/managers compare period when they started working and today they put forward that today more quipped and qualified personnel are employed (87%).
It is understood that in companies among criteria used for selection of new employees primary criterion is personnel able to apply technological developments (26%).
When employees assessed their levels of information technology 37% of them described themselves as moderate, 40% as adequate and 14% as expert. 19% of employees received training on the use of technology in their workplaces.
In the aquaculture industry, almost all of the employees seem to prefer to benefit from new technology. This situations important for universities and also sectors.
On the other hand, expertise and work of 40% of managers are not related to each other.
Achieving the expected benefits from technology is proportional to personnel who use it. Legislation should be made for stipulating in-house training mandatory about forcing employers/managers to work in their expertise area and use of technology by employees. Thus, "dismissal fear" of 28% of employees will be eliminated and employees will work with peace of mind and work peace will be reinforced.
Employers/Managers specify that through the use of new technologies in addition to formation of new departments in companies, work accidents and occupational diseases will be reduced and employee performance will increase (Table 2).

Table 2. Opinions of employers / managers and employees on use of technology

	I disagree (%)	***I agree (%)***	***I disagree (%)***	***I agree (%)***
Technological change has resulted in the formation of new departments in company.	7	93	-	-
Technological developments reduced occupational accidents.	13	87	-	-
Technological developments reduced the occupational diseases.	7	93		
Using new technology and machines in company makes a positive impact on my performance.	-	-	14	86

*Source: Author's elaboration based on the questionnaire survey results.

Conclusion

In this study it is aimed to disclose importance of human resources in ability of production in fish flour and oil factories as one of the important components of fishery sector to satisfy social needs based on modern science and technology in terms of quality and quantity. Furthermore, this study is also important as an example of interdisciplinary cooperation.

It is believed that it is possible to utilize technology and human resources more effectively by application of theoretical knowledge derived from research findings. As in all sectors it is advised that growing fully qualified staff is the most valuable resource to ensure the sustainability and increase competitiveness in fishery sector.

Employee job descriptions should be made within the system, powers should be increased, ergonomic work environment must be created and salaries should be improved taking into account economic structure of the country and sector. Moreover, it is recommended to take measures for occupational health and safety under the legislation, training staff about new technologies and other issues and improvement of career management for continuation of service of qualified staff in company.

EFFECT OF NON-GENETIC FACTORS ON 305-DAYS MILK YIELD IN SIMMENTAL COWS REARED IN SUBTROPICAL CLIMATE CONDITION

Yahya ÖZTÜRK[1*], Memis BOLACALI[2]

[1] Mehmet Akif Ersoy University, Burdur Vocational School, Program of Meat and Meat Products, Burdur, Turkey
[2] Siirt University, Faculty of Veterinary Medicine, Department of Animal Husbandry, Siirt, Turkey

Abstract

This study was carried out to determine 305-days milk yield of Simental cows grown in a private farm in Çorum private center (Black Sea Region of Turkey) which is classified as subtropical climate region according to Trewarta climate classification and as CSB according to Köppen-Gieger system, and to investigate effects of non–genetics factors on these parameters. For this purpose, a total of 1904 lactations records of 706 Simmental cow raised at Çorum province particular farm between 2001 and 2014 were used. Eight age groups were formed beginning from 2 years and ending 9 years and older for calving age, 4 groups for calving season, 14 groups (between 2001 and 2014) for calving year, 2 groups for birth type, and 2 groups for parity. The 305-days milk yield was estimated from milk yields. To determine non-genetic effects of calving years, lactation number, calving season, calving age, birth type, and parity on 305-days milk yield, general linear model was applied by using SAS program. Duncan's multiple range tests was used for multiple comparisons in important subgroups. In this research, 305-days milk yield were detected as 6060.30 kg. The effect of calving year, lactation number, calving age, birth type and parity on 305-days milk yield were statistically determined with different levels of significance ($P<0.001$, $P<0.05$, $P<0.05$, $P<0.05$, $P<0.001$, respectively); but the effect of calving season on 305-days milk yield was statistically determined non-significant ($P>0.05$). Consequently, when Simmental cows are applied ideal growing conditions and care-feeding, milk yield parameters at world standards can generally be obtained in subtropical climates.

Keywords: *Simmental cow, 305days milk yields, non-genetic factors.*

Introduction

Cattle population of Turkey is approximately 14.2 million based on 2015 TUİK's animal data. Total number of cattle milked is approximately 5.5 million and amount of milk produced per year is about 16.9 million tons/year. Approximately 82.6% milk produced in World and 90.77% milk produced in Turkey come from cattle (TUİK 2016; FAO, 2016). Even though Turkey has been ranked as 23rd in the Word in terms of number of cattle owned, Turkey has been ranked as. 63.rd in terms of productiveness (FAO, 2016). To improve animal production, in addition to improving animal genetics, it is also important to provide optimum environmental conditions for animals.

The Simmental cattle breed is one of the oldest and most widely spread of all cattle breeds in the world. And an official herd book opened in 1806, the total numbers are estimated between 40 and 60 million Simmental cattle worldwide, with more than half in Europe (Huyghe et al., 2014).

Genetic and environmental factors have great impact on milk yield. Environmental factors can be listed as lactation period, calving season, dry period, body weight, nutrition, calving age, estrus, pregnancy, ambient temperature and etc. (Alpan and Aksoy, 2009; Özbeyaz and Küçük 1999).

This study was carried out to determine 305-days milk yield of Simental cows grown in a private farm in Çorum private center which is classified as subtropical climate region according to Trewarta climate classification and as CSB according to Köppen-Gieger system, and to investigate effects of non–genetics factors on 305-days milk yield.

Material and Methods

A total of 1904 lactations records of 706 Simmental cow raised in a private farm at Çorum province. Cows (Black Sea Region of Turkey) were milked twice a day.

Lactation days less or more than 305 days were adjusted for 305-day lactation. An adjustment factor has been applied for lactation days less or more than 305 days. Lactation milk yields of cows that were culled off without any reason (such as sickness etc.) were assumed as 305 lactation milk yield. Then, standard 305-day lactation milk yield were adjusted according to mature age using calculated correction factors based on age and twice milking for Simental breed cows (Çilek and Tekin, 2006).

General linear model of SAS program (SAS, 1998) were applied to determine non-genetic effects of calving years, lactation number, calving season, calving age, birth type, and parity on 305-d milk yield.

Following model was used for milk yield traits. The model: $Y_{ijklmno}= \mu+ Y_i + L_j+ S_k + A_l+ B_m+D_n+e_{ijklmno}$ was used to analyze effective factors on milk yield and where: μ= mean milk yield traits of Simmental cow population, Y_i = effect of calving years (i= 2001, 2002,…,2014), L_j = lactation number (j= 1, 2, ….,8), S_k = effect of calving season (k= winter, spring, summer, autumn), pA_l = effect of calving age (l= 2, 3, 4…9>), B_m = effect of birth type (m= single, twin), D_n = effect of parity (n= heifer, cow), $e_{ijklmno}$ = error term. It was assumed that there was no significant interaction among evaluated factors and the sum impact of factors on their sub-group was zero.

Results and discussion

Least square means, significance and multiple comparison test results for 305-d milk yield of Simmental cows are presented in Table 1. Mean 305-day lactation milk yield was 6060.30 kg.

Table 1. Least squares means, significance and multiple comparison test results belong to 305-day milk yield.

Factors	n	305-Day Milk Yield (kg)	Factors	n	305-Day Milk Yield (kg)

NS: Non-Significant (P>0.05); *: P<0.05; **: P<0.01; ***: P<0.0012

a, b, c, d, e, f: Subscripts with different letters within columns significantly (P<0.05) differ.

[#]Heifers (parity 1) or cows (parity ≥2); for example, a gestation that produced a second calving is parity 2.

In this study, adjusted 305-day lactation milk yield was 6060.30 kg. The effects of calving year (P<0.001), lactation parity (P<0.05), calving age (P<0.05), birth type (P<0.05) and parity (P<0.001) on 305-day lactation milk yield were significant but the effect of calving season were not significant (P>0.05). The results of the current study were in agreement with the results of Çilek and Tekin (2005), and Pantelić et al (2010); Petrović et al., (2015); Çilek and Tekin (2005); Özkan and Güneş (2011) regarding the effects of calving year, lactation parity, calving age and birth type, calving season on 305-day lactation milk yield, respectively but different from the results of Pantelić et al (2014), and Petrović et al.,(2015) with regards to birth type, calving season on 305-day lactation milk yield.

Conclusion

In conclusion, it was observed that Simental cows can produce milk yield at World standard for Simental cows at subtropical climate conditions with ideal feeding and management strategies. Moreover, considering that the lactation period was longer in the current study, more efficient and profitable farming can be performed with keeping the lactation period in normal standard.

Abstract

Preference and feed intake on poultry is normally affected by physical feed form and require attention when producing poultry diets. Tedera or psoralea (*Bituminaria bituminosa* C.H Stirt) is a drought tolerant legume that grows in African and Mediterranean areas traditionally used as forage for ruminant with high protein and nutritive value. This study was conducted to evaluate the effects of tedera feed form on voluntary intake and preference in male growing chicks. The two dietary forms of tedera offered were fresh and dried, with the same particle size during 15 consecutive days. The preference and voluntary intake were investigated with a total of 10 chicks divided on five replicates (n=2) and compared with the control group (only commercial diet). Two chicks from each group (control and experimental) were randomly chosen for blood sampling at the end of the study. Control group average daily feed intake (ADFI) shown significant differences compared to tedera group. However, average daily gain (ADG) did not. Hematocrit and total plasma protein values from each group were similar. However, this research demonstrated that the intake was affected by the tedera feed form (dry or fresh): the poultry preference for fresh tedera was significantly higher than for dry tedera ($p<0.01$).

Key words: *Bituminaria bituminosa, feed-form, poultry diets, preference, intake.*

Introduction

Tedera (Bituminaria bituminosa C.H. Stirt.) is a perennial legume well-adapted to Mediterranean climatic conditions and a diverse range of soil types (Real and Verbyla, 2010). Tedera is as a drought-tolerant legume enables to produce biomass under low-rainfall conditions and add symbiotic nitrogen that improve soil structure (Moore et al., 2006; Real et al., 2009; Real and Verbyla, 2010). Most recent studies have focused on tedera as a forage for ruminants. This report takes a new look at tedera as a promising new forage for poultry.

An important aspect of poultry diet composition is the protein content (Carré et al., 2008). Intensive poultry production systems tend to deprive chicks of leguminous plants that are readily available. However, supplementing diets with leguminous feeds containing high crude protein could contribute significantly to meeting the protein requirements for growth (Willianson et al.,1989). Moreover, the higher price of the main poultry feed production ingredients that not are available in arid areas make necessary a search for alternative feedstuff (Babiker et al., 2012; Dei et al., 2007). Recent studies observed that feed cost is 60% of the total cost of broiler production in Nigeria and 70% in Cameroon (Teguia et al,. 2005; Iyayi et al,. 2005). In addition, in the poultry industry, broiler rations contain 60–65% maize, that competing with the world-wide demand for human consumption. For that reason is important to search alternative feed sources for poultry production (Shiferaw et al,. 2011; Diarra et al., 2014). Thus, tedera could be a good alternative protein source in African and Mediterranean arid areas.

Poultry are able to consume 10-20% of their dietary requirements from fresh, dried, or ensiled grass. Various authors have reported that daily plant intake can reach up to 30 g of dry matter

(DM) in laying hens (Hughes and Dun, 1983), and soil intake also can reach up to 23% of the ingested DM (Jondreville et al., 2010) or even 30 g per day. Diet presentation can also impact the ability of birds to consume feed as well as its palatability for consumption (Latshaw, 2008).

There are no reports on the effects of feeding tedera on poultry. This paper reviews the chemical composition of tedera and investigates the influence of tedera feed form (fresh or dried) on the preference, average daily feed intake (ADFI), average daily gain (ADG) and feed conversion ratio (FCR).

Materials and methods

Experimental procedures were conducted with a total of 12 male chicks (15 days-old), individually weighed and randomly allocated into six groups. Each pen measured about 1-3m with diurnal temperature ranging between 24 and 30ºC. Thus, ten male chicks were then housed for 15 days in five pens, where they had free access to 15 feeders. In this way, in each pen, 2 chicks had daily access to 3 feeders each containing dried tedera, fresh tedera and commercial diet. Additionally, another group with two chicks that only have access to commercial diet, was utilized as a control group. Tedera (dried and fresh) and the commercial type poultry diet were introduced to the pens simultaneously on a daily basis. The experimental diets were offered *ad libitum* during 15 days and the water was freely available. Tedera (dried and fresh) was offered in the same particle size, because is known that poultry distinguish the differences in feed particle size (Amerah., et al., 2007, Chewing et al., 2012).

For the chemical composition of commercial diet and tedera, fresh samples were weighed, cut and dried at 60˚C to about 90g/kg dry matter (DM). They were then ground to pass a 1 mm screen prior to duplicate chemical analyses. Dry matter, ash and crude protein (CP) were determined according to standard methods as described in AOAC (2000) (methods 930.15, 942.05, and 976.05, respectively). Ash-free neutral detergent fibre (NDF) was determined using sodium sulfite in the ND according to Van Soest et al. (1991).

The chicks were monitored for feed intake and weighed, individually, at the start of the experiment and daily. Feed offered and refusals were weighed and recorded daily in all groups to determine the average daily gain (ADG). Finally, two birds per replicate were, randomly, selected at the end of the study of blood samples. ADFI, body weight gain (BWG), feed conversión ratio (FCR) and ADG, were calculated.

The results were subjected to analysis of variance (ANOVA) to determine differences. Differences were considered to be significant at $P < 0.05$.

Results and discussion

The proximate composition of commercial diet and tedera are summarized in Table 1. Tedera resulted to have higher CP than commercial diet (241,0 and 140,0 g/kg, respectively), as well as the DM (91,3 and 85,7 g/kg, respectively), OM (83,8 and 73,8 g/kg, respectively), FND (306,1 and 167,6 g/kg, respectively) and FAD (173,1 and 45,2 g/kg, respectively). On the contrary, the Ash content of the commercial diet was higher than that of the tedera (118,8 and 75,9 g/kg DM, respectively). The crude protein content obtained in this study for tedera was slightly higher than values reported in literatures (Ventura et al. 2004; 2009).

The chemical compositional result has shown that tedera is a good sources of protein according to the nutritional requirements of poultry (NRC., 1994). However, the fibre component is also a major fraction of the dry matter (DM), but it was a similar lignificated fibre compared with the commercial diet. According with Awosanya et al,. (1998), fresh green feeds, especially leguminous, could supply protein and contribute significantly to improved performance of birds

Table 1. Proximate analysis of commercial diet and tedera.

Constituent	Commercial	Tedera	SEM
DM (g/kg)	85,71	91,37	4,00
CP (g/kgDM)	140,00	241,00	71,42
Ash (g/kgDM)	118,83	75,96	17,37
OM (g/kgDM)	73,82	83,77	3,94
FND (g/kgDM)	167,60	306,11	51,27
FAD (g/kgDM)	45,21	173,08	57,87
LAD (g/kgDM)	20,85	21,36	0,51

The effects of supplemented with tedera on poultry performance are shown in Table 2. Overall, the chicks showed a preference for the commercial diet. Only an interaction for ADFI was significant between groups ($p<0,01$).

Table 2. Effects of tedera on average daily feed intake, feed intake of comercial diet, body weight, feed conversión ratio, hematocrit and total plasma protein values.

Parameter	Control group	Experimental group	SEM	p-value
ADFI (g/d)	170,00	147,14	16,16	<0,01
FI commercial diet (g/d)	170,00	111,60	24,18	<0,02
Initial BW (g)	664,00	665,70	3,56	0.66
Final BW (g)	984,00	931,30	39,14	0.12
Total BW gain (BWG) (g)	320,00	265,60	41,22	0,12
ADG (g/d)	21,33	17,71	2,63	0,14
FCR	7,97	8,31	0,24	0,6
HCT (g/dl)	3,50	3,25	0,18	0,15
TPP(%)	29,00	28,00	0,71	0,55

Chicks fed only commercial diet consumed more than those supplemented with tedera. However, both groups had no significant differences in average daily gain, feed conversión ratio or performance parameters. However, the results for average daily gain were lower than the reported by Etela et al. (2006), who investigated supplementation of poultry diet with fresh centrosema, pueraria and waterleaf, reported highly ADG (35 g/d, 33,9 g/d and 37,7 d/d, respectively).

In all the experimental groups there was no sign of toxicity or mortality reported in the course of the experiment. The values obtained for hemoglobin (Hb) and total plasma protein (TPP) was in the normal ranges and there were no significant differences ($P<0,05$) observed between treatment means.

Feed preferences are presented in Table 3. A significant interaction between tedera feed form was observed. Voluntary intake of fresh tedera was significant higher than dried tedera for all experimental groups given the same feed with the same particle size during the same period (15 days).

Table 3. Effects of tedera feed form on preference and voluntary intake.

Experimental groups	Fresh tedera	Dried tedera	p-value
1	30,08 ± 9,17	4,33 ± 7,71	<0,01
2	23,79 ± 11,40	5,17 ± 6,16	<0,01
3	28,00 ± 6,12	4,83 ± 4,14	<0,01
4	34,92 ± 10,01	3,50 ± 2,76	<0,01
5	33,83 ± 6,83	3,08 ± 1,72	<0,01
Mean	30,124 ± 4,52	4,181 ± 0,88	<0,01

The results of this study showed that tedera feed form affected the preference. This supported the findings of Bricked et al., (2004), who reported that the feed form of the diet had a significative effect on intake and results are also according to Latshaw et al. (2008), who reported the impacts of feed form of the poultry diet on palatability.

Conclusion

The dietary inclusion of tedera decreased average daily feed intake. However, resulted in a similar body weight gain, average daily gain and feed conversion ratio. The results demonstrated that the tedera feed form (dry or fresh) had a greater effect on poultry intake and preference. Voluntary intake of fresh tedera was significantly higher than for dry tedera and daily plant intake can reach up to 30 g. First results suggest that tedera is a promising new legume for poultry diets. This knowledge may be important for increasing the local and alternative resource utilization on poultry diets. Although, more results are needed to perform the dietary effect of tedera supplementation on carcass and egg quality of poultry.

Abstract

The aim of this study was to determine the effects of using different varieties and levels of participation of raw soybeans in the final mixtures for broiler chickens on chemical and amino acid composition of dark and white meat. The research was conducted at the experimental farm of the Institute for Animal Husbandry in Zemun using Hubbard F15 heavy line hybrid broilers. A total of 2000 one-day broilers were distributed in 40 equal boxes reared on deep litter (50 chickens per box, 4 boxes replicates per treatment diet). Chickens in all groups had uniform requirements in terms of population density, food area, temperature and light. Until the age of 35 days all birds in the experiment were fed the same diets. The study was carried out on chickens at the age of 35-42 days, according to the principle of two-factorial trial 2 x 5 (2 varieties of domestic varieties x 5 levels of participation of raw grains in the mixture) with a total of 10 treatments. At the end of the experiment, 6 broilers per each tested treatment and gender were randomly selected, a total of 120 chickens, from which the sample of breasts and thigh muscle tissue was taken after the slaughter in order to determine the quality of the meat. It was established that increased concentration of trypsin inhibitor in the final mixtures for chicken had no negative impact on the quality of meat (basic chemical and amino acid composition of dark and white meat).

Key words: *nutrition, soybean, trypsin inhibitors, broiler chicken, chemical and amino acid composition of meat*

Introduction

The nutrition of broilers, in addition to genetics, is the most important factor that can influence the chemical composition of chicken meat. The soybean in chicken diet is the number one protein component and is valuable feed in terms of amino acid composition (*Tan Wilson et al., 1987; Kho and Lumen, 1988*). In comparison with grains and leguminous species, soybean has the highest percentage of proteins (on average of about 38%, with 2.1 to 2.5% lysine). The nutritional value of raw soybean is reduced by the presence of numerous anti-nutritive substances such as trypsin inhibitors (TI) (*Palacios et al., 2004*) and lectins (*Douglas et al., 1999*). The nutritional value of soybean can be increase by proper heat treatment and deactivation of anti-nutritional factors which are mainly proteins, but this procedure also increases its price.

Selection/breeding work has resulted in soybean varieties with reduced content of certain anti-nutritional substances. Variety Lana was developed by *Srebrić and Perić (2008)* as a result of domestic soybean breeding program aimed at reducing the activity of TI. Variety Lana has a lower TI level by 50% compared to conventional soybean varieties. The use of raw soybeans (especially varieties with reduced TI content) influences primarily the reduction of feeding costs and improves the economy of broiler production.

Comparing the nutritional value of soybeans with lower TI level in the diet of broiler chickens, *Petričević et al. (2015)* have found better production results compared to soybeans with standard level of TI, however no significant differences in the quality of the carcasses were identified. Comparing raw and heat-treated soybeans, *Beuković et al. (2012)* have established better quality of chicken carcass, expressed by dressing percentages, in chickens fed heat-treated soybeans. *Petričević et al. (2016)* have determined that the increased levels of raw soybeans in the final mixtures for broiler chickens hinder the utilization of protein in the ration, resulting in weaker development of the most valuable parts of the carcass, primarily the breast.

The aim of this research was to investigate the effects of replacing a part of heat processed soybean of standard variety "Lydia" and variety with reduced TI content "Lana" with raw soybean grains in the final mixtures for broiler chickens on chemical and amino acid composition of dark and white meat.

Materials and methods

The research was conducted at the experimental farm of the Institute for Animal Husbandry in Zemun municipality (Belgrade, Serbia) using Hubbard F15 heavy line hybrid broilers. In the final mixtures for broilers two local varieties were used, variety "Lana" with reduced TI level and variety "Lydia" with standard TI level, extruded and raw (Table 1).

Table 1. Level of trypsin inhibitor in soybean

Treatment	Raw soybean		Heat-treated (extruded) soybean	
Variety	Lana	Lydia	Lana	Lydia
TI (mg/g)	17.71	36.74	4.38	14.03

A total of 2000 one-day broilers were distributed in 40 equal boxes reared on deep litter (50 chickens per box, 4 boxes replicates per treatment diet). Chickens in all groups had uniform requirements in terms of population density, food area, temperature and light. Until the age of 35 days all birds in the experiment were fed the same diets. Finisher as the final mixture contained 17.5% crude protein and 13.2 MJ/kg metabolic energy in all experimental groups, it was available to broiler chickens from 35 to 42 days and differed for all the tested treatments in regard to soybean varieties and the participation of the heat-treated and the raw soybean. (Table 2).

Effect of different levels of raw soybeans in diets was determined in a two-factorial trial 2 x 5 (2 varieties of soybean x 5 levels of participation of raw grains in the mixture) with 10 dietary treatments.

Table 2. Trial design/plan and extruded and raw soybean ratio in the final mixtures

Treatment	Broilers	% of soybean in the diet (Extruded : Raw)	Soy bean ratio % (Extruded : Raw)
Lana - 0% (K)	200	20% (20% : 0%)	100/0
Lana - 5% (I)	200	20% (15% : 5%)	75/25
Lana - 10% (II)	200	20% (10% : 10%)	50/50
Lana - 15% (III)	200	20% (5% : 15%)	25/75
Lana - 20% (IV)	200	20% (0% : 20%)	0/100
Lydia - 0% (K)	200	20% (20% : 0%)	100/0
Lydia - 5% (I)	200	20% (15% : 5%)	75/25
Lydia - 10% (II)	200	20% (10% : 10%)	50/50
Lydia - 15% (III)	200	20% (5% : 15%)	25/75
Lydia - 20% (IV)	200	20% (0% : 20%)	0/100

At the end of the experiment, broilers were selected randomly, 6 for each test treatment and gender - total of 120 chickens, from which post-slaughter samples of breast and thigh muscle tissue were taken in order to determine the chemical and amino acid composition of meat. The basic chemical and amino acid composition samples of white and dark meat was determined:

- Moisture content was determined according to standard SRPS ISO 1442/1998;
- The content of free fat was determined according to standard SRPS ISO 1444/1998;
- Content of total ash was determined according to standard SRPS ISO 936/1999;
- The nitrogen content was determined according to standard SRPS ISO 937/1992 and protein content according to the following formula: CP (%) = N (%) x 6.25;
- The amino acid composition was determined by HPLC (IC with electrochemical detector).

The software package STATISTICA Version 6 (StatSoftInc.) was used in the statistical analysis.

Results and discussion

Table 1 shows data on the basic chemical composition of dark and white meat of broiler chickens of both genders.

Table 3. Chemical composition of chicken meat (%)

Treatment	Dark meat				White meat			
	Water	Fat	Ash	Protein	Water	Fat	Ash	Protein

Level of raw soybean	0.129	0.338	0.675	0.180	0.181	0.143	0.740	0.078
Variety x Level	0.237	0.118	0.984	0.709	0.406	0.499	0.609	0.683

Statistical analysis of the data obtained for the chemical composition of dark and white meat of broiler chickens of both genders showed absence of significant differences under the

influence of investigated factors (p>0.05). The use of raw soybean with reduced TI levels in mixtures for broilers did not affect the significant changes in the content of water, fat, ash and protein in the dark and white meat compared to soybean of variety Lydia. Increasing the level of raw soybeans in the final mixture did not cause poorer quality of meat. Also, the interaction of investigated factors did not influence the chemical composition of meat.

The quality of chicken meat is determined by sensory properties and nutritional value i.e. chemical composition (water content, protein, minerals and fats). The favourable chemical composition, high content of protein with low fat content, is what makes the chicken meat very desirable food of animal origin (*Kralik et al., 2007*). The chemical composition of poultry meat, in addition to diet, can be influenced by other factors: genotype, age, gender (*Ristić et al., 2008*). In the literature, there are few results that are directly related to the impact of increased TI concentrations on the chemical composition of chicken meat. Similar to our results, *Sardary (2009)* have found no statistically significant differences in the chemical composition of dark and white meat of chickens fed diets with different amounts of heat-treated whole soybean and raw soybean. *Marcu et al. (2009)* and *Haščík et al. (2011)* have found a slightly higher water content and lower content of fat in the breast meat as compared to our results. *Lonergan et al. (2003)* suggest that breast meat contains 24.02% protein, 73.42% water and 1.08% fat. *Ristić (2007)* point out that the protein content of the breast meat is by 3.5% higher than in the thigh meat, which is consistent with our results.

Data for the amino acid composition of chicken meat of broilers of both genders under the influence of tested factors are shown in Table 2. The contents of valine, leucine, lysine and tryptophan in dark and white meat are determined.

Table 4. Amino acid composition of chicken meat (%)

Treatment	Dark meat				White meat			
	Valine	Leucine	Tryptoph.	Lysine	Valine	Leucine	Tryptoph.	Lysine
Soybean variety								
Lana	1.04	1.59	0.24	1.81	1.03	1.57	0.24	1.80
Lydia	1.05	1.61	0.25	1.81	1.04	1.59	0.24	1.81
Level of raw soybean, %								
0 (K)	1.04	1.59	0.25	1.81	1.06	1.61	0.25	1.82
5 (I)	1.03	1.61	0.25	1.82	1.03	1.57	0.25	1.82
10 (II)	1.05	1.61	0.26	1.82	1.05	1.60	0.23	1.80
15 (III)	1.06	1.58	0.24	1.82	1.01	1.55	0.23	1.78
20 (IV)	1.06	1.62	0.25	1.82	1.05	1.57	0.25	1.81
p value								
Soybean variety	0.461	0.530	0.451	0.756	0.373	0.353	0.516	0.564
Level of raw soybean	0.339	0.438	0.275	0.346	0.292	0.148	0.370	0.194
Variety x Level	0.185	0.218	0.382	0.619	0.152	0.254	0.339	0.484

The analysis of the data reveals that the soybean variety and different levels of soybean grain in chicken final mixtures exerted no statistically significant impact on the amino acid composition of dark and white meat (p>0.05). It was also determined that the interaction effect of studied factors had no significant effect on the content of valine, leucine, tryptophan and lysine in the dark and white meat.

The chicken meat is a rich source of biologically valuable protein, essential amino acids, minerals and vitamins in the human consumption. Compared to other types of meat chicken meat represents a significant source of essential polyunsaturated fatty acids, especially omega-3 (*Losso, 2002*).

Conclusions

Based on the results of the study of the individual impact of the variety and level of participation of raw soybeans and interactive influence of both factors in the diet of broiler chickens aged from 35 to 42 days, it can be concluded that the increased concentration of trypsin inhibitors in the final mixtures for chickens had no negative impact on the quality of chicken meat. The use of soybean of variety Lana did not influence ($p>0.05$) achieving of more favourable chemical and amino acid composition of dark and white meat compared to soybean with a standard TI level. The 20% of raw soybean grains in mixtures did not cause poor results of the tested parameters of chicken meat quality in relation to groups with lower participation and without the raw soybeans ($p>0.05$).

THE EFFECT OF LAYERS FEED SUPPLEMENTATION WITH ORGANIC SELENIUM ON THE QUANTITATIVE AND QUALITATIVE INDICATORS OF PRODUCTION

Vezir JANUZI, Lumturi SENA*

Faculty of Agriculture and Environment, Agricultural University of Tirana, Albania
*Corresponding author: lumturisena@yahoo.com

Abstract

The experiment was conducted for a period of 13 weeks in a poultry farm near Podujevo. 400 Lohman Brown layers, were divided into four groups as following: Control Group (C), Experiment 1 (E1), Experiment 2 (E2) and Experiment 3 (E3). The same food formula was applied for the four groups, but if the control group was fed with the basic diet, the food formula of the consequent other three was supplemented with Organic Selenium (Se) Sel-Plex®, Alltech, inc., 0.2, 0.3 and 0.4 ppm respectively. During the experimental period the following parameters were consistently recorded, monitored and evaluated: live weight, egg production, egg mass, egg quality and food conversion ratio (FCR). At the end of the study, it was concluded that different levels of organic selenium did not significantly influenced (P <0.05 level) neither on the egg production nor on the egg's quality and on the body weight. In the group supplemented with 0.4ppm Selenium, a tendency for the production increased and FCR's improvement was observed. The increasing dose of Se in the food, as it was observed, had a tendency to improve egg weight. E3 group eggs resulted in a higher weight; 3.7, 3.6 and 2.1% respectively than Control one, E1 and E2. The egg mass, slightly improved in the group supplemented with 0.4 ppm Selenium.

Key Words*: Selenium, poultry production, egg production, egg weight, chicken*

Introduction

Selenium is an essential microelement for poultry. Various authors have studied that the food with Se supplementation may affect egg quality parameters, the freshness of eggs (Arpasova H, et al, 2009) and in improving the quality of egg white (HU). Se supplementation of food affects not only improve the health and performance of production, but also can be a natural way to produce functional products - eggs rich in selenium (Chinrasri O, et. Al, 2009; Gorgovska N., et al, 2011). So far indicate that information in the form of organic selenium has a series of important advantages compared with selenite. Organic selenium absorbed as an amino acid similar to methionine. Based on what has already been highlighted in this study proved the use of dietary supplementation with organic Se with different concentrations in poultry production.

The aim of the study was to determine the effect of supplemented feed formulas in laying hens in different concentration of organic Selenium Sel-Plex - Alltech, on performance indicators.

Material and Methods

The study was conducted in a commercial layers' farm in Podujevo within a 13 weeks period of time. Based on the principle of comparative analogy of body condition, age, production and health condition, 4 groups of 100 chicken/each were established. Hybrids chickens for eggs were Lohman Brown. During the entire experiment the chickens were hold in the same ambient, in a 4 tier cage, with 5chickens/cage and in environmental conditions of equal treatment and service.

The feed composition was the same for every group, while the difference was in the level of Selenium's inclusion. The control (C), the basal diet contained a trace mineral premix that provided no Supplemental Se, while for the other 3 groups of experiment the feed was suplemented respectively 0.2ppm (experiment 1 - E1), 0.3ppm (experiment 2 - E2) and 0.4ppm (experiment 3 - E3) organic Selenium. The feed was prepared in the feed mill, near poultry operation. Sel-Plex, Alltech, Inc. organic selenium was used.

Table 1. Composition of the ration

Ingredients	Structure (%)
Corn	60
Soybean meal	20
Sunflower meal	10
Calcium carbonate	8.75
Premix	1.25

At the end of the experiment, by randomly selecting10 eggs/group were collected in order to determine both internal and external qualitative parameters.
It was determined the weight of the egg, the weight of the white, yolk weight, the shell and the shell thickness, index format and intensity of egg yolk.
While the egg mass (EM) for each group was calculated with the following formula:
EM = EW (Egg Weight) x EN (Egg Number)/NH (Number of hens)

Recorded indicators were:

1. The daily production of eggs for each group
2. The egg weight/group;
3. Internal and external egg quality;
4. Feed consumption/group in kg;
5. Feed Conversion Rate/egg unit;
6. Body weight; For this, 5% of the flock was weighed every week.

The obtained results were statistically processed via ANOVA and descriptive analysis, for the comparison tTest was applied.

Results and discussion

Egg production for each group
As seen in the table 2, a slight superiority of E3 on all groups is noted, starting from the 4^{th} – 9^{th} week of the study and as a weekly average for the whole period of the study. Although these differences are statistically non-significant, for $p \leq 0.05$. Also, a decline of egg production each week until the week 13 is evidenced, respectively 30% at the control group, 31.6% at E1, 27.5% at E2 and 28.8% at E3. It needs to be mentioned that the layers are at the second phase of production (experiment started at week 38), meaning that this declination is acceptable.

Table 2. Average daily egg production weekly by each group

Week	Control	Experiment 1	Experiment 2	Experiment 3
1	94.2	97	93.7	93.9
2	97	91.9	91.1	91.7
3	88.9	85.7	85	87.7
4	76.9	76.7	77.6	84.3
5	75	74.7	78.4	77.6
6	71.9	70	74	74.4
7	71.9	71.9	74.9	76
8	71.7	71.7	72.7	74.3
9	67.1	67.3	74.3	73.6
10	65.6	68	69.9	69.7
11	71.4	71.9	72.3	72.9
12	69.7	69.4	66.9	66.7
13	66.6	66.4	67.7	66.9
Egg production/day	76±10.52	75.6±9.80	76.8±8.36	77.7±8.99
Egg/hen /week	5.48±0.58	5.46±0.59	5.46±0.56	5.51±0.59
Egg/hen total	71.3	70.93	71	71.67

Our results for egg production agree with those of Cantor et al. (2000) and Patton (2000) who reported no difference in egg production when hens were fed a basal diet supplemented with 0 or 0.30 ppm of Se. In accordance with our results Chinrasri et al. (2009) have not found any significant effects of additions' of Se yeast.

Indicators of egg quality

Table 4. The weight of the components of the egg and it's qualities by group

Egg quality indicators	Control	Experiment 1	Experiment 2	Experiment 3
Egg weight (g)	61.02±5.04	61.09±3.47	62±5.15	63.28±5.34
The white weight (g)	37.89±4.88	37.77±2.68	39.10±4.29	38.92±3.14
The yolk weight (g)	14.95±1.05	15.37±1.18	15.15±0.90	15.91±1.32
Shell weight (g)	8.18±0.93	7.95±0.97	8.05±0.61	8.45±0.68
Shell thickness (mm)	0.58±0.04	0.60±0.04	0.59±0.03	0.59±0.01
Shape index	1.36±0.00	1.35±0.00	1.40±0.00	1.40±0.00
The intensity of the yolk (Roche)	11	11	11	11
Egg mass (kg)	4.35	4.33	4.40	4.54

A tendency is noticed for improving the quality of eggs by increasing the Se dose. The eggs of Group E3 respectively have a weight of 3.7, 3.6 and 2% larger than those of control (C), E1 and E2. However, it can be said that there is a tendency for larger weight of eggs and their components in the group that got 0.4 ppm Se dose, since the differences are statistically non significant ($P<0.05$). This can also be confirmed by other studies (Arpasova, et al., 2009; Skrivan et. al., 2006; Utterback et. Al., 2005).

Even the shape index appears to be better in E2 and E3. As for the intensity of yolk, it is the same for all groups. The egg mass in the best group (E3) respectively is 190g bigger than Control, 210g bigger than E1 and 140g bigger than E2.

The eggs for incubation or for the market should be of oval form, a characteristic which is expressed by the index of shape, which is 1.32. -1.40 for chicken eggs (Sena L, Stefi G, 2009). This indication was within the limits in all groups.

The intensity of egg yolk for the four groups in experimental period was defined with special calorimeter for this purpose (Roche calorimeter). It results that the yolk intensity for all groups was the same 11 Roche degree. Intensity of the yolk is within normal in two groups.

So, supplementation of food ration with organic Selenium for chickens in mass 0.2, 0.3 and 0.4 ppm doesn't show impact on weight and eggs quality.

Feed Consumption

Feed consumption was monitored and the feed conversion rate (gr. feed/egg) was calculated for four groups during the experiment:

Table 5. Feed Conversion Ratio (FCR)

Week	Control	Experiment 1	Experiment 2	Experiment 3
1	121.96	118.56	122.71	122.53
2	125.59	125.19	125	125.39
3	128.18	134.17	133.94	131.11
4	143.75	146.90	146.90	135.07
5	147.17	150.75	143.75	145.31
6	152.17	157.84	152.17	151.32
7	152.17	153.63	150.47	148.25
8	152.46	152.46	155.11	151.60
9	162.63	162.30	151.60	153.04
10	166.67	160.68	161.32	161.64
11	153.04	152.17	156.01	154.81
12	156.6	157.23	168.41	169.12
13	164.29	164.62	166.32	168.41
Average	148.21±14.64	148.96±14.34	148.75±14.32	147.51±15.17

During the experiment confirmed a worsening of FCR in all groups. E3 group has the best result for FCR. E3 used the food with more efficiency. In E3 is saved 0.45% food/ egg compared with Control, 0.97% compared to E1 and 0.83%, compared to E2. However, the differences were not significant. The result achieved at E3 is close to other studies regarding this factor. Ševčikova et al. (2006) reported that the FCR was not affected by Se supplementation. Results of studies Jiakui and Xialong (2004), Utterback et al. (2005), De Lange L.L.M. and G. Oude Elferink (2005), and Leeson et al. (2008) indicated no differences in egg production, and FCR of laying hens due to inorganic and organic Se supplementation.

Body weight

Table 6. Body weight of poultry (kg) per week group (M ± SD)

Week	Control	Experiment 1	Experiment 2	Experiment 3	Standart
day 1	1.44±0.08	1.52±0.11	1.52±0.04	1.53±0.21	1.843-2.037

11	1.79±0.15	1.75±0.09	1.74±0.11	1.86±0.15	1.870-2.066
12	1.79±0.12	1.76±0.11	1.85±0.11	1.88±0.14	1.872-2.070
13	1.80±0.16	1.81±0.10	1.87±0.04	1.90±0.11	1.874-2.072
Body weight gain (Kg)	0.36	0.29	0.35	0.37	

During the weeks of study, a tendency for higher weight was noticed in group that got 0.4ppm Se (E3). However the differences aren't significant ($P<0.05$), especially in the last six weeks of study. However, even the hens of the best Group (E3) reached lower weight, compared to those hybrid standard (Management Guide Layers Lohman Brown-Classic.), with exception for those in the last two last weeks. Even the addition in weight for whole period of study, was close to that in control group, E2 and E3, with exception to E1, which had a lower weight.

Conclusion

Supplementation of layers diet with organic Selenium with different concentration 0.2, 0.3, 0.4ppm didn't show any effect on performance indicators. The group that the diet was supplemented Selenium in 0.4ppm shows tendency for improving of egg production, weight of eggs and its compounds, egg mass and for higher body weight.

A tendency for slight improvement of FCR was evidenced in this Group.

Abstract

Aim of study was to examine the impact of thawing temperature on quality parameters of bull's semen. A total of 120 commercial doses of deep-frozen bull's semen, originated from three Simmental bulls, were examined. Semen was thawed at 38°C for 30 seconds (n=60 doses, 20 from each bull) or at 50°C for 15 seconds (n=60 doses, 20 from each bull). Thawing temperature did not have effect on average percent of progressive motility and sperm concentration (66.08% and 24.03x10^6at 38^OC, vs. 66.05% and 24.11 x10^6at 50^oC, respectively). Live sperm percent and dead sperm percent in each bull's semen samples was lower after thawing at lower temperature (55.74%, 44.14% and 55.29% vs. 56.08%, 44.67% and 57.68%; 6.78%, 10.67% and 4.26% vs. 7.88%, 10.90% and 5.72%, respectively).Percent of sperms died during staining in each bull's semen samples was lower after thawing at lower temperature (20.02%, 21.92% and 27.13% vs. 20.83%, 23.31% and 25.67%, respectively).Total percent of damaged sperms in each bull's semen samples was higher after thawing on lower temperature (17.46%, 23.27% and 13.31% vs. 15.20%, 21.10% and 10,99%, respectively). Percent of sperms with intact membrane damage in each bull's semen samples was higher after thawing at lower temperature (49.67%, 53.12% and 45.97% vs.41.39%, 46.03% and 43.15%, respectively), contrary to percent of sperms with other types of damage (50,33%, 46,88% and 54,03% vs.58,61%, 53,96% and 56.85%, respectively).Our results indicate positive impact of higher thawing temperatures on bull's semen quality parameters, and consequently its fertilisation ability.

Keywords:*bull's semen, thawing temperature, quality.*

Introduction

The percentage of progressive motility of sperm is considered to be the most important parameter of insemination doses quality (Miljković, 1998), as only a vital and progressive motile sperms are able to pass through the female sex organs to the fallopian tubes and carry out insemination. To assess the quality of the ejaculate, or preservation of spermatozoa fertile ability after thawing, progressive motility should be evaluated immediately after taking of ejaculate and also immediately after thawing.

Vakanjac et al. (2013) state that the lower limit of sperm motility for ejaculate acceptance immediately after taking is 70%, while that value after thawing should be at least 50%, since one part of sperms are ireversibly damaged during the cryopreservation and thawing.An additional factor that ensures high fertilisation ability of insemination doses is sperm count, ie. number of sperms in the dose, which should be form 10 to 20 millions (Snoj, 2014). A critical point in the semen cryopreservation and thawing is passing through a temperature range between -60°C and -80°C, because of intensive formation of ice crystals, which can severely damage sperms (Miljković, 1998).Therefore, in both phases of work with the semen, it is necessary to ensure that the semen pass through that temperature range as fast as it can, to

reduce the number of damaged sperms. The process of cryopreservation of bull's semen is standardized and mainly automated, so damage of sperms during the freezing process can not be reduced by changing the conditions, while in the process of thawing it can be modified by changing of thawing temperature and exposure time, as found by many authors.
The aim of this study is to examine the impact of two different thawing temperature on quality parameters of bull's semen.

Material and methods

The study included a total of 120 commercial insemination doses of semen, originating from three Simmental bulls (Indurein, Strellas, Polian, 40 doses for each of bulls). Bulls were housed in standard conditions of commercial reprocenter and fed in accordance with the norms for a given breed. In order to avoid the impact of the various terms of ejaculate taking on the parameters of semen quality, all doses from each bull originated from the same ejaculate. Doses of semen were taken from the commercial center for artificial insemination (AD Veterinary Cattle Breeding Center Banja Luka), and their thawing and analysis of quality parameters were carried out in the Laboratory of Genetics and Reproduction, Faculty of Agriculture, University of Banja Luka (Republic of Srpska, Bosnia and Herzegovina). Half of the selected doses of each bull (n=20) were thawed by using standard procedure (at 38°C for 30 seconds), while the remainder (n=20) was thawed at a temperature of 50°C for 15 seconds. After thawing, concentration of sperms, percentage of progressively motility and morphological integrity of sperms were determined for each dose of semen.
The concentration of spermatozoa for each dose was determined using the standard method in Burkher's sperm counting chamber. Sperm counting was done under a microscope, magnified 20 times, in five fields of mesh.Percentage of progressive sperm motility was assessed semi-quantitative, by visual observation of thawed semen drops under a microscope at 10x magnification. As the lower limit of progressive sperm motility after thawing, to take dose into further consideration, value of 50% was taken. Evaluation of the morphological integrity of sperm (percentage of dead sperm, deformities and defects that are potentially incurred during the thawing procedure), was performed using HOS (Hypoosmotic Swelling) test or supravital staining sperm after Blom with eosin-nigrosine. At least 200 sperms were counted in each dose.
The influence of different temperature treatments on sperm quality parameters was tested by combined factorial analysis of variance and Pearsons χ^2 test, with software package SPSS 22 (IBM 2013).

Results and discussion

Average values of progressive motility and sperm count in insemination doses thawed at different temperatures are shown in Table 1.

Table 1. Average values of progressive motility and sperm count in the insemination doses thawed at different temperatures

Parameter	t (°C)	n	X	Sx	Min.	Max.	CV
Progressive motility (%)	38	60	66,08	0,78	55,00	75,00	9,14
	50	60	66,05	0,68	55,00	75,00	7,96
Sperm count ($x10^6$ in dose)	38	60	24,03	0,14	22,50	25,00	4,50
	50	60	24,11	0,13	22,50	25,00	4,25

The thawing temperature had no statistically significant effect on the average percentage of progressive sperm motility, as well as the average number of sperm in the examined semen doses. The results indicate a satisfactory effect of both thawing protocols on the fertilisation ability of semen and its preservation after thawing. Similar results were found by Suljkanović and Šabanović (2002), who did not found significant differences in the percentage of progressive motility after thawing bull's semen at 35°C for 15 seconds or 55°C for 7 seconds (74 vs. 71.7%). Nur et al. (2003) found a favorable effect of the thawing temperature on the percentage of progressive motility (59.8% at 55°C vs. 56.6% at 37°C). In both of these studies the percentage of progressive motility of sperms was lower compared to our results. Zobel et al. (2009), investigating the relationship of the thawing temperature and the results of conception in cows, found that semen thawing in a temperature range from 10°C to 37,5°C had no significant effect on sperm survival and conception results.

To take native ejaculate for insemination doses preparation, the concentration of spermatozoa should be at least $500x10^6$ sperms per ml. The commercial insemination doses are packaged in straws of 0.25 ml, with at least 10 to 20 million sperms (Vakanjac et al., 2013). Most commercial centers produce doses with 20-30 million sperm in each dose,in order to provide a satisfactory fertilisation ability of dose in the field conditions. Results of this study indicate high average number of sperm in the examined insemination doses, and the absence of impact of thawing temperature on the sperm count (24.03 vs. 24.11 x 10^6 at a dose), which, together with the high percentage of progressive motility, should provide high fertility of these doses.

Processes of cryoconservation and thawing of semen are cause of damaging the one part of sperms morphological integrity, and consequently loosing of their fertilisation ability. Thawing protocol is one of the main factors that affect the intensity of damage or preserve the morphological integrity of sperm during freezing and thawing, primarily due to appearance of ice crystals (Miljković, 1998). With this in mind, it is important that the semen pass through the temperature range between -60°C and -80°C as quickly as it is possible, to reduce the percentage of damaged sperms. That can be achieved by increasing the temperature of thawing. On the other hand, high temperatures also lead to sperm damage, because of protein denaturation, so the exposure time of semen to high temperatures during thawing must be reduced to a minimum.

Table 2 shows the results of the morphological integrity of spermsafter thawing at different temperatures.

Table 2. Parameters of the morphological integrity of the sperms after thawing at different temperatures.

Bull	t (°C)	n	Distribution of sperms (%)					
			live	dead	died during staining	damaged		
						total	damaged intact membrane	other damages
Indurein	38	20	55,74±0,29	6,78±0,34	20,02±0,23	17,46±0,20	49,67±0,87	50,33±0,87
	50	20	56,08±0,37	7,88±0,26	20,83±0,23	15,20±0,30	41,39±0,66	58,61±0,66
Polian	38	20	44,14±0,42	10,67±0,32	21,92±0,58	23,27±0,43	53,12±1,03	46,88±1,03
	50	20	44,67±0,22	10,90±0,17	23,31±0,24	21,10±0,18	46,03±0,55	53,96±0,55
Strellas	38	20	55,29±1,13	4,26±0,53	27,13±0,98	13,31±0,78	45,97±3,69	54,03±3,70
	50	20	57,68±0,64	5,72±0,43	25,67±0,79	10,99±0,38	43,15±1,88	56,85±1,88

The present data indicate the beneficial effect of thawing temperature on the percentage of live sperm in all three bulls, but also the impact of individual bull on the percentage of live bull spermatozoa after thawing, regardless of temperature. Higher temperature of thawing adversely affected the percentage of dead sperm in all three bulls, with influence of the bull again. The percentage of sperms died during staining was approximately the same in all three bulls, regardless of thawing temperature. Higher temperatures of thawing decreased the percentage of damaged sperms, and within it reduce the percentage of sperm with damaged intact membrane, as the main consequence of ice crystals damaging.

Statistical data analysis, by using multivariate analysis of variance, found that there is a statistically significant difference in the frequency of certain categories of sperm in relation to the applied thawing protocol ($\chi2=56.91$, $p<0.01$). Generally favorable impact of higher temperature thawing parameters on morphological integrity of sperm is indicated by a higher percentage of live sperm in all three bulls and a smaller percentage of sperm with damaged intact membrane ($\chi2=44.96$, $p<0.01$), as confirmed by Suljkanović and Šabanović (2002), which found a higher percentage of live sperms after thawing at 35°C in relation to the doses thawed at 50° C (80.7 vs. 78.8%). Favorable impact of higher temperatures of semen thawing for preservation of the sperm morphological integrity was also found by Chandler et al. (1984), Nur et al. (2003), Muino et al. (2008) and Pace et al. (2013). At the same time, higher percentage of dead sperms indicate the need for shortening the period of semen exposure to higher temperatures ($\chi2=6.93$, $p<0.01$).

Conclusion

The thawing procedure is a key factor affecting the preservation of the semen quality and its fertilisation ability. Literature data indicate a beneficial effect of higher thawing temperatures on the preservation of fertile ability of insemination doses, through the increase in the live sperm percentage with preservation of progressive motility, which was confirmed in this study. Our results of the morphological integrity of sperms after thawing on different temperatures indicate that the resistance of spermatozoa to cryoconservation and thawing is individual characteristic of each bull, so it should be considered before choosing the optimal thawing procedure, in order to preserve the overall fertile ability of insemination dose.

EFFECTS OF PARTIAL REPLACEMENT OF FISH MEAL BY DDGS ON BLOOD HEMATOLOGICAL AND BIOCHEMICAL PARAMETERS OF RAINBOW TROUT

Baki AYDIN*, Erkan GÜMÜŞ

Fisheries Faculty, Akdeniz University, Antalya, Turkey
*Corresponding author: bakiaydin@akdeniz.edu.tr

Abstract

The present study investigated the effects of distillers dried grains with solubles (DDGS) meal as a partial replacement to fish meal on hematological and serum biochemical parameters of rainbow trout (*Oncorhynchus mykiss*) fry. Four isoproteic (45.47% CP) and isocaloric (3570 kcal DE/kg) diets were formulated: DDGS0 as a control group and DDGS10, DDGS20 and DDDGS30 which included 0%, 10%, 20% and 30% DDGS meal, respectively. Fish were stocked in each of 12 fiberglass tanks with a water volume of 200 litres and a flow rate of 10 litres/min. The fish were fed to apparent satiation three times daily for 84 days. Blood sample of two fish from each tank (6 fish per treatment; mean fish weight 103.9 g) was drawn gently from the caudal vein by 5-mL sterile syringe. The first part of the collected blood was transferred to a tube coated with EDTA as anticoagulant and was used for hematological indices. The second part was transferred to an tube without EDTA for serum biochemical indices. At the end of experiment, DDGS had no significant ($P>0.05$) effect on hematological parameters such as RBC, WBC, hemoglobin, hematocrit, MCV, MCH and MCHC. Significant decreases ($P<0.05$) in the biochemical parameters such as glucose were found with increasing in DDGS, whereas alkaline phosphatase, alanine aminotransferase, total protein, albumin, globulin, triglyceride, cholesterol, blood urea nitrogen, and creatinine concentrations were not significantly different between groups ($P>0.05$). Partial replacement of fish meal with DDGS could not affect haematological and biochemical parameters (except glucose) in rainbow trout.

Keywords: *Fish meal, DDGS, Rainbow trout,Haematological, Biochemical*

Introduction

Fish meal is the main protein source in fish feeds especially for carnivorous fish species such as rainbow trout (*Oncorhynchus mykiss*). However, fish meal is the most expensive protein source in fish feed and limited availability (Hardy, 2010). Hence, sustainable, lower-cost protein sources are needed to replace fish meal with alternative protein sources in fish diets. After removal of ethanol by distillation, the remaining non-fermentables are centrifuged, dewatered, mixed,and finally dried to produce the particulate co-product known as distiller's dried grains with solubles (DDGS) (Welker *et al*., 2014). DDGS, a major by-product of the dry mill ethanol industry, is currently readily available and competitively priced relative to other alternative protein sources. DDGS derived has a relatively high protein content (24-37% crude protein) without the presence of antinutritional factors commonly found in most plant protein sources and high lipid (3-15% crude lipid). DDGS has been tested in some diets for several fish species, such as rainbow trout, *Oncorhynchus mykiss* (Cheng and Hardy, 2004; Stone *et al*., 2005; Barnes *et al*., 2012; Reveco *et al*., 2012), European seabass, *Dicentrarchus labrax* and meagre, *Argyrosomus regius* (Magalhães *et al*., 2015), Nile tilapia, *Oreochromis niloticus* (Wu *et al*., 1994; Schaeffer *et al*., 2010; Salama *et al*., 2011). These stadies demonstrating its potential as an alternative ingredient in fish feed.

The objective of this study was to evaluate the effects of replacement of fish meal protein with DDGS protein on hematological and serum biochemical parameters of rainbow trout (*Oncorhynchus mykiss*) fry.

Material and Methods

Feed formulation and preparation

Four isoproteic (45.47% crude protein) and isocaloric (17.42 MJ/kg digestible energy) diets were formulated using DDGS (0, 10, 20 and 30%; Control, DDGS10, DDGS20 and DDGS30) to meet NRC (2011) requirements for rainbow trout (Table 1). All feed were thoroughly mixed until homogenous, extruted (3.0 mm diameter) using a Double Screw Inflating Food Machine (Jinan Eagle Machine Co., Ltd., DP65-II Double Screw Inflating Food Machine, Jinan, China), dried in an oven, then cooled to room temperature, and stored at -20 ºC until needed.

Table 1. Feed ingredients and proximate composition of the experimental diets

[8]Digestible energy of experimental diets was calculated according to values 4.9 kcal g^{-1} protein, 9.01 kcal g^{-1} fat, and 3.49 kcal g^{-1} carbohydrate (NRC, 1993)

Rearing conditions of fish and feeding

This study was conducted at the Toklu Balık Çiftliği Co., Ltd. (Antalya, Turkey), from January 01, 2015 to March 29, 2015. Rainbow trout (*Oncorhynchus mykiss* Walbaum, 1792) were obtained from Aydemir Alabalık Co., Ltd. (Isparta, Turkey). Prior to the start of the

experiment, all fish were acclimated to experimental conditions for 2 weeks and fed a commercial diet three times daily during the acclimation. At the beginning of the experiment, each 12 cylindrical fiberglass tanks (200 L water/tank) were randomly stocked with 25 fry with an initial mean weight of 19.88 g with three replicate tanks for each dietary treatment (4 treatments x 3 replicates). Each tank was supplied with 10 L/min flow-through freshwater with temperature, dissolved oxygen and pH at 14.3±1.2 ºC, 8.4±0.4 mg L^{-1} and 7.19±0.10 respectively. Fish were fed by hand up to apparent satiation with experimental diets three times a day (09:00 13:00 and 17:00 h) for 84 days. A photoperiod was set at natural conditions.

Sample collection and analysis

All fish were anaesthetized with clove oil to ensure ease in handling during the blood collection. Blood sample of two fish from each tank (6 fish per treatment; mean fish weight 103.9 g) was drawn gently from the caudal vein by 5-mL sterile syringe. The first part of the collected blood was transferred to a tube coated with EDTA as anticoagulant and was used for hematological indices. The second part was transferred to an biochemical tubes without anticoagulant for serum biochemical indices. The haematological parameters such as red blood cell count, white blood cell count, hematocrit value, hemoglobin value and trombocytes value were determined using the blood cell counter (Beckman Coulter AcT Diff 2, California, USA) (Fazio *et al*., 2012). The mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH) and mean corpuscular haemoglobin concentration (MCHC) were calculated using the total red blood cell count, hemoglobin value and hematocrit value (Fazio *et al*., 2012). Blood chemical parameters, such as alkaline phosphatase, alanine transaminase, total protein, albumin, globulin, glucose, cholesterol, triglyceride, creatinine, blood urea nitrogen were determined using bioanalytic test kits (Bioanalytic Diagnostic Industry, Co) and measured spectrophotometrically with an automated analyzer (Vet Test 8008 idexx, Europe).

Statistical analysis

The data (means±SD, standard deviation) were analyzed statistically by one-way analysis of variance (ANOVA) and Duncan's multiple range tests to determine significant differences using P<0,05. All statistical analyses were performed using SPSS Statistics Base v23 statistical software.

Results and Discussion

The hematological and serum biochemical parameters of experimental fish fed different diets throughout the experiment are given in Table 2 and Table 3. The survival of experimental fish ranged between 96.3% and 98.7%, and there was no significant difference among survival values of experimental groups. DDGS had no significant effect on hematological parameters such as red blood cell count, white blood cell count, hematocrit value, hemoglobin value, trombocytes value, MCV, MCH and MCHC (P>0.05) (Table 2), similar to the findings in Nile tilapia (Li *et al*., 2011). In our study, red blood cells, white blood cell counts, and hemoglobin value did not differ significantly among the groups, and they were in normal range as reported by Blaxhall & Daisley (1973) for healthy trout. Whereas in another study (Hemre *et al*., 2005), significant reduction in MCV on increase in the content of soybean meal in salmon diet was observed. Soltan et al. (2008) observed that fish meal replaced by mixture of plant proteins in Nile tilapia diets that lead to the lower haematocrit values. In this study, fish meal replacement with DDGS had no significant effect on haematocrit values (P>0.05).

A significant decreases (P<0.05) in the biochemical parameters such as glucose were found with increasing in DDGS, whereas alkaline phosphatase, alanine aminotransferase, triglyceride, cholesterol, creatinine and blood urea nitrogen were not significantly different between groups (P>0.05) (Table 3). Similar results except glucose were obtained in meagre (*Argyrosomus regius*) juveniles when carob seed germ meal was used in diets (Couto *et al*., 2016). The concentration of total protein in blood serum is used as a basic index for health status of fish. The increase of total protein, albumin and globulin levels indicates the increase

in innate immune response of fish (Yilmaz *et al*., 2015). There were no significant differences in the serum total protein, albumin and globulin values among the groups in this study.

Table 2. Effects of experimental diets on the haematological parameters in the blood of rainbow trout (*Oncorhynchus mykiss*) juveniles

Parameters	Experimental diets			
	DDGS0 (Control)	DDGS10	DDGS20	DDGS30
RBC (10^6/ul)	1,82±0,50	1,76±0,66	1,52±0,58	1,76±0,36

PRELIMINARY DATA ON DAIRY FARMERS' LEVEL OF EDUCATION: THE CASE OF ALBANIA

Grigor GJEÇI[1,2*], Ylli BIÇOKU[2], Medin ZEQIRI[2]

[1]Ministry of Agriculture, Albania

Abstract

The objective of this exploratory study was to assess the impact of farmers' education on dairy farming knowledge, national food safety standards, animal diseases, and farm production practices. Farmers' lack of awareness is likely a contributing factor to food standards not being met in most cases. 144 interviews were carried out on randomly selected larger farms. These farms were selected from Shkodra and Lushnje regions; and the data were collected through face-to-face interviews and personal visits based on a structured questionnaire. In regard with knowledge about Brucellosis and TBC diseases, significant differences were found among farmers (higher level of education compared with primary education) 50-58.6% vs 25.6-27.9%, respectively. In addition, the farmers with a higher level of education use more milking machines and cooling tanks than the farmers with a lower level of education. The farmers with a higher education level have a slightly better result (yet not significant) for animal identification, farm register, food safety standards and institutions, etc. Based on these and other findings, extension and veterinary services must plan and implement activities that increase farmers' awareness. They also need to commence teaching and training programs for dairy farmers, specifically targeted at improving safety standards at farm level. Finally, public and donors' farmer-support schemes should be strongly linked to the implementation of food safety standards.

Key words:*education level, dairy farming, dairy farming knowledge, Albania.*

Introduction

Agriculture is one of the most determinative sectors of the Albanian national economy with a contribution to GDP of about 17%, which is high, when compared to EU and neighboring countries (DSA, 2011).Animal husbandry in general and especially cattle (milk and meat) activities have a long tradition in Albania due to the favorable natural resources and the last two decades has signed a positive development of the production. Generally, livestock production is seen as the backbone of Albania's agriculture. The value of livestock production is almost 50 percent of the total value of agricultural production (MAFCP, 2012). Within the livestock sector, the primary output is cow milk (42% by volume), followed by bovine meat 21% (Foy Reed and Skreli, 2013). Livestock products constitute a main source of food and a high share of production still serves subsistence purposes. The livestock sector is an important source to farm income and to market supply, with raw and processed products, and engages a significant part of the labor force in rural areas.The number of larger farms has increased during the last years; however the sector is still dominated by small farms, whereas larger farms represent only a small percentage of the farming structure (about 1% in cattle).

Approximately 214 000 farm household are managing cattle for milk and meat production (MAFCP, 2012). The majority of cow milk and beef production units are very small with 2 or 3 cows per farm and their off-springs.In small dairy farms (1 to 10 cows) cows are usually milked by hand, which affects negatively hygiene and food safety. Only dairy farms, specialized in milk production (normally more than 10 cows) started to use the mobile

milking machines over the last years. Farms with more than 50 cows usually have milk storage tanks with cooling system and farms with more than 100 milking cows have milking parlor.

There are limited or no financial incentives to increase milk quality, since prices are determined mainly by quantity and fat content. The majority of the milk producers have no information about the microbiological status of their raw milk. (MARDWA, 2014)[1].

Regarding farmers education only 3% of the farm holders have university education and 37% have upper secondary or tertiary education, while the remaining 63% have lower secondary, primary or no education. About one-third of the farm holders have agricultural education background. These are likely to be the older farmers, who have accomplished agricultural vocational high schools in the past. (MARDWA, 2014).

The weak knowledge of modern production technologies and animal welfare and health requirements are the main problems faced by farmers and where the advisory service needs to work in the future. The extension service suffers from lack of qualified field staff and dissemination means. In the short-run, an overall increasing of rural income due to larger farm operations is less likely to occur.Upgrading farmers' knowledge becomes important to keep pace with technological progress in the field, implement good farm management practices and take appropriate decisions, become responsive toward market behavior and challenges following correct information.The main source for farmers to receive the new agricultural knowledge is the public extension service, through Agriculture Technology Transfer Centers, as the main source of information, as well as from Agriculture University of Tirana. In addition several projects and private extension services provider are working to a less extent to train farmers and provide the information needed by them. Extension and Veterinary Services must plan awareness, teaching and training programs for dairy farmers to improve safety standards at farm level.

Several authors (Hicks, 1987; Hanushek E A and Wößmann L, 2010;) emphasized that education and training are not only acknowledged as contributors to national economic wellbeing and growth but also as: (i) a major factor in explaining differences in productivity and income between countries; (ii) facilitators of the diffusion and transmission of knowledge needed to understand and process new information and to successfully implement new technologies, which again promotes economic growth.The objective of this exploratory study was to assess the impact of farmers' education on dairy farming knowledge, national food safety standards, animal diseases, and farm production practices.

Material and Methods

The present study was conducted in the regions of Albania, Lushnje and Shkoder. The data were collected during 2014.The questionnaire was designed based literature review including national minimum standards - the draft questioner was consulted with various experts and was tested in the field with 8 farmers. 144 interviews were carried out on randomly selected larger farms. In principle interviewers were instructed to interview farmers with more than 3 cattle; thus focusing on market oriented rather than subsistence farms (which typically have 1 cow) - the average sample farm size having been 8.5 cows (Table 1).

The questionnaire was designed to capture information related to general characteristics of the farm, situation of milk production and marketing, milk yield in different farm sizes, age and education level of household head, family size, experience in dairy production, numbers of dairy cow, farmer training, farmers' awareness on animal health and food safety issues.

[1] Ministry of Agriculture full name was Ministry of Agriculture, Food and Consumer Protection (MAFCP) until 2013and as of 2013, following institutional changes, it is named Ministry of Agriculture, Rural Development and Water Administration (MARDWA).

The obtained data was stored in Excel and imported to software SPSS for analysis. Stored data were tabulated and arranged as a percent value. Descriptive statistics (i.e. means, frequencies, etc.) was done to estimate the different variables.

Results and discussion

The data collected are analyzed with focus the relationship between level of formal education and farmers practices, in Lushnje and Shkoder regions of Albania. For this purpose education is included by using six point Likert scale: 1-no education, 2- primary education (up to 4 years of school), 3-obligatory education (up to 9 years of school), 4- agricultural middle school (12 years of school), 5- other middle school(12 years of school), and 6-university degree.The results of group 1-3 (primary education) are compared with those of better educated farmers' group 4-6 (secondary + education).

Sample socio-demographic and farm indicators

Table 1: Main sample socio-demographic and farm indicators.

Education level	Sample farm household indicators					
	Age		**Working experience**		**No. of cows**	
	Mean	**Std.Dev.**	**Mean**	**Std. Dev.**	**Mean**	**Std. Dev.**
Primary education	50.49	12.285	25.94	12.156	9.77	10.837
Secondary+ education	51.38	9.799	24.19	12.066	7.17	5.648

In this research are targeted market oriented farms (7.17-9.77 cows) as usually they are more aware of the standards;could invest more in the future, toward improving standards; and compare with small subsistence farms (1-2 cows) are more likely to "survive" the growing competition in the future.

As it is mentioned by MAWARD (2014) many farms are continued to be run by older people, and the average age of head of farm household is increased (more than 30 percent of farm operators in 2010 were above 65 years old as compared to 23 percent in 2006), which implies a migration of younger generation outside agriculture. The older farmers have knowledge limitation in feeding, breeding, animal health care practices and national minimal standards.

The mean age of primary education farmers is 50.49 years (20 to 78 years) and their farm experience is 25.49 years (4 to 64 years) while the mean age of secondary + education group is 51.38 years (28 to 72 years) and farm experience of 24.19 years (1 to 54 years).

Animal diseases. Most of the farmers of the primary education group stated that they don't know the symptoms of Brucellosis (72.1%) and TBC (74.4%) (Table 2). Farmers of the secondary+ education group have a much better knowledge of the symptoms Brucellosis (58,6%) and TBC (50%). People who are infected with Brucellosis and TBC might significantly impede from seeking medical services as result of poor knowledge of zoonosis.

Table 2: "Do you know the symptoms of the following diseases?

Education level	Brucellosis				TBC			
	Primary education		Secondary+ education		Primary education		Secondary+ Education	
	Freq.	**Percent**	**Freq.**	**Percent**	**Freq.**	**Percent**	**Freq.**	**Percent**
Yes	24	27.9	34	58.6	22	25.6	29	50
No	62	72.1	24	41.4	64	74.4	29	50
Total	86	100	58	100	86	100	58	100

Milking and cooling tank. 53.5 percent of the farmers of the secondary + education level group are using milking machine, in addition, 19 percent of the farmers, of this group, are using milk cooling tank which shows us for better milk quality and less risk for diseases (Table 3).

Table 3: Do you use hand or machine milking? and "Do you have milk cooling tank"?

Education level	Machine milking				Milk cooling tank			
	Primary education		Secondary+ education		Primary education		Secondary+ education	
	Freq.	**Percent**	**Freq.**	**Percent**	**Freq.**	**Percent**	**Freq.**	**Percent**
Yes (machine)	32	37.2	31	53.5	8	9.3	11	19.0
No (hand)	54	62.8	27	46.5	78	90.7	47	81.0
Total	86	100	58	100	86	100	58	100

The secondary + education group compare with the primary education group have slightly better resultof the knowledge(yet not significant) according to the:

a. institution in charge with food control (31% vs. 25.6%);
b. institutionin charge with issuing the animal health certificate(44.8% vs. 36%);
c. keeping book register on livestock (58.6% vs 50%);
d. notification of the veterinary service before slaughter of animals (15.5% vs. 8.2%);
e. use of the feed ration of cows according to the milk production (93.1% vs. 91.9%).

The primary education group compares with the secondary + education group have slightly better resultof the knowledge according to the:

a. use of ear tags for livestock identification (69.8%% vs. 60.3%);
b. consulting with extension service for the production technologies (73.2% vs. 55.2%).

Conclusions

This is an exploratory study, aiming at assessing the impact of farmers' education on dairy farming knowledge, national food safety standards, animal diseases, and farm production.
The mean age of primary education farmers is 50.49 years and their farm experience is 25.49 years while the mean age of secondary + education group is 51.38 years and farm experience of 24.19 years. According to the survey, most of the farmers of the primary education group stated that they don't know the symptoms of Brucellosis and TBC, while farmers of the secondary+ education group have a much better knowledge of the symptoms of both diseases.
About 54 percent of the farmers of the secondary + education level group are using milking machine, in addition, 19 percent of the farmers, of this group, are using milk cooling tank which shows us for better milk quality and less risk for diseases. The lack of cooling tank for storing the milk is a prerequisite for attaining milk safety and quality standards.

A major key of raising animal agricultural production to a sustainable level is building an agricultural education system for farmers however in Albania there has been little progress in the area of food safety and veterinary policy. There is a need to coordinate actions between extension and veterinary services. This is needed to develop institutional coordination and inter-organizational communication; keys to providing useful information and effective support to farmers; those farmers needed for implementation of the National Minimum Standards and GAPs. Otherwise small scale farms will face difficulties in selling their dairy products as they fail to meet market and statutory hygienic standards. Except raising the awareness, there should be scaled up financial support towards investments that enable improvement of safety standards at farm level.

Acknowledgment

The authors thankfully acknowledge the Professor Associated Dr. DriniImami and Development Solutions Associates for providing facilities and valuable guidance for the research work.

TAENIIDOSES IN DOGS AND LARVAL CESTODOSES IN SHEEP AT FARMS IN KABARDINO-BALKARIA

Vera BEREZKO, Amina THAKAHOVA*

All-Russian scientific research institute of fundamental and applied parasitology of animals and plants of name K.I. Scriabin, Russia
*Corresponding author: amina7161@yandex.ru

Abstract

Taking into account the fact that infected dogs were the main source of infection of sheep by *Taenia hydatigena larvae* we conducted research in this field in different climatic zones of Kabardino-Balkaria paying special attention to pasture, domestic and stray dogs. The results of coproskopic analysis of these 3 categories of dogs were given for different climatic zones of the republic. 44 domestic, 55 pasture and 29 stray dogs were tested. Coproscopic analysis showed that the rate of infection in different dogs by parasites of the family *Taeniidae*on average reached 45.5% in domestic dogs, 76.03% – in pasture dogs and 90.5% in stray dogs. In order to determine species composition of helminths 19 dogs were tested bythe method of postmortem examination. The results of this test also showed high extensity of infection (EI) in dogs by *Taenia hydatigena* and *Echinococcus granulosus* which amounted to 73.3% and 57.9%, respectively. Studies carried out at slaughter houses in different regions of the republic demonstrated that *cystic hydatidosis* and *Taeniahydatigena larvae* in sheep were registered at all farms. According to the results of our work the average EI by *E. granulosus larvae* and *T. hydatigena larvae* amounted to 33.0% and 24.6% respectively in the region. Based on the analysis of the obtained data we found out that EI of sheep by *Taenia hydatigena larvae* was almost as high as in the case of *larval hydatidosis* and also was a widespread helminthosis at farms of Kabardino-Balkaria. Such a situation depended on the high rates of infection by *E. granulosus* and *T. hydatigena* in dogs.

Keywords:*Taenia hydatigena, Echinococcus granulosus, dog, sheep, infection*.

Introduction

Infections caused by parasites attributed to the *Taeniidae* family have a special place among dog and sheep parasitic diseases. According to the data of different researchers *larval cestodoses* are widely spread in domestic and farm animals throughout the world and such situation depends on high rates of infection with *Taeniidae* parasites in dogs and wild carnivores. Dog infections caused by these parasites (in particular *E. granulosus*) represent a serious problem not only for agricultural animals but also for people. Harm from *larval cestodoses* as well as from other helminthoses consists of mortality, forced slaughter, reduction of productivity and production quality shortfall of animal offspring, considerable expences for preventive and therapevtic measures (Safiullin, 1997; Melnikova, 2008; Samuel, Zewde, 2010).There are many reports on wide spread of these helminths in the Southern Federal are and particularly at farms of Kabardino-Balkaria Republic (Bittirov et al., 2009; Elkanova, 2010; Khaidarova, 2013).

Taking into account the absence of concrete targeted research on estimation of epizootological situation concerning these parasitoses in Kabardino-Balkaria the purpose of our study has been to determine the rates of infection of dogs by *Teniidae* and sheep by *Echinococcus granulosus larvae* and *Taenia hydatigena larvae* in different nature and climatic areas of the Republic.

Materials and methods

As infected dogs of different economic purposes are the main sources of *larval cestodosis* prevalence we have testedcoproscopically128 dogs for presence of *Teniidae*parasites (44 – domestic, 55 – pasture and 29 – stray dogs). There were 14 dogs from flatland, 17 – from foothill zone and 13 – from mountain area, 18, 16, 21 – pasture dogs and 9, 11, 9 – stray dogs respectively.To determine the species composition of parasites helmintofaunistic analysis was carried out by necropsy of 19 dogs corpses. The recovered parasites were counted, the species – identified. We also estimated the extensity and intensity of infection by each parasite species.

The prevalence of *larval cestodoses* (*E. granulosus larvae* and *T. hydatigena larvae*) in different natural and climatic zones of the Republic was studied on the basis of detection of infection rates of slaughtered sheep by necropsy of parenchymal organs and mesentery. For this purpose 215 and 235 slaughtered sheep were examined in order to detect *E.granulosus cysts*and *T. hydatigena cysts* respectively. At the same time we took into account the rates of sheep infection with the both parasite species, recorded the number of such animals in each zone, extensity and intensity of infection with *E. granulosus (l)* and *T. hydatigena (l)* on average in the Republic.

Results and Discussion

Based on the results of necropsy analysis it was found that the rates of infection in pasture dogs with parasites of the family Taeniidae were 72.2% in the flatland region, 75.0% – in the foothill zone and 80.9% – in the mountain area of the Republic; on average – 76.03%. And zonal analysis was carried out in the similar way for domestic and stray dogs; their rates of infection with *Taenidae* parasites were 35.7%, 47.05%, 53.8% respectively (on average – 45.5%) and 88.9%; 81.8%, 100% respectively (on average – 90.2%) (Table 1.). These results convincingly proved the high rates of infection with different species of *Taeniidae* parasites in dogs (especially in pasture and stray dogs).Taking into account that pasture dogs are necessary in sheep breeding process we can say with reasonable certainty about high rates of infection with *larval cestodoses* in sheep. Based on this we carried out similar tests to determine the rates of infection with *Taenia* in pasture dogs at farms from different areas.

Table 1.Infection rates with the *Taeniidae* family parasites in dogs of different practical application and in stray dogs in natural-climatic zones of the Republic

Zones	Pasture dogs			Domestic dogs			Stray dogs		
	Examined	Infected	Extensity of infection, %	Examined	Infected	Extensity of infection, %	Examined	Infected	Extensity of infection, %
Flatland	18	13	72,2	14	5	35,7	9	9	88,9
Foothill	16	12	75,0	17	8	47,05	11	9	81,8
Mountain	21	17	80,9	13	7	53,8	9	9	100
In total	55	42	-	44	20	-	29	27	-
On average	-	-	76,03	-	-	45,5	-	-	90,2

*calculation based on the results of coproscopy

As our further studies needed monitoring of sheep *larval echinococcosis* and *larval cysticercosis* it was necessary to identify species of helminths in dogs and find out whether their rates of infection with *T. hydatigena* and *E. granulosus* could be epizootologically

dangerous. The results of necropsy of 19 dog corpses gave answers to these questions and showed that in the region dogs were infected not only by different *Taenia species* such as *T. hydatigena* (extensity of infection – 73.7%; intensity of infection – 3.0 ± 0.2); *E. granulosus* (extensity of infection – 57.9%, intensity of infection – 2.4 ± 0.2); *Multicepsmulticeps*(extensity of infection – 31.5%, intensity of infection – 1.9 ± 0.3); but also with *Toxocara canis* (47.3%; 6.2 ± 0.4) and *Toxascaris leonina* (36.8%; 4,1 ± 0.3) (Figure 1.).

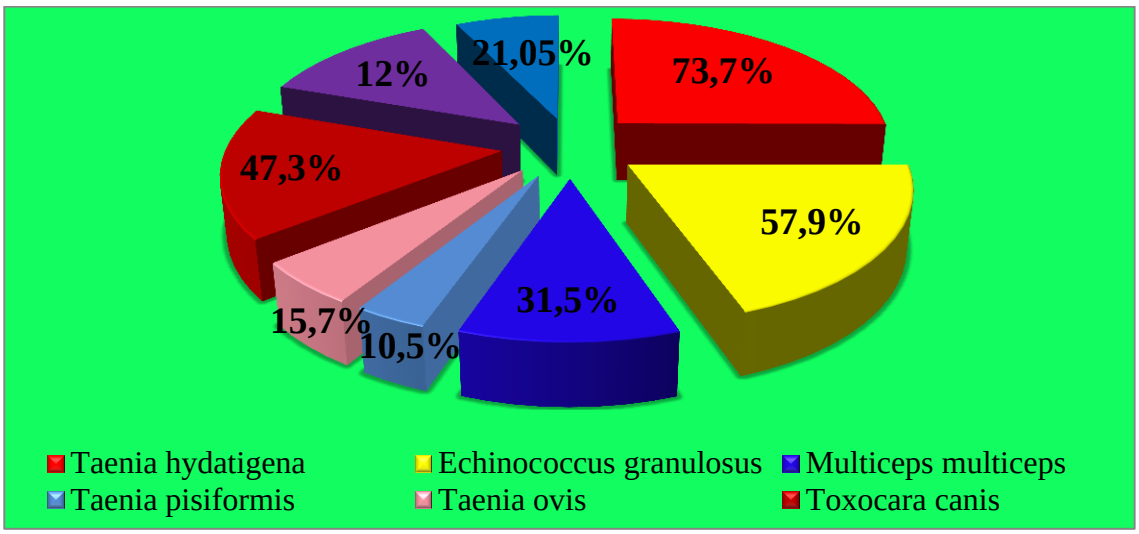

Fig. 1. Species composition and values of extensity level of infection in dogs with helminths according to the results of necropsy

While working at slaughterhouses of different areas of the Republic we found out that sheep *larval cestodoses* were registered at all farms. At that, differences in extensity and intensity level of infestation with these helminth species were inconsiderable with regard to natural-climatic zones and sheep breed. According to our data on average extensity of *E. granulosus (l)* and *T. hydatigena (l)* infections amounted 33.0% and 24.6% respectively. As for zonal aspect, examinations of parenchymal organs of slaughtered sheep from farms of different regions of the Republic showed that the values of extensity of infestation with *E. granulosus (l)* and *T. hydatigena (l)* were 34.7%; 27.3% – in flatland area, 32.6%; 25.3% – in foothill region and 31.4%; 20.6 – in mountain region respectively. (Table. 2).

Table. 2*Echinococcus granulosus larvae* and *Taenia hydatigena larvae* infection rates in sheep at farms of different natural-climatic zones in the Kabardino-Balkarian Republic (according to necropsy data)

Zones	Sheep dissected	Of which infected	Extensity of infection, %	Intensity of infection, sp/
Echinococcus granulosus larvae				
Flatland	75	26	34,7	13,7±1,52
Foothill	89	29	32,6	17,8±1,52
Mountain	51	16	31,4	14,8±1,5
In total	215	71		
On average			33,0	15,4±1,6
Taenia hydatigena larvae				
Flatland	88	24	27,3	6,2±0,4
Foothill	79	20	25,3	5,7±0,5
Mountain	68	14	20,6	4,8±0,6
In total	235	58		
On average			24,6	5,6±0,5

According to Table 2 the values of the rate of infection with *E. granulosus (l)* in sheep were slightly higher at farms in foothill and mountain regions where conditions of grazing system with a great number of animals per area unit and a large number of pasture and stray dogs infected with *E. granulosus* provided maintenance of epizootic process.

As for the rate of infection with *T. hydatigena (l)* in sheep its extensity and intensity was almost as high as in *larval echinococcosis* and was widely spread at farms of the Republic.

At necropsy, we also payed attention to sheep with mixed infections by *E. granulosus (l)* and *T. hydatigena (l)*. As a rule, the number of such animals appeared to be 5-10% of the total number of the examined ones.The results of our tests were convincing evidences of a problem at farms in Kabardino-Balkarian Republic concerning infection of agricultural animals with *Taeniidae* parasites and *cestode larvae*. Moreover, the analysis of similar works of other authors showed that the situation regarding parasitoses infection in animals was not improved in the region but became even worse in case of *echinococcosis* and that affected epidemiological situation. According to the Federal Service for Supervision of Consumer Rights Protection and Human Welfare analysis of multi-year rates of infection with *E. granulosus* among population also showed that this index remained higher in Kabardino-Balkaria than the average one in Russia.

This situation is the result of complete absence of planned preventive measures such as scheduled dehelminthizations of pastures dogs, capture and placement into special shelters of stray dogs and sanitary-educational work among personnel and population.

Conclusion

Our work demonstrated the presence of all components for maintenance of epizootic process in case of *E. granulosus (l)* and *T. hydatigena (l)* at farms in all natural-climatic zones of the Republic. The high extensity and intensity of infection with *Taeniidae* family parasites in dogs were observed all year round in the region in presence of the object of infection providing dynamics, biological activity and parasitic system protection for a long time.The conducted analysis convincingly demonstrated that *echinococcosis* in dogs was registered at all farms of the region and was not only serious ehpizootological problem but also a social one.The last statement was confirmed by considerable deterioration of the epidemiological situation conserving human *echinococcosis*.According to the data of medical statistics and the results of medical epidemiological service the rate of infection with echinococcosis in people

since 2012-2013 increased from 0.00046 to 0.0061 per 100000 people.Studies of rates of infection with *Echinococcus* in sheep carried out at farms of all climatic zones of the Republic with the consideration of welfare technology did not reveal any significant differences because contact with infected dogs could not by excluded in any technology especially if one had in mind that the main republic technologies were based on distant-pasture grazing and pasture-stable maintenance.

Abstract

The immunostimulatory drugs in recent years are widely usedfor helminthiasis in veterinary medicine. In our study we evaluated the protective effect of cycloferon and roncoleukin in experimental trichinosis of mice. We used 30 mice weighting 16-18 g, divided into 3 groups of 10 animals in each. The first group was injected with cycloferon; the second group was injected with roncoleukin; the third control group was injected with 0.9% NaCl. The drugs were injected twice with an interval of 48 hours. The cycloferon was injected intramuscularly in the dose of 2.16 mg/mouse. The roncoleukin was injected subcutaneously in the dose of 100 U/mouse. After 48 hours the mice were infected by T. spiralis larvae in the dose of 80±5 larvae/mouse. Analysis of the data indicates that in the experiment in the application of these drugs has been significant protective effect. The number of T. spiralis larvae detected in animals was 733.5 ±25.1 and 869.5 ±16.61 larvae/mouse respectively. This was 6.1 and 5.2 times less than in the mice of control group (4485 ± 430.6 larvae/mouse. Based on this, we consider it expedient to continue the study of immunostimulatory drugs in the complex immunoprophylaxis of trichinosis.

Keywords:*Immunostimulatory drugs, Trichinosis, Immunoprophylaxis.*

Introduction

The immunostimulatory drugs in recent years are widely usedfor helminthiasis in veterinary medicine. The use of these drugs increases immunoreactivity to specific antigens, increases the resistance of animals, which leads to a decrease and in some cases prevents infection of animals.

So, there are scientific data about the use of biologically active drugs in the literature. On the model system of nippostrongylus invasion it has been shown that the drug T-activin shows protective effect in the range of 51.8-60.8%. Subsequently, the stimulating effect of T-activin was revealed in the combined treatment of strongylatosis of the digestive tract of sheep. The application ofT-activin with helminthicidepanacur not only increased the therapeutic effect, but allowed to prevent the development of undesirable reactions of the immune system of the host by stimulation of cellular immunity factors (Mamykova O.I., 1997, 2004).And it was established on the model of mice trichinellosis that roncoleukin at dose level of 10 000 IU/kg of body weight enhanced nonspecific antiparasite resistance. The tendency to potentiation of helminticidealbendazole action and reliable increased level of specific antibody in serum by administration roncoleukin with albendazole was revealed (Mamykova O.I. andNapisanova L.A., 2012). There is also evidence of modeling effect on the immune status of cows of immunomodulators (ligfol, ligavir and seledant) in combination with a vaccine against parainfluenza-3 and infectious rhinotracheitis in cattle, manifested by increased bactericidal,

lysozyme and complementary activity of blood serum, phagocytic activity of leukocytes and titers of specific antibodies (Shakhov A. G. et al., 2013).
Based on these data, there is a certain confidence that the effectiveness of protective activity of specific antigens of helminths can be improved if to use immunostimulatory drugs,which provide the increase ofantiparasitic resistance. This is the basis for their use in complex immunoprophylaxis of helminthiasis.
Therefore, the purpose of this study was to evaluate the protective effect two immunostimulatory drugs in experimental trichinosis.

Materials and methods

We used in our study 30 albino mice weighing 16-18 g, divided into 3 groups of 10 animals in each. The first group was injected with cycloferon; the second group was injected with roncoleukin; the third control group was injected with 0.9% NaCl. The cycloferonreleatedto the group of antiviral and immunostimulatory drugs. It is the inducer of interferon synthesis. The roncoleukin is from the group of interleukins and it possesses antitumor and immunomodulatory activity. The drugs were injected twice with an interval of 48 hours. After 48 hours the mice were infected by T. spiralis larvae in the dose of 80±5 larvae/mouse. Evaluation of the protective effect of immunostimulatory drugs was carried out 45 days after invasion. The mice of each group including controls ware slaughtered humanely and digested separately in artificial gastric juice. Detected then in sedimentary fluid of T. spiralislarvae were washed waterseparatelyand counted for each mouse in the groupseparately.
The counting of larvae of T.spiralis in sedimentary fluid was performed by a binocular microscope.We have defined the arithmetic mean of the number of larvae in each group of experimental animals to evaluate.Investigations were performed in All-Russian Scientific Research Institute of Fundamental and Applied Parasitology of Animals and Plants named after K.I. Skryabin in Moscow.

Results and discussion

The number of T. spiralis larvae detected in animals was 733.5 ±25.1 and 869.5 ±16.61 larvae/mouse respectively (Table 1.). The degree of protection of mice injected with roncoleukin was slightly lower than that of mice administered cycloferon. Even so, this was 5.2 times less than in the mice of control group (4485 ± 430.6 larvae/mouse). The number of larvae of mice injected with cycloferon was 6.1 times less than in the mice of control group. In this case, the use of these drugs activates the immune response and the injection of these drugs significantly reduces subsecuently infected of parasits animals.

Table 1.Evaluation of the protective properties of immunostimulatory drugs in experimental trichinellosis of mice

The groupof animals	The drug	A dose of drug	The multiplicity of the drug and method of administration	The average number of larvae; larvae/mouce
I (n=10)	cycloferon	2,16mg/mouce	twice, intramuscularly, the interval 48 hours	733,5±25,1
II (n=10)	roncoleukin	100 U/mouce	twice, subcutaneously, the interval 48 hours	869,5±16,6
III (n=10) controls	0.9% NaCl	0.2 ml/mouce	twice, intramuscularly, the interval 48 hours	4485,0±430,6

Our data are considered with the data of other researchers, which worked inthese scientific areas. So, according to Adelshin F. K.(1993), timalin stimulates the immune response in infected by alveococcosis in mice and rats. Protective action of the immunostimulating drug of ribotan in experimental alveolar echinococcosis was revealed by Klenova I. F.(1999).Rudneva O. V. andBerezhko V. K.(2005) founded that the antigen from Echinococcusmultilocularisprotoscoleces 2 and 6 months of age in combination with an immunostimulatoryribotan have a greater protective efficacy in experimental secondary alveolar echinococcosis than the only antigen from E. multilocularisprotoscoleces of age 2 and 6 months.Protective action of immunomodulatorroncoleukin (within 40%) was showed against echinococcosis in dogs (Berezhko V. K.andSasikova M. R., 2010). The combined use of anti-parasitic drugs and immunomodulators, according to Ismagilov A.M.(2010), helpsto the quick recovery of animals in melophagus.

Numerous experimental studies have found that immunization of worms is very real, especially with tissue invasion (Golden O. et al., 2010;Dalton J.P. et al., 2013).

Also it is many references about the succeful use of vaccines. Feng S. et al.(2013) succefulyused of vaccines based on recombinante antigens derived from T.spiralis. Accoding to Gu Y. et al.(2013) multi-epitope recombinante vaccines provided better protective effect than individual epitopes, causing a higher level of IgG.

Thus, the immunostimulatory preparations have stepted up protective reactivity and the administration of drugs reduces subsequent contamination of animals.

Conclusion

Analysis of the data indicates that in the experiment in the application of these drugs (cycloferon and roncoleukin) has been significant protective effect. Based on this, we consider it expedient to continue the study of immunostimulatorydrugs in combination with a specific antigen in the complex immunoprophylaxis of trichinosis.

Abstract

The objective of this experiment is to diagnose the metabolic disorders of late pregnant and early lactation dairy cows based on changes in characteristic blood biochemical indicators. Blood samples were collected from 15 late pregnant cows and 15 early lactation cows to measure beta-hydroxybutyrate (BHB), non-esterified fatty acids (NEFA), triglycerides (TG), glucose, and the activity of aspartate transaminase (AST). Cows in early lactation had significantly higher ($p<0.05$) levels of serum BHB, NEFA and AST, and lower ($p<0.05$) glucose and TG compared to late pregnant cows. High lipomobilization (NEFA > 0.4 mmol/l) was detected in 6 (40%) of early lactation cows but in none of late pregnant cows, while subclinical ketosis (BHB > 1.2 mmol/l) was detected in 14 (94.4%) of early lactation cows and 4 (26.6%) of late pregnant cows. AST activities above 100 U/l were detected in 2 early lactation cows and in none of late pregnant cows. TG levels below 0.12 mmol/l and glucose below 2.5 mmol/l were found in 7 (44%) and 10 (66.6%) of early lactation cows, respectively, and in none of late pregnant cows. Results on blood serum levels of glucose, TG, BHB, NEFA and AST in early lactation cows suggest metabolic disorders associated with ketosis, and some degree of hepatic lesions, probably due to fat infiltration. These serum parameters may have a key role in diagnose the metabolic disorders of late pregnant and early lactation dairy cows.

Keywords: *blood metabolites, subclinical ketosis, hepatic lipidosis, dairy cows, transitional period*

Introduction

Production diseases i.e. diseases associated with improper nutrition or management are common in dairy cows. The diseases listed in this include: the fat liver syndrome, ketosis, laminitis, mastitis, milk fever, retained placenta, metritis and infertility. Ketosis and fatty liver are closely linked and are responsible for severe economic losses in dairy farms due to drop in milk yield, reproductive performance and increase in culling rates (Gross et al. 2001, Oetzel 2004). Clinical ketosis in dairy cows usually occurs between the second and seventh week of lactation. Nevertheless, most of cows in this stage of lactation may suffer a subclinical form of ketosis defined as increased blood ketone bodies without any other symptoms but accompanied by considerable decrease in milk yield and susceptibility other diseases (Duffield et al.1997). Dairy cows suffer from negative energy balance (NEB) during the first week of lactation because of energy expenditure due to milk production and limited feed intake. As a consequence, such a state caused NEB, a high mobilization of lipids from body fat reserves as well as hypoglycaemia in early lactation (Veenhuizen et al.1991, Djokovic et al. 2007). Lipomobilization characterized by high blood NEFA concentrations starts within late pregnancy and reaches a high intensity in the early lactation and during lactation

(Djokovic et al. 2007, Civelek et al. 2011, Gonzalez et al 2011). NEFA are preferentially and greatly accumulated as TG in the liver cells (Sevinc et al 2003, Djokovic et al. 2007). The main blood indicators of lipomobilization in ruminants are BHB, the most important and abundant ketone body, and NEFA (Civelek et al. 2011, Gonzalez et al. 2011). Consequently, physiological situations leading to a NEB (fasting, parturition and lactation) are coupled to an increased uncontrolled rate of body fat mobilisation and the increased NEFA accumulation in hepatocytes, resulting in disturbances of the morphological and physiological liver integrity (Veenhuizen et al.1991, Bobe et al. 2004). However, when an important steatosis occurs, the endogenous liver syntheses are lowered leading to decreases in blood concentrations of glucose, total protein, albumin and globulins, cholesterol, TG and urea. (Veenhuizen et al.1991; Sevinc et al. 1998, 2003, Bobe et al. 2004). The fatty liver infiltration and the hepatocyte degeneration involve cell membrane damage and hepatocyte destruction coupled to the release of cytoplasm enzymes (AST, GGT, LDH) and marked increases in the circulating activities (Pechova et al. 1997, Lubojacka et al 2005; Stojevic et al.2005). Diagnosing liver lipidosis and susceptibility of ketosis in dairy cows may include liver biopsy or ecography, but a less invasive and more economical analytical method may be the measurement of blood biochemical indicators (Bobe et al.2004). According to blood biochemical indicators, ketosis in cows may be diagnosed when the following values match the clinical signs: BHB > 1.2 mmol/l, glucose < 2.5 mmol/l, and TG < 0.12 mmol/l, and blood values: NEFA > 0.7 mmol/l and AST activity above 100 U/l, which is indicative of hepatic lipidosis. (Sevinc et al.,1998, Oetzel, 2004; Xu et al., 2008, Gonzalez et al., 2011).
The objective of this experiment is to diagnose the metabolic disorders of late pregnant and early lactation dairy cows based on changes in characteristic blood biochemical indicators.

Material and methods

Animals: This experiment was carried out at dairy herd of Simental cows. The cows (n=30) were middle-yielding with a preceding lactation about 6,500 l. Two groups of cows were chosen from herd of dairy cows. One group consisted late pregnant cows in period from 25 to 1 days to partus (n = 15), and a second group included early post-partum cows in the first month of lactation (n = 15). The experimental cows were kept in tie-stall barns. The diet and the housing facilities were adapted to research purposes. The diet suited the energy necessary for cows in late pregnancy and early lactation. The cows in late pregnancy were fed with a diet consisting of 6 kg lucerne hay, 15 kg maize silage (30% DM) and 3 kg concentrate (30% crude proteins, CP). The cows in early lactation were fed with a diet consisting of 7 kg lucerne hay, 20 kg maize silage (30% DM) and 5 kg concentrate (30% CP). Dietary nutrient contents for dairy cows in late pregnancy and in early lactation are given in Table 1.

Table 1. Nutrient contents in daily ration for dairy cows in late pregnancy and early lactation.

	Late pregnancy	Early lactation
Dry Matter (DM) (kg)	11.94	16.05
Net energy of lactation (NEL) (MJ)	65.25	87.15
Crude protein (CP) (% of DM)	12.55	13.58
Rumen undegradable protein (RUP) (% of CP)	30.86	35.91
Fat (% of DM)	3.27	3.15
Fiber (% of DM)	25.28	23.26

Biochemical analysis: The blood samples were collected at 10:00 h or 4 to 6 hours after milking and feeding, by puncture of the jugular vein into sterile disposable test tubes without anticoagulant. After clotting for 3 hours at 4°C and centrifugation (1500g, 10 minutes, 4°C), sera were carefully harvested and stored at -20°C until analysis. Blood samples collected on fluoride were immediately centrifuged according to the same modalities and plasmas were assessed for glucose concentrations. The following biochemical blood components were measured by different colorimetric techniques using a spectrophotometers (Cobas Mira and Gilford Stasar): BHB and NEFA levels were measured using a kit from Randox (Ireland), AST and glucose were measured using kits from Human (Germany), and TG) using kits from Elitech (France).

Statistical analysis: The statistical analysis of the obtained data was carried out by ANOVA-procedure (Statgraphic Centurion, Statpoint Technologies Inc.Warrenton, Va, Virginia, USA). The LSD test were used to evaluate the probability of the significance of the statistical differences between mean parameter values in each group and the Pearson test was performed for evidencing significant correlations. Differences were considered as significant when p values were below 0.05 or 0.01.

Results and Discussion

The present experiment compared the metabolic status of dairy cows during transitional period. Results of the serum biochemical analyses for both groups of cows are shown in Table 2.

Table 2. Blood biochemistry in transitional dairy cows (n=15 in each group). Results are expressed as mean standard ± deviation.

Parameter	Late pregnant cows	Early lactation cows	p
Glucose (mmol/l)	3.36 ± 0.30	2.29 ± 0.48	< 0.05
BHB(mmol/l)	1.14 ± 0.36	1.59 ± 0.25	< 0.05
NEFA(mmol/l)	0.17 ± 0.06	0.38 ± 0.29	< 0.05
TG(mmol/l)	0.29 ± 0.07	0.12 ± 0.02	< 0.05
AST (U/l)	33.55 ± 9.38	69.46 ± 30.89	< 0.05

Table 3. shows the correlation coefficients among the biochemical parameters calculated for all cows in this experiment.

Table 3. Correlation coefficients for the biochemical parameters calculated for all cows in the present study. Significant correlations ($p<0.05$) are indicated in bold letters.

	NEFA	BHB	TG	AST
Glucose	r=**-0.35**	r=**-0.47**	r**= 0.65**	r=-0.23
NEFA		r= **0.39**	r=-0.21	r= **0.34**
BHB			r**=-0.36**	r= 0.15

In early lactation animals, NEFA and BHB values were significant higher ($p<0.05$) than of late pregnant cows. NEFA concentrations >0.40 mmol/l indicate problems with energy balance and subsequent intensive lipomobilization (Oetzel, 2004). According to this report, 6 early lactating cows (40%) and none of the late pregnant cows in the present study had NEFA concentrations above the value indicative of subclinical ketosis. Given the fact that concentrations of serum NEFA >0.70 mmol/l are associated with ketosis (Oetzel, 2004), 2 early lactating cows (13.3%) and none of the late pregnant cows in the present study had NEFA concentrations above the value indicative of subclinical ketosis. Subclinical ketosis may also be diagnosed at serum BHB concentrations above 1.2 mmol/l, while clinical ketosis is associated with BHB concentrations above 2.6 mmol/l (Duffield, 2000, Oetzel, 2004). In the present experiment, 14 early lactation cows (94.4%) and 4 late pregnant cows (26.6%) had serum BHB concentrations above 1.2 mmol/l. These data suggest that serum NEFA levels are most likely less efficient indicators of subclinical ketosis (13.3%) compared to serum BHB (94.4%) in dairy cows during the periparturient period. This is in agreement with Duffield (2000), who stated that the use of NEFA is a better indicator of energy imbalance in prepartum animals compared to BHB, which is more useful postpartum. In this study, a significant positive correlation ($r = 0.39$, $p<0.05$) was observed between NEFA and BHB in the sera tested, suggesting that both parameters are helpful indicators of energy balance during the periparturient period. Blood glucose values in late pregnant cows were within the physiological range of 2.5-4.2 mmol/l (Oetzel, 2004), whereas hypoglycemia was detected in early lactation cows. In the present study, 10 early lactation cows (66.6%) and none of the late pregnant cows had blood glucose concentrations below 2.5 mmol/l. According to the serum parameters, ketosis in cows may be diagnosed when the following values match the clinical signs: BHB >1.2 mmol/l, glucose <2.5 mmol/l, and TG <0.12 mmol/l (Sevinc et al.1998, Oetzel, 2004, Xu et al. 2008, Gonzalez et al. 2011). Given this criterion, 7 cows in early lactation (44%) and no late pregnant cow had the indicative values, but did not display any clinical signs, suggesting that they had a typical subclinical condition, compared to the results of Gonzalez et al. (2011), who showed that a typical subclinical condition was detected in 22% of high-yielding cows in early lactation. Serum TG levels were significantly lower ($p<0.01$) in ketotic cows compared to healthy cows (Djokovic et al. 2007). These results showed that TG accumulate in the liver cells of ketotic cows and cause their blood values to decrease. The present experiment showed that 7 early lactation cows (44%) and no late pregnant cow had TG concentrations below 0.12 mmol/L. In addition, no significant correlation ($r = -0.21$, $p>0.05$) was found between TG and NEFA, suggesting that TG values may not be considered as an adequate indicator for lipomobilization in dairy cows. The values of AST in the present study were statistically higher ($p<0.05$) in early lactation cows than in late pregnant cows. Given that AST activity higher than 100 U/l is indicative of hepatic lesions (Gonzalez et al. 2011), 2 early lactation cows (13.3%) in our study suffered from some degree of hepatic lesions, probably due to fat infi ltration. These animals included 2 out of 7 cows considered to be ketotic according to our criteria and with blood NEFA values above 0.70 mmol/l. Meanwhile, none of the late pregnant cows had AST values higher than 100 U/l. A positive correlation between AST activity and lipomobilization (NEFA values) was observed by the significance coefficient($r = 0.34$, $p<0.05$). In the present study, all data

regarding liver enzymes suggested that the process of lipomobilization was sufficient to cause liver lesions in 13.3% of the early lactating cows Possible alterations in liver function may have deleterious effects on the metabolism of these animals, and may adversely impact milk production or reproduction.

Conclusion

Biochemical evaluation suggested that early lactation cows had metabolic disturbances associated with ketosis, and some degree of hepatic lesions, probably due to fat infiltration. Serum levels of BHB, NEFA, TG, glucose and AST activities may have a key role in diagnose the metabolic disorders of late pregnant and early lactation dairy cows.

Abstract

Survival analysis is a commonly used method in medical fields. It is a tool for examining possibilities of an eventdefined by the researcher and time until that eventoccurs. In medical fields, it is generally used to determine the length of time until the symptoms occurred, the response to the treatment or death. Additionally, it is used in industrial area in order to determine the first-failure-lifespan or total-economical-lifespan of machinery. Although it is rarely seen in agricultural researches, survival analysis has the potential to take place in many agricultural applications. In this study, life curves obtained by survival analysis, Kaplan-Meier method, and log-rank are compared along with a numerical example of quails data in animal science. For the last sixteenth week, in first group, survival probability and cumulative survival probability were become 0.991 and 0.9236 respectively. In second group, these probabilities were also become 0.993 and 0.897.In that example, log-rank value was obtained as 4.7 and the null hypothesis of similar survival plots was rejected ($P<0.05$).

Keywords:*survival analysis, Kaplan-Meier, log-rank*

Introduction

Survival analysis is a commonly used method in medical fields (Agarwal, 2012; Gunbatar et. al., 2012; Inceoglu, 2013; Kartsonaki, 2016; Miettinen, 2008). It is a tool for examining possibilities of an "event"defined by the researcher such as the length of time until occurrence of the symptoms, the response to the treatment or death. Additionally, it is used in industrial area in order to determine the first-failure-lifespan or total-economical-lifespan of machinery. Although it is rarely seen in agricultural or some other fields (Hutchison,.1988; Woodall, 2005), survival analysis have the potential to take place in many agricultural applications. In this study, life curves obtained by survival analysis, Kaplan-Meier method, and log-rank (Yuklu, 2013) are compared along with a numerical example of quails data in animal science (Ozdemir (Aktas), 1994; Doğan and Dundar, 2002).

Material and Methods

Because the main purpose of the study is to show that the method may be applied in animal science, hypothetical data from two groups, each containing 1000 quails are used (Table 1).

Table 1.Death records of two quail groups*.

		Group 1		Group 2				Group 1		Group 2	
i	***t***	d_{1i}	k_{1i}	d_{2i}	k_{2i}	***i***	***t***	d_{1i}	k_{1i}	d_{2i}	k_{2i}

7	7	0	0	0	0	15	15	0	0	0	0
8	8	5	0	5	0	16	16	8	0	6	0

*t : time (week), d : event (death), k : censored

Survival analysis can be investigated in two categories. These are:
1) Life tables analysis,
2) Kaplan-Meier survival analysis.

Basically, these two type of analysis are related to death and survival probabilities versus time. In Kaplan-Meier analysis, censored data does not affect the survival probability contrary to life tables analysis (Chung et. al., 1991; Harrel, 2001, Karasoy and Tuncer, 2015; Machin and Gardner, 1988).
In Kaplan-Meier analysis, t is a time period known as the survival time, d_i is number of deaths and is k_i number of censored individuals up to point i and n_i is number of individuals at risk just prior to t_i. P_i is survival probability and Pt_i is cumulative survival probability for any particular one of the t_i time periods.IfP_i and Q_i are used for survival and death probability respectively, equation $P_i + Q_i = 1$ is written. Here $P_i = 1- Q_i$ or $Q_i = 1- P_i$and $P_i= (n_i-d_i)/n_i$ .Cumulative survival probability is $P_{ti}=P_{t(i-1)}* P_i$. For i=1 and i>1, $P_{t1}=P_1$.
Comparing survial curves for two groups can be done by using log-rank test given below.

$$\text{Log-Rank}= (G_1-B_1)^2/B_1 + (G_2-B_2)^2/B_2 .$$

This test statistic is approximately distributed as a chi-square random variable with one degree of freedom ($\chi^2_{1,\alpha}$).

Results and Discussion

Kaplan-Meier analysis for group 1 data is given in Table 1.

Table 2.Kaplan-Meier analysis for group 1.

	time (week)	number of individuals at risk (at the beginning of time $t_{i)}$	event (death)	number of censored data at the end of time t_i	number of alives at the end of time t_i	survival probability at the end of time t_i	cumulative survival probability
i	**t_i**	**n_i**	**d_i**	**k_i**	**y_i**	**P_i**	**P_{ti}**

6	6	964	0	0	964	1	0,964
7	7	964	0	0	964	1	0,964
8	8	964	5	0	959	0,995	0.959
9	9	959	15	0	944	0,984	0,944
10	10	944	0	0	944	1	0,944
11	11	944	10	0	934	0,989	0,934
12	12	934	1	0	933	0,999	0,933
13	13	933	0	0	933	1	0,933
14	14	933	1	0	932	0,999	0,932
15	15	932	0	0	932	1	0,932
16	16	932	8	0	924	0,991	0,9236

*t : time (week), d : event (death), k : censored

At the beginning of the first week, there are 1000 quails. At the end of this week, 20 deaths (d_1) were observed and the rest of individuals, number of alives (y_1), was 980. Hence survival probability (P_1) and cumulative survival probability (P_{t1}) can be evaluated as 0.980. At the beginning of the second week, there are 980 quails and at the end of that week, 7 deaths (d_2) were observed and number of alives was 973. Survival probability (P_2) and cumulative survival probability (P_{t2}) will be evaluated as P_2=(980-7)/980=0.993 and P_{t2}=0.980*0.993=0.973 respectively. As an example, one can say that any individual has the probability of being alive 99.3% at that week.

For example, in second week, while a quail was alive at the beginning of that week, its survival probability is 99.3% during that week. In other words, one can say that 99.3% of quails that they are alive at the beginning, will be alive at the end of the week. Moreover, one can also say that 97.3% of quails are alive from the beginning of trial to the end of the second week. At the beginning of the last sixteenth weekwhile 932 (=n_{16}) quail was alive, 8 (=d_{16}) deaths or 924 (=y_{16}) alives were observed at the end of that week. So, survival probability was become 0.991 (=(932-8)/932=P_{16}) at that week and cumulative survival probability was become 0.9236(=0.991*0.932=P_{t16}) from the beginning of trial to the end of the last week.

Table 3.Kaplan-Meier analysis for group 2.

	time (week)	number of individuals at risk (at the beginning of time $t_{i)}$	number of event (death)	number of censored data at the end of time t_i	number of alives at the end of time t_i	survival probability at the end of time t_i	cumulative survival probability at the end of time t_i
i	**t_i**	**n_i**	**d_i**	**k_i**	**y_i**	**P_i**	**P_{ti}**
1	1	1000	40	0	960	0,960	0,96
2	2	960	19	0	941	0,980	0,941
3	3	941	10	0	931	0,989	0,931
4	4	931	10	0	921	0,989	0,921
5	5	921	0	0	921	1	0,921
6	6	921	0	0	921	1	0,921
7	7	921	0	0	921	1	0,921
8	8	921	5	0	916	0,995	0,916
9	9	916	0	0	916	1	0,916
10	10	916	5	0	911	0,995	0,911
11	11	911	0	0	911	1	0,911
12	12	911	0	0	911	1	0,911
13	13	911	8	0	903	0,991	0,903
14	14	903	0	0	903	1	0,903
15	15	903	0	0	903	1	0,903
16	16	903	6	0	897	0,993	0,897

From Table 3, it can be seen that survival probability is 96% at the end of the first week and is 98% at the end of the second week. For the third week, cumulative survival probability will be 0.931 (=0,941*0,989). If one desires to evaluate the death probability, it can be found as 1-0,989=0,011.

Pre-calculations necessary for comparing the groups using by log-rank test that it needs sums of observed and expected values of survival probabilities for two groups, were given in Table 4.

Table 4.Pre-calculations for log-rank test

		1'st GRUP		2'nd GRUP		Total			1'st GRUP		2'nd GRUP

10	10	0	0	5	0	5	1860	0,00269	944	2,54	916	2,46
11	11	10	0	0	0	10	1855	0,00539	944	5,09	911	4,91
12	12	1	0	0	0	1	1845	0,00054	934	0,51	911	0,49
13	13	0	0	8	0	8	1844	0,00434	933	4,05	911	3,95
14	14	1	0	0	0	1	1836	0,00054	933	0,51	903	0,49
15	15	0	0	0	0	0	1835	0,000	932	0	903	0
16	16	8	0	6	0	14	1835	0,00763	932	7,11	903	6,89

When the table investigated, it can be seen that there are 1000 quails in each group, totally 2000, at the beginning of trial. In first week, 20 deaths from first group and 60 deaths from second group, totally 80 deaths, were observed. These values are also called observed frequencies (G_{1i} and G_{2i} respectively). Death probability over two groups is 0.030 ($=Q_1=D_1/N_1=60/2000$). If this probability is multiplied by the total number of alives for two groups at the beginning of the first week, same expected value (B_{1i} and B_{2i}) of death for two groups is found as 30 (=1000*0.030). Expected values in other weeks can be evaluated similarly. Then, for two groups, sum of expected and observed frequencies over all weeks are obtained as $B_1=90.54$, $B_2=88.46$, $G_1=76$ and $G_2=103$ respectively. Using this sums, log-rank test can be obtained as below;

Log-rank=$(76-90.54)^2/90.54+(103-88.46)^2/88.46=2,334+2,389=4,7230$.

At 0.05 and 0.01 significance levels chi-square values are $\chi^2_{1,\ 0,05}= 3,841$and $\chi^2_{1,\ 0,001}= 6,635$ respectively. Hence, null hypothesis of "trends of death probabilities are similar" is rejected at 0.05 significance level while it is failed to reject at 0.01.
Cumulative survival probability curves for two groups were showed in Figure 1.

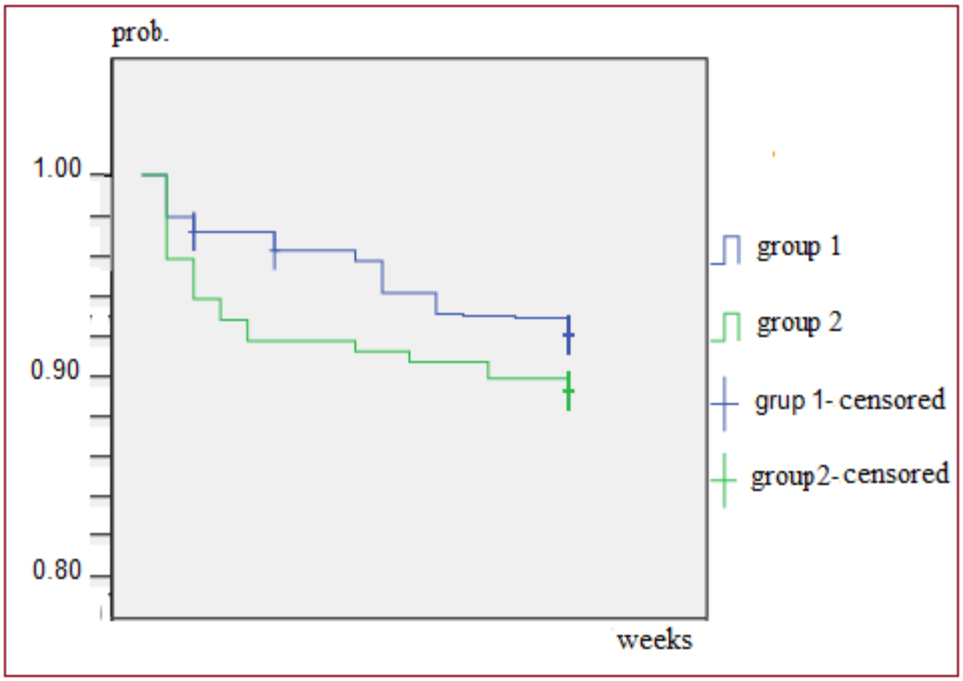

Figure 1. Cumulative survival curves.

Conclusion

In this study, a survival analysis method Kaplan-Meier is investigated using a hypothetical sample of quails data in Animal Science. Death probabilities between two groups were compared using log-rank test. Results showed that death probabilities of two groups were not found to be similar ($P<0.05$). When the survival curves are examined, one may conclude that this difference is due to the drastic drop within the first four weeks.

Death, survival and cumulative survival probabilities were also shown for each week in Table 1 and 2. Even though the censored observations are all zero in this study, they are included in the tables as separate columns since it is quite natural that some studies may have censored data. Censored data does not affect death or survival probabilities; however, it must be considered while calculating the number of alive at the beginning of the next week.

In the study, sixteen weeks were examined seperately. Time variable might be in different scales (hour, day, month, year, etc.) in some studies. If there are great number of raws in a table, it is possible to reduce it using groups as,for example, 1-3, 4-6, 7-9 month.Grouping the time variable does not change the way of calculation.

It is expected that this study will be useful for Animal Science researchers as it is for medical field.

Abstract

Casein polymorphisms are related to milk quality and milk composition. In goat milk, four casein (αS1, αS2, β and k-casein) coded by four autosomal gene were identified. One of these casein is calcium-sensitive casein 2 (αS2-CN) coded by CSN1S2 gene. Presence of seven alleles (A, B, C, D, E, F and O) has been identified at CSN1S2 locus. In this study, three different alleles ($CSN1S2^F$, $CSN1S2^O$and $CSN1S2^D$) at CSN1S2 locus in Hair goats were investigated by PCR-RFLP method. In total, 70 samples were used from four populations reared in different regions of Antalya. Digestion results with Alw26I restriction enzyme showed that specific F/F genotype (0.057), F/N genotype (0.157) and N/N genotype (0.786) are present where N non F allele (one of A, B, C, D, E and O alleles). Also O and D alleles couldn't be determined at CSN1S2 locus, according to digestion of *Nco*I restriction enzyme. F allele at CSN1S2 locus has been shown in Hair goats reared in Turkey for the first time.

Keywords: *Casein,* CSN1S2, PCR-RFLP, Polymorphism, Hair Goat

Introduction

In many developing countries, goats have gained an important role in livestock production. While goats in the past were preferred for subsistence of poor people underestimating their economic roles and potentials, today goat production has gained importance in the area acknowledged as modern civilization because their milk plays a vital role in human nutrition. Also, the importance of goat milk in infant diets is growing for it is less allergenic than cow's milk (Haenlein, 2004).

Protein is one the most valuable goat milk components. Casein in caprine milk accounts for approximately 80% of total proteins synthesized by cells of the mammary gland during lactation and whey proteins cover for the remaining 20% (Ambrosoli *et al.*, 1988).

Table 1. Approximate average milk composition of different species (% w/w) adapted from Walstra *et al.,* (2006).

Animal	Dry Matter	Casein	Serum Protein	Fat
Goat	13,3	3,0	0,6	4,5
Sheep	18,8	4,6	1,0	7,5
Cow	12,7	2,6	0,6	3,9
Buffalo	17,5	3,6	0,7	4,8
Horse	10,8	1,3	1,2	1,7
Camel	13,4	2,7	0,9	4,5
Reindeer	35,0	8,5	2,0	18,0

It knows that casein polymorphisms are associated with milk quality, milk composition and technological properties. Also, casein genes have high polymorphism and in this case affects the casein and protein content of the milk in goat species. Therefore, the genetic

polymorphism of goat caseins has drawn attention to the use of molecular markers in this field. As reported by Hayes *et al.,* (1993), casein genes are located cluster region spans about 250kb on goat chromosome 6. Caseins are divided into four main groups; αS1-casein, αS2–casein, β-casein, κ-casein. These caseins are coded by CSN1S1, CSN1S2, CSN2 and CSN3 autosomal genes, respectively. It is know that the amount of CSN1S2 was associated with allergenic properties of milk. A, B, C, E and F alleles displayed more high allergenic potency in comparison with D and O alleles (Marletta *et al.,* 2004).

The goat CSN1S2 gene is 18.5 kb long and consists of 18 exons, this locus is characterized by a total of eight alleles including A, B, C, D, E, F, G and O alleles (Boulanger *et al.,* 1984; Bouniol *et al.,* 1994; Ramunno *et al.,* 2001; Erhardt *et al.,* 2002). The alleles A, B, C, E, F and G have been associated with a normal synthesis level of αS2–casein protein per allele (about 2.5 g/l). D allele is associated with lower synthesis level while O allele determines null synthesis level (Ramunno *et al.,* 2001). Thus, the alleles occur with the differentiation in point mutations by determiningthe amino acid substitutions at the protein level (Bouniol *et al.,* 1994).

Ramunno *et al.,* (2001) identified that $CSN1S2^{F}$ allele is characterized by a G - A transition at the 13^{th} nucleotide of exon 3 in the goat CSN1S2 gene. This mutation affects a *Alw26*I restriction site and leads to changes the $GTC^{Val} \rightarrow ATC^{Ile}$ codon. The $CSN1S2^{D}$ allele is characterized by a 106-bp deletion, involving the last 11 bp of the exon 11 and the first 95 bp of the following intron.

In the present study, three different alleles ($CSN1S2^{F}$, $CSN1S2^{O}$ and $CSN1S2^{D}$) at CSN1S2 locus were investigated by PCR-RFLP method in Hair goats used from four populations reared in different regions of Antalya.

Materials and Methods

Total of 70 blood samples were randomly collected from four hair goat populations reared in different regions of Antalya, Turkey. Blood samples were taken (approximately 5 ml) from the jugular vein, using sample tubes containing K3-EDTA. The blood samples were kept at -20 ºC until the isolation of total DNA. Genomic DNA from blood samples was made using method by Miller *et al.,* (1988). DNA quality and quantity were analyzed on agarose gel and measured by spectrophotometric methods. After isolation of DNA it was adjusted 50µl/ml using bidistilled water (H_2O) for the PCR procedure.

The primer sequences and anneling tempratures were given in Table 1. DNA was amplified initial denaturation at 95°C for 5 min, followed by 30 cycles consisting of denaturation at 95°C for 1 min, annealing (temperatures for each primer pair are shown in Table 2) for 2 min, extension at 72°C for 2 min, with final extension 72°C for 10 min on Thermocycler (Thermo Fisher Arktik). The PCR reaction was performed in a 50 µl reaction mixture containing; 50 ng/µl genomic DNA, 5 µl 10 X PCR buffer (containing $(NH_4)_2SO_4$, pH: 8.8), 2.5 mM $MgCl_2$, 2.5 mM dNTP mix, 1.0 U Taq DNA Polymerase and 0.5 µM of each primer. PCR products were separated by electrophoresis on 2 % agarose gel at 80 V for 75 min.

To determine polymorphism at $CSN1S2^{F}$ allele 310 bp size PCR products digested with *Alw*26I, and for $CSN1S2^{O}$, with $CSN1S2^{D}$ alleles 301 bp size PCR products digested with *Nco*I restriction enzyme (Table 2). 10 µl PCR products were digested with *Alw*26I and *Nco*I restriction enzyme (5U- Fermantase) to determined $CSN1S2^{F}$ and $CSN1S2^{O}$, with $CSN1S2^{D}$ alleles overnight at 37 ºC. The digestion products were separated on 3% agarose gel.

Allelic frequencies were obtained by direct counting in examined samples (Nei 1987).

Results and discussion

The results of the genomic analysis of 70 samples belonging to the hair goat reared in different regions of Antalya are reported in Table 3. To detect F allele, a specific fragment of about 310 bp in length by the PCR-RFLP technique was obtained. Digestion of the amplified DNA fragment with *Alw26*I restriction enzyme showed an undigested fragment of 310 bp for the $CSN1S2^{F}$ allele. On the other hand, N alleles (non F alleles) showed two fragments of 179 bp and 131 bp for the other alleles (A, B, C, D, E and 0) of this locus (Figure 2). Analysis results showed that F/F genotype frequency is 0.057, 0.157 for F/N and 0.786 for N/N where N non F allele (one of A, B, C, D, E and O alleles).

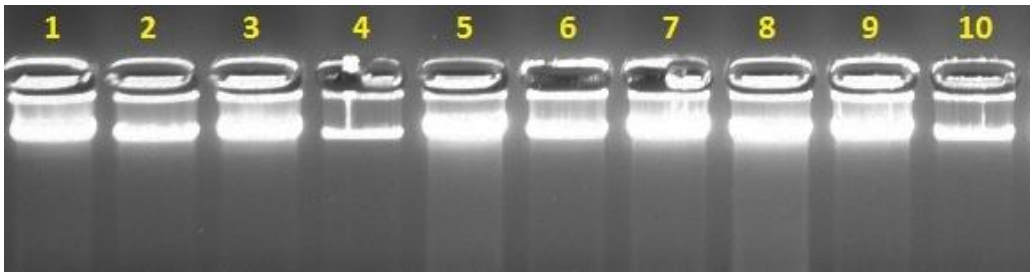

Figure 1. Image of DNA extraction on 1% agarose gel

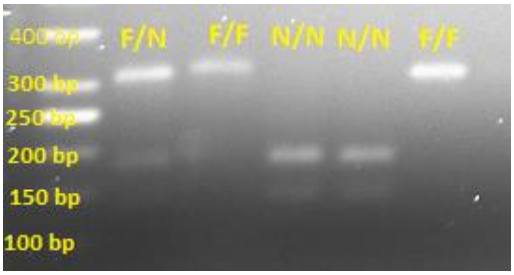

Figure 2. Observed genotypes for $CSN1S2^{F}$ allele after cutting the PCR products with *Alw26*I restriction enzyme. N/N genotype, where one of A, B, C, D, E and O alleles (DNA Ladder; Thermo Scientific, Cat. No: SM0371, 50 bp)

Table 3. Observed genotypes and allelic frequencies at CSN1S2 locus in hair goat population reared in Antalya.

	αS2-casein genotype			Gene frequencies	
	F/F	F/N	N/N	F	N
Hair Goat	4	11	55	**0.1357**	**0.8643**
Genotype frequencies	**0.0570**	**0.1570**	**0.7860**		

F allele at CSN1S2 locus has been shown in Hair goats reared in Turkey for the first time. F allele frequency of hair goat population in present study were lower than allele frequencies reported in previous studied population (Ramunno *et al.*, 2001; Marletta *et al.*, 2004; Sacchi *et al.*, 2005; Kusza *et al.*, 2007; Vacca *et al.*, 2009; Yue *et al.*, 2013; Sztankoova *et al.*, 2013). Ahmed and Othman (2009) reported that FF genotype was not displayed in tested Egypt goats.

When PCR products digested by *Nco*I restriction enzyme, two fragments 168 bp and 133 bp size were obtained. Namely, O and D alleles were not observed in any of the digested samples by *Nco*I restriction enzyme (Figure 4).

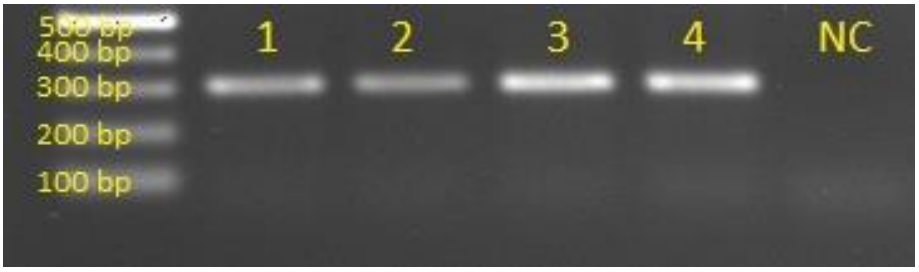

Figure 3**.** Image of PCR amplification for CSN1S2^{O} and CSN1S2^{D} alleles

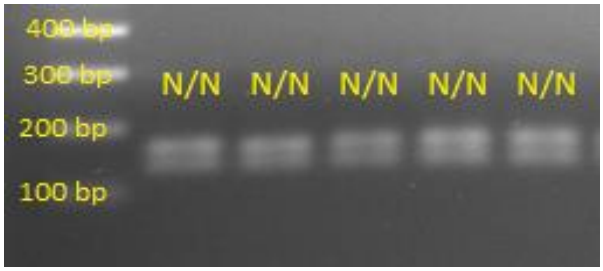

Figure 4. Observed genotypes for CSN1S2^{O} and CSN1S2^{D} alleles after cutting the PCR products with *Nco*I restriction enzyme. N/N genotype, where one of A, B, C, F and E alleles (DNA Ladder; Thermo Scientific, Cat. No: SM0242, 100 bp)

In study by Bozkaya *et al.,* (2008) in goat reared in Şanlıurfa, Siirt and Kilis region of Turkey, D and O alleles were not displayed like in this study. Similar results were found in several studies on used goat breeds as Vallesana, Roccaverano, Girgentana, Garganica and Egypt goats (Marletta *et al.*, 2004; Sacchi *et al.*, 2005; Othman and Ahmed, 2006; Kusza *et al.*, 2007; Ahmed and Othman, 2009; Vacca *et al.*, 2009), on the other hand, in some goat breeds like Hungarian milking (D:0.005; 0:0.146), Italian (D:0.019; 0:0.08), Naples (D:0.019; 0:0.08) D and O alleles were detected (Ramunno *et al.*, 2001; Kusza *et al.*, 2007). Also, Sacchi *et al.*, (2005) reported that D allele were detected in Maltese and Jonica goat breeds as 0.007 and 0.005, respectively.

Conclusion

As a conclusion, couldn't determined O or D alleles but F allele at CSN1S2 locus has been shown in Hair goats reared in Turkey for the first time. Further studies are required other milk proteins (as β-Lactoglobulin) genes and other casein loci. These genes can be use as candidate gene for marker assisted selection in goats.

Summary

In the laboratory of arachnoentomology of FGBNU «Skryabin All-Russian Scientific Research Institute of Fundamental and Applied Parasitology» the formulation of «d-cyphenothrin 5%-emulsion» was complied and composition of this medicinal product was prepared in the form of an emulsion. The drug belongs to anti-parasitic medications and is active for animal myiasis and acarinoses. Tests of various concentrations of aqueous solutions of the drug «d-cyphenothrin 5%-emulsion» were completed. The aqueous solutions of 0025%, 0.005% and 0.01% concentrations with rate of application of 50 - 100 ml per animal were tested. The results have shown that concentration of 0.005% of working solution is optimal and gives a high acaricidal effect. 100%-therapeutic effect was confirmed by using concentration of 0.005% working aqueous solution of drug «d-cyphenothrin 5%-emulsion» in working environment when sheep scab and cattle ixodidosis take places. Persistence of acaricidal drug action was 30 days after a single application in case of ixodidosis. During and after the treatment of the animals no abnormalities were observed.

Keywords: *d-cyphenothrin, ixodidosis, psoroptosis, sheep, cattle*.

Introdution

Animal ectoparasitoses are commonly spread. For example, more over 25000 species of ticks are recognized all over the world. In veterinary practice representatives of the following families: Psoroptidae (Canestrini, 1892); Sarcoptidae (Murray, 1877); Demodicidae (Nicolet, 1855); Psorergatidae (Dubinin, 1954) and Ixodidae (Murray, 1877) have the high value for studying.

Arachnomyiases do the huge economic harm such as reduction of milk yields of cattle, goats, etc.; reduction in weight gaining, decrease in hides and wool clip as well as death of animals with high degree of animal damage because of demodectic ticks and sarcoptidaes.

It should also be noted that ixodic ticks are carriers of contagious, viral and parasitic diseases of any kinds, which are dangerous for animals and humans such as encephalitis, plague, tularemia, tick-borne relapsing fever, Q-fever, Crimean-Congo hemorrhagic fever, piroplasmoses etc.

Now there is a huge number of domestic and imported drugs of different classes of chemical compounds for arachnomyiases control, which can be used for animal protection. Despite this fact, development and the implementation of science-based effective schemes for cattle and domestic animals protection from ectoparasites, allowing minimize production limitation and costs, remains the relevant task.

In general, drugs the most frequently used in veterinary practice for external work are based on pyrethroids: permethrin, deltamethrin, cypermethrin, etc. These pyrethroids are the second generation. The main disadvantages of pyrethroids are restrictions to manufacturing and toxicity.

On the basis of Skryabin All-Russian Scientific Research Institute of Fundamental and Applied Parasitology the formulation was complied and composition of the medicinal insectoacaricide drug «d-cyphenothrin 5%-emulsion» was prepared in the form of an emulsion. The drug belongs to anti-parasitic medications and is active for animal enthomoses and acaroses

The mechanism of D-cyphenothrin'a action contains the prolonged inhibition of sodium channels nerve conduction, depolarization of cell membranes, which leads to irreversible paralysis and death of the arthropods. D-cyphenothrin has a fast knockdown effect on insects and ixodic ticks that occurs at the first contact with the surface of the treated animal (destroys before the bite). It has a repellent effect on the bloodsucking flying insects.

Pursuant to the degree of impact on the body «d-cyphenothrin 5%-emulsion» falls into the category of moderately hazardous substances (hazard class 3 according to GOST 12.1.007-76). It does not have local irritative, resorbtive toxic or sensitizing effect as well as embryotoxic action, if it is used in recommended doses; has slightly eye irritation in case of contact with eye. The drug is well tolerated by animals of different breeds and ages.

The drug is made up for sheep, cattle, pigs, rabbits and dogs in case of arachnomyiasis and disinsection and disacaridisation of livestock buildings and other objects of veterinary supervision.

Extended testing of the drug's efficiency in case of cattle ixodidosis, sheep and cattle psoroptosis were conducted.

Materials and methods of research

Acaricide efficiency of "D-cyphenothrin 5%-emulsion" of different concentration of working solution was examined under cattle ixodidosis of cattle in the Republic of Dagestan. For the experiment 4 groups of 30 animals were selected, 3 of them were experimental groups and 1 was the control group. The animals from different groups were treated aqueous solutions of 0.0025%; 0.005%; 0.01%. Before the experiment and then after 24 hours and 2, 7 and 30 days, all cows were carefully examined, number of ticks was counted and extensive efficiency was calculated (EE, %). Extensive production tests of D-cyphenothrin 5%-emulsion's efficiency using aqueous solution in concentration of 0.005% were carried out on the basis of farm firm "Shangoda", APC "Choh" and PFC "Bukhty" located in Gunibskiy district of the Republic of Dagestan from September 2013 to May 2014, age of Red Steppe Breed cattle was 2-3 year, weight was 450-500 kg, all cattle was naturally infected with ixodic ticks. 200 beasts in each farm, 170 from experimental group and 30 from control group, were totally treated.

Initial studying of the efficiency and commission tests of the drug " D-cyphenothrin 5%-emulsion" under sheep sarcoptosis were carried out in a private farms dealing with breeding of sheep breed "Prekos" and "Edilbaevskaya" in the territory of Danilovsky district of Volgograd region. The work was held in the period of September-October 2015 in accordance with the plan of treatment and preventive measures for parasitic arthropods using naturally infected 2-3 years old sheep (diagnosis of sarcoptosis) weighing 65-75 kg and the lambs, aged of 5-6 months. Condition of animals living was loose in the open.

Research of the drug efficacy in case of cattle psoroptosis was held on the basis of farm JSC "Gorbatovskoe" located in Pavlovsky District of Nizhny Novgorod Region, Popad'ino village from March 1 to March 20, 2016. 40 breeds of 2-3 years old cattle weighing 400 - 450 kg were chosen. Animals were naturally infected with ticks (Psoroptes bovis). Concentration of the aqueous solutions of 0.001%, 0.005% and 0.01% was tested.

For preparation of the working solution with active substance in concentration of 0.001%, 0.005% and 0.01% the medication was diluted with water in a ratio 1:5000; 1:1000; 1:500 respectively immediately before use. Animals were treated by low-volume spraying with rate of

application rate of 50 - 100 ml per animal. Milk-cows were treated at least 7 - 8 hours before the next milking.
After treatment daily monitoring of general conditions of the animals, eating and water delivery as well as behavior, were held and skin covering for ticks detecting was examined.

Under conditions of farm firm "Shangoda" 4 groups of animals were formed, 30 animals in each group. Cows of the first group were treated the working solution of 0.0025%, the second - 0.005% and the third - 0.01% of the test drug. Before the experiment, and then after 24 hours and 2, 7 and 30 days all cows were carefully examined and the number of ticks was counted (II – invasion intensity, AR - abundance rate) and calculated extensive efficiency (EE, %).
When we used aqueous solution of D-cyphenothrin 5%-emulsion of concentration of 0.005%, the animals unloaded of ticks in a day. It was found that this concentration retains acaricidal properties during one month. Several ixodic ticks were found on animals in 35-40 days after treatment.
The researches of the drug efficiency of concentration of D-cyphenothrin 5%-emulsion were held under the conditions of farm firm "Shangoda", APC "Choh" and PFC "Bukhty". Total number of the treated animals amounted to 200, 170 of them were in the experimental group and 30- in the control group. Extensity of animal infection was 100%, the abundance rate in the experimental groups varied from 118.6 to 139.2, in the control group- from 106.8 to 142.8. Parasites were mostly founded in the udder, groin, chest and forelegs. We have founded that animals had anxiety, itch, skin thickening and dermatitis, crusting and cracking, average rate of daily milk yields were significantly reduced.

Efficiency, %		100	-	100	-	100	-

Note: Exp. – experimental (group), cont. – control (group)

Under production conditions of three livestock farms in case of treatment of aqueous solution D-cyphenothrin 5%-emulsion of concentration of 0.005% 100% acaricide efficiency in total tick invasion of cattle was observed, preventive efficiency amounted to 30 days.
During the experiment we monitored the animals and their conditions. The essential markers were body temperature, heart rate and respiratory rate. Table 3 contains this information.

Table 3. Control of body temperature, pulse and respiration rate of cattle before and after the experiment (n = 30; P ≥ 0,05)

Note: here and elsewhere T – temperature, P – pulse, R – respiration.

Before and during the experiment all animals from the experimental and the control groups had indexes, studied in Table 3, that were statistically unreliable and were within the reference values.

2. The study of efficiency of "D-cyphenothrin 5%-emulsion" in case of sheep psoroptosis

Initial study of efficiency of "D-cyphenothrin 5%-emulsion" in case of sheep psoroptosis was held in a private farms engaged in breeding and raising business of sheep breeds "Prekos" and "Edil'bai" in the territory of Danilovsky district of Volgograd region. Extensity of invasion ranged from 70 to 100%. We observed that sheep had itch, skin scratching, sheep hair tangled in the affected areas, lambs had slightly itching. Psoroptosis diagnosis was made on the basis of epizootiological data, clinical signs and results of acarological analysis of skin scrapings in case of Psoroptes ovis ticks detecting. The material for the research was taken from fresh lesions, on the border between the modified and the formally healthy skin.

40 goals of sheep and lambs infected by Psoroptosis were selected and they were divided into two groups: the control group and the experimental group, each group contained 20 goals. The animals of the experimental group were treated by means of group wet inspection for whole skin cover using the aqueous solution of the drug twice with an interval of 10 days. Sheep were treated by low-volume spraying with a rate of application of 50-100 ml per animal. Spraying was performed by spraying device, making small-drop air-spraying. The control group was not treated.

After treatment daily monitoring of the general condition of animals as well as eating and water delivery, behavior was held. Skin cover was examined, dynamics of affected areas recovery was fixed. 10 days after the second treatment, laboratory test of skin scrapings was held. During the experiment neither complications related to drug using nor adverse effects were detected.

As a result, it was found that the efficiency of the drug "D-cyphenothrin 5%-Emulsion" confirmed by the negative results of two-fold negative results of acarological researches and clinical data, was 100% in case of psoroptosis of sheep and lambs.

Tests for drug efficiency was performed in subdivision "Chernorechenskiy cattle-breeding complex», dealing with breeding and rearing of sheep breed "Edil'bai and located within the territory of Beloprudskoe rural settlement, Danilovsky district of Volgograd region. 110 animals from clinically infected sheep and lambs were chosen and then they were divided into two groups: the control group of 10 beasts and the experimental group of 100 beasts. The animals were treated by means of group wet inspersion for whole skin cover using the aqueous solution with concentration of 0.005% of the drug twice with an interval of 10 days. Sheep were treated by low-volume spraying with a rate of application of 50-100 ml per animal. The control group was not treated.

In order to confirm the therapeutic efficiency we randomly chose 25 animals and in 10 days after the second treatment we performed acarological tests for skin scratching. Thus, the drug efficiency was 100% and was confirmed by the absence of clinical signs and two negative results of acarological tests of skin scrapings. In the control group, according to microscopy data ticks Psoroptes ovis were founded.

3. The study of efficiency of "D-cyphenothrin 5%-emulsion" in case of cattle psoroptosis

Researches of the drug efficiency under cattle psoroptosis was carried out in Nizhny Novgorod region. The animals had anxiety, itch, scratching areas on the skin, crusting, level of milk production was reduced. Diagnosis was made on the basis of results of clinical examination and detection of ticks Psoroptesbovis under laboratory conditions.

4 groups of 10 animals were formed: the first group was treated with working solution of drug with concentration of 0.001%, the second group - 0.005%, the third group - 0.01%, and the fourth group was considered as the control one. After treatment daily monitoring of the general condition of animals, eating and water delivery as well as behavior was held. Skin cover was examined.

During the experiment and the drug's using there were neither adverse effects nor complications. After 7 days, there were no ticks Psoroptes bovis in the second and third groups, animals had no anxiety symptoms, crusts were dry and fell down. In first group in scrapings of two cows live ticks Psoroptes bovis were detected. After 15 days there were no ticks in all groups as well as no clinical signs, hair began growing at affected areas. The animals of the control group remained infected during all research.

Thus, drug's efficiency of "D-cyphenothrin 5%-emulsion" in working concentration of 0.001%; 0.005% and 0.01% after 15 days was 100% in case of cattle psoroptosis. However, after 7 days live ticks Psoroptes bovis were detected on animals, treated with working concentration of 0.001. In connection with the results founded the concentration of 0.005% of aqueous solution «D-cyphenothrin 5%-emulsion» was considered optimal.

Conclusion

In this paper we offered a medicinal product for veterinary use in case of ectoparasites of farm animals. Tests of various concentrations of aqueous solutions of drug "D-cyphenothrin 5% - emulsion" were hold. Concentrations of 0.0025%, 0.005% and 0.01% with rate of application of 50 - 100 ml per animal were examined. The results have shown that the concentration of 0.005% of aqueous solution is optimal and has a high acaricidal effect.

100% therapeutic effect was confirmed by using a working concentration of 0.005% of aqueous solution of the drug "D-cyphenothrin 5% -emulsion" under production environment in case of Psoroptosis and Ixodidosis of cattle and sheep. Persistence of drug acaricidal action after single use under Ixodidosis was 30 days. During and after the treatment no abnormalities have observed.

Abstract

In order to investigate the effect of the age of cows on some of the reproductive traits, 30 Holstein-Friesian cows, cultivated on the 'Spreča' farm in Kalesija, have been investigated. Based on the data obtained from the records for 30 cows, these reproductive features have been analyzed: age of cows during their first conception, gestation length, duration of service period and inter-calving interval and the weight of calves in the first three calving, or first two lactations. According to the analyses and statistic processing of mentioned reproductive parameters, the conclusion is that the average age of cows during their first conception was 22.29 month and the average gestation, for both genders, was longer for the second conception. The average duration of service period and inter-calving interval was 172.88 days and 448.98 days, after which it can be concluded that these parameters lasted long. Male calves, in all three calving, were heavier than female calves and when it comes to both genders, the highest average weight of calves was in the second calving (42.53 kg).

Keywords*:* *age, reproductive traits, Holstein-Friesian cows.*

Introduction

Fertility of cattle is a trait that other productive segments are dependable on, like economic value of milk and meat production. Reproduction field of the cattle is the most important but also the most expensive phase of the production in comparison to other phases. During this process, throats for replacement in the herd, production of milk and production of meat is processed. Considering the fact that the reproduction of the cows is very important segment in the cattle field, all phases of the reproduction need to be organized. Knowing more influences to certain reproductive features, fertility can easily be improved (Trifunović, 2004). Focus should be on the proper raising of heifers, their age in the first year of fertilization and the period between two calving, with the goal of one calf per year. In Bosnia and Herzegovina, we are seeing more and more of the black and white Holstein-Friesian species, which is the most superior species when it comes to production of milk.

Materials and methods

Research of the reproductive features of Holstein-Friesian cows, conducted on the contemporary 'Spreča' farm (Kalesija, entity of Federation of Bosnia and Herzegovina), that owns high quality dairy cows. Capacity of farm is 2500 throats, from which 1500 are dairy and 1000 different categories. Yearly production of milk on this farm is around 12 million liters of milk. With a random sampling for this research, 30 Holstein-Friesian cows have been chosen, in their first three lactations. The most basic reproductive indicators have been monitored: gestation length, service period, inter-calving interval and the weight of calves. Basic data processing and testing of the importance of the differences between these indicators are shown by the application of common variation and statistical methods

(Hadživuković, 1991), and calculation of the coefficients phenotypic correlation connection between the parameters is made by the form for correspondent sample (Latinović, 1996).

Results and discussion

To establish fertility it is important to evident all of the phenomenon and activities related to reproductive features, and that's why in this paper the results of all these traits of 30 Holstein-Friesian cows, can be found. Throats have been bred on the 'Spreča' farm and have been chose by random sample method from the farm's records. Parameters that have helped to come to results related to reproductive features that are shown in the tables below. Results in the tables represent reproductive parameters like: the age of the heifer during their first, second and third insemination, gestation length, duration of service period and inter-calving interval and the weight of the calves during the first, second and third delivery.

Table 1. Average values and variability of age of cows, inter-calving period and service period in the first three lactations

Lactation	Indicators	$\bar{x}$	$S_{\bar{x}}$	S	C.V. (%)
I	Age of cows – first insemination (months)	22,29	0,77	4,23	18,97
	Service period (days)	158,2	11,69	63,96	40,42
	Inter-calving period (days)	437,66	11,46	62,69	14,32
II	Age of cows – second insemination (months)	36,53	0,99	5,45	14,91
	Service period (days)	187,56	15,46	84,62	45,11
	Inter-calving period (days)	460,30	15,67	85,75	18,62
III	Age of cows – third insemination (months)	52,06	1,28	7,02	13,48

Average age of all of the heifers during their first insemination was 22.29 months, while the average age during the second and the third insemination was 36.53 months (second) and 52.06 (third).

Perišić et al. (2004) have come to a conclusion that the average age during the first insemination was 17.89 months (536.70 days), which is below the results that have been gathered in this paper. From table 1 we can see that the variability of the service periods was very expressed during both of the service periods (C.V. % = 40.42 and C.V. % = 45.11).

Basic parameter that is used to measure reproductive efficiency of herd of dairy cows is the duration of the interval between two constant deliveries. (So called inter-calving interval) (Stančić and Košarčić, 2007).

The results show that there are differences between the first two inter-calving intervals, and also during the service periods, the second one (460.30) inter-calving interval lasted longer than the first one (437.66).

In the table 2 average values and the variability of the duration of pregnancy have been shown. When we consider the fact that the duration of pregnancy is a biological constant, there have not been much of the differences in the first three calving. There is an ascertainment in the table that pregnancy period for the second time (both sexes) lasted longest (275.20), while the shortest was during the first calving (269.66). Also, the accent should be at the pregnancies with cows that had male calves lasted longer than with the cows that gave birth to female calves.

Kosovac (1984) states that the pregnancy for the Holstein-Friesian cows is 281.78 days and for the black and white (Holland-Friesian) cows 277.60 days which is longer comparing to the results in this paper.

Table 2. Average values and the variability of the duration of gestation depending on the age of the cow and gender of the calf (days)

Gestation	Calf gender	n	$\bar{x}$	$S_{\bar{x}}$	S	C.V. (%)
I	♂	9	288,11	0,77	2,15	0,75
	♀	6	288,33	0,66	1,63	0,56
	♂ + ♀	15	288,20	0,49	1,90	0,66
II	♂	8	287,25	0,45	1,28	0,45
	♀	7	287,14	0,59	1,57	0,55
	♂ + ♀	15	287,20	0,35	1,37	0,48
III	♂	6	288,50	0,56	1,38	0,48
	♀	9	287,67	0,60	1,80	0,63
	♂ + ♀	15	288,00	0,43	1,65	0,57

Table 3 shows the average value and variability of the weight of calves at birth in kilograms. Both sexes had the highest weight during the second calving and it was 42.53 kg, and the smallest weight was found at the cows giving birth for the first time (39.93).
Looking at the results from the table, we came to a conclusion that male calves in all three calving weighted more than female calves.

Table 3. Average values and the variability of the weight of calves at birth (kg)

Order of calving	Calf gender	n	$\bar{x}$	$S_{\bar{x}}$	S	C.V.%
I	♂	12	41,58	1,06	3,67	8,82
	♀	18	38,83	1,07	4,55	11,71
	♂ + ♀	30	39,93	0,79	4,37	10,94
II	♂	14	41,64	1,44	5,41	12,99
	♀	16	43,31	1,45	5,83	13,46
	♂ + ♀	30	42,53	1,02	5,61	13,19
III	♂	14	42,28	1,14	4,30	10,17
	♀	16	39,18	0,75	3,01	7,68
	♂ + ♀	30	40,63	0,71	3,93	9,67

The differences between the most reproductive traits that are confirmed in previous tables are statistically confirmed and those parameters have been shown in the table below (table 4).

Table 4. The significance of differences in gestation length, inter-caving interval duration, service period duration and weight of calves in the first three lactations

Indicators	Lactation	Average	Difference	Significance
Gestation length (days)	I-II	269,66 – 275,20	-5,540	***
	I-III	269,66 – 272,83	-3,170	***
	II- III	275,20 – 272,83	2,37	**
Inter-calving interval (days)	I-II	437,66 – 460,30	- 22,64	***
Service period (days)	I-II	158,20 – 187,56	-29,36	***
Weight of calves (kg)	I-II	39,93 – 42,53	-2,600	***
	I-III	39,93 – 40,63	-0,700	ns
	II-III	42,53 – 40,63	1,900	*

***P<0.001; **P<0.01; *P<0.05; ^{ns} P>0.05

In the presentation we have mentioned that the longest pregnancy was the second one (275.20) and the shortest was the first one (269.66). Statistically, highly significant differences (P<0.001) have been found between the first and the second pregnancy, and between the first and the third pregnancy, while the differences between the second and the third pregnancies were very significant (P<0.01).

Looking at the results from the tables for the parameters of the service period and the inter-calving interval, we conclude that the differences of 29.36 (for the service period) and 22.64 (for inter-calving period) were statistically highly significant and confirmed on the level of (P<0.001).

Confirmed differences between the weights of the calves at birth during first three lactations are also shown in the table 4. We conclude that there are differences highly significant between the weight at first (39.93 kg) and second (42.53 kg) calving and that difference (2.60) has been confirmed on the level (P<0.001). Difference from 0.70 between weight of the calves during the first and the third calving, did not show statistical significance (P>0.05), while the difference between the weight of the calves at the second and the third calving was significant at the level of P<0.05.

Conclusion

Based on the analyses and statistic processing of mentioned reproductive parameters, the conclusion is that the age and lactation, respectively, had the effect on the most of the reproductive features. The other conclusion is that in the aspect of the reproductive features there hasn't been satisfying results, considering the fact that the service period and the inter-calving interval lasted long. From detailed analyses, one can see that the selection plan of the farm 'Spreča' was to get the production rate to the highest level, affecting the fertility and shortening the lifetime of the cows.

Abstract

The main threat for bovine tuberculosis (bTB) officially free qualification of cattle herds is the presence of a wildlife reservoir species around livestock farms. Without a regular and systematic surveillance, the epidemiological risk caused by the disease cannot be estimated; hereby plan of action is hard to work out. In Hungary, the Southwestern part of the country is known as a bTB endemic area. Our study aimed to identify those species, which can be a target of a systematic surveillance. For this purpose, we investigated 238 specimens of six species between 2014 and 2016 to look for visible lesions of bTB; and then we cultured all investigated specimens. During evisceration we carried out a visual-only game meat inspection, and then we collected lymph nodes (submandibular, retropharyngeal, tracheobronchial, mediastinal, hepatic, mesenteric) and submitted those to bacteriological examination. Our results confirmed that the wild boar *(Sus scrofa)* and the red fox *(Vulpes vulpes)* showed the highest infection prevalence inside the endemic area (21.7% and 22.2%, respectively), although during our investigation, the red fox never showed visible lesions of bTB. Nevertheless, among wild boars, the prevalence of post-mortem lesions proved to be 63.4%. All of the examined wild boar carcasses with visible lesions contained lesions inside the submandibular lymph node, as well. These findings suggest that wild boar can be a good target species for bTB surveillance. The observation that the submandibular lymph node was affected in each case, suggests that game meat processing plants, where the head can be accessible, should be a place of a systematic surveillance on bTB in wildlife.

Keywords: *Bovine tuberculosis, Wildlife, Surveillance, Hungary.*

Introduction

Bovine tuberculosis (bTB) is a re-emerging infectious disease all over Europe. The former method, test and slaughter (tuberculin testing of cattle herds and removing all the reactors), cannot be successful to reach and maintain freedom from the disease, where natural reservoir exists in the close surroundings of free-ranging livestock (Cvetnic *et al.*, 2006; Meng *et al*., 2009).

Dense wildlife populations serve as both animal health and husbandry problems that can threaten the efficacy of both wildlife management and livestock health (Gortázar *et al.*, 2008, Naranjo *et al*., 2008; Schöning *et al*., 2013; Vicente *et al*., 2006), furthermore, bTB doubts the sustainability of intensive wildlife management systems (Vicente *et al*., 2006).

Special ecological factors determine the maintenance or spill-over roles of a host. These factors might be population density, social behaviour, feeding ecology of the host species; moreover, other characteristics of the local ecosystem (Rhyan and Spraker, 2010; Martin *et al*., 2011).

Former studies consider the badger to be an important reservoir species on the British Isles exclusively (Gallagher and Clifton-Hadley, 2000; Sobrino *et al*., 2008), whereas on the Continent the species which may play a significant role in the epidemiology of bTB is wild

boar (Naranjo *et al*., 2008). Moreover, other species, such as the red deer *(Cervus elaphus)*, fallow deer *(Dama dama)* and red fox are investigated as a reservoir of bTB (Fitzgerald and Kaneene, 2012, Martín-Atance *et al*. 2005; Matos *et al*. 2014; Schoepf *et al*., 2012).
Mycobacterium caprae has proven to be the major cause of bTB in central European livestock and wildlife (Prodinger *et al*., 2005). In the last decade several investigations confirmed that wild boars can maintain bTB infection even in the absence of another susceptible species (Naranjo *et al*., 2008).
Although, diseases are not the most important mortality factors in wildlife species, there were several attempts to control bTB in wildlife (Gortázar *et al.*, 2011; Schoepf *et al*., 2012; Vicente *et al*., 2006). It is confirmed that without an appropriate surveillance system disease management cannot be successful (Hadorn and Stärk, 2008). In the course of surveillance planning it is essential to select the most eligible target species. In this point of view scavenger species that act as bio-accumulators of infectious agents, can come into question (VerCauteren *et al*., 2008).
The aim of our study was to determine the most appropriate target species for bTB surveillance inside an endemic area. Therefore we investigated six potential host species and we searched for visible lesions of bTB. We hypothesized that among the most abundant mammal species, we could find one, in which the prevalence of infection and the visibility of the lesions should allow to be the base of a surveillance system.

Materials and methods

Our study was carried out in Somogy County inside the south Transdanubian region of Hungary, which is known as a bTB endemic area (Prodinger *et al*., 2005).
Between 2014 and 2016 we collected 238 samples from six species (wild boar, red deer, fallow deer, roe deer *(Capreolus capreolus)*, red fox and golden jackal *(Canis aureus)*) during hunting events. All examined animals were hunter-harvested as a part of management practice and not for animal health purpose. During group hunting events game animals were shot randomly without any special selection for age, gender and health status. In a certain hunting event each carcass was examined without any selection in order to keep the randomization provided by non-selective hunting. Roe deer were harvested individually, but we made an effort to collect as many specimens of this species as we could. Carcasses in which regional lymph nodes of the head, neck and chest cavity were destroyed by the shot were excluded.
Post-mortem examination and sample collection were carried out in the field during evisceration. The regional lymph nodes, lung, liver, spleen, kidney were examined visually, by palpation and all were dissected to 2 mm slices. Individual samples submitted to bacterial culture included all organs with suspect bTB lesions (Vicente et al., 2006) and the submandibular, retropharyngeal, tracheobronchial, mediastinal, hepatic, mesenteric and caecal lymph nodes (independently of post-mortem findings).
These individual samples were homogenized in a pool and decontaminated in 5% oxalic acid solution for 15 min; then centrifuged at 3000× *g* for 10 min. The sediment was re-suspended in 2 mL sterile phosphate buffered saline and inoculated into Middlebrook broth and onto Herrold's, Lowenstein-Jensen and pyruvate supplemented Lowenstein-Jensen slants; which were incubated for at least 8 weeks at 37 ^{o}C and checked for contamination and mycobacterial growth weekly, while Middlebrook broth was checked by Ziehl-Neelsen (Z-N) staining every month. All isolates were tested in a multiplex amplification system (Wilton and Cousins, 1992).
Bacterial culture results were defined as *M. caprae*, MAC, MAP and NTM, if *M. caprae*, *M. avium* complex without *M. avium ssp. paratuberculosis*, *M. avium ssp. paratuberculosis* and non-tuberculous (environmental) mycobacteria were isolated, respectively.

Results and discussion

Among the investigated species the red fox didn't show any visible signs of bTB, even at high prevalence of infection. Deer species always showed visible lesions in the case of infection but the prevalence was relatively low. The golden jackal proved to be free from the infection during our study; although the sample size was small. Our study confirmed that the wild boar could be the best target of a surveillance system, because both visible lesions and culture positivity occurred at a high prevalence in the species (Table 1).

Table 1. Post-mortem and culture results by species

Species	**Number of examined**	**Number of positives by necropsy**	**Number of culture positives**	**Prevalence of lesions**	**Prevalence of *M. caprae***
Wild boar *(Sus scrofa)*	**175**	**111**	**38**	**63.43%**	**21.7%**
Red deer *(Cervus elaphus)*	**25**	**5**	**3**	**20.0%**	**12.0%**
Fallow deer *(Dama dama)*	**23**	**3**	**2**	**13.0%**	**8.7%**
Roe deer *(Capreolus capreolus)*	**3**	**2**	**0**	**66.7%**	**0.0%**
Red fox *(Vulpes vulpes)*	**9**	**0**	**2**	**0.0%**	**22.2%**
Golden jackal *(Canis aureus)*	**3**	**0**	**0**	**0.0%**	**0.0%**

Our results were in accordance with other European experiences as the wild boar, especially the submandibular lymph nodes, showed visible lesions, which could be detected by post-mortem examination of carcasses (Naranjo *et al*., 2008). In our study, all of the examined wild boar carcasses with visible lesions contained lesions inside the submandibular lymph nodes.

The role of the other scavengers, the red fox and golden jackal, could not be ascertained by our investigation. The complete absence of lesions in the red fox and the apparent freedom from the infection in the golden jackal might have been due to the smaller sample size in these species. Study results from the Iberian Peninsula confirm that the red fox can develop advanced stages of bTB (Martín-Atance *et al*. 2005; Matos *et al*. 2014). Notwithstanding, canids as bio-accumulators of infectious materials proved to be good sentinels of bTB as well (VerCauteren *et al.*, 2008).

In this regard canids need more considerations.

Cervids as a host of bTB was confirmed by this study; nevertheless, the relatively low prevalence of infection could not allow these species of being a good indicator of epidemics in the natural environment.

Conclusions

Wild boar as a natural reservoir of bTB in Europe is well known. Our study confirmed that within an endemic area, this species could become infected at a higher rate and it could show visible lesions of bTB, especially inside the submandibular lymph nodes.

In Europe thousands of wild boars are hunter-harvested and processed by the game meat industry. Carcasses enter the game meat processing plants with the head; accordingly with submandibular lymph nodes. These plants should be adequate places for large-scale screening of wild boars by post-mortem examination. The data yielded from this survey can be applied in planning of an epidemiological strategy against bTB in free-ranging cattle herds.

Abstract

Four 4.5±1.2 years old male Sicilo-Sarde local sheep ruminally cannulated and with live weight 45.25±3.5kg were used to evaluate the effect of replacing corn and soya beans by white sorghum and horse beans on the parameters of facies fermentation, protozoa and degradability. Each animal received, during a first period of the experience, 1.5 kg of oat hay and 500 g of concentrate (C) to basis of corn (43.3%), barley (25%), soybean meal (17.7%) and mineral and vitamin supplement CMV (4%). Then, in the second period, these rams received 1.5 kg of oat hay and 500 g of concentrate (S) to basis of white sorghum (66%), horse beans (30%) and mineral and vitamin supplement CMV (4%). The rams were lodged in in individual pens. The result of the replacing revealed that feed intake was not significantly affected (1.54vs. 1.53 kg DM/d, for C and S, respectively). Rumen pH was significant ($P<0.05$) before the distribution of the morning feed and 2 hours after while the diet doesn't affect it after in 5 and 8 hours. Ammonia nitrogen and gas production were not affect by the diet ($P>0.05$) The dry matter digestibility was significant ($P<0.05$) in 3, 6, 12, and 36 hours but the diet didn't affect it in 24 and 48 hours. Total ciliate protozoa counts was little higher for (C) than (S) while the different genus of protozoa were comparable for (C) and (S) but the diet did not affect the number and genus of protozoa.

Key words: *Sicilo-Sarde Rams, local feed resources, facies fermentation, degradability*

Introduction

Sheep are considered to be one of the most important animals that can affect the social and economic status of people inhabiting arid and semi-arid regions. The development of ruminant livestock uses different sciences (nutrition, reproduction, genetics, health) need to conduct in parallel, in an integrated manner in a culture system. Indeed, ruminants can transform highly diversified plant biomass, in particular fiber materials, animal proteins. So to improve and increase the productivity of livestock (meat, milk, egg) which is among the main objectives of agricultural policies in the world in response to increasing populations , it is particularly clear understanding of the technical and rationing know the scientific basis of the components of food - animal -system.

The feeding of sheep is based on forages with a low nutritional value and undiversified and concentrated formed by imported raw materials (corn and soybeans) even their price is high. So the farmer must look for the local raw materials to feed his livestock to cover their needs .The purpose of this present study was to focus on the effects of the local raw materials on rumen metabolism and in situ degradability in sheep.

Materials and methods

Animals and management

The experiment was carried on 2010 out at the experimental station of the higher school of agriculture of Mateur in Tunisia. Four 4.5 ± 1.2 years old male Sicilo-Srade local sheep ruminally cannulated with live weight at the beginning of the trial 45.25 ± 3.5 kg were used in this experiment. The rams were housed in individual pens (length 1.6 m and width 1 m) where fresh water was freely available. Each animal received 1.5 kg of oat hay/ram/day and daily supplemented with 0.500 kg /ram/day of two concentrates (C) and (S), different by the nature of protein and energy ingredient. Rams received in the first period the concentrate (C) and in the second period the concentrate (S) during a 30 days separated by an adjustment period of fourteen days. Feeds were offered twice daily at 9:00 and 17:00 hr. Samples of different meals distributed and refuse were weighted and sampled daily (10% per day from each animal). The samples were dried at 50ºC for 48 hours and preserved for later analysis.

Rumen fermentation

The rumen liquor was taken 0 hour before serving meals and 2, 5 and 8 hours after via a plastic rod. The pH was measured on the rumen contents just after collection with a digital pH meter. Before each measurement of pH, the electrode was rinsed with distilled water and wiped dry.

For counting different protozoa genera a volume of 5 ml of unfiltered samples juice and 5 ml of a solution composed of 500 ml glycerol and 20 ml formaldehyde and 480 ml distilled water were stored in a refrigerator set at 4°C until the count. With a HAWSKLEY counting room, we were determined the enumeration and the genera of protozoa after several dilutions and using a microscope with a lens 100X.

The method of Conway (1962) was used to measure the concentration of ammonia nitrogen (NH3-N). after filtering the rumen liquor with four layers of of cheesecloth 1 ml of sample was acidified with one drop of sulphuric acid (0,1N) and kept frozen until analyzed. the concentration of ammonia nitrogen was determined using this formula:

NH3-N mg/ml of juice = (V (HCl E) – V (HCl T))* N (HCl) *14 g

Where:

V (HCl E): volume of the sample.

V (HCl T) : volume of the witness.

N (HCl) : HCl normality.

Gas production

A filtered rumen liquor, collected before the morning feeding was used to determine the gas production (CO_2 and CH_4) following the method described by Menke and Steingass (1988). 0.5 g (DM) of substrate (oat hay milled at 1 mm) was weighted into glass syringes with 10 ml of rumen fluid and 40 ml of artificial saliva and incubated at 39°C. The gas production was determined every 2 hours until 24 hours. At the end of incubation a 5 ml NaOH was injected in each syringe, the piston moves back, the difference in volume reflects the amount of methane produced.

In situ rumen degradability

Samples of 3 g DM of oat hay were placed in nylon mesh bags calibrated (5 × 15 cm; pore size of 50 µm) and sealed. the weight of each bag is determined before each use. the bags were fixing to a plastic rod of about 20 cm long bearing at its ends a counter weights about 100 g so it does not float in the rumen. The 0 h bags (bags witnesses) and the bags attached were washed under running water for 5 minutes. After that the bags witness were placed an

oven at 60°C while the bags were incubated in the rumen for 3, 6, 12, 24, 36 and 48 hours. One bag was taking per pet, per stay time. After removal from the rumen, the bags containing forage residues were rinsed with water until no further colour appeared. Then these were dried at 60°C for 24h. Digestibility was determined as follows:

$$\text{Dg DM (\%)} = \frac{\text{(DMC – DMR)}}{\text{DMC}} * 100$$

Where:
DMC: Dry matter corrected (g)= DM x (1-loss rate)
DMR: Dry residue (g) of the bag incubated in the rumen.

Statistical analysis

The parameters measured were subjected to analysis of variance by GLM procedure of SAS (1989)) and compared by Duncan's test (1955).

Results and discussion

Composition of diets

The chemical composition of different diets is documented in Table 1.

Table 1. Chemical composition (%, DM basis)

Nutrient	Concentrate		hay
	C	S	
Dry matter	94.7	94.7	92
Organicmatter	91.0	88.3	92.1
Crude fibre	12.7	3.7	35.6
Crude protein	16.3	14.65	4.9

C: 10% barley; 43.3% corn; 25% wheat bran; 17.7% soybean meal and 4% CMV; S: 66% white sorghum; 30% horse bean and 4% of CMV;

The results of this analysis show that the hay is low in CP (4.9%) and rich in crude fibre (35.6%) confirming the results reported by several studies (Mahouachi and Khaldi, 1987). The CP and crude fibre concentrations in the diets containing corn were greater than diet containing sorghum.

Feed intakes

Table 2 shows that feed intakes of hay oat (g/Kg0.75/d) was 1,07 ± 0,08 for (C) and 1,06 ± 0,1 for (S). Feed intake of animals was not affected by diet. This result is similar to this of Mason (1981).

Table 2. Effect of diet on feed intake

	Mean	*P*
M	1.07 ± 0.08	*ns*
S	1.06± 0.1	*ns*

ns = non-significant; SEM = Standard error of means.

Rumen fermentation

The effect of diet on rumen metabolites are shown in tables 3, 4 and 5. The diet tended to decrease rumen pH during the day. The pH before serving meals and after 2 hours was significantly (P<0.05) for diet M and S 6.67 ±0.34 and 6.28 ±0.22 at 0h and 6.48 ±0.38 and 6.18 ±0.13 after 2 hours. Fabiao et al (2008) previously observed similar results that were also coherent with those of Dayani et al (2007). After 5 hours there was a difference but without a significant difference . It was a decrease in pH to 2 and 5 H , this trend could be attributed to the negative correlation between rumen pH and the concentration of volatile fatty acid end products of digestion of carbohydrates (Cuvelier et al, 2005). At 8H, the pH increased , this can be explained by the stabilizing effect of ciliated protozoa in degrading starch that comes from horse beans. These findings agree with those reported by Santra and Karim (2007) and Hammami et al (2009).

Table 3. Effect of diet on rumen fluid pH

	Time(h)			
	0	**2**	**5**	**8**
M	6.67 ±0.34	6.48 ±0.38	6.22 ±0.42	6.25±0.34
S	6.28 ±0.22	6.18 ±0.13	5.97±0.22	5.99±0.31
Diet effect	*	*	*ns*	*ns*

ns = non-significant;

Before the meal NH3-N concentration was 9.21 ±2.63 mg/100 ml of rumen fluid for diet corn and soyabeans while it was 8.05 ±2.93 mg/100 ml for diet sorghum and horse beans. Then after 2 hours the ammonia reached his peak for two diets. Kayouli et al (1991) explained this that the ruminal pH is favourable to the proliferation of ciliated protozoa and high microbial activity. Hammami et al (2009) reported similar findings, which confirmed the previous findings of Rouissi et Guesmi (2004) and Castillejos et al (2007). On the other hand Jouany and Senaud (1982) explained this by significant correlation observed between the concentration of NH3-N and the total number of ciliates. After 5 and 8 hours, NH3-N concentration in the rumen decreased for the two diets. This may be due to the absorption through the rumen wall and use by bacteria to synthesize their own proteins (Hammami et al., 2009). However, NH3-N concentration was not affected by the diet (P>0.05)

Table 4. Effect of diet on ammonia nitrogen (mg/100ml)

As shown in Table 5, for the diet C , the total number of protozoa was between 5.80*105 / ml 6.35*105/ml with an average of 6.08*105/ ml. While for the S oscillated between 5.73*105/ ml 6.38*105/ml and with an average of 6.06*105/ml. For Entodiniomorphe genus, The percentage of Entodinium was 55.64 % ± 6.21 and 54.86 ± 15.00 % while for Ophryscolex was 10.95% ± 1.32 and 8.06 ± 2.62 % (for RM and RS respectively). While the group of Holotriches which was represented by the Isotricha , the percentage was 27.31% ± 6.46 and 29.7 ± 15.29 to C and S respectively. However, the total number of protozoa and genus were not affected by the nature of the diet. Rouissi (1994) and Selmi et al (2009) reported similar findings

Table 5. Effect of diet on protozoa number (×105/ml) in lambs (n =4)

Diet	**Protozoa number (10^5 /ml)**	***Genus(%)***

P	*ns*	*ns*	*ns*	*ns*	*ns*

ns : Non Significant..

Gas production

The data represented in table 6 showed, the gas production was evolved gradually after 6 hours of incubation 19.16 ± 7.03 ml for C 15.66 ± 7.80 ml and S. then after 12 hours of incubation, an acceleration gas production was recorded for both plans but with superiority for the C. The maximum gas production for C and S respectively was 77.66±11.65ml and 78.41±16.61ml at 36 hours (Selmi et al.,2009). The proportion of methane (CH4) produced for the two diets was 22.08±4.18 and 21.16±3.21% of the total gas volume. The gas production and the proportion of methane (CH4) were not significantly affected by diet.

Table 5. Effect of diet on protozoa number (×105/ml) in lambs (n =4)

	T6	**T12**	**T24**	**T36**	**CH_4**	
					V (ml)	**%**

S	15.66±7.80	35.25±13.65	64.33±16.37	78.41±16.61	21.16±3.21	26.98
P	*ns*	*ns*	*ns*	*ns*	*ns*	

ns : Non Significant.

In situ rumen degradability

To characterize the feed for animal, we use in situ degradability like a test. In table 6, the data of DM degradability of oat hay was presented. After 3 hours, the digestibility was 9.815±4.69 % DM for C and 14.56±3.13 % DM for S. then the degradability was evolved to reach 36.04 % ± 6.12 and 39.91 ± 5.4 % respectively for C and S. At 48 hours of incubation, the digestibility was relatively low for two diets (36.04 % ± 6.12 and 39.91 ± 5.4 % respectively for C and S) in comparative with those were advanced by Kayouli et al. (1992) and Rouissi

(1994). The degradation of DM demonstrated a significant difference (P<0.05) at T3, T6, T12 and T36. The results agree with those reported by Andrade et al. (2004).

Table 6. Effect of diet on rumen degradability

	Temps (h)

Conclusion

The current study revealed that the effect of the incorporation of local raw materials in the alimentation of animal can improve some rumen parameters and the degradability of the dry matter of the ration. The pH rumen is between 6 and 7 favourable for the development of rumen microorganisms with no significant difference between the two diets. The ammonia nitrogen concentration is the same throughout the day for both. A similar total gas production for both diets and the amount of methane produced. Digestibility of the basic diet is more important for the regime based white sorghum and horse beans. The total of protozoa and percentages of different genus are similar for both diets.

Abstract

Based on the monitored and acquired results related to reproductive traits of the parent flock of the White Italian Goose kept on the private commercial farm "Trijesnjica", Bijeljina city area, entity of Republic of Srpska (Bosnia and Herzegovina), following was established: fertilisation of eggs was 88.99 %; hatchability of goslings from laid and fertilised eggs was 79.00 % and 89.77 %, respectively; average egg mass before incubation was 169.31 g; average egg width was 5.84 cm, and average length 8.90 cm; average egg shape index for both sequences was 66.51 %; average mass of one-day old gooslings 112.50 g; absolute correlation was established between average egg mass before incubation and mass of one day old goslings, in both sequences and calculated phenotype correlation coeficients (r_p = 0.958 – first sequence and r_p = 0.988 – second sequence**)** were statistically confirmed at $P < 0.001$; in both sequences, a very weak positive correlation was established between egg mass and shape index, with the correlation coefficient between these traits (r_p = 0.154) not statistically significant in the first sequence ($P > 0.05$), while in the second sequence the correlation coefficient (r_p = 0.197) was statistically confirmed at $P < 0.05$.

Key words: goose, egg weight, incubation, gosling, correlation.

Introduction

It is well established that the composition of eggs supports embryonic development. Namely, weight and other physical (external) and structural (internal) characteristics have a significant effect on embryonic development of poultry (Mitrović *et al.*; 1996, 2010; Moran, 2007, Đermanović *et al.*;, 2008, 2016). The main difference between the reproduction of birds/poultry and mammals, is that birds do not give birth to live offspring. Instead, in birds the new organism develops outside the womb, in the egg, i.e., the poultry reproduction implies that eggs are fertilised in order for offspring to be developed from them. Actually, a well fertilised egg is a "package" consisting of an embryo and necessary nutritional matter which facilitates its development until the hatching and for a few days afterwards.

In relation to this, Whiting *et al.* (1983), Shanawany (1984), Yannakopoulos and Tserveni-Gousi (1987) and Altan *et al.* (1995) report that the egg weight and shape index affect incubation results and subsequently weight of hatched offspring of different kinds of poultry. Puchajda *et al.* (1988), Willin (1995), Saatci *et al.* (2005) and Đermanović *et al.* (2008) have established in different goose breeds, stocks and cross-breeds (Bilgoraj goslings; various lineages of domestic Turkish geese according to feather color, two-breed geese, etc.) positive correlation between the egg weight and gosling weight. For example, Đermanović *et al.* (2008) have established statistically significant total correlation (r_p = 0.987***) between the

egg mass before laying into the incubator and the mass of one day old goslings of two-breed geese. The average egg mass was 150.79 g and average of one day old goslings was 103.07 g.
It should be taken into account that, in comparison with chicken, geese and ducks have significantly lower reproductive potential, primarily due to the reason that the number of eggs they produce during the production cycle is considerably lower than the number produced by hens and also because the embryonic mortality during incubation is significantly higher (Rosinski i Bednarczyk, 1997.).
There is a lack of data in international and particularly in the national literature about the incubation of goose eggs (goslings are mostly bred naturally), as well as about the influence of certain genetic and para genetic factors on goose reproduction. For this reason the main purpose of this research was to establish the optimal egg weight and shape index, gosling weight, as well as correlation between examined traits of White Italian Geese. The geese examined were from a 4 year old flock kept on a registered family farm "Anser" (Triješnjica, Bijeljina, Republic of Srpska) where the main activity is goose breeding (semiintensive management system), production of hatching eggs and production of one day goslings as the final product.

Materials and Methods

"Anser" family farm acquired 2000 male and female geese four years prior to this study, i.e. one parent flock of the White Italian Geese. The farm has an adequate number of housing installations for the geese to use at night and during the periods of bad weather, while they spend the rest of time outdoors where there is abundance of grass for grazing so the need for additional feeding is moderate (consisting mostly of cereal grains).
Apart from keeping daily records of production/reproduction indicators of the parent flock, an experiment was conducted with the purpose of acquiring better understanding of above mentioned traits of the White Italian Geese. Two hundred eggs were collected randomly in February and then again in March (400 in total) and then incubated during this same period.

During the incubation period the number and percentage of fertilised eggs was determined as well as the number and percentage of goslings hatched from the incubated and from fertilised eggs. All eggs were individually weighed before being put into the incubator (egg mass, width and length), the shell was marked with pencil, and eggs were disinfected with formaldehyde vapors. The gosling mass was measured immediately upon hatching and drying.
Eggs were laid into incubators in two sequences of 200 eggs each. Before transferring eggs from the incubator to the hatcher (25. day of incubation) fertilisation was determined and the percentage of fertilised eggs out of the number of laid eggs was calculated. At the end of the incubation period, the number and percentage of hatched goslings from both laid and fertilised eggs was calculated.
Based on these measurements, average egg mass before laying, as well as egg width and length were determined and based on this data, egg shape index (ESI) was calculated according to the following formula: ESI = (egg width, cm/egg length, cm) x 100. At the end of the incubation period, average mass of one day goslings was determined for both sequences.
Basic data processing was carried out applying the ordinary variational statistics methods which means that the elementary indicators of descriptive statistics were calculated: arithmetic mean value (x), standard error of arithmetic mean value (s_x), standard deviation (S) and variation coefficient (VC). Furthermore, established differences between the sequences related to monitored traits were evaluated using the Student's t-test for different levels of probability risk. Finally, correlation coefficients (r_p) between monitored traits were calculated and their level of significance was determined (Latinović, 1996.).

Results and Discussion

Two hundred eggs were incubated in February (first sequence) and then additional 200 in March (second sequence) i.e, a total of 400 eggs of White Italian Goose were incubated. Egg fertilisation and gosling hatchability from the laid and fertilised eggs is given in Table 1.

Table 1. Fertilisation and hatchability of goose eggs per sequence

Indicators	**1st sequence**	**2nd sequence**	**Total**
No. of laid eggs	**200**	**200**	**400**
No. of fertilised eggs	**174**	**178**	**352**
% of fertilised eggs	**87.00**	**89.00**	**88.00**
No. of hatched goslings	**150**	**166**	**316**
% of hatched goslings from laid eggs	**75.00**	**83.00**	**79.00**
% of hatched goslings from fertilised eggs	**86.21**	**93.26**	**89.77**

Generally speaking, data given in Table 1 show that the eggs of the White Italian Goose demonstrated good incubational values, particularly in terms of gosling hatchability, both in relation to the number of laid eggs and to the number of fertilised eggs. Fertilisation of eggs amounted to 87.00 % (first sequence) and 89.00 % (second sequence), i.e. 88 % for both sequences. As shown in Table 1, hatchability of goslings from the number of laid and fertilised eggs amounted to 75.00 % and 86.21 % respectively (first sequence), 83.00 % i 93.26 % (second sequence), while the percentage for both sequences was 79.00 % and 89.77 % respectively.

Similar but somewhat worse incubation results of half-bloods obtained by reciprocal crossbreeding of several goose breeds (White Italian being one of them) have been reported by Mazanowski and Chelmonska (2000), Mazanowski and Adamski (2002), Mazanowski and Bernacki (2006). Poorer and considerably lower fertilisation of eggs and hatchability of goslings of the White Italian Goose and two-breeds were reported by Rosinski (2000) and Đermanović et al. (2008).

Average egg mass before incubation was 173.99 g (first sequence – 200 eggs), 164.64 g (second sequence – 200 eggs) and 169.31 g (both sequences – 400 eggs). From a commercial aspect, it is desirable to have as many fertilised eggs with a healthy and vital embryo that the goslings will be hatched from. In this particular case, out of the total of 400 eggs (200 per sequence), 150 from the first sequence and 166 from the second sequence were fertilised eggs from which goslings were hatched. Mean values, absolute and relative variation measures of certain indications of this most significant group of eggs, as well as significance of differences, are given in Table 2.

Table 2. Mean values, variability and significance of differences of several egg traits from which goslings were hatched

*** $P<0.001$; $^{ns}P>0.05$.

In the first sequence, goslings were hatched from 150 eggs out of 200 eggs laid into the incubator, while in the second sequence, the number was considerably higher – 166. The average egg mass before laying (1. day) was 173.47 g (first sequence) and 164.79 g (second sequence), i.e. 168.91 g for both sequences. Eggs from the first sequence were heavier than

the eggs in the second sequence by 8.68 g and the established difference was statistically confirmed at P<0.001 (Table 2).

Some authors have reported considerably lower egg mass (under 151 g) than shown in this study - Saatci *et al.* (2005) in all breeds (white, yellow, multicolor and black) - and Đermanović *et al.* (2008) in two-breed geese. Depending on the mixbreed, Mazanowski and Chelmonska (2000), Mazanowski and Adamski (2002) and Mazanowski and Bernacki (2006) have reported both higher average egg mass (184 g) then reported in this study (168.91 g), and significantly lower average egg mass (148 g). Similarly, Razmaitè *et al.* (2014) have established higher (186.69 g - 3rd year of breeding) and also lower (123.40 g - 1st year of breeding) egg mass in case of Lithuanian Vishtinè Goose. Somewhat lower egg mass in case of White Italian Goose (under 168 g), as well as considerably lower, in case of a strain of Kuban goose (under 143g) have been reported by Bednarczyk and Rosinski (1999).

Data given in Table 2 show that the eggs incubated in the first sequence, apart from being larger, were also statistically significantly ($P < 0.001$) longer and wider than the eggs incubated in the second sequence. Egg width was 5.89 cm (first sequence) and 5.79 cm (second sequence) and the length was 8.98 cm (first sequence)and 8.83 cm (second sequence), i.e. for both sequences: width was 5.84 cm and length was 8.90 cm.

Contrary to the egg mass, egg width and length which were significantly larger in in the first squence, egg shape index was similar in both sequences (65.66 % - 65.58 %) and the difference was not statistically significant ($P > 0.05$). Egg shape index mean value was 66.51 % for both sequences (Table 2).

Insignificantly higher egg shape index (66.19 % and 67.12 %) was reported by Saatci *et al.* (2005) and significantly higher (67.5 %) or significantly lower (64.9 %) were reported by Mazanowski and Chelmonska (2000), Mazanowski and Adamski (2002) and Mazanowski and Bernacki (2006). Apart from the goose eggs, Salahuddin and Holider (1991) as well as Halaj and Veterany (1998) report different mean values of egg shape index of various chicken breeds and hybrids, Ksiazkiewicz *et al.* (1998) also report different mean values of egg shape index of three different breeds of ducks, and Altan *et al.* (1995) of the Japanese quail.

Similar to the egg mass, mass of one day goslings was larger in the first sequence, and for both sequences the average mass amounted to 112.50 g. Average gosling mass of the first sequence goslings (115.69 g) in comparison to the second sequence goslings (109.61 g) was higher by 6.08 g and the difference was statistically confirmed at ($P < 0.001$) (Table 2).

Somewhat lower average mass of hatched goslings (103.07 g) were reported by Đermanović *et al.* (2008), while Saatci *et al.* (2005) report significantly lower mass of one day old goslings in all goose breeds (the highest average mass of hatched goslings was observed in breeds with white feathers – 98.41 g, and the lowest in breeds with multi color feathers – 92.95 g).

Based on the coefficient values of the phenotype correlation between the average egg mass before the incubation and the mass of one day goslings in both sequences, total correlation was established and correlation coefficients calculated ($r_p = 0.958$ – first sequence and $r_p = 0.988$ – second sequence) were statistically confirmed at $P < 0.001$. Furthermore, a very low positive correlation was established between the egg mass and egg shape index in both sequences. Established correlation coefficient between these traits ($r_p = 0.154$) in the first sequence was not statistically significant ($P > 0.05$), while the correlation coefficient in the second sequence ($r_p = 0.197$) was statistically confirmed at $P < 0.05$.

Many authors studied the correlation between egg mass before incubation and the mass of hatched offspring of various types of poultry, eg. Skewes *et al.* (1988), Altan *et al.* (1995) in quails; Shanawany (1984, 1987) and Đermanović *et al.* (2008), and in most cases established positive correlation coefficients which were statistically significant. Shanawany (1984, 1987) and Đermanović *et al.* (2008) have also established total correlation ($r_p = 0.980$ and $r_p = 0.987$) between average gosling egg mass and one day old goslings. In contrast to our results,

Đermanović *et al.* (2008) have established negative correlation between egg mass before incubation and the chicken percentage in the egg mass (r_p = -0.425*).

Conclusion

Based on the monitored and acquired results related to reproductive traits of the parent flock of the White Italian Goose, and on the established traits of incubated eggs and hatched goslings and their correlation, following can be concluded concisely and chronologically:

- Fertilisation of eggs amounted to 87.00 % (first sequence) and 89.00 % (second sequence), i.e. 88.00 % for both sequences.
- Hatchability of goslings from the number of laid and fertilised eggs was 75.00 % and 86.21 % respectively (first sequence), 83.00 % and 93.26 % respectively for the second sequence, and for both sequences 79.00 % and 89.77 respectively.
- Average egg mass before incubation was 173.99 g (first sequence – 200 eggs), 164.64 g (second sequence – 200 eggs) and 169.31 g (both sequences – 400 eggs).
- Eggs incubated in the first sequence, apart from being larger, were also significantly ($P < 0.001$) longer and wider than the eggs incubated in the second sequence. Egg width was 5.89 cm (first sequence) and 5.79 cm (second sequence) and the length was 8.98 cm (first sequence) and 8.83 cm (second sequence), i.e. for both sequences width was 5.84 cm and length was 8.90 cm.
- Contrary to the egg mass, egg width and length which were significantly higher in the first squence, egg shape index was similar in both sequences (65.66 % - 65.58 %) and the difference was not statistically significant ($P > 0.05$). Egg shape index mean value was 66.51 % for both sequences.
- Similar to the egg mass, mass of one day goslings was significantly ($P<0.001$) larger in the first sequence, and for both sequences the average mass amounted to 112.50 g. Average mass of the first sequence goslings (115.69 g) was higher by 6.08 g in comparison to the second sequence goslings (109.61 g).
- Total correlation was established between the average egg mass before the incubation and the mass of one day goslings in both sequences, and phenotype correlation coefficients calculated (r_p = 0.958 – first sequence and r_p = 0.988 – second sequence) and were statistically confirmed at $P < 0.001$.
- A very weak positive correlation was established between the egg mass and egg shape index in both sequences. Established correlation coefficient between these traits (r_p = 0.154) was not statistically significant ($P > 0.05$) in the first sequence, while the correlation coefficient in the second sequence (r_p = 0.197) was statistically confirmed at $P < 0.05$.

These conclusions indicate that incubation values, as well as egg traits (particularly egg mass) and hatched goslings are also variable during the laying season. This should be given particular attention in practice in order to produce the maximum number of eggs per goose, i.e. achieve the maximum number of hatched goslings (final product).

Abstract

With the aim the effect of pork adipose tissue substitution with plant oils and fats in poultry frankfurters production to be investigated, six variants of frankfurters were produced: control – with pork fat, with olive oil, rapeseed oil, sunflower oil, palm fat and a mixture of 12% rapeseed oil and 8% palm fat. Cooking loss, pH-value and basic chemical composition were tested on the final product. It was found that palm and pork fat, as well as sunflower oil significantly ($P<0.01$) influenced the reduction of cooking loss of frankfurters. Frankfurters with palm fat, a mixture of 12% rapeseed oil and 8% palm fat and those with rapeseed oil had a lower pH than the other three variants ($P<0.01$). Regarding the content of water and ash there were no significant differences, while in the content of protein there was significant difference ($P <0.01$) only between variants with pork fat and sunflower oil. Frankfurters with olive oil and those with pork fat had significantly ($P<0.01$) higher fat content than all the other variants. Frankfurters with palm fat contained significantly ($P<0.01$) lower fat percentage compared to other variants, except that with a mixture of 12% rapeseed oil and 8% palm fat. Total pork fat replacement with plant oils and fats in poultry frankfurters production is possible.

Keywords:*frankfurters, plant oils, cooking loss, pH, chemical composition*

Introduction

Fats play an important role in meat products. Historically, meat rich in fats was used mainly for the production of sausages which increased the value of used meat (Bishop *et al*., 1993). However, diets rich in animal fats is associated with obesity, hypertension, cardiovascular and coronary heart disease (Özvural and Vural, 2008; Vural and Javidipour, 2002).The recommended dietary intake of fat should be no more than 20 to 35 % of total caloric intake (National Academy of Science, 2011). As a result of this, the popularity of meat products with high content of animal fat is reduced (Vural and Javidipour, 2002). Consumers are becoming increasingly aware of the nutritional quality and health effects of the food they consume. Lipid composition, particularly of the products from animal origin, has become the primary area of interest to consumers. This is due to the increased awareness regarding the link between the quantity and composition of fats in the human diet and increased coronary heart disease as well as certain forms of cancer (Arihara, 2006; Pike, 1999).

One approach to develop healthier meat products is through reformulation of meat products during processing (Jiménez-Colemenero, 2007). Modification of the fats is mainly based on the replacement of animal fat with oils that meet dietary recommendations (Fernández-Ginés*et al*., 2005). Vegetable oils are free of cholesterol and have a high content of

unsaturated fatty acids. Thus, vegetable oils have positive effects for the cardiovascular system (Özvural and Vural, 2008).
Frankfurters are non-fermented, emulsion type sausages (Gonzalez-Vinas*et al*., 2004). They are very popular, frequently-consumed meat products with significant economic importance worldwide (Jiménez-Colmenero *et al*., 2010). However,their consumption have a negative health effects regarding the amounts and types of animal fats that they contain (Bloukas and Paneras, 1993).
This was an occasion to perform replacement of pork fat with several plant oils in chicken frankfurters and to examine their influence on certain physico-chemical characteristics of the product.

Material and Methods

Frankfurters made from chicken (boneless breast and thigh) were used in the present research. As an alternative to pork fat plant oils were used as: olive, rapeseed and sunflower oil, as well as palm fat. Six different frankfurters were produced which compositions are given in Table 1. The control frankfurters were prepared with pork backfat (Po). The other five treatments were prepared with olive oil (O); rapeseed oil (R); sunflower oil (S); palm fat (Pa), and a mixture of 12 % rapeseed oil and 8 % palm fat (Mi).

Table 1. Frankfurter formulation (%)

Ingredients	Treatments					
	Po	O	R	S	Pa	Mi
Chicken breasts without skin	23	23	23	23	23	23
Chicken thighs without skin	23	23	23	23	23	23
Pork backfat	20					
Olive oil		20				
Rapeseed oil			20			12
Sunfower oil				20		
Palm fat					20	8
Nitrite curing salt	1.7	1.7	1.7	1.7	1.7	1.7
Ice	32	32	32	32	32	32
Sodium tripolyphosphate	0.2	0.2	0.2	0.2	0.2	0.2
Mixture of spices	0.2	0.2	0.2	0.2	0.2	0.2
Sodium isoascorbate	0.075	0.075	0.075	0.075	0.075	0.0705
Soy protein isolate	2	2	2	2	2	2

Artificial collagen edible casings, 23 mm in diameter, product of Naturin GmbH, Weinheim, Germany were used for stuffing the batter.
Heat treatment was performed in smokehouse at a temperature of 78^0C until achieving an internal temperature of 72^0C.
pH value was measured by pH meter Testo 230. The cooking loss during heat processing of frankfurters represents the difference in weight before and after heat treatment, expressed as a percentage of the initial weight.
Chemical composition was determined using AOAC (1997). The water content according to official method 950.46; protein according to 928.08; fat according to 991.36 and ash according to 920.153.
The program package SAS/STAT (SAS Software. Version 8.01, 1999) was used for statistical processing of data and significance, means were separated using the Duncan test.

Results and Discussion

Cooking loss and pH

During heat processing and chilling of frankfurters the lowest cooking loss (9.04%) was established in frankfurters produced with pork backfat (Po), and the highest (10.21%) in those with rapeseed oil (R). Palm and pork fat, as well as sunflower oil significantly ($P<0.01$) influenced the reduction of cooking loss in the heat treatment of frankfurters (Table 2). Cooking losses during thermal processing of low-fat frankfurters with vegetable oils were high, whereby the type of oil did not influence the loss, while the amount of fat had a major impact (Paneras and Bloukas (1994). Somewhat lower values for cooking loss of chicken frankfurters were obtained by Kratovalieva (2007).

Cooking loss during thermal processing is influenced by cooking method (Yoo*et al*., 2005), cooking temperature and time (Kim and Chin, 2007; Vasanthi*et al*., 2007; Banon*et al*., 2008), the type and the amount of fat (Choi *et al*., 2010; Choi *et al*., 2009; Hong *et al*., 2004; Fernández-Ginés*et al*., 2004), ingredients (Huang *et al*., 2005), the casing (Choi *et al*., 2008). Great number of factors affecting the amount of cooking losses during thermal processing of meat products is a reason for diversity of the data published in the literature.

Table 2. Cooking loss during thermal processing and pH of frankfurters (mean ± standard deviation)

Parameters	Treatments					
	Po	O	R	S	Pa	Mi
Cooking loss, %	9.04±0,31^{b}	10.18±0.17^{a}	10.21±0.35^{a}	9.38±0.09^{b}	9.38±0,09^{b}	10.18±0.17^{a}
pH	6.38±0,01^{a}	6.38±0.01^{a}	6.37±0.01^{b}	6.38±0.01^{a}	6.36±0,00^{b}	6.36±0.01^{b}

^{a,b}– Means within a row with different superscript letters are significantly different ($P<0.01$)
Po – Pork back fat (control);
O – Olive oil;
R –Rapeseed oil;
S – Sunflower oil;
Pa – Palm fat;
Mi – Mixture of 12% rapeseed oil and 8% palm fat.

Frankfurters with palm fat (Pa), a mixture of 12% rapeseed oil and 8% palm fat (Mi) and those with rapeseed oil (R) had a lower pH than the other three variants ($P<0.01$). Kratovalieva (2007) reported similar results (6.34 – 6.38 %) for chicken frankfurters. According to Paneras and Bloukas (1994) pH in frankfurters produced with vegetable oils is usually in the range of 6.30 to 6.46 and in those with pork fat is higher. In Turkish type beef frankfurter with different percentage of sunflower oil (12.5 – 20%) pH ranged from 6.02 to 6.07, and in those with 20 % beef fat pH acounted 6.21 (Yilmaz, 2004). The pH value of beef frankfurters produced with 10 % beef fat (control treatment) or 10 % interesterified oils or oil blends was ranged from 6.28 to 6.38, although there were found significant differences between the treatments (Özvural and Vural, 2008).

Chemical composition

The water content in all variants of frankfurters was almost equivalent (60.06 – 60.85 %), so the differences between variants were statistically insignificant (Table 3). In terms of protein content significant difference (P<0.01) was found only between Po (with pork backfat) and S (with sunflower oil) variants. Higher differences were observed in the fat content. Frankfurters of the variant Po (pork fat) and O (olive oil) contained significantly (P<0.01) more fat than the other variants. Furthermore, variant S (sunflower oil) contained significantly (P<0.01) more fat than variant R (rapeseed oil). The ash content was approximately the same in all variants (2.71 – 2.81%).

Table 3. Chemical composition of frankfurters (mean ± standard deviation)

Parameters (%)	Treatments					
	Po	O	R	S	Pa	Mi
Water	60.18±0.73^{a}	60.18±0.44^{a}	60.06±0.37^{a}	60.35±0.46^{a}	60.85±1.26^{a}	60.55±0.34^{a}
Protein	13.08±0.38^{a}	12.65±0.19^{ba}	12.73±0.20^{ba}	12.28±0.47^{b}	12.72±0.56^{ba}	12.81±0.58^{ba}
Fat	25.34±0.40^{a}	25.45±0.18^{a}	23.88±0.17^{cb}	24.13±0.07^{b}	23.38±0.35^{d}	23.62±0.27^{cd}
Ash	2.79±0.10^{a}	2.71±0.07^{a}	2.75±0.27^{a}	2.81±0.12^{a}	2.74±0.07^{a}	2.77±0.13^{a}

$^{a-d}$ – Means within a row with different superscript letters are significantly different (P<0.01)
Po – Pork back fat (control);
O – Olive oil;
R –Rapeseed oil;
S – Sunflower oil;
Pa – Palm fat;
Mi – Mixture of 12% rapeseed oil and 8% palm fat.

Similar content of water and ash, and slightly lower of protein and fat in chicken frankfurters were found by Kratovalieva (2007). Jiménez-Colmenero*et al*. (2010) reported that there were no differences in the water content (range from 60.6 to 62.3 %) of the different frankfurters formulations. This is consistent with the fact that the amount of added water was similar in all the treatments. Addition of interesterified oil and oil blends affected the moisture (56.98 – 60.85 %) and fat (19.55 – 24.08 %) content of frankfurters (Özvural and Vural, 2008).Frankfurters with pork fat contain more protein than that with vegetable oils (Stevanović, 1993).

Future developments will be dictated by the marketplace and the ability of the meat industry to deliver products with high nutritional value (Barbut, 2011).

Conclusion

In terms of cooking loss during thermal processing, pH and basic chemical composition, total pork fat replacement with plant oils and fats in poultry frankfurters is possible. In order to produce low fat frankfurters, further research is needed to reduce the total amount of fat.

EFFECTS OF NATURAL PIGMENT SOURCES AND STORAGE DURATIONS ON EGG QUALITY

Esin UNVER, Aylin AGMA OKUR*

Namik Kemal University, Faculty of Agriculture, Department of Animal Sciences,
Tekirdag, 59030, Turkey.
*Corresponding author: aagma@nku.edu.tr

Abstract

Egg and egg quality is one of the most important issues for egg industry and consumers worldwide. This review contains the information of the internal and external quality of eggs, effects of storage conditions and natural pigment sources on hen's egg. Internal quality of egg has been measured for many years as albumen height (Haugh Unit) and weight, yolk index and air cell. The external quality of egg has been measured as egg weight, egg shape, shell thickness, breaking strength and specific gravity. And Haugh Unit werewas evaluated to reveal albumen quality. Environmental factors such as storage time and temperature affected egg quality. During storage of egg, vitelline membrane quality will decrease. Therefore, egg yolk elasticity will be destroyed and finally broken up. Strain and age of laying hens are also important parameters, thatparameters that affect egg quality. Egg yolk is the most important criterion taken into account by consumers and it has been preferred close to amber to red-yellow in many countries. According to consumer preferences to obtain the yellow egg yolk, synthetic or natural pigment sources are used in diets. Yellow color is obtained from yellow-lutein and zeaxanthin-gold (marigold, alfalfa etc.). Red color is provided by substances such as capsanthin and capsorubin (red pepper etc.). This review focuses on the hen's egg and effects of natural pigment sources and storage conditions on egg quality.

Keywords:*Egg quality, storage, egg yolk color, red pepper*

Introduction

The eggs have always been an excellent source of nutrients and very important in human nutrition (Li-Chan and Kim, 2008). Besides its nutritional value, It has been ovulated from hen in a special package and this feature is also an advantage for marketting.

Eggs consist of three main parts, such as the shell (9-12%), albumen (60%) and yolk (30-33%) (Li-Chan and Kim, 2008; Roberts, 2004). The eggshell has three different layers; Cuticle, Spongy (calcium carbonate), Mammillary. Li-Chan and Kim (2008) mentioned that albumen was composed of four layers: outer thin white (23.3%), outer thick white (57.3%), inner thin white (16.8%), and a inner thick (2.7%) layers (Figure 1; Figure 2).

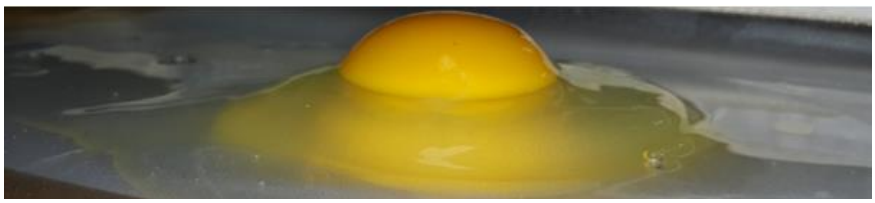

Figure 1. Side view of fresh egg

Figure 2.Top view of fresh egg

Nutrient Composition of Eggs

Table 1 reveals nutrient composition of a large egg. Although water composition of edible parts of egg was approximately 75% (Li-Chan and Kim, 2008). Egg proteins are found 56% at albumen and 44% at yolk according to Table 1.

Table 1. Nutrient composition of a whole egg (WPSA, 2016)

Nutrient	Albumen	Egg yolk	Whole egg

Egg Quality

Layer strain, hen age,nutrition, rearing systems, stress, storage durations and storage temperature are separately well defined as the major factors affecting egg quality parameters (Silversides and Scott, 2001; Roberts, 2004; Barbosa Filho et al., 2005;Li-Chan and Kim, 2008; Bozkurt and Tekerli, 2009).

Bozkurt and Tekerli (2009) investigated the effects of two commercial hybrids (Isa brown and Lohman white), hen age, egg storage conditions on quality of eggs. They found some differences between brown and white eggs. Fresh egg weights affected by hen genotype and age. Also, increasing storage temperature and storage durations have negative effects on egg weights. However, genotype had no significant effect on weight loss during storage. Older hens' eggs found heavier than young hens. Altough these heavy eggs lost more weight by storage. Also, internal quality parameters were significantly affected by hen genotype ($P<0.05$) and age ($P<0.01$). Shell thickness decreased and shell weight increased with hen age ($P<0.01$). The hen age and strain did not affected shell weight (Bozkurt and Tekerli, 2009).

The most important internal and external egg quality traits have been shown such as; egg weight, egg shape, shell thickness, breaking strength, specific gravity, air cell height, albumen height and weight, yolk index, yolk color,Haugh Unit, albumen and yolk pH (Samlı et al., 2005b; Agma Okur and Samlı, 2014). Monitoring egg quality parameters are considered as an important economic policy in egg production. However, External and internal egg quality traits of the breeds that affect performance changes between generations (İslam et al., 2001).

Factors Affecting Egg Yolk Color

Egg yolk color may be influenced by the dietary ingredients, such as natural and synthetic carotenoids.However, in some countries such as Sweden, there is a ban on synthetic carotenoid usage in feeds.

The yolk color is an important feature which is determinative for consumers' choices.Spada et al. (2016) asked panelists which egg characteristic was important for them. Yolk color was mentioned by 85% of the panelists.However, consumers's preferences changes all over the world. For example; in Australia desired yolk color is about 11 on the Roche Scala. Some countries prefer lighter or darker yolk color (Roberts, 2004).

Egg yolk color; might change from light yellow to dark orange and it is covered with vitelline membrane (Agma Okur and Samlı 2014). Egg yolk color affected by β-carotene, xanthophylls and oxycarotenoids (Samlı et al. 2005b, Agma Okur and Samlı 2014). Shape, weight, strength of the shell, freshness and the structure of the egg as well as the quality measurement standards are among the most important characteristics to estimate the egg yolk color(Gouveia et al.1996). Egg yolk color can bedeterminedby subjective and objective methods (Roche Color Fan, Colorimeters).

Also, housing systems might affect egg yolk color. Van Den Brand et al. (2004) found that yolk colour was considerably darker in the outdoor group compared to the cage group (11.0 vs 9.3).It was an expected result, because laying hens reared at the outdoor and/or free range systems can consume grass and herbs in the pasture.

Carotenoids are lipid soluble compounds responsible for the orange-yellow color of the egg yolk. The health promoting properties of carotenoids are well documented (Nimalaratne and Wu, 2015). Chickens can not synthesize carotenoids and must be obtained them through the diet (Rossi et al., 2015).

Natural Pigment Sources in Diets

Natural pigment sources are;corn, gluten meal, alfaalfa meal, red pepper, marigold, algae, tomato powder, fresh green hay etc.

Rossi et al. (2015) used (0, 75, 125, 225 ppm) sweet green pepper as a natural colorant. While increasing usage ratio of red pepper, performance did not affected, but yolk color affected positively.

Some studies showed that natural antioxidants does not have an effect on antioxidant composition of yolk, only do have an effect on yolk color. Spada et al. (2016) researched the effects of sytntetic and natural carotenoids. The experimental design was conducted of 8 treatments with 2 strains (Carijo-Barbada and Isa-Brown) and 4 dietary treatments (1.5 and 2.0% fresh annatto, 0.001% of Carophyll yellow, 0.006% of Carophyll red). In the trial they were analyzed raw, boiled and fried eggs (fresh and 36 days stored). They found no effect of strains and carotenoids on lipid oxidation of raw eggs.However, boiled and fried eggs had higher lipid oxidation after storage. The color analysis revealed theat control groups are lighter compared to to the treatments. the highest a* values were found in treatments with synthetic additives. Sensorial panel results of boiled eggs demonstrated that color of fresh eggs were significantly found darker at treatment groups. However in fried eggs, control groups had higher values.

Storage Conditions and Egg

The results Albumen height and Haugh units decrease with increasing storage time, and this sharp decline occurs more quickly at higher temperatures (Roberts 2004; Shin et al. 2012).

Rapid cooling of eggs with carbon dioxide was found to improve Haugh Units of stored eggs (Keener et al., 2000). During storage of eggs, the pH of the albumen increases and this is thought to be related to the deterioration of albumen quality (Benton and Brake, 2000). The changes occurring in albumen quality during egg storage to be related to changes occurring in ovomucin, particularly the thick albumen (Kato et al., 1981; Toussant and Latshaw, 1999). During egg storage, the quality of the vitelline membrane declines, making the yolk more susceptible to breaking (Kirunda and McKee, 2000).

Bozkurt and Tekerli (2009) investigated the effects of two commercial hybrids (Isa brown and Lohman white), hen age, egg storage conditions on quality of eggs. They concluded that internal egg quality parameters deterioration during the increasing storage time was dramatic in brown eggs, laid by younger hens and stored at 24ºC. However, Samli et al. (2005) conducted that HU, pH of albumen, and air cell size were parameters greatly influenced by storage period and temperature of eggs from aged laying hens.

Shin et al. (2012) stored eggs at different temperatures, such as -1.1, 0.6, 2.2, 3.9, 5.6, 7.2ºC for 0, 2, 7, 14,21, 28 days. This experiment demonstrated that eggs stored at 0.6 and 2.2ºC had the highest Haugh Unit values. Albumen pH values increased by the effect of storage time and temperature, because of the gas diffusion from inside the eggs.

Unver (2016) examied the effects of storage time and temperature on the quality parameters of eggs obtained from free range reared laying hens fed with 0.75% red pepper supplemented to diet. Red pepper supplementation statistically had no effect on external egg quality parameters ($P>0.05$). The highest egg weight loss was observed at room temperature stored eggs by extension of the storage time up to 3 wks. In addition, storage time and temperature had statistically an important effect on the air cell size (ACS). The highest ACS values was determined at 2 and 3 wks stored eggs at room temperature. Red pepper supplementation, storage time and temperature were observed to be effective on Roche color fan (RCF) score, Hunter L* (lightness) and b* (yellowness and blueness) values ($P<0.001$). The fresh egg's yolk colour was determined as 12.07 and 9.60 by RCF at the groups fed with/without red pepper supplementation. However, HunterLab colorimeter analysis evaluated that a* (redness and greenness) values of red pepper supplemented groups were found the highest for all storage times and temperatures. Red pepper supplementation had no effect on some of internal egg quality parameters, such as yolk height, albumen height, Haugh unit, albumen

weight, yolk pH, albumen pH, yolk diameter, yolk index, yolk viscosity and albumen viscosity (P>0.05). The results indicate that 0.75% red pepper supplementation to layer diets had positive effect and could lead to desired yolk colour. Because of that, red pepper might be used as natural pigments. Also, Unver (2016) reported that storage conditions and durations have also negative effects on egg yolk color.

Conclusions

The consumers tend to prefer natural products for health concerns, animal welfare and environmental conscious. Also, consumers' demands and regulations guide producers to change chickens rearing systems and use of natural feed additives. The experiments reveal us, natural pigment sources might be used in layer diets, safely and effectively without any deterioration in performance.

PROTECTION AND PROMOTION OF DOMESTIC EGG PRODUCTION:EXAMPLES FROM THE REPUBLIC OF CROATIA

Dubravka ŽIVODER, Josipa PAVIČIĆ*

Department of Market and Agricultural Products Marketing, Croatian Agricultural Agency,Croatia
*Corresponding author: jpavicic@hpa.hr

Abstract

Food production has a strategic importance for the economy of any country, including the Republic of Croatia. Unfortunately, the food market is not sufficiently developed. On the one hand there are problems with product placement on the market while on the other hand the external trade balance is also unfavorable, because the imports of agricultural products are increasing. For that very reason and with the aim of protecting and promoting domestic agricultural production there is a strong need for the introduction of food marketing. The application of all elements of the marketing mix - product, price, place and promotion - will create distinctive products. The main goal of marketing projects and putting recognizable labels on domestic agricultural products is to promote domestic production, as well as informing consumers about the origin of products, with the aim of protecting and strengthening the agricultural production in the Republic of Croatia. Several institutions in the country are working in the field of food marketing, and one of them is the Croatian Agricultural Agency. Department of market and agricultural food marketing, in Croatian Agricultural Agency, has developed eight marketing projects so far, and one of them which will be described in this paper is branding fresh eggs for human consumption with protected label *Eggs from Croatian farms.* The paper contains a positive example of consuming domestic local products produced on Croatian farms, and we will also show the path of egg production, and provide the research results of egg producers whose products are labeled with the protected label.

Keywords: *food marketing, domestic production, label, eggs*

Introduction

Nowadays, the need for stronger promotion and protection of domestic agricultural products is increasing because the market is overflowing with products that are extremely diverse in terms of declarations and origin, and consumers demands are growing too.

Marketing in agriculture and food production in the Republic of Croatia is not sufficiently present. Marketing methods are applied in big companies involved in the food production, but small agricultural farms are not familiar with marketing bussiness principles.

Marketing has a great meaning because it is connecting producers with consumers, it helps food producers to better understand consumers needs, and also helps all producers to decide which product will be produced and offered on the market.

Production chain, Producers – Processors – Consumers, is essential to ensure that the products can be protected and that the marketing projects are going to be successful.

For all reasons mentioned above, the Croatian Agricultural Agency, as a government institution with a long tradition in agriculture, has launched a new marketing project named *Eggs from Croatian farms.*

The main goal of labelling fresh eggs for consumption with the label *Eggs from Croatian farms* is to promote domestic production of fresh eggs produced on Croatian farms, to

increase their production, but also to inform consumers about the origin of fresh eggs that are systematically controlled.
The Department of Market and agricultural products marketing, which is responsible for the implementation and control of marketing projects, made the *Terms of use* for project *Eggs from Croatian farms*, which prescribes the procedure for getting and using the protected label.
The permission to use the label is given to the egg producers who produce eggs by Croatian laying hens on Croatian farms. To ensure the traceability, egg producers and egg packing stations must keep a record about breeding method on a weekly basis. All label users must fulfill the terms prescribed by the *Terms of use* for the voluntary labelling of eggs with the protected label *Eggs from Croatian farm.* They also have to sign a contract for using protected label with Croatian Agricultural Agency.

Figure 1. Steps to getting the label *Eggs from Croatian Farms*

In collaboration with the Ministry of Agriculture, the Croatian Agricultural Agency conducts a control of the project through VETI applications and additional controls are carried out on the basis of prescribed documentation by the Terms of Use for using the label *Eggs from Croatian farms.*
Since the project was established, the Agency signed contract with twelve egg farms for using of the protected label, and those twelve egg producers achieved more than 80% of the total national production of fresh eggs in the Republic of Croatia.
In the period from 1 May 2015, when the project started, until 1 January 2016, 4.012,942 packing box of eggs were marked with the label *Eggs from Croatian farms*.
In order to better inform the consumers, the Croatian Agricultural Agency created the web application for the project *Eggs from Croatian farms,* through which consumers have possibility to check the producer code of the eggs on www.hpa.hr and where they can find all important information about the egg producers.
According to the Regulations of the egg quality, prescribed under the legislation, each egg on the market must be properly marked. Marking of eggs is a form of egg labeling that includes an *egg code* stamped on the egg itself. The EU has defined an egg code that consists of a number indicating the method of production, a two letter code for the country of origin, and a unique farm number ID.

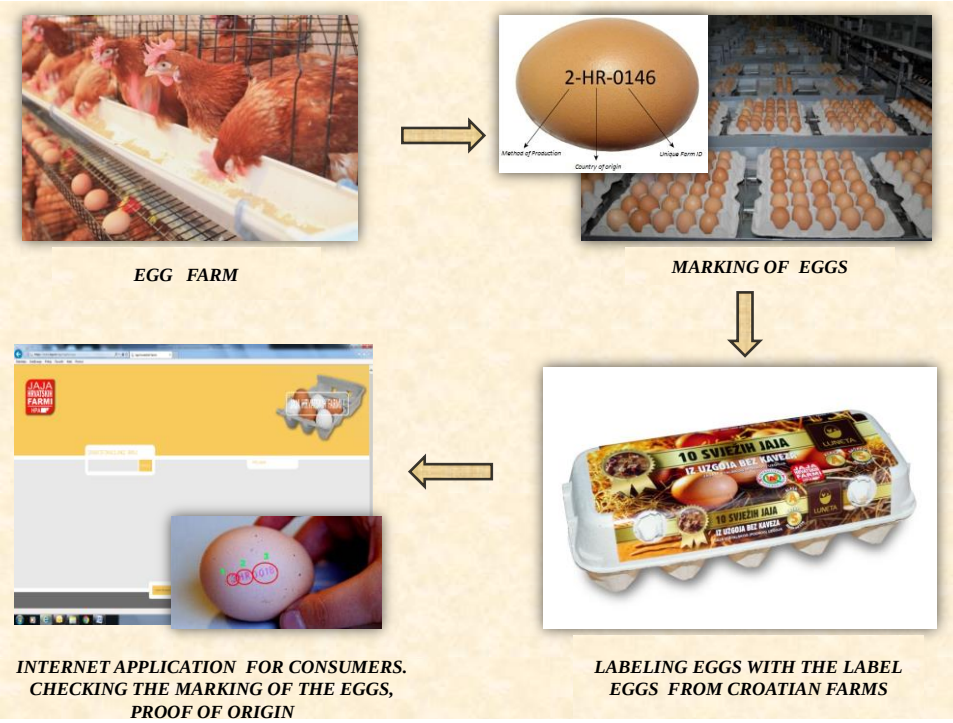

Figure 2. Traceability of labeled eggs

Materials and methods

The research was focused on the egg producers, our label users. The plan was to investigate their motivation, their thinking, and does the voluntary labeling of their products with protected label – *Eggs from Croatian farms* - helps their production.

The study used a method of primary data collection through a questionnaire as an instrument of research, and the questionnaire contained 7 questions of closed type and it was sent by email in January 2016.

The questionnaire was sent to all 12 label users, representatives of companies / managers, middle-aged people who have a university degree. Completed questionnaire was returned by 10 respondents. The study was conducted using quantitative research methods. Quantitative research is focused on the figures resulting from statistical analysis. The main characteristic of quantitative research is to standardize identical questions to all respondents which helps with statistical data processing.

The results were processed through a statistical data analysis, and the results are presented graphically.

Results and discussion

Marketing project *Eggs from Croatian farms* was launched in February 2014, and it is the sixth marketing project implemented by Croatian Agricultural Agency. The largest egg producers approached the project from the very beginning, and according to the results of our study we can conclude that the majority of our users are satisfied with its implementation. The questionnaire that was sent to label users was summarized at only 7 questions of great importance for our research.

We received the following answers:

1. What is your total annual production of eggs for human consumption? Average annual production of eggs for human consumption of label users Eggs from Croatian farms is 46.000,000 eggs.

2. When did you start to participate in the project *Eggs from Croatian farms*? All respondents participate in the project from the beginning of the project, February 2014.
3. Why did you join the project Eggs from Croatian farms?

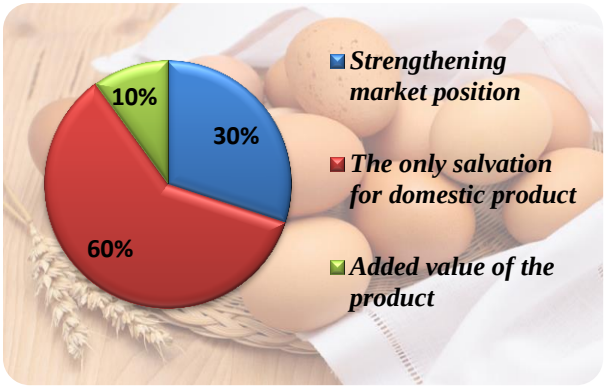

Figure 3. Why did egg producers joined the projec *Eggs from Croatian farms*

Marketing project *Eggs from Croatian farms* was partly created on the initiative of egg producers, so it was no surprise that 60% of respondents find that such project is the only salvation for the domestic product as we can see on the Figure 3. Why did egg producers joined the project *Eggs from Croatian farms*. 30% of respondents thought that the label brings stronger position on the market, while 10% considered that the label brings added value to the product.

4. Have you noticed positive changes after the application of a protected label on your products?

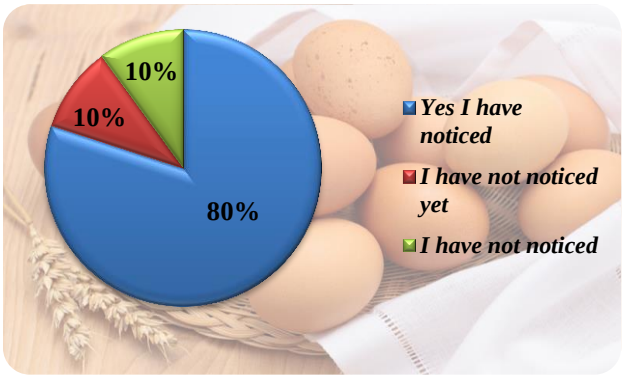

Figure 4. Did egg producers noticed positive changes after the application of a protected label

On the question, if the egg producers have noticed positive changes after the application of a protected label, 80% of users said they did, as the Figure 4 shows, because the label promotion has reached higher level and consumers started to recognize the label. Only 10 % of respondents said that they have not noticed any changes.

5. Did you increase the price of your products marked with the label *Eggs from Croatian farms?*

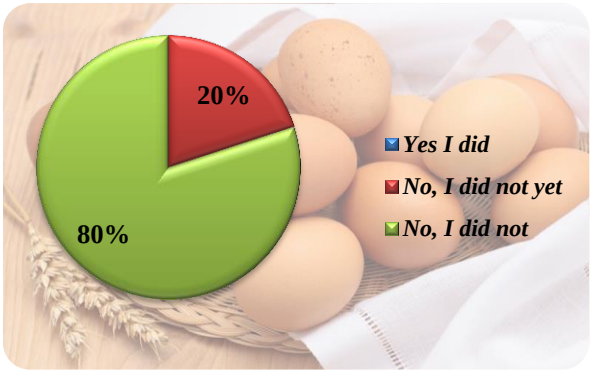

Figure 5. Did egg producers increased the price of their products marked with the label *Eggs from Croatian farms*

Figure 5. Did egg producers increased the price of their products marked with the label *Eggs from Croatian farms*, shows that none of the label users increased the price of their products marked with the protected label. Reason for this is that egg producers want consumers to get familiar with this label and what it represents, so the product could become competitive on the market. Because of the difficult economic situation, egg producers will wait with price increase.

6. Have you noticed a positive trend in the consumption of labeled products?

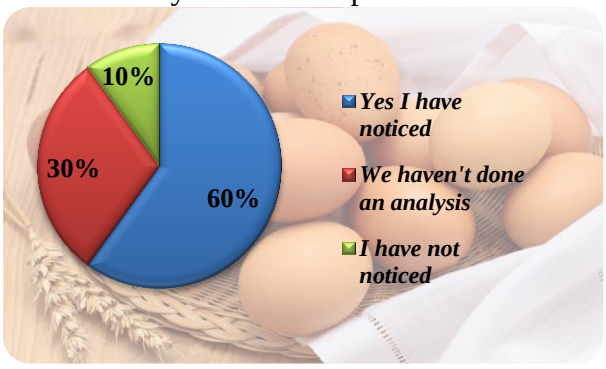

Figure 6. Did egg producers noticed a positive trend in the consumption of labelled products

When we asked if label users have noticed positive trend in the consumption of labeled products, 60% of users said they have noticed, 30%of them have not done any analysis, and 10% have not noticed positive trend in consumption. The results are shown in the Figure 6. Did egg producers noticed a positive trend in the consumption of labelled products

7. Are you satisfied with the marketing project for voluntary labeling of eggs implemented by Croatian Agricultural Agency?

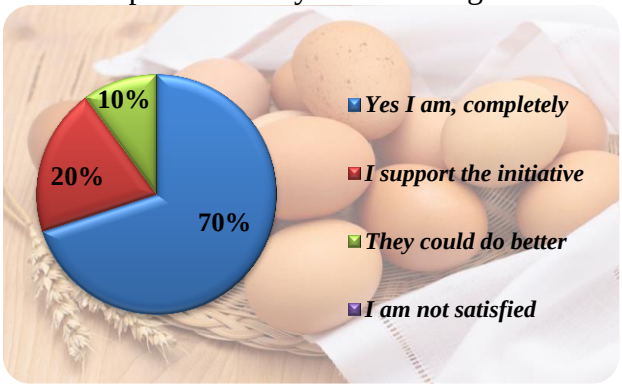

Figure 7. Are the label users satisfied with the marketing project for voluntary labelling of eggs implemented by Croatian Agricultural Agency

It was a great pleasure to see that 70% of our label users are satisfied with implementation of the project *Eggs from Croatian farms*. 20% of users responded that they support the initiative, but only 10% of users believe that the project could be implemented in a better way. As the Figure7. shows none of egg producers said that they are not satisfied with the project.

Conclusion

We are aware that nowadays, especially since the Republic of Croatia joined the EU, there is an abundance of food on the market and the quality and origin of the products has a great importance for consumers.

For this very reason marketing labels on domestic agricultural products are extremely necessary, because in this way we help consumers to identify domestic product and by recognizing these labels the way to conscious shopping is insured.
Also, marketing labels are salvation for domestic agricultural production as they strengthen the market of domestic products as the questionnaire showed.
It is clear that after launching of marketing projects a certain time is required for positive trends to appear, but our research proved that consumers are becoming more aware of the label *Eggs from Croatian farms* and its meaning.
Also, by buying these products consumers directly affect the increase of consumption of the same, which encourage the preservation of local agricultural production and national identity, preserve jobs and ensure the future of our children.

POSITION OF THE POLISH FOOD PROCESSING IN THE FOOD CHAIN

Agnieszka JUDZIŃSKA*, Robert MROCZEK

Department of Food Industry, Institute of Agricultural and Food Economics – National Research Institute, Warsaw, Poland
*Corresponding author: judzinska@ierigz.waw.pl

Abstract

Polish food industry is one of the main components of the food economy. It is the largest recipient of unprocessed agricultural commodities, and, at the same time, the main supplier to the food trade (bothe wholesale and retail). The importance of the food industry is also due to the fact that processing plants integrate the entities involved at all stages of food chain (from farm to table). This proces is favored by a steady increase of Polish agriculture marketability, as well as the growing demand for highly-processed foods. In the past decade, has occured a rapid growth of the Polish food industry. The number of processing plants certified to sell their products on the EU market has significantly increased. It was also noted a large (more than three-quarters) increase in the sold production value of the whole food industry (including tobacco). After the Polish accession to the European Union a strong growth of food exports took place. Its value, in the years 2004-2014, accounted for more than a half of the sold production value of the whole food industry. At present, the Polish food industry employs approx. 415 thousand. people, while its share in the creation of GDP (measured by gross value added) is fairly stable at 2.7-2.9% on average. The main objective of the study was to determine the position of Polish food industry in the food chain.

Key words: *Food industry, food processing, agriculture, trade, Poland.*

Introduction

The food industry is, apart from agriculture, the main element of food economy. It is an important link of the food chain which integrates its other elements, i.e. agriculture, purchase and trade in agricultural products, as well as trade in food. Position of the food industry in the food chain results from its main function which is processing of agricultural products in order to make them suitable for consumption or sale, hence, to increase their usability for the final consumer. The food industry in Poland is one of the most important sectors of economy. It has a significant share in the national economy, for instance, in gross value added, number of companies, employment or sold production. This sector uses in the production premium raw materials, the technological level of processing is considered as one of the most advanced, and Polish food enjoys growing interest of the foreign recipients (Firlej et al. 2015).

The food industry occupies the central place in the Polish food economy. Its main purpose is to fulfil basic needs of population which are, on the one hand, determined by the needs and expectations of consumers and, on the other hand, by production capabilities of agriculture. The food sector is characterised by a large diversity of conducted operations, where initial processing of crops exists side by side with production of high degree of processing (Kapusta 2008). The significance of the food industry in the food chain increases along with the growing urbanisation, i.e. increasing distance between the regions of consumption and the agricultural regions and along with increased agricultural production and progressing specialisation and globalisation.

Currently the main problem in most branches of the food industry is excess of supply over demand, large number of market participants and strong competition, in particular on the part of large global industrial companies and retail chains. The primary purpose of the entities of

food industry is maximisation of profit and raising the value of company. Every branch solving the basic problem of distribution, which is to ensure the maximum availability of their products at the possibly lowest costs, without jeopardising its quality in the course of trade, uses different strategies, which results from the specific nature of production of particular branches of food industry. Basically, manufacturers develop cooperation with retail chains mainly in terms of their dominant share in the market and the possibility to reach consumer faster, as well as benefits from cooperation with significant recipients (reliability of payment, lower costs of transportation) (Morkis et al. 2010).

Materials and methods

The purpose of this study was to demonstrate the role and importance of food industry, one of the main links of the food chain, as compared to its other two important elements, namely agricultural manufacturers (suppliers of raw materials for processing) and trade. The comparison includes, among others: number of entities and their size, value of production (sold, commodity), value of sales, employment and share in gross domestic product.

The work has a form of comparative analysis in which secondary source materials were used. The study used, first of all, published and unpublished data of the Central Statistical Office and publications on matters related to the broadly understood food economy. The collected data were analysed with the use of descriptive method. Appropriate indicators were used to determine changes over time. The results are presented in tabular form and depicted by graphs.

Results and discussion

Processing as one of the major elements of food chain

The ISO 22000 Standard defines the food chain as a sequence of stages and processes taking place in production, processing, distribution, storage and handling of food and its components, starting from primary production until its consumption. The main elements of food chain are: food processors, manufacturers of crops and sellers. This chain is, however, more complex, as basic cells thereof cooperate with other entities providing means of production or services, e.g. producers of feeds, fertilisers or providers of banking or repair services. A significant element of the chain is also an information flow accompanying all of these processes, i.e. from the mere creation of product until a good being found at the final recipient's (Szymanowski 2008)

Food products in modern economy are the result of cooperation of the whole food chain a significant part of which is food industry. The food chain is subject to continuous transformations. Not only do its constituent cells evolve, but also its participants. Along with evolution of food chain, which is closely linked to the social and economic development, its leading link is changing. Currently, the main regulator of relations between particular links of food chain are market mechanisms (Chechelski 2015). The inflow of foreign capital, increase in domestic demand and concentration of processing companies have resulted in the fact that the food industry became the most important link of the food chain.

The food industry, agriculture and trade differ from one another not only by the character of conducted operations, but also by economic parameters describing their potential and business performance or work efficiency (table 1).

Diverse economic parameters result from the following phenomena:

- the value of global production of food industry is two times greater than the agriculture's, and the value of production sold of this industry is over 2.5 times greater than goods production of agriculture and by ca. 1/10 lower than retail sale of food,
- the gross value added of food industry is by ca. 1/5 greater than the one generated by agricultural manufacturers and comparable to the one from retail sales of food,
- the number of employed persons in food industry is 5 times smaller than of those involved in agriculture and comparable to the number of persons working in retail trade.

Table 1. Basic economic parameters of the Polish farming, the food industry and the retail trade with foodstuffs in 2014.

Specification	Agriculture	Food industry	Retail trade[a]
Number of entities in the thousand	1413	14,6	354,8
in it: goods, industrial and supermarkets	294[b]	6,1	11,8
Number working in the thousand of persons	2331,4	445,6	490
in it in goods, industrial companies or supermarkets[c]	450	400	48
Production value in current prices (in bln PLN)			
▪ global,	105,3	220,0	.
▪ goods,	76,7	204,4	.
▪ retail	.	.	220,4[d]
Gross value added in the bln PLN	41,3	50,4	48,5
Export in the bln PLN	13,4	73,9	10,0
Import in the bln PLN	19,2	40,7	8,0-10,0
Value of the food consumption, drinks and tobacco products in the bln PLN	248,9[e]		

a - stores with large slaes area (supermarkets, hypermarkets, department stores),
b - farms where the production value exceeds 15 thousand euro,
c - stores with sales area of 401 m^2 or larger,
d - retail sales value of food, beverages and tobacco products including sales at wholesale and processors,
e - the sum of private consumption, ie. consumption in households, non-profit institutions, as well as in central and local government institutions.
*Source: The Statistical Yearbook of the Central Statistical Office 2015 and own calculations on the basis of Eurostat and unpublished data of the Central Statistical Office about the number of food industry companies.

All the basic links of food chain involve the processes of production concentration, as a result of the growing value of production, sales, and the decreasing value (though to a various extent) of overall number of companies, agricultural farms or stores. At the same time the number of the largest entities in all sectors increases. In the years 2006-2014 the value of sold food industry production (along with tobacco) increased by 57.8% from PLN 129.5 billion to PLN 204.4 billion (in current prices), value of agricultural goods production increased by 67.0% from PLN 45.9 billion to PLN 76.7 billion, and value of retail sale of food increased by 31.2% from PLN 168.0 billion to PLN 220.4 billion. In this period, the number of processing companies (together with micro enterprises) decreased from PLN 17 thousand to ca. PLN 12.6 thousand, (6% decrease) and the number of food industry plants decreased from 6.4 thousand down to 6.1 thousand (14.9% decrease). Insofar as the agriculture is concerned the number of farms (above 1 ha) decreased from 1,810 thousand to 1,413 thousand (21.9% decrease) at the increase of commodity farms to ca. 300,000. In retail trade the number of shops selling only food supplies reduced by 22.5% (from 145.8 thousand to ca. 113 thousand), with addition that there is ¾ more large-area stores (growth from ca. 6.7 thousand

to 11.8 thousand, including double growth in the number of hypermarkets and supermarkets from ca. 3.5 thousand to ca. 7.1 thousand

Every sector of economy is dominated by the largest entities, as they have the greatest share in the market. As regard the food sector, already more than half (55%) of the value of sold production falls on large industrial companies, employing more than 250 persons. In the years 2006-2014 the average value of production of one industrial company (without micro enterprises) increased by 71.0% from PLN 18.3 million to PLN 31.3 million. Assuming that ca. 80% of production (goods) comes from ca. 300 thousand agricultural farms, the average value of sold agricultural products increased by ca. PLN 200 thousand up to ca. PLN 256 thousand per farm.

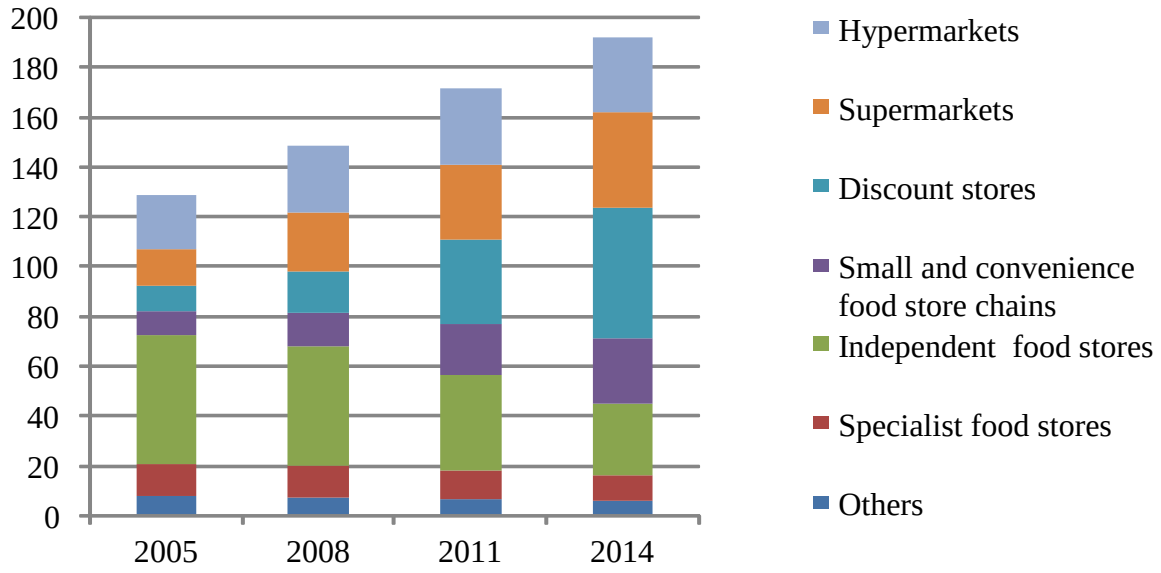
Average work efficiency in food industry companies measured by the value of production sold in 2014 amounted to PLN 451.3 thousand/employee and was more than 3 times higher than in commodity farms. Work efficiency measured by gross added value [1] in the food sector amounted in 2014 to PLN 113.5 thousand and in agriculture to PLN 17.1 thousand/employee. Since Poland's accession to the European Union, the value added of the Polish food industry increased more than twice from PLN 24.1 billion to PLN 50.4 billion, and in the value added of the Polish agriculture increased by 62% from PLN 25.5 billion to PLN 41.3 billion.

The past decade was characterised by dynamic changes in the area of retail trade, an expression of which was fast increase in number of large-area stores, including hypermarkets and supermarkets. In the years 2005-2014 the value of retail sale of food stores in Poland increased from PLN 129 billion to PLN 192 billion (net). At that time discount stores increased sales over five times, contributing along with supermarkets and small store networks to a decline in the importance of traditional food trade[2] the market share of which decreased from 56.6% to 23.2%, i.e. by 33.4 percentage point (Fig. 1). According to the estimations of the Polish Organisation of Trade and Distribution the value of Polish products (including food and beverages) exported by means of retail chains amounted in 2014 to approx. PLN 10 billion, i.e. ca. 11.5% of the whole Polish export of food (agricultural raw materials and food products).

[1] The value added in the food industry consist of: the cost of remuneration along with loads, depreciation, taxes encumbering costs (without VAT and excise), financial costs and gross financial result.

[2] it is generated, first of all, by independent food stores and specialist food stores

Figure 1. The value of retail sale of food stores[a] in Poland (net, in PLN billion)



a – data takes account of the whole sales of a given channel (not only food products), gas stations and cash&carry were omitted.
*Source: Own study on the basis of the KPMG's study "At the crossroads". Challenges and priorities of food chains in Poland. Warsaw 2015, p.16.

Large number of participants of food chain results in formation of various types of connections and sometimes also conflicts of interest. The purpose of every entity, whether it is a farmer, processor or merchandiser, is to sell produced or purchased product and make money from it. This dictates the conditions of who is stronger or better organised. Various types of slotting fees imposed by large retail chains on food suppliers generate additional costs, hence they reduce profits of food processors. In extreme cases this can resebmle a situation where processors become fully dependent on large retail chains. Such risk is present especially in the case of those manufacturers and processors who will bind themselves with only one recipient (one retail chain).

The role and importance of food industry in the food chain

The role and importance of food industry in the food chain can be considered in various aspects. The following can be distinguished: economical, socio-economic and health (food safety). From the economic point of view food industry companies are focused on making profit and raising value. Companies having profits find it easier to develop, invest, strengthen their position on the market and compete with other entities (national and foreign). Furthermore, in economic terms, the food industry, like many other economy sectors, contributes to gross domestic product the share of which, measured by gross added value, amounted in recent years to 2.7-2.9%.

A dynamic development of export of agricultural and food products after Poland's accession to the European Union contributed to limitation of Poland's trade deficit and at present, it improves a positive trade balance. It should be emphasised that the balance of trade exchange of food products is positive, whereas it is negative for trade in raw agricultural materials. It results from the fact that export of food industry products exceeds the import. In 2006 the positive balance of trade in food articles amounted to PLN 10.7 billion to increase in 2014 to PLN 33.2 billion (for comparison, a negative trade balance was recorded in export of agricultural products which in 2006 amounted to PLN 2.6 billion and in 2014 to PLN 5.9

billion)[1]. By developing the export, processing plants make use of current production surpluses and effectively promote Polish food on foreign markets. In the years 2006-2014 the export was "responsible" for 72.4% of growth in the sold production value of food industry which increased at that time from PLN 33.1 billion to PLN 87.2 billion.
Considering the socio-economic aspect, an important role of the food industry is to create and provide workplaces. In 2014 ca. 445 thousand persons were employed in the food industry. The food sector substantially contributes also to creating changes in the quality of manufactured agricultural raw materials by setting higher requirements for their producers. An example is the dairy industry which within a relatively short period of time (few years) succeeded in its effort to deliver to dairies only milk of extra grade. It would not be possible without economic stimuli in the form of, among others, favourable prices of high quality raw material and improvement in efficiency. Number of milk manufacturers decreased from 1.092 thousand in 2010 to 181 dairies in 2014 at relatively stable milk production. At the present time, the national offer of dairy products apart from high quality, is characterised also by rich assortment and considerable price competitiveness on the EU market. The second example is meat industry which actions resulted in improvement in meat content of pork livestock produced in the country, which amounts now to ca. 55% Rewarding of larger batches of uniform raw material of desired qualitative parameters contributes to the growth in marketability of agricultural farms as well as significant interest in Polish food on the part of foreign recipients.
The Polish food industry appeared to be resistant to the recent world economic crisis. Despite fears, no mass bankruptcy of processing plants and dismissals of employees or remuneration reductions were recorded and the lower level of investments and profits appeared to be only a temporary phenomenon.
An important thing is also the fact that the food industry alleviates rapid increases in purchase prices of agricultural products, as price changes on its side are usually much lower, also from those in retail trade (table 2).

Table 2. Changes in prices on the agricultural and food market in 2006-2014 years.

Specification	Prices annual changes (%)		
	Agricultural	Food processing	Consumer (retail)
Average price growth rate on the agro-food market	3,05	2,13	3,24
in it: meat,	3,39	2,37	2,82
cereal,	7,28	2,49	4,48
dairy	4,42	2,97	3,23
Average changes in prices (+/-) on the agro-food market	6,02	2,79	3,10
in it: meat,	8,54	3,93	3,84
cereal,	20,48	8,89	4,48
dairy	8,99	4,56	3,57

*Source: Own calculations on the basis of purchase prices of agricultural products, indicators of changes in the sold production value of food industry (food and non-alcoholic beverages) and indicators of retail prices of food established by the Central Statistical Office.

The comparison of average rate of increase of prices on the market of agricultural and food products suggests that in years 2006-2014 the average growth rate of prices of processors amounted to 2.13% annually and was lower than the growth rate of prices paid to farmers (3.05%), as well as lower than the growth rate of retail prices of food and beverages (3.24%).

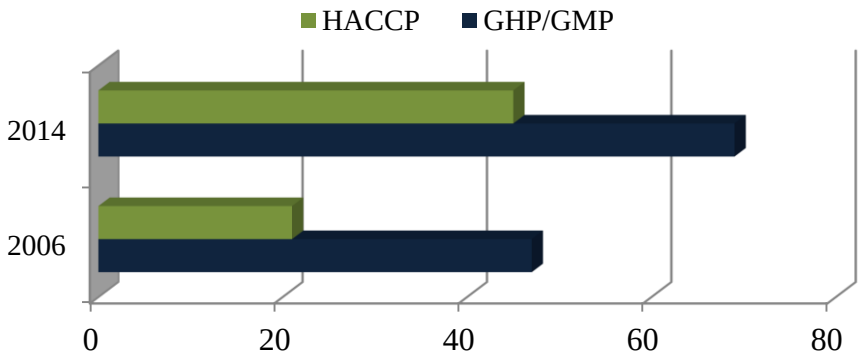
[1] Negative balance of commercial exchange of Poland in 2006 amounted to ca. PLN 50.4 billion; in 2010 it increased to PLN 55,2 billion, and in 2014 decreased to PLN 11.1 billion.

These spans varied from one market to another. Average changes in the market of agricultural and food products were similar for processing and retail trade and were the highest in agriculture. For cereals the variability of purchase prices amounted to as much as +/-20.5% annually and was more than twice as high as the selling prices of processors and 4.5 times higher than the average changes in retail prices. A great instability of the growth rate of prices (their changeability) was a problem also on the meat and dairy market, especially for farmers. Average changes of prices on this market were higher than the average changes in prices of agri-food products at the level of processor and consumer. It can be concluded from this short analysis that the food industry was in the past decade a link mitigating the effects of high volatility of prices paid to farmers, hence, stabilising the food sector.

The basic role of food industry is manufacturing of food and beverages from agricultural raw materials which, subjected, in lesser or greater degree, to processing at subsequent distribution stages of food chain (trade, gastronomy), are offered to the consumer. In this way the processing along with the agriculture and trade secures one of basic living needs of human, namely hunger satisfaction.

Food industry entities in an increasingly larger scale meet tastes and expectations of consumers as to the range and diversity of the assortment of produced food. At the same time, the awareness and responsibility of manufacturers for ensuring the appropriate quality of offered food and care for safety of consumers' health is growing systematically. Contemporary thinking about the quality consists in the fact that the desired quality of product should be achieved at every stage of production, starting from the selection of relevant raw material through processing, storing, distribution to final recipient. This approach is reflected in a constant increase in the level of implementation of obligatory systems of quality management companies of food industry (figure 2). This process proceeds most rapidly in large and medium enterprises, and relatively slow in micro enterprises.

Figure 2. State of implementation of obligatory safety and quality management systems in the total number of food industry enterprises (in %).



*Source: Own calculations on the basis of unpublished data of the Veterinary Inspection and State Sanitary Inspection.

A pursuit of continuous improvement of effectiveness of quality management and food safety results in the fact that Polish manufacturers more and more often invest also in implementation of non-obligatory systems of quality management, mainly in the one consistent with ISO 22000 Standard and in BRC standard required by foreign retail chains.

Food industry plants often act as an integrator of entities involved in the manufacturing process from field to table. However, as R. Urban notices, this function, more and more often,

may be taken over by trade and large retail chains, as they begin to play a dominant role in the food chain (Urban 2012).
Growing position of hypermarkets and supermarkets on the market (apart from the fact that a large foreign capital is present there) results also from low prices of sold goods and large commercial offer, which effectively attracts customers. In the period of last ten or so years shopping preferences of Poles have substantially changed with regard to the place where they buy food products. Hypermarkets and supermarkets have gained the most while the biggest loss concerned small stores and kiosks, where products are served directly by the seller, as well as bazaars and marketplaces. In 2010 more than a half of respondents (54%), indicated hypermarkets and supermarkets as the most common place for buying food (increase by 35 percentage points as compared to 1997). 40% of the surveyed declared buying of foodstuffs in small shops and kiosks, which means a decrease by 32 percentage points as compared to 1997. Only 8% of persons indicated bazaars and marketplaces as places of buying food (31% in 1997). Small and medium self-service stores (up to three cash registers) retained quite stable group of buyers (ca. 35%). In these studies one person could indicate different places of purchasing as preferred ones. (Sobocińska 2011). Currently the pace of opening new commercial areas (supermarkets and hypermarkets) has slowed down. Some networks see the possibility for further expansion in taking over of the already existing retail outlets (stores). Internet shopping also enjoys the increasing popularity among consumers.

Conclusions

The food industry belongs to one of the major links of food chain. Its position is important because:

- ca. 14.6 thousand companies operate on the market, of which 6.1 thousand are industrial companies employing more than 9 members of staff,
- overall employment in the food industry amounts to ca. 450 thousand persons,
- the share of food industry (including production of tobacco products) in gross domestic product of Poland is ca. 3%,
- the food industry is the main recipient of agricultural goods production,
- the Polish food industry became a leading food producer on the European market, and Polish food processing plants are considered as one of the most advanced in the EU,
- together with agriculture and trade it meets one of the essential living needs of human which is to satisfy hunger.

Polish food industry has made the most of the opportunity which opened up after our accession to the European Union. In the years 2006-2014 the value of production of food industry (including tobacco) increased by 57.8% . The export was "responsible" for more than 70% of the growth in the value of sold production of food industry, which value, at that time increased by 2.5 times.
In the studied period the variability of product trading prices at the food processor's was lower than the variability of prices paid to agricultural manufacturers. Therefore, the food industry was a link stabilising the food sector.
Along with the progress of consumption and development of export of products with higher degree of processing the significance of food industry in the food chain will continue to grow, whereas agriculture will become mainly a raw material department of national economy.
However, a noticeable development of global retail chains may, in the future, contribute to another shift in power in the food chain. The progressive globalisation, manifesting, among others, in the prevailing share of corporations in food trade, results in slowly weakening of a strong position of manufacturing companies. Currently, commercial corporations are able to affect with its activities food industry companies (force them to reduce costs, imposing branding, etc.), agriculture (production of low-cost raw materials or organic food),

merchandisers (eliminating them from the market), as well as consumers (change of preferences and habits through advertising and other marketing activities.

Abstract

Albania is well known for its very rich in its agro-biodiversity. In the North of Albania, the Hasi goat breed is a good example of using agro-biodiversity as a resource for local development. Animals of this breed have a clear genetic profile, are well-adapted to harsh conditions and to abundant pastoral and sylvio-pastoral resources in the karstic plain. Products as goat kid meat and milk have e good reputation. In order to address the territorial dimension of local value chains; Geographical Indication (GI) was identified as a possible adequate sign of sustainability and origin to be developed. The objective of this work is to identify the specifics of the product (Hasi goat kid meat) in order to complete a successful GI building process and direct support to the value chains. For this purpose it was implemented a territory-based study mainly based on bibliography, interviews of farmers but also morphological measurements of animals. Four main points of attention have been identified; (1) a strong delimitation of the area of origin based on geo-morphological criteria where sinkhole agricultural and forage production is an important part of this; (2) the specificities of the breed including genotypic and phenotypic characteristics as well as the quality and reputation of its products, especially kid-meat goat. (3) the environmental issue and management of the pastoral resources in naturalist terms and their relation to the quality of meat;(4) the traditional management, breeding system and pastoral practices; and specifications to be potentially included in the Code of Practice (of the GI).

Keywords: *Albania, Geographic Indication, Territory, Value chain, Hasi goat*

Introduction

Landscape patterns' diversity in the north-eastern part of Albania have been a good foundation for development of a very rich biodiversity. Moreover, combination of landscape and biodiversity with a wide variety of production systems and traditional practices have produced a very rich agro biodiversity. Agro biodiversity is a great potential for economic development of rural areas, which actually are the most poor and marginalized. This very rich agro biodiversity and diversity in mountain areas have not yet affected the living standards , even in developed urban areas local products of mountain origin are preferred and requested. This appreciation is not reflected in higher prices because of lack of consolidated Value Chains (VC), as well as lack of identification and standardization of these products. One of these products is the meat from Hasi goat kids. Even this product has very good reputation for its quality and taste, this hasn't been sufficient to build sustainable VC that may increase income for population in remote areas.(Kipi, B. et al. 2013) One of most successful strategies in this case could be building value chains based on Geographic Indications.(Bernard, J-P. et al. 2014) To complete a successful GI building process in Albania and direct support to the value chains with a territory-based action it is necessary to explore and identify linkages between the product, in our case Goat kid meat, with the territorial elements, geo morphologic

characteristics of the territory, local goat population, environment and management of pastoral resources and traditional breeding and management practices.

Materials and methods

The methodology used is an essential part of this study. In order to identify all elements of the GI building process we have used previous research as well as studies and research completed during this project.

Data production. Data were collected in two different ways: extensive literature review and field research (semi-directive interviews, survey, and direct field observation) on which inductive method was applied.

During the bibliographic research phase there were used: scientific publications, the grey literature which represents all the documentation except scientific ones.

Collective field work and interviews. The collective fieldwork was organized based on the ECRIS method-guidelines for investigation in social situations. A socio-anthropological approach of the field consisting in comprehensive and semi directive interviews. interviews were made all around the Hasi region (Albania) in order to have the largest panel of interviewees possible.

Interviews and Survey were made with the population of villages, Cahan, Mujaj Kishaj, Domaj, Pus I Thate, Gjinaj, Vlahen, Golaj and Vranisht in the region. A survey grid was prepared in order to have the same questions for each people interviewed. The questionnaire has 51 questions, 9 of them have multiple answer options with check boxes and two were open ones with descriptive answers

Delimitation of the territory is mainly based on its geographic and morphological structure, as well as on traditional links and connections of the local communities.

Specifics of the goat breed are based on DNA analysis for the genotype and on morphological evaluation of goats according to Food and Agriculture Organisation (FAO) criteria for local breeds and populations (FAO 2012).

Traditional management and pastoral practices and breeding system have been described based on interviews and partly opened questionnaires made on 24 farmers having more the 100 goat per farm. The selection of these farms' size is based on the fact that such farms are more market oriented. Those farms have together, more than 50% of goat population in Hasi region. Before each interview, a free open discussion was made in order to get confidence of farmers and avoid non-realistic information especially on farm production.

Results and discussion

Product characteristics are based on several elements which have been thoroughly studied and analysed:

1) a strong delimitation of the area of origin

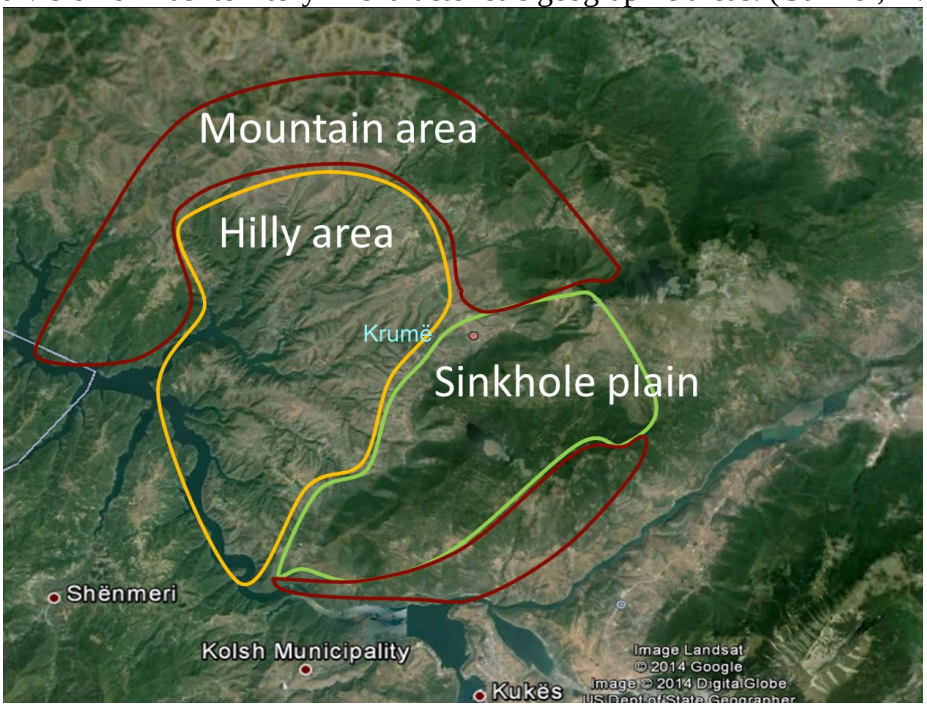
Hasi goat breed is endemic to the region and has a strong link with its territory and has been affected by its characteristics. The breed and its products have been identified as the most adequate first step toward a sustainable rural development strategy (Medolli, 2013). Homogeneous flocks had been identified especially in the plateau area, characterized by its geomorphologic "sinkhole" system.

According to bibliographic study (Garnier, A. 2013), Hasi area is composed by several geomorphological parts:

- A mountain ridge along the entire Northern Has. It forms a crescent stretching from Mount of Shkami on the west, Mount Suka southeast, passing by Pashtriku Mountain where there is the highest peak of Hasi (1998m). The mountainsides are covered with trees, scrubland, and grassland in the soft slopes.

- A sinkhole plain, where villages Cahan, Mujaj and Kishaj are located. The plain is extended in the South-Eastern Has, with an altitude between 1000 and 1500m. Karst formations such as sinkholes are characteristic of this plateau. They are formed due to the presence of limestone structures (basement) in this area.
- A hilly area, at an altitude between 300 and 800 m. This hilly area is divided by rivers and streams that meander through the plateau. Land of the area is mainly composed of sedimentary soil allowing the cultivation of cereals, vegetables, and forage.

Fig. 1 division of Hasi territory in characteristic geographic areas. (Garnier, A. 2013)



The above geographical features (according to Garnier, A. 2013), have been crucial for the development of three types of villages in Hasi:

- ***Hilly area villages with high production capacity*** (Red Lake, Zaharisht, Krumë, Golaj). These villages are located in the plateau of Kruma where there are abundant hilly pastures, and capacities to develop agricultural and animal production
- Access to hillside pastures;
- Good capacity for agricultural and forage production;
- Little purchase of forage and concentrates.
- **Hilly area villages with poor production capacity** have almost no arable land (Gjinaj, Domaj) or they are unproductive and production costs are higher then the price of products in the market (Letaj).
- access to hilly pastures, and possibly to mountain pastures;
- Low forage production capacity and very low capacity for agricultural production;
- Purchase of forage and concentrate
- **Villages of sinkhole plain (Cahan, Kishaj**).
- Access to mountain pastures;
- Good ability to forage production, but almost no agricultural production;
- Purchase of concentrates, little purchase of forage.

The common characteristic of goats living in this area is that all of them use for almost all or part of the year pasturing and browsing in the sinkhole plain.

2) **The specificities of the breed.**

Hasi goat is recognized as an endemic breed (Dobi et al., 2006). Based on the results of this study and results of previous studies (Ajmone Marsan P. et al 2008) microsatellite markers (Hoda et al., 2014) and SNP markers (Hyka et al. 2013) it was concluded that….. "*Albanian goat breeds are important reservoir of genetic diversity, have a low level of differentiation and high level of admixture...*". Anyway, Hasi goat has a distinct morphological traits which are main identification sources and selection criteria. Animals are…. "*Adapted to harsh environment and extensive management. Strong and rustic even during winter season. Well-developed body, long legs, well developed udder. Reddish, long hair. Pending ears of middle size, backward curled horns* " (Dobi et al., 2006)

The phenotypic differentiation is based on traditional selection criteria applied by farmers. Even nowadays they continue to select goat kids for replacement based on: "Reddish colour, medium size pending ears, and backward curled horns, high milk productive mothers with good developed teats, as well as the ability to browse high branches". Proud of their breed, farmers don't accept crossing their goats with other local or imported goat breeds, guaranteeing in this way the purity of the population. Morphological uniformity of Hasi goat breed in this territory is an important element of differentiation. This is one of criteria introduced in the Code of Practice.

3) The environmental issue and management of the pastoral resources

The current situation in Hasi district can be defined as a sort of "residual pastoral system", based on a multitude of very small mixed crop and livestock holdings. As grazing areas are not a limiting factor in this "last remaining people" situation, feeding strategies are mainly based on pasture or non-cultivated land. Nowadays, livestock farming activities are reshaping a new agrarian landscape around different evolution patterns. The systems of funnel-shaped hollows in a karst region allow higher forage production on a poor limestone soil, but also a diversity of plants, so important for a pastoral system.

Livestock development that relies mainly on the exploitation of natural pastures has as challenge to maintain or improve the productive potential of the environment and quality of available resources. Currently pasture resource management are driven by the individual strategies and it is not organized or regulated, and therefore, there is pressure in certain areas, especially near villages, while in other areas we have a situation of under grazing.

For this purpose, the project it is focused on the promotion of modern grazing methods, application of appropriate stocking rate, and taking measures for the regeneration of damaged or overgrazed grasslands. This can be enabled through farmers group decision-making, organized around a quality mark and the implementation of the Code of practice drawn up by farmers themselves.

4) The traditional management, breeding system and pastoral practices;

Farm typology is strongly related with geomorphology and natural resources. Based on their interaction with the market the farms are classified into four main types:

- Auto-consumption farms (<10 heads). Products from this type of farm are consumed by the family. Goat farming is a secondary activity, complementary to other agricultural or non-agricultural activity. This type of farms concerns 26% of the 153 goat farms of Hasi region.
- Subsistence farms (10-50 heads). These little flocks (27% of the goat farms), are producing less than 25 kids per year, supplying a low income when kids are sold. The family often combine another activity (mainly sheep and/or cattle farming) giving additional income. Feeding is mostly based on the use of natural resources as pastures, scrublands and oak leaves, and very few cereals.

 Semi-specialized farms: (50-100 heads). Beyond 50 goats, animals and milk commercialization may supply a decent income for a family. But the marketing issue is crucial and is, in our diagnosis based on field-work enquiries, a limiting factor for increasing the number of animals in this type of farm, which actually concerns 21% of the goat farms.
 Specialized farms: (>100 heads). Those farms often have high means of production (workforce, capital, agricultural capacity) and are supported by the state through the subsidy of 500 lekë (3.6 Eur) per breeding goat. They are mainly located within the sinkhole plateau, where the trade opportunities are facilitated by the settled partnerships with goat-dealers. This type of farm may concern 26% of goat farms in Hasi region and the flocks seem to grow, particularly in sinkhole plateau.

Breeding season is short and starts in second half of October, defining in this way lambing season in the second half of March. Farmers have chosen to breed goats in this season in order to save food they need for goat kids for their second month of life, so new goat kids may start browsing in their second month of life when new leafs burst in April and May. Weaning is made during the third month of age, but in some cases farmers prefer to keep goat kids with their mothers for longer with the argument that this produces better meat quality with lighter colour. This breeding season gives to farmers the opportunity to sell goat kids during summer months, when farmers from other areas have already sold their product.

Feeding strategy in Has, is mainly based on natural forage resources such as low oak forests, scrublands and pastures. Goat breeding is the only way to valorise those ligneous resources, converting them into foods products and substantial farm incomes. During part of winter animals are kept indoor and fed with dried oak leafs collected during summer and autumn, hay harvested in rich pastures as well as small quantities of cereals produced on the farms or purchased in the market. From 24 farmers' interviews, appeared that the average of pasturing time in one year is 10.34 month, but no one uses pasturing less than 10 months per year. One of them says "*the goats may die if we keep them inside the barn... if the snow layer is under the goat knees, they should go to browse in shrubs*"

Most of farmers use pastures around their village, in the distance they may reach in one day. From all interviewed, only one applies transhumance, this mainly because of lack of water supply in pastures but also because of availability of pastures close to villages. Considering these management elements as specifics of the area and the production process, they have become crucial elements for the Code of practice. This document was prepared in very close collaboration with the Hasi goat farmers association, considering that the collective action is the only way to implement common production standards and develop GI. This process brings shareholders and stakeholders together with a common understanding of these challenges, and finds the best fit between private interests, management of the common good (labels), and public good (agro-biodiversity conservation).

Conclusion

A comprehensive sustainable development approach – agro-biodiversity valorisation and conservation– requires a reflexive and practical interactive method all along the collective action process. Geographical Indication building is a complex process that has to combine collective action and knowledge-based product specification of such silvo-pastoral systems.

This process brings shareholders and stakeholders together with a common understanding of these challenges, and finds the best fit between private interests, management of the common labels, and public good (agro-biodiversity conservation). It has to be complementary to the breed identification process, environmental assessment, production system analyses and support to appropriate pastoral practices.

All above mentioned elements which gives specific profile to the product are crucial for developing the GI. These elements are already part of the code or practice, which is a standard of the product.

OPTIMIZATION OF ENZYMATIC SACCHARIFICATION FOR QUALITY IMPROVEMENT OF BIO-OIL FROM RICE STRAW

Khan CHAND*, Manish PANT

Department of PHP&FE, College of Technology, G B Pant University of Agril& Tech, Pantnagar, India
*Corresponding author: kcphpfe@gmail.com

Abstract

The reducing sugar ranged from 25.1 to 34.8 g/L and glucose content ranged from 15.1 to 28.9 g/L, lignin ranged from Bio-oil, another category of renewable energy has gained significant interest of scientist in recent years. The major problem in production of bio-oil is its increase in density with the passage of time. The reason for such phenomenon is the cross-linking of lignin which was bound to bio-oil after pyrolysis. The aim of this work was to reduce the content of lignin in rice straw and study the effects of decreased lignin content in bio-oil. Additionally enzymatic saccharification of rice straw was also conducted after pre-treatment to estimate optimum conditions for bio-oil production. The independent variables for the optimization of enzymatic saccharification were, time (24, 48, 72 hours), Enzymatic loading ratio (5:10, 10:10, 15:10), substrate concentration (4, 5, 6%w/v) were taken into account. Designed experiments were conducted randomly to find the effect of these variables on reducing sugar, glucose concentration, lignin, ash, cellulose, hemicelluloses. The analysis of variance for each sample was calculated. The reducing sugar increased with increase in time and enzyme loading ratio while lignin content increased with increase in substrate concentration48.1 to 51.1% w/w and 9.1 to 12.1 w/w. Optimum value of levels of predicted variables obtained by compromise optimization of the responses were; 64.8 h time, 15:10 enzyme loading ratio and 4.62 substrate concentrations.

Key words: *Rice straw, lignin, ash, cellulose, bio-oil and reducing sugar*

Introduction

Lignocellulosic substrates are regarded as one of the most important sources of carbon and related carbohydrates. Its subsequent bioconversion and utilisation into useful products can be regarded as better sources of energy and fuel. Rice straw consists of three main components: cellulose, hemicellulose, and lignin. The complexity of these components leads to the stability of its biomass and results in the difficulty of its enzymatic disassembly. Rice straw consists of cellulose (35–40% w/w) and hemicellulose (25–30% w/w) in close association with lignin (10–15% w/w), is one of the most abundant lignocellulosic crop residues (Thygesenet al. 2003).

In terms of total production, rice is the third most important grain crop in the world behind wheat and corn. As per commodity profile for rice (March 2015), world annual rice production in 2014-15 was estimated about 475 million tons (Source: International Grains Council). Similarly for commodity profile of rice (March 2015), India's annual rice production in 2014-15 was estimated about 103.04 million tons (Source: Directorate of Economics and Statistics). Rice production in Uttarakhand in 2014-15 was estimated to about 5.5 lakh tonnes(Mani, 2015). Every kilogram of grain harvested is accompanied by production of 1–1.5 kg of the straw (Maiorellaet al. 1985). It gives an estimation of about 480–720 million tons of rice straw produced per year globally and a large part of this is going as cattle feed and rest as waste. The options for the disposition of rice straw are limited by the low bulk density, slow degradation in the soil, harbouring of rice stem diseases, and high mineral content. Nowadays, field burning is the major practice for removing rice straw, but it

increases the air pollution and consequently affects public health (Mussatto and Roberto, 2004). As climate change is extensively recognized as a threat to development, there is growing interest in alternative uses of agro-industrial residues for energy applications. In this context, rice straw would be a potential candidate for our future energy needs.

Bio-oil is normally derived from biomass such as rice straw. The benefit of energy generation is often offset by the increased emissions, thus restraint it value as fuel for incineration. Therefore, alternative technologies should be invented in order to transform this beneficial renewable biomass into useful products. Liquefaction of rice straw using thermo chemical conversion process such as pyrolysis offers an option for conversion of solid biomass into liquid bio-oil. Bio-oil is easier to transport, store, and can be upgraded to improve its quality. Bio-oil is also utilized as specialty chemicals like flavourings, renewable resins and slow release fertilizers (Baratieriet al. 2008, Abdullah and Gerhauser 2008). However, bio-oil cannot be used as a direct substitution for petroleum and chemical feedstock since it has high viscosity, high content of unstable oxygenated molecules and high density (1.2 kg/L). Therefore, upgrading of bio-oil into higher quality liquid product with wider applications is necessary. Various upgrading methods have been reported including solvent fractionation, steam reforming, hydrogenation, and catalytic cracking.

The main objective of this thesis is to investigate the potential of chemically pretreated rice straw as a promising endeavour for bio fuel production. The usage of alkaline chemical in the pre-treatment of rice straw and enzymatic hydrolysis to degrade lignocelluloses biomass and saccharification of cellulose is expected to alter the original biomass structure.

Response surface methodology by Box–Behnken design employing the multivariate approach enables substantial improvement in the method development using fewer experiments, without wastage of large volumes of organic solvents, which leads to high analysis cost (Waniet al. 2012) it can be used to get an optimum process conditions considering single response or multiple responses. It encompasses statistical and mathematical techniques. In view of the above, present study was undertaken with the following objectives:

1. To study the effect of alkali treatment on rice straw after drying and mechanical treatment.
2. To identify optimum operating conditions for enzymatic saccharification.
3. To prepare the bio-oil after pyrolysis of untreated and pre-treated rice straw.

Materials and Methods

Rice straw (*Oryza Sativa L.*) was procured from Crop Research Centre (C.R.C.) of GovindBallabh Pant University of Agriculture and Technology, Pantnagar. Chemicals and enzymes used in the sample preparation for the pre-treatment of rice straw and for proximate analysis chemicals were purchased from Himedia Pvt. Ltd.

Drying of Rice Straw

The procured rice straw was dried in a hot air oven simultaneously moisture content was also evaluated. The rice straw was dried at 115°C until it kept constant weight during estimation of moisture content (Zhang et al. 2008). After that the rice straw was bone dried for size reduction process.

Determination of moisture content:

The moisture content of the sample was calculated using the following equation:

$$\%W = [(A-B)/B] * 100 \quad \text{.....(1)}$$

Where:

%W = Percentage of moisture in the sample,
A = Weight of wet sample (gm), and
B = Weight of dry sample (gm)

Size Reduction of Rice Straw

The dried rice straw was subjected to size reduction process in hammer mill. The mesh size being used was of 2 mm size. The size reduction process was done for better availability of grounded straw to alkali during pre-treatment process.

Alkali Pre-treatment

The alkali pre-treatment was used for reduction of lignin content in the sample. The alkali pre-treated samples were used for enzymatic saccharification. The rice straw was treated with 2% (w/v) NaOH solution at 85°C for 1 hours. Then the treated rice straw was washed with water until neutral pH achieved and then oven dried.

Enzymatic Saccharification

Preliminary experiments

Preliminary trials were conducted for subjection of enzymes to the pre-treated rice straw. The objective of this experiment was to examine the effects of one step enzyme addition and two step enzyme addition during saccharification process. The one step enzyme addition included the addition of enzymes viz. cellulase (10 FPU) and βglucosidase (10 IU) at conditions mean to their optimum activity in individual action for 24 hours. On the other hand in two step enzyme addition the enzyme in similar amounts were added but at varied conditions as provided by manufacturer's recommendation on optimum activity of individual enzymes in the intervals of 12 hours. The substrate used in the experiment was cellulose powder (5% w/v concentration) with the two enzymes viz. cellulase and β-glucosidase. The operating conditions of each enzyme and used in one step enzyme addition are shown in Table 1.

Table 1 Operating conditions of preliminary experiments

Method	Temperature	pH
One step enzyme addition	37°C	4.8
Two step enzyme addition:		
Cellulase	40°C	4.5
β-glucosidase	35°C	5.0

Enzymatic saccharification

The experiments designed by Design-Expert software included 17 experiments. The enzymatic saccharification process was based on independent parameters. The parameters of process was introduced in software are in numeric forms varied over 3 levels.

Thus here, designs are format of Box-Behnken design of response surface methodology. Various experiments to be conducted were accordance to the ratio included in the RSM with Run time analysis.

Experimental Design

Experimental design, defined as a specific set of experiments which are defined by a matrix, a matrix composed by the different level of combination variables. Response surface methodology (RSM) was used for the design and analysis of all experiments for three predicted variables at three levels. It also helps to reduce the number of experiments without affecting the accuracy of results and to decide the interactive effects of influencing factors on the response. Box-Behnken model was selected for the optimization of the process variables (Sharma 2014). Box-Behnken is a class of rotatable second order design based on thoursee levels incomplete factorial design. This design does not contain for which all factors are simultaneously at their highest and lowest levels. So this design is useful in avoiding experiments performed under extreme conditions for which unsatisfactory results might occur (Bezzeraet al. 2008). The detailed values of independent and constant variables of experimental design are given in Table 2 and 3.

The number of experiments (N) required for development of Box-Behenken Design. This design is defined as:

$$N=2K(K-1)+C_0 \quad \text{..... (2)}$$

where,

N= Total no. of experiments

K = No. of variables

C_0= Centre point

In order to determine a critical point (maximum, minimum or saddle) it is necessary for the polynomial function to contain the quadratric terms. According to the equation presented below:

$$y = \beta_0 + \sum_{Ki=1}\beta_i X_i + \sum_{ki=1}\beta_{ii} Xi_2 + \sum_{k1<=i<=j} \beta_{ij} X_i X_j \quad \text{..... (3)}$$

where

β_{ii}, β_0 and β_{ij} are the coefficients of regression. (i=1, 2, 3, ...n) (j=1, 2, 3, ...n)

Table 2. Values of level of independent variables

Independent variables	Values		
	-1	0	+1

Enzyme loading ratio	5:10	10:10	15:10
Substrate concentration (% w/v)	4	5	6

Table 3. Values of constant variables

Variables	Values
Temperature	37°C
pH	4.8
Buffer concentration	0.1M

Experimental Procedure

The whole experiment was conducted in three phases. Experiments were planned with a view to develop pre-treated, enzymatically hydrolysed agricultural waste, which could be a better method for bio-oil extraction by pyrolysis. In the first phase experiments were carried out by already optimised pre-treated conditions for rice straw for maximum breakdown of lignin. The said conditions utilised in alkali pretreatment were NaOH at 85°C for 1 hours. The analysis of sample was done on the basis of proximate parameters which are important for the sample analysis.

During the second phase, enzymatic hydrolysis was carried out and the independent variables (reaction time, enzyme ratio, substrate concentration) were optimised for best reducing sugar yield. Again, the analysis of sample was done on the basis of proximate parameters which were important for the sample analysis.

Reducing sugars

The DNS method for estimating the concentration of reducing sugars in a sample was originally invented by G. Miller in 1959. Reducing sugars have the property to reduce many of the reagents. A reducing sugar is one that in a basic solution forms an aldehyde or ketone. The aldehyde group of glucose converts 3,5-dinitrosalicylic acid (DNS) to 3-amino-5-nitrosalicylic acid, which is the reduced form of DNS. Water is used up as a reactant and oxygen gas is released during the reaction. The formation of 3-amino-5-nitrosalicylic acid results in a change in the amount of light absorbed, at wavelength 540 nm. The absorbance measured using a spectrophotometer is directly proportional to the amount of reducing sugar (Miller, 1959).

Ash estimation

Samples of air dried, ground (0.5 mm) lignocellulosic biomass (0.7 g each) were boiled with 5 mL of 72% w/w H2SO4 solution for 4.5 hours in order to hydrolyze the cellulose and hemicellulose. The suspension remaining after the above treatment was filtered thoursough a crucible and the solid residue dried at 105°C for 24 hours and weighed (W1). The residue was then transferred to a pre-weighed dry porcelain crucible and heated at 600°C for 5 hours. After cooling down, it was weighed (W2) and ash content (%) was determined (Ververiset al. 2007).

Lignin estimation

The lignin can be estimated gravimetrically by klason or 72% w/w H_2SO_4 Method. The most widely used method for lignin determination by chemists is probably the simplest and overall the most reliable, despite its limitations. Samples were digested with 72% w/w sulphuric acid, then with dilute sulphuric acid, to hydrolyze and solubilise the polysaccharides; the insoluble residue

were dried and weighed as lignin (Liu, 2004). Following from ash estimation, acid insoluble lignin was then calculated by the difference (W1-W2) (Ververis*et al.* 2007).

Results and Discussion

Effect of independent variables on reducing sugar

Experimental data in Table 4 shows that in case of enzymatic pretreatment, the reducing sugar ranged from 25.1 to 35.2 g/L. Maximum reducing sugar was found 35.2 g/L for experiment number 17, with the combination of time 48 hours, enzyme loading ratio 10:10 and substrate concentration 5% w/v. Minimum reducing sugar was found 25.1 for experiment number 3, with the combination of time 48 hours, enzyme loading ratio 5:10 and substrate concentration 4% w/v. It can be concluded that enzyme activity for an optimum time proves highly significant in release of reducing sugar.

Effect of independent variables on lignin

Experimental data in Table 4 shows that in case of enzymatic pretreatment, the lignin ranged from 7.7 to 10.8% w/w. Maximum lignin was found 10.8% w/w for experiment number 9, with the combination of time 24 hours, enzyme loading ratio 10:10 and substrate concentration 6% w/w. Minimum lignin was found 7.7% w/w for experiment number 5, with the combination of time 48 hours, enzyme loading ratio 15:10 and substrate concentration 4% w/v. Lignin showed no significant reduction by enzymes. Lignin was directly proportional to substrate concentration.

Effect of independent variables on ash

Data tabulated in Table 4 shows that ash ranged from 7.8 to 9.8 % w/w. Maximum ash was found 9.8 % w/w for experiment number 11, with the combination of time 48 hours, enzyme loading ratio 5:10 and substrate concentration 6 % w/w. Minimum ash was observed 7.8 w/w for experiment number 5, with the combination of time 48 hours, enzyme loading ratio 15:10 and substrate concentration 4% w/w. Losses of ash content could be concluded from activity from enzymes because of conversion of cellulose to reducing sugar.

Statistical analysis of dependent variables

Reducing sugar

The statistical analysis of reducing sugar was given in Table 5. The model of reducing sugar was found highly significant ($P < 0.01$) because it had higher F-value (44.63). It was also observed that the effect of independent variables on reducing sugar was highest at quadratic level due to highest calculated F-value (99.15) followed by linear level and interactive level.

Table 5. Analysis of variance for reducing sugar

SOURCE	**DF**	**SS**	**MS**	**F_{value}**

Total	16	222.4	24.83	

*, ** and *** Significant at 1, 5 and 10% level of significance respectively.

From **Fig. 1** at linear level, observed the effect of time on reducing sugar at optimum point of enzyme loading ratio 1.0 (15:10) and at substrate concentration -0.38 (4.62 % w/w) for producing quality improved bio-oil. It depicted that reducing sugar increased rapidly with increased level of time from -1 to 0.5. While it is constant with respect to time. Afterwards reducing sugar decreased with increased time and this point quality of bio-oil could decrease.
The readings were supported by **Hsu *et al.* 2008**

From **Fig. 2** at linear level, observed the effect of enzyme loading ratio on reducing sugar at optimum point of time 0.7 (64.8 hours) and at substrate concentration -0.38 (4.62 % w/w) for producing quality improved bio-oil. It depicted that reducing sugar increased rapidly with increased level of enzyme loading ratio from -1 to 0.5. While it is constant with respect to enzyme loading ratio. Afterwards reducing sugar decreased with increased enzyme loading ratio and this point quality of bio-oil could decrease. The readings were supported by **Hsu *et al.* 2008**

From **Fig. 3** at linear level, observed the effect of substrate concentration on reducing sugar at optimum point of time 0.7 (64.8 hours) and at enzyme loading ratio 1 (15:10) for producing quality improved bio-oil. It depicted that reducing sugar increased rapidly with increased level of substrate from -1 to 0.25. While it is constant with respect to substrate concentration. Afterwards reducing sugar decreased with increased substrate and this point quality of bio-oil could decrease. The readings were supported by **Hsu *et al.* 2008**

Fig. 4 shows the variation of reducing sugar with time and enzyme loading ratio at optimum point of substrate concentration -0.38 (4.62%, w/v) in interactive level of the model. The reducing sugar increased with increase in the level of time and after some time it decreased steeply from -1(24 hr) to 1(72hr) while reducing sugar increases with increase in the level of enzyme loading ratio. The readings were supported by **Hsu *et al.* 2008**

Fig. 5 shows the variation of reducing sugar with substrate concentration and enzyme loading ratio at optimum point of time 0.7 (4.62%, w/v) in interactive level of the model. The reducing sugar increased with increase in the level of substrate concentration and after some time it decreased steeply from -1 (4% w/v) to 1 (6% w/v) while reducing sugar increases with increase in the level of enzyme loading ratio. The readings were supported by **Hsu *et al.* 2008.**

Lignin

The statistical analysis of lignin was given in Table 6. The model of lignin was found highly significant ($P < 0.01$) because it had higher F-value (7.87). It was also observed that the effect of independent variables on lignin was highest at linear level due to highest calculated F-value (18.47) followed by quadratic level and interactive level.

Table 6 Analysis of variance for lignin

SOURCE	DF	SS	MS	F_{value}
Model	9	12.07	1.34	7.87*

*, ** and *** Significant at 1, 5 and 10% level of significance respectively.

From **Fig. 6** at linear level, observed the effect of substrate concentration on lignin at optimum point of enzyme loading ratio 1 (15:10) and at time 0.7 (64.8 h) for producing quality improved bio-oil. It depicted that lignin increased regularly with increased level of time from -1 to 1. While it is constant at point A with respect to enzyme loading ratio. More of the substrate concentration analysed provided for the increased lignin content.

Fig. 7 shows the variation of lignin with substrate concentration and enzyme loading ratio at optimum point of time 0.7 (64.8 h) at interactive level of the model. The lignin increased steeply with increase in the level of substrate concentration (X_3, %, w/v) and the lignin is reduced with increasing enzyme loading ratio.

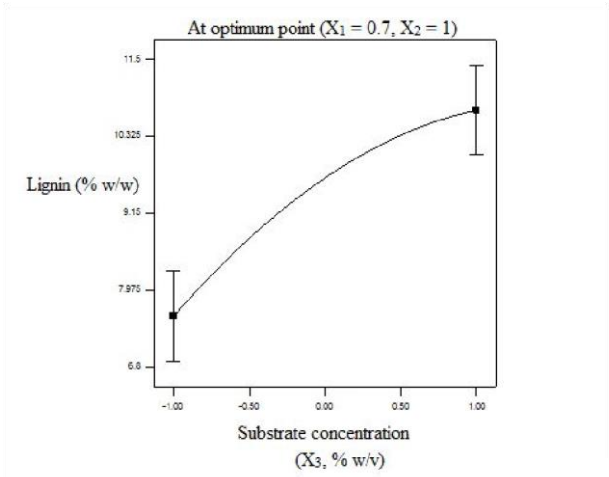

Fig 6 Effect of substrate concentration

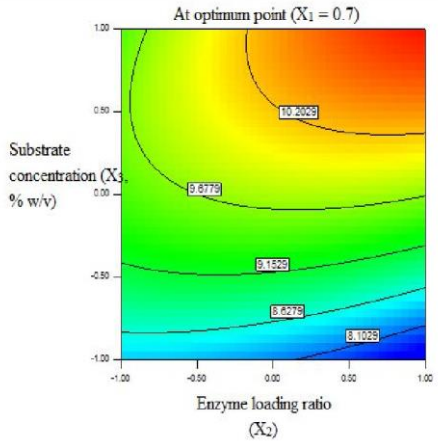

Fig 7 Effect of enzyme loading ratio and substrate concentration on lignin at optimum point

Ash

The statistical analysis of ash was given in Table 7. The model of ash was found highly significant ($P < 0.01$) because it had higher F-value (13.69). It was also observed that the effect of independent variables on ash was highest at linear level due to highest calculated F-value (33) followed by interactive and quadratic level.

Table 7 Analysis of variance for ash

SOURCE	DF	SS	MS	F_{value}
Model	9	4.89	0.54	13.69*
Linear	3	3.96	1.32	33*

Conclusions

The present study was aimed at removal of lignin and saccharification of rice straw for quality improvement of bio-oil. In the proposed work, lignin removal was achieved upto 10% and saccharification resulted in high yields of reducing sugar. Experiments were planned and carried out on size reduced and alkali pretreated rice straw. The best suited set of experiments were used to optimise the process. RSM was used for designing of the experiments and to select the optimum levels of independent variables. Box-Behnken was chosen to design and to determine the combination and levels in each experiments. The three levels of independent variables were time (24, 48, 72 hr), enzyme loading ratio (5:10, 10:10, 15:10) and substrate concentration (4, 5, 6 % w/v). Data obtained from statistical analysis was utilised to get the optimised set of predicted variables. Graphical optimisation was done drawing counters.

On the basis of the experimental results and data analysis shows following conclusions:

The enzymatic saccharification released reducing sugar may have multiple fates viz. Bio-ethanol, Biogas, Bio-oil, Bio-diesel. Reducing sugar yields describe its effects from all three independent variables. Moreover interactive effects were also seen in both numerical and

graphical analysis. Lignin showed responses from substrate concentration. Although little effects were observed from both time and enzyme loading ratio. Ash showd linear effects from all three independent variables.

Hence it could be recommended that for production for better quality of bio-oil, the best suitable saccharification condition of independent variables should be: time 64.8 hours, enzyme loading ratio 15:10, substrate concentration 4.62% w/v. The future scope of this study could show a path towards sustainable, renewable and pollution free energy source.

Abstract

In extracting the highest possible amount of milk from a dairy animal, it is important that the functional and structural features of the milking machines used do not cause irritation to the animal or discomfort to their udders. To ensure that the highest quality of milk is extracted from the milking machines, it is key that a hygienic milking process is employed using hygienic devices. As part of this hygienic process, system cleaning is performed through imitation milking, where milking clusters are attached to artificial milking liners that are connected to a washing boiler, instead of a milking animal. With the system operating in washing mode, detergent and rinse water, rather than milk, are delivered through hoses. The use of a fully automated milking system to minimize errors and reduce the amount of human labor involved in the milking process benefits both manufacturers and consumers. In this paper, a 2x5 (for ten animals) milking unit, operated using Programmable Logic Controllers (PLCs) was designed. The necessary power and control circuits were controlled by software installed on the PLC. With this technology, the milking process can be programmed to automatically stop once the milking is completed. The operator can intervene to stop the system. The system can also be operated manually.

Keywords: *Milking parlor, Programmable Logic Controller, Automatic Washing System*

Introduction

Milk is defined as a whitish liquid, with a specific taste, smell and texture, which is secreted from the mammary glands of mammals immediately following the birth of offspring. Milking is the process of obtaining milk, which is a primary source of income for a dairy plant. Consistency in performance, meaning that the milking is continued until the milking animal is completely dried up, is the key feature of the milking process (Alıç & Yener, 2006).

Turkey is among the fifteen largest milk producing countries in the world, with a total annual milk production of 10 billion liters. Of this production, 90% is derived from cows, with the remaining amount produced from among a distribution of goats, sheep and buffalos lower rates (Demir et al., 2012). In terms of production values, milk production constitutes 15% of the dairy industry (Sağlam et al., 2014). Given the significant economic value of milk and its importance in food products, competitive advantages have been determined by high quality, efficient production practices (Alıç & Yener, 2006). In securing greater operational efficiency to improve profit margins, attention has been increasingly focused on obtaining a high quality and high amount of milk through automated control of the milk production process (Özer, 2014).

In businesses engaging in dairy farming, the milking process constitutes 65% of internal operations, making it a time consuming and demanding production phase (Demir & Öztürk, 2010; Numan & Kadir, 1997). A quickly performed milking process has importance in terms

of operating cost. Failure to perform the milking process in an even manner can significantly affect the health of the milking animal. The style, method and technical performance of milking has both direct and indirect impacts on udder health and milk quality (Hülya & Bilgen, 2004). To increase productivity and quality in milk production, any problems that are present must first be properly addressed, particularly those involving matters related to the hygienic production of milk, which can be overcome by milking as many milking animals as possible in a healthy, clean way, using less manpower and energy, and by following the latest advances made in milking machine technology to develop a strong infrastructure and make favorable investments (Işık & Ünal, 2003).

Today, various types of milking systems are used. These can be grouped under four main classes: hand milking, milking parlors, robotic milking and single-machine milking (Ordolff, 2001; Rossing & Hogewerf, 1997). Out of all the types, hand milking is the poorest quality milking method, as it almost always leaves a little milk in the animal's udder. This milk left in the udder spoils, causing a decrease in the milk productivity of the milking animal, which over time results in major economic losses (Nedret & Tülay, 1997).

In contrast to hand milking, machine milking offers a higher quality of milking. Milking parlors, which feature the use of machines and have a complex structure, have become an indispensable system for milk producers due to their ability to perform mass milking and to conduct hygienic, fast and efficient cleaning.

Material and methods

The Programmable Logic Controllers (PLCs) used in industrial systems provide very effective solutions for general purpose control and automation procedures in all areas of industrial practices (Gök, 2008). The PLC systems have gained an advantage over classical control systems thanks to the flexibility of its software. PLCs can be divided into three main units: Input, Program and Output. The program unit processes the data received by input units via sensors, using a program installed in the memory by the process unit. Outputs are then sent to output units, which enable machine control (Özerdem & Samurkaş, 2003). As part of the industrial development that has taken place in the agricultural sector, these control devices have proven to be effective in producing successful results (Tekin & Değirmencioğlu, 2010).

Figure 1 presents a block diagram demonstrating the PLC input/outputs. A total of seven inputs are used start button, stop button, washing boiler level sensor, transfer boiler level sensor, washing direction button, milking direction button and emergency stop button– matched by a total of seven outputs–vacuum pump, transfer pump, waste water pump, cold water valve, hot water valve, detergent pump and emergency stop.

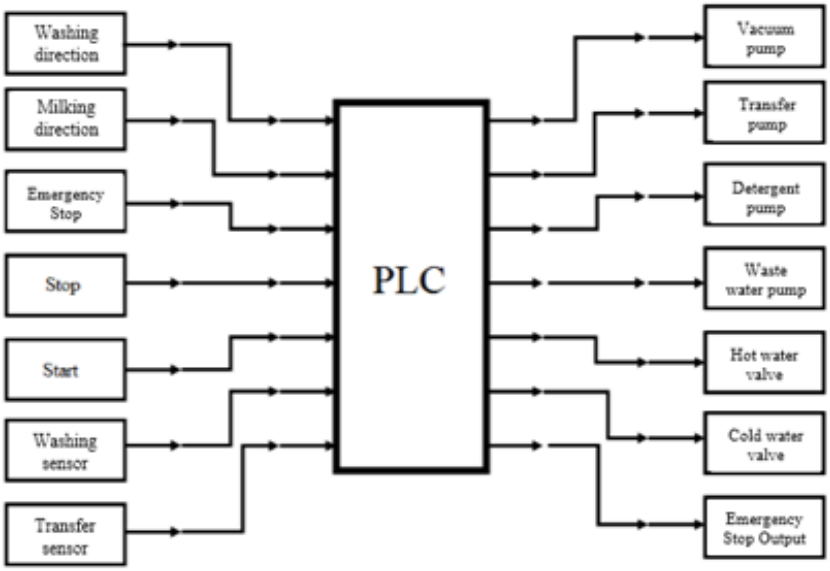

Figure 1. Inputs and Outputs of PLC for Milking Parlor

The system involves two main processes: washing and milking. In the milking mode, the vacuum pump directly activates the milking process once the milking machine liners are attached to the teats of the animal. The milk suctioned from the vacuum hose pours into the transfer boiler. When the transfer boiler is filled up, the milk is transferred into a cooling tank. During the milking process, the transfer boiler is filled up and discharged an average of 10-12 times, depending on the number of milking animals. This process continues until the milking is completed, at which point the milking animals are removed from the milking area.

Once the milking process is finished, the system must be cleaned. System cleaning is done by performing imitation milking, which involves attaching the milking clusters to artificial milking liners that are connected to a washing boiler instead of a milking animal. When the system operates in washing mode, detergents and rinse water, rather than milk, are delivered through the hoses.

The washing procedure is somewhat more complicated than the milking procedure, as it requires more manual actions to be taken. To begin, the milking clusters need to be attached to the artificial milking liners connected with the washing boiler. Next, the pipe between the transfer motor and the cold water tank need to be connected to the washing boiler before switching the routing configuration to the washing mode. When the washing process starts, the washing boiler starts to fill with cold water. Once the washing boiler is filled up, the system-connected sensor activates the vacuum motor by sending a signal to the PLC, and the water inlet is closed. The vacuum motor starts to spin water into the vacuum hose by drawing cold water from the system. Like the milking process, the water discharges into the transfer boiler, and when the transfer boiler is filled up, it sends water back into the washing boiler via transmission of a signal to the PLC (during the milking process, this line is connected to the cold water tank and the milk pours into this tank). This washing cycle continues until completion of the time entered on the PLC screen. When the prescribed time is up, the vacuum motor stops and the transfer boiler transfers all residual water from the hose to the washing boiler, regardless of whether it is completely filled. Any dirty water that has accumulated in the washing boiler is removed from the system via a waste water pump and is sent to the sewage or other proper waste area. The first washing is concluded upon completion of this procedure. The reason for spinning the cold water when performing the first washing is due to the fact that cold water softens solid wastes and prevents them from adhering to the inside of the hoses.

The second washing, which the PLC software automatically proceeds to perform once the first washing is complete, should be done using detergent and hot water. This cycle starts with the simultaneous activation of the hot water pump and the detergent pump. When the detergent, in the amount entered into the PLC system, is poured into the washing boiler, the detergent motor stops and stays open until the hot water washing boiler is filled. Once the washing boiler is filled with detergent and hot water, the sensor directs the vacuum motor to activate again by resending the command to the PLC. The only difference between the first and the second washing is that in the latter hot water is spun into the system instead of cold water. The detergent decomposes the milk and has a chemical structure that inhibits bacterial growth and is effective in breaking down food. When the time entered in the system has been completed, the vacuum motor stops and the transfer pump transfers all detergent water from the system to the washing boiler, and the waste water pump discharges the dirty water out of the system.

The third washing involves rinsing using warm water and is required to remove the detergent from the system. The rinsing process starts as soon as the waste water motor discharges the detergent from the system. Both cold and hot water simultaneously start to flow into the washing boiler. When the washing boiler fills up, the vacuum motor activates and the hot and cold water inlets close. The same washing cycle as mentioned above is exactly repeated. Finally, one more rinsing process is carried out by circulating only cold water. When the entire cycle is completed, the transfer boiler transfers any residual water in the system to the washing boiler. The waste water pump discharges the residual water from the system, marking the end of the washing process. Time, type and number of washings can be changed by entering the desired values onto the PLC screen.

The entire washing process, from the use of detergent, hot water and cold water inlets, activation and deactivation of the vacuum motor to the filling/discharging of the washer boiler and the entering/removing of waste water in/from the system, begins by simply pressing one single button and is automatically controlled by the PLC. Operator does not need to stand over the milking parlor machines while the washing process is in progress.

Although the milking process can be controlled by the PLC, it is important that an operator always be present in the milking parlor throughout the entire course of the milking process, including after performing liner attachment and in the intervening time before removing them from the animal, in order to manage any problems that may occur. While the operator should remain in the milking parlor until the milking process is completed, this, however, is not necessary for the washing process, which only requires that the operator push the button on the screen indicating washing mode and then manually redirect the hoses that are connected to the cooling tank to the washing boiler and attach milking liners to the washing clusters. The washing process lasts between an average of 60 and 90 minutes. Assuming that the washing process is done twice a day, a milking parlor with PLC control saves an average of 2 or 3 hours for the operator.

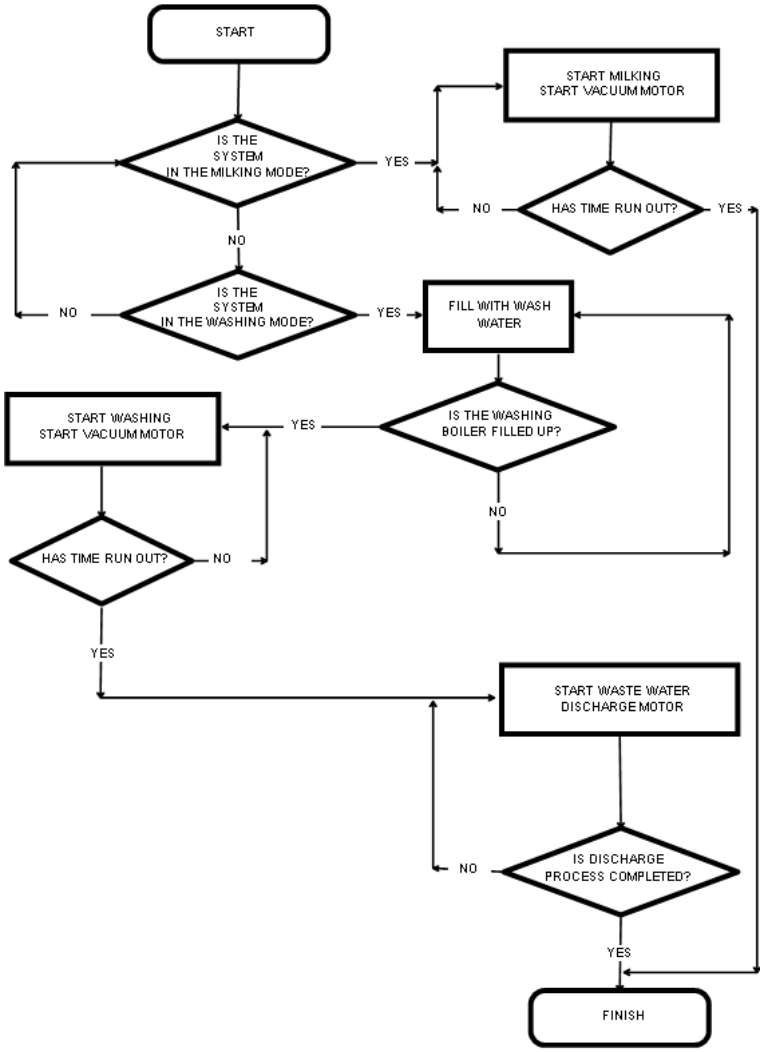

Figure 2. The PLC Process Flow Diagram

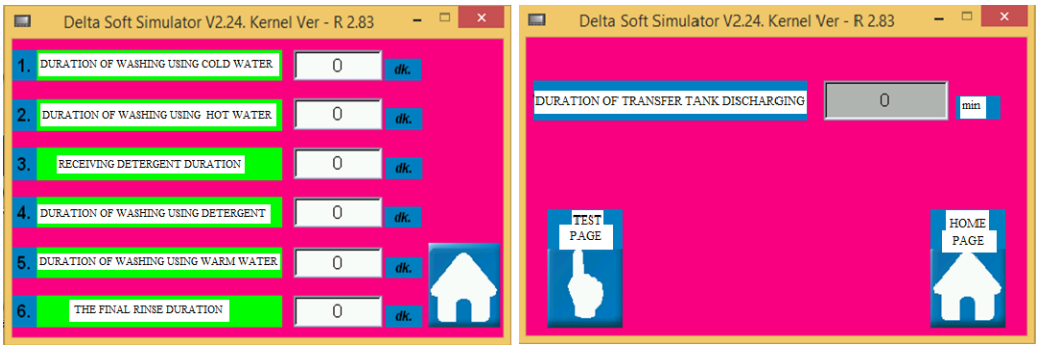

Figure 3. Interface view of Touch Screen Software Developed for the Milking Parlor

The PLC system features a touch screen interface. The screens below are input unit pages which allow operators to assign values to different functions, such as detergent amount, and time, duration and numbers of washing.

Results and discussion

The dairy livestock sector in Turkey has experienced rapid growth over recent years, as it has transitioned from an individual dairy plant system into a much larger system whereby many animals can be fed and milked on one single farm occupying a large area of space. However, the increase in the number of milking animals generates many challenges, such as the loss of time and money that results from having to milk a large number of milking animals by hand or via single machines. To address this particular challenge, milking parlors located on farms can be used for performing the milking process. However, this still leaves the cleaning of the system, which is labor intensive, once the milking process is completed. The cleaning process takes between 60 and 90 minutes on average to complete, and considering that the milking process is done twice a day, this would mean that the cleaning tasks last between a total average of 120 and 180 minutes. Operators in milking parlors generally initially monitor the minutes allotted to the cleaning process; however, in cases when the allotted time for cleaning needs to be reduced for whatever reason, the quality of cleaning is diminished. By performing both the washing and the milking processes with the PLC system, the former of which can be performed simply by entering into the system values for functions such as detergent amount, and times and numbers of washing, major time-saving benefits are realized. On top of that, the benefit of having a hygienic milking parlor, one that is ready for the next milking process, will result in a higher quality of milk.

Conclusion

Cleaning the milking machine is very important in view of milk quality and life of milking equipment. An efficient wash up will remove milk residues and bacteria from the milking plant. No matter which system is used, the milking machine will not be cleaned unless wash up solutions come into contact with all soiled parts of the plant. In the cleaning process of the system, wash up removes any remaining soil, rinse removes milk residues after milking and disinfectant kills bacteria remaining in the cleaned plant. Therefore the sequence of the process is important. Manual systems can execute these processes but the control is depending on the person's experience working in the farm. When suitable program for PLC is prepared, cleaning process can automatically be started after milking. In this way, wash cycle, degree of hot water, cleaning and circulation time can be adjusted in accordance with the manufacturers' recommendations. The wash up system with PLC is more flexible and useful when compared to manual systems.

Abstract

Turkey is one of the main fruit producing countries in the world, which is bestowed with very good topography, soil, and climate conditions that highly support growing of fruit cultivars. In Turkey, more than 85 fruit species are grown naturally. The East Marmara Region had been an important transmission route of trade and cultural interaction through the regions of the Asia and Europe during the past. This study used a questionnaire to obtain data from 97 enterprises about the situation of fruit culture and also employed secondary data of fruit production for the Kocaeli Province, and investigated fruit cultivation opportunities. The information about current and past grown cultivars, technical conditions, and traditions was collected via face-to-face interviews with growers. Frequency distributions, variance analysis, and chi-square tests were performed by using SPSS 22 data analysis program. The results are presented as percentages. In the study, the main problems, we determined, are industrialization and unplanned construction, which have negatively impacted fruit culture. The reported facts in favor of fruit cultivation are increasing awareness of nature and mechanization. Walnut and sweet cherry production has potential value for the future.

Keywords: *Kocaeli, East Marmara Region, Turkey, fruit growers, questionnaire, survey*

Introduction

Turkey is one of the few self-sufficient countries in the world in terms of agricultural produce, which is one of the major income activities of Turkish people. Farming is carried out in all regions in Turkey, and Kocaeli is an important city in the Marmara Region in agriculture field. The geographical location of Kocaeli is between 40°–41° N and 29°–31° E, surrounded by the Gulf of İzmit at south, Istanbul and the Sea of Marmara at west, the Black Sea at north, and Sakarya at east. The climatic conditions in Kocaeli are very suitable for fruit cultivation. The average temperature is 14.8 ºC, the number of sunny and frozen days is 75 and 15.1, respectively, and total average rainfall is 798.6 mm in a year (Anonymous, 2007). Precipitation is high and evenly distributed throughout the year. The favorable conditions, such as fertile soil, adequate climate, and abundant rainfall, allow growing of almost all kinds of fruits. Kocaeli includes total twelve districts, and of them, fruit orchards are mostly common in six: Karamürsel, Gölcük, Kartepe, Başiskele, İzmit, and Körfez. Total cultivated area in Kocaeli is 156.759 ha and around 19.239 ha of the cultivated land is irrigated. Fruit produce accounts for 12374 ha of the total agricultural production (Anonymous, 2013). Sweet cherry, walnut, olive, and apple are among the most common fruit products, while hazelnut is common in Kandıra district, but was not taken into consideration in this study.

Since, in Turkey, natural conditions are very suitable for agriculture and it is the main source of income for Turkish people, the main objectives of the current study were:

- To study the enterprise structure of fruit growing farms in Kocaeli;
- To examine the cultural and technical properties of enterprises;

- To determine the conflicts and opportunities, to suggest possibilities and make recommendations for improving the fruit cultivation in the study area.

Material and Methods

This study was conducted between the years 2013 and 2014 in two phases. In the first phase, the data about fruit production in Kocaeli Province were collected and from this, the secondary data (statistical data) were obtained. In the second phase, fruit cultivation was investigated for technical and social aspects in Kocaeli region. A questionnaire-based survey was carried out for the enterprises to determine the situation of fruit culture, and the major limiting factors for quality production were determined. In a historical and current scenario, the grown cultivars, technical conditions, evaluation, and traditions were investigated. For this purpose, face-to-face interviews were conducted with 97 growers individually. The data were evaluated for frequency distributions, variance analysis, and chi-square tests using SPSS 22. The obtained data were analyzed in the light of literature. The study was carried out in six districts of Kocaeli region: Karamürsel, Kartepe, Gölcük, Başiskele, İzmit, and Körfez. These areas are important and rich in fruit cultivation around the İzmit Gulf (Figure 1).

Results and Discussion

Most of the participants are between 61 and 70 years of age, more than 50% of growers are over 50 years. Among the participants, 68.04% are graduated from primary school. Only six participants are having university degree (Table 1). Table 1 shows that most of enterprise owners are solely involved in fruit growing only, and few of them are involved in other jobs. It was observed, while examining the past of agricultural activities, that the fruit cultivation was started 70–80 years ago with apple, pear, and sweet cherry and walnut. Of the enterprises, 35% were established 31–45 years ago, and most of the growers acquired this as their parental business (Table 2). The various modern agricultural tools used by most of the enterprises in the study area are tractors, mechanization, insecticides, fungicides, herbicides, fertilizer, grafted saplings, and modern harvesting. Tillage, pruning, and spraying are common cultural practices in all enterprises; however, modern irrigation system has recently started to be used. Generally, flood irrigation is common and irrigation water is supplied from irrigation channel, artesian, and natural stream (survey results).

For the surveyed enterprises, the different cultural criteria were compared with chi-square analysis, and a significant relationship between the owners' job and the preferred irrigation system was found. Flood irrigation system is the most preferred system among the farmers (39.8%) and factory workers-farmers (60%), while tradesman-farmers prefer to use sprinkler irrigation system. It also depends on available time of the people. Farmers have much more time than other owner groups, so if water resources are enough, flood irrigation is preferred owing to its low cost (Table 3). There is a relationship between the job of owners and irrigation system (Table 3).

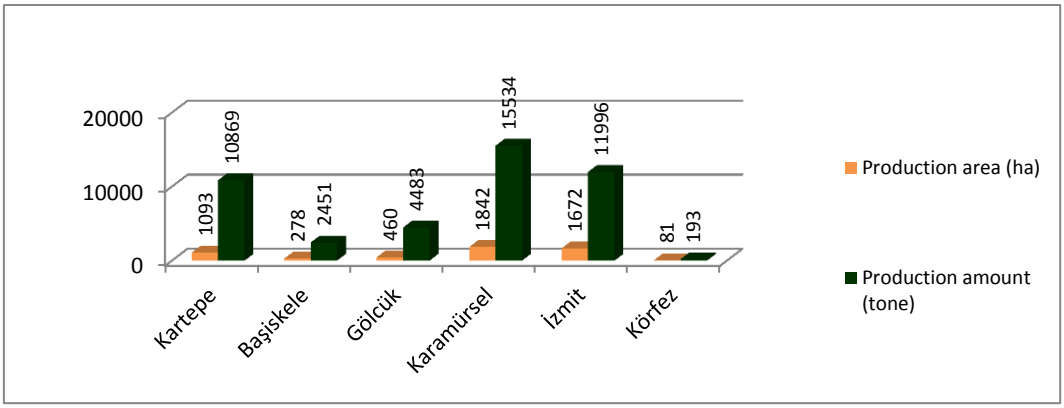

Figure 2. Distribution of fruit growing in districts*

* Source: Kocaeli Provincial Directorate of Food, Agriculture and Livestock, 2013.

The highest fruit production area and the production amount were reported for Karamürsel district in Kocaeli region (Figure 2). The maximum fruit production area and production amount were reported for hazelnut.

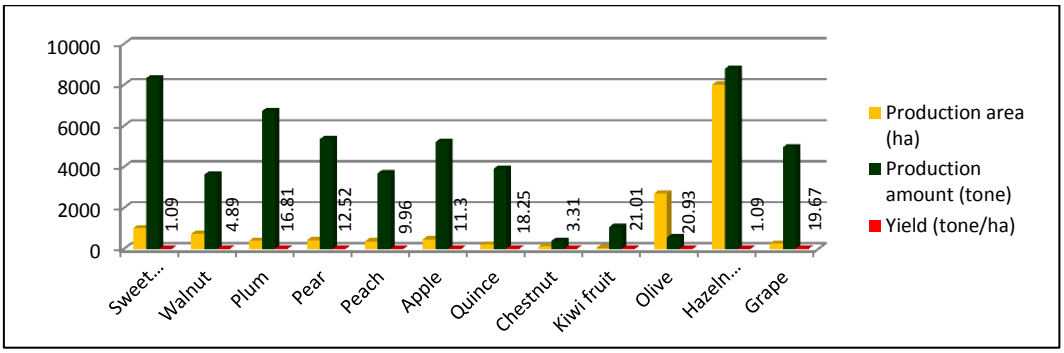

Figure 3. Fruit production in Kocaeli Province according to fruit species**

*Hazelnut production is common in Kandıra district while other fruits are cultivated at low level. Kandıra was not studied herein.
** Source: Kocaeli Provincial Directorate of Food, Agriculture and Livestock, 2013.

Sweet cherry is the most produced fruit in the studied field and plum production is the second one (Figure 3). Most of the studied enterprises are located in Gölcük (sweet cherry and pear are the most grown products) and Kartepe (pear, walnut, and apple are the most grown products); and fruit cultivation is an important income activity in these places (Table 4). The major cultivars grown in these areas are given in Table 5. Chestnut is mostly cultivated in forest land, and modern chestnut orchards have recently been planted.

Pruning is common in Gölcük and Kartepe orchards. Among the farmers, 93.81% accepted practicing pruning. Regular pruning is done every year in all districts except Başiskele (Figure 4). Some pruning courses were organized in these districts in the recent years. There is a relationship between the experience level of growers and the soil analysis for fertilization (Table 6).

Table 4. Distribution of cultivated fruit species in the studied enterprises**

Fruit species	Number of enterprises in the districts*

Table 6. Relationship between the experiences level of growers and soil analysis for fertilization**

	Yes			No			F Degrees	P*
	n_1	X	S_d	n_1	X	S_d		
Experience level (year)	56	35.6	17.8	41	40.6	16.5	0.650	0.920

*$p<0.05$

**Before determining the relationship between the variables, soil-analysis and experience of the growers, was tested with normal distribution test, and both parameters were found normally distributed. However, no significant difference between these parameters was found as a result of variance analysis. Experience levels of growers who carried out soil analysis are less than others.

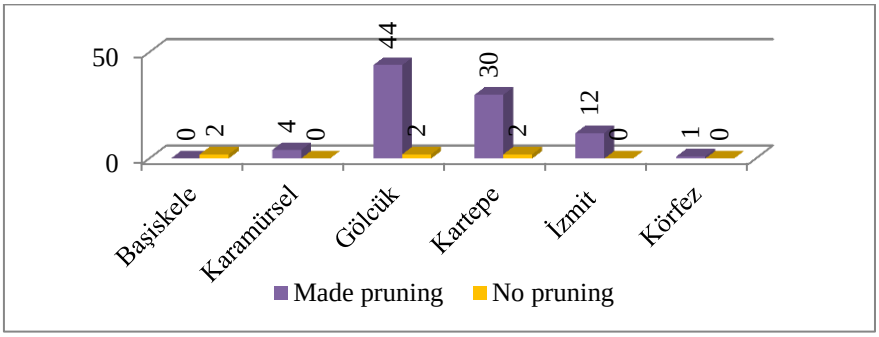

Figure 4. The distribution of pruning practice in orchards in the surveyed districts

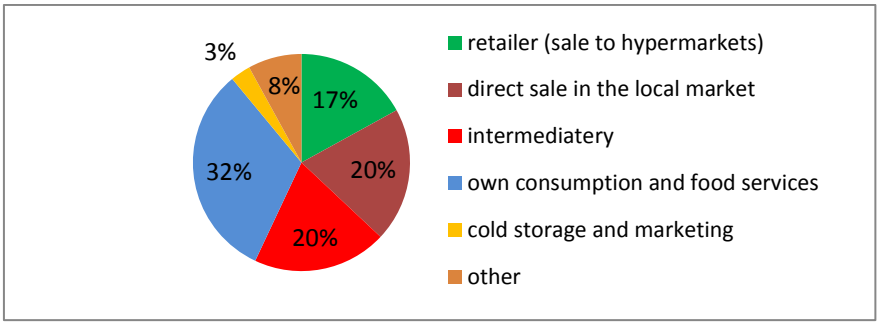

Figure 5. The marketing means of produced fruits in Kocaeli

The products are mostly used for own consumption or sale for jam or other processed products. Of the produce, 20% is sold as fresh in local markets by the growers, and 20% is sold to intermediaries.

Cold storage is limited in the study area and only 3% of the produced fruits are stored by the growers and sold at higher prices out of the season (Figure 5). This study revealed that the wholesale market is the most preferred marketing channel for fresh agriculture produce, followed by local market.

Conclusion

The main supporting factors for fruit cultivation are ecological conditions (climate and soil fertility), people's knowledge level, and environmental awareness. The greatest strength of fruit cultivation in the surveyed area is the willingness of the people and widespread use of mechanization. The survey results indicate that the environmental awareness is high among the growers. The measures of plant protection against pests are taken in due time with implementation of integrated pest management. The lack of enough credit to support a small enterprise was found as the most important weakness of the growers. The uncontrolled construction is the most important threat to agricultural fields. Industrial pollution is another threat to agriculture, especially for production of sensitive fruits. The division of agricultural land by inheritance is increasing the production costs. Input cost is very high and credit supports are limited. Based on these results, it can be concluded that fruit production has a vital role in the surveyed area. The important strategies need to be employed for a sustainable fruit cultivation include,

- The development of infrastructure for modern fruit cultivation;
- The planting of economical varieties with high economic values;
- The development of governmental supports;
- Considering the quality of crops and development of marketing programs based on farmers' needs.

Abstract

Tourism is an economic event that provides a balance between natural, social, cultural and economic values. It is a sector that leads to recognition of other communities and individuals. In Turkey, the draw of tourism is primarily the sun in the summer; tourism is perceived as a type of triangle formed by the sea and sand. In recent years, in rural areas of Turkey, rural tourismhas beenadopted as a new approach that shows rapid progress. The rapid progress is what makes rural tourism be included in the regional analysis. Rural tourism must say that talking about the importance of making the regional analysis. This study examines the status of rural tourism areas and aims to determine the existing and potential rural tourism value of Kastamonu by the GIS method. GIS modeling of mapped areas shows the rural tourism potential of the area. Identification of regional opportunities for rural tourism in general is very important in terms of determining more realistic tourism strategies. The development potential of rural tourism is determined based off of the details of the strengths and weaknesses of the region, exposing the threats and opportunities. The main aim of this study is based on this idea. Turkey will be an important area in terms of rural tourism. This study will evaluate the rural tourism potential of Turkey in 2023 based ona study of the Kastamonu province, highlight the importance of the tourism strategy and make recommendations for improvement.

Keywords:*Rural tourism, Kastamonu, GIS, SDG 2015-2030*

Introduction

Oppermann (1996) researched that the negations of researches on rural tourism is joined further by the absence of a mostly accepted description as to what creates rural tourism. The large variety of rural areas with respect to size and type further perplexes what creates rural tourism. In an attempt to sieve the incoherency surrounding the notion of nonurban, farm, and rural tourism, a cognitive model may be advised (Redclift 1992; Sidali et al. 2015; Marzo-Navarro et al., 2016). Peng & Lin (2016) concluded that it considered to the cultural and economic well-being of rural societies, the protection of the environment or the addition of local citizens in decision-making (Sidali et al. 2015; Guzman-Parra et al. 2015; Kim & Jamal 2015). Briedenhann & Wickens (2004) studies that tourism has been determined as a catalyst to revive economic development ascend the property of being viable of undeveloped areas and develop the normal of living of local societies, In Eastern Europe, where cases of the last ten years have launched a sudden increase in rural unemployment (Redclift 1992; Jepson & Sharpley 2015; Nair et al. 2015; Marzo-Navarro et al., 2016). According to the forecasts of the World Tourism Organization, the tourism sector has been recognized as an industry that will continue to grow and develop quickly over the next 20 years. As of 2020, the world-wide tourism pie is estimated to be approximately $7.6 trillion (WTTC, 2015). Described as a service industry, the tourism sector takes an important place in the economies of developing

countries such as Turkey. Tourism is one of the important dynamics in the spreading of income because it enables balanced regional development in terms of economic and social development (Cetin & Sevik 2016a; Cetin & Sevik 2016b; Cetin, 2016a, Cetin, 2016b).

The development of industrialization has considerably changed the direction of the demand experienced today with rapid urbanization, tourism and people moving away from tiring and unhealthy environments. The ocean areas and mountainous, forested regions have turned to rural areas. The richness of traditional culture stresses the natural environment and causes the recreational needs of urban people today to demand the tourism aspects of the sea, sand and sun (Bramwell, 1994; Fleischer & Felsenstein, 2000; Sharpley, 2002; Wilson et al. 2001; Cetin, 2015c; Cetin, 2015d; Cetin, 2016a, Cetin, 2016b). On the other hand, the increasing of development between rural and urban areas in Turkey is deepening. This has led to an increased population migration from rural to urban areas. One of the leading sectors of rural development seen as a way to resolve the disparities is rural tourism. Especially in rural areas where the density of the geographic care of promoting rural tourism in rural areas of agricultural organizations using both agriculture and tourism resources as a significant contribution to economic growth and development of rural areas will be provided. In the determination of tourism policies and plans, the economic and social functions of rural tourism should be considered carefully (Fons et al., 2010; Getz & Carlsen; 2000; Cetin, 2015c; Cetin, 2015e;Cetin & Sevik 2016c; Cetin & Sevik 2016d; Cetin, 2016a, Cetin, 2016b). Because of its rich geography, Turkey is ready to be evaluated in regards to rural tourism in rural areas, and there are a lot of options. Kastamonu is one of the locations with rural tourism potential that is waiting to be assessed. In the province of Kastamonu, in the north of Turkey, is the city center. It gets away from crowded places. It has types of tourism that should be considered in the city but that have been neglected for several reasons: cave tourism, plateau and mountain tourism and cultural tourism include watching endemic plants.

The aim of this work follows this direction: The potential of Kastamonu rural tourism to the identification of potential problems so it can take its rightful place in tourism.Tourism resources are a sustainable way to develop suggestions as to what should be done in order to make an impact on development in the countryside. According to a study done by the European Union (EU), rural tourism includes agricultural areas or tourists who nested to be purpose nicely spend time with local values, stay in line with expectations, food, drinks and other services that small where small-scale business settlement is defined as a set of implemented activities (Bramwell, 1994; Fleischer & Felsenstein, 2000; Sharpley, 2002; Wilson et al. 2001).

Rural tourism, which integrates rural culture, the natural environment and agriculture, is a type of tourism that can be extremely easy to integrate with other types of tourism. On the other hand, there is a correct relationship between rural tourism and rural development. Rural tourism in non-agricultural diversification of rural areas is a symbol of success. The richness and diversity of natural and cultural assets in rural areas pose a significant potential in terms of tourism and the development of recreation activities. Rural tourism development, while ensuring a balance of history, provides for the protection of cultural and natural tourist attractions. It is characterized by the maintenance of more sustainable mass tourism (Fons et al., 2010; Getz & Carlsen; 2000;Wilson et al. 2001;Cetin, 2015a; Cetin, 2015b; Cetin, 2015c; Cetin, 2015d). However, tourism should not be considered as an alternative to agricultural activities in rural areas. Rather, it should be a complementary position. Because there used to be important agricultural production in this region, it is opened to tourism.By leaving agricultural activities such as farming and forestry, however, that region has crafts and architecture, and the cultural structure is protected from degradation. From this point of view, rural tourism is the most compatible type of tourism with a sustainable tourism approach. The protection of tourist attractiveness is something essential for sustainable tourism (Getz &

Carlsen; 2000; Wilson et al. 2001; Cetin, 2015a; Cetin, 2015b; Cetin, 2015c; Cetin, 2015d; Cetin & Sevik 2016b; Cetin, 2016a; Cetin, 2016b).
Ecotourism, which may be referred to as sub-category of sustainable tourism, requires responsible travel to natural areas in order to ensure the sustainability of the welfare of the local people and environmental protection. Although travel is very popular, it cannot protect or improve the attractiveness of a destination if it cannot keep its place in the international market. The concept of sustainability indicates that without putting in danger the future of tourism resources, the best way to benefit is of paramount importance (Cetin & Sevik 2016a; Cetin & Sevik 2016c; Cetin & Sevik 2016d).
Sustainability is not only true of natural resources; it is also an aspect of a long-term cultural resources (Cetin, 2015b). The continuation of the attractiveness of tourism ina region is possible with sustainable tourism development. Tourism development, a market share in international markets andthe added value created in the sectors connected to tourism between growth and conservation are seen as a development model that allows benefits to be transferred to future generations through efficient use of tourism resources and the present generation but also aims for the maximum satisfaction of future generations.

Materials and methods

Kastamonu is a research area that isrich in natural, rural areas. In order to put forward the research area of Kastamonu as having rural tourism potential, visits to the region have been made at different times in order to obtain detailed information.
The northern part of the Kastamonu, Turkey province is located in the Black Sea region as shown in Figure 1. There are provinces in the north of the Black Sea coast. The province of Kastamonu also has a city of the same name.
All of the northern part of the province creates the Black Sea coast; the province's coastline length is 170 km. Kastamonu Black Sea coast has the longest coastline length of this province, 13 108 km^2, located in Kastamonu, Turkey, and accounts for 1.7% of the territory. The city center is 780 meters above sea level. The average height of land in the province is 775 m above sea level. The province forms the highest point of the hill with Çatalılgazat 2,565 m. Mountains across the province extend parallel to the sea;they cover a large portion of Turkey's projection extending towards the Black Sea (Municipality, 2016).
Obtained in the field of researchphotos and documents has been reached.
Data analysis in research, synthesis and evaluation play basic base as of 2015 Tape 10 × 10 m spatial resolution satellite imagery, digital elevation models (DEMs) image of 1:25,000 scale topographic maps are used in the study to support the creation of the necessary methodological approach to the planning of a landscape-oriented system. In this context, the research method used consisted of main phases: (1). Determination of the areas to be the focus of shots, (2).To reveal the weight of the rural tourism potential of this focus, (3).consists of three sub-stages, according to the classification of focal potential rural tourism shooting weight.

This study was formed after a detailed review of the literature as well as related issues; it has also benefited from various Internet sources. All data obtained from the survey was transferred to this work.

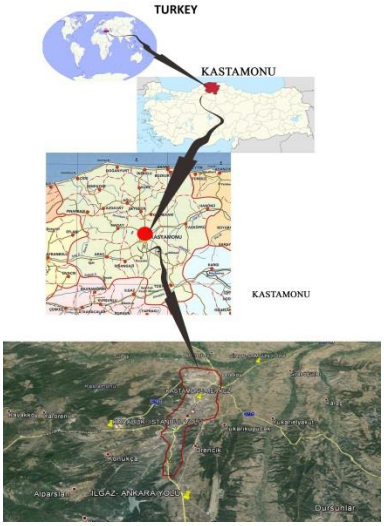

Figure 1. Location of Kastamonu

Results and discussion

In regards to developments in Turkey and the uniform distribution of cases between regions, uneven distribution of the level of development of tourism between regionsis a sector that can have the maximum level of importance. However, a well-planned structure can minimize disparities between provinces, districts and even counties.

A very important responsibility for local managers at this point is reduced because local officials have more information on local issues and can decide quickly about them. In addition, a local manager of development policies and economic development, according to the rules of good governance in the region, will also provide socio-cultural development. In order to eliminate disparities in the region, tourism planning should be structured to include both the rural and the urban areas of the province.

In Kastamonu and the surrounding area, in addition to cultural tourism and nature tourism there are many suitable alternative tourism areas of potential. However, tourist arrivals to Kastamonu do not know enough about the potential of rural tourism alternatives, because the tourism potential has not been introduced to the visitors. Therefore, the majority of tourists are daily visitors from Kastamonu.

In order to solve these problems for the tourist and increase the value of Kastamonu, there needs to be a sustainable tourism plan with a holistic perspective. As is known, tourism is an important sector in terms of social welfare and development. If the relevant institutions and organizations identify and target their efforts in this direction, it will determine the future situation of Kastamonu tourism.

Conclusions

Rural tourism conducted with this research subjects in Europe, in Spain in Malaysia, In Korea that rural tourism model created and redefining rural tourism perspective (Sidali et al. 2015; Jepson & Sharpley 2015; Nair et al. 2015; Guzman-Parra et al. 2015; Kim & Jamal 2015)

In accordance with data obtained under investigation,the city is ready to be evaluated in regards to the rural tourism potential so it can take the place it deserves and recommendations can be made to make an impact on the development of rural tourism resources. Figure 2 shows those rural potential areas.

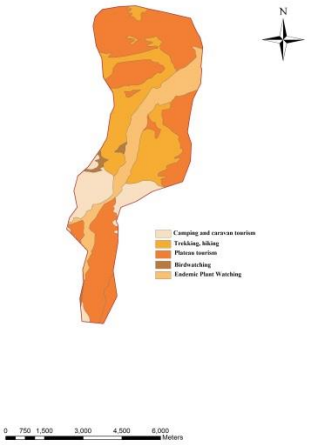

Figure 2. Potential of Kastamonu rural tourism

Cooperation and coordination between tourism stakeholders should be ensured. Kastamonu in general, tourism businesses local governments should all act together with universities and Non-Governmental Organizations in planning what should be done,because tourism planning should be limited to the sector itself. The planning of tourism should strengthenthe local people's priorities and values while integrating public participation.

The city's infrastructure and superstructure facilities must be reviewedand conditions improved accordingly. In addition to tourism in a way that will not harm the environment, infrastructure and superstructure facilities should be brought to the appropriate level to meet the expectations of tourists.

Local people should be trained regarding the city's tourism value, and local people must also be respectful to ensure awareness of protection for this resource value. Awareness is of great importance to the sustainability of tourism.

Each destination has the property of being unique in itself. However, it is important to realize the development of tourism and planning, understanding that the differencesare the uniqueness and value. The most important factor affecting the success of a tourist destination and its accurate positioning is a strong brand image created by a viable and attractive areas.

A destination brand is the transmission of a certain image to tourists and is an effective and popular tool to the destination becoming placed in a key role. The words brand destinations based on the quality and high service performance and are located in the fulfillment of these promises.

Region-specific products (food, drinks, crafts, etc.) must be converted into tourist products. In rural areas,studies on the preparation of a comprehensive inventory of culture and folklore studies in regards to development, handicrafts, local festivals, traditions, etc. should be performed in regards to the value to tourism.As understood from botanical research, theregion is rich in endemic plant diversity. Rural areas across the surface flora

Revealing the research and inventory is recommended.

Historic houses with their own unique aesthetic architecture of the city should be restored and transformed into places that display of the value of the region. Authentic regional dishes for tourism activities can be offered in locations.

Making some arrangements without destroying the cave is recommended for tourism, because improvements being made in and around the cave is of vital importance for the evaluation of a future tourist city.

Arrangements for some of the needs of visitors while maintaining the charm of the plateau should be made, and it should be opened to tourism. In rural areas, cool, fresh-air springs are

springs with high landscape valueneededfor tourism and nature, with clean, potable water sources.

As a result, the basic economics of tourism in rural areas complement and increase the employment of women supporting the use of local products.Visitors play an important role in supporting rural development that enables participation in local events. Diverse natural and cultural tourism resources are located in the city. However, these resources will make an impact on rural charm when used for tourist development. A holistic perspective of Kastamonu tourism city planning and the potential of rural areas directing a rational evaluation of potential tourism resources can be an important tool for the rural development of the existing tourism resources in the city.

RURAL ECONOMIC DEVELOPMENT STRATEGY THROUGH PRIORITY RURAL SECTORS IN THE REPUBLIC OF MACEDONIA

Blagoj GORGIEVSKI[1]*, Marija GJOSHEVA KOVACHEVIKJ[2]

[1] University "St. Kliment Ohridski", Bitola, Faculty of law, R Macedonia,
[2] Institute of Sociological, Political and Juridical Research University, Skopje, R Macedonia

Abstract

The rural areas of development strategy is an inhabited territory where the social, economic and residential evolutions are led within the framework of an integrated and prospective project of development. The rural pole is not a small town, an agglomeration, but they are treated as a whole and guided by an integrated project of territory. Initially, this study are focused to priority regional sub-sectors in R. Macedonia in order to identify the major weaknesses to be addressed and potentials to be boosted. Furthermore, the elaboration refers to assessment development strategy of priority economic sectors in the rural areas, defining the main problems, possible solutions to solve them. The analysis of the regional differences is also included in the paper as well as the differentiation and prioritisation in itself . In terms of the structural adjustment through priority rural areas of the country's, the emphasis of study will be placed in particular on increased production competitiveness and higher quality of products. For that goal have to pay attention to measures at improving the competitiveness of economically viable agricultural holdings and food industry in selected sub-sectors through proper investment policies.

Keywords: *rural, strategy, development, policy,sectors , strategy.*

Introduction

The theories of economic geography primarily address issues of relevance for the spatial distribution of the production, they also contain clear connections to growth. The endogenous growth theory constitutes the bridge between agglomerated production structures and growth. According to the latter theory, growth is primarily increasing in the accumulation of knowledge through spillover to other users, i.e. it is only partially excludable and appropriated by the firms investing in knowledge. Economic geography contends that proximity is essential in order to access spillovers, pecuniary and non- pecuniary, originating in the interaction between people, firms and institutions, through vertical and horizontal linkages. Furthermore, concentrated production also gives rise to external scale effects. Thus there would appear to be a clear link between growth and densely concentrated production. This has preciously been discussed in the theoretical literature (Fujita and Thisse, (2002) Perroux, Kaldor (1961), Myrdal (1957) and Hirschman (1958)).

The recognition of the rural areas as development poles, and neither only as natural and agricultural spaces, is a precondition to stimulate advantageous and balanced exchanges between the urban and rural poles and to motivate the convergent mobilization of the urban and rural actors.

The rural pole of development is an inhabited territory where the social, economic and residential evolutions are led within the framework of an integrated and prospective project of development. The rural pole is not a small town, an agglomeration, but a rural areas as a whole and guided by an integrated project of territory.

Also, the emergence and the animation of these rural issues of development must be based on the principal following elements:

- a rural territory with a project built on a common political ambition and on shared economic and social interests;
- an integrated project of sustainable rural development, including means and measures within the scope of a multiannual programming;
- collective implementation and local partnership based on a co-operation between public and private institutions;
- co-operation between rural areas and between rural and urban areas, with a networking approach which favours a process of continuous training ;
- a framework of evaluation, to enhance the effectiveness and the efficiency of the of rural development trough rural areas and its sustainability.

This paper study rural development of priority rural sectors in the regional structure in the country, defining the main problems, possible solutions on the basis of the priorities set forth. Analysis of the regional differences is also included in the paper as well as the differentiation and prioritisation thereof. A detailed summary of priorities and support measures are also included. At first it makes identification of sectors in the rural areas in certain regions with the greatest formative development potentials. Further are elaborate policies, programs and measures to help reinforce existing economic potential in the respective rural sectors. Hence the need to develop appropriate institutional structure that will enable full support for rural regional development.

Material and methods

In the first stage of elaboration, the principal priorities were identified priority rural sectors in consultation with various rural sector stakeholders. Initially, this study was prepared for priority sub-sectors in the regions (milk and dairy, meat and meat products, fruit and vegetables and wine and grapes) to identify the major weaknesses to be addressed and potentials to be boosted. The four sub-sectors were selected based on their importance in the agricultural GDP and according to the process of adoption of the EU acquis according to the NPAA and institutions related (Self-governments, regional agricultural departments, regional offices of the National Extension Agency, Farmers Federation and Non-governmental organisations). The programme was based on the National Development Plan (NDP), the National Strategy for Agriculture and Rural Development and the National Programme for Adoption of the Acquis (NPAA), as well as the Multi-annual Indicative Planning Document (MIPD), framework of available measures under Instrument for Pre-accession Assistance for Agriculture and Rural Development (IPARD) and the results of the independent sub-sector analysis.

Results and Discussion

Regional development in the R. Macedonia is a process of identification, promotion, management and use of development potentials of the planning regions and the areas with specific development needs. The policy for regional development, on the other hand, is a system of goals, instruments and measures directed towards a decrease of regional disparities, and the achievement of equal and sustainable development in the Republic of Macedonia.

General feature for all regions are that rural areas show much better results from urban because of the collapse of obsolete industrial plants. The regional disparity analyses shows an greater participation in GDP formation in the regions with predominantly participation of agriculture as an economic activity (Pelagonija, Polog and Southeastern regions) of the country.

For administrative purposes, the differentiation between rural and urban areas in the country is based on the local territorial divisions according to the Law on Territorial Organization of the Local Self-Government (OG 55/2004, 12/2005) i.e. Article 6. The common method,

which will be applied for the purpose of this investigating is defining rural areas as being located outside of urban area and characterised by three main characteristics:

- settlements placed in municipalities based in rural centers (rural Municipalities),
- settlements placed in municipalities based in town centers with predominantly agricultural and forests land use systems (urban versus agriculture land (incl. forests, pastures, marshland,

fishponds) and

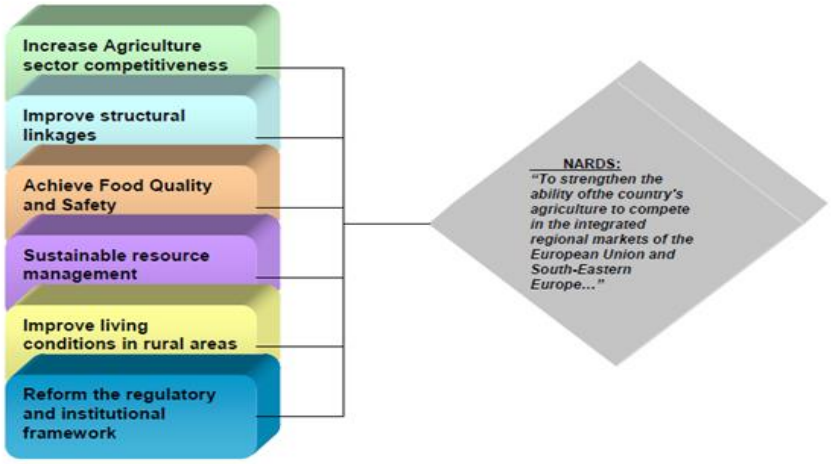
- towns with population of less than 30,000 inhabitants with predominantly agricultural and forests land use systems (urban versus agriculture land (incl. forests, pastures, marshland, fishponds) and has rural identity of the community

According to the National Agricultural and Rural Development Strategy (NARDS), has translated the overall development vision into following long-term sectoral strategic objective as the basis for agricultural and rural development and formulation of future agricultural policy: **"**To strengthen the ability of the country's agriculture to compete in the integrated regional markets of the European Union and south-eastern Europe through measures to increase the efficiency of agricultural production, processing and marketing, and to build appropriate, effective public and private institutions; to improve farm incomes; to ensure that consumers have access to safe, healthy food; to optimize the use of scarce land, forest and water resources, in an environmentally sustainable manner; and to build viable rural communities through sustainable rural development.[1]

The main general objective (figure 1) of the rural development is to: "Improve the competitiveness of agricultural holdings and the food industry developing them to comply with Community standards, while ensuring sustainable environmental and socio-economic development of rural areas through increased economic activities and employment opportunities."

[1] Nacional strategy for agriculture and rural development 2007-2013, p. 210

Figure 1 – National Agriculture and Rural Development Objective



Final version of the IPARD programme for the Republic of Macedonia

This shall be achieved through following specific objectives:

- Improving the technological and market infrastructure of commercial agricultural holdings and food processing industry aimed at increased added value of agri-food products and achieved compliance with EU quality, health, food safety and environmental standards
- Improved quality of life of rural population, increased income and creation of new employment opportunities,

The main priority are planning the agricultural development and the development of the rural areas, agricultural policy measures and the holders of the right to benefit from those measures, minimum quality and designations of the agricultural products, setting up of databases and supervision over its implementation.

In support to the structural adjustment of the country's agricultural sector (the main sub-sector in the rural economic sector), the emphasis will be placed in particular on increased production competitiveness and higher quality of products. For that goal have to pay attention to measures at improving the competitiveness of economically viable agricultural holdings and food industry in selected sub-sectors through investment policies to improve technological and market infrastructure aimed at increased added value of agricultural products and achieved compliance with EU quality, health, food safety, animal welfare and environmental standards.

The investments per priority sectors (wine and grapes; fruits and vegetables; milk and dairy; and meat products) broadly cover costs for replanting the areas covered with perennials (vineyards and orchards), construction and reconstruction of farm buildings and installations for farm buildings as well as auxiliary buildings, purchase of equipment for farm buildings, improvement of on-farm irrigation systems and specialised agricultural machinery as well as on-farm manure handling to upgrade the agriculture holding to meet EU environmental requirements.

The investments per priority sectors broadly cover costs for improvement and optimisation of production flows in processing and marketing of agricultural products; setting up or modernisation of local collecting networks, of reception capacities, storing, conditioning, sorting and packing of agricultural products of agriculture products .

For that goal must be fulfilled the certain priority measures as is : improving the technological and market infrastructure of commercial agricultural holdings and food processing industry

aimed at increased added value of agri-food products and achieved compliance with EU quality, health, foo safety and environmental standards. For achieve that it is necessary to investments in agricultural holdings to restructure and to upgrade to Community standards and investments in processing and marketing agriculture products to restructure and to upgrade to Community standards.

The potential key issues to be addressed are investments in agricultural production to restructure and upgrade the sector to Community standards and to increase competitiveness and improving market efficiency and implementation of Community standards. Therefore the upgrading of the farms and the food establishments to meet the environmental, hygiene, food safety and animal welfare standards is of high importance.

Ongoing task is improved quality of life of the rural population, increased income and creation of new employment opportunities The potential key issues to be addressed in country are investments to develop and to diversify economic activities in rural areas which creating additional income sources and employment opportunities in rural areas. Priority sectors and the type of eligible investments concern to support to micro enterprises in the rural areas (reconstruction of on-farm houses for rural tourism activities complemented with recreational facilities; construction of catering premises, outdoor accommodation camping sites and recreational facilities; reconstruction of old traditional on-farm buildings for rural tourism activities complemented with recreational facilities) and promoting rural tourism activities.

Well-placed and developed general targets and measures to achieve them but lacking public rural institutions to established capacity to design and implement appropriate rural policies in priority rural sectors. Lacking also appear in identification and evaluation of rural areas as a pole of rural development and built of rural policies and programs for their support. Furthermore, it is necessary the emphasis role of young rural labor in the rural areas as one of the determining factors of rural development in the country not given sufficient attention. Not sufficiently designed policies and programs for the use of scientific knowledge (especially in the field of modern agricultural technologies) for the purpose of rural development

Conclusion

The rural development is to improve the competitiveness of agricultural holdings and the food industry developing them to comply with Community standards, while ensuring sustainable environmental and socio-economic development of rural areas trough improving the technological and market infrastructure of commercial agricultural holdings and food processing industry. In this way is increased added value of agri-food products and achieved compliance with EU quality, health, food safety and environmental standards as and improving quality of life of rural population, increased income and creation of new employment opportunities.

In support to the structural adjustment of the country's agricultural sector, the emphasis will be placed in particular on increased production competitiveness and higher quality of products. For that goal have to pay attention to measures in order to improving the competitiveness of economically viable agricultural holdings and food industry in selected sub-sectors through development investment policies.

The investments per priority sectors broadly cover costs for improvement and optimisation of production flows in processing and marketing of agricultural products; setting up or modernisation of local collecting networks, of reception capacities, storing, conditioning, sorting and packing of agricultural products of agriculture products .

The potential key issues to be addressed are investments in agricultural production to restructure and upgrade the sector to Community standards and to increase competitiveness

and to *develop and to diversify economic activities in rural areas* which creating additional income sources and employment opportunities in rural areas

THE COMPETITIVENESS OF POLISH FOOD PRODUCTS ON THE INTERNATIONAL MARKET

Małgorzata BUŁKOWSKA

Institute of Agriculture and Food Economics, National Research Institute, Poland

Abstract

The enlargement of the European Union (EU) resulted in a significant increase in trade in agri-food products within the EU, particularly among the new Member States. The purpose of this article is to evaluate to what extent an increase in trade in Poland's agri-food products, which took place between 2003 and 2014, translated into the strengthening of its position in EU trade in agri-food products. First, there is a brief presentation of results of Polish foreign trade in agri-food products, broken down into agricultural products and food industry products, that are the main subject of Polish foreign trade. Then, the paper presents Poland's position in agri-food trade after accession and among 28 European Union Member States. Furthermore, changes in the level of competitiveness in Polish exports were assessed on the basis of two indices: the revealed comparative advantage index (RCA) and the trade coverage index (TC). The analysis was conducted on the basis of trade data from the WITS Comtrade database, expressed in USD.

***Keywords**: food industry, foreign trade, competitiveness, competitive position*

Introduction

Foreign trade in agri-food products has played an important role in Polish foreign trade for years, but it has become even more important during Poland's membership in the European Union. The share of agri-food exports in total Polish exports ranged between 8-9% prior to EU accession, increased to nearly 10% in the following years and has fluctuated around 12-13% since 2009 (13.2% in 2015). The share of agri-food imports in total Polish imports was lower and ranged between 6-7% in 2003-2008. Since 2009, the share of agri-food products in total imports has stood at 9% (9.1% in 2015). These changes are due to a clearly higher growth rate in trade in agri-food products than in trade in products of other sectors of the economy (Tereszczuk, 2016).

Polish foreign trade in agri-food products is primarily trade in food industry products which account for nearly 85% of Polish exports. This index is one of the highest in the EU (Szczepaniak, 2014). In 2015, approx. 40% of food industry production was exported. The food sector is one of few sectors of the national economy that enjoys a positive trade balance. Surplus trade in food products has a very large impact on the total trade balance. This means that exports became not only an important sales channel for surplus production, but also an increasingly important factor in the development of the food industry in Poland and an important factor in the stabilisation of the internal market. The purpose of this article is to evaluate to what extent an increase in trade in Poland's agri-food products, which took place between 2003 and 2014, translated into the strengthening of its position in EU trade in agri-food products.

Material and methods

The article assesses results of trade and changes in the competitive position of individual sectors of the Polish food industry in 2003-2014. Trade flows were analysed based on statistics from the United Nations (UN) Comtrade database. Agri-food products were

considered as commodities marked in the customs tariff with HS (Harmonized System) codes 01-24. The article divides agri-food products into food industry products and agricultural products and the former are further broken down into 17 individual sectors, i.e. meat, fish, fruit and vegetables, oilseed, dairy, milling and starch, bakery and pasta, sugar, confectionery, coffee and tea, concentrates, feed, spirits, wine, brewing, soft drinks and tobacco sectors.
The competitiveness of Polish trade in food products on the world market was assessed by comparing values of two indices, i.e. TC (trade coverage index) and RCA (revealed comparative advantage index).
RCA indices were calculated according to the following formula:

$$RCA = \frac{x_i / \sum_{i=1}^{N} x_i}{x_{iw} / \sum_{i=1}^{N} x_{iw}}$$

where:
RCA_{ij} – revealed comparative advantage index in Polish exports of the ith product group to the jth market,
X_{ij} – Polish exports of the ith product group to the jth market,
X_{iw} – world exports of the ith product group to the jth market,
N – number of product groups (here: total food exports).

The essence of the RCA index is to determine whether the share of a given commodity group in the export of a given country is higher/lower than the share of this commodity group in the world export to the specific market. When the index is greater than 1 (the share of the given commodity group in the export of a country is higher than the respective share in the world export) – a given country has revealed comparative advantage in the export to the specific market. Otherwise, when the index is lower than 1 (the share of the given commodity group in the export of the country in question is lower than the share of this product group in the world export) – the analysed country does not have revealed comparative advantages in the export to the specific market [Ambroziak 2015].

Another index used to examine the competitiveness of Polish agri-food exports is the trade coverage index (TC)

$$TC_{ij} = \frac{X_{ij}}{M_{ij}} \cdot 100$$

where:
TC_{ij} – trade coverage index in exports of the ith product group to the jth market,
X_{ij} – Polish exports of the ith product group to the jth market,
M_{ij} – Polish imports of the ith product group to the jth market.

TC index determines the extent to which expenses on imported goods are covered by the revenue from their export. The TC index is used to study the relationship between the export and the import at the level of entire trade, sector or product. The TC index greater than 1 means that the export value exceeds the import value, thus the given country has the relative competitive advantage over partners [Ambroziak 2015].

Results and discussion

Trade in food products in Poland

In 2003-2014, there was a dynamic increase in trade throughout the European Union which was an immediate result of the successive enlargements in 2004 and 2007 as well as the progressive liberalisation of world trade. In the period under analysis, the value of exports of EU food industry products increased 2.5-fold and reached USD 453 billion in 2014 (table 1). The share of the new Member States in EU food exports increased as well, from 5.6% in 2013 to 12.8% in 2014. The share of processed products in sales in the "old" Member States was higher than in the EU-13 by 5-6 percentage points on average. Against this background, Poland stands out with its share of food industry products which is much higher than the EU and EU-15 average, standing at nearly 85% in 2014 (in the period under analysis, the share of food industry products in EU exports was similar – 76%). Such structure of exports is very beneficial, as the food sector entities, pursuing higher added value, make better use of available resources and achieve higher profits [Ambroziak, Bułkowska 2014].

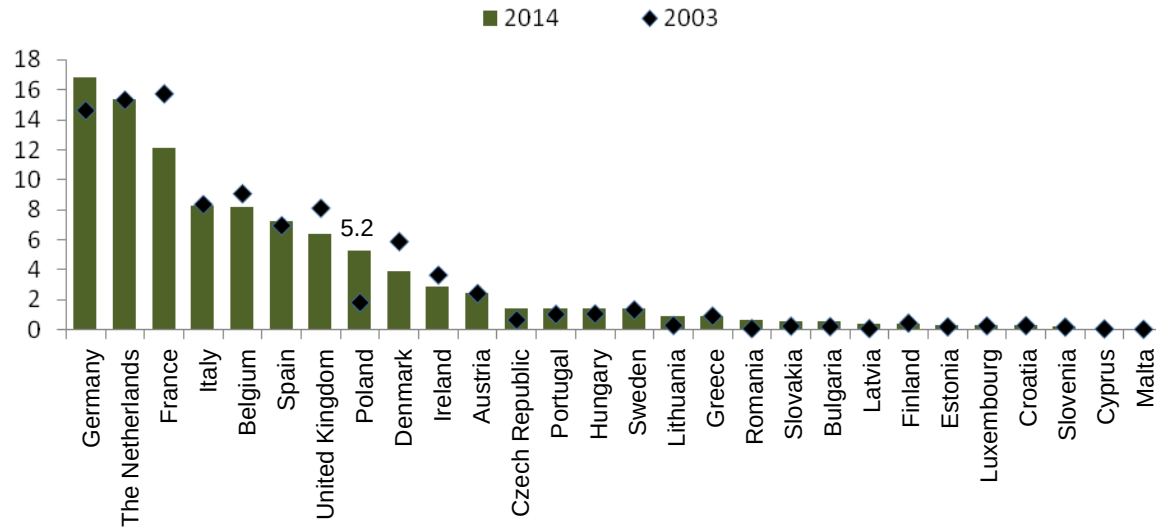
Table 1. Share of food industry products in Polish and EU agri-food exports in 2003 and 2014

	Exports (USD '000 000)	Share in agri-food exports	Share in exports of EU food products	Exports (USD '000 000)	Share in agri-food exports	Share in exports of EU food products
	2003			2014		
EU-28	198 144	75.6	100.0	452 781	76.2	100
EU-15	187 109	75.7	94.4	398 110	76.8	87.9
EU-13	11 035	74.8	5.6	54 670	71.7	12.1
Poland	3 653	82.6	1.8	23 682	84.7	5.2

Source: Own calculations based on UN COMTRADE data.

In the period under analysis, not only the importance of food industry products in Polish foreign trade, but also the role of Poland as a food exporter among EU Member States increased. In 2014, Poland was the 8th largest exporter of food industry products (Figure 1). However, higher sales revenues were recorded in Germany, the Netherlands, France, Italy, Belgium, Spain and the United Kingdom (in 2013, Poland was ranked 11th with its 1.8% share).

Figure 1. Share of individual countries in exports of EU food industry products in 2003 and 2014



Source: Own calculations based on UN COMTRADE data.

The EU market is the largest and most important destination of exports of Polish food products, but its absorption is limited. Unfavourable external circumstances related to the embargo imposed by Russia in mid-2014 and growing competition on the EU market forced food producers to seek alternative outlets for their products. In recent years, the dynamic development of Polish exports to non-EU countries, in particular Asia, the Middle East and Asia, has been observed. It can be expected that the role of these outlets for Polish food will increase in the future, but it is still minor [Bułkowska 2016].

Commodity structure of Polish exports of food products

In 2014, the value of Polish exports of food industry products reached USD 23.7 billion which accounted for 85% of total agri-food exports. The largest share in Polish exports of food products was that of the meat sector (nearly 24%) which was followed by dairy and tobacco sectors (10.6% each), the concentrates sector (8.3%), the fish sector (7.9%), the confectionery sector (7.7%) and the fruit and vegetables sector (7.1%). Compared to 2003, the largest increase in exports was recorded in tobacco, wine, oilseed and brewing sectors. Despite this, the share of alcoholic products in Polish exports is still low and stands at less than 1%. In 2014, the share of oilseed industry products was slightly higher – 3.8%. Although each of the 17 analysed sectors increased the value of exports in the period under analysis, the share of 5 of them dropped. The largest drop in importance was recorded in the fruit and vegetables sector (by 11.6 percentage points), the soft drinks sector (by 3.8 pp) and the sugar sector (by 2.2 pp).

Table 2. Results of trade in food products by food industry sectors

Sector	Value of exports		Average annual export growth rate		Value of imports		Average annual import growth rate	
	2014	2014, 2003=100	Value (%)	Value (USD '000 000)	2014	2014, 2003=100	Value (%)	Value (USD '000 000)
meat	5 630	739	18.1	443	2 199	903	20.1	178
fish	1 874	656	17.0	144	1 124	362	11.3	74

in total	23 682	648	16.9	1 821	13 045	496	14.3	947

Source: Own calculations based on UN COMTRADE data.

In 2014, the balance of trade in food industry products amounted to USD 10.6 billion. Only 3 of the 17 analysed sectors achieved a negative trade balance, i.e.: oilseed, wine and feed sectors (in 2003 – 8 sectors). The largest trade surplus was recorded in meat, tobacco and dairy sectors.

Assessment of the competitiveness of Polish trade in food industry products

The assessment of Poland's competitive position in trade in food products on the world market, which was conducted based on RCA and TC indices, reveals that the number of sectors, in which Poland had comparative advantages on the world market, rose in 2003-2014 from eight to ten. In 2014, exports of products of these sectors accounted for 89% of total food exports (75% of agri-food exports).

Products of meat, fruit and vegetables, fish, dairy, bakery, confectionery, coffee and tea, concentrates, soft drinks and tobacco sectors may be considered as strongly competitive in Polish trade in food products. Polish food producers did not have comparative advantages on the world market in exports of wine and oilseed industry products. However, the assessment of the competitive position of the other five sectors, i.e. milling, sugar, feed, spirits and brewing sectors, is unclear due to different values of both indices.

Compared to 2003, the competitive position of producers in meat, coffee and tea, concentrates and tobacco sectors increased, while that of producers in the sugar industry was lost.

Table 3. Assessment of the competitive position of Polish food producers

		TC	
		TC>100	TC<100
RCA	RCA>1	meat fruit and vegetables fish dairy bakery confectionery coffee and tea concentrates soft drinks tobacco	feed
	RCA<1	milling sugar spirits brewing	oilseed wine

Conclusions

Foreign trade in agri-food products has played an important role in Polish foreign trade for years, but it has become even more important during Poland's membership in the European Union. Polish foreign trade in agri-food products is primarily trade in food industry products which account for nearly 85% of Polish exports.

Compared to 2003, the value of Polish exports of food industry products grew 6.5-fold and thus Poland increased its share in EU exports of this product group from 1.8 to 5.2%. The largest share in Polish exports is that of products of meat, tobacco, dairy, fish, confectionery and concentrates sectors.

Poland had comparative advantages on the world market in trade in food products of meat, fruit and vegetables, fish, dairy, bakery, confectionery, coffee and tea, concentrates, soft drinks and tobacco sectors. Polish food producers did not have comparative advantages on the world market in exports of wine and oilseed industry products.

SELECTION OF FARMS FOR THE FARM ACCOUNTANCY DATA NETWORK SYSTEM IN THE REPUBLIC OF SERBIA

Mirjana BOJCEVSKI[1]*, Zorica VASILJEVIĆ[2], Vlado KOVACEVIC[1]

1Ministry of Agriculture and Environmental Protection of the Republic of Serbia, Belgrade, Serbia
[2]Department of Agricultural Economics, University of Belgrade - Faculty of Agriculture, Belgrade, Serbia

Abstract

The aim of this paper is to analyze the process of selecting farms in the Farm Accountancy Data Network (FADN). All European Union countries through the FADN system collect technical, financial and economic data from over 82 thousand farms. In some countries, FADN system was introduced back in 1965. Over the years FADN has developed as a unique system that provides information on agriculture in the member states; FADN is arranged by the common EU regulations. The biggest challenges within FADN system is the implementation of the methodology for the selection of farms in terms of the number, type and certain economic size, as well as the motivation of farmers to agree to be part of the system. FADN research is a very complex and delicate one because the collected data include all activities on farms during the twelve-month period. Selected farms from which are received detailed financial information are very important sectors of agriculture and therefore represent an important source of information for agricultural policy. The collection of FADN data can provide valid data to be used for the purpose of managing agricultural holdings and therefore is valuable tool for farm advisory services and farmers' associations assisting farmers in improving the profitability and competitiveness. Methodology for farm selection has to be standardized at the level of the European Union and the candidate countries for accession. Standardized and uniform sample allows standardized results which can be compared between countries. Results of this study showed the importance of the process of selection of farms in FADN which includes a methodology development and implementation of the chosen methodology.

Keywords: *FADN, selection plan, farm sample, agriculture.*

Introduction

FADN system is based on the collection of production, financial and other relevant data on farms (Vasiljević, 2012). FADN is mandatory for all EU member states and for all candidate counties. There is a prescribed uniform standard methodology so that the data can be processed at the EU level and also standardization allows the comparison between situations in the agricultural sectors of individual EU member states. Considering the fact that it is almost impossible to cover all the farms in the EU, a representative sample is used for the report drafting.

The Republic of Serbia is a country with the status of candidate for EU membership. The negotiation process for accession of the Republic of Serbia to the European Union, include the establishment of a system of accountancy data on agricultural holdings in the Republic of Serbia i.e. FADN (Vasiljevic et al., 2012).

The first data were collected in 2011 from 41 farms. In 2012 the data were collected from 172 farms, in 2013 from 497 farms, while in 2014 from 989 farms.

In the coming period the sample of farms is expected to continuously increase according to the EU FADN methodology requirements. This will fully ensure the representativeness of the FADN research and meet the EU FADN requirements.

Furthermore, taking into consideration that the FADN system in the Republic of Serbia is still in the phase of establishment, the current FADN sample size does not reflect the real economic situation of the agricultural sector due to its logical uncertainty. Therefore, the conclusion concerning the Standard Results of FADN research in Serbia should be made with regards to EU requirements and national needs. The paper objectives are to evaluate process of the selection of farms for the FADN.

Materials and Methods

For the purpose of this paper, the desk research method and method of interview with relevant experts have been used. This research covers the 3-years' period (from 2013 to April 2016). In order to provide objective results, the method of descriptive statistics, interviews with relevant experts and the comparative method were also used.
Further, has been used unique replicable European Union (EU) methodology that has been applied and adjusted in accordance with national conditions in the Republic of Serbia. More specifically, in this paper has been used the FADN methodology described in the following Regulations:

- Council Regulation (EC) No 1217/2009 of 30 November 2009 setting up a network for the collection of accountancy data on the incomes and business operation of agricultural holdings in the European Community;
- Commission Implementing Regulation (EU) 2015/220 of 3 February 2015 laying down rules for the application of Council Regulation (EC) No 1217/2009;
- Commission Implementing Regulation (EU) 2015/2323 of 11 December 2015 amending Implementing Regulation (EU) 2015/220;
- Regulation (EU) No 1318/2013 of the European Parliament and of the Council of 22 October 2013 amending Council Regulation (EC) No 1217/2009.

Results and Discussion

Data collected in FADN are used for the calculation of Standard Output as well as Economic Accounts for Agriculture. Standard Output is calculated by the Liaison Agency, following the methodology set up in the Annex 4 of the Commission Regulation (EC) No 220/2015, while Economic Accounts for Agriculture is calculated by the Statistical office.

Data collected by the FADN system are used to calculate the standard value of production as well as for the economic accounts for agriculture. Standard production value is calculated by the FADN agency, according to the methodology established in the Regulation (EC) No. 220/2015.
There are several requirements of the European Union in terms of methodology. These requirements are as follows:

- Connection / relations with other statistical data and research;
- Determination of sample / selection of farms;
- Requirements in terms of the data collected and results;
- Requirements in terms of data processing.

The selection of farms for the FADN sample is based on data from the official statistical farm register. The Statistical Register of Agricultural Holdings contains data collected in the Agricultural Census and it can be updated with information collected from other sources[1].

[1] Regulation (EC) No 1166/2008 of the European Parliament and of the Council of 19 November 2008 on farm structure surveys and the survey on agricultural production methods and repealing Council Regulation (EEC) No 571/88.

The Regulation (EC) 220/2015 lays down the rules for the implementation of Council Regulation (EC) No 1217/2009 defining the rules for creation a detailed plan for the selection of farms applied by all Member States.
Models and methods relating to the form and content of the data referred to in Article 5a paragraph 4 of Regulation (EC) No. 1217/2009, are set out in Commission Regulation (EC) No 220/2015 in Annex III. According to the Article 3 of this Regulation, FADN sample stratifies according to three different criteria:

• FADN region,
• Type of production,
• Economic size of agricultural holdings.

The definitions and breakdowns in the typology and economic size are according to Article 4 of Commission Regulation (EC) 220/2015, which defines the part of establishing a Community typology for agricultural holdings, and Annex IV and V.
Council Regulation (EC) No 1217/2009 and No 1318/2013 oblige Member States to draw up a plan for the farms selection for the FADN system, and will be developed on the basis of the latest statistical data and presented in accordance with the farm typology.
To avoid biased results, the farms within the FADN sample must be selected according to statistical rules of the statistical farm register. Usually, the Statistical office prepares a list of farms that should be chosen for each stratum while local governments collect data, or employed in local units should contact farms and agree with them on their voluntary participation.
The development of the plan for the selection should start in the spring, and to be submitted to the National Committee in early June, the first reading needs to be held in late June, the second reading in September, and the third, if necessary, no later than mid-October.
The selection plan is made on the basis of data from Agricultural Census 2012, which has to be conducted every 3 years[2].
In order to draft a plan for the selection of farms it is necessary to prepare:

a) The coefficient for the calculation of the standard output (SO) of production,
b) The total of standard production value,
c) Classes of economic size of agricultural holdings,
d) The typology of agricultural holdings,
e) The SO in 2007 for all types of production, accounted for two regions.

The coefficient for the calculation of the standard output (SO) is the average unit value of production of agricultural products (crops, multi-annual plantations or livestock). This ratio has been calculated as follows:
a) according to the manufacturer's price (loco farm);
b) for each product separately;
c) taking in account the five-years' average;
d) per unit of product (ha, throat, etc.);
e) with exclusion of the direct payments (subsidies), taxes on products and similar;
f) expressed in Euros.

[2] The first comprehensive Agricultural Census was conducted in 2012, while research on the structure of agricultural holdings is planned for 2017 and will be carried out on the basis of a sample (FSS- Farm structure survey).

The economic size of the farms is measured as a total output value of the property, or the sum of the individual SO of agricultural products represented on the farm, expressed in Euros. It is expressed in the "European unit size" (European Size Unit - ESU).

The most recent Regulation (EC) No 220/2015 prescribed the use of FADN methodology for the preparation of a detailed plan for the selection of farms, defines methodology for determination of the economic size and type of farms. Therefore, it is important to analyze the sensitivity of the plan for the selection of farms.

The typology of farms is precisely defined by Regulation (EC) No 220/2015 laying down the types of agricultural production. The type of agricultural production is determined by the relative contribution of the standard values of individual lines of production in relation to the total value of agricultural production.
There are 3 types of agricultural production:
1) General types of farming;
2) The main types of agricultural production;
3) Special types of agricultural production.

For creating a detailed plan for the selection of farms, the FADN methodology stipulates that it is necessary to fulfill the following requirements in defining the criteria for determining the FADN field of research as follows:

1) "Commercial farms"
    - > 90% of agricultural land;
    - > 90% of output (value of production);
    - Thresholds are defined for each country.
2) Representativeness
    - At the state level;
    - At the regional level.
3) Participation is voluntary
    - The number of farms for each country (Serbia around 2000);
    - Agricultural producers may refuse to participate;
    - Included the farms that have and have no based accounting.

The National Plan for the selection of farms must contain:
a) FADN regions;
b) Threshold of economic size of the research field;
c) Types of agricultural farms, the representativeness;
d) Number of holdings in the FADN survey.
Once established criteria for developing a plan for the selection of farms, the next step is to compile a list of farms that are included in the plan.
In accordance with the Article 5a paragraph of Regulation (EC) No 1217/2009, the table that defines the model and methods for implementing the plan for the selection of farms should be submitted to the Commission. This table consists of:

a) Information Sheet;
b) Plan for selection tables.
Detailed information on the reference population and sample for the relevant accounting year should be submitted on the basis of the following tables:
a) Table 1. Rules that apply for the selection of farms;
b) Table 2. Sample Coverage;

c) Table 3. Distribution of farms in the population;
d) Table 4. Plan Selection.
It is necessary to ensure that the sample is representative in all aspects relevant to the national level. For example, sectoral analysis based on FADN survey can be compared with data in agencies for payment or statistics on the total number of animals, the total area under different crops or total production of various agricultural products and farm economy classes. The structure of FADN sample in 2014 is shown in Table 4.

Table 1. Structure of the FADN sample by type of farming and economic size classes in Serbia, 2014

		Economic size classes						Total	%
		3	**4+5**	**6+7**	**8+9**	**10+11**	**12+13+14**		
1	Specialist and general field cropping	36	116	139	23			**314**	*33.3*
2	Specialist horticulture indoor	1	19	5		1		**16**	*1.7*
3	Specialist horticulture outdoor	6	4	6				**16**	*1.7*
4	Specialist vineyards	4						**4**	*0.4*
5	Specialist fruit	24	10	5				**39**	*4.1*
6	Specialist dairying	25	114	50	5			**194**	*20.6*
7	Various grazing livestock combined	16	95	30	4			**105**	*11.1*
8	Specialist pigs		4	4	3			**11**	*1.2*
9	Specialist poultry		6	15	4			**25**	*2.7*
10	Various crops and livestock combined	33	121	60	5	1		**219**	*23.2*
	Total	**145**	**439**	**314**	**44**	**0**		**943**	*100*
	%	*15.4*	*46.6*	*33.3*	*4.7*			*100*	

Source: Ministry of Agriculture and Environmental Protection.

Upon completion of data collection and verification of all data, FADN unit analyzes and prepares a report on the implementation of the plan for the selection of farms that provides accounting information. This plan is sent to the National Committee for approval, and the European Commission's checks by predefined RICA tests.

The farmers' motivation to participate in FADN is very important and it is necessary to motivate farmers to participate in the FADN survey. It turned out that the main motivation of farmers to cooperate and to submit the information is trust and good cooperation with advisors at the local level. The main motive of agricultural producers is to ensure a successful farm business and realize efficiency and productivity by using FADN feedback, which is an excellent instrument to compare individual farm with average results for same type of farms.

Conclusion

During 2013 and 2014, in Serbian FADN were included about 1,000 farms of different economic sizes and types. FADN results indicate that the selection of farms in the Republic of Serbia is appropriate and that the choice of farms is in accordance with EU rules. In the coming period the methodology of the FADN research should be further developed and adapted in accordance with the EU requirements, and the FADN organizational structure should be further improved and strengthened as well.
In the next period Serbia will gradually increase the number of farms included in the FADN sample corresponding to the established plan for the selection of farms. Based on the total

number of farms in Serbia, and in order to ensure the representativeness of different agricultural sectors, the Serbian FADN sample size should be finally 1,800-2,000 farms.

KNOWLEDGE-BASED ECONOMY: THE POLISH CASE

Bożena NOSECKA, Łukasz ZAREMBA

Institute of Agricultural and Food Economics - National Research Institute, Warsaw, Poland
*Corresponding author: zaremba@ierigz.waw.pl

Abstract

Knowledge is considered a basic factor defining the scope of economic growth and an improvement in efficiency and at the same time the level of competitive advantages in the present world. Virtually key features of knowledge-based economy are narrowed to a common use of information and communication technologies, implementation of innovations and increasing role of human capital. The implementation of knowledge-based economy assumptions was approved as a common objective of development in the European Union (EU). In the Strategy 2020, the development model concerns three mutually complementing priorities, i.e. intelligent development based on knowledge and innovations, sustainable development and the development supporting social inclusion. Poland occupies one of the lowest positions among the EU countries in the world and the EU ranking in respect of the knowledge-based economy development. Relatively low level of the indicators concerning knowledge-based development in Polish economy and other new member countries largely reflects the situation in agriculture. The pace of innovative progress in agriculture is much lower than in other sectors of Polish economy. The support for "intelligent" development of agriculture in Poland is provided by the Rural Development Program (RDP). Over the period 2014-2020, the share of total support for the activities targeted at the implementation of first pillar of the Strategy 2020 (intelligent development) is fixed at 40% of the total RDP budget. Broad implementation of innovative solutions and knowledge-based actions to Polish agriculture requires primarily the rise in financial allocations for R&D and better use of the EU support.

Keywords: *position of Poland in the EU, indicators, agriculture, support*

Introduction

In the post-industrial stage of development of the global economy, which is characterised by globalisation of economic activities and flows of goods, broadly defined capital and services, accumulated knowledge becomes the primary development factor and even the material foundation for the industrial economy (Kleer, 2003). This material basis for the development and competitiveness in the modern world is defined as a "knowledge-based economy" (KBE)[1].

The basic features describing and distinguishing a knowledge-based economy boil down to: treating knowledge as the most important production (manufacturing) factor, a widespread use of information and communication technologies, creating new or improved products on the basis of knowledge using innovative solutions, increasing the role and significance of the quality of human capital in the process of development and building competitive advantages, highlighting the role and importance of the demand factor and an intrinsic shift in influences from the producer to the consumer (Dworak et al., 2014), but also increased uncertainty and risk in doing business (market acceptance of new or improved products).

[1] The concepts of a knowledge society and knowledge economy have been introduced to the economic literature by Drucker (1995). By formulating these concepts, Drucker based on the experience of developed countries, mainly the US and the Japanese economies.

Knowledge-based economies mainly tend to build competitiveness by conveying features to products to "distinguish" them from the products offered by competitors. According to Porter (1980), it is a basic factor, apart from unit costs of production, of a market presence greater than other competitors. Modern technical, technological or organisational solutions also have an impact on the level of production costs.

It is obvious that the modern development paradigm, i.e. developing the economy and building the competitiveness on the basis of knowledge, does not make obsolete the economic order contained in the hitherto research theories on the factors of economic development and improvement in the competitiveness.

Implementation of the assumptions of a knowledge-based economy has been adopted as the primary objective of the development strategy of the EU Member States. The development plan for the entire EU on the basis of KBE was defined for the first time at the European Council Summit in Lisbon in March 2000. The development strategy adopted in Lisbon was to make the Community the most competitive knowledge-based economy in the world, capable of sustainable and balanced development.

A continuation of the Lisbon Strategy (and the revised Lisbon Strategy) is represented by the Europe 2020 strategy adopted for implementation in the EU in 2010. (Europe 2020 strategy (12 September 2012))The current development model is based to a greater extent than before on three mutually complementary priorities (pillars). They include:

I. smart growth – based on knowledge and innovation;
II. sustainable growth – aimed at increasing the importance of a low-carbon, resource-efficient and competitive economy;
III. inclusive growth – supporting employment growth with economic, social and territorial cohesion at the same time.

Materials and methods

The study uses data from the European Commission and the World Bank, the Polish Rural Development Programme (RDP) and the information from the Central Statistical Office (CSO) in Poland. The research method was to make comparative analyses of expert assessments. There were also used indicators methods, as well as descriptive statistics to conduct evaluation of position of Poland among other countries.

Results and discussion

Measurement of the development of knowledge-based economies

A commonly used measure of the development of a knowledge-based economy is represented by the share of expenditure on research and development in GDP (a ratio that has been adopted as one of the basic ones in the assessment of the implementation of the 2020 Strategy). Some economists (e.g. Kodama, 1995) tend to measure the development of a knowledge-based economy by means of the level of expenditure on R&D in relation to expenditure on fixed capital. The economy or economic operators can be considered knowledge-based when the investment in R&D is higher than the investment in fixed assets.

The most extensive research covers the studies on the development of knowledge-based economies conducted by the World Bank since 1998 in relation to over 100 countries. The assessment of the progress in the implementation of the 2020 Strategy is also fostered by the research and rankings conducted by the European Commission. The research of the World Bank and the European Commission has resulted in the development of a synthetic indicators to assess the development of a knowledge-based economy. These are: the Summary Innovation Index (SII) developed by the European Commission and the KEI (Knowledge Economy Index), which is prepared annually by the World Bank.

When calculating the indices referred to individual pillars, dozens of variables are taken into account. The key parameters of the three pillars of a knowledge-based economy – i.e. education and human resources, innovation and information and communication technologies – are the basis for determining the level of the Knowledge Index (KI).

Table 1. Evaluation pillars of a knowledge-based economy in the KEI, KI and SII indicators

Indicators	Pillars			
	I	II	III	IV
KEI	Legal and institutional regime	Education and human resources	Innovation	Information and communication technologies
KI	-	Education and human resources	Innovation	Information and communication technologies
SII	Human capital	Financial support	Openness and attractiveness of the research system	-

Source: Own compilation on the basis of: KEI http:info.worldbank.org/etools/kram2/kram; Innovation Union Scoreboard (IUS) 2010 r. Pro Info Europe, 1 February 2011; The World Competitiveness Scoreboard; The Global Competitiveness Yearbook.

Position of Poland in the results of the measurement of the knowledge-based economy

In 2012 (latest available data), Poland was ranked 25th in the EU in terms of the KEI level, ahead of Romania and Bulgaria only (Fig. 1). The highest ranked countries included, just like in the previous years covered by the study, the Nordic countries – Sweden, Finland and Denmark as well as the Netherlands and Germany. Among the new Member States, the highest position in the ranking in 2012 was occupied by Estonia (11th place) and the Czech Republic (14th place).

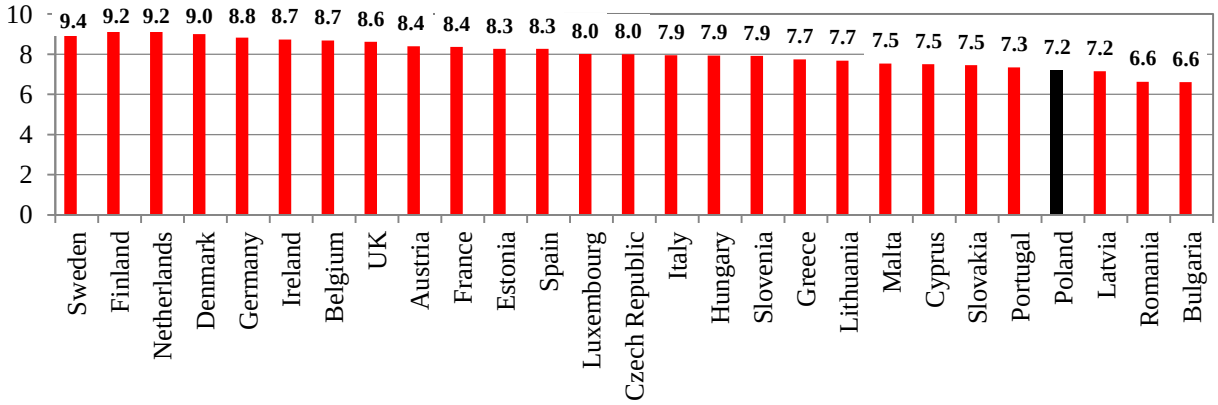

Figure 1. Ranking of the EU-27 on the basis of the KEI index in 2012

Source: www.worldbank.org/kam

The rankings developed on the basis of the KI listed Poland on the 24th position ahead of Romania, Bulgaria and Latvia.

The place of Poland in the development and innovation ranking developed by the European Commission in the EU (SII) is also low. In all the years of the Polish presence in the Community, this index was lower than in Poland only in Bulgaria, Romania and Latvia (Fig. 2). The highest SII level is observed in Sweden, United Kingdom, Finland, the Netherlands, Germany, Denmark and Belgium. The Summary Innovation Index in Sweden in 2014 was 2.4 times higher than in Poland, and in Germany it was 2.2 times higher. Poland, beside most new member states, as well as the southern EU-15 countries (Greece, Portugal, Italy, Spain), is considered a moderate innovator. By far the largest distance can be found between Poland and

most EU-15 in terms of the level and the development of information and communication technologies, the implementation of innovative solutions, the development of research networks and co-operation of academic and scientific institutions with production plants. Poland comes out relatively well only in terms of the level of education in society. The SII level in Poland in 2005-2014 has not changed significantly and fluctuated around 0.27-0.31[2]. Just like in Poland, the SII level has not changed significantly only in Lithuania.

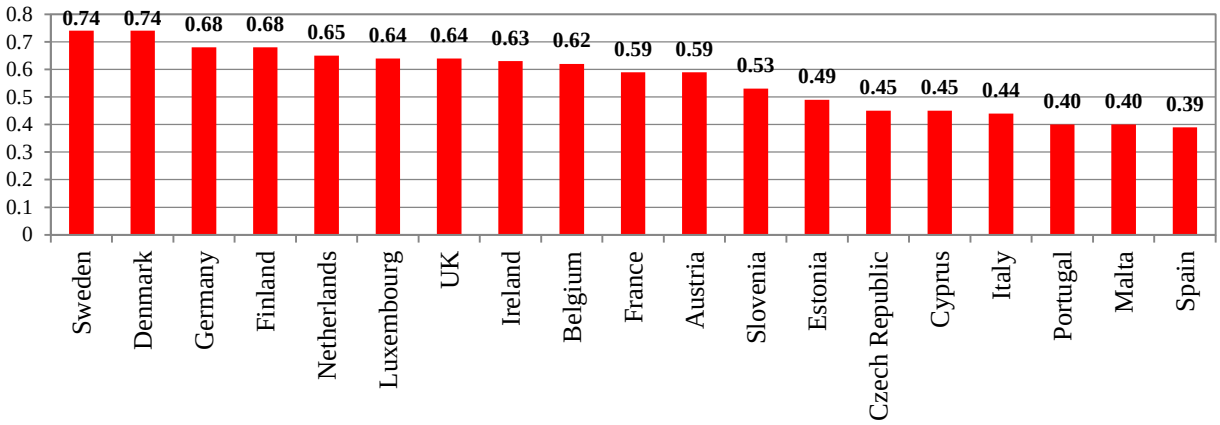

Figure 2. The level of SII indicators in EU Member States in 2014
Source: Innovation Union Scoreboard (IUS) 2014, http://www.proinno-europe.eu/metrics

The distant position of Poland in the rankings covering the development of knowledge-based economies in the EU results mainly from the relatively low level of development of ICTs and innovation, but what is not quite advantageous in comparison with most of the countries in the EU, including the new Member States, is the institutional environment, which creates incentives first of all for the implementation of innovation. This environment includes administrative, legal and financial procedures. Obviously, however, the scale of the development of a knowledge-based economy depends on the economic condition of the market players and the wider society as a whole, and this condition depends on the scale of economic development of individual countries.

Selected indicators of a knowledge-based economy in the Polish agriculture

The indicators concerning the development of a knowledge-based economy in the Polish agriculture are worse than for other sectors of the national economy. This applies to all areas taken into account when assessing the smart growth, i.e. the quality of human capital, the condition and the use of information and communication network (information society) and the level of implementation of broadly defined innovative solutions. The lower level of development indicators based on the knowledge in agriculture is evident due to the worse income situation of farmers in comparison with other sectors of the economy and, consequently, their lower chances and opportunities for introducing innovative solutions, access to information or the level of education. This means a very strong dependence of agriculture on the basis of modern factors of competitiveness on external factors – mainly the financial, but also organisational and managerial support.

According to the Polish statistical data, 9.9% of the rural population over the age of 13 (in urban areas 21.4%) had higher education level in 2014. 25.5%, 26.5% and 31.6% respectively of the population in rural areas had secondary, vocational and primary or lower secondary education. Among the persons running farms, only 2.6% had higher agricultural education, 25.3% had secondary education (vocational, primary and post-secondary education), and

[2] Indicators calculated from 0-1.

20.2% completed agricultural courses. Among the managers of farms with an area over 15 ha (15% of the total number of farms), 6.3% of people had higher education, and 47.6% had secondary education. In the smallest farms (1-1.99 ha – 20% of farms), these indicators in 2013 amounted to 1 and 13% respectively (CSO Statistical Yearbooks 2014, CSO Warsaw).
The percentage of the rural population having primary and secondary education is higher in Poland, just like in most new member states, than in the EU-15. On the other hand, the share of people with higher education is higher in the countries of the "old" Community. These disparities are similar with reference to the agricultural population (there are no data on the level of education of the rural population in the EU Member States).
The absence of research methods associated with the selection of evaluation criteria and measurement methods makes it difficult to determine the scale of the current innovation progress in agriculture. However, it is estimated that what is primarily disseminated in this sector are the results of the achievements used in farms in economically developed countries (an imitative progress). This applies mainly to the storage system for agricultural products, the use of modern machinery for the harvest and the improvement of the genetic potential of plants and animals. The development of the genetic potential in agriculture is fostered by a high supply and availability of innovative means of production for agriculture – agricultural equipment, plant protection products, yield-enhancing products, seed and seedlings. The problem is still a low (compared to many EU countries) scale of their use in farms in Poland. This is due to the relatively poor economic condition of most farms, a small degree of their organisation and the still small scope of co-operation with entities operating in the agricultural environment – mainly with academic and research centres and counselling entities.
Expenditure on research and development in agriculture in 2014 amounted to 1.0 billion Polish Złoty (PLN) and was higher than in 2000 by PLN 0.6 billion (Table 2). At the same time, however, the share of expenditure on research and development in the total expenditure on the R&D in Polish agriculture has been steadily decreasing since 2005. In 2000, this share amounted to 8.3%, in 2010 to 7.7% and in 2014 to barely 6.2%.
Among EU Member States, the share of expenditure on R&D in agriculture in the total expenditure on R&D in Romania, Bulgaria, Hungary, Slovakia, Latvia, Cyprus, Estonia, the Czech Republic is higher than in Poland, and among the EU-15, it is higher in Spain, Greece and Ireland.

Table 2. Employment and expenditure on R&D

Item	Employment in the R&D sector (thousand persons)				Expenditure on the R&D sector (PLN billion)			
	2000	2005	2010	2014	2000	2005	2010	2014
Total	**78.9**	**76.8**	**81.8**	**104.4**	**4.8**	**5.6**	**10.4**	**16.2**
In the agricultural sector	8.2	6.5	5.4	5.9	0.4	0.5	0.8	1.0
Share of agriculture (%)	10.4	8.5	6.6	5.7	8.3	8.9	7.7	6.2

Source: Central Statistical Office (CSO) - Statistical Yearbooks (2007 and 2015).

A still small scale of vertical linkages of agricultural producers and processing units results in a negligible impact of food industry stakeholders on the implementation of scientific and technical progress in the agricultural production and improvement in the quality of the supplied products.

Support for the development of the knowledge-based economy in Poland

The implementation of the 2020 Strategy in the Polish agriculture and in a broader sense in the agri-food sector is carried out on the basis of the funds provided under the Rural Development Programme (RDP).

The following measures are directly connected with the first pillar of the 2020 Strategy (smart growth): Transfer of knowledge and information measures, Consulting and Co-operation. Implementation of the first two measures, which are oriented towards training centres (academic institutions, agricultural advisory centres, agricultural chambers, private advisory entities), is primarily aimed at developing the knowledge and skills of farmers, disseminating of innovation and good practice in the field of agricultural production and processing of agricultural products. The measure Co-operation applies only to innovative projects, and the support is oriented towards the European Innovation Partnership (EPI) operational groups, which are created in order to develop efficient and sustainable agriculture.

The support provided under the Modernisation of farms in measure "*Investment in fixed assets*" is very strongly connected with the implementation of the first pillar of the Strategy. Modernisation is understood as implementation of innovation, but also as improvement in product quality. Modernisation is unrealistic without proper knowledge of farm managers. The improvement in the quality of labour force in agriculture by changing the age structure of farm managers and the opportunities for supplementing the education is fostered by the support in the form of premiums for young farmers.

Approximately EUR 13.5 billion, i.e. ca. PLN 55 billion, are expected in 2014-2020 for the implementation of all RDP measures (ca. PLN 43 billion were disbursed in 2007-2013 under the RDP funds). The financial plan for 2014-2020 for measures that can be directly referred to a knowledge-based economy (transfer of knowledge, advisory services, co-operation) provides for a budget of approx. EUR 191 million. The share of the overall support for the measures directly and indirectly associated with the implementation of the first pillar of the 2020 Strategy in relation to the agri-food sector is projected in 2014-2020 at ca. 40% of the RDP budget. Just like in the previous RDP implementation period, the largest funds (EUR 2.4 billion) will be allocated for the modernisation of farms.

Conclusions

Wider implementation of innovative solutions in the Polish economy, in particular in agriculture and support for the development on the basis of knowledge requires primarily increased expenditure on R&D and better use of EU support funds. When it comes to agricultural entities, it is necessary to increase the scope of co-operation with the entities operating in the environment of agriculture – mainly food processing entities, advisory centres and research institutions.

The role of the participants in the agri-food sector boils down first of all to maximising the use of EU and national support funding under the Rural Development Programme. The scale of obtaining support by agricultural producers depends to a very large extent on the organisational support by institutions operating in the environment of agriculture, but also on the willingness of producers to operate in larger economic organisations – mainly in producer groups and associations and in the system of clusters.

The measures conducted by government administration should come down mainly to: creating favourable conditions for the operation of market players in the aspect of innovative measures and extension of the scope of knowledge (tax and legislative instruments, making the access of market entities to the EU and national support funds more flexible).

Abstract

The competitiveness of tourism destination is conditioned or limited by the influence of many factors that appear outside of a destination or are in its immediate environment. In accordance with the strategic management concepts, elements of the external environment of rural tourist destinations are analyzed on two levels: macro and micro. The aim of this paper is to explore how destination environment – economic stability, characteristics of demand and socio-cultural changes, community participation and attitudes, cooperation between stakeholders in tourism (intra-industry interactions) and incentives and financial support for the development of tourism by the government and local authorities - affects competitiveness of rural tourism destinations in Vojvodina (Serbia) and selected counties in Hungary. Tourism experts from Serbia (136) and Hungary (138) were asked to evaluate the current condition of 17 attributes which affect the competitiveness of rural tourism destinations. Likert scale of five marks was used in order to determine the effect of the environment on the competitiveness of Vojvodina/Hungary as a rural tourism destination. Selected tourism experts were interviewed from September 2015 until the end of January 2016. The research in this paper examined the relative importance of actions taken by the industry stakeholders and government efforts to improve the competitiveness of the sector. It was found that companies have a greater impact, because they have a major role in providing services to visitors and enable tourists to experience the rural areas, while state and provincial institutions are responsible for managing and supervising the work of different rural tourism enterprises and providing appropriate support.

Keywords: *Rural destination, Competitiveness, Vojvodina (Serbia), Hungary*

Introduction

In the tourism industry, the competition between tourist destinations and products has become very intense which has contributed to greater market transparency, price and other elements of products and services (Cracolici, Nijkamp, Rietveld, 2008). Global competition in the tourism industry has become a challenge for many countries that are competing to become a desirable tourist destination, so understanding the factors that contribute to the competitiveness of destinations is essential to maintain the current level of development of tourist destination, its growth and vitality (Ritchie, Crouch, 1993; Hassan, 2000). Therefore, measurement of competitiveness can be considered as a key factor in ensuring the success of tourist destinations.

Rural tourism is one of the priorities in tourism development in many European countries. Rural tourism market is on the rise, while at the same time the future of many rural areas is uncertain, due to changes in agricultural production and the attractiveness of urban areas due to higher living standards. Rural tourism is considered to be one of the appropriate instruments for the revitalization of rural areas. Individual tourism enterprises in rural tourism

are interdependent and connected, and those are primarily small and medium-sized enterprises. Problems in rural tourism which contribute to the reduction of competitiveness are reflected in the existence of strong competition instead of cooperation among providers of tourist products and services in rural areas. Given the importance of tourism to rural areas, determining the factors that influence the improvement of the competitive position of the tourism market is of great importance for their further development.

In this paper, the focus is on one of the three components of the competitiveness of rural tourism destination, and that is tourism destination environment. The aim of this paper is to analyze the tourism destination environment - factors (Economic stability; The characteristics of demand and socio-cultural changes; Participation of local communities and their attitudes; Cooperation between stakeholders in tourism; Incentives and financial support for the development of tourism by the government and local authorities) and 17 attributes belonging to this determinant affecting the competitiveness of Vojvodina (Serbia) and Hungary as a destination of rural tourism. Theoretical framework of the tourism destination environment is described in the next chapter and after that, results and discussion are presented. In the end, conclusions are made.

Tourism destination environment – theoretical framework

The competitiveness of tourist destinations is conditioned or limited by the influence of many factors that appear outside the destination or are in its immediate environment. As for the company, the external environment of the tourist destination consists of two parts: macro (global) and micro (competitive) environment. External environment of destination includes economic, technological, environmental, political, legal, socio-cultural and demographic changes, while the competitive (micro) environment consists of suppliers, marketing intermediaries, consumers, tourism and hospitality companies, related and supporting industries, local organizations of destination management and public services.

In accordance with the strategic management concepts, elements of the external environment of rural tourism destinations are analyzed on two levels: macro and micro. At the macro level, a number of macro trends have the potential to affect the rural destinations, both positively and negatively. Among them, of vital importance for the development of rural tourism in Vojvodina are economic stability and socio-cultural changes. According to the author Dwyer and others (2000), socio-economic factors are an important generator of tourism turnover. Leisure time, income level, and more importantly, the level of economic growth and economic stability are prerequisites. At the micro level, competition and cooperation between destinations, demand conditions, and community participation and attitudes affect the competitiveness of the tourism sector. This is because stakeholders in tourism are tourists, businesses and local communities in which the industry operates (Williams, Lawson, 2001). They are key players in destination who are interested in tourism development, or are exposed to its influence.

Derived from Crouch-Ritchie and Dwyer-Kim model of destination competitiveness, this paper discusses the factors of the destination strategy through:

1. ***Economic Stability*** - Analysis of the economic environment involves monitoring of changes in the macroeconomy and its impact on companies and consumers (Evans, Campbell, Stonehouse, 2003). The phenomenon of rapid economic growth in Serbia (and Vojvodina) has implications for the tourism industry. The average gross salary has been increased from 8,691 RSD in 2001 to 61,420 RSD in 2014, thus increasing the opportunity and inclination to travel. The number of people who are more educated is increased and they have higher incomes and appreciate the value of travel (traveling to rural areas). However, although the average salary is increased, the economic situation in Serbia - high unemployment rate of 17.9%, a reduction of salaries and pensions, the growth rates of

absolute poverty, an increase in consumer prices, have impact on reducing the opportunities for citizens to travel for leisure and entertainment. Therefore, the increase in disposable income and general economic stability of the Serbian economy can contribute to fostering the development of the tourism market, where rural tourism, as a form of tourism whose development depends on the domestic market, will benefit from this growth and will acquire a significant share of the tourism market.

2. ***Characteristics of demand and socio-cultural changes*** - In the context of tourism, a new group of people, changes in attitudes and flexible free time are among the most significant social changes. These social trends have reduced the importance of standardized mass tourism in favor of tourism which is characterized by diversity, segmentation and customized travel experience. The demand for differentiated tourism products and experiences has led to a number of tourist destinations that focus on specific activities. Rural tourism can be an example of such a trend. Customers and their needs and desires, are still one of the driving forces in the environment of the tourist destination. Consumers are no longer a homogeneous group of people with the same motives for the trip. They are becoming more heterogeneous and more sophisticated, and affect the competitive activities of tourism enterprises and operation of tourism in the destination as a whole. According to Porter (1990), more sophisticated and demanding customers are the foundation of competitiveness, because it puts pressure on companies to achieve high standards in terms of quality products and services. In addition, the size and characteristics of demand growth can boost competitiveness by leveraging on for example, the investment policy. Also, the conditions of demand, especially domestic demand and its internationalization in foreign markets, provide a basis for economic development of a nation.

3. ***The participation of local communities and their attitudes*** - Community is a group of people who live in the same region with common interests and identity. The community is a major player in the development of tourism because tourism industry "benefits the community as a resource, as well as product and in the development process affects the quality of their life" (Murphy, 1988, p. 97). Authors Sheldon and Abenoja (2001) argue that there must be a broad involvement of local communities and the continuous evaluation of the perception of residents in order to ensure the development of a tourist destination, but also should be in accordance with the local character and values. Understanding the attitudes of local community on tourism development and their involvement in as many aspects of development, can create a welcoming and friendly environment, which will bring benefits to the tourism industry and to the local community, and therefore will improve the quality of the tourist experience.

4. ***Cooperation between the stakeholders in the tourism industry*** - Stakeholders in the tourism are representatives of government institutions and local authorities, owners of tourism and tourism-related businesses, local community and visitors (tourists) (Conaghan, Hanrahan, 2010; Byrd, Bosley, Dronberger, 2009). Also, the stakeholders in the tourism industry can be divided into tourists (demand), industry (offer) and "hosts" (local community and the environment of destinations) (Pavlovich, 2003). The knowledge and experience held by stakeholders in the tourism industry, and their involvement in the process of tourism planning and development and involvement of local communities in the long term has a significant role in the management of tourist destinations. The participation of all relevant stakeholders in planning the development of tourism can contribute to increased efficiency in achieving sustainable development of tourism in a destination. Also, the greater involvement of stakeholders will allow each of the actors to increase their self-confidence, gain a better overview and awareness of the problems that need to be solved in the area, and very often to facilitate a compromise among actors who have conflicting interests.

5. ***Incentives and financial support for the development of tourism by the government and local authorities*** - In rural tourism, small businesses are the most common, and even small businesses are faced with a small amount of resources for management than other companies on the market, they are more flexible, more responsive and can faster adapt to changes. Small businesses are particularly dominant in the tourism industry where they make up 95% of the total number of enterprises, and are especially present in rural tourism where entrepreneurs develop a personalized relationship with customers of products and services (with tourists). One of the important characteristics of agritourism enterprises is that their work depends on their own resources and they are responsible for all services provided to tourists. Decision-making is characterized by informality, but this can be an advantage, because small businesses can be easier established than the larger, but also new ideas are easier to implement (Aragon-Sanchez, Sanchez-Marin, 2005). Survival, growth and development of small (and medium) enterprises is primarily determined by the possibilities of financing from the budget sources. Limited access to sources of funding, particularly in terms of price and conditions of use, is perhaps the most important and the biggest problem of these companies.

Materials and Method

Tourism experts from Serbia and Hungary were asked to assess the current state of 17 attributes which affect/could affect the competitiveness of rural tourism destinations in Vojvodina/Hungary. Likert scale of five scores was used, where "1" means very bad condition of the attribute, score "2" bad condition, "3" average condition, "4" very well and "5" excellent condition of the attribute. Respondents were not offered to assess the current state of the attribute in relation to the set or a competitive destination (which tourism experts would identify by themselves) because it would not give a true picture of the competitiveness of Vojvodina/Hungary, because experts would compare rural tourism in Vojvodina/Hungary with several different destinations.

In this paper, survey research covered all those tourism experts who have the knowledge and/or experience relevant to the subject, and whose area of research and action is related to rural tourism and competitiveness of tourist destinations. In Vojvodina and selected districts in Hungary, interviewed tourism experts are as follows: teaching staff at higher education institutions, employees of the tourist organizations, employees of national and provincial institutions of importance for the development of tourism, tourism managers of travel agencies, owners of tourism enterprises in rural areas (farms, restaurants, ethno-houses, museums, wineries, souvenir shops, event organizers) and others (societies, associations, clusters).

The survey was conducted in two ways - a personal interview (technique of "face to face") and by sending a questionnaire via e-mail. Research in Vojvodina was conducted in the framework of its three regions - Bačka, Banat and Srem, while research in Hungary was conducted in seven counties - Somogy, Baranya, Tolna, Bács-Kiskun, Csongrád, Békés and Jász-Nagykun-Szolnok. These seven districts in Hungary have similar rural tourism offer as Vojvodina. Selected tourism experts in Vojvodina and Hungary were interviewed in the period from September to the first half of December 2015. The response rate in both countries is about 50%. Statistical analysis of the data collected through the survey will be done in the software statistical program SPSS 17.

Results and discussion

Respondents from Hungary and Vojvodina assessed the state of the factors within the determinant "Tourism destination environment" of the five subscales (factors) and there is a statistically significant difference at the level p <0.01 (Table 1), except for the factor "Participation of local communities and their attitudes". Rural areas of Vojvodina have achieved lower scores compared to districts in Hungary.

Table 1. T-test for dependent samples - comparison of results between Vojvodina and selected Districts in Hungary for the determinant "Tourism destination environment"

Factor	Region/ Country	AS	SD	T	Relevance
Economic stability	Vojvodina	2.3051	.74826	-7.856	.000
	Hungary	3.0912	.89775		
The characteristics of demand and socio-cultural changes;	Vojvodina	3.3544	.63338	-5.857	.000
	Hungary	3.7912	.59846		
Participation of local communities and their attitudes	Vojvodina	3.3431	.62320	-.880	.380
	Hungary	3.4112	.65463		
Cooperation between stakeholders in tourism	Vojvodina	2.4877	.78453	-6.271	.000
	Hungary	3.1290	.90048		
Incentives and financial support for the development of tourism by the government and local authorities	Vojvodina	2.5423	.77433	-3.896	.000
	Hungary	2.9599	.98343		

Source: Authors based on analysis of data from the survey

When it comes to economic stability, as an important factor that allows traveling, tourists in Hungary have a higher portion of income that is available for travel to rural areas, while differences in the economic situation in the countries were not assessed significantly different. Tourist demand in Hungary is characterized by tourists who share vacation in several short trips during the year (which may be the impact of higher standards of living and of awareness for travel in relation to Vojvodina), as well as tourists who visit the rural areas have heightened awareness of the importance of health, so they will choose one destination that will enable them active recreation (walking, hiking, swimming, running ...) in the preserved nature (visit protected natural areas, the choice of units that operate in a sustainable way, etc.). What is common for rural tourism Vojvodina and Hungary is that tourists who visit rural areas belong to all age categories, and the domestic tourists are dominant in this form of tourism. Cooperation between all stakeholders is a significantly better evaluated by participants from Hungary, which indicates that they recognized the importance of association and trade of capacities and experiences among all stakeholders involved in the development of rural tourism. Also, financial support for the development of rural tourism in Hungary is more intensive and efficient, but it takes place not only by the state institutions, but stakeholders were trained to apply for European funds and thus receive significant funds to improve all aspects of tourism offer.

Conclusion

The research in this paper has examined the relative importance of action by the industry and government efforts to improve the competitiveness of the sector. It was found that companies have a greater impact, because they have a major role in providing services to visitors and allow tourists to experience the rural areas, while state institutions and provincial governments are responsible for managing and supervising the work of different rural tourism enterprises and provide appropriate support. The role of the government sector is to act as a regulatory body and to assume responsibility for the strategic planning of development of rural destinations, and should undertake a systematic review of the destination attribute. Also,

the work of national and provincial institutions should have the aim to ensure that the destination has clear ideas where its development is going and what it takes to become successful in the long run. The attitudes of residents towards the development of rural tourism, their approval and participation in activities related to tourism, are often the key that contributes to the sustainable development of rural tourism. The absence of community participation and their support in the decision making process of planning the development of rural tourism destinations may result often in reduced level of support from the local population for the development of tourism in their community; reduced tolerance of the host to tourists; and increased sensitivity towards the further development of tourism. However, the participation of local people in the planning of tourism development is not easy in practical terms. Encouraging community members to participate in the management and provision of tourist services companies in their midst is one possible approach. Competition and cooperation should contribute to greater efficiency in service delivery and to improve rural tourism products, which in turn can strengthen the competitiveness of the sector.

Comparing the results of research between Vojvodina and selected districts in Hungary, it was concluded that the level of development of rural tourism in Hungary is at a significantly higher level than in Vojvodina, as there is a statistically significant difference in the assessment of all attributes. Tourism experts from Hungary do not see Serbia (and Vojvodina) as its competitors, suggesting that carriers of tourism policy and tourism offer should look to Hungary as a market that requires higher investment and significant efforts in order to meet the sophisticated demands of their rural tourists, which can not happen in a short period of time. Hungary, in the future, should be seen as partner and try to develop joint projects which will contribute to increased quality of rural tourist offer in Vojvodina.

Abstract

On the international women's day 8 march 2016, the world reaffirms that gender equality is first of all human right. Women have the right to live in dignity and enjoy the same rights and opportunities as men. However, despite many international agreements affirming their human rights, women all over the world have less access to the economy, credit, training and employment than men. They are far less likely than men to be politically active and to have access to leadership positions. Such persistent gender inequalities incur high costs for many countries around the world and particularly the developing ones. Great strides have been made to reduce gender gaps and improve the states of women and girls over past three decades, yet, significant gender gaps remain across sectors in all countries and are often greater among the poor developing ones and particularly in rural areas where socio economic disparities between men and women are the most acute. Experiences gained and learned lessons are evidently showing how important is the role played by rural women in improving economic growth, increasing food production and achieving sustainable development of their communities. Aware of this, nowadays to improve gender equality and to promote women empowerment an increasing wide range of institutions from business, civil society and governments have committed resources, rhetoric and political capital to realize both goals, but, due to the surrounding difficulties, the progress is still limited far away from the expectations. The presented paper will mainly focus on describing the needed actions to be implemented for moving towards sustainable rural development through the promotion of gender equality and rural women empowerment.

Keywords: *rural development, gender equity, women empowerment, needed actions*.

Introduction

Gender equality and female empowerment are core development objectives, fundamental for the realization of human rights and key to effective and sustainable development outcomes. Moving successfully towards sustainable rural development can not be reached without providing equitable opportunities, resources and life prospects for males and females.

The cited review and the learned lessons from most case studies evidently indicate that no society can develop sustainability without increasing and transforming the distribution of opportunities, resources and choices for males and females so that they have equal power to shape their own lives and contribute to their communities. Nowadays, it is well recognized that long-term sustainable development will only be possible when women and men enjoy equal opportunities to their potential. But today, women and girls continue to working sector. Unless women and men are able to attain their social, economic and political aspiration, and contribute to and shape decisions about the future, the global community will not successfully promote peace and prosperity. World Bank/IFAD/FAO (2009) UN women (2013) and FB (2009)

Rural women and sustainable development

In most countries rural women are not equal partners in the development process despite the fact that approximately one person in four falls in this demographic. Although rural women make essential contribution to the rural economy of all development opportunities are still remaining limited. Women are still held back by many education, unequal workloads and prosperity rights, limited control over resources and limited participation in decisions that affect their capacity to improve their lives and to better contribute to the economic growth and sustainable development of their countries. (FAO, 2009, 2011). Most published reports confirm that women face a surprisingly consistent gender gap in access to productive assets inputs and services. FAO in her response to such women's inequality taking as an example the agricultural sector showed that if women have the same access to productive resources as men, they could increase yield on their farms by 20-30 percent. This could raise total agriculture output in developing countries by 2.5 – 4.0 percent, which could in turn reduce the number of hunger people in the world by 12-17 percent. Actually many countries are taken several steps to close the gender inequality gap by reforming marital and property rights laws, but, the implementation and enforcement are inconsistent. (World Bank, World development report (2012). Lessons learned from numerous case studies evidently indicated that no society will progress satisfactory unless women, who contribute almost half of their population are given equal opportunities. Now, women are influencing the course of social change in society, having their aspiration, abilities and qualities as a man does have. It is quite true that once women are on the move, the family moves, the community moves and the nation moves. (Abu Zeid and Hamdy (2010).

Women empowerment: An overview

Globally, the essential role that women play in sustainable development is well recognized (The international conference on population and development, 1994; the Beijing Declaration of Action, 1995; The World Summit on Sustainable Development, 2002 and 2005). Such international conferences and world summits highlighted the need to involve women activity in environmental decision making at all levels; integrate gender concerns and strengthen or establish mechanism at the national, regional and international levels to assess the impacts of development and environmental policies on women (UN, 2008). Empowerment occurs when people, women and men take control of their own lives. Empowered people set their own agendas, gain skills, build self confidence, solve problems and develop self reliance. Women's empowerment is when women develop confidence in their own capacities and gain political, social or economic strength. No one can empower another but it is possible to support processes that nurture the self empowerment of individuals and groups, there is no single path to strengthening women's empowerment. Experiences and lessons learned demonstrated that progress towards gender equality and women's empowerment is prerequisite for realizing human rights and achieving inclusive development, democratic governance, social and economic justice and peace for all. (Kabeer, 2012, Best Essays (2012; USAID, 2012; and GEF 2014,2015)

Women empowerment: what does it refer to?

It refers to strengthen the social, economic and educational powers of women. It refers to an environment where there is no gender bias and has equal rights in community, society and work places. The women empowerment means to authorize power or increase the overall position, status and condition of women in every sphere of life. Women empowerment definition is given in (Box 1).

Box 1- Women Empowerment definition
It is defined as "women ability to make strategic life choices where that ability had been previously denied them (Kabeer, 1999) it is achieved when women and girls acquire the power to act freely, exercise their rights and fulfil their potential as full and equal members of society.

Empowerment of women must be a ranked as our top priority for achieving our development goals as its main advantage is the overall development of the society. There are several reasons which give greatest importance to women empowerment (Box 2). AFDB, (2008), Hamdy et al (2010)

Box 2- Women empowerment and its importance to sustainable development: Major-reasons:

- Under employed and unemployed women population constitute around 50% of the world population.
- Equally competent and inelegant like men in many socio economic activities.
- Talented: women are talented as men, and by showing their talents will benefit not only her individually but equally the whole world.
- Reduce poverty: the added earning of women due to their empowerment helps their families to come out of poverty trap.
- Economic progress: empowering women lead them to stand on their own, become independent and also to earn for their family which grows the society's economy.

Women empowerment: the barriers

Barriers for women empowerment could be outlined in: (IFAD 2012)

- The inherent superiority complex among the mate, they often doesn't allow their female counter-part to rise as high as them.
- High level of domestic responsibilities.
- Restrictions to participate in social economic and religious activities.
- In most societies particularly in rural areas, the boy child often gets preference for education and healthy diet over the girl child. In fact, preference for male child still exists among many families in the society.

How does one really empower women? The solution

There are several tools which we have in our hands among them: (Hamdy 2005)

- Education through mass communities is very important. Both women and men should be made aware of the responsibilities to promote and practice—gender equality.
- Gathering national data and identifying the areas where gender inequality is the most. This data should be worked and deeply analyzed by government's NGOs, and field workers to raise the status of women and to overcome the women empowerment constraints.
- Awareness is vital part of the solution. The society should be made aware that both boy child and girl child are equal and they both should have equal access to resources.
- Efforts should be focusing on key programmes and projects that could generate significant results for gender equality and women's empowerment to contribute to achieving the goals of global environmental benefits.

Gender equality

Over the post two decades several efforts were taken to narrow gender gaps, yet in developing low income countries and among disadvantaged groups, sustainable inequalities are still remaining in most working sectors, seriously and negatively constraining any sustainable rural development. Gender inequality refers to the gender based inequality against women. Women are often denied their social, cultural, economic, and political rights leading to a decline in the condition of women Gender equality definition is given in Box 3.

Box (3). Gender equality definition

It concerns women and men and it involves working with men and boys, women and girls to bring about change in attitudes, behaviours, roles and responsibilities at home, in work place and in the community. Gender equality means expanding foredooms and improving overall quality of life so that equality is achieved without scarifying gains for males or females.

There are several reasons which are behind the inequality against women, among them we would like to highlight the followings

- The glass ceiling effect: it refers to the invisible barrier that obstruct a women to rise to higher position inspite of having merits on the basis of education, ability, and reporting records.
- The feminization of poverty. It also reflects the different treatment that women face through the world. It is unfortunate that women constitutes a greater proportion of world poor.

Inequality against women: The cost

The persistent gender inequalities incur high costs for many countries around the world and particularly the developing ones. As an example the OECD estimates that gender inequality costs the MENA region at least 25% of its GDP. This is also the case for most developing countries of the Mediterranean where most case studies demonstrated how great those countries are losing due to women empowerment and gender inequality. Gender and water alliance (2003 a, b)

Gender equality and female empowerment: the policy

The new update policy on gender equality and women empowerment should be designed to enhance women empowerment and reduce gender gaps, the policy should affirm the critical role women play in accelerating progress in development and developing global prosperity and security. The updated policy should reflect policy the requirement for all UN entities to adopt the gender mainstreaming methodology, as mandated by the 1995 Beijing platform for action, defined by ECOSOC 1997 and reinforced by the chief Executives board for coordination (2006) and the terminal comprehensive policy review 2007. The new policy have to provide guidance on pursuing more effective, evidence-based investments in gender equality and women empowerment. Under this policy a strong emphasize should be placed on building high impact partnerships, harnessing the power of innovation and conducting rigorous programme evaluation to deliver meangful results. Equally, it should ensure that the composition of the proposed policy is reflecting our principles, creating a work environment that empowers and rewards women and men fully and equitably, as well as reflecting our values and commitments endurable meangful results for all. WFP (2009)

For this policy, national, regional and international investments should be aiming to the following two overarching outcomes mainly: UNICEF (2010)

- Reduce gender disparities inaccess to control over and benefit from resources, welth, opportunities and services- economic, social, political and cultural.
- Increase capability of women and girls to realize their rights, determining their life outcomes, and influence decision making in households, communities and societies.

The policy guiding principles those principles those principles characterizing the policy to advance gender equality and women empowerment could be outlines in the following. (Box. 4) USAID policy 2012.

Box. 4. Policy guiding principles

- Integrating approaches and actions
- Pursue an inclusive approach for faster equality
- Build partnership across a wide range of stakeholders
- Harness science, technology and innovation
- Promote women's participation in all work sectors and running efforts
- Show successes and failure from learned lessons and disseminate best practices
- Onsider contribution and collective commitment of involved stakeholders

Strengthening women's empowerment, gender equality and women's rights: the several paths.

According to the anthers in order to achieve our collective efforts towards gender equality, women's empowerment and women's rights, there are several paths to be followed among them:

Information and communication technology: ICT are emerging as a powerful tool for women empowerment in many developing countries around the world. It is now a potent force in transforming social, economic and political life globally. Lack of access to information and communication technologies becomes a significant factor in the further marginalization of women from the economic, social and political mainstream of their countries. Indeed, ICT can be a powerful catalyst for political, social and types of empowerment and the promotion of gender equality.

Mainstreaming gender issues: It is vital for the empowerment of women due to its role in:

1-Understanding the institutional systems and how they really work.

2- Identifying, enabling and disenabling agencies and actors that can work to improve the livelihood of members of local community, their roles, motivations, organizational culture and behaviour.

3- Establishing a dialogue with both women and men, besides facilitating the role of enabling actors.

Legal institutions to improve the status of women: Legal institutions must be changed to create a level playing field for men and women and an environment in which women can realize their full potential. Change is needed in property rights laws. Equally it is needed to enhance partnerships among government institutions, gender specific ministries, organizations and agencies; and gender experts in order to promote gender mainstreaming in developing and implementing environmental and sustainable development programmes and policies. But, those legal changes do not automatically translate into changes on the ground. Having an effective change requires that both who implement the laws the public are aware of the changes. Here it is to be emphasized that the institutional framework for sustainable development should be gender-responsive. Policies and programmes to empower women can strengthen and better in the rate of the economic, environmental and social standards of sustainable development.

A critical look to policy formation process:

Gender policy must have the following three strategic objectives:

1- Promote economic empowerment to enable rural women and men to participate in and benefits from profitable economic achieving.

2- Enable women and men to have equal voice and influence in rural institutions.

3- Achieve more equitable balance in workloads and in the sharing of economic and social benefits between women and men.

The existing cultural divide separating gender staff from technical staff and economic staff needs to be narrowed by increasing mutual understanding of the concepts, priorities, strategies and instruments developed by both groups. It would be crucial to intensify research and impact assessments that bring into the picture the impact of gender relations on the achievement of policy reforms and rural development.

Education:

Education is the most powerful weapon which we can use to change the actual women situation. Emphasis on women's education, including incentives and scholarships form women in science and policy is important to ensure a pipeline of well-qualified women candidates for senior positions in public and private organizations.

Training for women:

Training and skills development: women with low levels of literacy find it impossible to participate in decision making processes. Their capacity to participate meaningfully in the drafting of micro projects requests and participatory procurement mechanisms is thus seriously constrained. This can be done through training and by removing barriers to the productive use of women's time and energy. In this respond, it is also required special outreach and training for poorer and less educated women and for those who hesitate to voice their needs in front of men for cultural reasons. (Hamdy et al (2004)

Concluding remarks and recommendations

- The topic of women empowerment is a burning issue all over the world. Women empowerment and women equality with men is a universal issue.
- Nowadays, all nations are working hard to overcome both economic and social crisis. They are facing and crossing the road towards sustainable development. However, technical solutions all admit clearly that there are greater efforts to promote gender equality and women empowerment. It should be well understood that sustainable development cannot be imposed from the outside but must come from within the country side.
- Global efforts to reduce gender gaps have met only partial success. Across every development priority worldwide - from education to economic inclusion - gender inequity remains a significant challenge.
- To fulfill gender gaps, it is needed a coherent, relevant and up to date policy on gender equality and female empowerment that provides an overarching frame work for gender integration through out all aspects related to the work sectors.
- Gender inequality cannot be fully eliminated merely by the legal administrative measures. The educated people consciousness of the positive impact of gender equality. There is need for changes in perception towards women. The human society would be most advantaged only if women are treated equally and are not deprived of their rights.
- Now it is quite understood that gender equality among adults, expressed in equal enjoyment of rights and mutually respectful relationships in both the public and

private spheres, provides an essential context in which girls and boys can learn the gender equal attitudes and behaviors that will sustain human development and development goals.

- Empowering millions of women who live in poverty is essential for their intrinsic human rights and bread benefits for global development and economic growth.
- To promote women's empowerment, while this goal has been a challenge to realize in the past, the current convergence of commitment and shifting paradigms provides an unprecedented opportunity to forge new alliance and unleash innovation to achieve women's empowerment and gender equality, which have proved difficult to realize.
- The key issues to be addressed for strengthing women empowerment have to include: financial inclosing for women in agribusiness, capacity development across value chains, knowledge sharing platforms and up-scaling of models that can facilitate partnership between government, industry and academic to promote women's rights, empowerment and decent employment.
- Promotion of women's empowerment and gender equality to be achieved there is an urgent need to strengthen the capacities of rural institutions beside continues supporting efforts to harness sciences technology and innovation with talented men and women.

ECONOMIC BUSINESS ANALYSIS OF DAIRES FROM PESTER AREA

Mersida JANDRIĆ*, Zoran RAJIĆ, Dragić ŽIVKOVIĆ, Milovančević ZORAN

University of Belgrade, Faculty of Agriculture, Belgrade-Zemun, Serbia
*Corresponding author: mersida.jandric@hotmail.com

Abstract

This paper presents the results of business analysis from the dairy areas of Pester which produces, purchases, processes and sales milk and milk products. The analysis of business results involves business incomes and expenses of financing and financial incomes and expenses, i.e. financial result from continuing operations for the period from 2011 to 2014. year, while other income and expenses are excluded for they are generally unique, and as such are not essential for the survival and growth of the company. The goal of the analysis is to identify untapped potentials and current problems, and more rational use of available resources in order to improve the business.In this paper were used the original dairy data (financial report for the period from 2010 to 2013, and related accounting records). The main conclusion is that the dairy despite the achieved business results hasn't fully exploited the resources at its disposal.

Key words*: business analysis, business result, business risk, dairy*

Introduction

Dairy farming is the largest sector of the world's agriculture production. It is an important industry sector in many countries. For example, in the USA, dairy farming contributes with more than 160 billion $ in total economic output and provides more than 90,000 *jobs (Junaid et al., 2013).*

The share of milk production in total value of agricultural production in EU is 14%. Although the dairy industry made significant investments (Pavlović et al 2011), trends in milk production sector are not moving towards the direction that promises for Serbia to be on the list of important producers of milk and dairy products after joining the EU. Trends show that milk production is filled with structural problems and it is high time for sector to make serious reforms to increase its competitiveness and enable to initiate sustainable growth from negative trends of decrease / stagnation. Inadequate resolution of these issues will not only disable the potential benefits of the European integration process, but will cause further deterioration of the situation in the dairy industry.

It should be emphasized the fact that the quota system for milk, present in the EU countries, will be abolished in 2015. In conceptual terms, this system proved to be a weaker solution than a system of free pricing of milk and dairy products. In addition to stabilizing the price of milk and dairy products, reduced budgetary costs and preserving the income levels of farmers, there was an increase in production costs, which is particularly reflected in the stagnation of exports and higher prices than the competition and world (Grbić et al., 2010). Production diversification could be a chance for Serbian producers, given that the production quantities of milk can hardly compete with European producers.

One of the goals of the Republic of Serbia in the dairy sector is the creation of stable producer who can cope with the turbulence in the free market.

Organizational problem is one of the major obstacles at improvement in milk production. The situation in processing industry is such that several dairies process 80% of milk, while the rest amount processes nearly two hundred small dairies. Large ones mostly have an elaborate system of suppliers, while small ones operate randomly. In the future, small dairies will

remain suppliers to the local market for milk, yoghurt and their products. One of the fundamental determinants of effective and efficient business operation, regardless of their size is appropriate organizational form complied with the environment and the conditions prevailing in the market. Experiences from other EU countries point to the fact that most of the small dairies would not survive the coming period for they will not have the economic ability to align its business according to the requirements and standards of the EU. Many of the problems we face in the economy, particularly those related to business organizations, typically include request of optimal, from various aspects, use, or allocation of resources that are available at limited quantities.

Materials and methods of paper

The subject of study is a that manufactures, purchases, processes and sales of milk and milk products, its supply chain and distribution channels, as well as the company actions taken in order to identify untapped potential and current problems and all this for business improvement. Standard methodological procedures were applied in the research (indices, comparisons, tabulation, calculation methods), methods of analysis and balance, risk factors analysis in the achievement of financial results and threshold profitability. The analysis of business operations, analysis of organizational and economic conditions and all available resources, that dairy disposes with was done. Performed analysis could be used to plan further diary work. In this paper were used the original dairy data (financial report for the period from 2011 to 2014 and related accounting records) and appropriate literature sources.

Results with discussion

Basic characteristics of the region in which analyzed dairy operates are: a large number of raised cattle and sheep, the tradition of the region in dairy production, a large number of young agricultural households, exceptional natural conditions for the development of livestock, availability of raw materials base, short supply diary lines existence of HACCP, ISO and HALAL certificates and segmented market.

The dairy started its operation 20.05.1996, with a modest production in family owners circle. At the beginning was bought off 900 liters of milk per day from farmers. With great enthusiasm and with a lot of invested labor, the dairy continually developed and expanded the scope of its production. A new technology for the collection and processing of milk was introduced. During its work the dairy has expanded the scope of its production, range of products and number of employees. In a record time it has grown into a company which is one of the leading manufacturers of the region. The main activity is the purchase of milk and production of dairy products. With its personnel and technical potential is able to fully meet the expectations of customers in terms of product quality, price, service quality and delivery. As a recognized manufacturer in the region with a tendency of assortment expand and continuous monitoring of produced products quality , the use of high quality raw materials with constant monitoring and updating of technological processes, as well as the daily product quality control , are safe guarantee that the products are completely correct and safe for consumers. By the end of 2014, the dairy employed 22 workers, with a tendency for capacity expand and hiring more employees. At this level of company development such management proved to be successful. However, for further expansion is necessary to upgrade the existing organization as the only way to realize ambitious growth plans.

In this type of activitybasic raw material is raw cow's milk, but nevertheless accessories such as rennet for cheese, yeast for yogurt, salt and more are procured. Raw milk is provided by small farmers with 3-4 milking cows and exclusively from the area of Pester. Milk purchase is done in its close proximity, which significantly reduces transport costs. The raw material is delivered by transport vehicles to company storage units. By internal transport are delivered

to production capacities, where is, after a quality check, implemented a process of refinement and development of the final product. Final products are stored until the moment of delivery. The main advantages are favorable purchase prices, for the real battle is fight for suppliers of fresh milk, and then the speed of milk delivering to the customer. Certainly, one should add quality and rational organization at minimal costs.
The most common problems that occur are market opportunities that have been identified as a problem with customers (payment of products itself), difficult terrain conditions when purchasing, expressed gray market and the lack of logistics.
The business concept is based on collection and purchase of milk from a wider area, its processing and distribution and sale to interested buyers. The entire product range is reduced to a few items: fresh milk, yogurt, white cheese, butter, paprika in sour cream and cream.
Core segments are: Equipment for milk reception (cold room, gauges and chamber); Line for fermented products (pasteurization machine, cooler, and duplicator); Line for pasteurized milk production (separator, packing machine, pasteurization machine); Line for cream production; Line for cheese production.

Table 1. Equipment that dairy disposes with

	Equipment name	**Pieces**	**Year of production**	**Value**	**Total value**
1.	Line for milk reception	1	2000	2.430 000	2.430 000
2.	Line for milk pasteurization and homogenization	1	2002	3.240 000	3.240 000
3.	Packing machine	3	2002	1.350 000	4.050 000
4.	Line for fermentation	1	2007	2.900 000	2.900 000
5.	Cooling chambers	4	2003	405 000	1.620 000
6.	Vehicles for transport and distribution	8	1995	637 500	5.100 000
7.	Line for cheese	1	2008	1.800 000	1.800 000
8.	Total				21.140 000

Source:Internal data

Production capacities are utilized 50%. Line for milk reception can accommodate 6.000 000 liters annually, and in 2014. the dairy has processed 3.000 000 liters of milk. In 2014., the utilization level of production capacities was slightly increased and amounted to 53.33%.

Table 2. Production capacities

	Description	Measure unit	Daily capacity
1.	Milk reception	l	20.000
2.	Milk pasteurization	l	500
3.	Fermented products	l	10.000
3.1.	Yogurt 1 l	l	3.000
3.2.	Yogurt in cup 0,18 l	l	7.000
4.	Cream production	kg	20
5.	Cheese production	kg	600
6.	Paprika in sour cream production	kg	500
7.	Butter production	kg	140

Source: Internal data

Strategic raw material of dairy is milk. Cost market and the most important of dairy suppliers for raw milk, are the agricultural producers from Pester territory. The criteria by which the suppliers were selected are raw milk quality as well as reliability of delivery and quantity. The advantage of this diary is that its subcontractors offer milk obtained from the area of ecologically health environment.

Table 3. The packaging purchase prices

no.	Packaging	Price in RSD
1.	Carton for yogurt	10,00
2.	PET bottle	10,00

4.	PVC for milk	2,00
5.	Box for cheese, cream and paprika in sour cream	20,00
6.	Can (Bulgaria import)	140,00
7.	Foil for butter	3,50

Source: Internal data

The analysis of business results included business income and expenses of financing and financial income and expenses, i.e. the financial result from continuing operations, while other income and expenses are excluded for they are generally unique, and as such are not essential for the survival and growth of the company. The aim of financial result review is the assessment of financial result as a difference of two opposite flows - income and expenses. Breakdown of financial results provide information from which income group improves financial result (Živković et al., 2013).

Business company risk is the risk of achievement business loss as the gross yield of total capital, i.e. the *risk of coverage* from all business revenue expenditures, other than financing expenditure. This risk is measured by a factor of business risk, and is obtained from cover margins and operating profit relation. Height of business risk depends on sales volume, parity of sales and purchase prices, cost-effectiveness of material consumption, energy, services and labor, and the rationality of investment in capital assets and generally rationalization of all functions of company.

Business risk factor indicates how many times business profit changes faster at each change in operating income, i.e. at any change in margin of coverage. As a risk factor of business risk lower, it is a risk of business achievement profit lower.

Factor of business risk - business leverage is obtained from the ratio of coverage margin and operating profit relation. The dairy has realized positive results in all previous four years and a factor of business risk is lower every year.

Factor of financial risk - is calculated from the ratio of business profit and regular profit activities, i.e. from relation of business result and gross financial result. It shows how to change faster the gross financial result when the business result changes by 1%. Factor of financial risk in our example is, for analyzed years, from 1.02 to 1.05.
Overall risk factor is obtained by multiplying the previous two risks. Overall riskfactor for the analyzed Dairy is 2011/1,88; 2012/1,64; 2013/1,54 and for 2014/1,52 which indicates that each year gets better results. As a overall risk factor is lower even more the overall risk of business achievementprofit is lower, and vice versa.

Table 4. Risk of financial results achievement (in 000)

	Position	**2011**	**2012**	**2013**	**2014**
1	Business income	97.952,00	115.843,00	133.219,90	159.863,88
2	Variable expense	82.353,00	91.976,00	101.173,50	121.408,20
3	Coverage margin (1-2)	15.599,00	23.867,00	32.046, 40	38.455,68
4	Fixed and mainly fixed costs	7.113,00	9.035,00	10.842,00	11.950,00
5	Business results (3-4)	8.486,00	14.832,00	21.204,40	26.505,68
6	Net financing expense (income financing-expenditure financing)	- 141,00	- 254,00	- 560,00	- 1.310,00
7	Gross financial result	8.354,00	14.578,00	20.674,40	25.195,68
8	Business risk factor (3/5)	1,84	1,61	1,51	1,45
9	Financial risk factor (5/7)	1,02	1,02	1,02	1,05
10	Total risk factor (8x9)	1,88	1,64	1,54	1,52
11	% participation of margin coverage in business income (3/1)x100	15,92	20,60	24,06	24,05
12	Required operating income for the realization of a neutral business result (4/11)x100	44.680, 00	43.859,00	45.062,34	49.688,14
13	Required business income for the achievement of neutral gross financial result ((4+6)/11)x100	45.565,00	45.092,00	42.734,82	44.241,16
14	% utilization of business income for the achievement of neutral business result (12/1)x100	45,61	37,86	33,83	31,08
15	Elasticity rate of neutral business result achievement ((1-12)/1)x100	54,38	62,14	66,17	68,92
16	%utilization of business income for the achievement of neutral gross financial result (13/1)x100	46,52	38,93	32,08	27,67
17	Elasticity rate of gross financial result achievement(1-13)/1x100	53,48	61,07	67,92	72,33

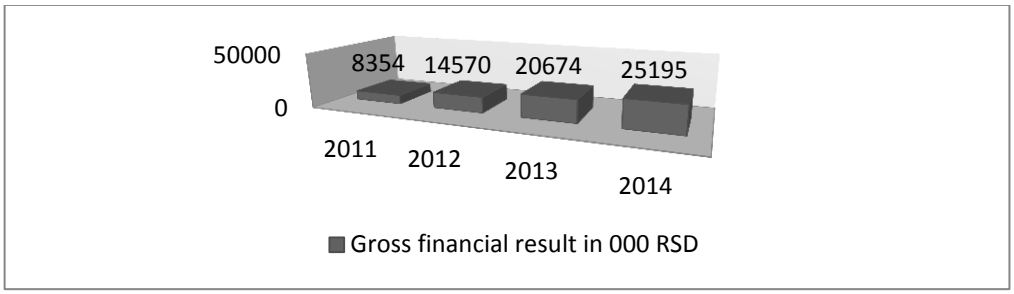
Source: calculation by authors

Negative rate of elasticity occurs when is realized business loss, and it shows for how much percentage is realized business income lower than required, for achieving business income of neutral regular activities profit. In case of analyzed diary these items are positive and have recorded an increase.

The lower break-even point is the point at which incomes equal with expenditures, which means that at this point financial result is neutral. In our example two lower break-even points are determined.

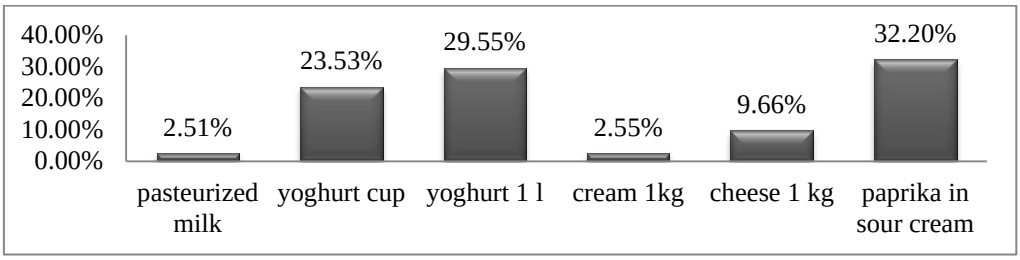
- *The point of neutral business result* is the point in which business income equals with fixed and mainly fixed expenses and partially variable costs, which are included in income which provides neutral business result.
- *The point of neutral gross financial result* is the point in which business income equals with fixed and mainly fixed expenses, net financing expenses and partially variable expenditures that are included in income which provides neutral gross financial result.

Figure 1. Gross financial result in period of 2011-2014. year



Source: calculation by authors

Figure 2. The percentage share of product in the achievement of gross results for 2013



Source: calculation by authors

The percentage share of margin coverage in business period of 2011-2014 is increasing as a result of lower variable costs.
Required business income for achieving neutral business result is, in all four years, lower than the actual business income
Required business income for achieving gross financial result is also lower than the actual business income. The percentage of business income utilization for achieving neutral business result is in decline - which is good.
Paprika in sour cream has the highest percentage of participation in the achievement of gross financial result in 2014.
Gross financial result clearly shows that the dairy is moving upwards.
Global parity has increased, and since we have no global parity of competition, the position of the company cannot be inferred in the market in comparison to the competition.

Table 5. Global parity (in 000 RSD)

	Position	**2011**	**2012**	**2013**	**20134**
1.	Business income	97.952,00	115.843,00	133.219,90	159.863,90
2.	Variable material incomes	82.353,00	91.976,00	101.173,50	121.408,20
3.	Global parity (1/2)	1,1894	1,2595	1,3167	1,3167

Source: calculation by authors

Conclusion

By business analysis of Dairy, which is located in the southwestern part of Serbia led to the conclusion that the dairy, in the period from 2011 to 2014., operated with positive financial results and the best financial result were achieved in 2014. Although the dairy operated with a positive financial result, the data clearly indicate that the available resources are underutilized. Production capacity of the dairy were used only about 50%, product diversification is weak, and the market to which the analyzed dairy is mostly oriented, is mainly at the level of local. Given the availability of raw materials base, short lines of supply, reduced costs and a high percentage of young working-age population, in the next period of dairy work should be to work on the optimization of production.

In recent years, there is evidence of a growing domestic demand for products of yoghurt, flavored yoghurt and fermented milk products with added probiotics. The analyzed dairy production should be focused on this group of products, where the greatest degree of products and packaging diversification could be achieved.

The proposed measures could be directed towards greater diversification of products. Special emphasis should be given to a product that stands out as a specific product of the area i.e. peppers in sour cream, which percentage of participation in the achievement of gross financial result is highest. Of course, that with all of the above is needed to develop quality of products and marketing activities should be directed towards developing markets beyond the local area.

ECONOMIC DIVERSIFICATION OF RURAL HOUSEHOLDS IN THE REPUBLIC OF MACEDONIA

Marija GJOSHEVA KOVACHEVIKJ[1]*, Blagoj GORGIEVSKI[2]

[1]Institute of Sociological, Political and Juridical Research, Skopje, Republic of Macedonia
[2]University "St. Kliment Ohridski", Faculty of Law, Bitola, Republic of Macedonia
*Corresponding author: marija9272@yahoo.com

Abstract

Sustainable rural development is vital to the national social and economic situation of the Republic of Macedonia since 43% of the population lives in rural areas, which make up 86.7% of the total territory. Most of the rural households are engaged in agriculture (primarily family farms) and very small portion in other activities. Agricultural wages tend to be significantly lower than other sectors and almost half of the labour force is consisting from unpaid family members. To that end, modern understanding of rural development exceeds the concept that agriculture is the only non-urban element of territorial areas and move to a broader concept that refers to all resources of the territory and its entire economic structure: natural and human resources, crafts, small industrial facilities, tourism, recreation, etc. The goal of this paper is to review the new direction of rural development in Macedonia - income diversification, focused on contribution of non-farm activities to total rural household incomes. The methods of descriptive statistics of data analysis were used to process official data for incomes, from the State Statistical Office. The findings demonstrate that the number of rural households with incomes from non-agricultural activities accounts for only 16%, with highest proportion (69%) of households with share of only up to 10% of non-farm incomes in total turnover. Policy for strengthening of the conditions for development of the rural diversification activities, as one of the tool for economic stability of rural households, is recommended to be one of the highest governmental strategic priorities for rural development.

Keywords: *rural development, income, diversification*

Introduction

The rural households compared to urban areas, have more limited economic opportunities and undeveloped markets as well as other socio-economic problems (World Bank, 2008). Distinguishing between the rural and urban economy occurs because the specifics of the rural way of life and work of the rural population (Čustović et al., 2013). Viewed globally, the majority of poor households lives in rural areas in developing countries and depend mainly on agriculture and related activities for providing life existence. The pressures of limited available resources and environmental degradation create additional challenges to the well-being of the population in rural areas and accelerating rural-urban migration (Čustović et al., 2013). Therefore, it is important that the members of rural households, through a good management way, to combine their abilities, skills and knowledge with the resources at their disposal to create activities that will enable better living conditions (Messer and Townsley, 2003).

Rural households that operate farms often provide, in addition to their reword from farming, income from running non-agricultural businesses, from waged employment, from social transfers, etc. Hence, the rural non-farm economy (RNFE) may be defined as comprising all those non-agricultural activities which generate income to rural households (including income in-kind and remittances), either through waged work or in self-employment. In some contexts,

rural non-farm activities are also important sources of local economic growth (e.g. tourism, mining, timber processing, etc.) (Davis, 2004). The RNFE is of great importance to the rural economy because of its production linkages and employment effects, as well the non-farm income represents a substantial and sometimes growing share of rural incomes. Often this share is particularly high for the rural poor. There is evidence that these contributions are becoming increasingly significant for food security, poverty alleviation and farm sector competitiveness and productivity (Davis, 2004).

In the Republic of Macedonia, agriculture and income from agriculture and related processing and services are still sustainable source of income for rural population. The country's rural areas are home to 43 per cent of the population and two thirds of its poor people (IFAD, 2016). Most rural households depend largely on crop and livestock production for their income. Poor people in rural areas are either members of traditional small-scale agricultural households eking out a livelihood at subsistence level, or they are among the poor rural unemployed, who may be even more disadvantaged than poor landholders (IFAD, 2016). Approximately 60% of the villages are affected by de-population, particularly the sensitive hill and mountain regions (Jakimovski, 2002). Food security and poor nutrition are not critical development issues in the country, but rural households are extremely vulnerable to external economic shocks. Because of economic transition and regional instabilities the reliability of local food production is far from assured (IFAD, 2016).

Therefore, the non-farm sector is crucial to rural households in transition economies as it is Macedonian economy, since it offers employment, reduces urban migration and can contribute to poverty reduction, economic growth and a more equal income distribution (Mollers *et al.*, 2006).

Assessment of the Ministry for agriculture, forestry and water economy in Macedonia (MAFWE, 2014) indicates that efforts to promote entrepreneurship and crafts in rural areas outside agriculture are constrained by low educational status labor and lack of professional experience (cf. National Strategy for agricultural and rural development, 2014-2020). Application of measures for encouraging entrepreneurship in rural areas through grant support capital investments from the Instrument for Pre-accession Assistance for Rural Development (IPARD) establishment of micro and small businesses in rural areas identified that there is a lack of mature business ideas, entrepreneurial skills and knowledge. New businesses are constrained by low incomes and low purchasing power of rural residents and saturation of activities that require low initial capital (small shops, restaurants, services) (Mollers *et al.*, 2006).

Materials and methods

In order to determine the differences between urban and rural household income, data for three-year period, 2012-2014, from survey on Income and Living Conditions from State Statistical Office (SSO) has been used. Data are collected, from 5030 households, through using of questionnaires and direct interviews. The same database was used to calculate share of incomes from non-farm activities in rural households in the total turnover.

In order to review the standard output and to calculate share of economic size by types of the agricultural holdings, data from the survey of the State Statistical Office (SSO) conducted in 2013, for typology and structure of agricultural holdings, has been used. The economic size is determined on the basis of the total standard output of the holdings taken as the average monetary value of the agricultural output at farm–gate price. The agricultural holdings are classified according to their economic potential in 14 economic size classes.

Results and discussion

Data for disposable household income in the table 1 shows that the total average income of rural households for period of three years (2012-2014) is lower for 12% compared to

households in urban areas, with dominance of incomes from wages and salary (49% in rural and 61% in urban areas). This indicates that people living in rural and urban areas have a similar standard, especially taken into account 2014 where the difference is only 5.5%. However, separate field surveys demonstrate higher differences between rural and urban incomes values than the data from the State Statistical Office, what fits with the fact that two thirds of poor people lives in rural areas. As a source for income, wages and salary in urban areas are higher by 30% compared to rural. However, there is a visible difference in source of income from self-employments in rural households (share of 28% in rural and 11% in urban areas), due to the large scope of agricultural activities, accounting for 128% higher average income share compared to urban areas, whose part of the income is mostly exposed to high production and market volatility of agricultural production. This is in fact the main potentials for development of rural diversification activities. Positive corrections in this part can be done through using of available resources and creating non-farm activities. Also, the difference in income received from remittances are almost twice higher in rural than in urban areas.

Table 1: Total disposable household income by types in urban and rural areas, 2012 – 2014, annual average per household in euros.

	2012			2013			2014			Average		
Indicator	All house.	Urban area	Rural area	All house.	Urban area	Rural area	All house.	Urban area	Rural area	All house.	Urban area	Rural area

Source: State statistical office, 2016

In regards to agricultural activities, according to the last executed derivative classification of agricultural holdings as a result of structural survey in 2013, the largest portion (34.4%) shares agricultural holdings specialist in manufacture of cereals and industrial crops within 9 structured agricultural holdings groups according to type of agricultural production. The second place shares agricultural holdings with mixed crops-livestock production, with 18.2%, followed by specialist for permanent crops (mostly in vineyards and fruits) with 17.3%, 10.3% are classified in the type - mixed cropping, and 9.6% specialised in grazing livestock (cattle, sheep, goats). The smallest share or 2.1% are specialist in horticulture production. The high percentage of holdings with multifunctional or mixed farming is mostly due to the reduction of the risk of climate and market volatility.

According to the classification of economic size of the farm (SSO, 2015), 49.6% of farms are classified in the first lowest category, EUR 2,000 standard gross margin or 1.5 units of economic size which is equivalent to about 1.8 ha cereals or 2 cows or 25 sheep or a combination thereof according to the categorization of the European Union. The biggest number of agricultural holdings with highest economic size, from VII till IX class (from 50,000-500,000 euros), are in group of specialised grazing livestock, however mixed farms with plant and livestock production takes third place in this group. The agricultural holdings in the European Union are on average more than five times the economic size of the agricultural holdings in Macedonia. These figures indicate unfavorable level of economic power of agricultural households in Macedonia, what has negative impact on boosting of entrepreneurship and creating of new businesses within farm households.

In terms of gainful activities, data in Figure 1 shows that only 10,467 rural households (16% of total number of rural households) are dealing with non-agricultural production activities, mainly focused on processing of animal production (39%) and picking of forest plants (24%). Very small portion (less than 1%) takes households with aquaculture, tourism and accommodation and handicraft activities, which from globally perspectives represents the most often potential diversified activities out of agriculture. Data for non-farm activities in Macedonia, compared with EU countries where over one third of EU-27 family farmers (36.4%) carry out another gainful activity with increasing tendency (European Commission, 2014), implies very low diversified rural economy in the country.

In terms of the share of rural nonfarm incomes in total rural incomes in Macedonia, analysed data in figure 2 demonstrates that the biggest portion (69%) of the rural households that are dealing with non-agricultural production has only 10% income source of the non-farm activities and only 9% of this group of rural households with non-farm activities has non-farm income accounting for more than 50% in total income sources. This data conforms that in the most cases, other gainful (non-farm) activities has low influence in the total income in the rural households.

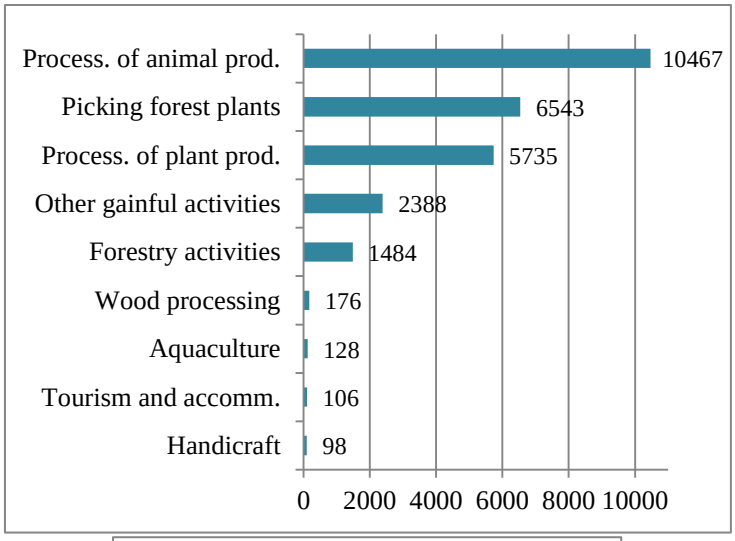

Figure 1. Number of individual agricultural holdings with other than agriculture gainful activities, by type of activity.
Source: SSO, 2014

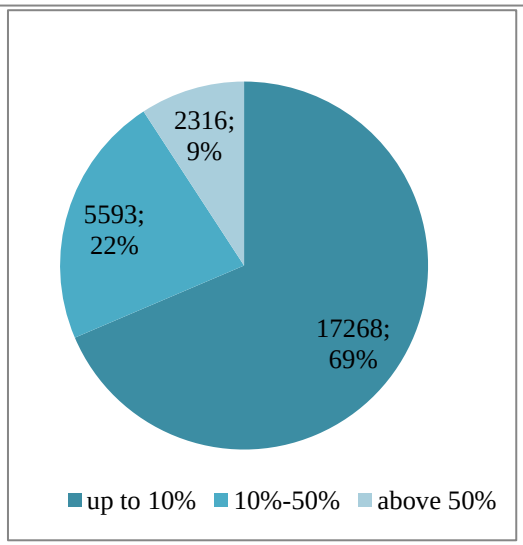

Figure 2. Share of turnover of other gainful activities in total income.
Source: SSO, 2014

Much of the rural non-farm economy literature highlights the role of the following determinants of capacity to engage in rural non-farm (RNF) employment household composition (availability of surplus labour, gender constraints and patterns, decision-making responsibility), education and skills (appear to be a stronger determinant of higher income in the non-farm sector than in on-farm incomes); access to finance (closely linked to land ownership and farm size in rural areas in some but not all countries); infrastructure (helps create the conditions for growth – and also improves access to employment); and social capital, vertical and horizontal network issues and differential conditions of access due to socio-economic status (Gordon, 1999).

Conclusion

The rural economic development in Macedonia is very important as 43% of the total population lives in rural areas, but also two third of poor population are coming from these areas. Many villages in the Republic of Macedonia have suffered from demographic, economic and social decay over the past decade.

The rural households' incomes compared to incomes in urban areas are smaller due to less economic opportunities and undeveloped market in rural areas. In addition, the weather, especially climate change, market conditions and other factors can significantly affect the yields and incomes from agricultural activities, which implies high risks for sustainability of rural households. The rural economy in Macedonia is mainly characterised with large portion of traditional small scale farms, with agricultural activities as main source of income. The most of farms are specialised in filed crop production but also mixed farms, with both, plant and livestock production are dominant, in order to alleviate climate and market risks. Although Macedonian rural areas and rural population possess huge potential and have available investment opportunities in IPARD programme, non-farm activities are insufficiently developed, deploying only 16% of the total rural households, with insignificant share in total income.

The competitive part in rural income structure can be found in self-employment activities showing only stronger position compared with urban incomes from these activities, where are the mainly human potentials for non-farm activities.

In order to boost entering the rural non-farm economy, affordable finance means need to be made available in rural areas; as well education and quality extension services are also necessary in order to encourage people to start competitive and sustainable businesses. In addition, the public infrastructure and services such as utilities, health and roads are of great importance for development of diversified households' incomes and diversified rural economy.

STATUS OF AGRICULTURAL TOOLS AND MACHINERY CAPITAL IN TURKISH AGRICULTURAL ESTABLISHMENTS AND EVALUATION OF ADEQUACY

Mehmet Arif ŞAHINLI[1], Ahmet ÖZÇELIK[2]

[1]Ankara University, Agricultural Economics Department, Ankara, Turkey, Phone: +(90) 312 596 14 77, Ankara 06110 Turkey, e-mail: asahinli@ankara.edu.tr (Corresponding Author)

Abstract

The active capital in agricultural enterprises consists of land (farm) capital and tenant capital. One of the most important elements of the tenants capital is tools and machinery capital. The presence of the tools and machinery capital repeatedly helps to provide employment in the manufacturing of many products in agricultural establishments. This capital is mainly assessed as lifeless stock or inventory. Capital consisting of all kinds of the tools and machinery is found to increase the success of work in business and makes indirect impact on production. The tools and machinery capital in accordance with the activities of agricultural enterprises is essential to work with sufficient capacity and regularity. In this study, we discuss the conditions of tools and machinery capital in the agricultural sector of Turkey. Quite a number of studies have been carried out on machinery capital. Some secondary data have been obtained for the purpose of this study. One of the most important database belong to the tools and machinery capital of Turkish Statistical Institute and other different Institutions and Organizations in national and international arena. The data obtained would be used to evaluate the level of the tools and machinery capital in the agricultural sector and appropriate proposals suggested.

Keywords: *Agricultural tools and machinery, Tractor and the combine harvester statistics, Turkey*

Introduction

The Turkey Gross Domestic Product (GDP) by production based approach increased by 9.0% in 1998 prices increased by 15.9% at current prices in 2010 compared to the previous year. As a result, GDP was 105.738.813 thousand TL in 1998 prices and 1.103.749.801 thousand TL at current prices in 2010. At of 1998 prices, agriculture sector value was 9.999.429 thousand TL and current price value was 92.739.021 thousand TL. Agriculture sector grew by 2.4 percent in 2010 compare to the previous year. Agriculture sector share in GDP is 10.1 percent in 2000 and 8.4 percent in 2010. According to this statistics, the share of agriculture are observed to decline (Turkstat, 2014).

As could be expected the 2008 global economic crisis effected the Turkish economy greatly. During the 2010 year, private sector fixed capital investments were observed to increase by 20 percent and then the shares of agriculture in the private sector fixed capital investment was also seen to increase. At the same time, public sector fixed capital investments were observed at 8.6% in 2008, 9.8% in 2009 and 12.8% in 2010 that these shares were increasing steadily. In 2010, the central government budget investments of 19.3 billion TL, which accounted for 69.3 % of the 27.8 billion TL investment budget allocated. Agriculture sector has 17.8% in this central government budget investment (Mod, 2014).

As part of the EU accession process, ensuring competition in markets and providing sustainability in sectors are taken into account. It is of important that agriculture supports be

differentiated on product and area basis and their implementation and control will be based on areas. The prices of agricultural crops which are subject to activities of Agricultural Sales Cooperatives and Associations and State Economic Enterprises increased at an average rate of 9.5% and 7% in 2008 and 2009, respectively. The primary objective in the agricultural sector is to ensure food security, reliability and an established organized and highly competitive structure while observing the sustainable use of natural resources. During the EU accession process, necessary institutional and administrative transformation would be given priority in order to increase the competitiveness after full membership (Mod, 2014).

Şahinli (2014) in his study emphasizes food and agriculture trade and used data belonging to Food and Agriculture Organization (FAO) for the years 2000 to 2011. The Revealed Comparative Advantage Index (RCA) was calculated for the 601 agricultural firms inTurkey. The RCA greater 1, indicated that *i*th goods in the *j*th country has a comparative advantage. On the condition that only 78selected agricultural firms were found to have over one value for the RCA. Turkey's economy has been steadily growing since the year 2002. Turkey has many well-qualified agricultural engineers, employees, sufficient and necessary infrastructure, and good geographic conditions, which create important opportunities for Turkey in the current global market. However, in order to maintain and further improve its competiveness Turkey should give priorities to improving existing infrastructure and productivity.

Materials and method

This study employed data of Turkish Statistical Institute for the period from 2000 to 2015. In mechanization of agricultural practices, the most widely used power source is tractor and the combine harvester statistics. Start with, we examine the combine harvester statistics indicator. By using these statistics, base year (2000=100 and 2001=100) and the previous year values are calculated. Regarding with these statistics and indicators are preliminary examined and compared to the years.

According to the Table 1, combine harvester numbers are given by age group. These groups are categorized into four different age groups and total number of combine harvester is given, too. For the base year 2000=100, Turkey's combine harvester numbers and previous years' increasing are calculated. According to the base year, combine harvester numbers have been increasing from 2000 and onwards. Especially after 2008, this value has been steadily increasing. When we use the previous year's value of combine harvester, combine harvester values have been slowly increasing since 2005.

(Gokdogan, 2012) explained the indicators of the level of mechanization of agriculture in Turkey and these indicators have been compared with indicators of the European Union. This study examines Turkey and the European Union's agricultural structures and mechanization properties. This study elaborates the current situation of Turkey and the European Union's agricultural structures and agricultural mechanization properties. Indicators of the level of mechanization in Turkey are 1.68 kW ha-1; 24.80 ha/tractor; 40 tractors/1,000 ha; 5.20 equipments/tractor; 4.20 tons/tractor; in the European Union however 6 kW ha-1, 11.30 ha/tractor; 89 tractors/1,000 ha; 10 equipments/tractor; 12 tons/tractor. According to these comparisons, the level of mechanization in Turkey in terms of the degree of mechanization of the indicator values is higher than the EU average.

Table 1. Number of combine-harvester, 2000-2015

Year	Total	Age group				2000=100	% (Previous year)
		0 - 5	6 - 10	11- 20	20+		
2000	12 578	-	-	-	-	-	-
2001	12 053	-	-	-	-	-4.17	-4.17
2002 (1)	11 539	1 213	2 125	3 526	4 675	-8.26	-4.26
2003	11 721	1 352	2 214	3 545	4 610	-6.81	1.58
2004	11 519	1 430	2 298	3 489	4 302	-8.42	-1.72
2005	11 811	1 659	2 405	3 551	4 196	-6.10	2.53
2006	12 359	2 036	2 598	3 596	4 129	-1.74	4.64
2007	12 775	2 338	2 739	3 652	4 046	1.57	3.37
2008	13 084	2 558	2 873	3 657	3 996	4.02	2.42
2009	13 360	2 643	2 950	3 669	4 098	6.22	2.11
2010	13 799	2 820	3 116	3 721	4 142	9.71	3.29
2011	14 313	3 038	3 293	3 834	4 148	13.79	3.72

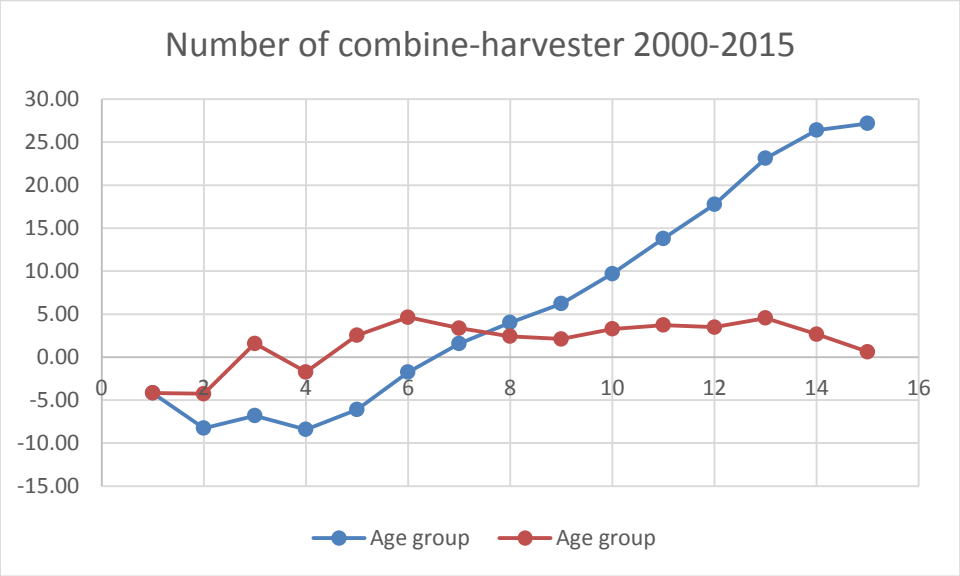
(1) Data related to age group have been compiled since 2002.

Figure 1. Number of combine-harvester 2000-2015



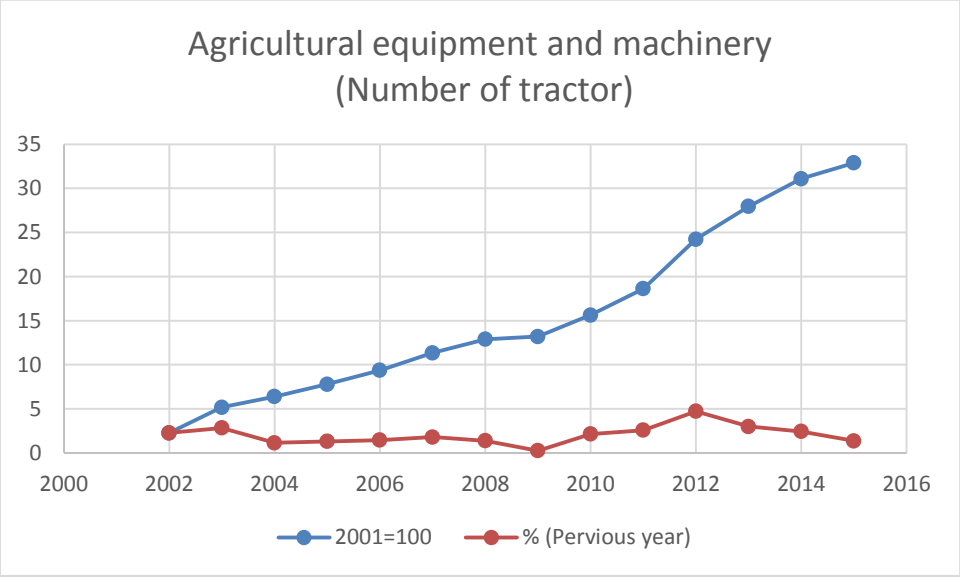
According to the Table 2, tractor numbers are given by the years. These values show that the tractor numbers have been smoothly increasing. By using this number, we calculated to examine the differences for the base year (2001=100) and previous years' ratio. As you see from these tractor numbers, these values have been sharply increasing according to the base year.

(Durgut and Arın, 2005) in their study carried out in Trakya Region (Provinces of Edirne, Kırklareli and Tekirdağ). Parameters of the mechanization level were found to be 33.73 kW/ha, 4.1 equipment unit/ enterprise and 5.02 equipment unit/tractor. Mechanic energy usage for the most applications except tillage and sprayers was found to be insufficient because of inappropriate plantation for agro-technique needed.

Table 2. Agricultural equipment and machinery

Year	Number of tractor	2001=100	% (Pervious year)
2001	948.416		
2002	970.083	2.28	2.28
2003	997.620	5.19	2.84
2004	1.009.065	6.39	1.15
2005	1.022.365	7.80	1.32
2006	1.037.383	9.38	1.47
2007	1.056.128	11.36	1.81
2008	1.070.746	12.90	1.38
2009	1.073.538	13.19	0.26
2010	1.096.683	15.63	2.16
2011	1.125.001	18.62	2.58
2012	1.178.253	24.23	4.73
2013	1.213.560	27.96	3.00
2014	1.243.300	31.09	2.45
2015	1.260.358	32.89	1.37
Source: Ministry of Food, Agriculture and Livestock			

Figure 2. Agricultural equipment and machinery (Number of tractor)



According to the Table 3, total utilized agricultural land in Turkey is given by hectares. As can be seen from this Table 3, 2001=100 base year and % (Previous year) are calculated. According to the base year, total utilized agricultural land have been slightly decreasing from 2006 and onwards. Compared to the previous year, total utilized agricultural land value has been increasing from 2012 and onwards.

As I mentioned earlier, tractor power per hectare is an important indicator of mechanization. Statistical indicators emphasized that average tractor number per area in Turkey increased from 2001 to 2015. A strong relationship between tractor number and agricultural productivity was observed in the situation of Turkey.

Table 3. Total utilized agricultural land (Thousand Hectares)

Year	Hectares	2001=100	% (Previous year)
2001	40.967		
2002	41.196	0.56	0.56
2003	40.644	-0.79	-1.34
2004	41.210	0.59	1.39
2005	41.223	0.62	0.03
2006	40.493	-1.16	-1.77
2007	39.504	-3.57	-2.44
2008	39.122	-4.50	-0.97
2009	38.912	-5.02	-0.54

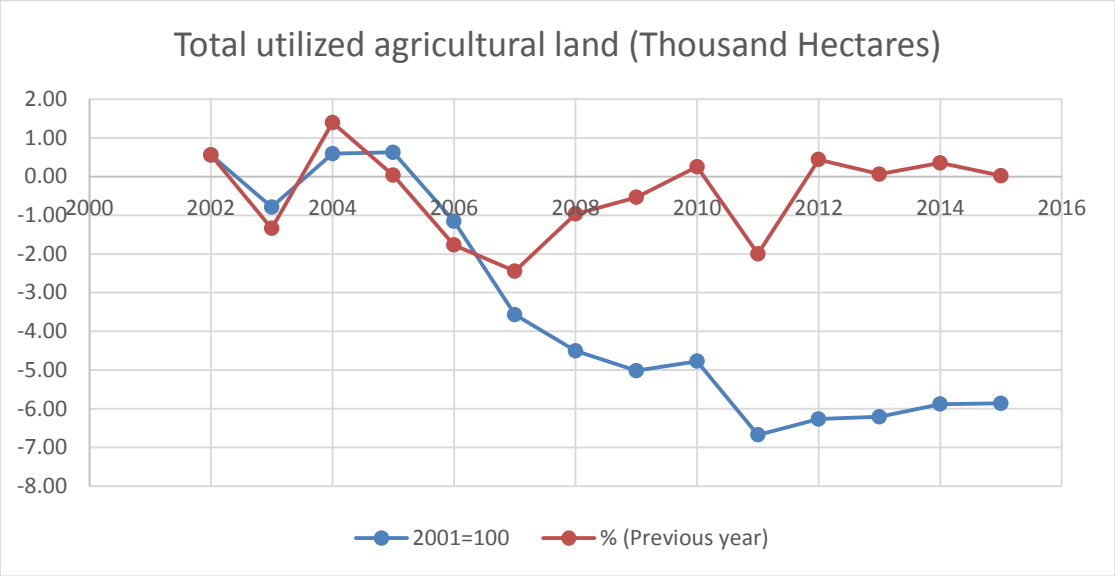
2011	38.231	-6.68	-2.00
2012	38.399	-6.27	0.44
2013	38.423	-6.21	0.06
2014	38.558	-5.88	0.35
2015	38.566	-5.86	0.02

Source: For land under permanent meadows and pastures 2001 General Agricultural Censuses, for other Ministry of Food, Agriculture and Livestock

Figure 3. Total utilized agricultural land (Thousand Hectares)



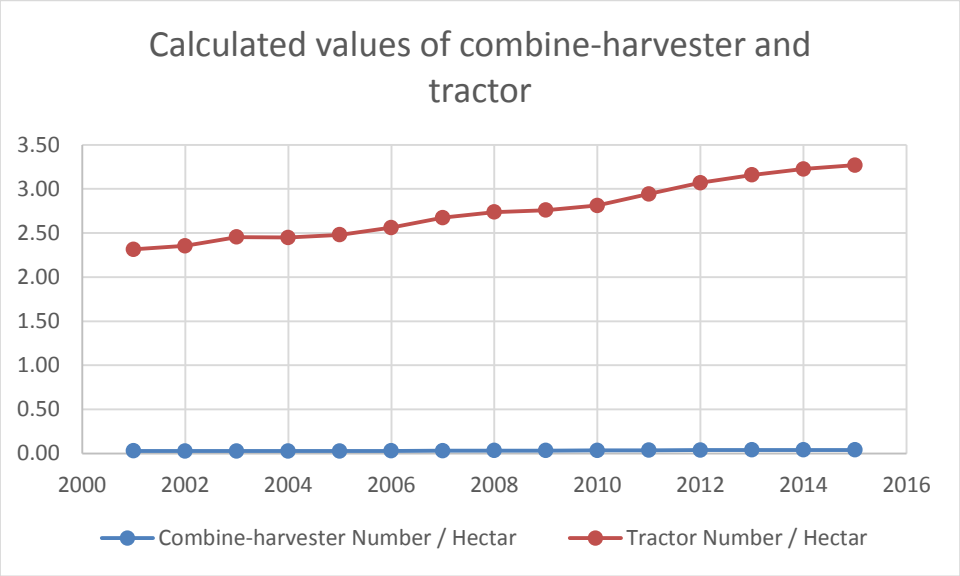
According to the Table 4, there are two indicators, combine-harvester number / total utilized agricultural land and tractor number / total utilized agricultural land. Approximately, while combine-harvester number has 3 per total utilized agricultural land (10000 hectar), tractor number has 25 per total utilized agricultural land (1000 Hectar). As a conclusion, tractor numbers are more superior than the combine-harvester numbers in Turkey.

(Baran et. al. 2016) in their study explained that machinery-equipment group has been included under the scope of grants by the state in Turkey since 2007. Under the grants scheme, 50% grant assistance in the form of machines were distributed. In all from 2007 to 2013 about 221.620 machine-equipment from 41 different tool machine types were distributed to the 81 provinces of Turkey in a period of 7 years. The grants assistance programme does not only enable farmers to park the old machines but it also presented the opportunity for farmers to use high-tech new machinery.

Table 4. Calculated values of combine-harvester and tractor

Year	Combine-harvester Number / Total utilized agricultural land (10000 Hectar)	Tractor Number / Total utilized agricultural land (1000 Hectar)
2001	3	23
2002	3	24
2003	3	25
2004	3	25
2005	3	25
2006	3	26
2007	3	27
2008	3	27
2009	3	28
2010	4	28
2011	4	29
2012	4	31
2013	4	32
2014	4	32
2015	4	33

Figure 4. Calculated values of combine-harvester and tractor



Conclusions

Agricultural mechanization has a vital role as far as the improvement of total agricultural production by farmers. There are many important technologies and inputs which are the most important elements are tractor numbers and the other mechanization. By increasing the mechanization and technological devices, agricultural production will be increased in Turkey before the years. In this study, mechanization level of tractor numbers and the other machines in Turkey were examined and compared using statistical indicators.

The increase in the agricultural production is generally depend on mechanization as such agricultural mechanization stands as one of most important agricultural production technologies and inputs. This study concludes that the main reason of the increasing tractor numbers has been attributed to the increasing Purchasing Power Parity (PPP) of the agricultural farmers in Turkey.

It has been observed that not all the regions have larger numbers tractors and engine powers. Due to this efforts should be made to examine the available tractor and power equipment in every province befor new allocations.

Agricultural subsidies should be allocated to farmers to enable them acquire strong machinery for production. Also, if interest rate are reduced, economically and socially disadvantage farmers can afford machines and thereby increase mechanization and also enhance their productivity and efficiency in production. This would have a positive effect on their income levels.

THE SHORTAGE OF AGRICULTURAL LABOUR FORCE IN ALGERIA: A CASE STUDY

Slimane BEDRANI*, Marouane CHAAMI, Fatma Zohra TAIBI, Bochra BOUHENDJEUR

National Agronomic School, Algiers, Algeria
s.bedrani@ensa.dz

Abstract

In Algeria, over the past fifteen years, more and more farmers are complaining about the lack of labor. To measure the phenomenon, give plausible explanations and report the behavior of farmers facing this problem, two surveys were conducted with farmers in two rural areas geographically and climatically very different: one covers an agro-pastoral area and the other an irrigated plain. After compilation and analysis of the surveys, it appears that the lack of labor is felt by the majority of farmers, especially by those who have no, or little, family labor. There are several causes to this: the state aid to the unemployed that does not encourage them to accept agricultural work, remuneration levels made by farmers are perceived as unattractive, the employment opportunities in the informal sector are numerous and provide interesting and earned income with less effort than that required by the agricultural work. Farmers are responding to this by increasing the mechanization of their work.

Keywords: Algeria, Agricultural Workers, Rural Development

Introduction

Algeria has a relatively high unemployment rate: 10.6% of the labor force in September 2014, with 11.4% in urban and 8.9% in rural areas. 27% of the unemployed population is in rural areas. In addition, 25.2% of young people (16-24) declare to be unemployed. During recent years, the press reported that more and more farmers complain about the lack of manpower to carry out the field work (APS, 2014; Benabbou, 2014; Bencherki, 2016, W.O.H, 2015).
What is the extent of the lack of agricultural labor phenomenon? If it is real, does it exist in all regions with the same intensity? What might be the main causes?

Materials and methods

In the attempt to answer these questions, two surveys were conducted in two agricultural regions which differ in both climate and farming systems. The first covers the municipality of *Hadj Mechri* which lies northwest of the *wilaya* of Laghouat; about 470 km southwest of Algiers. The second covers the four municipalities of the *Yellel daïra* (*Relizane*) which is 270 km west of Algiers.
The town of *Hadj Mechri* has a semi-arid climate with harsh winter due to its high altitude (1250 m). The area experiences a dry period from late April to late October, low rainfall (215 mm per year), which is very irregular not only intra- but also inter-annual.
With a density of 12 inhabitants per square kilometer, the town of *Hadj Mechri* is rural, largely dominated by the scattered settlements which include 75.6% of the population (24.4% living in secondary towns). In 2013, the population consisted mainly of young people (31.9% of 15-29 years old and 36% under 15 years), while the age groups of 30-59 years and over 60 years, form 26.1% and 6% of the population, respectively.
Nomadism - dominant in the fifties and still present in the seventies - has completely disappeared. The pastoral small ruminants (sheep and goats) are the main economic activity, 85% of the total agricultural area of the municipality consisting of rangelands. The cereal rainfed mode (low yields and very random) and irrigated agriculture from boreholes occupy

only 5% of the total agricultural area. Agriculture holds 35% of the employed population and the services and administration 62%. The industry is almost nonexistent (1% of the employed population) while the "building and public works" sector holds only 3% of the employed population.
In 2013, official statistics had an unemployment rate of 8.4% of the workforce.
Hadj Mechri surveys were conducted with a sample of herders and farmers and local administrative authorities. The sample size is 50 farmers forming 18% of the parent population (consisting of pastoralists and farmers rearing sheep). The sample was drawn by the *Hazard* Excel software. For farmers practicing irrigation (but not having sheep), the sample is not random because of the absence of the list of these farmers. Key informants designated 10 of the farmers to inquire.
The *Yellel daïra* consists of a plain with an altitude of 135 meters. The climate of the region is hot and dry in summer and cool and wet in winter. The average rainfall is 350 mm / year over the last decade (2004-2014) with a strong inter- and intra-annual irregularity.
With a density of 327.1 inhabitants per km^2, the *Yellel daïra* conceals a highly rural population (74% of the population).
In *Yellel*, a sample of 100 farms randomly drawn was investigated. Interviews were also conducted with some local authorities.

Results and discussion

Agricultural labor shortage is a reality. This is the first result of our investigations.
About *Hadj Mechri*, analysis by the hierarchical clustering method (CAH) identified two classes among respondents in our sample. These two classes cover the different production systems in a perspective that expresses the existence or not of difficulties in hiring of labor, the causes of these difficulties and the type of work needed by farmers.
Table 1 below shows that overall 30% of the surveyed farmers express a lack of manpower. But from this point of view, the differences are considerable between the different production systems.
The farmers of the "pastoral and agro-pastoral" production systems are the least affected by the phenomenon: only 13% of them complain about the lack of manpower. Yet this lack manifests itself acutely with landless farmers (without agricultural area).
The trade of sheep, that is considered as requiring a good qualification (which is acquired in the area only by practice), does not find candidates for reasons which will be below exposed.
The farmers of the production system "polyculture-farming" associate extensive rangelands with irrigated agriculture (potato, onion, other vegetables), some with a few plots in rain-fed agriculture. 70% of these farmers suffer from lack of work force.

Table 1. Number of farmers by production system and lacking manpower

Production system	Structure*	Farmers with lack of manpower	Farmers without lack of manpower
Pastoral and agro-pastoral system (40 farmers)	E	5	6
	E+S	0	25
	E+S+A	0	4
Mixed farming (agriculture and livestock) (10 farmers)	E+PT+O+C+M+A	1	0
	E+PT+O+C	3	0
	E+PT+C	1	0
	E+PT	1	1
	E+PT+M+A+S	1	1
	E+PT+M +S	0	1
Irrigated crops without livestock rearing (10 farmers)	PT+O+C+M+A	1	0
	PT+O+C	2	0
	PT+O	0	4 nomads[1]
	PT+C+M	1	0
	PT+C	2	0

** PT: potatoes ; O: onion; C: irrigated cereals; M: mixed (cucurbits, small-pea, other vegetable crops); A: fruit growing; S: rainfed grain; E: Livestock.*

Among the farmers lacking labor force, 55% lacked workers for land preparation, planting, spreading fertilizers, hoeing, weeding and mounding. 65% lack laborers for irrigation and 80% for harvesting. It should be noted that these farmers only need unskilled seasonal workers.

Farmers of the "Irrigated crops without sheep» production system all lack manpower but four of them. But these four are “itinerant” farmers from the region of *Mascara* (in the north) who bring with them their own workers (for fear of not finding workers in the area of *Hajj Mechri*).

In *daïra Yellel*, 67% of 100 surveyed farmers say that there is existence of a labor shortage; shortage affecting everyone, whatever the size of farm. However, correspondence analysis shows that the variables “agricultural area” (UAA) and “irrigated area” are the determining factors of the lack of manpower. This means that whenever the UAA and the irrigated area increase, the problem of lack of labor force increases, mainly for the following crops: cereals and olive growing. Farmers need labor especially for harvesting operations (about 40% of farmers surveyed), soil preparation (32%), sowing and planting (10.8%) and weeding (7.7%). For *Yellel* like *Hadj Mechri* for gardeners, farmers need mostly unskilled seasonal labor. In

[1] The itinerant farmers are originating in the area of Mascara. They rent plots of land in Hadj Mécheri to cultivate there mainly potato and ognon under irrigation. The blue-collar workers whom they use (for plantation, irrigation and harvest) come from *Mascara* and spend all the period from March to September in huts near the cultivated plots.

fact, only 8% need permanent workforce and 15% skilled workers. Overall, the labor shortage appears with crop intensification through irrigation and extensive sheep breeding herds of a hundred heads or more.

The causes of labor shortages in agriculture and livestock

The labor shortage has been - and still is - a problem especially in developed countries, which have been forced early to import labor from abroad. In France, for example, industrialization has caused a massive rural exodus. Cities attract - thanks to high wages - the poorest rural workers. As Darpeix (2013) pointed out "*The lack of arms is therefore felt in the cities, but especially in the countryside, mainly manual jobs, hard and low-paid*". Even now - despite their inclination to curtail immigration - all European countries import Seasonal Agricultural Workers: Spain mainly from Morocco, France from Morocco and Tunisia, Italy from Albania and Tunisia, Germany and the UK countries from Poland, Romania, Bulgaria... (Morice and Michalon, 2008). But, already, one announces in these countries the possibility of immigrant workers shortage, that being due to the very bad terms of recruiting and employment of this workers. These bad conditions are denounced by the defenders of the farm workers, defenders who push the States to enforce the labor law strictly. Now these poor conditions (low wages, flexibility, lack of social security, undeclared contracts, ...) are needed to make profitable fruit and vegetable crops for which immigrants are hired (Michalon and Morice, 2008). If the labor law of the host country is strictly observed, there is a risk that farmers abandon the intensive crops workforce, predict these authors.

By comparison, what about in Algeria?

Industrialization as a phenomenon that attracts rural workers to the cities and therefore reduces the available labor force in agriculture cannot be questioned in Algeria. Indeed, the industrial sector - after more than half a century of independence - is small. It contributes only 4.6% to GDP (2012) and includes only 10% of economic entities identified in 2011 (ONS, 2012). However, the trade sector powerfully attracts labor not only in its formal part but also, especially, in its informal part, which dominates the sector in question. In its only formal part (therefore traders with the commercial register), it forms 55% of economic entities recorded in 2011. If we add the service sector, it gathers 89% of economic entities.

The poor conditions of life and work in agriculture and livestock, as the second cause of the agricultural workforce shortages exist relatively in strong way in Algerian agriculture. Indeed, in both surveys, any agricultural worker hired - whether permanent or seasonal - is declared to social security (no dues for retirement, no health insurance and work injury). In addition to this lack of benefits, the drudgery of farm work is not the least because of the refusal of this work. According to 57% of respondents in *Hadj Mécheri* this causes workforce shortage. This is especially the case of the employees in sheep transhumance. The shepherd family moves very often (wife and children) staying in a tent, away from health services, schools, administrative services, undergoing the rigors of winter and the heat in summer, often far from camping water points for watering livestock and domestic needs. Given these working conditions, the monthly remuneration received (about 300 dinars per sheep or 30,000 dinars for a herd of 100 head) is well below the average net salary of a supervisor paid by an employer in non-agricultural sectors (around 41,236 AD[2]). At this price, it is not surprising that it is difficult to find a shepherd. In general, workers in agriculture are highly underpaid compared to workers in other sectors of the economy as revealed by the investigation of the National Statistics Office on wage income, which shows that the first receive only 59% of the overall average net salary (ONS, 2011).

[2] US $ 1 is worth 165.5 AD (Algerian Dinar) on the informal market and 111.3 AD at the official exchange rate.

Another cause of the labor shortage is, according to 60% of respondents in *Hajj Mechri*, in the social policy of the state (Table 2). This policy would offer many opportunities for the unemployed either to create their own jobs [through loans and grants from the National Agency for Youth Employment Monitoring (ANSEJ) and the National Micro-Credit Management Agency (ANGEM)], or to receive unemployment benefits, either in temporary employment positions in administrations, temporary jobs that can turn, over time, into permanent jobs.

Table 2. Causes of agricultural labor shortage given by farmers surveyed in *Hajj Mechri* (% of respondents)

Causes of the agricultural labor shortage	% of respondents
State policies for youth employment and the unemployed	60%
Preferences of labor forces to other areas	57%
Poor working conditions	57%
Refusal of agricultural work by young people	55%
Education of children and rural exodus	40%
Decreased family labor	32%

Source: Hadj Mechri Survey

In *daïra Yellel*, farmers give as reasons for the labor shortage, first, refusal by young people to work the land, second, preference among young people for "easy work" (almost 60% of responses to the two reasons). These two other reasons must be added: too much drudgery of farm work and the non-recognition by young people of the importance for the nation's agricultural sector. Considering all these reasons, it is almost three-quarters of respondents who think that agricultural work has a repellent effect for young people. The other big reason, as to *Hajj Mécheri*, is the policy to support youth employment implemented by the state (Table 3).

If young people "do not want to work the land" and "prefer easy jobs" is also, no doubt, because they believe that agricultural work is paid too little, given its vulnerability, its arduousness and given the fact that they are never reported to social security and receive no social benefit. According to the declarations of farmers surveyed in *Yellel*, the farm laborer receives about 1,000 dinars per working day (time period of 6 to 8 hours), amount slightly higher than the legal minimum wage (about 930 DA including social charges). In *Hadj Mechri*, the daily wage is 1200 DA for 6-7 hours per day). It should be noted that very few formal employees are paid with the guaranteed minimum wage tariff, including in the public service. Indeed, the least skilled workers in economic sector – either public or private - ("executing agents" in the list of official statistical services) in 2013 receive an average net monthly salary of 26,843 DA.

Table 3. The causes of labor shortages according to weary farmers in Yellel (% of respondents)

Causes	%	
Young people do not want to work the land	36.20%	**73.80%**
Young people prefer the easy work	21.70%	
Young people ignore the importance of the agricultural sector	11.60%	
The working conditions are perceived as too harsh	4.30%	
Support to youth employment implemented by the state	15.90%	**15.90%**
Many farmers are looking to hire agricultural workers	10.10%	**10.10%**
Total	**100.00%**	**100.00%**

Source: Yellel Survey.

Conclusion

The analysis of the results of the surveys conducted in two agricultural regions, which differ in both climate and farming systems, reveals that the labor shortage in the agricultural activities is very real. Both main causes of this labor shortage are the hard conditions of the agricultural work (to which is added a weak remuneration) and the opportunities which offer the policies of the State to the unemployed persons.

POSSIBILITIES DEVELOPMENT OF NEW RISK MANAGEMENT TOOLS IN AGRICULTURE

Joanna PAWŁOWSKA-TYSZKO[1*]

[1]Agricultural Finance Department, Institute of Agricultural and Food Economics – National Research Institute, Poland
Corresponding author: tyszko@ierigz.waw.pl

Abstract

The experience of countries of the Community clearly indicate that the existing risk management instruments (including insurance subsidized) are not fully utilized, and what more do not guarantee fully the financial stability of farms. Hence appear the new needs for innovative risk management tools in agriculture. The aim of the study will attempt to assess past experience in the implementation of risk management tools (including agricultural insurance subsidized) in Poland in terms of the possible the development of new risk management instruments. For the analysis of the legal status were used the Polish insurance regulations and EU legislation in the range of the functioning of risk management tools recommended by the CAP. Conducted analyzes indicate that the market for crop insurance and livestock is poorly used by Polish farmers. It is estimated that only 12% of farms in Poland insures the their crops. In the case of animals the situation is even more unfavorable, because in Poland we have insured only 5% of the animals. Moreover, the level of the utilization of subsidies for agricultural insurance is low. The analysis shows that many farmers do not decide to buy insurance. Lack of comprehensive system solutions for the protection of risk in agriculture will force the need to introduce the new instruments such as the: indexed insurance, Mutual Fund (MF) or Income Stabilisation Fund (ISF).

Keywords: *Risk management tools, Risk management in agriculture, Common Agricultural Policy, Poland.*

Introduction

The risk accompanies virtually every field of economic life and is an indispensable attribute of the business activity. In this regard, agriculture is not any exception. Śmigiel-Krajewska notes that in relation to the agricultural production the risk is a particularly complex phenomenon, not only due to the size of threats, fragmentation of production entities, but also due to the unpredictable variability of phenomena [Śmigiel-Krajewska, 2014].

Acquisition of the responsibility for the effects of such the risk by an agricultural holding seems to be a heavy burden, not only in the psychological, but, first of all, in the financial dimension, which makes this behavior unprofitable. In order to avoid greater losses, of essential importance is public aid as regards access to a properly organised – according to the needs of a given country – system of risk management instruments in agriculture geared towards mainly to stabilising farmers' income. This is indicated by the studies conducted by Cordier, who notes that the modern state policy should focus on instruments limiting the risk of a decline in income [Cordier, 2009]. These may be market instruments e.g. futures contracts, coordinated production systems supported by the state, inter alia, by creating commodity exchanges or supporting integration processes in agriculture. In case of large-scale losses, the role of the state should be to create crop and livestock insurance schemes supported by subsidies, or to create of a legal framework for the functioning of special funds in case of natural disasters or crises in the food market. Among the instruments that can play

an important role in mitigating the effects of the risk and stabilising agricultural income, we should mention those to which the European Commission pays particular attention within the framework of the CAP. They include subsidised crop and livestock insurance in case of natural disasters, mutual funds and income stabilisation funds. These instruments place a particular emphasis on reducing losses and stabilising income by means of funds based on the principles of reciprocity and solidarity. However, experiences of the Community countries clearly indicate that the risk management instruments (including subsidised insurance) are little used, and what is more, they do not guarantee fully the financial stability of the country.
The objective of this study was to attempt to assess the risk management system existing in Polish agriculture in terms of the use of existing instruments. An analysis of statistical data has been developed based on the FADN database, covering the years 2009-2014. The analysis used the methods of descriptive statistics as well as tabular and graphic summaries.

Risk management in agriculture as part of the CAP

The existence of risk in agriculture creates a need to search for an alternative way of protecting against its occurrence and effects. Farmers deal with the risk in a different way: by appropriate shaping of the activity in their agricultural holding (diversification, avoiding risky activities, flexible shaping of crop structures) and by a strategy, in which the risk is distributed over other entities, over the entire or a part of the community (insurance, contracting, etc.) [Adamowicz, 2002].
The issues related to the risk reduction are raised at the national, EU and global levels. At each of them, various legal instruments may be applied, which, primarily, should not preclude each other. The issues of risk management in agriculture have been raised under the common agricultural policy for many years. The need to support the agricultural sector by providing relevant risk management instruments, which are adequate to the modern needs of agriculture was noticed in 2006. So far, farmers have managed the risk by means of national programmes. Pursuant to the Regulation of the European Commission of 15 December 2006, the public aid rules have been established in a form of covering losses or subsidies to insurance contributions [Regulation, 2006]. In the new perspective 2014-2020, the European Commission pays special attention to the risk management tools from the so-called 2nd pillar of the CAP, which are allocated for rebuilding the potential of the agricultural production damaged by natural disasters [Regulation of the European Parliament and of the Council (EU), 2013]. These tools include:

- indexed insurance – is applied in case of losses caused by adverse climatic events, occurrence of animal or plant diseases or pest invasion. The mechanism consists in co-financing insurance contributions paid by farmers or support for national reinsurance schemes.
- mutual investment funds – their concept is to encourage farmers to share risk. They are financial compensation to farmers for losses caused by animal or plant diseases or environmental incidents.
- income stabilisation fund – financial compensation for farmers suffering a serious decline in income. The fund guarantees basic income insurance in case of crisis situations.

In the EU countries, the most frequently applied solutions are various types of insurance, including subsidised insurance and *ad hoc* compensation coming usually from the state budget and paid at the time of a disastrous event and their amount depends on the financial possibilities of the state budget. Only few Member States introduce other solidarity instruments, i.e. mutual funds and income stabilisation funds, which is presented in Table 1.

The risk management instruments in agricultural holdings, as presented in Table 1, shall be financed from the resources of the 2nd pillar of the CAP. However, it should be clearly stressed that many states, including Poland, finance this type of tools from the national policy resources [Act on crop and livestock insurance…, 2005]. An overview of the risk management tools in the EU countries clearly indicates that in case of a disastrous event the most frequently used is subsidised insurance of crops and farm animals (it is most heavily subsidised in Spain and Italy). Subsidised insurance is also the most common form in countries such as the USA, Japan, Canada and Brazil. The tools to secure farmers' income are very rarely used (Hungary, Italy, outside the EU – Canada), so are mutual investment funds. Little interest in mutual funds may result from legal and financial restrictions. However, it should be noted that many states finance this type of instruments from the national policy resources, including, inter alia, the Netherlands, where mutual funds have already a long tradition. This situation results from the fact that such institutions may be formed pursuant to the general rules (provided that they exist).

The application of individual risk management tools is largely determined by the type of the risk occurring in the EU Member States. Therefore, the states, within the framework of available financial resources, assess the imminent risk on themselves and make a decision on the adoption of the most beneficial solution. The general mechanisms based on general insurance supported usually by national budgets, have been applicable in all countries of the Community since 2010. Each Member State has an opportunity to develop its own legal system governing this issue. So far, in most EU countries insurance has been general, but voluntary.

Risk management policy in Poland

Risk management in Polish agriculture has a long tradition, however, both a set of used instruments and their universality, is not satisfactory. As it results from the existing studies, it is an area which is rarely used [Florek, 2012; Śmiglak, 2007]. The most common solutions are various types of insurance and *ad hoc* aid. Another commonly used, indirect form of securing against the effects of the risk is to exempt farmers from all sorts of fees. For example, reliefs in agricultural tax, in social security contributions or preferential loans are applied. Among insurance, the most common forms of risk protection is property insurance. It covers with protection the assets in the form of goods or economic position. The object of insurance is financial interest understood as the economic value or any kind of goods protected by law [Ronka-Chmielowiec 2002, Kowalewski 1997].

The basic provisions governing the issues of compulsory insurance coverage (including, *inter alia*, crops, livestock and movable property) in agricultural holdings appeared in Poland in the 1950s. Securing farmers against the effects of weather changes by means of crop insurance was at a satisfactory level. Free market policies in agricultural insurance were introduced as late as in the 1990s, thus cancelling the obligation to insure crops, livestock and movable property, which resulted in a drastic reduction in policies in the insurance market and large non-renewable damage to agricultural holdings. In 1990, only 5,000 policies were taken out, which, when compared to 1989, meant a five-fold decrease. Not before 2005, were system solutions introduced, consisting in subsidising the contribution for crop and livestock insurance by the state so as to increase the scope of using this insurance by farmers (Crop Insurance Act, 2005].

According to the Polish legislation, some types of insurance addressed to the agricultural sector are compulsory (third-party liability insurance, motor third party liability insurance, insurance of buildings, insurance for 50% of the cultivation area and livestock – quasi compulsory) [Act on compulsory insurance, 2003], while some are voluntary (insurance of the agricultural holding's property, forest stand, perennial plantations). The largest part of the collected agricultural insurance contribution is compulsory insurance. From the FADN data analysis it results that in 2014 a fee due to the contribution for compulsory insurance of buildings was paid by 97% of individual agricultural holdings, and for third party liability insurance – 99%. Similar values also apply to paying contributions for compulsory motor insurance. Against this background, the situation in case of taking out voluntary or quasi-compulsory insurance policies is much worse. Insurance for movable property is taken out by only about 30% of farmers and 21% of farmers insure their crops (Table 2). The results of analyses carried out based on the FADN data are also confirmed by the PFSA.

Table 2. Agricultural holdings paying contributions for economic insurace (compulsory and voluntary) (%)

Type of insurance	**% of all holdings**
Insurance of buildings	97
Farmer's liability insurance	99
Insurance of movable property	29
Motor third party liability insurance	92
Specific crop insurance	21
Specific livestock insurance	1
Production insurance	3
Insurance of forest stand	0
Insurance of perennial plantations	1
Other insurance	8

Source: own elaboration based on the FADN data.

In Poland, the market of risk management instruments in agriculture is only at the initial phase of development. The most developed are compulsory insurance or insurance with state budget subsidies. However, similarly as in the EU Member States the scale of implementation (cultivation area covered by insurance, number of farmers taking out policies) of these instruments in the Polish market is small.

An analysis of the FADN data indicated that from among about 12 thousand holdings being the FADN database, in the years 2009-2014 contributions for crop insurance with state subsidies were paid only by about 21% of holdings (Table 3). This means that about 80% of holdings still remain uninsured, in particular very small and small holdings. The largest group of entities insuring their crops were very large holdings (from about 37% in 2009 to about 40% in 2012). Very small holdings (up to 5 ha) had virtually no crop insurance, in the total number of holdings they accounted for, on average about 2%. It is worth noting that the number of those paying contributions for crop insurance in the group of very small holdings decreased over the analysed period by about 50%. Against this background, the other groups of holdings, in which the number of those paying contributions from 2009 to 2014 remained almost unchanged, look a bit different.

Table 3. Share of holdings according to area groups paying contributions to crop insurance in the total number of agricultural holdings of the FADN (%)

Area of AL	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**
Very small (<=5 ha)	2.7%	2.8%	3.1%	2.2%	1.6%	1.9%
Small (5<=10 ha)	7.9%	8.2%	8.9%	7.1%	6.8%	6.3%
Medium small (10<=20 ha)	11.8%	13.1%	12.9%	13.3%	13.8%	12.7%
Medium large (20<=30 ha)	19.3%	20.6%	19.6%	18.5%	17.8%	18.7%
Large (30<=50 ha)	24.7%	26.1%	26.3%	27.3%	28.1%	27.4%
Very large (>50 ha)	36.5%	38.5%	39.9%	40.1%	39.1%	38.9%
TOTAL	19.2%	20.7%	21.0%	21.2%	21.1%	21.0%

Source: own elaboration based on the FADN data 2009-2014.

An analysis of the data by FADN regions showed that the largest group of holdings insuring their crops are the entities located in the region of Wielkopolska and Śląsk (from about 32% to about 38%, depending on the analysed year), and then holdings from the region of Pomorze and Mazury (from about 20% to more than 23%). The smallest group are holdings

representing the region of Mazowsze and Podlasie, where only about 7-8% of the analysed entities take out insurance (Table 4). It is worth mentioning that in these regions there is the largest number of holdings engaged in the large-scale agricultural activity. This is related mainly to the production facilities in a form of good quality soils. It should be stressed that regardless of the region, the most numerous group paying contributions for crop insurance are large and very large holdings, which is shown in Fig. 1.

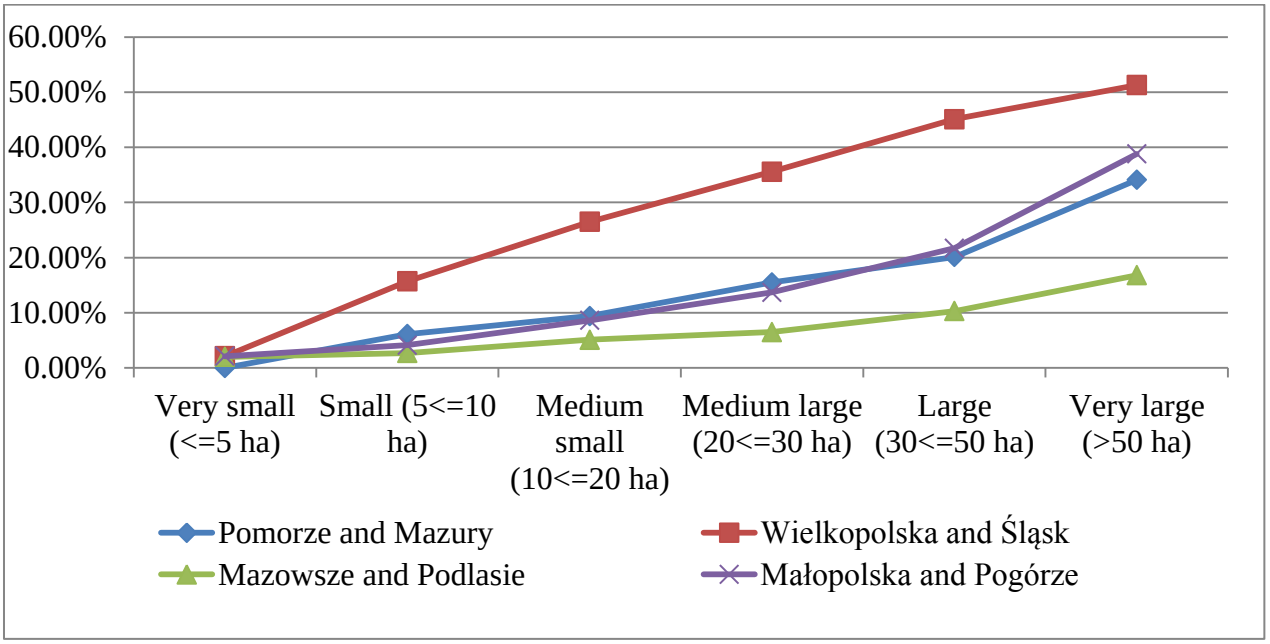
Table 4. Share of holdings in the agricultural regions of the FADN paying contributions to crop insurance in the total number of agricultural holdings of the FADN (%)

FADN regions	2009	2010	2011	2012	2013	2014
Pomorze and Mazury	19.9%	20.2%	21.4%	23.5%	22.6%	21.5%
Wielkopolska and Śląsk	31.9%	35.5%	35.7%	36.8%	37.6%	37.4%
Mazowsze and Podlasie	8.8%	8.7%	8.6%	7.7%	7.2%	7.2%
Małopolska and Pogórze	11.8%	13.2%	13.3%	11.8%	12.9%	13.4%
TOTAL	19.2%	20.7%	21.0%	21.2%	21.1%	21.0%

Source: own elaboration based on the FADN data 2009-2014.

In 2014, small holdings (up to 5 ha of AL) practically did not use the insurance offer. This situation looked worst in the region of Pomorze and Mazury, where no such holding paid contribution for crop insurance. However, it should be added that those holdings did not also insure (as part of compulsory insurance) their buildings, as well as did not pay contributions for farmer's liability insurance. As the area of the holding grows, interest in taking out crop insurance policies is also increasing. Most insurance policies were taken out by large and very large holdings. They most widely represented the regions of Wielkopolska and Śląsk (from 45% to 51% of households paying contributions).

Fig. 1. Share of holdings classified by their area, insuring their crops in the FADN regions in 2014



Source: own elaboration based on the FADN data 2014.

This little interest in taking out crop insurance policies results from their specific nature, requiring from an insurer specific knowledge of loss adjustment and of the agricultural industry. What is more, there are problems related to the low profitability of crop insurance, adverse selection of risk, seasonality of products and high price of insurance.

Conclusion

The studies conducted indicate that the most common financial form of securing Polish farmers against the effects of the risk in agriculture is insurance. From the risk management instruments recommended by the EC only subsidised insurance is used. Other forms of security in a form of mutual funds or income stabilisation funds are not used by farmers. Little interest in these instruments may result from legal and financial restrictions (the need for the existence of general provisions), as well as the need to reduce support for other measures within the framework of the 2nd pillar of the CAP in case of increased support for mutual funds or income stabilisation funds.

Analyses showed that the most popular form of insurance are property insurance and farmer's liability insurance, due to their compulsory nature. It turns out that the insurance obligation is so far the best form of making holdings conclude contracts securing them against the effects of risk. This is evidenced by the abolition in the 1990s of compulsory insurance of crops, which resulted in a drastic reduction in crop insurance policies (from about 25 thousand to 5 thousand).

From the analyses it results that many agricultural producers do not take out crop insurance (despite the fact that it is subsidised). Only about 21% farmers insure their crops. This situation particularly applies to small and very small holdings, especially from the region of Mazowsze and Podlasie.

The fact that farmers do not secure themselves from the effects of various types of risk may have serious consequences in the future, as the EU makes the Member States pay ad hoc aid, in case of damage to the insured, only to these farmers who have concluded contracts with an insurance company.

ENZYMATIC PRE-TREATMENT FOR QUALITY IMPROVEMENT OF BIO-OIL FROM SUGARCANE RESIDUE

Abhishek KUMAR, Navin C.SHAHI*

G B Pant University of Agril & Tech., Pantnagar, India
Corresponding author: ncshahi2008@gmail.com

Abstract

The lingo cellulose post-harvest sugarcane residue (tops + leaves) is a good feedstock for bio-oil production after conversion of its insoluble carbohydrates, mainly cellulose, to simple sugars. Main focus of the present investigation was therefore, to reduce the lignin content and to determine the optimum conditions, for enzymatic pre-treatment of post-harvest sugarcane residue using enzyme cellulose with β-glucosidase after physical and alkaline pre-treatment.

The independent variables for enzymatic pre-treatment of sugarcane residue,, time (24, 48, 72h) enzyme loading ratio (5:10, 10:10, 15:10) and substrate concentration (1.5, 2.5, 3.5% w/v) were taken into account. Designed experiments were conducted randomly to find the effect of these variables on reducing sugar, glucose concentration, lignin, ash, cellulose and hemicelluloses. Data obtained from RSM were subjected to the analysis of variance (ANOVA) and analysed using a second order polynomial equation. The reducing sugars increased with increase in time, enzyme loading ratio and substrate concentration (48h, 10:10, 2.5%) and then decreased while lignin decreased with increasing enzyme loading ratio. The reducing sugar varied from 30.1 to 39.8 g/L and glucose concentration was in range of 20.1 to 33.9 g/L while lignin varied from 7.2 to 10.3% w/w and ash ranged from 6.6 to 8.6% w/w while the cellulose ranged from 55.3 to 52.5% w/w and hemicelluloses varied from 9.2 to 6.4% w/w/ Under optimized conditions (substrate concentration 2.11% w/v, time 64.56 h and enzyme loading ratio of 15:10).

Keywords: Sugarcane residue, lignin, ash, cellulose and enzyme loading

Introduction

Biomass which is third largest global source of energy in world could be one of suitable renewable resource to solve this problem (Hyeon*et al.* 2010). Biomass is an abundant renewable source from which fuels can be obtained in relatively short span, reliable and eco-friendly manner (Roedl, 2010). It provides energy efficient fuels in the form of bioethanol and bio-diesel which makes up first generation biofuels. Bio-oils are obtained through a single step thermo-chemical conversion of nearly all kinds of wood biomass into a chemically complex liquid product. An estimated increase of nearly four to seven folds in energy density is readily achieved during this process termed pyrolysis (Badger *et al.*, 2006). During past three decades, researchers across the globe have emphasized upon evolving bio-oils as a potential substitute of petroleum (Czernik*et al.*, 2004). Considerable efforts are being continuously put in to develop upgrading strategies to transform it to engine fuel applications. Bio-oils are often termed 'clean' compared to fossil fuels since they offer several ecological benefits (Mohan *et al.*, 2006).

Extensive research in this area reveals a high level of diversity in selecting biomass comprising agricultural and forest scrap such as barley straw and hulls, rice husk, wheat straw, corn (stalks, leaves and husks), coconut and peanut shells, fruit bunches and pulps, waste furniture and wood (eucalyptus, pine etc.), forage crops, tea waste, bagasse, sewage sludge, swine manure and many more. Another important sugarcane residue is the leaves, which are usually left in agricultural fields during sugarcane harvesting. Sugarcane leaves

consists of cellulose (35.2% dry weight) and hemicellulose (23.4% dry weight) in close association with lignin (12.6% dry weight), is one of the most abundant lignocellulosic crop residues (Teerapatret al. 2013).Sugarcane is the world's largest crop by production quantity. In 2012, FAO estimates it was cultivated on about 26.0 million hectares, in more than 90 countries, with a worldwide harvest of 1.83 billion tons. India's annual sugarcane production in 2013-14 was estimated about 352.14 million tons from 50.12 lakh hectares area with a yield of 69.84 tonnes/hactares(Source: Directorate of Food & Public Distribution and Agricultural Statistics). Sugarcane production in Uttarakhand in 2012-13 was estimated to about 6.72 million tonnes from 1.10 lakh hectare area (Source: Department of Agriculture and Cooperation). Sugarcane shoots and leaves obtained after harvesting the crop, are used neither as animal feed (because of the rough texture of them), nor as fuel. Generally, leaves are burnt in the fields, which produce fly ash, severely damages soil microbial diversity, and raise environmental concerns.(F.A.O., 2014). It is a cost-effective way to remove the fibrous content of sugarcane residue from field. (Boopathyet al. 2002).These leaves can be used for bio-oil production.

The main objective of this research was to remove lignin chemically and enzymatically in sugarcane residue to improve the bio-oil quality. The usage of alkaline chemical in the pre-treatment of sugarcane leaves and enzymatic hydrolysis to degrade lignocelluloses biomass and saccharification of cellulose is expected to alter the original biomass structure. In view of the above, this study was focus oneffect of alkali treatment on sugarcane residues after drying and physical treatment. These data are required to optimize the enzymatic treatment for saccharification and prepare bio-oil after pyrolysis of untreated and treated sugarcane residues.

Materials and methods

Preparation of sugarcane residue

Dry leaves and tops of sugarcane (*Saccharumofficinarum Linn*) also called postharvest sugarcane residue were collected in the month of February, 2015 from the field at the harvest of the sugarcane crop growing at the farm of C.R.C. (Crop Research Center), G. B. Pant University of Agriculture & Technology, Pantnagar, India located at 29^{o} N, 79^{o} E and 243.8 m above the sea level. The residues were washed in running water to remove the dust, the foreign particles and air dried treatments. The dried residue was subjected to size reduction process in hammer mill. The mesh size being used was of 2 mm size. The size reduction process was done for increasing the surface area of residue for alkaline treatment process. The milled residues was analysed for its proximate (moisture content, ash, volatile matter and fixed carbon) and chemical composition (cellulose, hemicellulose, lignin and ash).

Alkali pre-treatment

The alkali pre-treatment was used for reduction of lignin content in the sample. The alkali pre-treated samples were used for enzymatic saccharification. The sugarcane residues were treated with 2% (w/v) NaOH solution and autoclaved at 121°C on 15 psi for 15 minutes. The treated sugarcane residues were washed with water to obtain neutral pH and then oven dried at 80^{o} C for 24 hours

Enzymatic saccharification

The experiments designed by Design-Expert software included 17 experiments. The enzymatic saccharification process was based on independent parameters. The parameters of process was introduced in software are in numeric forms varied over 3 levels.

Thus here, designs were in format of Box-Behnken design of response surface methodology. Various experiments were conducted in accordance to the ratio included in the RSM with Run time analysis.

Preliminary trials were conducted for subjection of enzymes to the pre-treated sugarcane residues. During the process, Cellulase + β-glucosidase, Cellulase andβ-glucosidase enzymes are used at 37.5, 40 and 35°C respectively. The objective of this experiment was to examine the effects of one step enzyme addition and two step enzyme addition during saccharification process.

Experimental Design

Experimental design, defined as a specific set of experiments which were defined by a matrix, a matrix composed by the different level of combination variables. Response surface methodology (RSM) was used for the design and analysis of all experiments for three predicted variables at three levels. It also helps to reduce the number of experiments without affecting the accuracy of results and to decide the interactive effects of influencing factors on the response. Box-Behnken model was selected for the optimization of the process variables (Sharma et al. 2014). Box-Behnken is a class of rotatable second order design based on three levels incomplete factorial design. This design does not contain for which all factors are simultaneously at their highest and lowest levels. So this design is useful in avoiding experiments performed under extreme conditions for which unsatisfactory results might occur (Bezeraet al. 2008).

The number of experiments (N) required for development of Box-Behenken Design. This design is defined as:

$$N=2K\ (K-1)\ +C_0$$

Where,

N= Total no. of experiments

K = No. of variables

C_0= Centre point

In order to determine a critical point (maximum, minimum or saddle) it is necessary for the polynomial function to contain the quadratric terms. According to the equation presented below:

$$y = \beta_0 + \sum_{Ki=1}\beta_i X_i + \sum_{ki=1}\beta_{ii} X_{i2} + \sum_{k1<=i<=j}\beta_{ij} X_i X_j$$

Where,

β_{ii}, β_0 and β_{ij} are the coefficients of regression. (i=1, 2, 3, ...n) (j=1, 2, 3, ...n)

Values of level of independent variables

Independent variables	Values		
	-1	0	+1
Reaction time (hrs)	24	48	72
Cellulase–β-Glucosidase enzyme ratio (FPU:IU)	5:10	10:10	15:10
Substrate concentration (% w/v)	1.5	2.5	3.5

The constant variables were as under Temperature 37.5°C, pH 4.8 and Buffer concentration 0.1 M.

Experimental procedure

The whole experiment was conducted in three phases. Experiments were planned with a view to develop pre-treated, enzymatically treated sugarcane residue, which could be a better method for bio-oil extraction by pyrolysis. In the first phase experiments were carried out by already optimised pre-treated conditions for sugarcane residues for maximum breakdown of lignin (Teerapatret al. 2013). Sugarcane residue (2mm mesh size) was taken in 25 gram quantity and alkali treated with 2% w/v NaOH and autoclaved at 121°C on 15psi for 15 min. The samples were analysed for its proximate (moisture content, ash, volatile matter and fixed carbon) and chemical composition (cellulose, hemicellulose, lignin and ash).

During the second phase, enzymatic treatment was carried out and the independent variables (reaction time, enzyme ratio, substrate concentration) were optimised for release of reducing sugar. These samples were also analysed for proximate parameters. During the third phase, pyrolysis was carried out by fast pyrolysis reactor for the extraction of bio-oil.

The following dependent variables were considered to check the quality of end product. Samples used for compositional analysis were prepared accordingly:

Reducing sugars

The total reducing sugars were estimated by DNS method, modified according to National Renewable Energy Laboratory, USA.

Glucose concentration

The glucose concentration was estimated using glucose estimation kit.

Cellulose estimation

The filtrate from the H2SO4 treatment that contained the sugars released from cellulose and hemicellulose was thoroughly stirred and homogenized. Glucose (C1) and reducing sugar (C2) concentrations in the filtrate were determined according to a glucose oxidase–peroxidase assay kit (Autospan, India) and the DNS method (Miller, 1959), respectively.

Following these measurements, the cellulose content in the starting material was calculated using the following equation:

$$\% \text{ w/w cellulose content} = (0.9/0.96) \times C1 \times (V/M) \times \alpha \times 100$$

Where 0.9 is the coefficient that results from the molecular weight ratio of the polymer and the monomer hexose. The saccharification yield was taken as 0.96, C1 as the glucose concentration (g/L), V the total volume of sugar solution (L), M the dry weight of the sugarcane residue sample (g) and α the dilution of the sample (Ververiset al. 2007).

Bio-oil extraction

Bio-oil from both untreated and treated sugarcane residue was prepared at Central Institute of Agricultural Engineering, Bhopal, Madhya Pradesh, India. 1 kg each of untreated and treated sugarcane residue was taken for the pyrolysis process. Conventional pyrolysis of each sample was carried out at 500°C temperature for 30 minutes of time (Plate 3.7). The gases were condensed as it passed through the water jacket and the pyrolysis liquid was collected (Plate 3.8). Two samples of Bio-oil were collected and they were evaluated for different propertiesviz: Kinematic viscosity, Dynamic viscosity, Relative density and Flash and fire point.

Results and discussion

Experiments were conducted for optimizing enzymatic treatment of postharvest sugarcane residue (sugarcane tops + leaves). Enzymatic treatment characteristic responses of post-harvest sugarcane residues were determined in terms of reducing sugars, glucose concentration, and cellulose.

Characterization of Treated and Untreated Post-harvest Sugarcane Residue

The proximate analysis of sugarcane residue showed that the raw materials contain higher percentage of volatile matter and less amount of moisture and ash content. The results showed that the raw material have potential for sugar production by conversion from their cellulose

Proximate analysis of untreated and treated Sugarcane residue

Raw material	Moisture (Wt. %)	Volatile matter (wt. %)	Ash (wt. %)	Fixed Carbon (wt. %)
Untreated sugarcane residue	8.4	72.6	8.1	10.9
2% w/v NaOH treated sugarcane residue	7	80.73	7.24	5.03

The moisture of biomass has a marked effect on the conversion efficiency and heating value. Higher moisture of biomass has a more tendency to decompose resulting in energy loss during storage. Volatile matter evolves in the form of gas, light, hydrocarbon and tars. Volatile matter of the biomass is higher than the coal (around 75%). Higher volatile matter of the biomass makes it more readily devolatilized than solid fuel. Liberating less fixed carbon hence makes them more useful for pyrolysis and gasification (Pitarelo, 2007). Ash content and moisture content affect the heating value. The ash content in the bio mass is an integral part of plant structure which consists of a wide range of mineral matter such as salt of calcium, potassium, silica and magnesium. Ash content depends upon the plant and soil condition in which the plant grows (Sila, 2014).The values of ash content were lower in untreated raw material than the reported by Pitarelo, 2007. This difference could be due to the varietal difference or soil condition of the sugarcane crop.

Effect of Alkaline Treatment on Sugarcane Residue:

The sugarcane residues were alkali treated which reduced 48.97% of the total weight of the sample. The lignin in the sample initially was 19.2 % which is reduced after pre-treatment to about 9.5 %. So revealed that, pre-treatment is removes half of the lignin in thesample. It has also reported by that the digestibility of NaOH-treated hardwood increased from 14% to 55% with a decrease of lignin content from 24-55% to 20% (Millet et al. 1976).

Chemical compositions of untreated and treated sugarcane residue

Treatment with 2% NaOH solution reduced lignin to 9.5 wt. % in sugarcane residue. The amount of cellulose was higher compared to hemicellulose (8.8 wt %) and lignin content (9.5 wt %). These findings were found close to the composition determined by Pitarelo, 2007. The cellulose, hemicellulose and lignin was determined as 34.4, 28.4 and 20.7 respectively. This difference could be due to the varietal difference of the sugarcane crop and environmental factors.

Table 1.Chemical composition of untreated and treated Sugarcane residue

Raw material	Hemicellulosewt%	Cellulose wt%	Ligninwt%
Untreated sugarcane residue	28.3	36.1	19.2
2% w/v NaOH treated sugarcane residue	8.8	57.2	9.5

Effect of Independent Variables on Various Responses

Effects of independent variables i.e. time, enzyme loading ratio and substrate concentration on responses viz. reducing sugar, glucose concentration, and cellulose was determined and statistically analysed.

Reducing Sugar

Experimental data shows that in case of enzymatic pre-treatment, the reducing sugar ranged from 30.1 to 40.2 g/L. Maximum reducing sugar was found 39.8 g/L for experiment number 17, with the combination of time 48 hours, enzyme loading ratio 10:10 and substrate concentration 2.5% w/v. Minimum reducing sugar was found 30.1 g/L for experiment number 3, at time 48 hours, enzyme loading ratio 5:10 and substrate concentration 1.5% w/v. The enzyme loading ratio and substrate concentration had a clear effect on the amount of reducing sugar. Similar results were also obtained by **Teerapatr*et al.* (2013).** Maximum reducing sugars released in the experiments having the centre values of enzyme loading ratio and substrate concentration and 48 hours of reaction time. The reducing sugar profile from NaOH pre-treatment of sugarcane shoots and leaves after enzymatic saccharification was higher than an unwashed pre-treated solid residue. The results showed that washing of solid residue could improve enzymatic saccharification.

Numerical analysis of reducing sugar

Second order regression was fitted into the reducing sugar data and the results of the regression analysis are reported. The model was checked using a numerical method employing the coefficient of determination R^2, adjusted R^2, LOF and then calculated as shown in equation (4.1), R^2 indicates how much of the observed variability in the data was accounted by the model. The response surface model was developed with values of R^2higher than 90% and the goodness of fit of model was high showing high R^2 (0.9835) for reducing sugar, with least residual error (0.99) in the fitted quadratic model. Furthermore, R^2 –adj (0.9632) value relatively satisfactory adjustment of the quadratic model to the experimental data also indicates the best fit of the model.

Predicted regression equation having significant terms given below

$$\text{Reducing sugar} = 39.74 + 1.01\ X_1 + 1.45X_2 + 0.66X_3 + 1.50X_1X_2 + 0.80X_2X_3 - 2.81\ X_1^2 - 2.93X_2^2 - 4.66\ X_3^2$$

Where,

The predicted variables of the model are response variable; X_1, time; X_2, enzyme loading ratio; X_3, substrate concentration. In eqn, the coefficients with one factor i.e. the ones in front X_1X_3, X_1X_2, $X_2X_3$and those with second order terms i.e. X_1^2, X_2^2 and X_3^2 represents the interaction between two factors and the quadratic effects, respectively the positive in front of the terms indicates a synergistic effect while the negative shows the antagonistic effect.

The model was found significant ($p< 0.01$). The highest effect of substrate concentration on reducing sugar was observed and highly significant ($p<0.01$) because it had high calculated F-value (46.34) than tabulated F-value (6.71). The effect of enzyme loading ratio followed by time was also found significant ($p<0.01$). It was clear that time, enzyme loading ratio and substrate concentration increased the reducing sugar of the material.

Glucose Concentration

The glucose content ranged from 20.1 to 33.9g/L.Maximum glucose content was found 33.9 g/L for experiment number 17, at time 48 hours, enzyme loading ratio 10:10 and substrate concentration 2.5% w/v. Minimum glucose content was observed 20.1 g/L for experiment number 2, having time 24 hours, enzyme loading ratio 10:10 and substrate concentration 1.5% w/v.The reaction time and substrate concentration has a clear effect on the amount of glucose concentration. Similar results were also obtained by Teerapatret al. (2013). Maximum glucose released in the experiments having the centre values of enzyme loading ratio and substrate concentration and 48 hours of reaction time. The glucose concentration profile from NaOH pre-treatment of sugarcane shoots and leaves after enzymatic saccharification was higher than an unwashed pre-treated solid residue. The results showed that washing of solid residue could improve enzymatic saccharification.

The statistical analysis of glucose concentration was given. The model of glucose concentration was found highly significant ($P < 0.01$) because it had higher Fvalue (20.44). It was also observed that the effect of predicted variables on glucose concentration was highest at quadratic level due to highest calculated F-value (45.150) followed by linear level and interactive level. The model was highly significant

Numerical analysis of glucose concentration

Second order mathematical model was fitted into the glucose concentration data and the results of the regression analysis are reported. The model was checked using a numerical method employing the coefficient of determination R^2, adjusted R^2, LOF and then calculated as shown in equation (4.1), R^2 indicates how much of the observed variability in the data was accounted by the model. The response surface model was developed with values of R^2 higher than 90% and here the goodness of fit of model was high showing high R^2 (0.9633) for glucose concentration, with least residual error (1.93) in the fitted quadratic model. Furthermore, R^2 –adj (0.9162) value relatively satisfactory adjustment of the quadratic model to the experimental data also indicates the best fit of the model.

Predicted regression equation having significant terms is given below

$$\text{Glucose concentration } (Y) = 31.98 + 1.26\ X_1 + 1.22X_2 + 1.90X_1X_2 + 2.35X_2X_3 - 4.25X_1^2 - 3.03X_2^2 - 5.90X_3^2$$

Positive coefficient of the model at the linear level indicates an increase in responses with increase in regressor of its influencing factors and vice versa. Positive quadratic terms give the minimum response at the centre. While negative quadratic terms give the maximum response at the centre. The negative interaction suggested that the regressor of one variable of the interaction can be increased while the other decreased to get the same response. At linear level X_1, X_2 and X_3, at interactive level X_1X_2, X_2X_3 and at quadratic level X_1^2, X_2^2 and $X_3^2$are highly significant with the value ($p<0.01$) showed. While the effect of predicted variables at interactive level $X_1X_3$was not significant.

Cellulose

The cellulose content ranged from 52.5 to 55.3% w/w in case of enzymatic pretreatment. Maximum cellulose was found 55.3% w/w for experiment number 3, at time 48 hours, enzyme loading ratio 5:10 and substrate concentration 1.5% w/w. Minimum cellulose was found 52.5% w/w for experiment number 10, at time 48 hours, enzyme loading ratio 15:10 and substrate concentration 3.5 % w/w. These findings are close to the results found by Chandelet al. 2011 showed the cellulose conversion into sugars increases with the increase in enzyme loading ratio. More amounts of enzymes hydrolysed the cellulose efficiently.

The model of cellulose was found highly significant ($P < 0.01$) because it had higher F-value (10.62). It was also observed that the effect of predicted variables on cellulose was highest at linear level due to highest calculated F-value (23.77) followed by quadratic and interactive level. The model was highly significant.

Numerical analysis of cellulose

The model was checked using a numerical method employing the coefficient of determination R^2, adjusted R^2, LOF and then calculated as shown in equation (4.1), R^2 indicates how much of the observed variability in the data was accounted by the model. The response surface model was developed with values of R^2 higher than 90% and here the goodness of fit of model was high showing high R^2 (0.9318) for cellulose, with least residual error (0.32) in the fitted quadratic model. Furthermore, R^2 –adj (0.8440) value relatively satisfactory adjustment of the quadratic model to the experimental data also indicates the best fit of the model.
Predicted regression equation having significant terms is given below

$$\text{Cellulose} = 54.68 - 0.54\ X_1 + 0.96X_2 - 0.35X_3 - 0.77\ X_2^2$$

Positive coefficient of the model at the linear level indicate an increase in responses with increase in regressor of its influencing factors and vice versa. Positive quadratic terms give the minimum response at the centre. While negative quadratic terms give the maximum response at the centre. The negative interaction suggested that the regressor of one variable of the interaction can be increased while the other decreased to get the same response. At linear level X_1, X_2 and X_3 and at quadratic level X_2^2 was highly significant with the value ($p < 0.01$). While the effect of predicted variables at interactive level X_1X_3, X_1X_2, X_2X_3, X_1^2, X_3^2 were not significant.

Optimization of Experimental Parameters

The experimental values of enzymatic pre-treatment of all samples are reported. Results of regression analysis are given. Numerical optimisation was carried using Design-Expert 8.0.7.1 statistical software. The individual goals for different predicted factors

Table 2.Constraints for optimization of variables for enzymatic pre-treatment

Factors	Goal	Lower limit	Upper limit
Time (X_1, h)	In range	-1	1
Enzyme loading ratio (X_2)	In range	-1	1
Substrate concentration (X_3, %, w/v)	In range	-1	1
Reducing sugar (g/L)	Maximize	30.1	40.2
Glucose concentration (g/L)	Maximize	20.1	33.9
Lignin (%, w/w)	Minimize	7.2	10.3
Ash (%, w/w)	Minimize	6.6	8.6
Cellulose (%, w/w)	Minimize	52.5	55.3
Hemicellulose (%, w/w)	Minimize	6.4	9.2

Recovery of Bio-oil

Bio-oil obtained from both untreated and treated sugarcane residue (Plate 4.1) after pyrolysis was collected. The bio-oil from untreated and treated sugarcane residue yielded
24.6 % and 25.2% respectively

Evaluation of Properties of Bio-oil from Sugarcane Residue

The properties such kinematic viscosity, dynamic viscosity, density, relative density, flash and fire point, pH and moisture content were measured for untreated and treated bio-oil to compare their properties with diesel fuel.

Table 3.Characteristic properties of diesel, bio-oil from untreated and treated sugarcane residue

Sl.No.	**Property**	**Diesel**	**Bio-oil from untreated sugarcane residue**	**Bio-oil from treated sugarcane residue**
1	Kinematic Viscosity (cSt)	4.12	0.31	0.64
2	Dynamic viscosity (cSt)	3.35	0.313	0.68
3	Density (g/ml)	0.812	1.013	1.039
4	Relative density (g/ml)	0.826	1.031	1.058
5	Flash point (°C)	61	69	95
6	Fire point (°C)	65	72	97
7	Moisture content (wt %)	0.05	29.9	27.8
8	pH	5.6	3.3	2.9

The kinematic and dynamic viscosity at 38°C of diesel, bio-oil from untreated and treated sugarcane residue in terms of centistokes is presented in Table. Bio-oil from treated sample recorded viscosity more close to viscosity of diesel fuel. It may be due to the presence of higher oil percentage in the bio-oil from treated sugarcane residue. Table also shows the relative density of diesel, bio-oil from untreated and treated sugarcane residue at 15°C. Oil from treated sugarcane residue found to have density more near to the diesel fuel than the untreated sugarcane residue. Fuel density increases with increasing molecular weight of the fuel molecules. Similar kind of results for relative density was 2.31 cSt.

The flash and fire point of diesel was found as 61 and 65°C. The bio-oil from untreated and treated sugarcane residue had flash point as 69, 95°C and fire point as 72, 97°C respectively. The flash and fire point of both oils were found more as compared to diesel fuel. Similar kind of results for fire point of diesel reported by Patil (2008) and Admuthe (2009) is 62 and 65°C respectively. Dinesh et al. (2006) reported flash and fire points of bio-oil as 92 and 97°C.

Conclusion

The present study was aimed at removal of lignin and saccharification of sugarcane residue for quality improvement of bio-oil. In the proposed work, lignin removal was achieved nearly up to 50% and saccharification resulted in high yields of reducing sugar. Experiments were planned and carried out on size reduced and alkali pre-treatedsugarcane residue. The best suited sets of experiments were used to optimise the process. Physical treatment to the sugarcane residue in hammer mill reduced the size up to 2 mm which broke down the crystallinity of the cell structure making the substrate more accessible for chemical and enzymatic treatments. Alkaline treatment with 2% w/v NaOH at 121°C, 15 psi for 15 minutes resulted in weight loss of the substrate. It reduced 48.97% of the total weight of the sample. The lignin in the sample initially was 19.2% which is reduced after pre-treatment to about 9.5%. Nearly half of the amount of lignin is reduced. Reducing sugar yields describe its effects from all three independent variables. Moreover interactive effects were also seen in both numerical and graphical analysis.

Glucose concentration also showed similar results as in cases of reducing sugar with depending on all three independent variables. Maximum reducing sugar was found 40.2 g/L for experiment number 8, with the combination of time 48 hours, enzyme loading ratio 10:10 and substrate concentration 2.5% w/v.

Bio-oil is prepared from both untreated and treated post-harvest sugarcane residue by employing conventional pyrolysis process carried out at 500°C temperature and for 30 minutes of time. Both samples of bio-oil was evaluated for different properties.

From the preceding discussion, it may be concluded that the chemical and the enzymatic treatments used have significant effect on the bio-oil quality as the bio-oil from treated sugarcane residue found having fuel properties more close to diesel fuel as compared to the bio-oil from untreated sugarcane residue.

AGRICULTURAL ADVISORY SERVICES AS A FACTOR OF ECONOMIC DEVELOPMENT OF AGRICULTURE IN NORTH KOSOVO

Tatjana IVANOVIĆ*, Goran MAKSIMOVIĆ

University of Pristina, Faculty of Agriculture, Lešak, Serbia
*Corresponding author: tatjana.ivanovic@pr.ac.rs

Abstract

The best way to implement scientific achievements in agricultural production in practice on country farms is through the Agricultural Extension Service. The main objective of the Agricultural Extension Service is education and training of farmers to improve production and other economic indicators on the farm. In Serbia there is state organized and financed Agricultural Extension Service and this advisory model is currently in accordance with the socio-economic conditions due to the fact that agriculture in Serbia is almost entirely organized on the family farms. The authors analyze the current state of Agricultural Extension Service in Serbia by the method of descriptive statistics. Particularly they analyzed the work of Agricultural Extension Service in the north of Kosovo. To assess the overall situation of Agricultural Extension Service in Serbia was used the available statistical data, and to analyze the work of the *Agricultural Extension Service Kosovska Mitrovica*, data of this institution was used. Agricultural advisory and professional services of the Republic of Serbia today number 34 with 251 advisors; 22 departments and 166 advisors on the territory of central Serbia and 12 departments and 85 advisors in the area of Autonomous Province (AP) of Vojvodina. In the area of northern Kosovo, Agricultural Extension Service encourages the development of agriculture and improves the economic effects on the farm, contributing to the education of farmers and the need is to involve as many farmers as possible.

Keywords: *advisors, Agricultural Extension Service, economic development*

Introduction

Objective of this paper is to determine the status of Agricultural Extension Service in Serbia and analyze the work of these services in the north of Kosovo.

Agricultural Advisory Services (or Agricultural Extension Services) deal with the application of scientific and professional achievements in agriculture and transfer of knowledge into immediate practice (Novković and Šomođi, 2001). Agricultural Advisory Service is one of the organizational development actions of agricultural policy and strengthens the connections between advisory agents, farmers, researchers and should be in line with the strategy of development of agrarian policy.

Improving the Extension Service of our country is very important, especially because agriculture has long been in a precarious position, as much as 85% of the Republic of Serbia consists of rural areas. It is therefore of particular importance to strengthen extension services and their role in rural development of Serbia and linking relevant institutions and agricultural producers in these areas. In the area of northern Kosovo advisory services should encourage the development of agriculture and improve the economic effects on the farm, education of farmers, production of healthy food and many other activities that should contribute to the further development of this area.

Materials and methods

The authors use the method of descriptive statistics to perceive the current state of agricultural extension in Serbia. They analyze the work of agricultural extension services *Kosovska Mitrovica* in northern Kosovo and the role of these services in the development of agriculture

in this region. To assess the overall situation of agricultural advisory services in Serbia they use the available statistical data, and for analyzing the work of the *Agriculture Extension Services Kosovska Mitrovica* (AES-KM) data of this institution were used.

Results and Discussion

The law about the provision of advisory and professional activities in the field of agriculture was published in the "Official Gazette of the Republic of Serbia" No. 30/10 dated on 07.05.2010. It deals with many issues relating to agricultural extension. In addition, for the development of agricultural advisory services in the territory of the Republic of Serbia is relevant also the "Strategy of development of agricultural extension services in Serbia" which was created in 2009 as part of a joint project of the Ministry of Agriculture, Forestry and Water Management (MAFWM), the International Bank for Reconstruction and Development (World Bank) IBRD/WB and the Global environment Facility (GEF).

Agricultural advisory and professional services of the Republic of Serbia today number 34 advisory services and 251 advisors of which 22 departments and 166 advisors in central Serbia and 12 departments and 85 advisers in the Autonomous Province (AP) of Vojvodina. In Serbia, the present service is state organized and financed by AES (Agriculture Extension Service), although there are a number of farmers ready to pay the advisory services they need.

At national level, the Ministry of Agriculture has the role of supervision and control of agricultural advisory services, as well as the role of providing the funds for the activities of agricultural advisory services. The Institute for Science Application in Agriculture (ISAA) role is to coordinate, control and evaluate of the work of consultants. Current number of advisers is less than the number of advisors who was in service in 2002 (cf. 326), when suddenly there was an outflow of advisers as a result of the unfavorable economic situation in the period 1997-2002 (Ševarlić, 2003). Petrović and Janković (2010) monitored the situation in Serbian Agricultural extension service and according to survey data from 2008, in the AES of the Republic of Serbia were engaged a total number of 206 advisors (134 in central Serbia and 72 advisors from Vojvodina). Today's state of extension service in the Republic of Serbia - compared with about 310 people who are engaged in extension service in Republic of Slovenia, whose arable land and the number of producers, as well as the overall importance of agriculture for the country is much lower than is the case in Serbia - suggests at what level is our extension service. In Croatia, the situation is similar to the situation in our country (Petrović and Janković, 2010).

Gender structure of advisers in the territory of the Republic of Serbia shows that men are more than 60% of total number of advisors and it means more than 150 advisors are men compared to women whose representation in advisory work is 40% or 101 advisors. This is situation in central Serbia and Vojvodina, which means that men are generally more present as advisers.

On the territory of the Republic of Serbia prevail advisory experts in farming and vegetable growing, then come advisers in the field of animal husbandry and finally advisers in the field of plant protection. In the structure of consultants by specialty is important that there are no specialists for agricultural machinery, and their number in 2002 was 8, in relation with total number of 326 advisors in that year (Ševarlić, 2003). The lack of specialists for agricultural machinery is same on the territory of central Serbia and Vojvodina.

Table 1. Structure of consultants by specialty on the territory of the Republic of Serbia

Specialty advisory	Number of advisors	%
Animal husbandry	61	24
Field and veget. production	67	27
Fruit growing and viticulture	39	16
Plant protection	46	18
Agro-economics	15	6
Land reclamation	7	3
Other	16	6
Total	251	100

Source: Agricultural advisory and professional services of the Republic of Serbia - ISAA, 2014.

So that agricultural extension service in the future could transmit modern solutions in agriculture it must provide a sufficient number of appropriate staff profiles that will fulfill all the tasks that their work organization and development department imposed. It must also work to increase the number of farms involved in the advisory process. Agriculture Census of 2012 shows that from registered 631,552 households in extension work are included 41500 households, of which part consists of selected households (4000 in central Serbia and 2500 in Vojvodina) and other farms that are included in the advisory system in other ways, mainly through participation in group sessions and through occasional visits to farms. This type of training covered 25,000 households in central Serbia and 10,000 in Vojvodina (Strategy of Agriculture and Rural Development of the Republic of Serbia 2014-2024, MAFWM, 2013).

Agricultural Advisory Service "Kosovska Mitrovica" Ltd. was founded on 04.05.1996 and its founder is of MAFWM (Ministry of Agriculture, Forestry and Water Management). *AES Kosovska Mitrovica* work in premises that they received on 01.01.2009 from the municipality of Kosovska Mitrovica in its northern part, because after the bombing in 1999 there were no suitable premises. All premises and equipment for the work of service remained in the southern part of *Kosovska Mitrovica*. *AES Kosovska Mitrovica* conducted advisory work in agriculture in the area which includes the municipalities of Leposavic, Zvecan, Kosovska Mitrovica, Zubin Potok and enclaves in the municipalities of Vucitrn and Srbica. The total area that contains these municipalities covers an agricultural area of 58890 hectares, has 180 villages, 7864 farms in which live 61000 residents. The work of this advisory service is carried out in difficult conditions, field visits is linked with security risk and data are collected mainly from the bigger farms in the larger towns of the enclaves, as well as in visits of villages in the northern part Kosovo.

Data of the area of operation, agricultural land, arable and cultivated land are given in the table below.

Table 2. Data on the area of operation of the *AES Kosovska Mitrovica*

Municipality	Agricultural land in ha	Area of arable land in ha	Area non-arable land in ha
Kosov. Mitrovica	2150	540	1610
Vucitrn (enclave)	9442	5247	4168
Srbica (enclave)	5692	303	5389
Zubin Potok	11175	4106	7069
Zvecan	7446	2077	5369
Leposavic	22985	6754	16231
Total	58890	19054	39836

Source: *AES Kosovska Mitrovica* – Work program,Year 2014

In the implementation of the Annual program of advisory services in agriculture, are engaged 4 advisory experts – advisors, 2 specialists for field and vegetable producing, one of them has a specialization in plant protection, one in animal husbandry and one in viticulture. In *Kosovska Mitrovica AES* there are two women and two men of four advisors employed. Therefore, gender structure is 50% to 50%.
Intensity of agricultural extension in *Kosovska Mitrovica AES* is displayed in the following table.

Table 3. Indicators of intensity of extension in *AES Kosovska Mitrovica* - average

Area of arable land in ha	Number of farms	The number of employed advisers	The average arable land (in ha) per advisor	Number of farms per adviser
19054	7864	4	4763	1966

Source: processing of the author based on data of *AES Kosovska Mitrovica*

Advisors provide expert advice, recommendations, services and assistance to selected farms (100 farms), but also to other farms and make written and electronic records on special forms.
In addition to individual working methods, consultants provide expert advice and through group work methods. In the district covered by this service there is only one agricultural cooperative, a specialist advisor - fruit grower specialist visiting a cooperative a minimum of 4 times per year. As one of the activities of advisors stands out and work with associations and informal groups of farmers. Advisors during the year as a group organized lectures, like group method, on current issues important for agricultural producers. For these lectures are invited they experts from universities and institutes. In addition to lectures, advisers *AES Kosovska Mitrovica* undertake other activities: practical lectures - "Field Days"; stands (lectures with discussion) workshops; winter school for farmers; experimental farms; mass media (TV shows, radio shows, articles on the portal of the Agricultural Advisory Service), print media (local newsletters).
AES Kosovska Mitrovica mainly implements new varieties in plant production through the demonstration experiments on the ground that handles Agriculture School Lešak or plots on selected farms. In the territory covered, *AES Kosovska Mitrovica* keep records for 3 farms that serve as experimental farms (demonstration). Sample farms serve as demonstration farms and they are the result of good agricultural practices, economic performance management holdings, the application of new and modern technologies of production and effects of the use of advisory services. *AES Kosovska Mitrovica* also implement monitoring and reporting on seasonal agricultural work in crop and vegetable production. Annual crops (winter and spring

grain crops, corn, alfalfa, potatoes, vegetables, etc.) and also perennial crops (plum, apple, pear, etc.) are plants that prevail in the production of the region.
The number of registered farms that are covered by the advisory activities *AES Kosovska Mitrovica* at the end of 2014 was as shown in table 4.

Table 4. The number of registered farms in municipalities covered by AES-KM

Municipality	registered farms
Kosovska Mitrovica	124
Vucitrn (enclave)	174
Srbica (enclave)	28
Zubin Potok	370
Zvecan	180
Leposavic	1601
Total	2477

Source: *AES Kosovska Mitrovica* - records of extension agents for 2014

Although the registration of farms is performed since 2005, on Kosovo and Metohija, as well as in the Kosovska Mitrovica district, major problem in the registration is unresolved property relations.
Livestock in the Kosovska Mitrovica district in relation to the post-war period slightly increased, but in relation to the condition it was before the bombing in 1999 is significantly lower (table 5). One advisor is responsible to monitor the situation in this production.

Table 5. Livestock in the territory of *Kosovska Mitrovica AES*

Cattle	6615
Sows	7400
Sheep	8317
Poultry	90000

Source: *AES Kosovska Mitrovica* - Personal records of adviser, 2014.

Data books about selection of livestock would help to improve the breed composition of livestock, and thus enhance and improve the health of the animals, but there is no responsible livestock registry office to perform this. In livestock production there is no contract production between producers and processors. There is no cooperative relation, especially in the fattening of calves and pigs. To improve the breed composition and selection of livestock is necessary to work on the technical and technological modernization of cattle-handling facilities and equipment in the barns, better use of genetic potential of livestock, the application of new technologies in livestock feed and more.

Conclusion

In Serbia is necessary to work on a gradual increase in the number of agricultural advisors and to take into account their distribution by AES to provide better coverage of the territory by the advisory service included in their work. At the same time we must work on systematic planning and implementation of extension activities by using group work methods which allow coverage of larger target groups of farmers. The unstable political situation is a significant factor in the slow development of agricultural production of the northern Kosovo, regardless of the role of agricultural extension in its development. Expanding the scope of work of the agricultural advisory services to other Serbian enclaves in Kosovo can contribute to the improvement of agricultural production in this area. Agricultural extension service and

interest association of agricultural producers should be decisive in the improvement of primary agricultural production and the general progress of the economy of this region.

THE SENSITIVITY OF NET FARM INCOME IN THE ZLATIBOR DISTRICT (SERBIA) TO CHANGES IN GOVERNMENT SUPPORT

Vladimir JOVANOVIĆ[1]*, Danijela PETKOVIĆ[2], Julijana MIJAILOVIĆ[3], Vlade ZARIĆ[4]

Abstract

In this paper we have analysed the impact of the changes in government support on net income of the agricultural holdings in Zlatibor district in the period 2015 - 2016. In 2015 total subsidies per ha for crop production were approximately EUR 100, while in 2016 they have been reduced to only EUR 33. Subsidies for dairy and livestock production have also been changed compared to the previous year. Objective of this paper is to demonstrate out the immediate consequences of these changes by pointing out their impact on the farmer's income and farming structure in the short time. Starting hypothesis is that these sudden changes in agricultural policy measures will have negative effects on farm net income and farming practices. Methodology used for writing this paper consists of the structure and sensitivity analysis of the net income, based on existing data and the data collected directly from agricultural holdings in Zlatibor district. Results show that farm net income will be reduced, as a consequence of reduced subsidies. Second, reactions on the farm activities show that the farmers are unable to adjust to sudden changes in government support and there is a clear need to have more sensitive policy measures. Also are presented the factors that need to be reconsidered in creation of agricultural policy measures and expectations from the latest changes in agricultural policy.

Keywords: *subsidies, Serbia, agricultural policy, farm net income*.

Introduction

In the period of accession to the European Union (EU), Serbia is facing the serious challenges of harmonizing the agricultural and rural development policy to the European Union Common Agricultural Policy EU CAP, but at the same time preparing its agricultural sector for competing in large EU market. At the same time, rural areas are mostly affected by poverty[1].
During this period, many changes have been made in agricultural policy regarding subsidies. Serbian agricultural sector is highly affected by these changes and inconsistency in agricultural and rural development policy. These frequent and, in many cases sudden changes, make participants in the market of agricultural and food products, especially farmers, unable to plan their business in the long or even medium term, which can make their production questionable[2].
Importance of financial support in agriculture is well described by the fact that almost every country in the world, with the exception of New Zeland, strongly regulates agricultural market

[1] Source: Bogdanov, N., 2007: Small Rural Households in Serbia and Rural Non-Farm Economy, UNDP Serbia, Belgrade

[2] Source: Zaric, V., 2008: Analysis of the competitiveness of agri-food products in the Republic of Serbia (Analiza konkurentnosti poljoprivredno-prehrambenih proizvoda Srbije), University in Belgrade, Faculty of Agriculture, Belgrade

by state measures[3]. One of the main purposes of interventionism and market regulations in agricultural sector is provision of sufficient quantities of food. When trying to provide food security, government must take into consideration food security in most affected, rural areas.
In February 2016 Serbian government has adopted the new Regulation on the Distribution of Support in Agriculture and Rural Development in the Year 2016. This regulation reduces, until than valid payments per hectare of arable land, from 100 EUR/ha to approximately 33 EUR/ha. These subsidies belong to the group of direct payments.
Authors have analysed impact of these changes in agricultural policy measures on 45 agricultural holdings in Zlatibor District. Zlatibor District covers ten municipalities: City of Užice, Bajina Bašta, Kosjerić, Požega, Čajetina, Arilje, Priboj, Nova Varoš, Prijepolje and Sjenica. All of these municipalities, except Priboj are covered by the survey. Zlatibor District mostly consists of mountain area, where livestock production and mixed farming are the most represented types of agriculture.
Starting hypothesis is that these changes will have significant negative impact on farm net income, and consequently quality of life of farmers affected. Social importance of this paper lays in the analysis of the impact of changes in agricultural policy on farm net income and quality of life in rural areas. Scientifically, this paper intends to initiate and set the basis for wider and more comprehensive research on the same topic, that should be very valuable in agricultural policy making process.
This paper will emphasize the importance of consistency in measures made by policy makers in the agricultural sector.
In order to conduct needed analysis before introducing new policies, Ministry of Agriculture and Environmental Protection should use available statistics from the instruments like FADN (Farm Accountancy Data Network), gross margin and similar calculations on farm level conducted by agricultural extension agents and similar data at their disposal.
From the Government Regulation on the Distribution of Support in Agriculture and Rural Development in the Year 2016 from February 2016, it is clear that none of such analysis has been made and that the Regulation was purely "office made", without any hint of using bottom-up principle in its creation. This statement is supported by the fact that the Ministry of Agriculture and Environmental Protection still does not use available FADN data for any kind of operative or public analysis.

Materials and methods

In order to test the starting hypothesis, authors have conducted the field survey on 45 agricultural holdings, collecting information about use of subsidies granted per hectare of arable land, which includes: payments per hectare for crop production, recourse for diesel fuel and recourse for fertilizers. Besides these, authors have also collected, processed and analysed data on utilized agricultural area, type of production and on indicators that define farm net income. Farm net income has been calculated by following procedure:

Total output – (Specific costs + Farm overheads) + Balance of current subsidies and taxes* = Gross farm income[4]
Gross farm income – Depreciation = Farm net value added
Farm net value added – External factors** = Farm net income

[3] Source: Koester, U., Zaric, V., 2009: Trade in agri-food products – principles and policy (*Trgovina poljoprivredno-prehrambenim proizvodima – principi i politika*), University in Belgrade, Faculty of Agriculture, Belgrade

[4] Source: Gogic, P., 2009: Theory of costs with calculations in agri-food production (*Teorija troškova sa kalkulacijama u proizvodnji i preradi poljoprivrednih proizvoda)*, University of Belgrade, Faculty of Agriculture, Belgrade

*Balance of current subsidies and taxes is the difference between subsidies except subsidies on investments and taxes.
**External factors include: paid salaries, paid rent and paid interest and other costs of financing.

Based on the changes included in the Government Regulation, where recourse for diesel fuel has been completely abolished, expected changes on farm net income have been analysed. Authors have started with assumption that the farms will apply for subsidies in 2016 for the same areas of arable land (same number of units/hectares) as they did in 2015. Farms that did not use subsidies granted per hectare of arable land in 2015 were not included in the sample, since the analysis of the effect of changes in regulation on these farms would be irrelevant.
Authors have used the simple questionnaire for the field survey and collected data directly from agricultural holdings. Zlatibor District has been chosen due to good contacts of authors with farmers in this area and limited budget for the survey. Besides field survey, authors have conducted desk research of available statistics and literature.

Results and discussion

After processing the collected data and analysing results of the calculations conducted, authors have come out with following findings:

a) Expected overall decrease in used subsidies granted per hectare of arable land in Zlatibor District is 50.78 % in average, comparing to 2015.
b) Expected decrease in farm net income, as a consequence of changes in granted subsidies per hectare of arable land is 14.25 % in average.
c) Farms with different types of production are differently affected by changes.
   - Expected average decrease in granted subsidies per hectare on farms specialized for livestock production is 50.85 % comparing to 2015 (29 farms);
   - Expected average decrease in granted subsidies per hectare on farms with mixed livestock and crop production is 46.58 % comparing to 2015 (22 farms);
   - Expected decrease in farm net income is 5.42 % on farms specialized for livestock production, as a consequence of changes in subsidies per hectare, and 38.98 % on farms with mixed livestock and crop production, comparing to 2015.
   Farms specialized for plant production, such as fruit farms or crop farms, were not analysed individually, since there are only 4 of them in the sample, which would make results of such analysis irrelevant and confidentiality of individual data from agricultural holdings would be jeopardized.

From the results above, we may conclude the following:

a) Changes in subsidies per hectare introduced by the Government regulation from February 2016 are significant in terms of value comparing to 2015;
b) Changes in subsidies per hectare introduced by the Government regulation from February 2016 are significant in terms of their share in total current subsidies and consequently, in their impact on farm net income. This means that regardless the fact that share of subsidies in farm net value added (FNVA) in Serbia is relatively small comparing to EU average, changes in current subsidies can still highly impact the farm net income (FNI).
   Share of subsidies in FNVA in Serbia in 2014 was estimated at only 13%, while the EU average was 41%.[5]

[5] Presented at Final Conference of FADN Conference for the Data Collectors, September 2015, Belgrade, Serbia

c) Changes in subsidies per hectare have much smaller impact on livestock farms, comparing to mixed farms (mixed livestock and crop production).

These conclusions confirm the starting hypothesis that these changes will have significant negative impact on farm net income, and will consequently influence quality of life of the affected farmers.

Conclusion

Latest changes in subsidies per hectare introduced by the Government regulation from February 2016 are only one of many examples of sudden and frequent changes in agricultural policy measures. This especially refers to the policy measures dealing with financial support from public funds.

Results of the conducted research proof that the farmers can hardly cope with sudden and frequent changes of agricultural policy measures, especially in the area of financial support from public funds. Based on the results presented above, we may draw the conclusion that changes in current subsidies directly influence farm net income, and consequently, the quality of life of agricultural producers. When trying to secure food security, government first needs to take into consideration food security in most affected, rural areas. Adjusting to sudden and frequent changes in agricultural policy is especially challenging if we take into consideration biological nature of agricultural production.

Taking all of this into consideration, it is clear how serious task is to create and distribute financial support for agricultural production. First, it is necessary to make a wide and comprehensive analysis of current situation in agricultural sector and to set the goals that are to be achieved by implementing policy measures. It is also needed to conduct sensitivity analysis of each of the measures. This paper is just an example for one of the analysis that should be conducted on state level.

Methods and results described in this paper are intended to serve as an idea and, maybe, starting point for wider and more comprehensive analysis of the situation in agricultural sector on yearly basis. They may also give an idea for using such analysis in agricultural policy making, since all of the policies and measure in the area of agriculture should be in the best interest of agricultural sector and agricultural producers. Therefore, agricultural producers should be encouraged to take a part in decision making process and in keeping precise and reliable records on their farm activities and economic indicators. After that, it is up to responsible institutions to use available data and statistics, in order to respond to actual needs of agricultural sector in the proper way and create attractive business environment for all participants in the market of agricultural and food products.

Abstract

In this paper the emphasis is put on the specifics of energy efficiency impact on the profitability of the service sector, with special insight into food retail. The theoretical and methodological presentations are illustrated by applying the comparative approach, on the original empirical data of food retailers. Because of the importance of energy costs in the retail food, it is important to take appropriate measures to ensure their reduction as a very important factor in increasing profits. These measures may be of a different nature. Thus, for example, sustainable ways to save energy costs in the retail food are: efficient lighting, cooling, heating, energy management and initiative for increasing the renewable energy sources use. This certainly includes the use of new energy efficient technologies and construction of energy efficient office buildings and stores in food retail sector (with continual improvement of existing ones). Energy costs are significant component of operating costs and profits in trade, especially in food retailing. The size and structure of energy costs in retail is influenced by numerous controlled and uncontrolled factors (climate zones, location, age and isolation of building, the size of store, type of commodity, energy system, caring staff, energy prices, the amount of energy consumed and others). Acquaintance of the effects of individual factors is important for efficient energy management in (food) retail. In recent years, the key factor for improving energy efficiency in (food) retail is usage of renewable energy sources. Due to this, the goal of global retailers in perspective is more use of renewable energy sources in total energy consumption. Likewise, it is the reduction of carbon dioxide with respect to energy consumption. All this will decrease the energy costs of the global retailers. (JEL classification: Q40, Q44, Q32, Q57)

Key words: *energy intensity, renewable energy sources, energy management, green energy, final energy consumption*

Introduction

In the context of the analysis of the impact of energy efficiency on the performance in service sector, special attention is given to the specifics of the trade energy efficiency, primarily the leading global food retailers, such as Tesco. In order to increase customer satisfaction, profits, and to achieve greater application of *the concept of sustainable development*, global food retailers develop special strategies for improving energy efficiency management, water consumption, carbon dioxide emissions and food waste treatment. In order to achieve fully integrated accounting information system reports, special public reporting known as - sustainable reporting became a business practice in recent years. *Sustainable reporting* of the global food retailers (e. g. *Wal-Mart*) is increasingly becoming an integrated part of their annual reporting for which the public is interested in. The research presented in this paper are the energy costs in trade with special reference to food retailers. The *goal* is to get as complete with the character looks, size and structure of energy costs in the retail food. This is a prerequisite for the efficient management of energy costs in the retail food. The effects of this are food retailers increase profits.

There is growing body of *literature* on energy efficiency analysis in recent years. It is understandable when one takes into account the fact that energy efficiency is a key factor in the profitability of all companies (Lukic, et al. 2013, 2014,2015, 2016a,b; Christina, 2015). Nevertheless, existing literature dedicated primarily to the issues of energy efficiency in the service sector, with particular reference to food trade is not extensive (Lukic, 2011a, b, 2012, 2016).

Material and Methods

All relevant issues are still not sufficiently *theoretically, methodologically and empirically researched*. In that we find the scientific and professional opportunity for writing this article. It seeks to draw attention to most significant aspects of managing energy in the service sector, with special insight into food trade. In order to draw attention to the researched issues, *theoretical and methodological* presentations are illustrated with original *empirical data* from different countries, especially the *European Union* and *Serbia*.

The research conducted in this and other studies show that the efficient management of energy can significantly reduce costs (total costs and energy costs), and thus increase profits in the service sector, including trade. The paper presented *hypothesis* that efficient energy management significantly affects the improvement of the profitability of the companies, including service and trading. *The research methodology of issues in this paper is based on the theory, norm and, in particular, comparative analysis of empirical data (indicators) of service sector energy efficiency, with a special insight into food trade of selected countries with developed market economy and Serbia*. Within the applied research methodologies, indicators of energy intensity are very important, and to some extent specific to the service sector, trade and food retail. Based on their comparative analysis it is very easy to perceive the energy efficiency and its impact on the profitability of the observed service companies, for example, food retailers (such as *Wal-Mart* or *Tesco).*The *empirical data* were collected from different sources: literature, Eurostat, annual reports and other relevant statistics. To some extent, they undergo secondary processing in accordance with the aim of the research issues.

Results and Discussions

Energy costs are significant component of operating costs and profits in trade, especially in food retailing (USDA's Economic Research Service's Food Dollar Series, accessed July 23, 2015 at: www.ers.usda.gov/data-products/food-dollar-series/documentation.aspx). The size and structure of energy costs in retail is influenced by numerous controlled and uncontrolled factors. These are: climate zones, location, age and isolation of building, the size of store, type of commodity, energy system, caring staff, energy prices, the amount of energy consumed and others. Acquaintance of the effects of individual factors is important for efficient energy management in retail. In recent years, the key factor for improving energy efficiency in (food) retail is usage of renewable energy sources. Due to this, the goal of global retailers in perspective is more use of renewable energy sources in total energy consumption. Likewise, it is the reduction of carbon dioxide with respect to energy consumption. All this will decrease the energy costs of the global retailers. Positive economic effects of reducing energy costs in retail are: further increase in sales, profits and return on investment. Energy consumption, carbon dioxide emissions and loss of food in the food supply chain (agricultural production, processing, distribution, retail and consumption) is significant. For example, in the United Kingdom - UK energy consumption (in % of the total) in the food chain is 18%, carbon dioxide emissions is 176 MtCO2e and 15 Mt of food loss (Tassou, 2011, 2014). In food chain, retail is significant consumer of energy and producer of carbon dioxide emissions. In developed countries it participates between 3 and 5% of total energy consumption. In the UK, retail food sale participates with 3% in total energy consumption (Tassou, 2014). According to estimates, the carbon dioxide emissions, arising from retail operations, ranges between 6

and 9.5 MtCO2e (Tassou, 2014). The reduction of energy consumption and carbon dioxide emissions is therefore a significant factor in increasing profitability in food retailing. In the United Kingdom, major supermarkets, such as Tesco, ASDA, Sainsbury's and Morrisons, achieved in 2005 lower operating margin of 4.2% on average based on the reduction in energy consumption (Spyrou et al., 2014).The primary sources of energy in the food retail are electricity and gas. On the research on hypermarkets it is established that in the structure of energy consumption gas accounts for 20% (Spyrou et al., 2014). In the food retail, carbon dioxide emission is very significant seen from the standpoint of energy consumption. Thus, for example, the total annual CO2 emissions related to the consumption of energy in major food stores in the United Kingdom is about 4.0 MtCO2 (Tassou, 2011). In the United Kingdom food retail sector accounts for more than 3% of the total energy consumption and approximately 1% of the total emission of carbon dioxide (Spyrou et al., 2014). The research on the case in 2570 food retailers which account for about 30% of the total number in the United Kingdom has found that 10% of energy savings contributes to reducing 355,000 tons of CO2 emissions (Tassou, 2011, 2014).It is estimated that the retail sector in Australia will produce about 2,52% of the total carbon dioxide emissions of greenhouse gases in 2020. It is associated with the consumption of energy (gas, wood, fuel and electricity) for heating, cooling, lighting and appliances (Low Carbon Growth Plan for Australia, Retail Sector Summary Report, June 2011, Climate Works, Australia. Available at http://www.climateworksaustralia.org/sites/default/files/documents/publications/climateworks_lcgp_australia_retail_sector_summary_june2011_0.pdf). (Accessed March 1, 2016).

Energy consumption and carbon dioxide emissions are significantly higher in the wholesale and retail trade sector in China than in Japan (Yokoo et al., 2015). In Japan, retail sales participate with about 40% of total energy consumption in the commercial sector. Primary consumption of energy in food retail in Japan is 6,000 MJ / (m2 per year) (Suzuki et al., 2011).In any case, in order to efficiently manage the energy costs in the retail food it is necessary to know their size - the percent of their participation in sale. Thus, for example, energy costs in Canadian supermarkets are around 1% of sales (Available at: http://www.nrcan.gc.ca/energy/efficiency/buildings/energy-benchmarking/17188). (Accessed March 1, 2016). In the *United Kingdom*, in major food retail chains (*Tesco, ASDA, Sainsbury's, Morrisons and small chains such as Somerfield, Waitrose, Iceland, co-ops and other multiple chains and independent*) energy consumption of electricity is 8385 GWh, gas 2,477 GWh, and the total carbon dioxide emissions are 4.0 $MtCO_2$ (Table 1).

Table 1. Annual energy consumption and carbon dioxide emissions in the 10 largest food retailers in the United Kingdom

	Supermarket electrical energy consumption (GWh)	Gas energy consumption (GWh)	CO_2 Emission electrical power (tonnes)	CO_2 Emission gas (tonnes)	CO_2 Total Emission s (tonnes)
10 major UK retail food chains	8385	2477	3538470	470630	4009100 (4,01 $MtCO_2$)

S*ource*: Tassou et al., (2011)

Energy consumption and carbon dioxide emissions vary widely between supermarkets. This is affected by many factors, such as type and size of store, business politics and product range, cooling, as well as used environmental control systems. By applying appropriate measures 10% of energy can be saved, or 840 GWh, which represents a reduction of 350,000 tons of carbon dioxide (Tassou et al. 2011). As in other countries, trade in *Serbia* has very significant energy costs. Table 2 shows the energy costs of selected trading companies in 2013. The first three deal with food products selling, and the remaining two with fuels and petroleum derivatives.

Table 2. Energy costs of selected trading companies in Serbia, 2013

	Sales revenue (in 000 dinars)	Fuel and energy costs (in 000 dinars)	Share of fuel and energy costs in sales revenue, (%)*
Delhaize Serbia	75,817,380	840,390	1,24
Mercator-S	59,252,435	930,213	1,56
IDEA	55,072,112	770,036	1,49
Knez Petrol	37,289,281	320,250	0,85
OMV Srbija	30,937,667	156,577	9,50

Note: * Calculation performed by the Author
Source: Annual Reports - Business Registers Agency

According to the data presented in the table, the costs of fuel and energy are much higher in the retail chains that sell food (ranging from 1.24% to 1.56%) compared to ones that sell fuel and petroleum products (in which it is less than 1 percent). Based on these data (Table 2) we can conclude that the energy cost in Serbian trade are higher than in countries with developed market economy. (See: Eurostat) The results of empirical research show that energy efficiency in the food retail sector in Serbia is considerably lower than in the European Union and other countries with developed market economy. (Thus, for example, energy costs in Canadian supermarkets are around 1% of sales (Available at: http://www.nrcan.gc.ca/energy/efficiency/buildings/energy-benchmarking/17188). (Accessed March 1, 2016) Given that, it is necessary to introduce appropriate measures to improve energy efficiency of the food retail sector in Serbia in the future. These are: modern energy technologies, increase of renewable energy share in total final energy consumption, reduction of energy consumption throughout the entire supply chain, reduction of carbon dioxide emissions related to the energy consumption, construction of energy efficient office buildings and retail facilities, and improvement of the existing. The ultimate effects of this are to improve profitability in the food retail sector in *Serbia*. The reasons for this are very low energy management efficiency, insufficient use of modern energy-efficient technology and

equipment, unsatisfactory improvement of energy efficiency in existing and slowed construction of new energy-efficient office buildings and retail facilities, as well as a slight use of renewable energy sources. All global food retailers devote considerable attention to the reduction of carbon dioxide emissions related to energy consumption in order to improve their overall efficiency. We will illustrate this on the example of the famous retailer *Tesco*, which devotes significant attention to sustainable development and environmental protection. In *Tesco* company food losses in the retail and distribution centres in the *United Kingdom* amounted to 55,400 tons, or 0.9% of total sales in the stores in 2014. Compared to the previous year they were reduced for 1,180 tons (Tesco - Annual report 2015. Available at: http://www.tescoplc.com/files/pdf/reports/ar15/download_annual_report.pdf).(Accessed March 1, 2016). Table 3. shows the dynamics of carbon dioxide emissions in the company Tesco for the period 2006 - 2014.

Table 3. Emissions of carbon dioxide in Tesco company, 2006 - 2014

	2006	2013	2014
Global net carbon dioxide intensity (total net emissions kg CO_2e/m^2)	64,33	39,71	37,99

Source: Tesco - Annual report 2015 (Available at: http://www.tescoplc.com/files/pdf/reports/ar15/download_annual_report.pdf) (Accessed March 1, 2016)

The *Tesco* company total carbon dioxide emissions in 2014 amounted to 5.6 million tons of CO_2e. That same year, global net carbon dioxide intensity in stores and distribution centres in the *Tesco* decreased by 4.3% compared to the previous year, and by 40.9% in comparison to 2006 (Tesco - Annual report 2015. Available at: http://www.tescoplc.com/files/pdf/reports/ar15/download_annual_report.pdf). (Accessed March 1, 2016). Thus, the objective to reduce the carbon dioxide in this company is accomplished and the situation in this company is similar with its competition, such as *Wal-Mart*. Energy consumption and carbon dioxide emissions depend on many factors, such as: type and size of store, business manner, assortment and interlinked cooling, climate zones and environment control system. Due to its economic importance, the majority of global retailers developed their own models of energy efficiency (Alcott, 2014), power management strategies and established special centres responsible for energy management. On this basis, they accomplish significant energy savings, lower energy costs, what positively affects their overall performance (Määttänen, 2014). Special system of indicators of energy performance is developed for retailers. These are: specific energy generators expressed in kWh/m^2 per year, primary energy use expressed in kWh/m^2 per year, specific energy consumption expressed in kWh/m^2 per year, consumption of green energy %, and carbon dioxide emission (expressed in appropriate measure unit, for example, kg). Also, internal energy performance indicators in retail are developed (such as, monitoring of power consumption by purpose: heating/cooling surface, cooling, lighting, etc., with detailed control of each energy segments, such as heating/cooling surface - heating loss in office building and shop, W/m^2) (Martos-Galvey, J.-L, et al., 2013). There are a number of actions to improve energy efficiency in the context of sustainable development in retail (The Food Retail Industry An innovative, sustainable retail environment, 2011 LG Electronics USA, Inc., Englewood Cliffs, NJ .Available at: http://www.lg-vrf.com/Assets/LG%20Retail%20-%20Why%20LG%20in%20Retail%20Space%202012%20V1_20111109090350.pdf). Accessed March 1, 2016). These are: energy efficiency of operations; use of renewable

energy sources in business; increase of product portfolio within the energy efficiency; collaboration with suppliers to improve energy efficiency of the supply chain; and reduction of packaging and packaging waste (Sustainable Energy for All: Opportunities for the Retail Industry, 2012, Accenture. Available at: https://www.accenture.com/t20150523T052048__w__/us-en/_acnmedia/Accenture/Conversion-Assets/DotCom/Documents/Global/PDF/Strategy_2/Accenture-Sustainable-Energy-All-Opportunities-Retail-Industry.pdf). (Accessed March 1, 2016). Integral application of these measures contributes significantly to improving energy efficiency in retail sales, which had a positive impact on its overall performance.

All retail companies increasingly use so called, "green energy" due to its economic importance. All global retailers have increasingly implemented best practices for sustainable development. In that context, significant attention is paid to energy management. This certainly has a positive impact on their overall performance. The company is *Wal-Mart*, as well as its major competitors, also devotes significant attention to sustainable development in order to continually improve its performance. The objective is to achieve long term 100% use of renewable energy, zero losses and sell products that fit consumers and the environment. *Wal-Mart* increases the share of renewable energy in total energy consumption (Table 4), and rapidly replaces the existing with new more efficient energy installation. Electricity is 26% used from renewable energy sources, and the share of renewable energy in the total energy consumption is 21% (Wal-Mart - 2015 Global Responsibility Report. Available at: http://cdn.corporate.walmart.com/f2/b0/5b8e63024998a74b5514e078a4fe/2015-global-responsibility-report.pdf). (Accessed March 1, 2016).

Table 4. Total renewable energy (GWh) in Wal-Mart, 2011 - 2015

	FY2011	FY2012	FY2013	FY2014	FY2015
Total renewable energy (GWh)	640	1,200	1,080	2,250	3,021

Source: Wal-Mart - 2015 Global Responsibility Report (Available at: http://cdn.corporate.walmart.com/f2/b0/5b8e63024998a74b5514e078a4fe/2015-global-responsibility-report.pdf) (Accessed March 1, 2016)

Considerable attention in *Wal-Mart* is given to reduction of carbon dioxide emissions. Table 5 shows the emissions of carbon dioxide and retail areas in *Wal-Mart* for the period 2005 - 2013. It is noticeable tendency for lower emissions carbon dioxide emissions related to energy consumption in recent years.

Table 5. Emissions of carbon dioxide and retail areas in Wal-Mart, 2005 - 2013

	2005	2006	2007	2008	2009	2010	2011	2012	2013
Carbon dioxide emissions (in million tons CO2e)	740	805	867	921	952	985	1,037	1,072	1,102
Retail area (in million square meters)	18,9	19,3	20,1	20,8	20,3	20,6	20,8	20,12	20,10

Source: Wal-Mart - 2015 Global Responsibility Report (Available at: http://cdn.corporate.walmart.com/f2/b0/5b8e63024998a74b5514e078a4fe/2015-global-responsibility-report.pdf) (Accessed March 1, 2016)

Generators (i.e. sources) of carbon dioxide in *Wal-Mart* are: purchased energy 72,0%, refrigerants 12.0%, transport fuel 8.5%, on-site fuel 8%, and mobile refrigerants 0.1% (Walmart - 2015 Global Responsibility Report. Available at: http://cdn.corporate.walmart.com/f2/b0/5b8e63024998a74b5514e078a4fe/2015-global-responsibility-report.pdf). (Accessed March 1, 2016). Continuous improvement of total energy efficiency has positive effect on the profitability of the company. *Wal-Mart* pays considerable attention to continuous improvement of energy efficiency in existing retail outlets and on that basis expects reduction up to 20% in energy consumption per square meter in 2020 (Wal-Mart - Saving Energy, Saving Money Through Comprehensive Retrofits, the US Department of Energy, Energy Efficiency & Renewable Energy, Commercial Building Efficiency Energy, Available at: http://www.nrel.gov/docs/fy15osti/63782.pdf). (Accessed March 1, 2016). All in all, the increasing application of the concept of sustainable development has a significant impact on the profitability of this company.

Conclusion

Energy costs are significant component of operating costs and profits in trade, especially in food retailing.. The size and structure of energy costs in retail is influenced by numerous controlled and uncontrolled factors. These are: climate zones, location, age and isolation of building, the size of store, type of commodity, energy system, caring staff, energy prices, the amount of energy consumed and others. Acquaintance of the effects of individual factors is important for efficient energy management in retail. In recent years, the key factor for improving energy efficiency in (food) retail is usage of renewable energy sources. Due to this, the goal of global retailers in perspective is more use of renewable energy sources in total energy consumption. Likewise, it is the reduction of carbon dioxide with respect to energy consumption. All this will decrease the energy costs of the global retailers.

In food trade, energy costs participate in sales with around 1%. In this respect, there are differences from country to country. They are, according to the analyzed empirical data, much higher in the food trade in *Serbia* than in countries with developed market economy. In order to increase profitability, reduction of energy costs should be implemented. This can be achieved by replacement of existing heating, refrigeration and cooling systems with new energy efficient, and improving energy efficiency by better insulation in existing and new office buildings and food stores. All in all, greater application of the concept of sustainable development in trade Serbia also results in increasing energy efficiency.

AGRICULTURAL COOPERATIVE AS A FACTOR OF INCREASING AGRICULTURAL PRODUCTION IN NORTHERN KOSOVO

Goran MAKSIMOVIĆ*, Božidar MILOŠEVIĆ, David JOVOVIĆ, Tatjana IVANOVIĆ

University of Prishtina, Faculty of Agriculture, Lesak, Serbia
*Corresponding author:goran.maksimovic@pr.ac.rs

Abstract

Agriculture has always been the primary activity of the inhabitants of Serbian enclave in northern Kosovo. Among agricultural sectors dominated by farming, there are good conditions for fruit growing, especially for the production of berries (raspberries, blackberries, blueberries). The mountainous landscape of the entire territory of northern Kosovo favours the development of animal husbandry. Qualitative method of observation and analysis method, were used during field research carried out in 2015.to examines the current operations of agricultural holdings. Using the method of synthesis, a solution for more harmonious economic development and prosperity of the Serbian population in the enclave in the north of Kosovo and Metohia is given in the paper. The authors upon research in the field suggest the reconstruction of existing and formation of new cooperatives in order to develop agriculture in the Serbian enclave in northern Kosovo in the field of production, processing , supply of inputs, services and marketing. Agricultural cooperatives despite the economic functions play a dominant role in the overall development of Serbian communities in northern Kosovo.

Key words: *agricultural cooperatives, production, economic development.*

Introduction

Agriculture is always being primary activity of the population in Serbian enclaves in north of Kosovo. Farming dominates among agricultural branches, there are good conditions for fruit growing of berries (raspberry, blackberry, blueberry). Entire territory of the municipality, by its configuration, is the hilly and mountainous, thus it is suitable for development of animal husbandry. Serbian population looks for an economic survival perspective in efficient dealing with agriculture. Intensive and economically justified agricultural production in Serbian enclaves has been disabled by a series of factors over many years. This paper defines problems in agricultural production and previous association of agricultural households.

Materials and methods

In this paper, we used qualitative method of observation to observe current situation of agricultural production in Serbian enclaves in Kosovo and Metohia. We used analysis method to study the performance of agricultural households and by synthesis method we provided the assumptions and options for more successful work and functioning of agricultural households in the Serbian enclaves in north of Kosovo and Metohia. Empirical research was realised through visits to family agricultural and existing cooperatives where we determined existing situation in the field in enclaves and interviewed the household owners and managers of cooperatives (where this wasn't possible, we obtained the information on cooperatives from the citizens of enclaves). Through interview, we got information on problems in performance of agricultural households and we will try to provide answers, propositions and solutions in order to help Serbian people in enclaves, at least a little, to remain and function in their ancestral homes. In addition to the data collected in the field, we also used the desk researching method (published materials and existing literature.)

Results and discussion

Through the interviews we carried out in the field in Serbian enclaves in north of Kosovo and Metohia, we analyze agricultural households, reach conclusions and list factors that have a significant effect on volume and structure of agricultural production after the war (1999.):

1) the households with small number of members dominate, 2) households whose members are rather old dominate (migration of younger population to central Serbia is expressed), 3) average surface of household is small, with great number of small parcels, which makes the use of mechanization significantly expensive and it makes more efficient production difficult, 4) impossibility to purchase varietal seeds and seedlings, as well as artificial fertilizers and rather difficult supply (due to administrative difficulties and safety), 5) lack and obsolescence of mechanization, 6) lack of bred livestock, 7) no organized purchase of agricultural products, 8) insufficient information about the use of funds meant for subsidies, premiums, regresses and crediting that is paid from the budget of the Republic of Serbia, which makes development of entrepreneurial initiatives in agriculture more difficult.The above mentioned factors point to the necessity of developing agricultural cooperatives and association of small agricultural households that have no perspective in the aspect of independent survival. Small agricultural households in Serbian enclaves in north of Kosovo and Metohia are economically powerless, exhausted, worn, obsolete and old and for that reason they should be joined and organized into agricultural cooperatives. They could jointly contribute to survival of Serbian population in ancestral homes and improvement of household's business, that will give the following: 1) contribution to the improvement of household supply (in supply of cooperative aimed at specific production needs for material and agricultural equipment, cooperative supply is cheaper and it involves lower margin), 2) contribution to the improvement of household's goods sale (cooperatives have more successful placement of greater amount of joint goods from family households), 3) contribution to more favourable use of services (avoiding irrational investments, cooperatives provide agricultural machines and vehicles in order to provide services for agricultural households). Cooperatives are specific organizations and for that reason they are simultaneously the enterprises that deal with business and the associations that have both economic and social goals (Zamagni, 2012. Dasgupta, 2012.). According to this organization, cooperative is an autonomous association of persons voluntarily associated, with the aim to achieve their common economic, social and cultural needs and desires, through jointly owned and democratically controlled enterprise. There are two different organizations in cooperative: cooperative itself and enterprise. Cooperative as an enterprise is a market entity, i.e. organization of different business activities. On the other hand, cooperative is the association of persons organized from the bottom according to principles of voluntariness, equality, democracy, solidarity of members, shareholders (Pejanović, 2013). Contributions that cooperatives achieve at local level can be classified into three categories: (1) employment increase, (2) local infrastructure improvement and (3) processing of agricultural products within local community (Lorendahl 1996). Principle by which the existing and newly formed cooperatives in Serbian enclaves in Kosovo and Metohija should do business is the principle of inter-cooperative cooperation. Cooperative as individual organization is alone and relatively powerless before big industrial systems and trade chains that are increasingly winning the market of rural areas. Therefore, it is required for the cooperatives to join the alliances because, when connected in this manner, they become a significant factor that can regulate the flows in local market and wider, depending on the number of cooperatives that joined the alliance, i.e. the volume of their business (Erokhin, 2009). This is the only way for alliances to represent a more adequate response of cooperative movement to globalization process. Joined in alliances, cooperatives remain consistent to their principles and respect

towards local community, but they are simultaneously able to economically more successfully confront gigantic enterprises in the market (Nikolić, and Popović, 2006). Development of agricultural households would be improved by activating the existing agricultural cooperative and purchase stations for agricultural products that would be placed to the factories for further processing. Agricultural cooperative „Leposavić“ in Leposavić in recent years does not work although it has potentials. It owns an administrative building, 2 warehouses (one in Leposavić and one in Sočani), 4 stores, equipment for dairy. It has about 50ha of agricultural land, about 30ha of which is arable land. For revival of agricultural cooperative it is necessary to use the existing potential (business and warehousing space, agricultural mechanization). It is necessary that the Republic of Serbia, through the Office for Kosovo and Metohija and local government provides financial funds primarily for the repair of the existing and supply of new mechanization, as well as purchase of consumable materials. Activation of cooperative is vital for the development of north Kosovo valley and it would have a positive impact on: 1) increase of production volume, 2) reduction of unemployment of population by employment on own households, 3) survival of existing and arrival of new returners, 4) self-sustainable development of this part of Kosovo

Agricultural cooperative “Zubin potok“ in Zubin Potok is the only cooperative in Kosovo and Metohija that hasn’t stopped working and that is still active. This cooperative owns a building of 900m^2, hangars 800m^2, stables 600m^2, auxiliary buildings 800m^2 and 1,30ha of arable land. Cooperative has a fishpond whose capacity is 60-80t and it operates with its full capacity, animal food factory, laying hens farm. Animal and green markets have begun to work within the cooperative. In addition, this cooperative owns a refrigerator whose capacity is 1.500 tons in one turn. Capacity of refrigerator owned by this cooperative is such that it could take entire market surplus of agricultural products from serbian enclaves of entire Kosovo and Metohija and sell them to familiar buyers in northern Kosovo (student canteen, clinical center, canteen for workers in Trepča). It is required from the local government in Zubin Potok to predict the subsidies of such projects in its budget through the existing agricultural cooperative which enables the members of local community to achieve business goals more easily.

Conclusion

Today, the agricultural cooperative “Zubin Potok” in Zubin Potok is the only functioning one. We believe that other eight agricultural cooperatives should be restructured in the following aspects: organizational structure, managerial structure, financial structure (part of the capital is already owned by cooperatives that would, with consent of the Republic of Serbia, transfer to cooperative’s ownership, part of the capital would be provided by members themselves from their shares and one part of the capital would come from the subsidies from local government) and human resources that will lead to enabling the cooperative to function in market business conditions. In town of Zavečan there are no cooperatives, although they have both resources and potentials, thus we propose the formation of new modern multifunctional cooperatives that could include: dairies, bakeries, mixers of animal feed, refrigerators. Principle by which already formed, restructured and newly formed cooperatives should operate in Serbian enclaves in Kosovo and Metohija is the principle of intercooperative cooperation. The necessity that motivates individual producers to join the cooperatives, because it is easier for them to face the market challenges, simultaneously affects the cooperatives. By promoting and developing cooperatives and cooperative alliance, by their activities, we achieve wider economic, social and general social interests of Serbian community from the employment increase in rural areas, stimulation of young people to survive in Kosovo and Metohia, to the improvement of agricultural production and preservation of living environment, as well as other aspects in rural areas.

Abstract

This study was carried out to compare the performances of agricultural production systems based on millet and sorghum in Sahelian and sudano-Sahelian areas of Mali in 2014. The two systems compared were production techniques of micro-dosing fertilizer and traditional cropping called conventional cropping system of millet and sorghum. One hundred and eight farmers (108) were selected and interviewed in the two areas. The techniques of micro-dosing used were manual and mechanical fertilizers distribution. The tools used for analysis were descriptive statistics (frequency, average, standard deviation) and analytical method (ANOVA). The software's used were EXCEL, SPSS 20 and STAGRAPHICS. The results of this survey show significant differences of mean at the plots levels. The production system based on fertilizer micro-dosing techniques is more efficient than traditional system of millet and sorghum through high yielding, lowing costs of fertilizers, diminution of farming operation work times and, high net profit at the plot level. The percent of yield obtained with manual technique is 41% and 52% with mechanical distribution (placement) for millet and respectively for sorghum 45% and 56%. The calculated cost ratio values (CRV>1) show that micro-dosing techniques are profitable for millet and sorghum production.

Keywords: *performance, production systems, millet and sorghum, Sahelian and sudano-Sahelian areas, Mali.*

Introduction

Agriculture in Mali occupies 70% of population workforce and provides 42% of gross income and 75 to 80% of annual exports constituted by agricultural and livestock products (MA/PNIP-SA, 2010). Millet and sorghum crops occupy an important position in the country food security system, supported since 2009 by the government as part of the Rice Initiative in the frame of inputs subsidies (USAID/MSU, 2011).With a total production of cereal estimated at 6,674,427 tons in 2013-2014, millet occupied the second rank with 1,802,095 tons followed by sorghum 1,201,397 tons (MA-CPS-SDR, 2015). These cereals are most consumed and used as basic food of rural populations (whole grain or processed into flour for porridge, couscous, bread and alcoholic beverages).

Although constant advances research on millet and sorghum, achieving substantial efficiency gains in unstable environment become a challenge. Their production and yields during the past 20 years (between 1990/91 and 2008/09) have slightly increased compared to rice and maize. The productions grew for millet to 68% and 42% for sorghum, compared to 224% for maize and 228% for rice (USAID/MSU, 2011). Their yields are strongly linked to the rainfall, but also locust attacks and the lack of agricultural equipment (Traoré et *al.*, 2002). From these identified factors, climate variability is quoted in the generality of cases as the main constraint of cropping systems in Mali (MAEP/CPS, 2004).

To solve these constraints, several technologies have been developed by Agricultural Research in collaboration with international research institutions such as ICRISAT. Improved

varieties and appropriate crop management technologies are part of the released technologies on-farm for their adoption by farmers.
The technique of fertilizer micro dosing which involves applying a small amount of mineral fertilizer(complex cereal, DAP) in bunches crop planting is cited as a method that has the potential to increase cereal yields under dry farming conditions(Aune et al 2008; Hayashi et al 2008).
In Mali, the technique is practiced on millet and sorghum crops in the Sahelian and Sudano-Sahelian rainfall zones between 400-600 mm and 600-800 mm. It is realized manually or mechanically with the use of the hopper called mechanical placement technique (Coulibaly and al. 2012).This study evaluates the performance of these techniques compared to traditional system production in the Sahelian and Sudano-Sahelian of Mali.

Materials and methods

Zone and samples

The study was conducted in the Sahelian and Sudano-Sahelian regions with a sample of 108 farms in three regions (Koulikoro, Segou and Mopti) of which 36 farms by region (Figure1).

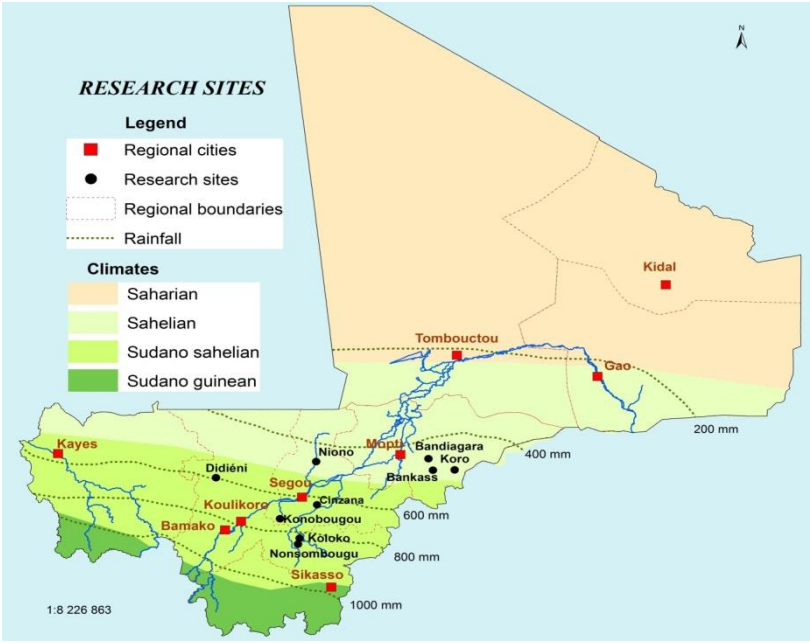

Figure 1: Map of regions and research sites in Mali.
Source: LABOSEP, IER-Mali, 2014.

Data collection and analysis

Data's were collected using semi-structured interviews (SSI) with farm heads. A previously established questionnaire was used as interview guide. The main data's collected are farm characteristics and production systems of which total and cultivated area farms, cultivated areas of millet and sorghum crops, quantities and costs of biochemical inputs used (seeds, fertilizers, insecticides and other, the labors (family and outside family) and agricultural equipments utilizations and their amortization. The descriptive statistics (average, frequency) and analytical methods (ANOVA analysis) were used for data's analysis with the software's SPSS and STAGRAPHICS.

Results and discussion

Socioeconomic characteristics and adoption technics by the farms

Surveys in research sites identified two (2) cultivation systems of millet and sorghum practiced by farmers. These are culture system with micro dosing techniques of fertilizer, and traditional culture or conventional culture system of millet and sorghum, called the farmer practice. The system with the micro dosing fertilizer is represented by two techniques: the manual and mechanical techniques. The mechanical called mechanical placement involves the simultaneous application of seed and fertilizer in the planting hole with hopper utilization. In all research sites, the adoption rate of these techniques is 69 % for mechanical against 31% for farmer practice.

Comparative performance of millet and sorghum production systems

Performance can be defined by search for high income, for the technical and economic profitability, employment and farms sustainability (Levallois, 2010). The concept of performance in objective or operational purpose is established by two other concepts, namely the effectiveness and efficiency. Efficient farm achieves the fixed goals and efficient farm maximizes the results with minimum resources and resources are managed with lower cost. The farm is successful, if it simultaneously efficient and effective, in other words it achieves its objectives while minimizing the use of its resources.
In this study, the performance of production systems is determined by the profitability and economic technique of identified systems on millet and sorghum crops. This profitability is assessed at agricultural plots of millet and sorghum. This is to compare the production system with fertilizer micro-dosing techniques and the traditional cultivation system of millet and sorghum.

Technical performance

Technical or agronomical performance of production systems in comparison is evaluated on millet and sorghum production and on the timework of farming operations.

Comparison of millet and sorghum production

- *Millet plots*

The results on millet plot show higher average yields on plots with fertilizer micro-dosing techniques than those obtained with the traditional farmer practice or system plots (Table 1). Average yields are respectively 1551kg/ha for micro-dosing technique with mechanical placement, 1256 kg/ha for micro-dosing technique with manual system and 741kg/ha for farmer practice. Increases in yields observed with the fertilizer micro-dosing technology compared with farmer practice are respectively 41% for the manual technique and 52% for technical mechanical placement.
The ANOVA test on yields shows a statistically significant difference between the yields in comparison techniques, indicated by the value P-value of statistic F test (table 2). The differences in average yields observed between techniques are 295kg/ha between the technique of mechanical placement and technique of manual micro-dosing, 514kg/ha between technical manual micro-dosing and farmer practice, and 810 kg/ha between the technique of mechanical placement and farmer practice.

Table1: Compared millet yields (kg.ha^{-1}) using three technics, 2014.

Technics	Count	Average	Standard deviation	Coeff. of variation	Minimum	Maximum
Manual microdo-sing	32	1256	320,84	25,55%	800	2200
Mechanical micro-dosing	15	1551	446,94	28,81%	1125	3000
Farmer practice	24	741	211,84	28,57%	400	1067
Total	71	1144	443,91	38,80%	400	3000

Sorghum plots

The results on sorghum plot show higher average yields on plots with fertilizer micro-dosing techniques than those obtained with the traditional farmer practice or system plots (table 3 and 4). Increases in yields observed with the fertilizer micro-dosing technology compared with farmer practice are respectively 45% for the manual technique and 56% for technical mechanical placement.

Statistical tests on yields (Table 4) show a statistically significant difference between the techniques in comparison (P value of statistic F test). Average differences observed between techniques are significant. They are respectively 295 kg/ha between the technique of mechanical placement and technique of manual micro-dosing, 514 kg/ha between technical manual micro-dosing and farmer practice, and 810 kg/ ha between the technique of mechanical placement and farmer practice.

Compared farming operations work times

The performance of techniques in comparison has been evaluated for farming work times operation's that are sowing and weeding times, evaluated in man day per hectare (Hoe.j/ha). The results show a reduction of work times achieved with the technique of mechanical micro-dosing (placement), compared to those of the farmer practice (Figure 2).

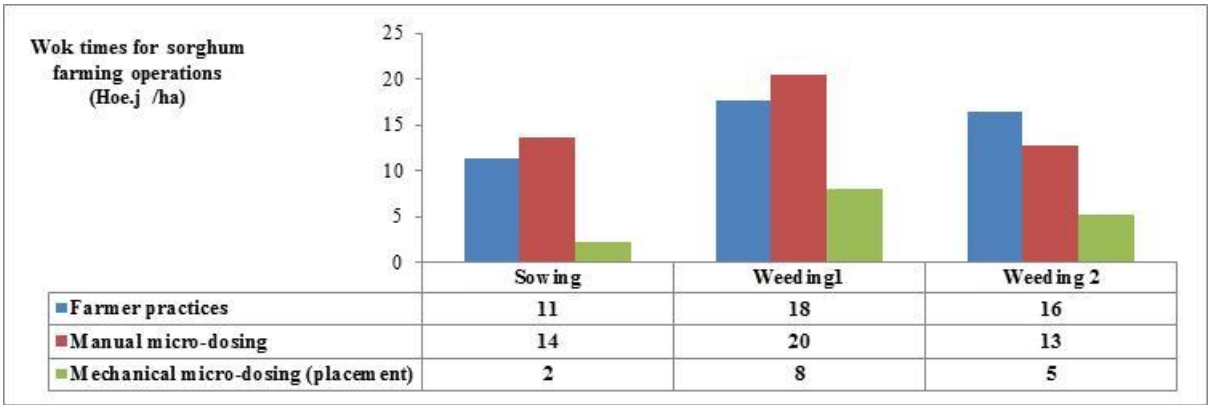

Figure 2: Wok times for sorghum farming operations (Hoe.j/ha)

Compared economic performance of technics

The benefit costs analysis (Ferraton and Touzard, 2009) were used to determine the economic performance of different production systems in comparison for millet and sorghum crops. The calculated performance indicators are in table 5.

- ***The Gross value (GV):*** is the value of crop system, calculated from the production quantity by area unit multiplied by the product market price. The market price during harvesting time for millet is 150 FCFA by kg, and 125 FCFA by kg for sorghum.
- ***Variable charges (VC):*** are represented by the cost of intermediate consumption (IC) which consist of input costs used (seeds, fertilizers , herbicides, pesticides and fungicides) and the labor costs (domestic and external) on millet and sorghum plots.

- ***Gross margin (Gm)*****:** is equal to the gross product (GP) minus variable charges (VC).

Gm= GP-VC

-***Net margin or benefit (Nm):*** is the GVA minus the value of amortization (Am) (or fixed costs) of agricultural machineries used on parcels.

Nm = Gm – Am

Economic amortization is calculated by dividing the acquisition value of the equipment (excluding inflation) by the number of years during which it is really used before being replaced, either its useful life (Ferraton and Touzard, 2009).

- ***Value Cost Ratio*** (VCR) was used as an indicator to compare the profitability of the two production systems. It is defined as the ratio between the value of the additional production and additional costs. In this study, the value-cost ratio is calculated from the ratio of production value on all charges (variable and fixed).

On millet and sorghum, the estimated economic performance indicators show that the fertilizer micro-dosing techniques allow generating on millet and sorghum parcels higher profits or margins compared to the farmer practice (table). The calculated cost ratio values show that these techniques are profitable (CRV> 1). A CRV equal to 2 is generally accepted as critical threshold (Henk Kieft et al , 1994).

Table 5: Economic performance indicators on sorghum and millet using cropping systems technics (FCFA/ha).

Economic indicators (FCFA[1] /ha)	**Millet**			**Sorghum**		
	Farmer practice	**Manual microdosing**	**Mechanical microdosing**	**Farmer practice**	**Manual microdosing**	**Mechanical microdosing**
1. Gross Value	111 213	188 343	232 667	85 796	155 245	196 091
2. Variables charges (VC)	91 420	80 360	44 894	102 983	92 461	58 843
Inputs	14 436	15 369	7 632	22101	11999	7811
Labor	76 984	64 991	37 262	80 882	80 462	51 032
Amortization (fixed charges)	5 468	3 392	3 937	3 087	3 617	1 891
Total charges (CT)	96 888	83 752	48 831	106 070	96 078	60 734
3. Gross margin	19 793	107 983	187 773	-17 187	62 784	137 249
4. Net margin or benefit	14 325	104 592	183 837	-20 274	59 167	135 357
5. C RV (value cost ratio)	**1,1**	**2,2**	**4,8**	**0,8**	**1,6**	**3,2**

Source : data survey, 2014.

Conclusion

Comparative analysis of millet and sorghum production systems in the Sahelian and Sudano Sahelian zones of Mali permitted to lay in evidence that the production system based on fertilizer micro-dosing techniques is more efficient than the traditional system cultivation of millet and sorghum. The technical and economic indicators assessed at crop parcels level show that these techniques can increase yields of millet and sorghum crops, reduce the work time of cultural operations and increase the profits of producers. The percent of yield obtained with manual technique is 41% and 52% with mechanical distribution (placement) for millet and respectively for sorghum 45% and 56%. The calculated cost ratio values (CRV>1) show that micro-dosing techniques are profitable for millet and sorghum production.

Abstract

The Republic of Serbia has comparative advantages for the development of rural tourism and the affirmation of the development of this type of tourism is supported if we observe the availability of resources, the relative development of agriculture as well as the possibility of rural development based on a multisectoral approach. The aim of this paper is to present the types of services provided by rural tourism subjects in the Republic of Serbia. In order to analyze the characteristics, authors have realized survey covering 104 rural tourism subjects in the 11 districts in the Republic of Serbia. The database of the National Association “Rural Tourism of Serbia” is used to form the sample. The sample was formed by random sampling. The instrument used in the study is a questionnaire. Methods that are used in this paper are: methods of analysis and synthesis, comparative method, field research and statistical methods. For the statistical analysis of data obtained by survey research, methods of descriptive statistical analysis and χ^2 (Chi-square) test are used and the SPPS software package. The authors analyze the results of research and propose measures and actions.

Keywords: *rural tourism subjects, services, the Republic of Serbia*

Introduction

The Republic of Serbia (RS) has great potentials for rural tourism development considering that 85% of its territory, according to the categorization of the Organization for Economic Cooperation and Development (OECD), make rural areas. Also, the Republic of Serbia has a favorable geographical position, rich historical and cultural heritage, preserved traditional rural architecture and attractive ethnic characteristics. In rural areas, numerous ethnographic and culinary events, and the population is characterized by traditional hospitality.

Factors which affect the growth of rural tourism offer are complex and according to some authors “the development of rural tourism is a long-term project” and its elements are: (a) people (expert) and the environment (clean); (b) a multi-sectoral approach to development; (c) engaging the local population in the drafting of development plans because “the local population has a better vision for the development of their region then the state authorities” (Koščak, 1995). A key feature of rural tourism is a rural identity, which “is crucial for the arrival and stay of tourists in rural areas”, and on the other hand, this type of tourism has a key role in preserving the identity of rural communities (Ružic, 2011). According to Pejanović (2013) rural tourism is a factor for stopping the migration from rural to urban areas.

There are significant linkages between agriculture and tourism. These economic activities are mutually complementary and multiply connected, because agriculture is producer, and tourism is consumer of agricultural product. According to Todorović and Štetić (2009), tourism is a factor in development trends of rural areas, additional activity to the rural population, agricultural markets, factor of agricultural development and “softener” of depopulation trends. According to the same authors, constraints affecting the development of

tourism and agriculture correlations can be divided into two categories: (1) the limitations that arise in the context of the agricultural households (lack of ambient tourist value of households, tourism offer, respectively accommodation and food supply with defined geographical origin); (2) limits of the community (non-existence of the concept of tourism development, legal vagueness and lack of adequate promotion of rural tourism).

According to Ciani (2003), appearance of rural tourism, or agritourism, and connecting these activities to existing agricultural activities, improved the quality of life on farms. Rural tourism development "cannot be seen only as economic growth, but also in terms of ecological and social development" (George et al., 2009). Sustainable development of rural tourism is part of integrated rural development, and it is defined as "a modern concept which represent a complex development of certain rural areas on the basis of available natural, financial, human resources and infrastructure, that need to be managed with due care to preserve the balance between man and nature" (Njegovan and Pejanović, 2009).

The affirmation of the development of rural tourism in the Republic of Serbia is supported if we observe the availability of resources, the relative development of agriculture, as well as the possibility of rural development based on a multisectoral approach. However, the average occupancy rate in rural tourism in the Republic of Serbia is only 4% (Program of sustainable development of rural tourism in the Republic of Serbia, 2011), while the average occupancy rate in rural tourism in the territory of the European Union is 25% (Bartlet, 2006). In order to achieve greater tourist traffic, as well as for the development of all forms of rural tourism in the Republic of Serbia, it is necessary to investment in: (a) the development of tourist facilities; (b) development of rural infrastructure; (c) the development and training of staff; (d) promotion (e) the development of sales channels of the rural tourism product in the domestic and international tourism market (Radović et al., 2015).

The aim of this paper is to present the types of services provided by operators of rural tourism in Serbia.

Materials and Methods

The starting hypothesis in the survey is: subjects of rural tourism, which provide both accommodation and food services, generate more revenue. In order to prove the thesis, survey research was realized on 104 rural tourism subjects Sources of data in the completion of the survey are the subjects of rural tourism: rural tourism households, handicrafts, ethno houses, ethno villages, farmsteads, hotels that are located in rural areas, as well as other service providers in rural tourism in the Republic of Serbia. The research was conducted in 2012 and 2013, in 11 districts and 30 municipalities in Serbia. Surveyed respondents are located in the districts of: South Bačka, South Banat, Kolubara, Mačva, Moravički, Pirot, North Bačka, Srem, Šumadija, West Bačka and Zlatibor. Within these districts surveyed rural tourism subjects are located in the municipalities: Arilje, Aranđelovac, Bajina Bašta, Čajetina, Užice, Gornji Milanovac, Irig, Ivanjica, Kosjerić, Kragujevac, Kovin, Kula, Kovačica, Knić, Loznica, Ljig, Ljubovija, Mali Iđoš, Mionica, Novi Sad, Nova Varoš, Osečina, Prokuplje, Prijepolje, Pirot, Požega, Sombor, Subotica, Srbobran and Valjevo. Districts were selected according to the level of rural tourism development in their area.

The database of the National Association "Rural Tourism of Serbia" is used to form the sample, because their database is the most complete, due to the fact that in Serbia there are no official data on the total number of entities engaged in rural tourism. The sample was formed by random sampling. The instrument used in the study is the questionnaire which contained 11 parts (groups of questions). The survey was conducted through a questionnaire, using a "face to face" technique and by sending the questionnaire by an email or post.

Methods that are used in this paper are: methods of analysis and synthesis, comparative method, field research and statistical methods. For the statistical analysis of data obtained by

survey research, methods of descriptive statistical analysis and χ^2 (Chi-square) test are used and the SPPS software package.

Results and Discussion

Sources of data in the survey are rural tourism subjects: rural tourism households, ethno houses, ethno villages, farms, hotels that are located in rural areas, as well as other service providers in the Republic of Serbia.

Table 1. Rural tourism subject classified by districts

District	Rural tourism Household	Homecraft	Ethno house	Ethno village	Farm	Rural hotel	Other service provider	Total
South Bačka District	1				6			7
South Banat District	7							7
Kolubarski District	9	1		1				11
Mačvanski District	4			1				5
Moravički District	10	1						11
Pirotski District	4	2						6
North Bačka District					3	1	1	5
Sremski District		5						5
Šumadijski District	8	2	1					11
West Bačka District	3	6	1		1			11
Zlatiborski District	18	2		4		1		25
Total:	**64**	**19**	**2**	**6**	**10**	**2**	**1**	**104**

Source: Radović, 2015 (Author s' elaboration based on the questionnaire survey results.)

Analyzing the structure of service providers in rural tourism in the Republic of Serbia (Table 1), it can be concluded that most of them are rural tourist households (62%). The entities listed by the current regulatory framework in the homecraft, account for 18%, 10% of farms, ethno villages 6% and 1.9% are ethno house and rural hotels, while 0.2% are other service providers. The dominant share of rural households is important in terms of the analysis of the types of services provided by subjects in rural tourism in the Republic of Serbia, especially the connection between agriculture and tourism, and the possibility of earning greater revenue by synergies these two activities. The sample is representative with respect to the fact that the survey covered 10.95% of the total number of providers in rural tourism in the Republic of Serbia.

Rural tourism subjects in the Republic of Serbia provide tourists services: (a) full board (accommodation and three meals); (B) half-board; (C) accommodation with breakfast; (D) lodging only, and (E) food only. According to the survey results, presented in Table 2, the majority of subjects (67.3%) provides the full board, which is the most cost-effective and economically, and provides them with the greatest potential for self-financing.

Table 2. Type of service that rural tourism subjects provide

Type of service:	Frequency (Number of providers)	Percentage (%)
– food only	2	1.9
– lodging only	15	14.4
– accommodation with breakfast	14	13.5
– half-board	3	2.9
– full board	70	67.3
Total:	**104**	**100,0**

Source: Radović, 2015 (Author s' elaboration based on the questionnaire survey results.)

Based on the results, we can conclude that the lowest number of surveyed rural tourism subjects (1.9%) provides food services only. We believe that this indicator is low, it shows little interest of agricultural producers to be involved in rural tourism activities, although providing food is a good start in tourism industry. Also, according to the results of realized research, 2.9% subjects provide half-board, bed and breakfast 13.5% and lodging 14.4%.

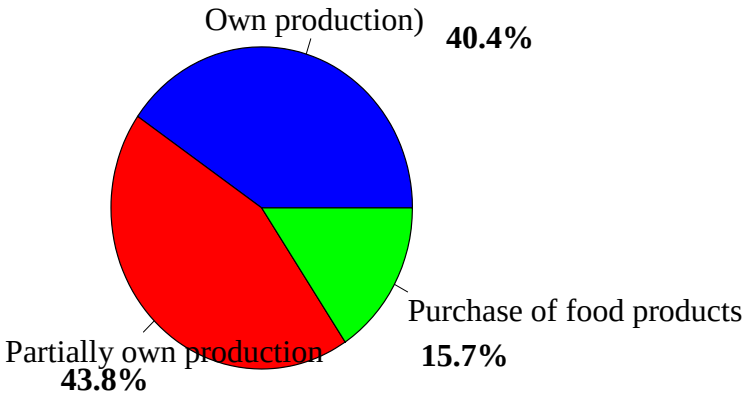

Figure 1. Relationship between food production and rural tourism
Source: Radović, 2015.

According to the results presented in Figure 1, the majority (40.4%) of the surveyed subjects in rural tourism have self-produced food products. Based on this data it can be concluded that there is a significant relationship between agriculture and rural tourism in the Republic of Serbia. Foodstuffs for tourist activity partly independently produce 43.8% subjects, while 15.7% surveyed subjects purchase food from other agricultural subjects or in retail stores.
Based on the results of Chi-square test, it can be concluded that there is a statistically significant relationship between the amount of realized income and the food service providing (Table 3). This result confirms the basic hypothesis that rural tourism subjects, which provide both accommodation and food services, generate more revenue. If the rural tourism subjects are also agricultural producers too, in this way, they will achieve a double benefit. This is because selling agricultural products through rural tourism creates a higher income than if agricultural products are sold independently on the markets.

Table 3. Crossbreeding of gross income and food service providing

Food service	**Results**	**Annual income (RSD)**					**Total**
		to 150.000	**to 300.000**	**to 500.000**	**to 1.000.000**	**Over 1.000.000**	
No	Number	33	23	13	8	9	86
	Expected number	30.6	20.7	12.4	7.4	14.9	86.0
	%	38.4%	26.7%	15.1%	9.3%	10.5%	100%
Yes	Number	4	2	2	1	9	18
	Expected number	6.4	4.3	2.6	1.6	3.1	18.0

Result: The value of Chi-square test is statistically significant *(χ^2=16,453, df=4, p=0,002).*

Conclusion

The development of rural tourism in Serbia is a possibility, but also the necessity, taking into account available resources, viewing the process of economic underdevelopment and depopulation of rural areas. The development of rural tourism would enable diversification of the rural economy, additional income for rural population, would reduce unemployment, and reduce differences in economic development between rural and urban areas. The development of rural tourism would allow the development of agriculture, if the rural tourism subjects are engaged in tourism and agriculture in parallel, or if they would provide both accommodation and food services, while through catering sell their own agricultural products.
According to the survey, 67.3% rural tourism subjects in the Republic of Serbia provide full board (accommodation and food). This is economically most profitable, and provides them with the greatest potential for self-financing. Based on the results of statistical analysis (Chi-

square test), the hypothesis is confirmed - rural tourism subjects, which next to the accommodation provide food services to tourists, generate higher revenues from those rural tourism operators who do not sell food.

Also, according to the results, majority (40.4%) of the surveyed subjects in rural tourism, self-produce foodstuffs, which suggest that in Serbia there is a significant relationship between agriculture and rural tourism. We believe that there needs to be a higher percentage of rural tourism subjects who produce agricultural products by themselves. To this end, it should be introduced a legal obligation, as in some European countries, that the majority of food products household produce by themselves, or to buy from neighbors farmers. This would also enable benefit for those rural tourism households that do not have accommodation facilities.

Abstract

The largest part of the Serbian territory (around 85%) belongs to the so-called rural areas, with a variety of ecosystem and biodiversity. The share of population living in the countryside is around 55%. Rural tourism has been identified as a key factor that can help in promoting Serbian rural areas as ecological oases with specific cultural, national and historic heritage. Grosso modo, rural tourism represents every tourism activity that takes place in rural areas.The basic premise on which is based this paper is that rural areas have significant potential for rural tourism development and for sustainable economic development of Serbia. Starting from this premise, authors analyze the basic characteristics of rural tourism, rural areas of Serbia and their real touristic potential.Work is based on several methods: induction and deduction, the method of analysis and synthesis, comparative method as well as historical method. Although the Serbian rural areas spread over a large part of its territory, they are facing numerous problems. Based on the results of the research conducted within the rural areas on the territory of Serbia, it was concluded that Serbian rural areas are characterized by a high degree of differentiation. This differentiation is reflected also in the field of social development, demographic trends, economic development, quality of life, environmental and other characteristics.

Keywords: *rural areas, rural tourism, ecology, sustainability, rural development.*

Introduction

Tourism represents one of economically most perspective activities in world. "Tourism industry" is rapidly evolving, creating a huge profit, which provides expansion of the material base and employment of a large number of people (Milenković, 2009). Tourism participates in the world gross domestic product with around 10%; over 6% of total exports in the world and about 30% of world trade in services are gained through tourism (UNWTO, 2016).

The most interesting destinations for modern tourists are rural areas with untouched nature and specific anthropogenic values. Therefore, tourism in rural areas- rural tourism is becoming an increasingly important form of tourism.

Rural tourism can be defined in many different ways. One of the first definitions of rural tourism was proposed by the European Commission in 1986: „Rural tourism is a broad concept that includes not only farm tourism or agritourism—accommodation provided by farmers—but all tourist activities in rural areas" (European Commission, 1986). Daugstag (2008) defined the discovery of the rural land as "a refuge from urban life". That is, it represents an alternative to embracing globalization. Cawley and Gillmor (2008) argued that we could speak of rural tourism when there were strong links with the land's economic and productive activities, and three main features were in evidence: integration, sustainability, and endogeneity. Schubert (2006), on the other hand, believed that rural tourism represented a key strategy for regional development. Zhou (2014) asserted that rural tourism was by nature mainly "domestic, and positioned as a small-scale activity" (Garau, 2015).

What is common to all of these definitions is that rural tourism offers the visitor a "rural environment", offering him a combination of experiences in nature, culture and people with typically rural character. Rural tourism is a specific form of tourism that includes a complexity of all activities and aspects of an integrated tourist product such as recreation in the countryside, enjoying environment and peace of rural areas, enjoying nature, national parks as well as nature parks, cultural tourism, tourism on rural households.

Materials and methods

Rural tourism takes place in a rural area, outside the city. Residents of large cities are increasingly seeking rest and relaxation in some of the rural areas far from the city and the city noise. Many villages- rural areas provide an opportunity for development of rural tourism, within existing as well as those partly or completely abandoned. The concept of village could be defined as an area where the majority of population makes a living by a primary agricultural production and mostly breeding animals and growing plants. Natural heritage such as arable land, forests, rivers, lakes and climatic conditions are usually the main factor that influences the development of a country (Radosavac et al., 2013).

The basic premise on which is based this paper is that rural areas have significant potential for rural tourism development and for sustainable economic development of Serbia. Starting from this premise, authors analyze the basic characteristics of rural tourism, rural areas of Serbia and their real touristic potential. The main objective of this paper is to determine basic characteristics of Serbian rural areas and their real possibilities for the rural tourism development.

Analyzes of the role and importance of tourism in preserving and promoting rural areas and fostering rural development in the Republic of Serbia are based on contemporary national and international theoretical knowledge and relevant sources. Work is based on several methods: induction and deduction, the method of analysis and synthesis, comparative method as well as historical method.

Results and discussion

In view of global economic dynamics, planning and programming for the development of sustainable rural tourism represents one of the new challenges for strengthening and revitalizing lands that are otherwise not competitive (Garau, 2015).

The basic assumption of the development of rural tourism consists of favorable natural and demographic conditions. Attractiveness of rural tourism is assessed by the availability of healthy food, unpolluted air and water, healthy climate and the environment, peace and tranquility, preserved nature, preserved social and cultural heritage, restaurants, good infrastructure, picturesque region and others. According to the World Tourism Organisation (UNWTO), the concept of rural tourism is based on rich natural resources, rural heritage, rural lifestyle and rural activities. Natural resources include mountains, rivers, lakes, forests, and rural heritage includes traditional architecture, industrial heritage, history, castles, churches, villages. Rural life is related to entrepreneurship, local events, gastronomy, traditional music, rural activities related to horse riding, cycling, fishing, hiking and sports (Radosavac et al., 2013).

The largest part of the Serbian territory as much as 85%, according to OECD criteria, belongs to the so-called rural areas, where live 55% of the total population in Serbia and where are most natural resources with rich ecosystems and biodiversity. Rural tourism has been identified as a key catalyst that should activate the differentiation in the rural economy by starting new business initiatives and by finding synergies between the existing agricultural production and tourism (UNWTO, Tourism & Leisure Advisory Services, 2011). Tourism can play a significant role in promoting Serbian rural areas as a kind of ecological oasis with a

specific nature and cultural and historical heritage. Given that sustainable tourism depends mostly on the geographical physiognomy of rural areas, comparative advantages for the development of this type of tourism in Serbia are obvious.

There are various definitions of rural areas - environments, depending on the country. When it comes to rural areas, the practice of the EU goes in favour of the fact that it is primarily necessary to define a rural area. By definition of the European Commission, the rural region is a territorial unit with coherent economic and social structure of diversified activities. This entity can include villages, small towns and regional centres. According to the OECD, typology of rural regions are divided into three groups:

1. Regions in which over 50% of population lives in rural communities – rural regions,
2. Regions in which 15% to 50% of population lives in rural communities – significant rural regions, or rural regions,
3. Regions in which less than 15% of population lives in rural communities – predominantly urban regions.

Using the OCED typology of regions on the example of EU, we get data according which rural regions are consisted around 55% of territory, significant rural regions of 37% of territory and 8% territory of EU can be considered as predominantly urban areas.

Nevertheless, rural areas are determined based on population density, land use and community identity. Based on these characteristics, rural areas can be defined as areas with a low concentration of the population whose primary occupation is agriculture, characterized by special customs and rural identity. Considered from the perspective of the modern business environment, rural areas are not only rounded agricultural areas intended solely primary production, but represent areas with significant potential for tourism development through meeting the various needs, such as environmental protection, preservation of traditional values, recreation, leisure, sports, different cultural and historical content, etc.

The Republic of Serbia does possess the comparative advantages, but they are insufficiently exploited for the purpose of rural tourism development. This is backed up by the fact that the average occupancy is only 4%, as well that it varies significantly throughout the year (Radović et al., 2012). Although the Serbian rural areas spread over a large part of its territory, they are in a very precarious position and are facing numerous problems.

The rural areas of Serbia are characterized by a high degree of differentiation in terms of size and morphology of the settlement, the natural conditions and infrastructure. This differentiation is sustaining on the plan of social development, demographic trends, economic development, quality of life, environmental and other characteristics.

In addition to the intense differences between the rural areas of Serbia, what they have in common, unfortunately, is „dying“ villages due to large migrations from rural to urban areas. As a result of migration from rural to urban areas, there is a so-called „depopulation“ of the village. Not only from the village leaving the working age population, thereby reducing the available workforce, but leaving young professionals and educated people that their knowledge could affect economic development and improving the current situation. Therefore, in solving the existing problems must start from the rural development policy and strategy formulation, but also from the lowest level - the level of rural municipalities. Using the appropriate instrument for stimulating local economic development, directly affects the rural development and development of the country as a whole (Pejanović and Njegovan, 2011; Premović and Pejanović, 2016).

The rural areas of Serbia, with its great variety of tourist resources, wants to become challenging for tourism development. That could achieve with the greatest inventiveness of their local communities, entrepreneurial initiatives, on clearly feasible target innovation in rural tourism. Also, in future development, rural areas of Serbia, in order to satisfy multiple challenges, must realize cluster grouping and systematization of themed rural-tourist entities,

so that all regions of rural areas in Serbia together become competitive in the tourism market without unfair competition tourist destinations within them.

Rural areas of Serbia provide many challenging activities. The most important can be marked the following:

> "a. challenge of the independent tourism offer, with complete rural-tourist facilities;
> b. challenge of the compatibility of rural-tourist area, with mountain centers, spas, urban and similar forms of tourism;
> c. challenge of marketing mix of rural-tourist area, with the promotion of tourism products facilities in rural areas of Serbia;
> d. challenges of transition rural-tourist area, through the valorization of tourism next to tourist traffic corridors in the area;
> e. challenges of excursion activities in rural areas, through the development of tourism in mainly hilly area of the space;
> f. challenges of the specific integrity of tourist-rural areas of Serbia, through diffuse resorts, didactic farms, ethno-villages and bio-tourism garden, as well as through identified „the country" (e.g., The fifth country in Italy), etc.; and
> g. all other challenges, which are a mix of forms and sub forms of tourist activities with „the central leader" rural tourism in rural areas of Serbia" (Milenković, Utvić, 2013).

In identifying real opportunities for activation of rural areas and their placement in the function of encouraging sustainable rural tourism in Serbia and local economic development, an important role must be handed over to local communities in these areas, primarily raising awareness and educating local rural population about the cultural, historical and natural attractions of the rural communities in which they live. Local municipalities, but also individuals in them are becoming increasingly important factors for success and effectiveness of rural development policy (Pejanović, Njegovan, 2011).

Practice has shown that the financial instruments are an extremely important tool for stimulating local economic development, and therefore rural development. Through the use of various financial instruments, such as financial assistance programs through micro-credit, guarantees, loans, various funds and instruments of public finance, self-taxation, public administration, foreign direct investment, international donations etc., can be influenced by the local economic development of rural areas, and thus indirectly on the economic development of Serbia overwhole (Premović, Pejanović, 2016).

In order to rural areas of Serbia could realize all the distinctive challenges of tourism development, must comply with accepted systems of standardization and product quality in rural tourism, as well as at each position, with ratified certificates, to allow unimpeded growth and development of tourism as an integral part of the economic system (Milenković, Utvić, 2013).

Taking into account the results of various studies that have been carried out in the country and the region, it can be assumed that for every eight new tourists to rural areas in Serbia a new direct job position is generated, additionally each 25 daily visitors present an opportunity for a new direct job position. Based on 10 years projections made on creating new jobs in Serbia arising from rural tourism that were made for the purpose of the Master Plan for sustainable development of rural tourism in Serbia, is expected to create realistic presumptions for as much as 250,000 new jobs in rural areas (Premović, Pejanović).

These are all reasons why rural tourism is emerging as a real possibility of development of rural areas and as an element of a better utilization of the comparative advantages of rural areas in Serbia.

Conclusion

The positive effects of sustainable development of rural tourism are numerous. Based on the research of basic characteristics of sustainable tourism and rural areas of Serbia, as the most important benefits of sustainable rural tourism are seen to be following:

- protection and preservation of natural, cultural, national and historical heritage
- keeping the local population in rural area and prevention of migration to urban areas
- development of related economic and non-economic activities, primarily agriculture and services
- an increase of employment of the local population
- increase in income (and/or additional opportunities for income)
- sustainable rural development and sustainable economic development of Serbia as a whole.

Research that is on Serbian territory enforced by the ministry responsible for tourism have shown that the key of success of rural tourism development should be sought in the optimal utilization of the potential of rural areas, active effort, modern approach, quality staff and managers, and in good use of known instruments of stimulating local economic development.

Therefore, rural tourism is emerging as a real possibility of development of rural areas and as an element of a better utilization of the comparative advantages of rural areas in Serbia. It can be concluded that Serbian rural areas have important role in fostering rural tourism and sustainable economic development of Serbia.

DISTRIBUTION CHANNELS OF APPLES IN THE REPUBLIC OF SERBIA

Marija UROSEVIC[1]*, Borislav RAJKOVIC[1], Vladimir JOVANOVIC[2], Vlade ZARIC[1]

[1]Faculty of Agriculture, University of Belgrade, Belgrade, Serbia
[2]NIRAS International Consulting
*Corresponding author: uro.marija@gmail.com

Abstract

This paper aims at analysing distribution channels of apples in the Republic of Serbia in 2015, with particular focus on export of fresh apples. Apple production of Serbia in 2015 is increased compared to the year before. Concurrently, apple export is increased when comparing the same intervals. Apples found in export originate mostly from orchards owned by big companies or from a well known fruit growing regions in Serbia (Grocka and Smederevo). Introduction and popularisation of Ultra Low Oxygen (ULO) keeping facilities had the big part in export development in Serbia since 2005. Efficiency of all business decisions is affected by choice of marketing channel. Serbia is a leading regional producer and exporter of apples. One of the biggest export problems is obsolete assortment. The most common variety is ”Ajdared”, followed by Golden Delicious, Red Delicious and Granny Smith. Other varieties are less frequent. Apples can be found in different types of distribution channels, such as processing, selling at green market, wholesale or retail, but more than a half of apple production is exported and this percent increases every year. Large quantities of fresh apples are processed into apple juice. Other types of processed apples products are puree, jams, dried apples, and apple brandy. These product categories has low share in total quantities of processed apple products in Serbia.

Keywords: *Distribution channels, apples, export, Serbia*

Introduction

Marketing mix includes several elements, and one of them is place, or distribution channel. Distribution is achieved by using one or more distribution channels, including retailers, distributors, wholesalers or direct selling. The choice of marketing channel affects the efficiency of all the other marketing and business decisions (Zaric, 2013). Agricultural products can be delivered to consumer by direct or indirect distribution channels. Direct selling contains advantages and disadvantages. Some of the advantages are: good way to meet new people and the environment, the possibility of flexible working hours, products demonstration, and positive image of product sold in this way (Stankovic and Djukic, 2013). On the other hand, the main disadvantages are: statutory requirements for higher hygiene, increased workload on the farm, distance market. Direct sales require additional work, like making calculations, sales planning, packaging and storage, delivery and invoicing, processing, which leads to increased costs.

Green market is one of the examples for direct distribution channels, where some of the agricultural products, like fruits and vegetables, have a large share of turnover. Individual producers, with low production, mostly sell their products at green market. Agricultural products at the markets are mostly fresh, with different quality, and consumers have habit to taste them (Miljkovic and Alcakovic, 2015).

When choosing indirect distribution channels, producers need to pay attention about reputation, credibility and strength of the trader, as well as consumer preferences and company goals.

Overall, the objective of this paper is to determine the direct and indirect distribution channels of apples in the Republic of Serbia.

Material and Methods

The paper is based on a review of Statistical Yearbooks issued by Statistical Office of the Republic of Serbia and on a review of data issued by Ministry of Agriculture and Environmental Protection. Other sources which are used in this paper are websites of different organizations and institutions, such as: Food and Agriculture Organization of the United Nations (FAO), International Trade Centre (INTRACEN), and The World Economic Forum (WEF). Information is also collected from several different scientific journals, magazines and newspapers. Collected data are related for 2015.

Methods used in this paper were collecting, arranging and analysing the relevant data. Data are analysed by calculating mathematical-statistical indicators (annual growth rate, share of total), after which they were presented in diagram.

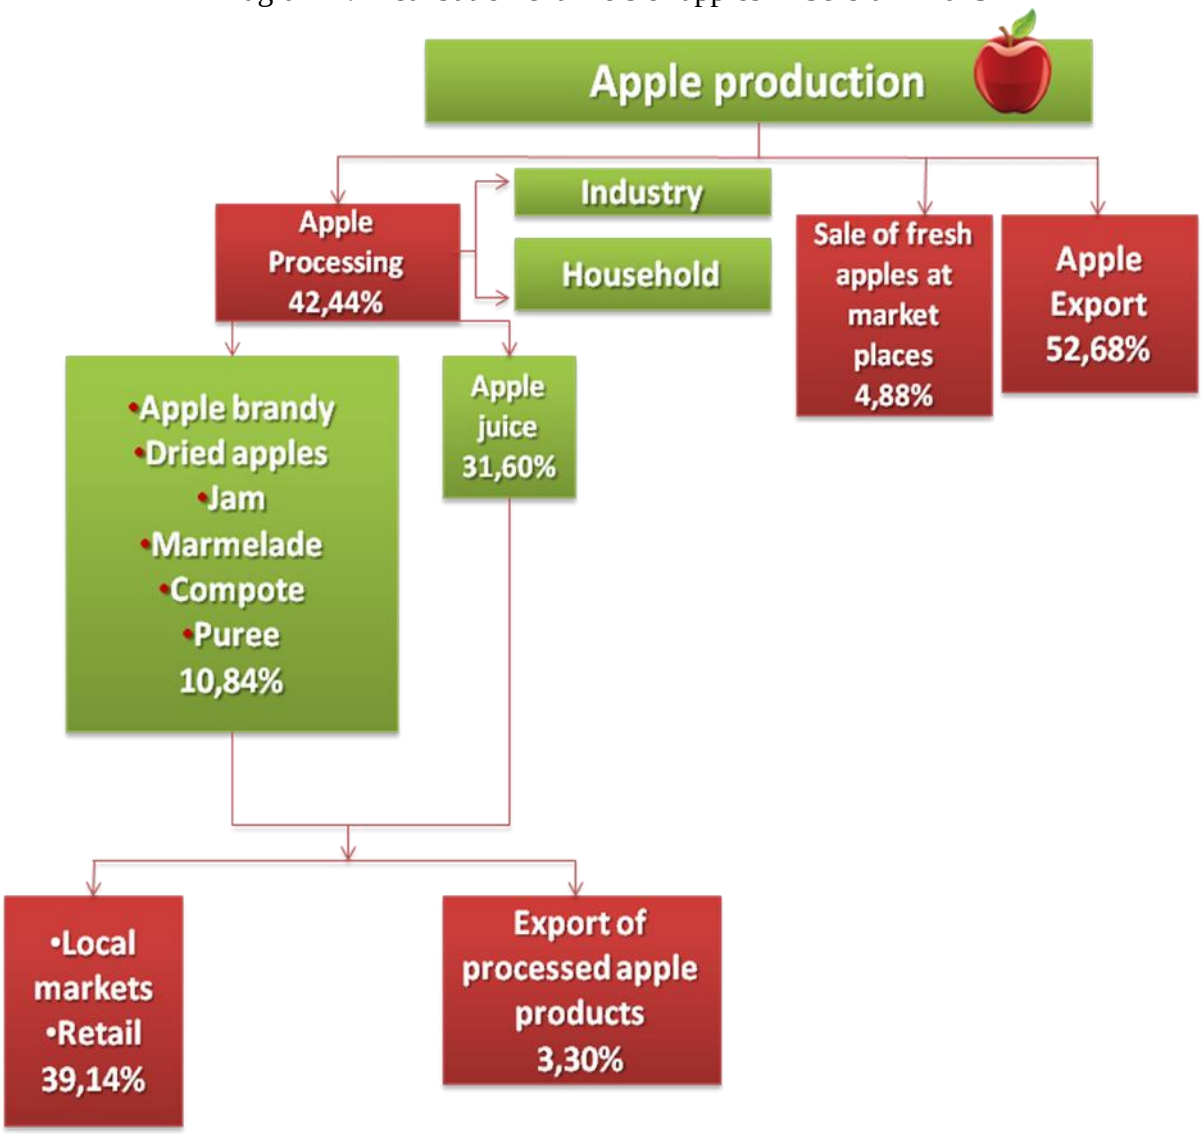
Results and Discussion

Serbia is a regional leader in apple production and export. Apple production in 2015 was 355.664t and has increased for 1.06% compared to 2014. In Vojvodina province, apple production is mainly based on intensive cultivation. The most of fruit growers have over 10 ha of orchard areas (Vlahovic and Puskaric and Velickovic, 2015). In this region importance of big companies is significant. During the recent years, they have begun intensive modern production. One of them is company Delta Agrar which has a modern apple orchard that extends over 400 ha. The other significant regions are Grocka and Smederevo. Producers with similar selling types are also in Topola and Cacak. Apple orchards in these areas are less than those in Vojvodina (2-10 ha). Producers from Grocka, Smederevo, Topola and Cacak usually sell their apples at local markets, the wholesale market in Belgrade, or through retailers.

State incentives help agricultural producers in raising orchards, and also provide institutional support for organic production and processing. Serbia became a significant exporter due to construction of the Ultra Low Oxygen (ULO) refrigerators in 2005.

Based on collected data, different types of distribution channels of apples have been found. The following diagram shows the distribution channels with their share in apple production.

Diagram 1. Distribution channels of apples in Serbia in 2015



*Source: Author's elaboration based on analysed data.

Compared to the total apple production (355.664t) in 2015, only 4.88% was sold through green market (i.e., about 17.000t). Apples at the green markets are mostly fresh, with different quality, meant for consumers with different purchasing power. Even though the share of green markets in selling apples is low, individual producers will sell their products directly, as long as appropriates the difference above the lower purchase and higher retail prices (Miljkovic and Alcakovic, 2015). Apples processing has share of 42.44%. The main processed products are: apple brandy, dried apples, jam, marmalade, compote, puree, and apple juice. Large quantities of apples were processed into juice (Djuric, 2009). The share of apple juice in total processed apple products is about 31.60%. Only 1-2% of produced apple juice was exported. The rest of processed products (apple brandy, jam, dried apples etc.) had only 1% of share in total export of apple processed products. About 39.14% of processed apple products were sold through local green markets and retailers. Quality standards in the European Union (EU) and other countries have become very high. Consumer's requirements for high quality products caused significant changes concerning quality standards that exported products have to fulfil.
More than a half of produced apples (i.e., 52.68%, or around 178.000 t) were exported. Share of fresh apples in total export was 50%, while apples for brandy accounted for only 2%. It is

assumed that apples for brandy are of lower quality. Around 90% of exported apples were exported to the Russian Federation and this figure increases every year. To export any product to Russia certain specific standards have to be fulfilled. These standards are regulated by GOST R certificate. Exporting large quantities of some product to one country implies big risks. Example is the Russian embargo that had significant impact on several countries. Thus, it is important to diversify export markets.

Conclusion

Agricultural products can be delivered to consumer by direct or indirect distribution channels. Serbia is the leader in apple production and export in region, but still has a lot to improve, in order to become competitive with the biggest world producers and exporters. More than a half of produced apples are exported (90% of is exported to Russia). Rest of the produced apples were processed, mostly into apple juice. Most of the processed products were sold in domestic markets. Only 5% of produced apples were sold on green markets. Green markets are still present, but their share in total sales of produced apples is decreasing every year. Exporting of processed products quantitatively is low, but value of processed products is high and it should not be ignored. Use of new production methods, like organic production, and modern varieties, such as Gala, Pink Lady, Fuji etc, shall be the first step in increasing of quality.

THE POTENTIALS AND PERSPECTIVES OF ORGANIC AGRICULTURE IN FRUŠKA GORA (VOJVODINA PROVINCE, SERBIA)

Sanja ĐUKIĆ*, Radovan PEJANOVIĆ, Mirela TOMAŠ-SIMIN, Danica GLAVAŠ-TRBIĆ

University of Novi Sad, Faculty of Agriculture, Novi Sad, Serbia
*Corresponding author: djukasanja@gmail.com

Abstract

The authors analyze the potential and future trends of organic agriculture in the area of Fruška gora national park. A special characteristic of this area is the presence of a national park and conservation area that require the application of sustainable solutions in the management of this area. Due to the specific nature-climatic and economic conditions, Fruška gora has an extraordinary potential for the application of organic agricultural production. Production potentials of this region are located in its protection zone in the following branches of production: fruit growing, viticulture, vegetable growing, animal husbandry, beekeeping, fishing, and medicinal herbs growing. However, despite the existing potentials, organic agricultural production in Fruška gora is at the beginning of development. The authors point out several significant factors that affect the further development of organic agriculture in Fruška gora. One of these factors is the inadequate sustainable management of this area so that organic agricultural production is not sufficiently represented and economically valorized in Fruška gora. Some of the other limiting factors of underdeveloped organic agricultural production in Fruška gora are the insufficient education of producers about organic production systems, inadequate level of incentives and subsidizing of organic farming, the insufficient number of processing and distribution companies, unfavourable demographic trends, insufficient organization of agricultural producers, etc. In order to define the optimum strategies for the further development of organic agriculture, the authors suggest a potential TOWS matrix.

Keywords: *Organic agriculture, potentials, perspective, Fruška gora, Vojvodina.*

Introduction

The region of Fruška gora is a unique geographical location in the Autonomous Province of Vojvodina (Republic of Serbia) and covers an area of approximately 139,430.01 hectares. In the midle of Fruška gora on the surface of about 25,525 km^2 is located National Park "Fruška gora", while in the broader scope are settlements and agricultural areas. Administrative-territorial units which are parts of this region are seven municipalities (Sremski Karlovci Beočin, Irig Inđija, Šid, Bačka Palanka, Ruma, Petrovaradin) and the city of Sremska Mitrovica. On entire area is performed the protection of natural resources and cultural values, according to the principles of sustainable development. The main economic activity in the region is agriculture of conventional type, organic agriculture is very little represented. In the area of Fruška gora are present negative demographic tendencies (Pejanović et al, 2012; Đukić, 2015), expressed through the depopulation and increasing ageing of the population.

According to Spatial Plan for the special purpose of Fruška gora until 2022, the areas of agricultural land have high participation (97,157.84 ha or about 70%), while the remaining area consists of forests (about 21%), and unfertile land (about 9%). This area has significant comparative advantages for the development of viticulture, fruit production, animal husbandry, as well as for growing medicinal herbs. The area of Fruška gora is singled out as one out of 35 ideal locations for organic agricultural production in Serbia (Arsić et al, 2012).

According to the Master Plan for Sustainable Development of Fruška gora, despite these comparative advantages, organic farming is not yet developed in this area.

Materials and methods

In order to identify the determinants of the development of organic agriculture of Fruška gora, a survey was conducted during 2014. The main topics for research were related to the role and importance of agriculture in the sustainable development of Frška gora. A research surveyed selected 117 examinees from different socioeconomic groups (municipal/city administration, regional organization, the media, non-government organization, financial organization, a public company, the private sector: industry, service sector, agriculture, hunting, forestry, fisheries, water management. The questions in a survey are close-ended type. In order to identify the degree of agreement of respondents with certain statements, the five point Likert scale was used. Data were analyzed with the SPSS software package. Techniques of descriptive statistical method were applied in a research (frequency, percentage, arithmetic mean, median and mode, standard deviation). In order to identify the key factors that influence the potentials and trends in the further development of organic agriculture in the area was used SWOT analysis and on that basis was formed TOWS matrix.

Results and discussion

Survey results show that among the key benefits of the implementation of organic agriculture in the region of Fruška gora are the proximity of the national park (mean 4.22, and mode 5) and the existence of the unpolluted natural resources (mean 4.07, and mode 5) in the area of Fruška gora. The least estimated variables are higher prices of agricultural products from the organic production model, the agricultural orientation and the willingness of producers for engaging in organic farming, and adequate expertise of agricultural advisors (table 1). According to the survey, respondents did not highly rate the importance of small farms for the development of organic agriculture.

Table 1. Advantages of the area of Fruška gora in terms of organic farming

Variables	Mean	Median	Mode	Standard Deviation
The unpolluted natural resources	4.07	4.00	5.00	1.187
The proximity of the national park	4.22	5.00	5.00	1.253
Tradition in agricultural production	4.04	4.00	4.00	1.125
Orientation of inhabitants of Fruška gora for performing agricultural activities	3.43	4.00	4.00	1.255
The willingness of producers to engage in organic farming	3.56	4.00	4.00	1.234
Higher prices of agricultural products from organic production model	3.31	4.00	4.00	1.399
Organic farming is an opportunity for small farmers	3.86	4.00	5.00	1.266
Adequate expertise of agricultural advisors	3.44	4.00	4.00	1.447

The research results show that the main disadvantages of this area for the development of organic agriculture are as follows: the poor financial condition of agricultural producers, limitation of subsidies and other incentives, high costs of certification and product control, as well as the low level of cooperation between the public and private sectors. Limitations that have less impact on the development of organic production of Fruška gora are a limited market for agricultural products originating from organic agriculture, as well as the lack of

implementation of the legislative framework relating to food safety and consumer protection (table 2).

Table 2. Disadvantages of the area of Fruška gora in terms of organic farming

Variables	Mean	Median	Mode	Standard Deviation
Limited experience of farmers with the techniques of organic agriculture	3.92	4.00	4.00	1.100
Poor financial condition of agricultural producers	4.10	5.00	5.00	1.199
The low level of education of farmers	3.84	4.00	5.00	1.259
Limitation of subsidies and other incentives	4.01	4.00	5.00	1.148
The long-term crisis in agriculture	3.85	4.00	Multiple	1.186
The limited market for agricultural products originating from organic agriculture	3.62	4.00	4.00	1.264
The lack of implementation of the legislative framework relating to food safety and consumer protection	3.65	4.00	4.00	1.213
High costs of certification and product control	4.01	4.00	5.00	1.126
The low level of cooperation between the public and private sectors	4.00	4.00	5.00	1.160

The majority of respondents emphasize viticulture (about 32.5%) and fruit growing (about 29.1%) as the most important sectors in the future development of organic agriculture, which should have better strategic support, and growing medicinal herbs (16.2%) and beekeeping (11.1%) (Figure 1). Highlighting the growing of medicinal plants as one of the branches of agriculture is surprising, because it is about a production that has not been present in this area.

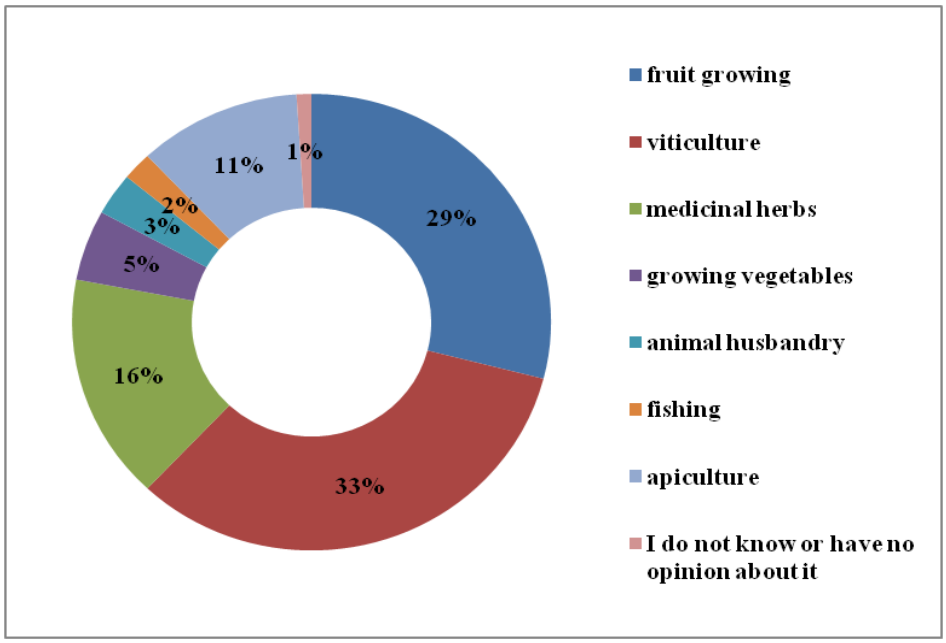

Figure 1. Rank of individual branches of agriculture in the future strategic support of organic agriculture in the area of Fruška gora

In terms of realization of priority investment (table 3), the survey results indicate that they should be directed to perennial plantings (fruit growing and viticulture - about 56.4 %), and then to the mechanization and equipment on farms (10.3%), as well as the expansion of farms (8.5%). In terms of providing funds for the improvement of organic agriculture, the survey results indicate that a large number of respondents believe that the funds from the agricultural budget of the Republic of Serbia (70.1%), as well as through credit lines (credits with subsidized interest rates, credits of commercial banks, development funds…) are not sufficient (50.4%).

Table 3. The realization of priority investments, the availability of funds from the agricultural budget of the Republic of Serbia, as well as through credit lines for the development of organic agriculture in Fruška gora

Variables	**Absolute frequency**	**%**
Priority investments		
for perennial plantings (fruit growing and viticulture)	66	56.4
for greenhouses	5	4.3
for storage	2	1.7
for livestock	5	4.3
for facilities in animal husbandry	1	0.9
for mechanization and equipment	12	10.3
for irrigation systems	4	3.4
for expansion of farms	10	8.5
do not know or do not have an opinion	12	10.3
Availability of funds of the agricultural budget of the Republic of Serbia		
yes	13	11.1
no	82	70.1
do not know or do not have an opinion	22	18.8
Availability of funds through credit lines		
yes	25	21.4
no	59	50.4
do not know or do not have an opinion	32	27.4
other	1	0.9

Small farms size, up to 5 ha, are the most numerous, and partly this may be a limiting factor in the future development of organic farming in Fruška gora (Đukić, 2015). However, small farms may have some advantages during the transition to organic agriculture because of the conversion period is short (Pejanović et al, 2010).

Fruška gora is mainly a rural area (Njegovan and Pejanović, 2009; Đukić, 2015), with the exception of municipalities of Sremski Karlovci and Petrovaradin that have the attributes of urban communities. This area is marked by negative demographic trends, which are manifested in decreasing population and senilisation. From these results is defined SWOT analysis of the potentials for organic production of Fruška gora (table 4). Perspectives for further development of organic agriculture in the Fruška gora are displayed as a possible strategy in the TOWS matrix (table 5).

Table 4. SWOT analysis of the potential for development of organic agriculture in the area of Fruška gora

Strengths	**Weaknesses**
• Proximity of the national park • Favourable geographical location and wealth of natural and cultural resources • Fruit growing and viticulture region • Tradition in agricultural production	• Small family farms • Insufficient self-organizing producers • Insufficiently represented certified organic agricultural production • The process of depopulation and senilisation • Insufficient number of processing and distribution companies
Opportunities	**Threats**
• National and regional strategic documents (organic production, agriculture) • European integration processes and inclusion in EU funds	• Insufficient interactions of institutions and the agricultural sector (extension...) • Insufficient state financial support (loans, subsidies...) • Insufficient visibility on market for organic agricultural products due to difficulties in certification of agricultural products • The competitive position of the other national parks in the country and the region

Table 5. TOWS matrix as perspectives for further development of organic agriculture in Fruška gora

SO (Strengths-Opportunities) strategy	**ST (Opportunities-Threats) strategy**
• Development and promotion of local capacities of Fruška gora for organic agriculture	• Using positive experiences of small farms in the development of organic agriculture
W (Weaknesses-Opportunities) strategy	**WT (Weaknesses-Threats) strategy**
• The possibility of using European financial support in the promotion of organic farming in Fruška gora	▪ Maximum and efficient utilization of existing resources of Fruška gora for organic agriculture ▪ Strengthening local initiatives to develop organic agriculture

Conclusion

The research results of the existing strengths of the area of Fruška Gora in the development of organic agriculture, show that economic development and organizational factors are less pronounced (higher prices of agricultural products from organic production model, orientation of inhabitants of Fruška gora for performing agricultural activities, willingness of producers to engage in organic farming, as well as an adequate expertise of agricultural advisors). The most important advantages of Fruška gora for the development of organic agriculture are natural values and proximity to the national park. Key disadvantages for the further development of organic agriculture of Fruška gora are of a financial-organizational character.

Fruit growing and viticulture are the optimum choices for the development of organic agriculture in Fruška gora, which is confirmed by the declaration of the respondents regarding the realization of priority investments. Also, the survey results indicate the limited availability

of funds for the realization of investments. Negative demographic trends and the dominance of small farms are additional limitations in the development of organic agriculture in Fruška gora. Further development of organic farming in Fruška gora should be based on the model of development that takes into account the existing potential and limits.

ACCREDITATION IN HIGHER EDUCATION IH THE FIELD OF AGRICULTURE IN SERBIA

Sofija PEKIĆ QUARRIE*, Ratko NIKOLIĆ, Slavica SPASIĆ

Commission for accreditation and quality assurance, Belgrade, Serbia
*Corresponding author: pekicq@gmail.com

Abstract

The paper presents comparative analysis of the accreditation outcomes in the sector of agriculture in 2 accreditation cycles: the first cycle done in the period 2007-2011 and the second cycle done in the period 2012-2016 run by Serbian accreditation body. The following parameters have been used for the analysis: higher education institutions (HeIs) and study progrms (SPs) number in state and private sector, number of students enrolled in the first year, type of studies (professional or academic), level of studies (basic, master or PhD). Study programs in the area of agriculture and related sciences are held in 6 faculties, 3 higher professional schools and in their HEI units. Analysis has shown that higher education sector of agriculture in general stable in number and type of programs in 2 cycles of accreditation. Around 80% of programs belong to academic studies and contribution of the private sector in this area small. Total number of students in the sector of agriculture increased in the second cycle for about 10%. Higher demand for some programs in the second cycle is observed in both: sector of agriculture and its area agronomy.

Keywords: *CAQA, Accreditation, Higher education, QA, agriculture*

Introduction

Commission for accreditation and quality assurance (CAQA) is the national body for quality assurance (QA) in higher education in Serbia founded in 2006. Since then CAQA has developed standards and procedures and implemented 2 cycles of accreditation of higher education institutions (HEIs) and study program and one cycle of external quality control (audit) of HEIs. In 2013 CAQA become full member of 2 European associations for quality assurance in higher education: ENQA and EQAR. This confirmed that national system of QA in Serbian higher education is in compliance with European standards and guidelines (ESG). CAQA has also analysed the impact of its activities by comparative analysis of accreditation outcomes in 2 cycles of accreditation in several thematic and system-wide analysis including 2 sectorial analysis (1,2). This paper presents such analysis for the field of agriculture and its areas: agronomy, food technology, agro-economy, agro-machinery and soil sciences. Analysis was also made within the most abundant area – agronomy.

Accreditation review on HEIs and programs in the sector of agriculture

Study programs in the area of agriculture and related sciences are held in faculties, higher professional schools and in their HEI units. Faculties mostly run academic studies at all 3 levels (basic, master and doctoral), higher professional schools run professional studies at basic and specialist level. Agricultural HEIs are geographically spread from the north to the south of the country.

There are 6 faculties with accredited academic programs in the area of agriculture:

1. Faculty of Agriculture in Zemun, Belgrade University
2. Faculty of Agriculture in Novi Sad, University of Novi Sad
3. Faculty of Agronomy in Čačak, University of Kragujevac
4. Faculty of Agriculture in Lešak, University of Kosovska Mitrovica
5. Faculty of Ecological Agriculture in Novi Sad, University EDUKONS
6. Faculty for Biofarming, HEI unit in Bačka Topola, University Dzon Nezbit

There are 3 higher agricultural professional schools with accredited programs in the area of agriculture:

1. Higher agricultural professional school in Šabac
2. Higher agricultural professional school in Prokuplje
3. Higher technical school in Požarevac

Table 1 summarizes the data on number of study programs and number of students enrolling the first year of studies for different types of HEIs. In the first accreditation cycle was accredited in total 99 programs and in the second 95. The majority (c.a. 70%) of all study programs are held at faculties. The number of students for enrolling the first year of studies has increased from 4032 in the first to 4470 in the second accreditation cycle, primarily due to the increase of students enrolling at HEI units.

Table 1. Number of study programs and number of students in 2 cycles of accreditation in different types of HEIs

	First round of accreditation (2007-2011)		Second round of accreditation (2012-2015)	
HEI	Number of study programmes	Number of students	Number of study programmes	Number of students
Faculties	74	2928	67	3299
Higher professional schools	20	905	21	865
HEI units	5	199	7	306
Total	**99**	**4032**	**95**	**4470**

Table 2 provides the numbers of accredited study programs of different types (basic, master, specialist, academic and professional). The majority of study programs (75-80%) belong to the academic studies based upon both number of programs and number of students in both cycles. The increase in the number of students in the second accreditation cycle is evident in all types of study programs, especially in basic studies. The only exception are specialist studies.

Table 2. Number of study programs and number of students in different type of study programs: BPS – Basic professional studies, SPS – Specialist professional studies, BAS – Basic academic studies, MAS – master academic studies, SAS – Specialist academic studies, DS – PhD

	First round of accreditation (2007-2011)		Second round of accreditation (2012-2015)	
	Number of study programmes	Number of students	Number of study programmes	Number of students
BPS	12	680	18	755
SPS	8	225	6	185
BAS	31	**1967**	31	**2265**
MAS	37	**921**	28	**971**
SAS	2	**64**	3	**78**
DS	9	**175**	9	**216**
Total	**99**	**4032**	**95**	**4470**

Table 3 presents the number of study programs and number of accredited students in state and private HEIs. It is obvious that the contribution of private sector in higher education in the area of agriculture is small in both accreditation cycles. It is to the great extent restricted to the HEI units, especially in the second cycle.

Table 3. Number of study programs and number of students in state and private HEIs with programs in agriculture

		Faculties		Higher professional schools		HEI units	
		Number of study programmes	Number of students	Number of study programmes	Number of students	Number of study programmes	Number of students
First round of accreditation (2007-2011)	State	74	2928	19	805	-	-
	Private	-	-	1	100	5	199
Second round of accreditation (2012-2015)	State	67	3299	21	865	2	134
	Private	-	-	-	-	5	172

Analysis of programs in different areas of agriculture

Further analysis was done on the accreditation outcomes in both cycles of accreditation in different areas of agriculture (agronomy understood as primary production of crops and domestic animals; food processing; agro-economy including marketing and related agro-business studies; agro-machinery and soil management). Table 4. presents number of programs and corresponding number of students enrolling the first year of studies in the first and second accreditation cycle. It is obvious that more then half of all programs are in the area of Agronomy in both cycles, and that contribution of other areas is, also, very similar in 2 cycles. Total number of students is higher in the second cycle due to the increase of students enrolling Food technology. Number of students enrolling programs in other areas has not changed in the second cycle.

Table 4. Number of study programs and number of students in different areas of agriculture

	First round of accreditation (2007-2011)		Second round of accreditation (2012-2015)	
	Number of study programmes	Number of students	Number of study programmes	Number of students
Agronomy	58	2588	56	2558
Food technology	15	**538**	17	**1047**
Agroeconomy	16	627	13	630
Agromachinery and soil sciences	10	279	9	235
Total	99	4032	95	4470

Additional analysis was made on accreditation outcomes in 2 cycles of accreditation for different areas of Agronomy divided as presented on Table 5. Total number of programs in this area has not changed in the second cycle, as well as the number of programs in various areas. However, the number of students has increased for general agronomy, organic agriculture and biotechnology and decreased in programs for plant and animal production and plant protection. This results in the similar total number of students enrolling Agronomy in two cycles of accreditation.

Table 5. Number of study programs and number of students in different areas of agronomy

	First round of accreditation (2007-2011)		Second round of accreditation (2012-2015)	
	Number of study programmes	Number of students	Number of study programmes	Number of students
General agronomy	13	**799**	14	**998**

Total	58	2588	56	2558

Conclusions

- Agricultural HEIs well spread geographically in Serbia
- Good diversity of programs / by subject and by types (levels) maintained in both cycles
- Higher education sector of agriculture in general stable in number and type of programs in 2 cycles of accreditation
- Sub-sector of agronomy also stable in number and type of programs and in total number of students
- Around 70% of programs are held in faculties
- Around 80% of programs belong to academic studies
- Contribution of the private sector in this area small
- Total number of students in the sector of agriculture increased in the second cycle for about 10%

- Higher demand for some programs in the second cycle observed in both: sector of agriculture and its area agronomy
- Increase in the number of students in the second cycle of accreditation evident in food technology, biotechnology, organic agriculture and general agronomy, while decrease was recorded for programs in plant and animal production and plant protection

Abstract

The Sustainable Development Goals 2015-2030 approved 25th September 2015 by the United Nation General Assembly insists in the 2- *End hunger, achieve food security and improved nutrition, and promote sustainable agriculture* and in the 8- *Promote Sustained, Inclusive and Sustainable Economic Growth, Full and Productive Employment and Decent Work for All.* Both of them attributes us the task to build up a model of development which take into account the potentiality of each area. This work , after an analysis of the role of Commons and the options proposed by EU with the Bottom Up and Community Led Local Development(CLLD), propose a new governance instrument of the Territorial Management Contracts (TMC) based on-Drivers-Pressure-State-Impact-Response approach (DPSIR) .The authors demonstrate, with several comparison, that from the hold Management of the Commons, thanks to the experience of the Local Action Group (LAG) and with the new CLLD approach of the Leader Program, is it possible to reach a new Governance of the TMC, in which the diffusion of the ICT is a concrete way for Local Community to design their own future in a Sustainable Strategy Approach .The paper point out that the Smart Communities in a Smart Territories are the new paradigm for the 21th Century of the Local Sustainable Development.

Keywords: *Sustainable Development, Local Development, ICT, Smart Communities, Smart land*

Introduction

The updating situation all around the world present two opposite direction. In the first, there are international Institutions as the UN which are able to propose in 2015 additional pillar to the approval, with the document "Transforming our world: the agenda for sustainable development for 2030 "*(UNGASS, 2015* and the COP 21 Paris Agreement *(UN FCCC, 2015).* These documents design a very attractive and modern roadmap for all the nations and peoples all around the world, to achieve the sustainable development targets and to improve the economic, environmental, cultural, managerial and social level of life.

On the other hand, the operative situation in many countries, especially in the last weeks, shows the difficulties of the National Governments to drive the internal issues toward the roadmap of Sustainable Development.*(WEF, 2016)*

Many issues like non-equity distribution of wealth, the radicalization of the culture the financial crisis, the difficulties to create an update and a suitable model of development and new governance which able to promote the introduction of innovations with traditions, prevents to the National Governments of drive the citizens toward a possible prosperity, peaceful and happiness future *(McMichael P.,2016).* This demonstrates that we have strong difficulties about the identification of an appropriate, transferable and repeatable model, to

achieve a successfully sustainable development by success in all areas of the world.
The objective of the paper is to demonstrate that, the updating experiences of some Institutions as the European Union with the Bottom Up approach of the Local Communities linked in a virtuous combination with tradition and innovation of the new vision of Smart Lands and Smart Communities, appear the possible way for a concrete subsidiarity, which can drives the local populations toward the future that they freely choose, implements and manages.

Material and Methods

The method is an exploratory logical tentative to approach the issues related to a new governance for the 21th Century. From the logical derivation of the literature, direct experiences and the will to create a modern and update vision, are derived the results and discussion of the contribute. The material used are reports, books, articles, projects, programs which were derived the logical elements to implement the present contribute.

Results and discussion

The Era of Sustainable Development

After 30 years from the launch of the concept of Sustainable Development (SD) *(WECD, 1987*), the model it's clearly designed.
After the publication of the *Our Common Future* many skeptics were not convinced about the driving force and innovative change (*Ruttan V., 1998)* and given the demand if SD was poetry, politics or science.
Nowadays the SD present four paradigms and for this reason it's possible to affirm that it have a scientific approach. The four paradigms are: 1) the direct relation between development and environment; 2) the multi-criterial approach; 3) the inter and intra-generational approach; 4) the measurability *(Pearce. D.W et al., 1996)(Sachs J.,2015).*Consequently it has been accepted by all at the world that current we are in the Era of Sustainable Development .It is changed also the consciousness of the approach by the policymakers and civil societies. Thanks the role played by the UN, we are passed from the vision of "Our Common Future" to "The Future we want" *(UN Rio+20, 2012)* and "Transforming our World" *(UNGASS, 2015).*This title have the message. People around the world must not delegate to policy makers or to Central Government the implementation of the Strategy, but take the opportunity to be actor directly. The 17 Sustainable Development Goals and the 167 targets *(UNGASS, 2015*) for 2030 are a big challenge to achieve a true economic democracy where the local populations (Local Community) are the creator of the own destiny. The Local Community consequently has the duty to build up, for the future generations, the Era of Sustainable Development.

The role of the Commons all around the world

In this vision of course it's necessary to change the approach about the role of the ownership of the Territory *(Ciani A. et al., 2015)* and the mission of it. The ownership can't not to be an absolute right of the single man which have in his hand, and he can exercise to decide outside of the needs of the society and /or Community. . We must, at this level, take into account, the juridical differentiation about the goods concerning the principles of the accessibility and the rivalry
To understand well this concept it's useful to see the Table 1.

Table 1. The Juridical differentiation of the Goods in relation at the Rivalry and Accessibility

Private Goods	Club Goods	Common Goods	Public Goods
-Rivalry Absolute -Accessibility only for the owner	-Not Rivalry when member of the Club -Accessibility only for the Members of Club	-Rivalry managed by the principle that the use is payed following the concept of Equity -Accessibility for all.	-Not Rivalry -Accessibility open for all.

*Source: Authors' elaboration

It's know by all that the Private Goods as the Club Goods, are main issues under the lens of sustainable development because the management is strictly far from the social function that the goods must have in an equal, democratic and modern society*(Papa Francesco, 2015).*,Public Goods, at the same time, because the markets failures *(Pareto,1994),* especially for the natural resources, free riders phenomena and the erosion and unsustainability of the use doesn't create the right base to build a Sustainable Development Model. In front of this big dilemma nowadays it's useful, .), try to contribute at the enlargement with the awareness and direct participation of the Local Community at the use and vision of the Territory as Common Goods. About the role of the Common Goods we must take into account that also the EU with the *Europe 2020(E.U. Commission, 2010),* with the slogan "to *build an Europe sustainable, smart and inclusive"* implemented the CAP 2014-2020 where the agriculture , territory and natural resources are understanding as Common Goods. In this approach it's very relevant the work of the Economic Nobel Prize Elinor Ostrom *(Ostrom E., 1990,1993 , etc..)* who dedicate to this topic, which is currently rediscovery as the base to set-up local participative project of development.

Local Development and Local Community

After the world financial crisis, from 2007, the International Agencies as UNEP and FAO and Institutions as UNGAS proposed reports and solutions to create a society that could guarantee the prosperity, decent work conditions for all, access at the minimum vital services (education, health, electricity, water, and nowadays the ICT network) we need, to empower the role of the Local Community. In the vision of the Common goods historically have gain a relevant role the form of Agricultural Communities in Italy (Comunanze Agrarie) and the Mir in the Slavian lands. Currently in Italy there is a rediscovery and an empowerment of this form of ownership around Local Communities which achieve some unbelievable targets.*(Ciani A., 2001).*The SDG 2015-2030 and the EU Regulation 1303/2013 support the role of the CLLD. More or less all SDG's drive nations to put at the center of Sustainable Development the Local Communities, and stress with a road map for an easy access and a friendly use of the updating Information Communications Technologies in an innovative social networking approach. The article 9 of EU Regulation n.1303/2013 affirm : *In order to contribute to the Union strategy for smart, sustainable and inclusive growth as well as the Fund-specific missions pursuant to their Treaty-based objectives, including economic, social and territorial cohesion, each ESI Fund shall support the following thematic objectives:……(Omissis)*In the Chapter II, from the articles 32-to 35, the same Regulation strengthens unequivocally the leading role that the Local Communities must have in local development processes.Consequently the approach of the CLLD it's one of the model that represent the base of the new paradigm for the 21th Century to implement the SD.

From Smart Cities and Communities Toward Smart Territories

In the last years many international Institutions as the same EU Commission stress the attention about the growing and the improvement of the Strategy of the Smart Cities *(EU Commission, 2010),(UCLG, 2016).*Of course this has caused a the big attention around the issue concerning the urban areas, particularly because the prevision that in 2050 the world urban population will be around 66%of the total.

In this way the main investments , supports, policies, etc. are spent for the urban areas and the city population, meanwhile the small local settlement and the world rural communities face the risk to decrease the right policy for a sustainable development and then for the future. Consequently it's more correct and appropriated to understand that to avoid the gradually and continuous loss of the role of the all areas, and not only the urbanized, it's necessary to realign the development policies, in order to search some better equitable paradigms of development to trigger. It is therefore considered that the Age of Sustainable Development must be based on innovation and creative networking. For this reason we have to opt for a significantly more holistic and inclusive vision that placed the Local Communities as true drivers of the local development.

Fig1-The option of Snart Cities, Smart Rural Areas and the of Smart Communities and Smart Territories.

Source:Smart Cities and Smart Rural Areas, (EU.Commission); Smart Communities and Smart Territories(Our Elebaoration)

The *new paradigm for the 21th Century* is for that the *Smart Communities and Smart Territories*. (Fig 2).This signify to reallocate all territories to the center of the development process, with all its layering of natural potentialities, economic, social, cultural, identity, etc. aspects.

The Territorial Management Contracts Proposal

For all above discussed the authors propose the following new instrument for the governance of the territory, using an holistic approach. It's time to significantly change the governing models. From an *"emergency management"* to an *"innovative preventive management"* of the territory with a proactive participation and a *"bottom up"* approach. The financial crisis, which still rages in the management of public finances all over the world, implies that public bodies do not have and will not have, perhaps for decades, the ability to enable direct political intervention for a proper and effective management in the territories. Consequently it's the time to move, with the necessary process of public involvement, to the model of the territory management by counting on the ability of self-management of local communities, who have always given and give wonderful examples *(Ostrom E.,1993)* . .The European Union itself with the Strategic Framework Unique derived by the various Funds (ERDF, EAFRD, ESF, etc.) pushes to encourage the active participation of citizens and communities with good practices linked at the targets of the goals of development.

This analysis leads us directly to use as possible, within this framework, tools that provide, through the mechanisms of Participatory Planning, Management Agreements between the

Public and Private to apply a preventive territory management. The farmer or the operator in rural and urban environment would perform actions agreed in the territory, useful to the pursuit of proper preventive management (the program must be established and participated), the public body (State, Region, Province, Municipality, Consortium, Community) would recognize an economic incentive (direct payment or tax relief) per hectare (or any other parameter provided simple, responsive and effective), with a system of strict control. On these principles is based the strong assurance that the Participatory management through Territorial Management Contracts-TMC's can guarantee a new era for preservation of the territory, to become intelligent, sustainable, inclusive. The approach to land management cannot be sectorial and partial but must be holistic and the TMC can be used of course to protect but also to manage and promote the territory in a vision of suitable Sustainable Local Development Strategy. The Territorial Management Contracts are the General Program of *defense, management and promotion the local territory* in which all the components (rivers, lakes, landscapes, forests, etc) can and must find a place. The idea therefore intends to turn the weaknesses of territories, due to the high risk, into intelligent opportunities, inclusive, sustainable, transparent, proactive, concrete. The TMC's approach needs, first of all, the implementation of the following stakes: *a model of governance, instruments and supports for decision making, strategic plan of the TMC, Project Financing* and *Project Management.* The model of governance must be participative for the local population with the involvement of all stakeholders in the *ideation, design, project, implementation and monitoring following the Iterative and interactive approach.* About the instruments and support for decision making, they are pillars to calculate the economic benefits that the single operator produce for the territory and the community (taking into account particularly the environmental benefit) and how much and how these benefits will be recognized. For this purpose the approach of DPSIR, proposed by the EEA-European Environment Agency (EEA, 1999), can help.

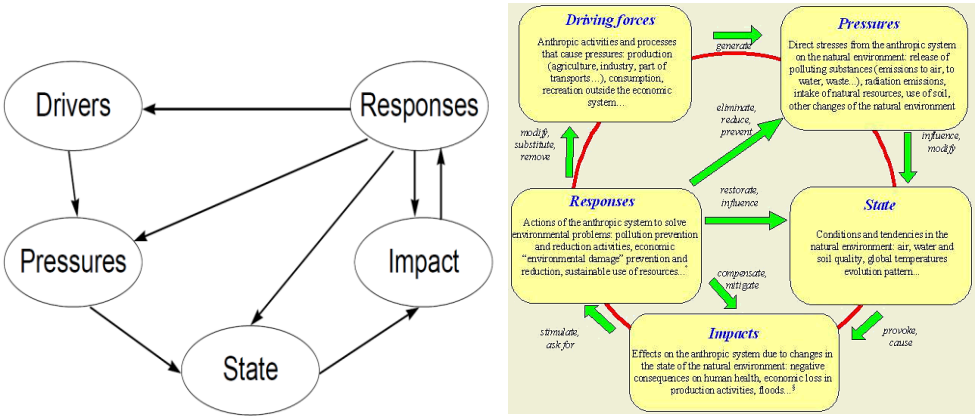

Fig 2- The DPSIR Framework for Reporting on Environmental Issue
Source: Our elaboration from EEA, 1999

Concerning the evaluation of alternatives for decision making a suitable approach is Multi-Criteria Decision Aid –MCDA. This approach can support decision makers to find solutions to problems at the preparation, implementation and monitoring level. The next phase is the preparation of the Plan, joint to the negotiation between the territorial higher-level government and the TMC organization. All of this must be coupled by a proper Project Financing that must respect the criteria *who, make, when,* between all the subjects involved as singles, privates or public bodies. The Financial Management must have a clear position and should be the only Committee Board of the Organization of the TMC. The implementation of a TMC is a concrete way to give a central role in the Sustainable

Development Strategy to the Local Population. With a proper dissemination policy of a friendly use of ICT local population can turn in a *Smart Community*, contributing to the validation of a *Smart Territory*, *which* means an *advanced and happy Territory*..

Issues and outstanding problems

The first open issue for research is to work in the future for the direct experience in the field to validate the approach to the empowerment of the role of the Local Communities in the implementation of the Local Sustainable Development Programs.

The proposal of the TMC needs the validation on the field with some specific Project.

However, this approach will not work if the access to the education and at the ICT will not be deeply diffuse.

Conclusions

This paper showed as that the approach of Smart Cities and/or Smart Rural Areas is not suitable to achieve the Sustainable Development Strategy in light of the *SDG 2015-2030* and of EU Commission Document *A strategy for smart, sustainable and inclusive growth,* because there is the risk to exclude and not to include all population and stakeholders, particularly regarding the great network of the Local Communities and Local Territories.

The authors stressed that there is a need for a new paradigm for the option of the Age of sustainability that must be *"Smart Communities and Smart Territories".* In this framework the proposal is that the TMCs-Territorial Management Contract are the realistic and logic solution for the protection, management and promotion of each area willing to achieve the goals and target of the Document of the UNGASS 2015 "*Transforming Our World: the Agenda 2030 for Sustainable Development".*

IRRIGATED FOOD SYSTEMS IN MARADI, REPUBLIC OF NIGER: A COMPARISON BETWEEN OPERATING ACCOUNTS

Ludovic ANDRES[1*], Lawali DAMBO[2], Sambo BODE[2], Awal BABOUSSOUNA[2], Martha POPULIN[3], Boubacar YAMBA[2], Philippe LEBAILLY[1]

1Department of Economy and Rural Development, University of Liege – Gembloux Agro Bio Tech, Belgium
2Department ofGeography, Abdou Moumouni University of Niamey, Niger
3IFAD Country Programme, (Programme de Développement de l'Agriculture Familiale),Niger

Abstract

In Niger, mostfood systemsare based on pluvial crops (millet, sorghum and cowpea).However, during the last decade, agricultural policy and technical and financial partners focused on increasing the productivity of irrigated food products. The region of Maradi, located in the Centre-South of Niger, is an area traditionally dedicated to agriculture. Some parts of this region are particularly adapted for irrigation, especially the Goulbi of Kaba and the Goulbi of Maradi valleys.The goal of this study is to establish the socio-economic situation of the main irrigated food productions, based on the following indicators: (i) the crop management technics used; (ii) the results of the operating account; and (iii) the comparison between the village and the adoption of new technic (farmer field school). This paper is based on direct surveysconducted in three areas of the Maradi's region: Soumarana (commune ofSafo, department ofMadarounfa); N'Yelwa (commune ofMadarounfa, department ofMadarounfa); Madarounfa (commune ofMadarounfa, department ofGuidan Roumdji). The software used is Minitab and Excel. The results highlighta good perspective for the irrigation system but this food system is conditioned by the petroleum price and some other input (fertilizer and seed). The operating accounts show that irrigation is a non-negligible income source, which increases the resilience of the farmers.

Keywords: *Maradi, irrigated food system, operating account.*

Introduction

The Maradi's Region located in the center of Republic of Niger is characterized by a rainy agricultural food system. Nevertheless some valleys, Goulbi N'Kaba and Goulbi of Maradi, are in favor of irrigation food system (Issaka M., 2001; Andres L. and Lebailly Ph., 2013). In Maradi, the population is mainly rural and represented 3.3 % of total Nigerian population (KarimouBarké M. et *al.,* 2015). The spatial evolution is characterized by a forest decrease in favor of an agricultural land increase (Mahamane A., 2001). During the last decade, agricultural policy and technical and financial partners focused on the increase of productivity of irrigated food products. The irrigable land in the Maradi's region is estimated by KarimouBarké M. et *al.,* 2015. This study identifies four irrigable areas: the Goulbi Maradi; the Goulbi N'Kaba, the Tarka valley and the flooding areas. The fossil valley (N'Kaba and Maradi) represents 33,576 hectares (ha) and 217,174 ha respectively. The Tarka Valley, located in the North of the department, is 150,002 ha. Finally, the flooding areas are defined by the temporary and permanent pond and their environment as the Madarounfa Lake. This area represents 102,922 ha (KarimouBarké M. et *al.,* 2015). The study's area located on the Goulbi Maradi is divided in 3 areas: Soumarana, Madarounfa and N'Yelwa in the commune of Safo and Madarounfa (Figure 1).

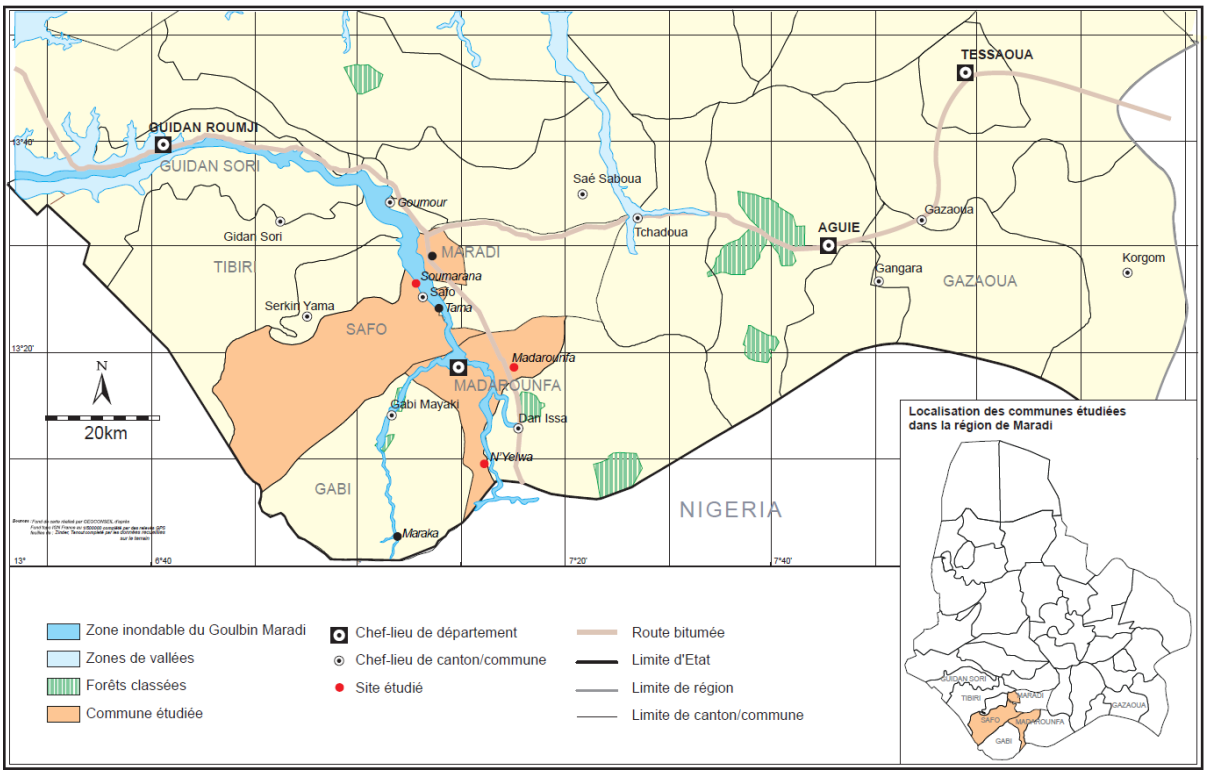

Figure 25.Location of the study's areas in the Maradi Region

Material and method

This paper was realized by an indirect survey in three irrigated areas. The survey tries to answerthe question about a socioeconomics' status, a characterization of farm; the factor who compose the operating account. In fact, the goal is to demonstrate the economic aspect of the irrigated food system. It was realized during November 2015 but also during January and February 2016. These periods are equivalent to the irrigated season: September to November; December to February. The questionnary is composed in three parts: socio-economic characteristics;irrigated production; project factors (farmer field school). Forty farmers located in three different areas on the Goulbi Maradi did participate: Soumarana (15); Madarounfa (11); N'Yelwa (14). The survey is an exploratory phase. The number of interviewed farmers varied in function of the area: fifteen for Soumarana; fourteen for N'Yelwa; eleven for Madarounfa. The variation did not affect the analysis because the number of farmers is very low and the main goal of this study is to consider a preliminary analysis of the irrigated food system. This preliminary study is linked and integrated to a partnership with International Fund for Agricultural Development (IFAD) and two research centers (University of AbdouMoumouni in Niamey and University of Liege Gembloux Agro Bio Tech). This research tries to establish the impact of the agricultural intensification.

Results and discussion

We observed that only two agricultural chiefs are female and one agricultural chief is Kanuri whereas the other chiefs are Hausa and male. There is no big difference between the three areas. The average age of the sample is 43 years old. The area is smaller than below 1 hectare (0.88 ha). The member's number per household is estimated to 11 members and the work force is 2 farmers.

Table 18 : Socio-economic characteristics

Location	Age	Area	Member	Agricultural worker
Soumarana	43	0.97	9	2
N'Yelwa	38	0.79	12	2
Madarounfa	48	0.89	12	3
Mean	43	0.88	11	2

The distribution of rainy and irrigated areas in each domain is different. The farmers of Madarounfa have more rainy areas (36 %) than them irrigated areas (36 %), while Soumarana and N'Yelwa present a balance between the rainy and irrigated area (Figure 2). In average, they area of Soumarana practiced the irrigation since 22 years old. N'Yelwa and Madarounfa practice respectively the irrigation since 16 and 8 years old. In average, the Soumarana's farmers have two plots whereas the two other areas are constituted by only one plot. The average of irrigated areas arerespectively estimated to 0.95 (Soumarana); 0.79 (N'Yelwa); 0.89 (Madarounfa).

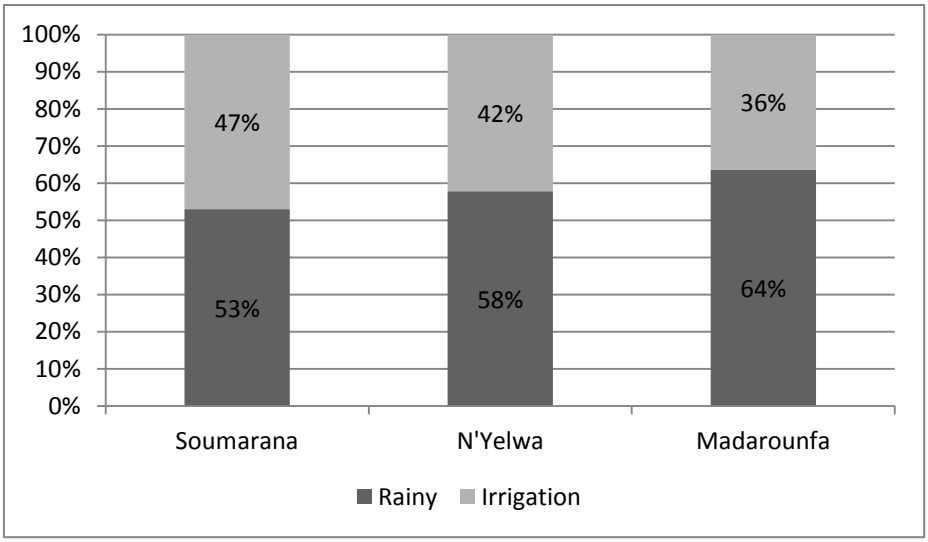

Figure 26 : Distribution of the rainy and irrigated area in a farm

Usually, the way to acquire land is by legacy or legacy adds with another mode such as purchase, loan and rental. Only 25 per cent of the farmers has land tenure to prove the property.

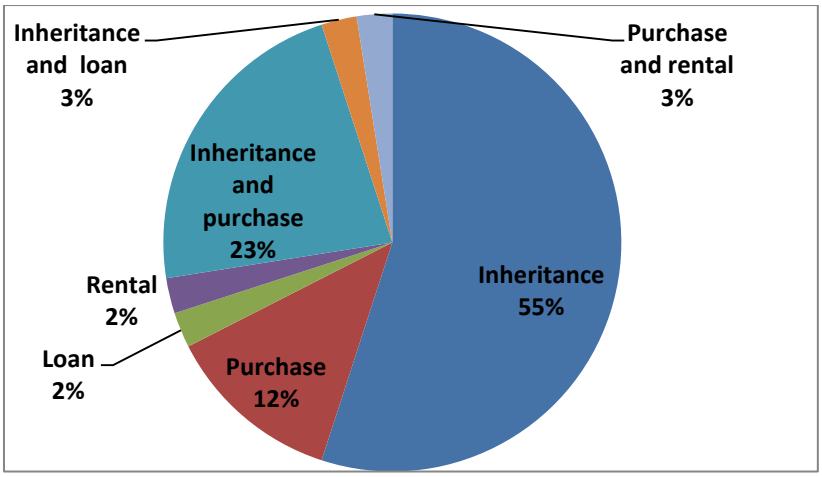

Figure 27 : Distribution of the transmission method

The operating accounts are calculated with the fees and the estimated income. The fees assemble the cost of seed, phytosanitary products, fertilizers, worker force, irrigation maintenance and usage fee. The income has been estimated with the farmer and regroups the estimated income per campaign. In the first time, we would like to develop the operating account per product but some costs were used for all production during the irrigated campaign. The fuel is the first charge concerning for the irrigated food system and is due to the introduction of motopump in this system. The second and third principal feesare the fertilizer and the seed. Before the last decade, the fertilizer and the phytosanitary goods were produced by the Nigeria Market but actually, most of the farmers buy them in the Maradi's market. According to this observation, the benefit of the irrigated activities depends on on the price of the fuel (figure 4).

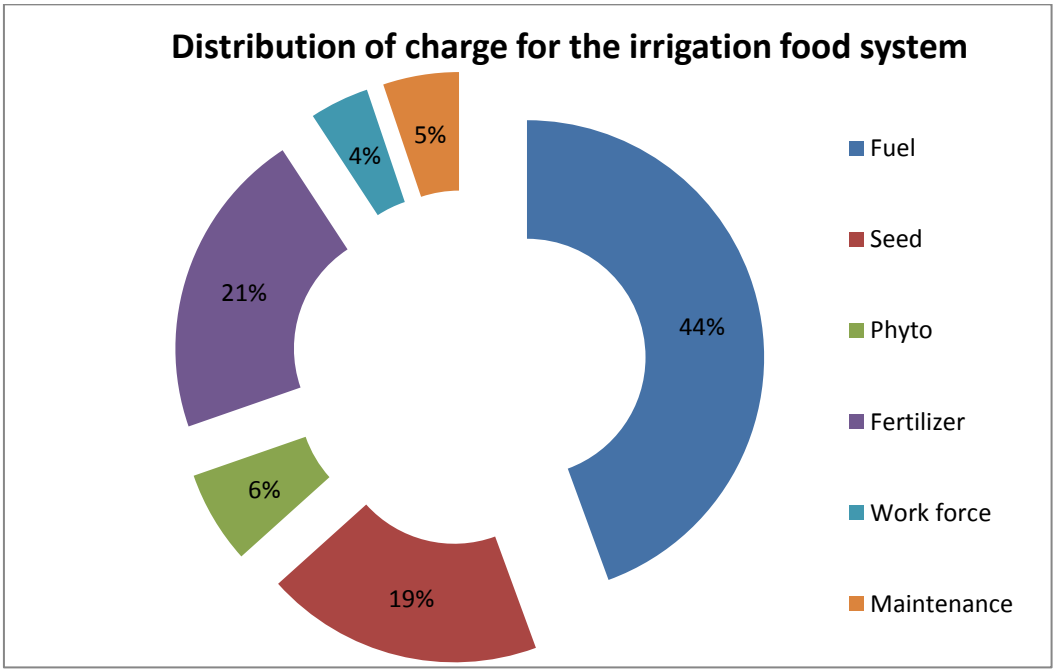

Figure 28. Distribution of charges for the irrigation food system

Each farmer from each village has presented a benefit per campaign. This average of benefit has beenestimated to 412 euros in Soumarana; 377 euros in N'Yelwa and 582 euros in Madarounfa (table 2).

Table 19. Charge and income of each studying area

	Charge	Income	Benefit
Soumarana	134,543	404,600	270,057
N'Yelwa	98,025	345,161	247,136
Madarounfa	112,227	493,955	381,727

The comparison of mean has been established to distinguish the difference between the targeted villages. The variance and normality test confirm the possibility to realize the test of equality of mean. The results in Figure 5 show a significant difference between the level of the income and the benefit in function of the village.

ANOVA Table[a]

			Sum of Squares	df	Mean Square	F	Sig.
Income * Village	Between Groups	(Combined)	386675,509	2	193337,754	4,380	,020

a. The grouping variable Village is a string, so the test for linearity cannot be computed.

Figure 29 : Comparison in function of the village

We compared the fees, the income and the benefit regarding to the activities of the farmer field school. Two activities are evolved with the charge, income and benefit. Those concern the visit of the Farmer field school and the support advice. The comparison of means is not significant for the advice and the farmer field school. But all farmers of the enquiry need a farmer field school and the indirect impact of the project is perhaps the causes of this non-difference between the beneficiaries and the non-beneficiaries.

Conclusion

In conclusion, in the Maradi' region, the irrigated food system presentsan interest to ensure a food security and a better income. The impact of the IFAD project is not clear, especially for the quantitative data (income, benefit). But the qualitative analysis demonstrates some impact of the project, especially for a crop management technic and the purchase of good fertilizer and phytosanitary, and improved seeds. The comparison of means is largely affected by the indirect impact. In fact, some non-beneficiary's farmers have adopted some innovation because the transfer is linked by the observation and discussion between the farmers.

Abstract

Prime focus of the study was to reveal the prevalence of central obesity (CO) in school students (age group 8-16 years) using anthropometric indicators. Interschool survey of four large primary and secondary schools of rural southern West Bengal (WB) North 24 Parganas were done, representative for the cross sectional study. Total 551 subjects were screened (based on PCI) among 690 students among which 283 are boys and 268 girls. The major indicators and indices considered here are BMI, waist circumference (WC), hip circumference (HC), waist-hip ratio (WHR), waist-height ratio (WHtR), and conicity index (C.I.), respectively. The main outcome measure is to reveal the prevalence of central obesity among students aged 8-16 years. One way ANOVA was performed to test the differences in mean anthropometric characteristics for age and gender. Pearson's correlations were done to find out the trends of the anthropometric indices with age. Statistical analysis was performed by using SPSS v. 16. Findings of the study highlighted that BMI is the best indicator of overall obesity, whereas WC, WHR, WHtR and C.I are very good indicators of central obesity, which are the probable precursors of cardiovascular diseases (CDVs), Kidney diseases, diabetes, hypertension etc. in adulthood. Growth of hip is higher than waist in both genders. WHR and WHtR show a negative correlation with age. Girls' waist and hip grow rapidly than boys' upto 12-13 years, boys outperformed after that. Girls exhibit a greater WHtR and C.I. than boys.

Keywords: *Central obesity, rural school students, Southern West Bengal*

Introduction

Obesity is a worldwide problem today. Childhood obesity is a rapid increasing problem in both developing and developed countries which may lead to adulthood obesity (Bose et al., 2007). A new word "globesity" is coined referring universal health burden of obesity (Mukhopadhyay et al., 2005). Pattern of overweight and obesity, differ by age and gender, rural or urban residence and socioeconomic pattern (SEP) and vary between and within countries (Matijavsevich et al., 2009). Number of studies undertook to assess the prevalence of students' overweight and obesity. Unfortunately, most of those dealt with height and weight only to investigate regional adiposity (Das et al., 2001). So, there was a strong need to deal with central obesity anthropometric indices other than considering height and weight only. Computed Tomography (CT) scan and Magnetic Resonance Imaging (MRI) can directly measure intra-abdominal fat, but are very costly. Anthropometry is the most reliable measure (based on cross sectional studies) to link fat distribution to health and its consequences (Bose et al., 2005).

Although this health burden is well documented in most developed and some developing countries, there is paucity of data in respect to the prevalence of overweight and obesity in school students of rural southern West Bengal. There is also less data available on sexual dimorphism in overweight and obesity, especially for Bengali community (de Onis et al., 2004). The present investigation is a unique approach based on anthropometric indices; to find out the level of overweight and obesity among rural school students (of lower and middle socioeconomic classes; Dudala et al., 2014) of southern West Bengal. This database may be compared with national and international prevalence levels for other population.

Materials and methods

Study design

A cross sectional study has been done during June 2012 to September 2013 among school going boys and girls from lower and middle socio economic class (Dudala et al., 2014) of age range 8-16 in 4 secondary schools of 24 Parganas (N) of rural southern WB. Ages were verified from respective school records. Anthropometric measurements of 551 rural school-going subjects (283 boy and 268 girl subjects, considering PCI) were taken from a total of 690 students selected. The values of anthropometric measurements such as weight, height, waist hip circumference were recorded for every subject in the study sample, indices like BMI, WHR, WHtR and C.I. are derived (Hu, 2002). Age and sex break-up were studied and compared with the World Health Organisation (WHO) standards (WHO, 2007). Correlations among age, sex and anthropometric parameters were considered individually to derive their patterns of growth. Statistical analysis was done with SPSS v. 16 include correlation and one way analysis of variance (ANOVA). Information was collected after an interview with the help of a semi structured questionnaire. Parental consents were taken from the all participating subjects and all necessary ethical protocols were followed accordingly. Students between the age group of 8 to 16 were selected because in the new generation subjects who were born after 2000 AD, age of adolescence has shifted/changed from 10 to 8 years (Kipke, 1999; Hagen et al., 2014). The logic behind limiting the upper age boundary of the subjects' to 16 years as secondary school students' upto class ten (X) commonly falls within this age. Only healthy subjects are included (without any physical deformities). Students belonging to Upper (S.E) classes (based on PCI) were not considered for this survey.

Anthropometrical Measurements

Anthropometric measurements were conducted twice on the same day for each student in same session to avoid technical errors with criterion accredited by the International Society for the Advancement of Kinanthropometry in anthropometry (ISAK, 2011). Method described in the manual was followed for taking all the measurements (Brožek et al., 1963).

- Height: Height was measured with an Anthropometric Rod (GPS) up to 1 mm. (Esrey, 1996).
- Weight: Body mass was calculated in minimal clothing. The subject stood on the centre position of the scales without support with the weight distributed evenly on both feet. Weighing was taken with a digital scale (calibrated beforehand, capacity 150 kg) having a precision of 0.5 kg. Time of taking weight was also noted (Waterlow, 1972).
- Body Mass Index (BMI): BMI was derived by dividing weight (kg) by height (m) squared. BMI categories were based on age specific cut-offs in adolescent. World Health Organization (WHO) based classification for global database on Body Mass Index (BMI) was used as a cut points for BMI (Gallagher et al., 1996).
- Waist-Hip ratio (WHR): The waist circumference of the abdomen was the narrowest point between the lower costal border and the top of the iliac crest, perpendicular to the long axis to the trunk. The hip circumference was the circumference of the buttocks at the level of their

greatest posterior protuberance, perpendicular to the long axis to the trunk (Visscher et al., 2001). Waist hip ratio was a better anthropometric index than BMI. It is a measure of relative adiposity in abdomen. It is measured as = waist (cm)/hip (cm)

- Waist Height Ratio (WHtR): The waist height ratio is a good indicator of body shape and future chronic diseases. WHtR= waist (cm)/height (cm)
- Conicity index (C.I.): Good indicator central obesity (Goran & Malina, 1999). C.I. = waist (cm)/, 0.109* sq root of weight (kg) /height (m).

Results and Discussion

Consistent increasing trend in central obesity (circumferences) is evident from 12-15 years of age. Similar findings have been observed among children in Baharian (Kaul, 1975; Eveleth & Tanner, 1991) and Jamaica (ICMR, 1972). Those studies have also reported a consistent increasing trend with age. There is also a trend of consistent fat deposition at central sites. Similar results found in adolescent students of Midnapore district of West Bengal, India (Das et al., 2001). Stagnation was absent in overall obesity (BMI acts as the best indicator) in both boys and girls.

Table 1. BMI for Age

Category for BMIZ	Frequency	Percentage
> -2 SD	65	11.7
SD-2<=Median	254	46.2
Median=> SD+2	192	34.8
>SD+2	40	7.3
Total	551	100.0

The z scores of BMI for age are presented in Table 1, compared to international standards (WHO, 2007). 92.7% of students belong to a normal range of BMI. Obese students are 7.3%. Rate of obesity is lower than other developing countries. It might be due to lack of awareness of healthy food habits. These results are consistent with earlier studies done in India in respect to children of the same age group (Subramanyam et al., 2003; Khadilkar and Khadilkar, 2004; Marwaha et al., 2006; Sadhukhan et al., 2007; WHO, 2007; Kaur et al., 2008).

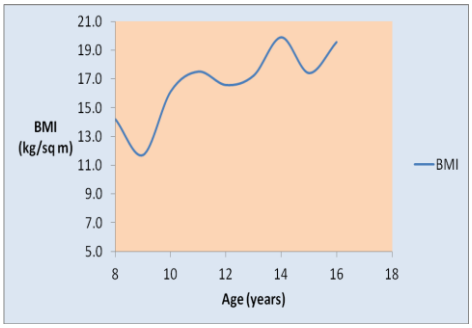

Figure 1. Pattern of BMI with age (Boys)

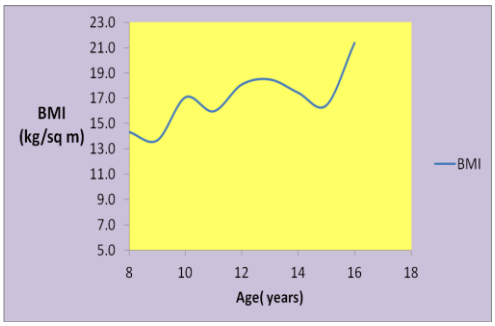

Figure 2. Pattern of BMI with age (Girls)

On the contrary, higher prevalence of overall adiposity found from abroad, developed countries. A study performed in Netherland demonstrated that there was no association between puberty and BMI (Trembly et al., 2002; Vignolo et al., 2004). Adolescent men are significantly taller and heavier than women (Bhadra et al., 2002). Rapid growing trend of BMI with age is seen in Figure 1 (in boys, avg. =16.6, 12 years of age) and slow increasing growth pattern of BMI with age is depicted in Figure 2 (in girls, avg. =17.0, at 10 years of age). Greater accumulation of body fat in the abdominal region might be the main determinant of obesity related diseases like Coronary heart diseases, type II diabetes and hypertension (Sadhukhan et al., 2007).

N =551; *implies significant at .05 level of significance & ** implies significant at .01 level of significance

The mean and S.D. of waist circumference by age and gender are presented in Table 2. It is evident that at 8 and 9 years of age mean waist circumference of the girls was slightly higher than boys. In age group of 9 (late childhood), 12 (early teenage), 14 and 16 (late teenage), here significant differences in waist breathe between the boys and girls ($p < 0.05$) is evident. But for the age group 10, 12 & 13 no significant difference in waist breath was observed among the subjects. Boys have a general tendency of having a higher waist circumference with age than girls. Correlation studies showed that WC is more correlated with diseases like cardiovascular diseases and chronic diseases like diabetes and hypertension. Similar findings recorded in earlier studies on this age group in Indian subcontinent (Bhadra et al., 2002).

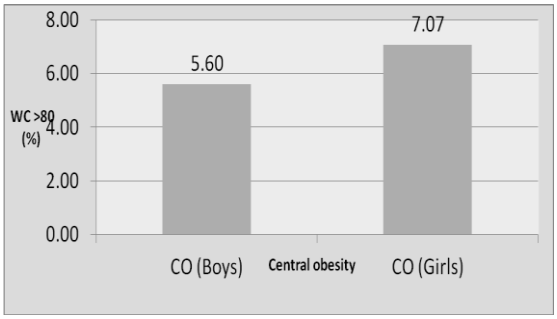

Figure 3. Rate of central obesity (CO) based on WC (Boys and Girls)

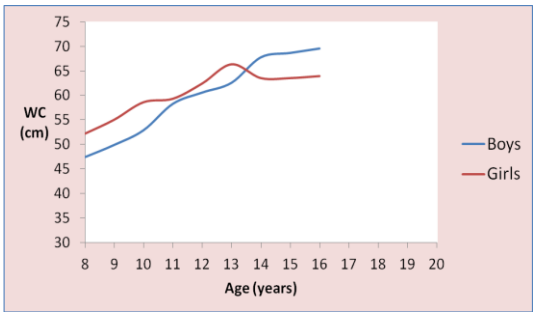

Figure 4. Rate of increase of WC with age (Boys and Girls)

Central obesity (CO) is the most consistent risk factor for hypertension (Mukhopadhyay et al 2005). Figure 3 exhibits a greater tendency of central obesity (7.07%) in girls than boys (5.60%). Classification of CO is based on WC>80 cm (Dasgupta & Hazra, 1999). Girls are generally taller and heavier than boys in the age group of eight (8) to 16 (sixteen) years (Freedman et al., 2007). Significant sex difference in central obesity found among young Punjabi students in Chandigarh, North India (Sanjeev et al., 1991). Sexual dimorphism existed in central obesity, irrespective of the level of overall adiposity (BMI) (Goran & Malina, 1999). Increase of WC with age is evident in boys and girls. Rate of increase is higher in girls (peak at 13 years), then it decreases. Boys show an increase in WC from 14 years of age. In both cases the two rates exhibit steady growth and become parallel thereafter 14 (Figures 3 & 4).

Table 3. Cross-tabulation between different age group in relation to gender and hip circumference (cm).

N =551; *implies significant at .05 level of significance & ** implies significant at .01 level of significance

Table 3 describes the mean and S.D. of hip circumference by age and gender. A much higher growth rate of HC in girls is seen up to 12 years of age, afterwards which gradually decreases up to 15 years and again grows steadily after 15 years of age. In age 12, most significant difference in HC is evident in boys and girls, whereas other age groups didn't exhibit that. The higher prevalence of hip circumference among girls may be related to adolescent growth spurt and the effects of hormonal surge which occurs earlier in girls (Chhatwal et al., 2004). A study from Israel found similar pattern of obesity among boys and girls (Seidman et al., 1991; Wang et al., 2002). Similar studies were done at Hoorn, Netherlands, where large hip and thigh circumferences are found to be associated with a lower risk of type 2 diabetes in girls in comparison to boys, independently of BMI, age, and waist circumference, whereas a larger waist circumference is associated with a higher risk (Snijder et al., 2003).

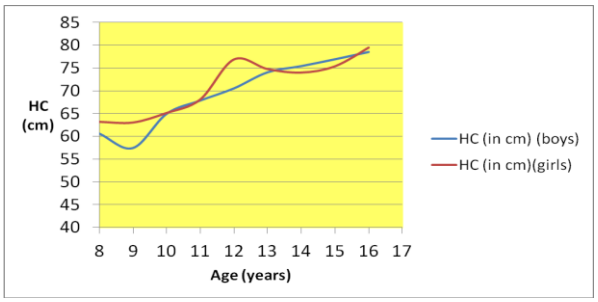

Figure5. Rate of increase of HC with age (Boys and Girls)

A much higher growth rate of HC in girls is seen up to 12 years of age, afterwards which gradually decreases up to 15 years and again grows steadily. In boys, a slow but steady hip growth rate is seen up to age 16, where it meets the growth curve of girls (Figure 5). Waist and hip circumferences measure different aspects of body composition and fat distribution and have independent and often opposite effects on cardiovascular disease risk factors. A narrow waist and large hips may both protect against cardiovascular disease. These specific effects of each girth measure are poorly captured in the waist-to-hip ratio (Seidell et al., 2001).

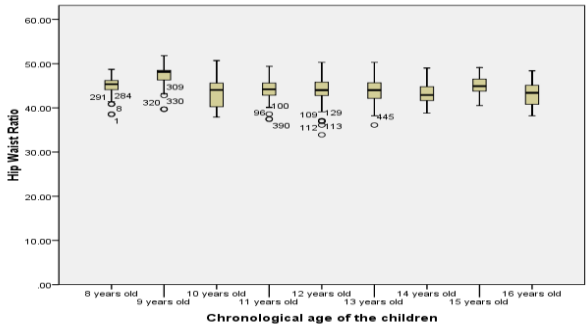

Figure 6. Relation of waist–hip ration (WHR) with the age of the subjects

Figure 6 discovered that median of the waist-hip ratio (WHR) was higher among the younger subjects and it fells down with increase in age. A zigzag relationship was visible in the box plot with 9 years group. These findings suggested that younger subjects got more attention and nourishments in comparison to the elder subjects in the study area. With respect to central body fat distribution, there was a significant decreasing trend with age in mean WHR. This indicated differential pattern and intensity of fat deposition at these two levels (Das et al., 2001). A study done among Sikh boys of India, in which a decrease of mean WHR is found (Sikri, 1972). Similar results also reported from Baharian (Kaul, 1975). Since WHR is influenced by age and sex (Walker et al., 1996), similar studies have undertaken on Bengalee girls. Longitudinal investigations of regional adiposity and WHR are needed to understand the dynamics of the change in them from childhood to adulthood. Figures 7 and 8 reveal tendency of WHR and C.I. in boys and girls, respectively. As it is clear, WHR decreases and C.I. increases with age in both genders. Both are good indicators of central obesity.

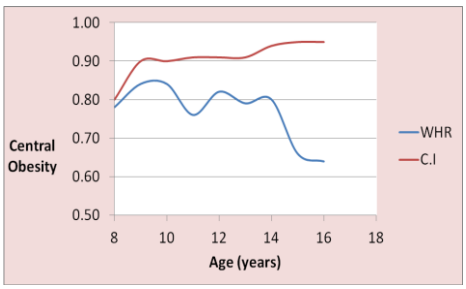

Figure 7. Pattern of growth of WHR and C.I. (Boys)

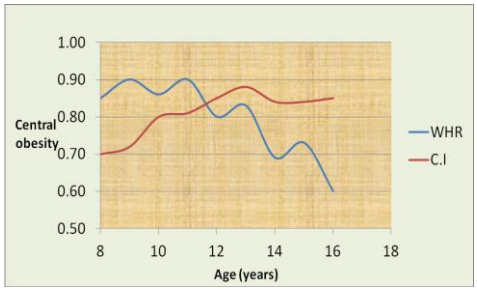

Figure 8. Pattern of growth of WHR and C.I. (Girls)

Table 4 describes the correlation of major CO indicators with age. BMI, WC, HC and C.I. are positively correlated. WHR (Figures 7 & 8) and WHtR (Figures 9 &10) show negative correlations; increase of hip with age is always greater than waist after attaining puberty. BMI is the indicator of overall obesity. From the clinical perspective, central obesity (approximated by the waist circumference, hip circumference, waist hip ratio) provides more information than general obesity (BMI). Because of their high correlation, from the statistical perspective, those indicators are unlikely to yield different answers (Vazquez et al., 2007).

Table 4. Binary correlation of major CO indicators with age (gender-wise)

Anthropometric parameters	N (boys)	r value	Sig value	N (girls)	r value	Sig value
BMI	268	0.82**	.001	283	0.79**	.005
WC	268	0.9**	.001	283	0.81**	.001

HC	268	0.97**	.001	282	0.9**	.001
WHR	268	-0.68*	.005	283	-0.62*	.005
WHtR	268	-0.49*	.005	283	-0.45*	.005
C.I.	268	0.82**	.001	283	0.84**	.001
*significant at 0.05 level and ** significant at0.01 level of significance						

The correlations between various anthropometric measures of obesity are presented in Table 4. WC, WHtR, C.I. were all highly correlated with weight and BMI, with the Pearson correlation coefficients varying from 0.82 to 0.9; WHR and WHtR showed much weaker correlations with weight and BMI. The indicators of central adiposity appeared to be more strongly associated with CHD (Coronary heart disease) risk than did BMI. No previous study has investigated WHtR in relation to risk of CHD. But WHtR has been shown to be a useful predictor of multiple CHD risk factors (Hsieh & Yoshinaga, 1995). In a study of correlations of selected anthropometric variables, including WHtR, WC, BMI, and WHR, with intra-abdominal fat measured by computed tomography, WHtR showed the highest correlation. These findings seem to provide some biological explanations for our observations that WHR and WHtR were strongly predictive of CHD. More body composition studies are needed to clarify the biologic relevance of these anthropometric indexes, particularly among different age groups. Such information is critical for interpreting the statistical associations between anthropometric measurements and disease risk. WC has been proposed to replace WHR as an indicator of abdominal obesity, because it is highly correlated with visceral fat and easier to measure and interpret. Several cross-sectional studies comparing WC, BMI, and WHR have shown that WC was the best indicator (Zhang et al., 2004).

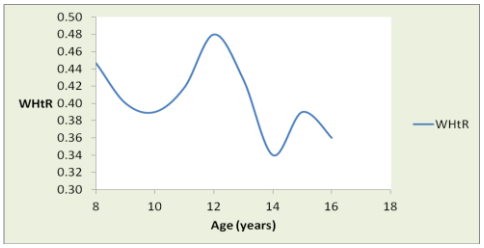

Figure 9. Pattern of WHtR with age (Boys)

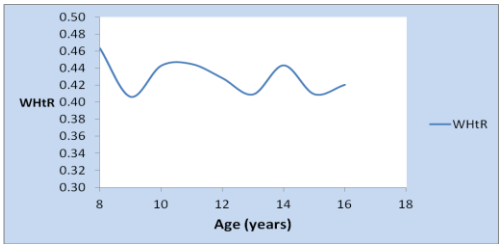

Figure 10. Pattern of WHtR with age (Girls)

WHtR (Figures 9 &10) shows negative correlations in both boys and girls as hip increase is greater with age than waist after attaining puberty. WHtR is a good indicator of body shape and chance of chronic diseases in adulthood. Incident diabetes rates were higher for people from US countries (13.5 new cases per 1000 person per year) and lowest for the people from Asian countries (5.2 new cases per 1000 person/year). WHtR provide information about body shape and type II diabetes. WHtR and C.I. are significantly associated with more chronic kidney diseases and cardiovascular diseases than increasing BMI. Increasing BMI and WC were associated with only a minority of risk factors for kidney diseases but WHR, WHtR and C.I. were associated among each others with multiple factors. BMI has a limitation there; it tends to decrease with age, but kidney diseases tend to increase with the same. Anthropometric measurements that include a measure a central fat deposition may be of greater importance as a risk factor in CKD (Coronary kidney disease) than BMI which might underestimate the risk of those chronic kidney or cardiovascular diseases (Evans et al., 2012). Conicity (C) is an index of body fat distribution which expresses an individual's waist circumference relative to the circumference of a cylinder generated with that person's weight and height assuming a constant for body density (Valdez et al., 1993). The more central a person is in fat distribution, the higher the value of C. In a pilot study of cardiovascular reactivity and dimensions of anger and hostility in 60 African and Hispanic-American

adolescents, anthropometry and sexual maturation were determined to assess their mediating influence on the relation between anger and cardiovascular risk. C and WHR are highly related (0.85) yet differ in important respects in both sexes. C relates not only to body shape but also to body fat. Indices of central fat such as circumference and skinfold ratio may "over-correct" for total fatness and thus miss important aspects of risk prediction. Conicity may be a useful indicator of body fat distribution in studies of adolescents (Mueller et al., 1996).

Conclusion

Moderate rate of obesity is found in rural southern West Bengal as compared with international standards (WHO, 2007), which might be due to lack of awareness of healthy food habits. WHR and WHtR are lower, exhibiting a less chance of acquiring cardiovascular disease (CVDs). BMI, WC, HC and C.I. exhibit a general increasing trend with age, especially in girls in pre-teenage and early teenage in boys. Afterwards, a parallel pattern is found showing a steady growth n both genders. The Cut-off point and boundary values of waist-to-height act as an indicator for coronary heart diseases in Chinese adults (Zhang et al., 2004). Girls are taller and WC is greater than boys up to age 13, then boys' growth spurt starts. Among anthropometric indicators, significance growth difference seen in Central Obesity (Ghosh et al., 2004). Among many possible outcomes higher prevalence of obesity could be the role of change in dietary pattern and physical activities. We recommend using the dietary pattern of subjects to get a clearer picture on obesity situation in India. An obesity map can be formed by using those databases which can be useful for health intervention at the government and non government level.

Abstract

Plumsare the most-wide spread fruit and the most important stone-fruit in Serbia. They are used for fresh consumption, dried, and for brandy, marmalade or jam production. It is important for farmers to be introduced to the economic effect of a certain production. Gross margin (GM) is a quick and efficient indicator for comparing production lines in different conditions. Gross margin was used as an indicator of economic effects of production. Data for GM calculations were collected through the questionnaire from the representative plum farms in city of Jagodina(Pomoravlje region, Serbia) in the period 2011-2014. For calculating the basic elements of gross margin, the following data were used: data on yield and price, by-product price, quantity and value of fertilizers, pesticides, and fuel, and costs for contracted services. GM does not indicate profits and it does not include the size, and value of fixed costs. It represents the total value of a production line subtracted by the direct costs for the production line in question (purchased inputs). Within the period 2011-2014, GM varies from 175.038 RSD/ha (2011), to 261.288RSD/ha (2014). At the same time, the total variable costs did not change as much, ranging from 132.279 (2012) to 169,963 RSD/ha (2011). With the average yield for the observed sample (28.2 t/ha) and significantly higher price, an outstanding GM for plum was obtained.

Key words: *gross margin, plum, variable costs, yield, price.*

Introduction

Analysis of the farm management is essential. It enables farmers and advisors to understand how the farm works, as well as to determine its profitability. Diagnostic techniques that can be applied at a farm level can help farmers and agricultural advisors to identify critical issues that limit the profitability of farms. Many of the conventional tools for farm management fit into this category. They include analysis of limitations, gross margin analysis, budgeting, cash flow analysis, as well as more specialized methods of farm management, such as financial reports, balance sheet and risk management. Gross margin is an indicator of the profitability of agricultural holdings and individual production lines. It is a result obtained by subtracting the variable costs of the gross income.

Calculation of gross margin is essential when deciding between different production lines. If a farmer wants to know whether to proceed with a particular production line, he can compare gross margins of two different lines of production. If the farmer plans on changing the line of production, fixed costs are not likely to change, but the production value and variable costsare about to change. Using gross margin will help agricultural producers to determine whether the change of production lines will be profitable or not.

Possible indicators are: gross income per hectare, the total variable costs per hectare, the cost of labour per hectare, the cost of machine operations per hectare, the cost of fertilizer per hectare, and gross margin per hectare.

There are many farmers who continue to speak about the biggest yield per hectare, the largest increment or production per head of livestock and so on. However, the highest yield is often not the production level that generates the biggest profit. Afarmer who wants to be competitive in the market needs to think about gross margins, profits, costs, and not only on maximum yields. (Kahan, 2008).

When using gross margin as an indicator of profitability, two factors that limit operations on the farm the most, should be considered when deciding. He must decide whether to use the total gross margin per hectare, the total gross margin per person per day, or a total gross margin per unit of capital (Kahan, 2010).

Materials and methods

Bearing in mind the nature and significance of research, several methods were used:

- Case study method with the use of examples based on research conducted on the territory of Pomoravlje region (Serbia), by the collection of gross margin calculations of 34 selected farms during the period of 4 years, with a fifth year as a control year.
- Method of analysis by which an influence of structural elements of gross margin on the gross margin result was established.
- A method of statistical analysis which was applied in order to establish connection between an influence of individual elements of gross margin on a gross margin end result.

Factors that influence gross margin result, such as yield, price and variable costs were recorded. Calculating the indicators of descriptive statistics in a certain period, average value, variation interval, coefficient of variation and rate of change are determined.In order to determine connection between parameters of research through degree, shape of influence and level of dependence, a method of regression and correlationanalysis was applied. Significance of previously determined values was established by t-test.Poll method, by which farms were examined in order to calculate gross margin at the end of each production year.

Total number of plum gross margin calculations is 34, with the following structure: 4 farms in 2011, 7 farms in 2012, 12 farms in 2013, 10 farms in 2014, 1 farm in 2015. Out of these 34 farms previously analyzed, for 2015 one farm was picked to compare with average results of these previous 4 years. It was done in order to establish the importance of advisory work on these farms, since agricultural advisors, according to their program of work did not work with the same producers, after 2014.

Results and discussion

Plum is still the queen of stone fruits. The dominant variety used to be *Požegača*, but there are"new" varieties which have been introduced in the last few decades, such as *Stanley* and some of the varieties deriving from Čačak, that have now become the most common (Mladenović et al, 2013).The average yield of plums on the observed farms, in the analysed period was at the level of 28.2 t/ha, and ranged from minimum 20 t/ha up to a maximum recorded yield of 36 t/ha.Plum yield shows a tendency to increase at an average annual rate of 1.02%, while a yield variability is within the normal variability. During the same period average yield in the whole of Serbia was only about 5,2 t/ha, ranging from 3,8 in 2012, up to 7,3 in 2013. This is a very poor result, since, for comparison, average yield of plum in Bosnia and Herzegovina in 2012.was somewhat over 35 t/ha , and was actually 38% lower than in 2011 (Alic-Dzanovic*et al*, 2014).During the period 2011-2015, plum had an average value of about 12,700RSD/ha.When it comes to price, it can be concluded that price in the reporting period showed a slight tendency to increase, which can be observed on the basis of rate of change (0.68%).Total variable costs of plumproduction amounted to an average of almost

141.000 RSD[1]/ha and showed a tendency to decrease at a rate of 0.45% per annum. Another positive feature is the relative stability of variable costs depicted by the coefficient of variation (Cv = 12.07%).Gross margin, as a result of production value averaged around 232.300 RSD/ha. If one compares gross margin/variable costs ratios, it can be seen that in our case, it was at a level of 1.64.These results are somewhat similar to those of Stirbu&Draghici(2010), where this ratio was 1.49 to 1.74, depending on the technology applied, and to a degree different thenthose established by Day *et al.* (2009), where this ratio was 1,06.Characteristic of gross margin is that it had significantly higher variability compared to other production parameters (Cv = 60%). Since a higher value of gross margin is a sign of greater profitability of production, when it comes to plum, an important characteristic is that it shows a tendency of growth at an annual rate of 5,82%.

Table1.Basic indicators of production parameters of plum during the 2011-2014period

Production parameters	Average value	Interval variation		Coefficient of variation (%)	Rate of change (%)
		Minimum	Maximum		
Yield (t/ha)	28.20	20.00	36.00	15.74	1.02
Price (rsd/t)	12.677	8.000	15.000	16.79	0.68
Variable costs (rsd/ha)	140.872	105.185	174.800	12.07	-0.45
Gross margin (rsd/ha)	232.275	88.145	373.600	59.99	5.82

In order to quantify the impact of yield, price and variable costs, a regression analysis was introduced inplum production. Results of the analysis (Table 2) show that the yield and price have a positive impact on the value of the gross margin, while there is a negative impact of variable costs. The increase in yield of plums for 1 ton will lead to the increase in gross margin to 21.250 RSD/ha. The increase in prices for plums 1 RSD/ha increase in gross margin to 36 RSD/ha. Variable costs in plum production have a slightly greater impact than in some other cultures, so that the increase in variable costs per 1 RSD/ ha, decreased gross margin by 2 RSD/ha. Beta value, and standardized regression coefficients show that the greatest relative impact on the change of gross margin of plums has yield, prices show somewhat of a lesser influence, while the impact of variable costs is twice less than the impact of yield. The corrected coefficient of determination is only 58.3%.

[1] Serbian Local Currency – Serbian dinnar

Table 2. Regression analysisof yield, price and variable costs of the gross margin in plum production

N=34	Regression analysis results in plum production R= ,78792754 R2= ,62082981 Corrected R2= ,58291279					
	Beta	Std.Err.of Beta	B	Std.Err.of B	T(30)	p-level
			-487030	164430,0	-2,96193	0,005930
Yield	0,677981	0,131027	21250	4106,8	5,17438	0,000014
Price	0,551190	0,112545	36	7,4	4,89751	0,000031
Var. costs	-0,292989	0,131022	-2	1,1	-2,23619	0,032928

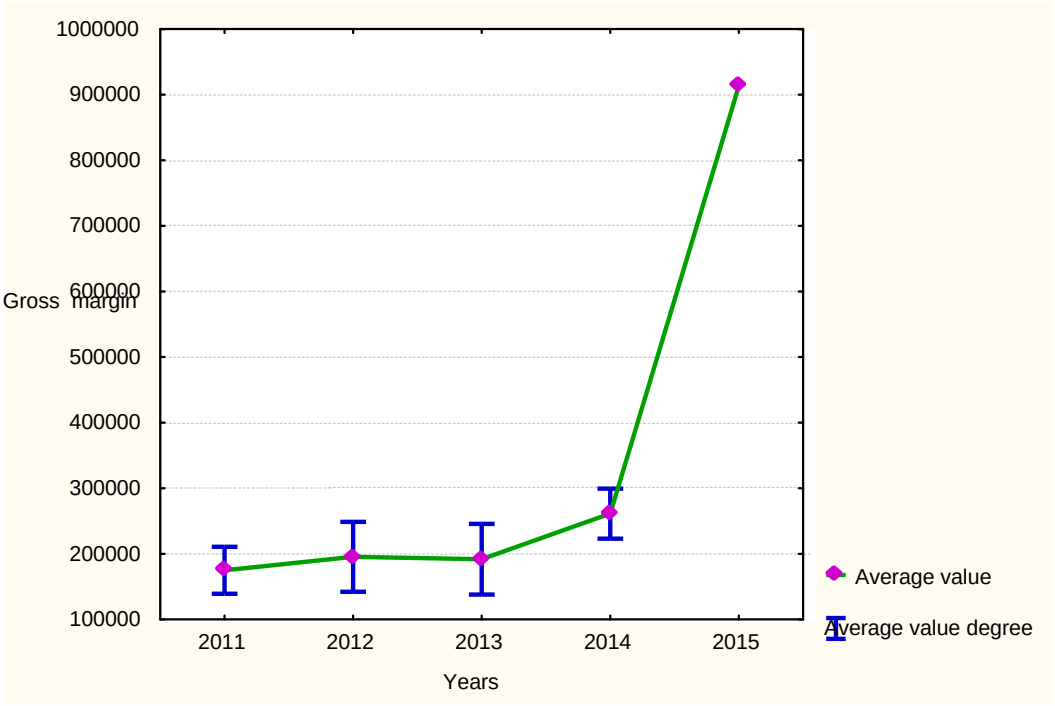
To check the assumption that the analysed results are to some extent influenced bythe work of advisory services, and to confirm the importance of the advisory service work a comparison between the years in which these farms were cooperated with advisory service and the control year of 2015 has been made. To check this assumption a t-test was executed (Table 3). It is noted that in the reporting period value of gross margin was continually increasing year by year, which leads to the conclusion that plum producers applied advices given by the advisory service. In 2015, the highest value of gross margin was achieved and it is significantly different from the value of gross margins in the previous years. Since this is the case of permanent cropsit is certain that the recommendations of advisors in the years preceding 2015, had they been adopted by the farmers, had an impact on the result achieved.

Table3. t- test for significant difference two middle

Years		Average value in the first year	Average value in the second year	t- quotient	p- value
2011	2015	175.038	913.225	-29,33540*	0,000087
2012	2015	195.579	913.225	-11,65861*	0,000024
2013	2015	191.838	913.225	-8,15783*	0,000005
2014	2015	261.288	913.225	-11,66022*	0,000001

*P <0.05, significant difference between the compared values

Conclusion made on the basis of indicators of descriptive statistics and based on the performed test of the significance of differences, are confirmed by a graphical presentation of trends in gross margins of plum in the analyzed period (Graph 1).



Graph 1. A trend of the average value of gross margin per year in plum production

Conclusion

Gross margin is a very useful tool for determination of economic efficiency of agricultural production. The average yield on the observed farms is a lot bigger than the average of Serbia. The records show that during the whole observed period 2011-2014, gross margins in plum production were positive, with yield and price having positive, and variable costs value having negative implications on the gross margin value. Gross margin value was especially high in the last year (2014), since this is the case of a permanent crop, while positive effects of advisory service measures could also be seen in 2015, in which gross margin was significantly higher than in 2014.

Abstract

Peppers are significant vegetable species produced in Serbia. They are considered to be the economically most effective plant in Serbia. Peppers are mostly produced in Vojvodina province and in the south of Serbia (city of Leskovac), being a product that is exported to Germany, Belgium, Slovenia, Croatia, but also imported from Macedonia. Gross margin (GM), or the calculation of variable costs, was used as a tool for determination of economic effects of this production. Data analyzed in this paper were collected through the questionnaire from the representative pepper producers in city of Jagodina (Pomoravlje region, Serbia) for the period 2011-2014. The basic elements of calculation, obtained by this form of GM, were: data on yield and price, quantity and price of inputs used, such as fertilizers, pesticides, and fuel, and costs of contracted services. GM is a simple, yet useful tool to indicate the profitability of a single production line. By neglecting the amount of fixed costs, it gives farmers an idea of the amount of money they can earn from a single product, after covering production costs.Within the period 2011-2014, GM for pepper varies from 4.323 EUR/ha (2011), to 18.978 EUR/ha (2014). At the same time, the total variable costs ranged from 5.513 (2011) to 7.041 EUR/ha (2013). With the average yield of 53 tonnes/ha in 2014 and a price of 430 EUR/t, an outstanding GM for pepper was obtained in the last of the analysed years.

Key words: *gross margin, pepper, variable costs, yield, price.*

Introduction

Gross margins in agriculture and their importance for farm and agricultural production were analyzed in numerous works and research worldwide, but in Serbia as well. Kahan (2008, 2010, 2013) shows in his works the significance of the GM, as well as a number of authors, both in the plant (Broad *et al.*, 2009; Nash *et al*., 2013), as well as in the livestock and milk production (Valvekar*et al*., 2010; Valvekar*et al.*, 2011; Bozic*et al*., 2012; Heikkilä and Peippo, 2012). Authors in Serbia also observed gross margin as a significant indicator of the business of agricultural households (Ivkov*et al*., 2008;Anđelić, *et al*, 2010;Janković*et al*, 2007, 2009;Munćan and Božić, 2013;Munćan*et al*., 2010), as well as Tomic*et al.* (2013) and Filipović*et al.* (2013).All these and other studies, and work relating to agricultural extension and gross margins in agricultural production, highlights the importance of extension services in agriculture as an inevitable element of the development of the agricultural sector, but also the importance of calculating the gross margin line of production on the farm as an important indicator of the profitability.

Pepper is considered as the most profitable crop culture in Serbia; it is the most cultivated in Vojvodinaprovince and southern Serbia (Leskovac), in the open field and in greenhouses. Average area under pepper in Serbia in the reporting period range from 12.5 to 11.8 thousand hectares and have a trend of annual decline.

The average yield for the period, amounted to 8.3 t/ha, and except in the dry year 2012, showing an upward trend. Compared to other vegetables, pepper is the only that showed growth in production and average yield of 14% as compared to the yield in 2013, were up to 9.6 t/ha. The average yield in the reporting period for the Region was 9.7 t/ha, which is 15% higher than the average in Serbia in the same period.Compared to the average yields of other countries, including the CEFTA countries, Serbia has an exceptionally low average yield of pepper. EU countries have up to four times higher average yields in relation to Serbia.The biggest problems in the cultivation of pepper in Serbia, in addition to poor irrigation and crop management are inadequate measures of protection and seed production of traditional varieties. More emphasis should be given incentives in vegetable production, for the purposes of greenhouse production and processing of vegetables, including peppers.

Materials and Methods

GM, or the calculation of variable costs, was used as a tool for determination of economic effects of this production. Data analyzed in this paper were collected through the questionnaire from the representative pepper producers in Jagodina (Pomoravlje region, Serbia) for the period 2011-2014. The basic elements of calculation, obtained by this form of gross margin, were: data on yield and price, quantity and price of inputs used, such as fertilizers, pesticides, and fuel, and costs of contracted services. All prices are given in EUR, but original data were collected in Serbian dinars (RSD). Prices were calculated based on Serbian National Bank average exchange rate against major world currencies for particular year (www.nbs.rs/internet/cirilica/scripts/kl_prosecni.html). Indicators of the value of production, total variable costs and gross margin were calculated according to the methodology provided by the website of the Serbian Agriculture Advisory Service (www.psss.rs). *Microsoft Excel* was used for processing data and calculating GM, and the program was set to calculate the average value of each element of the calculation. GM is the difference of total revenue and total variable costs, achieved in a line of agricultural production per unit of production area.

Results and discussion

Pepper yield at observed farms varied considerably, from a minimum of 28 to a maximum of 80 t/ha and 50t/ha on the average. Also, the yield showed a distinct tendency to rise and annual average of 32 %. The average price of peppers has been 390.95 Euro/t (with annual increse of 1,4%) and average yield per year had an increase of 2 %.

Total variable costs were 648.000RSD/ha on the average, but still show significant fluctuations (Cv = 25.59%) and a negligible tendency of yearly reduction by 0.11% (Table 1).Reduced variable costs, even symbolically, represent a favorable characteristic for farmers.

Gross margin inpepper production at observed farms averaged around 1.695.000 RSD/ha. Significant variability is one of the characteristics of these gross margin calculations, represented by high value of variance coefficient of almost 57%, although slight variations in gross margin values were obtained, this parameter shows a growth tendency at a rate of 5.74% annually.Listed characteristics of pepper production parameters are observed based on calculated values of basic indicators of descriptive statistics, which are shown in table 1.

Table 1.Basic economic parameters in pepper production (2011-2014).

Production parameters	Average	Variation interval		Variation coefficient (%)	Rate of change (%)
		Min	Max		
Yield (t/ha)	50,00	28,00	80,00	31,62	2,01
Price (Euro/t)	376,59	231,92	662,62	25,51	1,39
Variable costs (Euro/ha)	5.365,89	3.167,32	8.067,40	25,59	- 0,11
Gross margin (Euro/ha)	14.041,56	2.409,62	37.298,44	56,72	5,74

Impact of yield, prices and variable costs on a gross margin value, has been established and quantified through the application of regression analysis. All three of factors listed show statistically significant influence on a gross margin level. 96.3 % of gross margin value can be explained by the influence of yield, price and variable costs. Single most significant influence on gross margin comes from the yield obtained and if it rises for 1 ton, gross margin shall increase for a little over 48.000 RSD/ha.Next factor by significance of its impact is price, and if it gets higher for just 1 dinar, it will affect the increase of gross margin for 42 RSD/ha.Totally opposite from yield and prices, which have a positive influence on gross margin, that is – their increase results in an increase of gross margin, the influence of variable costs is negative, meaning that their increase decreases gross margin value.

Based on the aforementioned results of the research some conclusions related to the assessment of the effects of advisory work can be drawn, through changes in gross margins of the particular production lines on selected farms. Generally, all gross margins in all lines of production followed by a five-year period indicate significant increase. The annual growth rate of pepper production gross margin is significant (66.5% to 5.74%).This data clearly shows that there is a difference in the profitabilityamongfarms, but also differences in individual effectiveness of each advisor.The research results point to another important element that significantly affects the argument that the effects of advisory service, can measure the changes in gross margins. In fact, observed lines of crop production had the lowest gross margin in the first year (2011).Still, in control year (2015) gross margins continue to grow, although in that year advisors were not active on these farms, which proves that the previous work of the advisors gave positive results and that the producers accepted the advice on the right way and continue to achieve positive economic results in its production.Prices of products (eg. 2012) had some effect on the less significant increase or decrease of gross margins in period 2011 to 2015. As a reason for the lower gross margins of some production lines at a certain year, it is necessary to include climatic factors - rainfall and temperature, which is particularly reflected in field crops (Munćan andŽivković, 2006) and significantly affect the quality and reduce the yield of the product. Typical example is the year 2012, as a dry year with very high temperatures (Tomic*et al.,* 2013), and 2014 as the year of spring floods in Serbia and a high average rainfalls.Unfavourable weather conditions in certain stages of development of different crops have aneffect on the reduction in gross margin byincreasing variable costs in terms of consumption of plant protection products (Filipović et al., 2015).Although the results of the research show that on gross margin the largest influence had yield and price, while variable costs hadless importance, it is clear that the increase in variable costs reduces the amount of gross margin. Nevertheless, the importance of advisorywas determent and very important in proper terms of timely and cost-effective advice in the field of plant protection (Stanković*et al*., 2016).The increase in gross margin, related to advisory work, could be reached primarily through increased yields in vegetable production. Summarized results of the study are presented in Table 4.

Table4.Comparative overview of average pepper yield (2011 - 2015) in different locations

Crop	Yield(t/ha)for period 2011 - 2015			
	Serbia	Šumadija and Western Serbia Region	Pomoravlje district	Advisory Service Jagodina – selected (Leader) farms
Peppers	8,30	9,70	45,00	50,00

Source: Authors desk research and questionnaire results summary

Based on the data in Table 4, it can be concluded that the average yield for the investigated period is highest at farms that are selected and advised by Agricultural Advisory Service Jagodina. For a table of yield averages all selected (leader) farms with production lines investigated were taken in calculation. The fact that advisors, when selecting a leader farms selected mostly "good" farms and farmers with whom they can achieve adequate cooperation, may affect the significance of the above-mentioned data, as it can be said that they are already selected farms with higher yields and more serious production.However, the survey results show that all the farms involved in the survey had the lowest yields in the first year of research (2011), after which they had a more pronounced a level of growth.Results of this survey of pepper production can point to the conclusion that advisory work has a very significant impact on the improvement of production and economic factors on farms. Through the increase of gross margin on the monitored farms, it is clear that the effects of consultation

can be determined on the basis of the grossmarginof dominant production lines, individually for each of advisers, and for advisory service in general.

Conclusion

The agricultural sector in Serbia has excellent resources and conditions for agricultural production. It is the only sector of the economy in Serbia that actively participates and achieves a positive trade balance. In contrast, the Serbian agriculture is burdened by a series of structural problems. One of them is the performance of the basic agricultural production on small farms. The consequences of such situation, beside low production, are unprofitability and the lack of competitiveness of agricultural products, as well as unsatisfactory transfer of knowledge and new technologies to small and fragmented farms. Direct contact with farmers and the transfer of knowledge and skills, could be done only through SerbianAgricultural Advisory Service. Measuring of the results of knowledge transfer is quite difficult in all areas, including the advisory/ extension system. Therefore, it is possible in Serbia, as well as in other extension systems worldwide, to assess results of advisory work using gross margins of the dominant line of production on farms working with extension agents.

Abstract

Modern agricultural advisory can be traced back to the late 18th and the early 19th century, being more important in the 20th century. It emerged in the times when rural population had a greater percentage in total population, and when a need for transfer and dissemination of new technologies to farmers went along with the industrial revolution. Advisory first came up as a link between those in power, who were trying to implement certain agrarian policies, and farmers who did not perceive them as something positive. The current situation is characterised by the process of globalisation, which brings along progress and development in the field of communication and transportation. In such circumstances, a room for wider spreading of transnational capital emerges. A "shift of power" from public to private ownership has happened in this period. There were numerous objections against publicly-owned advisory services related to their inefficiency, lack of flexibility and high operational costs. Other reasons for privatisation of advisory were a need for charging costs and having cheaper advisory services. These and other arguments led to a diverse ways of organizing and financing advisory services in different countries, or even in different regions within the same country. Today, there are many ways to finance advisory: state budget, direct payments, voluntary contributions, agricultural chamber fees, etc. This paper presents the examples of financing advisory services in a larger number of the EU countries and in the USA.

Key words: *Advisory service, public, private, financing.*

Introduction

The first written records on the beginnings of agricultural advisory can be traced back to 1.800 B.C., when clay tables with scriptures on irrigation and crop protection were found on the territory of ancient Mesopotamia, present-day Iraq.

Although the data on the beginnings of advisory are diverse, advisory we know today originally comes as a result of the work of Philipp Emanuel von Fellenberg, who purchased an estate in Switzerland in 1799 and started to open agricultural schools. These schools, although not the first of that kind, had an impact on spreading the idea of advisory across Denmark, Germany, France and Great Britain. At the universities of Cambridge and Oxford, the idea of agricultural advisory gainedimportance in the 1890s, from where it moved to the USA, where agricultural advisory services were organized within land-grant universities. The Morrill act from 1862 established land-grant universities in the USA, within which advisory services were formed.The Smith-Lever act from 1914 formalisedagricultural advisory tasks, as well as ways of their financing.Presuming a partnership between agricultural universities and the US Department of Agriculture, this act prescribes the sources of financing of agricultural advisory from the federal level,through the U.S. Department of Agriculture that approves funding for each state based on a formula related to the size of the population of each state in the USA.

.

Materials and methods

In this paper, various ways of financing agriculture advisory servicesaround the world are observed. Evolution of agricultural advisory is presented, its transition from state owned to privately owned and financed, as well as the reasons for that transition are given in this paper. Various examples of models of financing agricultural advisory in European countries as well as in the USA are mentioned in this paper. Informationgiven hereare collected from a correspondent relevant literature – scientific articles, books on a related topic and FAO publications.

Results and discussion

Authors often mention that the most important counter-argument to the existence of state-owned agricultural advisory services is their inefficiency when it comes to cost-management. An information was given in the World bank study from 1992 (Saliu, 2009), which reveals that around 60% of costs for implementation of agricultural projectsfunded by the World bank were spent for advisory, while the governments of those countries absorbed around 18.5% of these costs. As a result, around 80% of total project costs of foreign financial assistance to advisory in 1992 went to sustaining a seemingly everlasting state administrative structure.

Although advisory emerged at the late19th century, most countries did not haveaformalized system of advisory before the 1950s and 1960s.A significant turn point in agricultural advisory occurred in the 1980s. Commonobjections against state-owned agricultural advisory services are related to their inefficiency and high operational costs. Although at the state level costs for engagingan agricultural advisor are not high, costs for engaging a great number of advisors havebecome a significant financial burden. According to the FAO web page data for 1990, there were about 600,000 agricultural advisors worldwide, 95% of which were employed in publicly owned agricultural systems. At the same time, there were 9,000 advisors employed in the USA, 4,000 of them specialised for a certain area, 1,000 directors and administrative staff (Swanson et al, 1990).

Modern times are characterized by globalization that carries along progress and development in the area of communication and transportation. Such circumstances leave some space for spreading of transnational corporate capital. Some authors, (Mathews, 1997)suggest this led to a so-called "shift of power" from public to private property.Along with this process, some bad sides of state-funded institutions came to surface – fiscal problems, reduced budgets which led to a decrease in their efficiency and productivity, thus makingthe costs exceedthe benefits. The nature of advisory work is basically about advisors being the link between those in power, who are trying to implement a certain agrarian policy, and directfarmers,to whom such a policy is not always favourable. Advisors can implement a certain agrarian policy only if farmerswho cooperate with those advisors are really willing to implement that policy,accepting the changes it brings. As an example, one can mention the limitations to the production of food surpluses, and imposing of more strict ecological rules in agriculture.This is mentioned as one of the reasons for privatisation of agricultural advisory services in Holland(Tacken, 1998).

In addition to the above-mentioned arguments, another argument in favour of privatisation of agricultural advisory services is also that advisory costs should be covered by farmers, since they are the ones who benefit from advice, and given that state budgets for public services are constantly decreasing. Another argument in favour of privatisation is that an increased competitiveness in this market would reduce the prices for these services (Quamar, 2005).When it comes to privatisation of public services, there are 3 scenarios proposed:

1) Public financing from tax payers, exclusively for services that contribute to the society as a whole;

2) Direct charging for individual services thathavesome specific results in terms of increased income, with the possibility of using different rates, depending on the specific situation or target group;
3) Mixed financing, depending on the contribution of public and private professional associations, in areas such as applied research, training of farmers and advisors and improvement of advisory methods and tools.

These methods of privatisation are typical for France, Great Britain and Holland.

Table 1.Different ways of organising and financing agricultural advisory services around the world

Advisory system	Relevant institutions	Sources of financing	Country
Public advisory			
State-run	Advisory work is carried out by public organisations, most often at regional level.	Fully financed from the national budget.	Belgium, Italy, Greece, Slovenia, Sweden, southern Germany, Spain, Portugal, Luxemburg
Partly state-run	Increasing role of advisory services rendered by private consultancy companies.	Farmers are partially or completelycharged for services; It could be in centralised or decentralised forms.	Ireland, Czech Republic, Poland, Slovakia, Hungary, Estonia
"Semi-autonomous" advisory	Advisory services offered by national organisations.	Limited state subsidising.	Lithuania, Latvia.
Private advisory			
Farmers' autonomic advisory	Advisory services offered by agricultural chambers, farmers' organisations and associations.	Finances from farmers' membership fees and direct payments.	Austria, France, Denmark, Finland, northern and western regions of Germany.
Commercial	Advisory services offered by commercial companies or private individuals.	Paying for services through project implementation or grants.	England, Holland, northern and eastern of Germany.

*Source: Agricultural Advisory Institutions on European Union countries, Mis, T. (2004), authors presentationbased on Kania 2006, Riviera 2001

FAO, in its chapter 22 on privatisation of agricultural extension mentiones different ways of financing, varying on the sector which provides advisory services.
In countries where the public sector provides advisory services, there could be some alternative ways of financing, such as:

1) General financing based on taxing, which is a traditional way of financing advisory;
2) Public taxing of certain goods (through tolls or parafiscal taxes), for example for agricultural products, such as coffee in El Salvador;
3) Public financing based on provision, where fees are charged for advisory services, usually to bigger farmers, like, for example in a crop-productive area of northern Mexico;
4) On a contract-based commercialization of public services, where there are contracts between the agricultural producer and public advisory services, like in New Zealand, for example.

In countries where private sector provides services, alternative ways of financing include:

1) State vouchers based on income, provided to farmers, who in turn conclude contracts from advisors from the private sector in order to get advisory service (information), such as in Chile;
2) An income-based coupon scheme derived from public loans, in connection with agricultural loans, which obliges the farmer who takes a loan to spend a certain amount of that money on agricultural advisory services;
3) Fees and commissions, including financing by taxing certain goods, where farmers pay the fee and customer services, while private organization (for example the agricultural chamber) also benefits from public tolls or parafiscal taxes payed on agricultural products, which are later being forwarded to organisations in the private sector. The private sector then provides agricultural services. Advisors from the private sector usually participate in steering committees of these agricultural chambers.
4) Fees in combination with sponsorships from certain groups or input suppliers, where educational advisory services are provided to groups of farmers by a consortium of consultants – private advisors, whose financing is partly provided from the sector of rural commercial sponsors;
5) Privatisation, where providing services and advisors' wages are in a domain of farmers' associations or other private entities.

Alistof ways of financing agricultural advisory services is given below (A.W. van den Ban, 2000):
1) State-owned service financed by tax payers;
2) State-owned service financed through tolls on a certain agricultural product;
3) Commercial company that sells inputs to farmers or buys their products;
4) Farmers' association that pays for advisory services from fees;
5) Farmers' association subsidised by the state;
6) Non-governmental organisation financed from donations of residents and non-residents and/or from the commercial companies for public relations;
7) Non-governmental organisation financed by state subsidies, whether from the national government or the government of the donor;
8) Consultant companythat charges provision to farmers who are its clients;
9) Publishing company that sells agricultural newspapers or similar publications to farmers;
10) Different combinations of ways from numbers 1 to 9.

Conclusion

Agricultural advisory services developed from a necessity of improvement of agricultural production in terms of both its quality and quantity, on a course desired by a wider community. Based on such needs, first they were organized within different state institutions. However, global trends of development of market economy, insisting on private property as a dominant form of ownership in the world, from economically strongest nations in the world gradually imposes trends of privatization also to some of conditionally speaking "smaller" countries in all areas of economy, as well as in the agricultural advisory. From this point of view, the knowledge which agricultural advisors transfer to farmers is observed as a form of intellectual property – a product, which is being exchanged between business partners represented by agricultural advisor and a farmer and which should have its market price. Participation of a greater number of suppliers of this service should lower its price, while gradual governmental withdrawal out of the sponsors role in this, affected the development of various ways of organizing, and thus financing of organization that provide these kind of

services. Therefore, currently in the world there is a pluralism of providing and financing of services of agricultural advisory.

MARKET PERFORMANCE OF SELECTED PEPPER SPICES IN IBADAN METROPOLIS, OYO STATE, NIGERIA

Catherine A. AKINPELU[1*], Kemisola O. ADENEGAN[2]

1Spices Improvement Program, National Horticultural Research Institute, Idi-Ishin, Ibadan, Oyo State, Nigeria
2Department of Agricultural Economics, University of Ibadan, Oyo State, Nigeria

Abstract

Hot pepper – *Capsicum frutescens* (HP), Black Pepper – *Piper guineense* (BP), Alligator pepper – *Affframomum melegueta* (AP) and Guinea pepper - *Xylopia aethiopica* (GP) were assessed in year 2014 for their market performance in Ibadan, Oyo State, Nigeria. Eighty spice marketers were interviewed using a structured questionnaire which captured the socio-economic characteristics and marketing indices for the selected spices from four (4) prominent markets in Ibadan namely; Bodija, Bode, Aleshinloye, and Oje markets respectively. Data were analyzed using descriptive statistics, marketing efficiency and regression analysis. Results showed that 96% of the marketers were women with most been middle-aged (46.3%) and married (81.3%). About 53% of the marketers had an average family size of between 1 and 5 people and the highest educational attainment was the primary education (38.8%). The marketing efficiency analysis revealed that spices with the highest average total revenue in the four markets sampled were in the descending order black pepper > alligator pepper > guinea pepper > hot pepper. The analysis showed the markets with the highest prominence in sales of these (4) pepper spices within Ibadan metropolis in the ascending order; Bode < Aleshinloye < Oje < Bodija. The regression analysis revealed family size, years of experience and cost price of spices as socio-economic factors affecting revenue generated from spices. However, to fully harness the benefits inherent in the utilization and marketing of these pepper spices, there should be a synergy in cost and selling price of the pepper spices in order to boost their market performance in the study area.

Keywords*: Pepper spices, Market performance, Condiments*

Introduction

Spices are aromatic and pungent herbal substances used as condiments. These substances generally give a characteristic smack, flavor, color and aroma (Gurib-Fakim, 2006; Khan and Balick, 2001). The story of spices and other flavorings' materials is one of the most interesting chapters in the history of vegetable products (Obadoni and Ochuko, 2002). Spices are used to season insipid foods and to add zest to an otherwise monotonous diet. They stimulate the appetite and increase the flow of gastric juice. For this reason they are often referred to as food accessories or adjuncts. They also play a role in many of the industries, and are used in perfumery, soaps, incense, as dyes in histology and in various acts (Onyesom and Okoh, 2006). Hot pepper/birds eye chilies (Capsicum frutescence) are one of the hottest pepper varieties found globally. It is produced in Eastern Africa (Malawi, Zimbabwe, Zambia, Kenya, and Uganda) as well as Nigeria and Ghana in West Africa (Kenya Horticultural Competitive Project, 2011). The bird's Eye chilli plant is a small bush that can grow to a height of 4 feet and sometimes more with a productive life of two to three years. Among others, bird's eye chillies are used as curry ingredient, pharmaceuticals, organic pest control spray and in making tear gas. Most Bird's Eye chillies are processed to extract the oleoresins for sale to the food and pharmaceutical industries (ADC, 2001).

Black pepper (*Piper guineense)* is commonly referred to as African black pepper or Ashanti pepper, is very similar to *Piper nigrum*. Black pepper (Piper guineense) nutritionally, is an excellent source of manganese, a very good source of iron and vitamin K, and a good source of dietary fiber (Nelson and Eger, 2009). Many Piper species have been found to have insecticidal properties, especially *P. nigrum, P. guineense,* and *P. tuberculatum* (Scott *et al*., 2005). Piperine in black pepper has also being discovered to possess some anti-fat effects which invariably reduces fat levels in the bloodstream and has other beneficial health effects (Goldberg, 2012).

Alligator Pepper (*Affamomum melegueta*), is a perennial herb commonly found in tropical regions, particularly in West Africa. They have been used extensively in the treatment of several ailments such as measles and leprosy. The fruit, apparently, also has an aphrodisiac property which is used to improve sexual stimulation and sexual performance (Oguntola, 2010). Guinea pepper has been reported to be recommended to women who have newly given birth as a tonic in the Ivory Coast as a woman remedy, it is taken also to encourage fertility and for ease of childbirth (Ogbe *et al*., 2009)

Guinea Pepper (*Xylopia aethiopica*), is a tree of 20 meter high or more with a clear straight bole to 75cm girth (Burkill, 1985). It has an English name of African Pepper. In Nigeria: (Yoruba) it is called Eeru; in (Igbo) it is called Uda. Negro Pepper has been reported in literature to possess medicinal and nutritional values (Nwachukwu, 2000). The fruit is used for soup making, particularly for nursing mothers. In folk-medicine, it is used for the treatment of biliousness, bronchitis and dysentery (Ogbe *et al*., 2009).

Despite the medicinal and nutritional potentials of these pepper spices, their demand and supply in Nigeria are still relegated to the background. It is against this backdrop that this research work was carried out to harness information on performance of spices marketing in Ibadan metropolis with a view of achieving the following objectives; to determine the demographic characteristics of the marketers, to assess the performance of three selected pepper spices in Ibadan metropolis and to determine the factors which influence the selling price of spices in the study area.

Materials and methods

The study area was Ibadan, the capital city of Oyo State which is located between 7°N and 9°N of the equator, longitude 3°E and 5°E of the Greenwich Meridian. Four (4) prominent markets in Ibadan namely; Bodija, Bode, Aleshinloye and Oje markets respectively in Oyo State were covered by the study. A purposive sampling technique was employed which led to the choice of four markets within the metropolis due to the concentration of these spice marketers within the markets.

Primary data for the study were obtained with the aid of a semi-structured, pre-tested questionnaire. distributed randomly to a selected number of marketers in each market via sampling proportionate to size thereby, giving a total sample size of 80 respondents which captured the socio-economic characteristics, marketing factors, benefit and cost parameters of the marketers in the study area.

The data collected were analyzed using descriptive statistics, marketing margin analysis and regression to capture socio-economic characteristics, performance of spices marketing and factors affecting spices marketing in the study area. Regression analysis was used to determine the level of relationship/significance between the gross margin (dependent variable), demographic characteristics and marketing activities (independent variables). The regression model is specified in the general form:

$Y = f(x_1, x_2 \text{ ------- } x_8)$

Where: Y = Revenue/selling price of spices in ₦/ bag

X_1 = Age

X_2 = Sex

X_3 = Marital Status

X_4 = Education level

X_5 = Family Size

X_6 = Ethnicity

X_7 = Years of Experience

X_8 = Purchase/Cost price of spices (₦/bag)

For the purpose of this study, four (4) pepper spices were exclusively analyzed. The marketing margin and efficiency procedure are as follows:

MM = TR - TMC……. (i)

ME = TR / TMC…….... (ii)

Where, TR = Total Revenue; TMC =Total Marketing cost:

MM = Marketing Margin and ME = Marketing efficiency.

TMC comprises of purchase cost in Naira per bag, cost of transportation in Naira/bag and cost of storage in Naira/bag

TR = Price/bag x quantity sold.

Results and Discussion

Socio-economic Characteristics of Marketers

The results of the analysis in table 1 showed that majority of the marketers (96.3%) were females, which implied that women are more into the marketing of pepper spices than men. Those who are middle-aged and active constitute the largest percentage (46.3%) amongst the marketers.

Majority of the marketers (81.3%) were married, which establishes the fact by Mafimisebi *et al*., (2000) that married people tend to have more financial commitment and home up-keep. Ninety three percent of the respondents had one form of formal education or the other with primary level of education ranking highest (38.8%). This depicts that a substantial number of the marketers had basic knowledge of how to read and write which could further enhance their marketing capabilities.

More than half of the respondents (52.5%) had an average family size of between (1-5) members, depicting that proceeds from the sales of spices will most likely meet the needs of the household due to the moderate size. Most of the respondents (85%) were from the Southwestern part of Nigeria. and highest revenue generated (52.5%) was within the range (0-5000) which implies that most of the marketers were low income earners.

Table 1: Socio-economic Characteristics of Spices Marketers in Ibadan, Oyo State

Items/Variables	Frequency	Percentage (%)
Gender		
Female	77	96.3
Male	3	3.8
Age Group		
22 - 40	36	45.0
41 - 60	37	46.3
61 – 80	7	8,8
Marital Status		
Single	6	7.5
Married	65	81.3
Divorced	1	1.3
Widowed	8	10.0
Educational Status		
Primary	31	38.8
Secondary	29	36.3
Tertiary	4	5.0
Illiterate	16	20.0
Family size

6 – 10	35	43.8
11 – 15	1	1.3
16 – 20	2	2.5

Field survey 2012

Performance of Spices Marketers in Ibadan, Oyo State

The market performance of spices in Ibadan was measured using the marketing margin and efficiency analysis procedure. Fig.1 showed that the pepper spice that was topmost on the supply chain was black pepper (1.26%) which was followed closely by guinea pepper (1.25%).Negro pepper was next with a marketing efficiency of (1.16%) and then lastly hot pepper (0.62%). This implies that, if ₦1 is invested in the marketing of black pepper, guinea pepper and negro pepper respectively, a gain of 26k, 25k and 16k will be realized, depicting that the marketing performance of the pepper spice is high and profitable. This study agrees with Usman *et al.,* (2007) on the marketing analysis of *Thaumatococcus danielli* in Ibadan, Oyo state of Nigeria which showed that the trade was highly profitable. It is also in agreement with Usman *et al.* (2006) on the marketing analysis of cabbage in Jos South Local Government area of Plateau State, which indicated that there was large marketing margin of sellers with significantly high returns.

However, the demand for these pepper spices in the markets under survey revealed sales in an ascending order of lowest to highest (Bode < Aleshinloye < Oje < Bodija) depicting that supply of these pepper spices was highest in Bodija market, probably due to the fact that it is one of the major food markets in Ibadan metropolis.

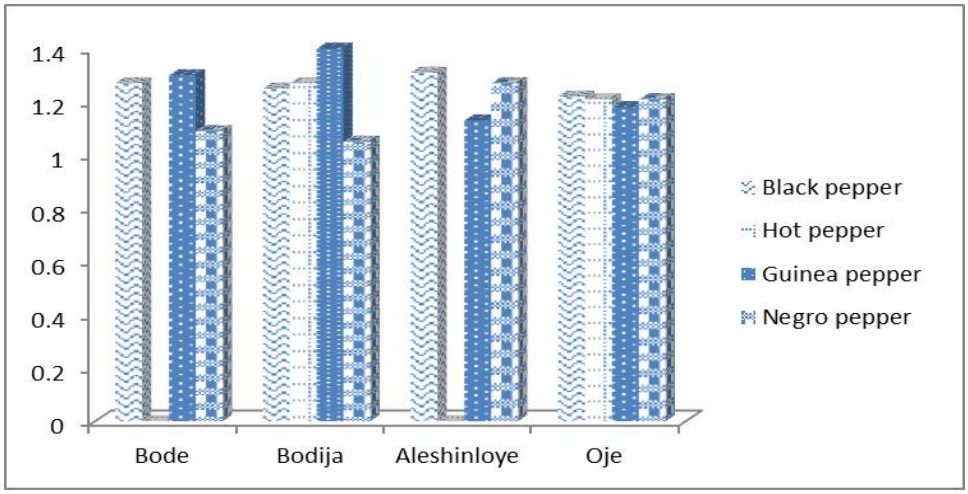

Fig 1: Marketing Efficiency of four pepper spices in Ibadan metropolis

Factors affecting Income Generated on Spice Marketing

The regression results in table 2; revealed family size, years of experience in spices marketing and cost price of spices as significant variables affecting gross margin/revenue on spices marketing. The family size of spices marketers had a significantly negative effect on income generation. This implies that the smaller the family size, the higher the income and vice-versa. The years of experience in spices marketing ($P<0.05$) was a significant factor affecting revenue generated from spices signifying that the lesser the number of years involved in marketing of spices, the higher the income generated will be and vice versa.. Using the coefficient values, the cost price significant explanatory variable on the selling price of spices could mean that a ₦1 increase in the cost price (Xi) of spices, will lead to ₦0.99 increase in revenue generated on spices in Ibadan. This buttresses the theory that selling price is a direct function of cost price. Other socio-economic variables; age, gender, marital status educational level and state of origin, affects revenue generated from spices marketing in Ibadan positively but the effect was not significant. Therefore, the null hypothesis which states that there is no significant relationship between the socio-economic characteristics of marketers and their generated revenue from spices is rejected and the alternative accepted which states otherwise.

Table 2: Result of linear regression analysis showing demographic characteristics affecting spices revenue

Variable	Coefficients	Standard Error	Y-Value

Source: Field survey, 2012

Conclusion and Recommendation

Most marketers of these pepper spices in Ibadan metropolis were married women with basic primary education. The performance of pepper spices marketing revealed that it was a profitable enterprise. Therefore, to promote profitability of spices marketing in Ibadan, there

should be a synergy in the cost and selling price of spices by marketing boards in the state while taking into consideration other marketing costs such as transportation cost, storage cost e.t.c in order to boost the market performance of pepper spices in the study area.

GLOBAL CLIMATE CHANGE AND FORESTRY

Michal V. MAREK,

CzechGlobe-Global Change Research Intitute, Academy of Sciences, Czech Republic, Bělidla 3a, 603 00 Brno, Czech Republic marek.mv@czechglobe.cz,

Abstract

Forest ecosystems are composed mainly oftrees, shrubs, plants and other autotrophic organisms. Thus, photosynthetic activity is acrucial and significant physiological process in this type of ecosystem. Photosynthetic activity is directly connected to carbon dioxide absorption. Thus, CO_2 in the atmosphere, which is regarded as the main source of carbon, is regarded as the "inorganicnutrient" for photosynthesis. Because CO_2 is the principal greenhouse gas, thephotosynthesis could be regarded as the crucial "massive biological pump" of carbon from the atmosphere. It means that photosynthesis of plantsis strongly related to global climate change, which is regarded as the crucial phenomenonof the current environment on the planet Earth. The ability of different ecosystems to be long-term carbon storages varies substantially. In particular, forests are of great importance. The long-term carbon storage in woody biomass and especially in the forest soil is significant. This carbon storage is strongly dependent on environmental impacts and anthropogenic activities. These sylvicultural activities substantially affect carbon storage. Thus, it is possible to formulate a special set of forest practises named "carbon forestry", which focuse on enhancing carbon storage and reducing carbon losses.

Keywords:*Carbon capture by forest, Carbon storage, Carbon forestry*

Introduction

Global Climate Change (GCC) is regarded as the crucial problem of the current environment onthe planet Earth. GCC iscoupled with the atmospheric CO_2 content, because of the role of CO_2 in the warming. The permanent exchange of carbon between the atmosphere and different ecosystems plays a very important role in the biosphere function. Autotrophic organisms, via the process of photosynthesis activity, are "pumping" huge amount of CO_2 from the atmosphere into biomass. Especially forest ecosystems are particularlyimportant. Forest stands play a crucial role inthe long-term carbon storage in the landscape. Forests are distinctive spatial bodies, they are long living organisms and occupylargeareas. Carbon is stored in the forest biomass and a huge amount of carbon is stored in the forest soil(Janssens at al. 2003). Thus, it is possible to define a newforest ecosystem service whichis related to the ability of forest ecosystems to be a huge and long-term terrestrial carbon stock. According to the Millennium Ecosystem Assessment, this service is classified as an ecosystem regulation service, i.e. carbon sequestration can be regarded as an important ecosystem service and a tool that contributes to meeting CO_2 mitigation objectives.Anthropogenic factors are having long-term impacts on European forests and forest management is regarded as a very important external factor which mainly affects the composition, stability and vitality of forest stands. Sylviculture practices are affected by different external (nutrition status, air pollution, insect and pathogens impact, global warming, water deficit) and internal (ontogeny and vitality of trees) factors. These events can be negatively strengthened by the unsuitable forest management activity. Despite these negative consequences,European forests are generally showing a substantial increase in tree growth as a result of the positive combination of

increased nitrogen storage, increased atmospheric carbon dioxide and improved forest management practises. Therefore, acontinued increase in the carbon stock stored in forest tree biomass across the European continent has been reported (Nabuurs at al. 2003). The final carbon accumulation in forest ecosystems is the sustained difference between the net primary productivity (which remarkably, has been increasing during the past decades) and carbon losses by active ecosystem respiration, decomposition and harvest (which has increased less over the same period)(Luyssaert at al. 2010). It is know that carbon sequestration is sensitive to the impact of environmental factors, particularly microclimatic and external synoptic factors. These factors are responsible for the large carbon storage dynamics between individual growing seasons (Marek et al. 2011). Moreover, forest stands are composed from different tree species, roughly from two basic types, i.e. coniferous and broadleaf species, respectively. It is possible to expect some differences in the seasonal course of carbon storage between these basic forest types. The presented paper focuses on the manifestation of environmental effects on carbon accumulation in different ecosystem types and highlights the potential of special sylviculture management, i.e. carbon forestry.

Material and methods

Carbon storage indifferent ecosystem types of the Czech Republic is permanently evaluated at a set of sites which are the part of EU ESFRI infrastructure, ICOS (www.icos-infrastructure.eu), and Czech national infrastructure, CZECHCOS(www.czechglobe.cz). These sites are located in different parts of the Czech Republic and they represent the principal ecosystem types found in the country. The investigated set of ecosystemsincludesa mountain spruce stand (910m a.s.l.), mountain grassland (905m a.s.l.), mountain beech stand (720m a.s.l.), highland spruce stand (480m a.s.l.), agrosystem (510m a.s.l.) and wetland (420m a.s.l.).

The evaluation of carbon storage in allthe investigated ecosystem types was based on the application of the eddy covariance technique (Aubinet et al. 2000). Unified eddy-covariance systems were applied for CO_2 flux measurement in investigated forest stands (Urban at al. 2007). CO_2, water vapour, sensible and latent heat exchange between the forest stand and adjacent atmospheric layer was measured using a closed-path IRGA (LI-7000, Li-Cor. USA) and an ultrasonic anemometer (Gill-R3, Gill Instruments UK). The eddy-system is located on ameasurement tower ata heightwhere acceptable observations can be made (Havránková and Sedlák 2004). After data post-processing (based on Aubinet et al. 2000 with several modifications according to recent CarboEurope and FLUXNET project protocols), half-hourly averages were available. Missing and bad-quality data were gap-filled according to interconnected models of the light response curve (Prioul and Chartier 1977) and Arrhenius type respiration function. For the purposes of this paper, daily sums of CO_2 fluxes (NEP) were used. Data were not filtered according to a limiting friction velocity (u*), as we used only daytime data, while problems with low turbulence appear predominantly during night-time. Only data with quality flags 0 (excellent) and 1 (good quality, according to CarboEurope codes) were used for the study.CO_2 efflux from stem, branch and soil was measured continuously over the whole growing season by the automatic closed gasometrical system SAMTOC (Pavelka et al. 2004). The adjusted chambers were connected to an infrared gas analyser WMA-3 (PP-Systems, UK) and closed only during measurement (150-200 seconds). Stem and branch temperatures in the cambium layer were measured by a set of sensors (calibrated thermocouples). Soil temperature measurements (thermistor model Pt100, Treston, Czech Republic) were conducted at a depth of3 cm and randomly positioned within the investigated forest area. CO_2 efflux rates were correlated against corresponding temperatures. The air temperature within the investigated stands was measured at the 5m level (thermistor model Pt100, Treston, Czech Republic).Incoming Global radiation (GS) was

measured by a solarimeter (CM5, Kipp & Zonnen, Holland) located 5m above the upper stand crown layer. Air temperature and incident precipitation were measured by standard sensors located on the measurement tower at each site.

Results and discussion

Carbon absorption is strongly dependent on the season as is shown during the example year of 2014 (Fig.1).Forests are the most important ecosystem from the carbon storage point of view(Marek et al. 2011). In particular, the time of active carbon accumulation is of great importance. For example in the year 2014, the active growing season in the mountain spruce stand was240 days, inthe highland spruce it was265 days and in the mountain beech it was166 days.The annual amounts of accumulated carbonat each site in 2014 were:

- Mountain spruce forest: 6.5 tC ha^{-1} $year^{-1}$
- Mountain beech forest: 3.4
- Mountain grassland: 0.4
- Highland spruce forest: 4.6
- Floodplain forest: 4.8
- Agrosystem: 4.1
- Wetland: 3.1

Carbon accumulation is a process which is very sensitive to environmental events. During the year 2015, the Czech Republic was suffering from an extreme drought. A period with limited precipitation and drought soil was evident during the middle of June until the end of September.

The final effect of the drought on the soil is strongly related to the altitude and vegetation type. The spruce in mountain location (cca 950m a.s.l.) suffers from the drought in small measure compared to the spruce highland (altitude cca 500 m a.s.l.). The type of the vegetation is important in determining the response of mountain beech stand to the drought, while the deep root penetration into the soil is responsible for negligible response to the drought. The NEE values were always negative, i.e. the stand was always a carbon sink, without the drought effect. However the investigated highland spruce stand was sometimes a source of carbon (positive values of NEE).

A very important environmental factor affecting the carbon uptake and storage, especially in coniferous stands, is the solar radiation type, i.e. direct beam or multidirectional diffusive radiation. The Latter is deeper penetrating radiation, which illuminates more leaf area within the crown body, resulting in higher carbon uptake and storage. Moreover, diffusive solar conditions are mostly connected with cooler days and thus the respiration is lower. (Urban et al. 2007). Because of the crucial and significant role of forests in GCC mitigation, the application of some special management approaches are imperative. Thus, special sylvicultural practices supporting this forest ecosystem service – climate regulation, are needed. This system, named “Carbon forestry” is focused on all sylvicultural activities which are responsible for maximization of carbon storage in the forest ecosystem biomass and in the soil and minimization of carbon losses from the system. The system of carbon forestry covers all principal sylvicultural activities, which are realized during the whole life span of the foreststand, i.e. site preparation before forest planting, thinning –an extremely effective tool increasing photosynthetic assimilation and harvest.

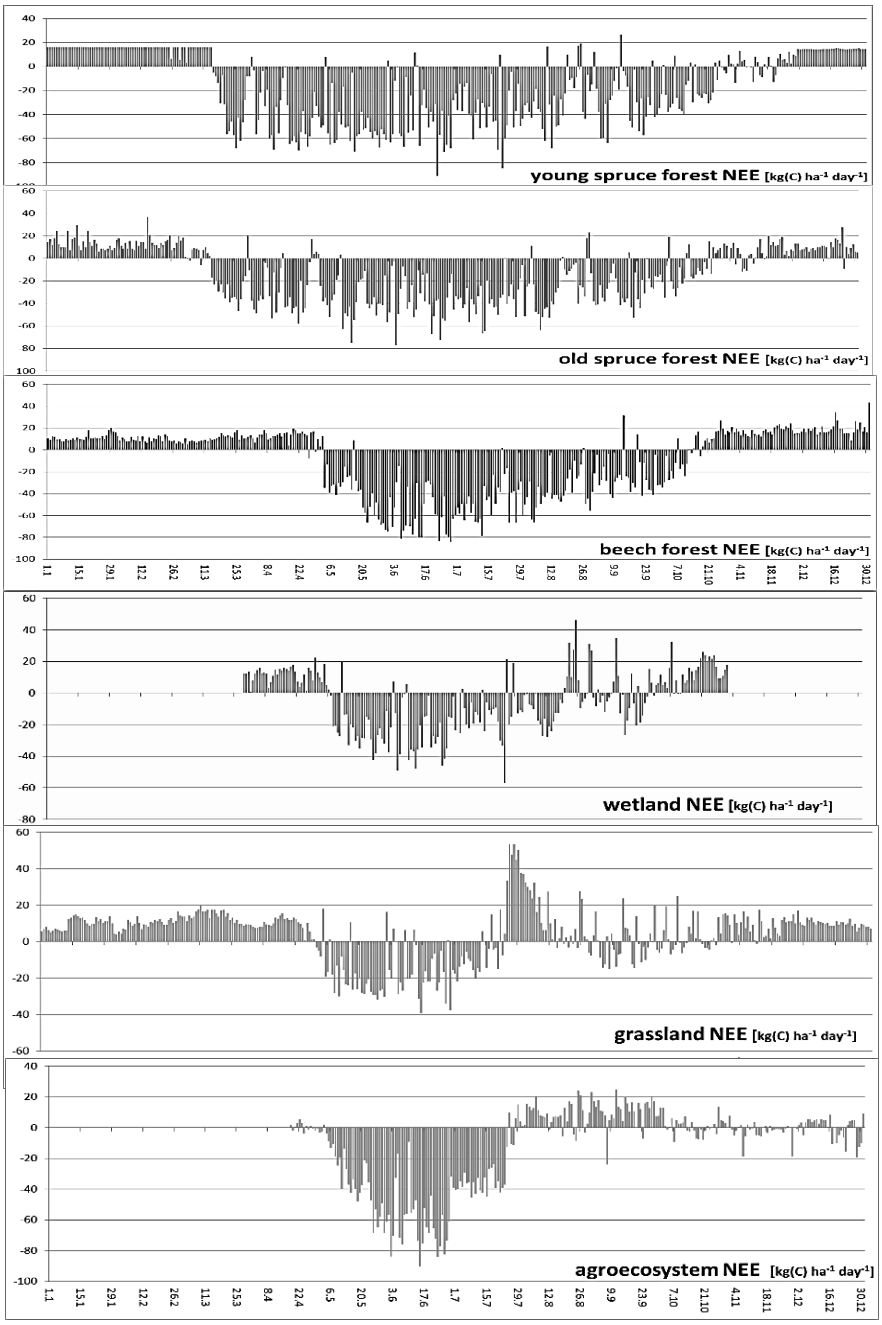

Fig. 1:Seasonal course of the Net Ecosystem Carbon Exchange (NEE) in different ecosystem types of the Czech Republic. The negative values indicate the situation when carbon is removed from the atmosphere

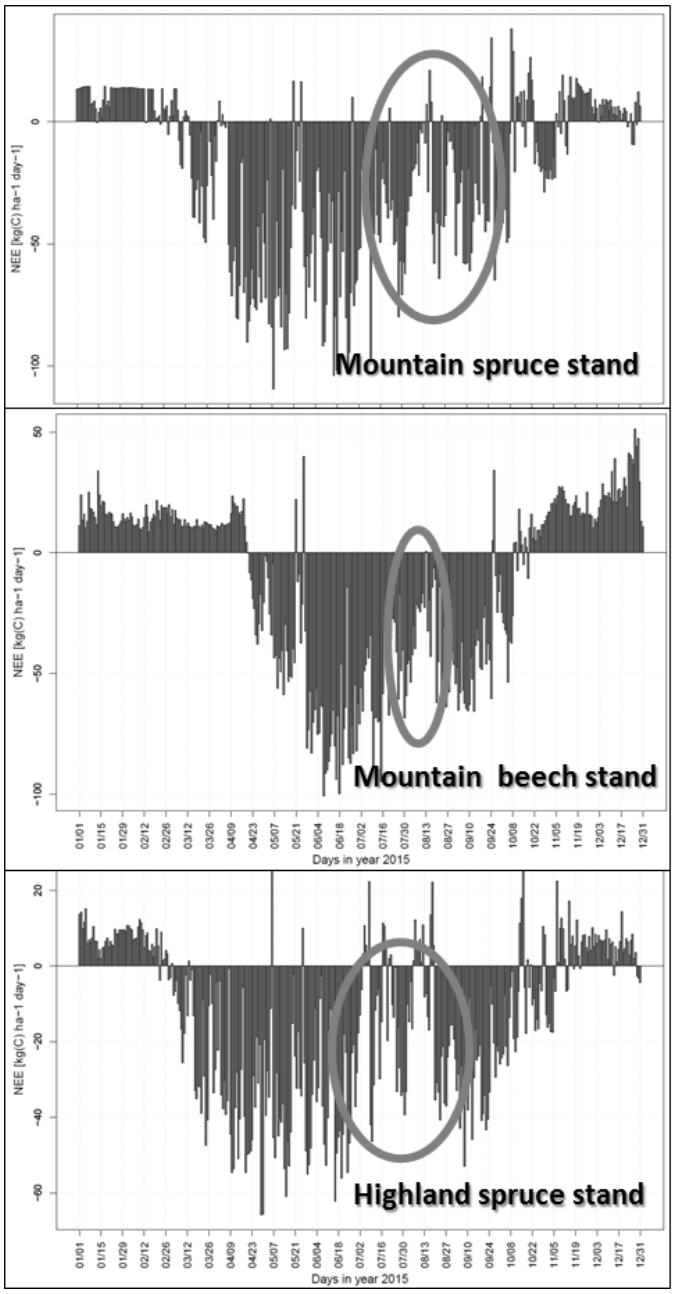

Fig.2: Comparison of the drought effect on spruce and beech stand NEE in different localities, different vegetation zones and altitudes

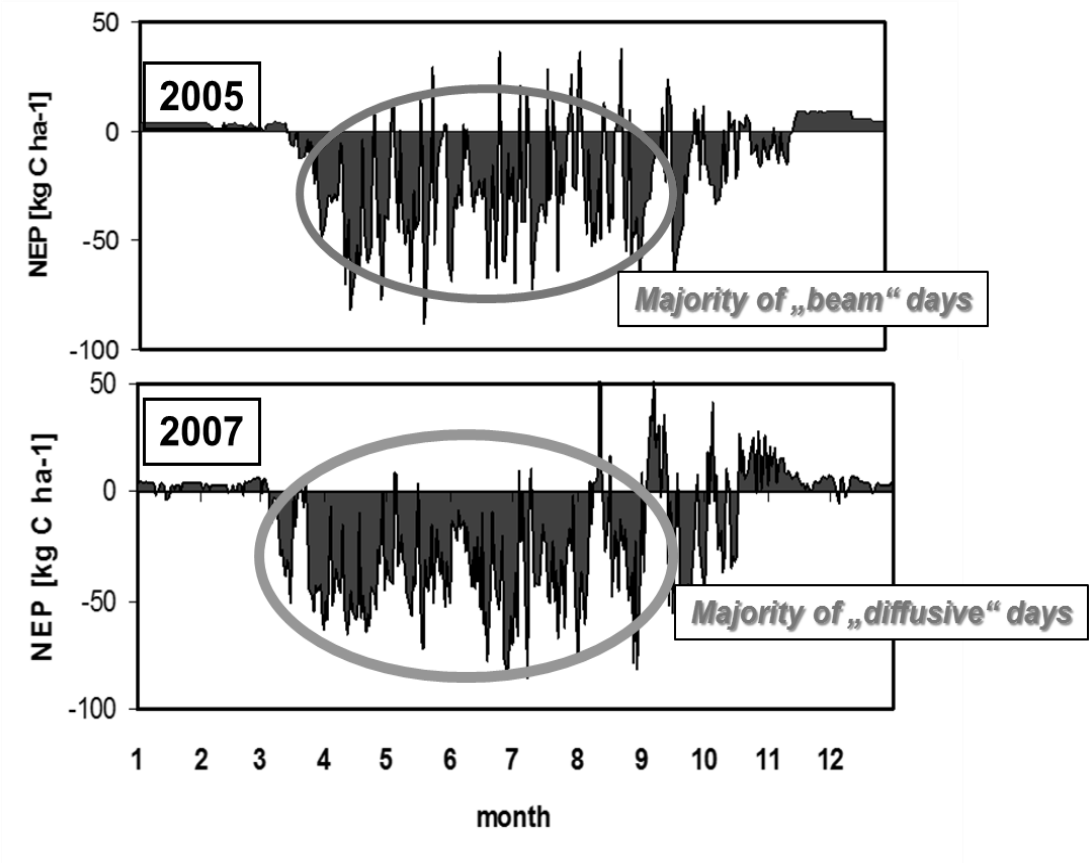

Fig.3: Comparison of the NEE, i.e. Net Ecosystem Exchange, on the longer seasonal scale, i.e. for two years which differ in the number of clear and difussive radiation

All mentioned activities have a significant impact on the carbon balance. Thinning as a "queen" of sylvicultural skills can significantly improve the assimilation "power" of a forest stand.Changing forest structure by the selective elimination of individual trees, results in the improvement of solar radiation penetration into the stand canopy resulting in the stimulation of the photosynthetic activity of lower crown parts. Thus the carbon assimilation "factory" is increasing its output, which enhances the carbon accumulation and finally biomass formation. Thus, thinning can be regarded as a tool for increasing forest stand carbon storage ability.
Thus, it is really possible to utilize forestry (soil damage avoidance, soft harvest techniques and thinning) practises toincrease carbon storage in the forest ecosystem. The role of forests in the mitigation andadaptation to GCC is undoubted.

Conclusions

Global climate change is a reality of the current world and its impact on forestry is extremelysignificant because of the role of forests in climate regulation and potential carbon storage in forest ecosystems. The storage capacity is strongly dependent not only on the conditions of the given locality, but is affected by the climate conditions. The seasonal course of carbon storage is different between individual seasons, depending on the actual temperature and precipitation conditions of the given season. The potential of forestry practises to positively influence the carbon storage of a forest in both important parts, i.e. biomass and soil, is very promising. In particular, thinning could be utilizedto permanentlyenhance the production potential of forest stands.

Abstract

This work analyzes the variability of the chemical composition of birch sap, which is obtained through a traditional tapping method in discontinuous time intervals in seasons: 2000, 2010 and 2016. The subject of research are two stands of silver birch (*Betula pendula* Roth, Syn. *B. verrucosa* Ehrh,). The first one on the Eocene flysch, in the belt of forests where sessile oak (*Quercus petraea*) alternates with European beech (*Fagus sylvatica*). Another one on silicate substrata, where birch trees form patches between spruce forest belt (*Picetum montanum*) and pastures. Samples of fresh birch sap (*Betulae sucus recens*) were measured in the following parameters: total solids, total sugars, total acids, tannin compounds, organic nitrogen, specific weight, refractive index, ash, Na, K, Ca, Mg, P, Fe, Cu, Zn, Mn, As, Cd, Co, Pb, Hg, Ni, Se. Also analyzed but not proven, were the presence of fat, flavonoids and vitamin C. Sugars were analyzed in qualitative and quantitative terms. Presence od individual sugars were determined applying thin layer chromatography, while the impact of terrain and stand conditions on total sugar concentration in birch sap was evaluated using the Kruskal-Wallis test. Having in mind that birch sap is consumed by people as a refreshing and healing beverage, standard microbiological analysis has also been carried out.

Keywords: *birch sap, chemical composition, tapping*

Introduction

Living trees sap exploitation, known as tapping is as old as human civilization. Tree sap is believed to have been used as early as neolith as a source of potable water in pile dwellings in marshes. The therapeutic use of birch sap probably goes back in the times of ancient Greeks and Romans (Anon, 2006). Nowadays birch sap is used as a refreshing beverage, either fresh or fermented in the form of beer or wine. Also, it is used in traditional medicine as a healing drink (Kûka et al., 2013; Łuczaj et al., 2014; Ljubojević, 2002; Semjonovs et al., 2014; Svanberg et al., 2012). According to the European Medicines Agency (Anon., 2006), birch sap provokes a week antiinflammatory activity to rats for a short period. According to the same source an antimicrobial activity of birch sap against *Staphyloccocus auerus* can be observed only with undiluted sap as well as weak anti-inflammatory and antipyretric effect. In comparison to anti-inflammatory drugs, the mentioned birch sap feature is quite inferior.

Birch sap is sold commercially in Scandinavia, Belarus, Russia, Ukraine and China (Helfferich, 2003). In our region, companies, "Šumaprodukt" Šamac and "Pliva" Zagreb had traded with birch sap. Slovenian company "Mariborske lekarne" produced "Birch Hair Water" whose main component was birch sap (Ljubojević, 2002). Today, birch sap is not yet in commercial production in our country.

Only a few works have dealt with sap exploitation from standing trees in Bosnia and Herzegovina (Alibabić et al.. 1980, Ljubojević et al., 2002, 2002a). The aim of our work was to further explore the content of common birch sap (*Betula sucus recens*) in order to provide a solid scientific base

for forestry and agricultural practice to eventually start tapping and select an appropriate way of processing. With that regard, this paper presents chemical composition and microbiological characteristics of birch sap, as well as influence of terrain and stand conditions on total sugars concentration.

Material and method

Field work

Silver birch, common birch (*Betula pendula* Roth., syn. *B. verrucosa* Ehrh.) belongs to Euro - Siberian floral elements. In our climate silver birch most often occurs as a pioneer species on felling sites and fire-affected areas, forming a smaller or larger groups of trees. Birch is also known to form pure forests on acid brown (Dystric Cambisol) and podzolic soils. We carried out research on two locations in three tapping seasons: 2000, 2010 and 2016. One was a hilly terrain Gavranovac in the northern part of the Republic of Srpska. Here birch builds pure sparse (light) groves on Eocene flysch, occupying borderline between sessile oak (*Quercus petraea*) and beech (*Fagus sylvatica*) forests at latitude 240 - 275 m (fig. 1). Another one was situated at locality Kneževo, at 1,050 m. Here birch trees form sparse patches at the border between pastures and the Norway spruce (*Picea abies)* forests on silicate substrata.

At the locality Gavranovac we selected 24 birch trees in a subjective manner, trying to cover variability of local factors considered to have some impact on flow regime and sap yield, such as breast height diameter (b.h.d.), branchnees, closure of canopy, inclination and exposition. In early spring 2000 we drilled holes of 1 cm in diameter and 5 cm deep at breast height, slanting them upward. We inserted plastic tubes into each hole and attached them to 20-litre tapping containers (fig. 2). The first drops of sap appeared as early as the same day, which means that trees had already accumulated a certain amount of sap. After some period of time we took 200 ml samples from each tree on the same day to determine total sugars and total acidity.

Figure 1: Tapping locality Gavranovac (photo: S. Ljubojević)

Figure 2: Birch tree prepared for tapping (photo: D. Miodragović)

Quantity of sap was measured by 1,000 ml graduated glass cylinder, with +/- 10 ml measuring accuracy. The number of wounds on trees was in dependence with b. h. d. One wound per tree was opened when diameter was thinner than 30 cm, two wounds on trees with diameter between 30 – 40 cm and three wounds on trees thicker than 40 cm. In the same place and with the same trees, we took two samples in the season 2016, one in the initial stage and another in the final stage of the tapping season. Collected sap have been consolidated into a collective

sample. At the locality Kneževo we selected in the year 2010 six birch trees in a subjective manner just for the chemical analyzes of sap.

Lab research

Lab research comprised chemical and microbiological analysis of birch sap. Dry matter content was determined by a refract meter. Ash content was determined by annealing at 600 ^{o}C. Organic acids and vitamin C were determined by HPLC with UV-VIS detector. Content of total sugar was determined by adapted Schoorl method based on Czech Standard ČSN 56 0016-7. Thin-layer chromatography was applied to identify sugars. Determination of organic nitrogen was done by the Kjeldahl method and of fat content by the Soxhlet method. Qualitative analysis of flavonoids and tannins was performed in accordance with Ph. Yug. IV. Sample preparation for determination of mineral substances was done by **"**wet**"** incineration with perchloric and nitric acids according to Trajković et al., (1983). Determination of mineral matter in prepared samples was done by analytical technique - inductively coupled plasma optical emission spectrometry on the instrument Optima 8000 ICP-OES Spectrometer, "Perkin Elmer". Arsenic (As) was determined by hydride method and Mercury (Hg) by cold streams method.

Microbiological analysis of samples from the years 2000 and 2010 had been carried out at the Public Health Institute or the Republic of Srpska. On that occasion were tested presence of: *Salmonella* spp., *Clostridium* spp., *Proteus mirabilis, Escherichia coli, Staphylococcus* spp., molds and yeast, and total microorganisms. Samples from the year 2016 were analyzed in the following way: after pasteurization (80 ^{o}C for 5 min), sap was tested for antimicrobial activity. Testing was performed on two bacteria: Gram (+) *Staphilococcus aureus* and Gram (-) *Escherichia coli*. In addition to the above bacteriological test, measurement of inhibition of the growth of mold *Asperillus niger* was performed. Antimicrobial activity was also tested by the minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) in microbiological growth medium MHB (Mueller Hinton Broth).

Data processing

In order to investigate whether and to what extent terrain and stand conditions influence total sugars concentration, we performed the categorization of these characteristics in accordance with the criteria listed in table 1. After that, we applied Kruskal-Wallis non-parametric test. We calculated test statistics (H) using the standard procedure (Pranjic 1986), compared them with table value of $\chi^2_{0.05}$ and drew certain conclusions based on the observed differences.

Table 1: Tree distribution according to basic characteristics of study area

Feature	Category of feature	Description of feature	Number of trees
Burdening with wounds	1 - Low	$D_{1.30} < 30$ cm ……. 1 hole per tree	13
	2 - Medium	$D_{1.30} = 30 – 40$ cm …….. 2 holes per tree	9
	3 - High	$D_{1.30} > 40$ cm ……. 3 holes per tree	2
Branchness	1 - Low	Length of crown up to 1/3 of tree height	2
	2 - Medium	Length of crown from 1/3 to 1/2 of tree height	19
	3 - High	Length of crown over ½ of tree height	3
Closure of canopy	1 - Open	Degree of canopy closure 0.0 – 0.2	8
	2 - Interrupted	Degree of canopy closure 0.3 – 0.6	10
	3 - Full	Degree of canopy closure 0.7 – 1.0	6
Terrain inclination	1 - Small	Inclination 0 - 20%	2
	2 - Medium	Inclination 21 - 40%	9
	3 - Big	Inclination > 40%	13
Terrain exposition (direction)	1 - Cold	N	6
	2 – Moderate	E, W, ∅	13
	3 - Warm	S	5

Results

Birch sap obtained from individual trees at the same time and locality, differs a lot in total sugars and acidity, most certainly due to genetic factors. The concentration of total sugars and acids were as follows: tree No. 1 - 0.33 % sugars/0.01 % acids, No. 2 - 0.64/0.03, No. 3 – 0.84/0.06, No. 4 – 0.69/0.07, No. 5 – 0.40/0.04, No. 6 – 0.84/0.07, No. 7 – 0.25/0.04, No. 8 – 0.36/0.06, No. 9 – 0.72/0.09, No. 10 – 0.43/0.12, No. 11 – 0.28/0.05, No. 12 – 0.53/0.01, No. 13 – 0.46/0.11, No. 14 – 0.41/0.05, No. 15 – 0.83/0.08, No. 16 – 0.79/0.04, No. 17- 0.64/0.07, No. 18 – 1.16/0.07, No. 19 – 0.98/0.04, No. 20 – 0.28/0.03, No. 21 – 0.33/0.04, No. 22 – 0.35/0.08, No. 23 – 0.64/0.06, No. 24 – 0.51/0.10.

Collective samples taken from the same locality and season, but in different times of the season, differs very little in terms of chemical parameters (tables 2 & 3). Seemingly, earlier collected sap is somewhat more “dense” than latter sap. Seasonal variations in observed parameters are more expressed, especially with total acidity. Even greater differences are observed when looking at samples from different localities. Apparently, sap from higher altitudes (Kneževo) is somewhat more “dense” than sap from lower heights (Gavranovac). In absolute terms, the average sugar content in our climate is generally lower than in other, mainly northern climates. So, in Lithuania sugars in birch sap amounted 1.1 % (Viškelis, et Rubinskienė, 2011), in Finland and Russia around 1.0 % (Kallio et al., 1985; Zyryanova et al., 2011), in Poland even 2.46 % with *Betula pendula* and 2.62 % with *Betula pubescens* (Łuczaj et al, 2014). When viewed tanning compounds, their concentration is quite low, and in the last season they are not even detected. Flavonoids, considered as main constituents of birch leaves (Anon., 2006), are not detected at all. The same is with fat, organic nitrogen and vitamin C.

Table 2: Chemical parameters of birch sap – part 1

Locality	Tapping season	Dry matter	Ash	Total acids	Total sugars
		%			
Gavranovac	2000	0.8	0.020	0.12	0.53
	2016 early s.	0.7	0.0238	0.036	0.56
	2016 late s.	0.6	0.0236	0.035	0.48
Kneževo	2010	0.8	0.032	0.154	0.61

Table 3: Chemical parameters of birch sap – part 2

Locality	Tapping season	Tanning compounds %	Specific weight g/cm^3	Refractive index	pH
Gavranovac	2000	0.072	n.m.	n.m.	n.m.
	2016 early s.	n.d.	1.0034	1.3334	n.m
	2016 late s.	n.d.	1.0033	1.3333	n.m.
Kneževo	2010	0.067	1.002	n.m.	3.71

n.d. – measured but not detected
n.m. – not measured

Sugar concentration in birch sap from trees on small and medium slopes is higher in comparison with trees on very steep slopes (table 4). The same can be said for birch trees from stands with full or interrupted canopy when compared to trees from open spaces (table 5), as well as for trees from southern and western positions compared to trees from eastern and northern expositions (table 6). We did not prove that b.d.h. and branchnees have significant impact on sugar despite earlier established positive linear correlation (r = 0.73) between b.h.d. and sap yield (Ljubojević et al., 2002b).

Table 4: Variation of total sugars in birch sap in relation to terrain inclination

Description of feature	Number of observations (trees)	Average rank according to total sugars (***Ri***)
Small and medium terrain inclinations (i </= 40 %)	11	8.85
Big terrain inclinations (very steep slopes) (i > 40 %)	13	15.10

H (test statistic of Kruskal-Wallis test) = 4.58 > $\chi^2_{0.005}$ = 3.84 indicates that the differences between average ranks are statistically significant, i.e. that samples do not belong to the same source.

Table 5: Variation of total sugars in birch sap in relation to closure of canopy

Description of feature	Number of observations (trees)	Average rank according to total sugars (***Ri***)
Full or interrupted closure of crown canopy (degree of canopy closure between 0.3 - 1.0)	16	10.28
Open stands (degree of canopy closure between 0.0 - 0.2)	8	16.94

H = 4.74 > $\chi^2_{0.05}$ = 3.84

Table 6: Variation of total sugars in birch sap in relation to terrain exposition

Description of feature	Number of observations (trees)	Average rank according to total sugars (Ri)
Southern and western expositions (S,W)	12	8.58
Eastern expositions (E)	6	14.58
Northern expositions (N)	6	20.2

$H = 10.48 > \chi^2_{0.05} = 5.99$

In sap samples from observed sites, we find five sugars: glucose, fructose, sucrose, arabinose and galactose. Glucose and fructose were found in all samples. Sucrose was find in two localities in two different seasons, but was missed in the last season (table 7). In earlier work Alibalić et al. (1980) had found three sugars in fresh birch sap taken from the locality Koševo/Nahorevo near Sarajevo - glucose, fructose and small quantity of sucrose.

Table 7: Presence of sugars in the fresh birch sap

Locality	Tapping season	Glucose	Fructose	Sucrose	Arabinose	Galactose
Gavranovac	2000	+	+	+	+	+
	2016 early s.	+	+	n.d.	n.d.	n.d.
	2016 late s.	+	+	.n.d.	n.d.	n.d.
Kneževo	2010	+	+	+	n.d.	n.d.

In view of sugars, Essiamah (1980) and Horvat (1980) have arrived to similar results. Glucose and fructose are two main sugars, and sucrose joins them in small quantities. Kalliou et al. (1985) assert that the content of these two monosaccharides in birch sap in Finland is 4 - 7 times higher than content of sucrose. Apart from these sugars they have also find galactose, while Sauter et Ambrosius (1986) have also established stachiose. According to the latter authors, sugars concentration in birch sap is distributed in the following descending order:

D-fructose > D-galactose > sucrose > stachiose

Sauter and Ambrosius (1986) have found two new sugars in phloem sap: maltose and raffinose and established the following descending order:

D-fructose > sucrose > stachiose > D-glucose > maltose > raffionse

When we look at similar birch species, downy or white birch (*B. pubescens* Ehrh.), we can notice the same relation between sap sugars. According to Kûka et al. (2013), one liter of birch sap in Latvia contains 5.39 g of fructose (51.7 %), 4.46 g of glucose (42.7 %) and 0.58 g of sucrose (6.3 %).

Birch sap obtained from the same locality and season, but in different times of the season, differs very little in terms of mineral composition (tables 8). When comparing different seasons at the same locality, differences become very large. Certainly, the same is when we look at different locations in different seasons. Similar situation is with trace elements (table 9), but in another context. Instead of differences in terms of quantity, simple difference appears in terms of "detected" or "not detected".

Table 8: Analysis of minerals in birch sap

Locality	Na	K	Ca	Mg	P	Fe	Cu	Zn	Mn
	mg/l								
Gavran, 2010	30.2	114.8	203.4	n.d.	n.d.	1.6	n.d.	n.d.	8.7
Gav. 2016, e.s.	143	667	81.2	22	19.2	0.8	0.5	0.9	3.5
Gav. 2016, l.s.	148	656	82.4	22.8	18.4	0.9	0.5	1.0	3.8
Kneževo, 2010	53.2	383.9	266.7	31	26.5	1.3	0.04	0.37	0.22

Table 9: Trace analysis of birch sap

Locality	As	Cd	Co	Cr	Pb	Hg	Ni	Se
		mg/l						µg/l
Gavran. 2010	< 0.05	n.d.	n.d.	n.d.	0.047	< 0.001	n.d.	n.d.
Gav. 2016, e.s.	n.d.	b.l.d.	n.d.	b.l.d.	b.l.d.	n.d.	n.d.	0.98
Gav. 2016. l.s.	n.d.	b.l.d.	n.d.	b.l.d.	b.l.d.	n.d.	n.d.	1.00
Kneževo	< 0.05	< 0.05	< 0.05	n.d.	< 0.05	< 0.001	< 0.05	n.d.

b.l.d. – below limit of detection (of instrument)

The heavy metals concentrations are below limits determined by the local authorities and by WHO for drinking water (table 9).

Results concerning anti-microbial activity of the birch sap, like previous chemical features are not unison. In some respects they are even contradictory. And so, no microorganisms were found either in fresh or in a year old sap samples taken from Gavranovac locality in season 2000 (table 10). The sap was kept in a simple bottle at room temperature and was opened occasionally to monitor color and odor. Atypical, intense and unpleasant smell lead to a conclusion that microorganisms may have colonized the sap shortly and then their autolysis occurred. This phenomenon can be explained through an already known fact that other portions of birch tree, such as leaves and buds (*Folia et Gemma Betulae*) already contain compounds which are effective against some microorganisms (Anon., 2006). More realistic option is that this effect was caused by penicilium grown in the sap, provoking destruction of existing and secondary populated microorganisms.

Table 10: Microbiological analysis of birch sap collected from the locality Gavranovac during season 2000 (analysis performed at the Public Health Institute or the Republic of Srpska)

Microorganism	Observed concentration	Fresh sap	One year old sap
Salmonella spp.	25 ml	not found	not found
Clostridium spp.	0.1 ml	not found	not found
Proteus mirabilis	0.1 ml	not found	not found
Escherichia coli	0.1 ml	not found	not found
Staphylococcus spp.	0.1 ml	not found	not found
Molds and yeast	1 mg	0	0
Total microorganisms	1 mg	0	0

To avoid imposed dilemmas, sap samples collected in the year 2016 were pasteurized prior to the microbiological analysis. Pasteurized sap showed no activity against the tested microorganisms, neither further measured MIC and MBC values.

Conclusions

Bich sap is a non-wood forest product with undisputed refreshing and certain healing attributes.

Considering the physiological role performed by the sap (transport of materials from the roots to the photosynthetically active parts of the tree), its chemical composition is strongly influenced by the time and the place of collecting. At the beginning of the tapping season, amount of material to be transported is greater which explains higher "density" of the sap at that moment.

Terrain and stand conditions affect the amount of synthesized materials, part of which is transported by sap. Birch trees on small and medium slopes, from stands with full or interrupted canopy on southern and western positions are capable to produce more sugars, as viewed in a broader sense, more "building materials" and nutrients.

Most of the variations in chemical composition between individual trees, beyond any doubt, are atrributed to genetic factor. This attitude is strongly documented in a number of scientific papers.
If one goes to a market-oriented production, at least two problems appear: shelf life and uniformity of the final product. And while the first question can be solved by known processing, the another one is difficult to be solved without "chemical intervention", in which case the product may compromise the attribute "organic".

Abstract

Forest fires destroy forests worldwide. Anthropogenic factors are the most frequent causes of forest fire. Negative consequences of forest fires in environmental and economic aspects are immeasurable and incalculable. Various preventive measures could be effectively used only if forest fires occurrence were discovered in the early stages (spatial and temporal). The use of modern technology can help in the forecast, detection, localization and fire extinguishing. Analysis of the vulnerability to forest fires is possible using Geographic Information System tools. Which provide thorough, time and spatial related analysis of parts of forest endangered by forest fire. Space surveillance and fire detection at an early stage might be carried with a watchtower or equipped by video surveillance. GIS tools provide the ability to set up an observation post simulation or camera system for identifying fire. Their use is obtained by covering the surface of each observation point, where it can be determined whether more observation posts or camera covering the same surface (location). The aim of this work is to analyse a rationality of settings of watchtowers by GIS tools.

Key words:*forest fires, GIS tools, watchtowers.*

Introduction

Forest fires destroy forests worldwide. In Bosnia and Herzegovina forest fires are the most significant cause of forest damage. In the period from 2008 to 2012 by forest fires 1118000 $m^3$of timber volume were damaged(FAO, 2015). High percentage of damages are consequence of ignoring the risk fires and preventive measures (FAO, 2015).

Various preventive measures can be used to minimize risk of forest fires outbreakor discover the occurrence in the early stages (spatial and temporal). The use of modern technology can help in the forecast, detection, localization and fire extinguishing. Analysis of the vulnerability of forest fires is possible using GIS tools (Fatih et al. 2014). In the analysis is needed to process the information about topography, vegetation, the usage of the ground, population and settlements (Xu et al., 2006), what is base for making the map of vulnerability. According to Ganteaume et al. (2013) the causes of forest fires are varied and their spatial and temporal distribution discerns from one to another country, and it also differs within the same country. One of the most common causes of the forest fires is human factor. Prevention measures are one of the most effective methods used in the wildfire protection (Fatih et al., 2014). The most commonly used method in prevention is forest monitoring (from the air or land). In this work the analysis of land monitoring and fire watchtowerswill be done. The watchtowers are usually used by the man, but recently surveillance is used more often. In both cases fire watchtowers must be positioned on the sites with best visibility covering the biggest area. The aim of this work is to determine the most effective and convenient position of watchtowers.

Materials and methods

Research area: The area under the management unit of Forest Estate "Romanija", Sokolac, (Entity of Republic of Srpska, Bosnia and Herzegovina) is located in 43º 56´ 09´´N and 18º 47´ 45´´E. It covers municipalities of Sokolac and Istočni Stari grad with surface of 794.23 km^2. It is a highland with distinguished configuration of the ground, where altitudes vary from 525 m to 1625 m.

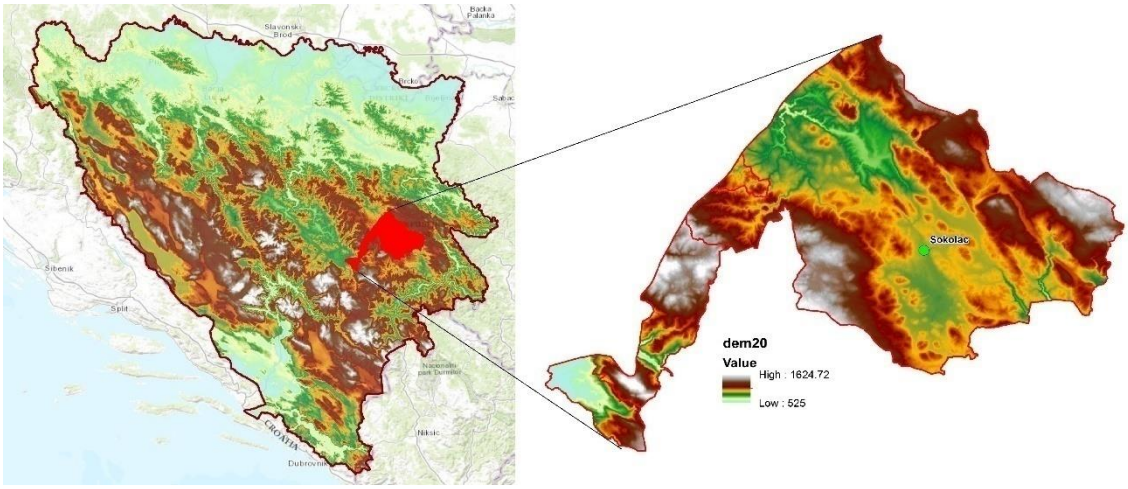

Figure 1. Object of research

Collecting data: In this work DEM (Digital Elevation Models) with resolution of 20m is used and it is made with Army-topographical maps. Data about roads and towns are taken from the base OpenStreetMap (2016). The position of the present watchtowers and forest density are taken from contemporary thematic maps used in Forest Estate "Romanija" (2013).

GIS preparation and analysis: The analysis is made with tools for raster analysis in frames of ArcGIS Platform. The height of watchtowers used for the analysis is 5 m. ArcGIS tools were used in calculation of surface which can or cannot be seen. In the part which cannot be seen from the watchtowers the altitudinal difference between the surface of the land and the height of the visible part is calculated due to be seen the largest depth of the invisible part (Above Ground Level). The Above Ground Level (AGL) result is a raster where each cell value is the minimum height that must be added to an otherwise nonvisible cell to make it visible by at least one observer.

The first thing done was to distinguish the sites where watchtowers might be built. These could be ridges, peaks and hills, and position of the watchtowers is on the highest altitude amongst them. Ridges and the highest points in the areas are gained via Topographic Position Index (TPI). Topographic Position Index (TPI) is an adaptation of this method which compares the elevation of each cell in a DEM to the mean elevation of a specified neighborhood around that cell (Abdollah, 2014; Weiss, 2001). Local mean elevation is subtracted from the elevation value at centre of the local window. Algorithm is provided as an ESRI tools.

$$TPI_i = Z_0 - \frac{\sum_{1-n} Z_n}{n}$$

Where;

Z_0 = elevation of the model point under evaluation,
Z_n = elevation of grid within the local window,
n = the total number of surrounding points employed in the evaluation

Positive TPI values represent locations that are higher than the average of the local window e.g. ridges. Negative TPI values represent locations that are lower e.g. valleys. TPI values

near zero are either flat areas (where the slope is near zero) or areas of constant slope (where the slope of the point is significantly greater than zero), high positive values relate to peaks and ridges.
The watchtower positions in ArcGIS are determined in three ways:

I. Using DEM only - The watchtowers positions are provided in the places where TPI showed a ridge or a hill, not counting any other factors.
II. Analysing DEM, roads, towns or areas covered with forests - A ridge or some other hill is gained via TPI, and then watchtowers are placed in the sites not covered by forests, near settled places (towns to 2 km, villages to 1 km) or roads (to 150 m)
III. Positioning already existing watchtowers - From contemporary forest fire maps are taken the locations of present watchtowers which are gained without the use of modern technologies.

While analysing each method the surface visible from every watchtower is calculated, and then these surfaces are lapped. We threw away the watchtowers or locations which were largely lapped with others, and having minimal covering surface because of their insignificant influence.

Results and discussion

In the next part, for each particular method, are shown results in tables which present mutual lapping of the fields visible from the watchtowers, and surfaces visible just from one single watchtower. On the photos is shown DEM with marked surfaces which are not covered from watchtowers and with gained values AGL.

Method I - Using this method we gained the locations of 24 watchtowers, which after mutual lapping and affirmed surfaces covered by them, were reduced to 6, covering 74053.18 ha or 93.23% of the overall research surfaces. The overall surface which can be seen from one watchtower is 18446.23 ha or 23.23% of the surface of the research area. The maximum value Above Ground Level is 254.19 m.

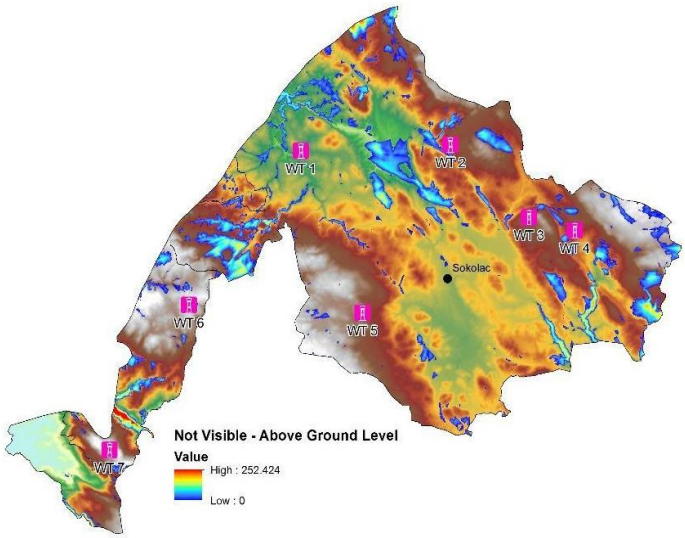

Figure 4. Method III - Spatial distribution not visible area with ABL

With the first method we provided largest visibility fields, while with the third way we got the smallest. During positioning of watchtowers in the first method we analysed only DEM, while other factors were not concerned. Here the watchtowers are located in the places of the highest ridges or peaks. Because the fact that these points may be situated in the forests,visibilitymight be declined or additional costs for setting the watchtower or opening the space around it might be needed. These watchtowers can also be far from the roads or towns and even unavailable in every moment. Opposite to this method, the second method covers smaller surface, but the watchtowers are located near the roads, towns and are not inside the forests. We did not locate all of the towers on the highest altitude points, but partly on the ridge or a hill depending on the free space which is not covered by forests. The number of the watchtowers is smaller, what can reduce the cost of the preventive measures. In the third method the number of the watchtowers is the largest. While setting the watchtowers the modern methodologies were not used, but they were settled according to the experience of the staff working on these job positions or on topographical maps.

While considering the surfaces covered just with one watchtower, id est the surfaces which are not overlapped with others, we can see that the largest surface is gained with method II. It can be concluded from the fact that the number of watchtowers is the smallest. With other methods we have larger number of watchtowers set in order to have better coverage of the

surface, accompanied with higher costs of maintenance. When we compare the position of watchtowers it can be seen that the location for two is identical in all three methods.
In all three methods the highest value AGL is on the same location of the research object. These locations are usually canyons, valleys or depressions. On this place, when the forest fire starts, the smoke must reach certain height to be seen from watchtowers, regardless to the method used because AGL is in all three cases pretty same. Beside all these fact, the support of local people who can be very helpful while doing everyday jobs. They are able because of configuration if the land, what can be seen in DEM.

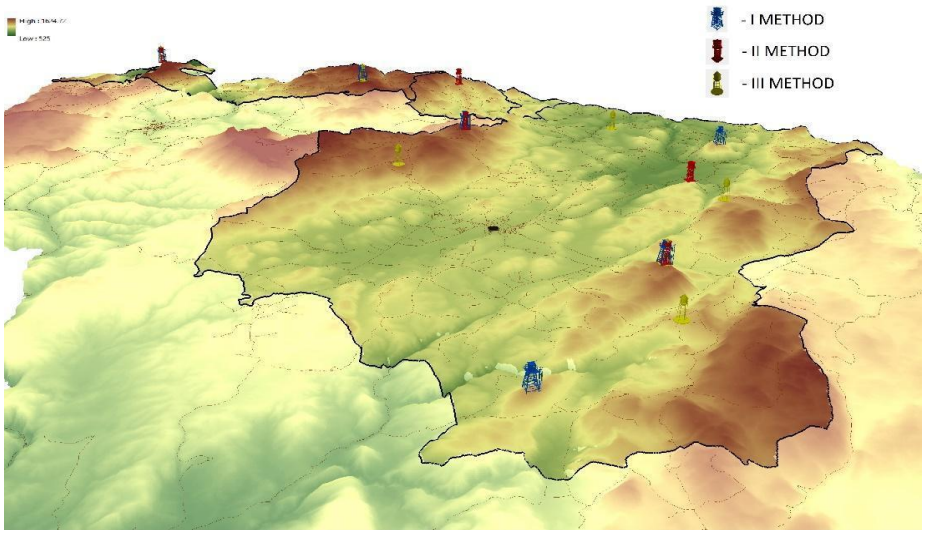

Figure 5. Spatial distribution watchtowers

Conclusions

When we consider all the information which can be accessed in every moment, it can be concluded that the use of contemporary methodologies in watchtowers settings can be helpful in their distribution. With first method we gained the largest visibility field, while with third the smallest.
The largest coverage surface with the smallest number of watchtowers is provided with method II. It can be seen from the fact that the number of watchtowers is the smallest.
In other methods we have larger number of watchtowers set to obtain better coverage, but with higher cost of their maintenance.
Locations got for watchtowers settings can be used for video surveillance which can detect automatically the smoke and then start the fire alarms.

STUDY OF THREE DIFFERENT METHODS FOR SUPPRESSION OF ASH WEEVIL

Milan DREKIĆ*, Leopold POLJAKOVIĆ - PAJNIK, Verica VASIĆ, Andrej PILIPOVIĆ, Predrag PAP

Institute of Lowland Forestry and Environment,University of Novi Sad, Serbia

Abstract

The ash weevil is the most important insect pestof ash in South East Europe. Mass occurrence of the ash weevil causes defoliation of ash that lead to growth reduction. The feeding of this pest has direct influence to physiological weakeningof colonized trees and creates preconditions for the development of secondary pests. This paper presents the examination results of three different methods for control of ash weevil adults. In field trials, we tested the effects of the use of cardboard niches, sticky tree belts and a biological insecticide containing conidia of fungi *Beauveriabassiana*, to the suppression of the ash weevil. As the direct protective measures the application of artificial cardboard niches for the overwintering adults proved to be much more attractive than the moss, that represent the natural shelter of the insect. Burning of the hibernating adults inside the cardboard niches would significantly reduce the population density. Despite the fact that high number of adults was recorded on the sticky bands applied to the stand-leaved ash trees, serious defoliation occurred.Due to the highnumber of caught beetles itmay be presumed that sticky tree bands application could reduce the population densityat certain level when used continuously, and this should be checked by further studies. Control of the ash weevil by applying abioinsecticide containing conidia of *B. bassiana* gave no positive results in suppression of the population density.

Keywords: *ash, weevil, Stereonychusfraxini, control*

Introduction

Outbreaks of the ash weevil *Stereonychusfraxini* De Geer (Coleoptera, Curculionidae) in ash stands and plantations are very frequent in Serbia.The ash weevil is distributed in Europe, North Africa and Asia Minor (Wingelmüller, 1921). In Serbia, it is registered on the narrow leaf ash, common ash and green ash (Drekić, 2011). Ash weevil outbreaks lead to defoliation of trees and ash stands, which causes growth reduction and physiological weakening. Published research data about the possibilities of ash weevil suppression are quite rare (Mikloš, 1954;Marović, 1963; Spaić and Mikloš, 1981; Cankov*et al*., 1990; Liović*et al*., 2001).Additional problem is that a large number of previously used insecticides today are not allowed for use in FSC certifiedforests. More recent studies have indicated the possibility of a successful application of fenthion, thiacloprid and bifenthrininsecticides for suppression of the ash weevil larvae and fenthion, thiamethoxam and bifenthrin for the suppression of adults of this insect species (Drekić*et al*., 2015).

Due to the fact that the chemical insecticides represent the contaminants for the environment we studied the possibilities of ash weevil control with the use of environmental friendly measures. The aim of this study was to investigate the possibility of protecting the ash using artificial niche, sticky belts and biological insecticide containing spores of the entomopathogenicfungus *Beauveriabassiana.*

Material and methods

Artificial cardboard niches were handmade and applied on total number of 54 ash trees in the forest of Branjevina near Odžaci(Serbia)on24th of April, 2009. The nicheswere placed around the trunk,atthe breast height of a standing person(Fig. 1).

Figure 1 Artificial cardboard niche on ash tree

The total surfaceof all mounted artificial cardboard nicheswas 9.36 m². The main aim of their use was to check their suitability as shelters for overwintering adults of the ash weevil. Artificial niches were removed from the trees on December 22nd 2009 and thoroughly observedin order to determine the number of hibernating ash weevil adults found insidethe artificialwinter shelter. The moss, that serves as natural shelter was removed from 41 trees mounted with cardboard niches and from 40 trees without artificial niches in order to determine the ratio betweenthe number of adults in the moss from the trees with and without available artificial niches. Collected moss was inspected in the laboratory for determination of number of adults.

Thesticky tree bands were set on 22 ash trees inthe forest of Branjevinaon February 27th2009. The belts were seton the trunk at the breast height of a standing person, onrepresentinga mechanical barrier for overwintered adults crossing from the ground and lower parts of the trunk to the tree crown and thereby to prevent defoliation of trees. The belts were inspected every 6-8 days and the adult ash weevils were counted. Assessment of damage to the leaves on the trees with sticky tree bands was performed at the end of June 2009.

Investigation of the possibility for thesuppression of adults overwintering in the moss was conducted on the 20thof November 2008in the Branjevina forest. The treatment was conducted by application of the biological insecticide containingthe spores of *Beauveriabassiana*in concentration of 2.11 x 10^{10} conidia/ml (commercial product:

BotaniGard SC).The test included 60 ash trees covered with moss:30 trees were treated with 0.5% concentration of the product, while other 30 trees remained untreated as a control group. The insecticide was applied with the hand sprayer. Moss was removed from treated and control trees on 21stJanuary 2009 and inspected in the laboratory in order to determine the number of dead beetles infected by*Beauveria bassiana*.

Results and discussion

After the inspection of 54 artificial cardboard niches, 525 adults of ash weevilwere found, resulting in the average number of 56,1 adults per square meter of cardboard niches surface.The moss was removed from 41 trees with cardboards, with the total moss surfaceof 12.73 m^2 andwith 52 adults recorded in the moss, resulting in the average number of 4.1 adults per square meter of moss. The number of adults per square meter of artificial niche was 13.7 times higher than the number of adults per square meterof natural niche. Such resultsindicate that the artificial niches were more attractive to the adults for overwintering then the moss on the same trees.

If we compare the average number of beetles per surfaceunit of moss removed from trees with and without set cardboard niches, the calculated number of 7.45 adults per square meter of mosson the trees without artificial niches was higher, but still significantly lower than the average number of adults recorded in the cardboards.Such results contribute to the presumption that the artificial cardboard niches are more attractive to the ash weevil as overwintering shelter than mosses andtherefore their control can be improved with the appropriate use of artificial, cardboard niches. Displacement and burning of the artificial niches with overwintering adults could significantly reduce the population density of overwintering adults .

Settingof the sticky belts on trees was conducted in order to test the possibility of theiruse to prevent the crossing of beetles whichoverwintered in the litter and in lower part of the tree trunk (below the belts) to the crown, and thus to prevent the damages. Adults of the ash weevil were recorded on sticky belts from the beginning of April to the first decade ofJuly (Fig. 2). The peak of the population density registered by this method was from the end of May to mid-June, when adults of the new generation appeared in highnumber on sticky belts. Despite the highnumber of adults trapped on the sticky belts, a significant defoliation over 50% was recorded. On the basis of obtained results, it can be concluded that the majority of adults in the spring flies to the crowns of trees. Such behavior resulted in low effectiveness of the applied sticky belts. However, the large number of adults caught on sticky belts demonstrate that this method, if used continuously, couldserve as additional tool to reduce the population density. However, further studies related to the most effective use of this method are needed.

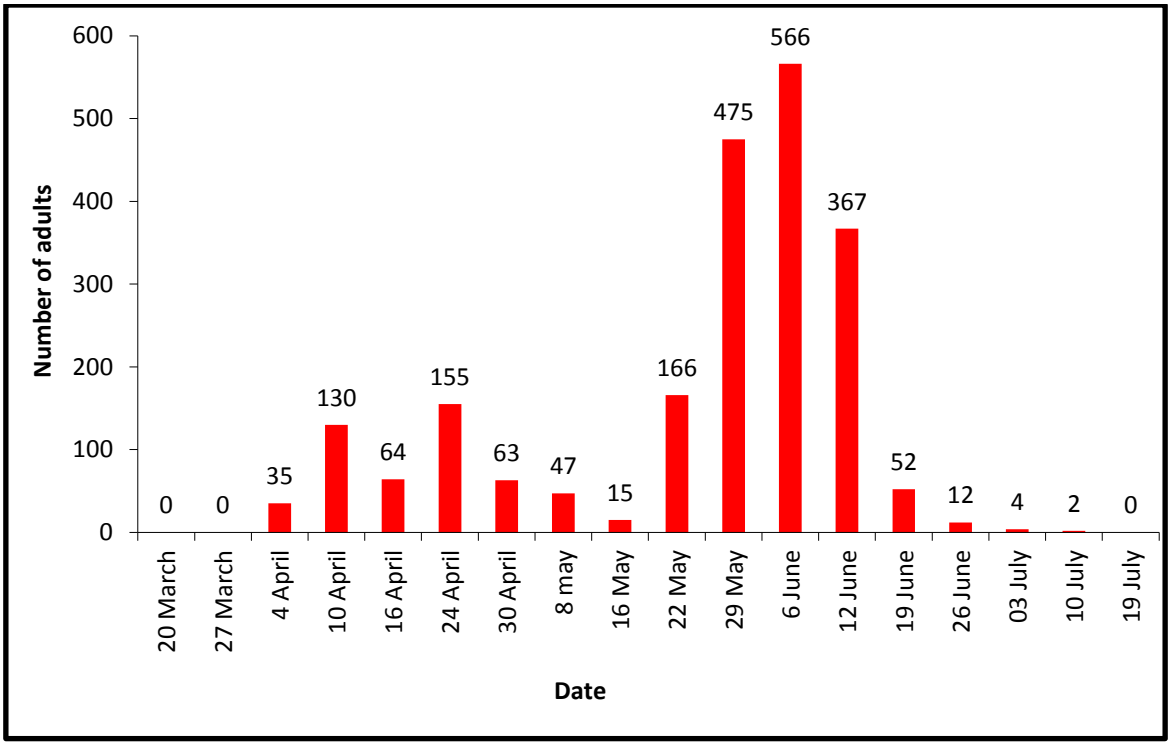

Figure 2Total number of adults recorded on sticky belts set on 22 ash trees in the forest of Branjevina (Odžaci, Serbia) during the season of 2009

After the detailed examination of the hibernating adults in the moss taken from trees treated with the bioinsecticideBotaniGard SC none of the recorded beetles shown signs of infection by the mycelia of *B. bassiana*. The occurrence of infected adults in untreated mosswas not recorded, as well. On the basis of suchresults, it can be concluded that the conductedapplication of this bioinsecticidewasnot effective in reducing the ash weevil population. In the researchesconducted by other authors (Markova, 1992; 1998; PernekandLacković 2011) *B. bassiana* was identified as a significant factor in reducing of ash weevil populations. On the other hand, the studyof Lacković and Pernek (2012) conducted in laboratory conditions shown that an experimental strain of *B. bassiana* from Hungary hadno effect on mortality of adults, while the contamination with spores of dead adults infected with *B. bassiana*authochtonous strain from Lipovljani(Croatia)resulted in the mortality rate of 83% of ash weevil adults. According to these authors, suchresults indicated the existence of a strain of *B. bassiana*, pathogenic for the local population of the ash weevil. This assumption mayexplain thelack of treatment efficacy of the applied product BotaniGard SC containing the unknown and probably non compatible strain of *B. bassiana*for the targeted insect population. Therefore, the future studies of biological control of the ash weevilshould give priority to the strains of entomopathogenicfungi isolated from the local populations of the pest.

Conclusions

Artificial cardboard niches were very attractive for overwintering of adults of the ash weevil. High number of recorded adults clearly demonstrated that artificial cardboard niches can be successfully used for the suppression of ash weevil population density. For this purpose niches should be placed on the trees starting frommid-May when adults of the new generation start to emerge..The cardboards with overwintering weevilshave to be removed and burnt at the beginning of autumn, at the latest untilthe beginning of March next year.

Sticky bands placed at breast height of the trunk in the early spring did not prevent defoliation of ash trees. Control of the ash weevil by applying acommercial bioinsecticide containing conidiae of *B. bassiana* gave no positive results.

Acknowledgments

This paper is part of the research done within the project III 43002 of the Ministry of Education, Science and Tehnological development of the Republic of Serbia.

Abstract

Forest management in protected areas requires multidisciplinary approach of both forestry and nature protection planning. The complexity of protected area management requires investigation of the issue from various aspects, including evolutionary analysis, program analysis (review of proclamation documents, plans for protection realization) and result analysis (that has been achieved by). When forests are managed in protected areas, one of the most important aspects is the harmonization of the goals set in forest management plans and in nature protection documents. To be able to cope with such a challenging situation, it is necessary to take a broader perspective, i.e. to look in detail at the bio ecological condition of the respective protected area, to analyse previous management regimes and to identify main problems to be worked on in the future in order to achieve the goals of sustainability and integral management. The aim of this paper is to analyse key aspects of the proclamation, the proclamation process, the participation and cooperation of stakeholders in that process, the legal base and other relevant documents about the proclamation and management by taking the case of the Special Nature Reserve "Kovilj-Petrovaradin Marshes" as a prominent protected area with significant share of forests. The paper also presents the main characteristics of the marshy wetland ecosystems, and analyse the primary objectives of protection, together with the measures already taken for their achievement. The analyses should serve as a base for later deeper investigation and analysing of potentials for integrated resource management.

Keywords: *Special nature reserve, Protection, Forests, Integrated management.*

Introduction

The need of people to protect natural areas for specific purposes reaches far into the past (Martinić, 2010). In India, some specific areas have been protected two thousand years ago with the aim to protect natural resources. In Europe, lots of forests have been protected as hunting areas about hundred years ago (Martinić, 2010). Nature protection presents a multidisciplinary approach of managing natural resources, which was created in order to solve numerous issuesfor thenature management in a sustainable manner(Panjković *et al*., 2016).
Special Nature Reserve "Kovilj-Petrovaradin Marshes" is a spacious flooded area by the River Danube in the south-east part of Vojvodina province in Serbia, with the total area of 5.895 ha ("Sl. Glasnik RS", br. 44/11). It spreads in the alluvial plane of the River Danube, in length of 25,6 km. It includes three divided unities: Petrovaradin marshes,that spreads on the right bank of the river (1.411 ha), Kovilj marshes, that spreads on the left bank of the River Danube (3.430 ha) and Krčedin island and a part of Gardinovci marshes (1.050 ha). The first regime of protection is established on 373 ha (6%), the second one on 1.738 ha (29%), and the

third one is established on 3.784 ha (65%). It is managed by the public company "Vojvodinašume".
Regarding the land use, it is mostly covered by forests (69 %), then by meadows and pastures (15 %), the share of water surfaces is about 8 %. The ownership of the land is as follows: state 4062 ha, other (Serbian Orthodox Church) 736 ha, mixed (Serbian Orthodox Church) 290 ha, mixed 357 ha, social 254 ha, private 194 ha (Panjković *et al*., 2010).
Mosaic of aquatic, marshy, wetland, meadow and forest ecosystems are the main characteristics of this area. The flow of the Danube has typical lowland characteristics that excels slow flow and small slope of the river. Sedimentation and deposition of the material transferred by the river resulted different orographic and hydrographic forms of relief with islands, elevated coastal beams and depressions in the lower parts. The whole area is cut by backwaters, meanders, ponds and swamps. Hydrological characteristics are defined by the permanent influence of flooding and groundwater (Panjković *et al*, 2010).
Depending on the relief and water regime, a variety of wildlife has been developed. 39 priority habitat types have been identified for protection on national and international level. 29 functionally instable and sensitive to degradation habitats are recorded, there are 6 rare habitats which regenerate slowly, and also two especially isolated habitats: forests of pedunculate oak and narrow-leafed ash (*Quercus robur, Fraxinus angustifolia*), and forests of elm (*Ulmus campestris*). 7 priority NATURA 2000 sites have been registered.
International importance: IBA area (9.594 ha), IPA area (142.376 ha including the Mountain Fruška gora), Ramsar area since 2012 (8.292 ha), ICPDR area by the Danube, DNPA area, EMERALD area (4.841 ha). Ecologically important area in Serbia: Fruška gora and Kovilj marches ("Sl. glasnik RS, br. 102/10).The affirmed conservationstatusdedicates the area a priorityin process of NATURA 2000 network designation, which is obligatory for all EU countries.
The reserve presents the biggest preserved wetland complex by the Danube in Serbia, which spreads in an inundation area and is in direct influence of the water level of the river.The aim of this paper is to provide analyses of the proclamation of the protected area as abase for further investigation of improved integrated resource management.

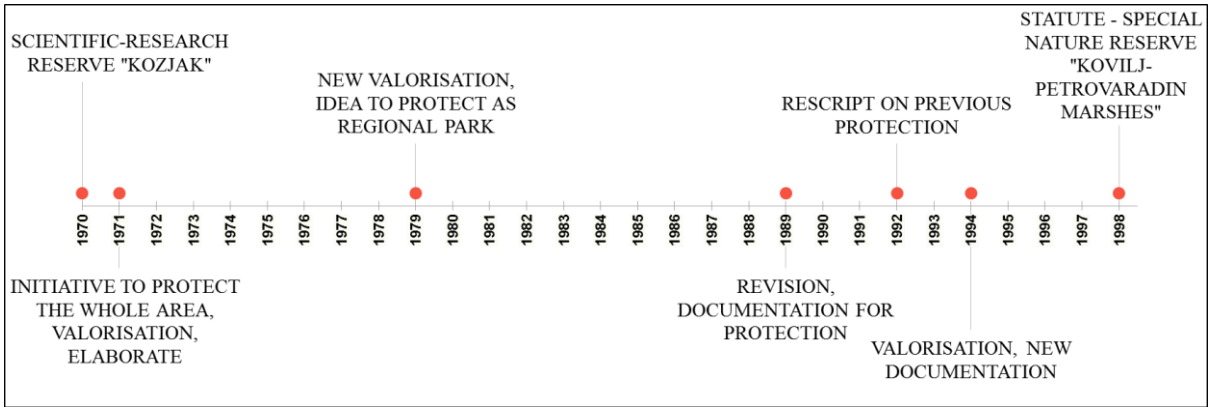
Materials and methods

Document analysis presents an iterative process which involves skimming (overview), reading (thorough examination) and interpretation. It combines elements of content analysis and thematic analysis. Content analysis is the process of organizing information into categories related to the central questions of the research (Bowen, 2009).
Different documents can be included for systematic evaluation as part of the study, such as advertisements, agendas, attendance registers, minutes of meetings, manuals, background papers, books and brochures, diaries and journals, event programs, letters and memoranda, maps and charts, newspapers press releases, program proposals, application forms and summaries, radio and television program scripts, organizational or institutional reports, survey data and various public records (Bowen, 2009).
Materials for this paper are all publications related to the examined protected area, the Study for the protection at the first place, but also other publications about the protected areas or nature protection both in Vojvodina province and Serbia. Management plans and revision documents have also been examined. All legal framework presented by Serbian laws or other legislation have been overviewed. Complete documentation about the protected area in the archive of the Institute for Nature Conservation of Vojvodina province has been prospected.
The main method of the research is analytical-deductive. Based on the existing knowledge in the references, documents, books, brochures, management plans and programs an analysis of the proclamation and the proclamation process of Special Nature Reserve "Kovilj-

Petrovaradin Marshes" have been done. The analytic procedure entails finding, selecting, appraising, and synthesizing data contained in these documents.

Results and discussion

The first recordings about the history of protection of Kovilj-Petrovaradin marches date from 1970. The Municipal Assembly of Novi Sad made a Rescript of protecting a part of Kovilj marches as a scientific research reserve "Kozjak" on 43,66 ha. The initiative to protect the whole area of Kovilj marches has been propounded by the Institute for Nature Conservation ofVojvodina province in 1971. They have made an elaborate about the valorisation of the area and the natural values of it. Suddenly it haven't been accepted a proclaimed as a protected area. In 1979/80 the Institute for Nature Conservation of Vojvodina province has made a new valorisation of the natural resources of Kovilj-Petrovaradin marches as an important, wider natural complex and proposed to protect it as a regional park. The municipalities in which the proposed protected area spreads didnot show any interest for the establishment of the spatial protection, and they didnot give their permission for it. Ten years later, in 1989/90, at the initiative of the City of Novi Sad, the Institute for Nature Conservation of Vojvodina province has again made a revision of the natural resources Kovilj-Petrovaradin marches. On the basis of this revision, it has begun the writing of the professional documentation for the proclamation of the protection of this area. In the meantime, there have been some changes in the territorial organisation of the municipalities on which the potential protected area spreads, so the protection wasnot proclaimed again.



Scheme 1 Proclamation process of Special Nature Reserve "Kovilj-Petrovaradin Marshes"

Regarding the crucial natural resources of this area and the necessity of the protection of the Danube wetland areas, and the marshy wetland areas in general, accordingly to the former initiative of the City of Novi Sad, the Institute for Nature Conservation of Vojvodina province on the base of 42. Clause of the Law on Environmental Protection ("Sl. Glasnik RS" 66/91, 83/92), issued a Rescript on previous protection of Kovilj-Petrovaradin marches. On the base of field examinations and evaluations in 1994, a new professional documentation about the protection has been made. The Statute about the protection of Special nature reserve "Kovilj-Petrovaradin marches" has been proclaimed in 1998. ("Sl. glasnik RS" 27/98). After that, two changes have been made to it about the list of cadastral parcels and the name of the manager of the natural resource („Sl. glasnik RS", 91/06, 81/08).

In the process of the revision of the protection and the expansion of the boundaries of the Special nature reserve "Kovilj-Petrovaradin marshes" several groups of stakeholders have been includedfor theparticipatory approach. They can be legal and natural persons who can have great influence on the success of the protection. The stakeholders are: the owners of the area (country folk, Serbian Patriarchate in Sremski Karlovci, Serbian Monastery of Holy

Archangels in Kovilj), managers and/or users (the protected areamanager, Water ManagementCompany "Šajkaška", Associations of stockbreeders from Kovilj and Beška, fishing associations, hunting associations from Kovilj, Beška, Gardinovci and Krčedin, weekend cottage villages), state and regional government with institutions (Institute for nature conservation of Vojvodina province, Secretariat for Environmental protection and sustainable development, Ministry of Environmental Protection and spatial planning), local government (municipality of Novi Sad, Sremski Karlovci, Inđija, Titel, local communities Kać, Kovilj, Petrovaradin, Gardinovci, Čortanovci, Beška and Krčedin), media, NGOs (Society for protection and study of birds of Vojodina. Arka, Epar, etc.). Some of these stakeholders are actively included in the process of protection, others are passively included (the protection affects them). The stakeholders can influence the protection and to support it, and also they can be against it (Panjković et al., 2010). Because of the great number and diversity of stakeholders, this area can serve as an assay protected area as an example of functioning of the needs of protection, owners, users and managers.

The stakeholders have been included into the process of proclamation through several meetings. On these meetings the representatives of the Institute for Nature Conservation of Vojvodina province presented the boundaries and the regimes of protection. They explained each measure of protection, and tried to harmonise the protection with the needs of the stakeholders. Public company "Vojvodinašume", as the manager of the protected area,Serbian Monastery of Holy Archangels in Kovilj (which owns 1094 ha of land in the protected area), and the Association of Stockbreeders "Dunav" have taken part in these meetings. The process of proclamation included a public hearing, too, where the study of protection was presented in detail to the interested stakeholders.

Urban and Spatial Planning Institute of Vojvodina has made the Spatial plan of the area of Special natural reserve "Kovilj-Petrovaradin marshes". They wanted to include the local community in the drafting of it, so they organised a meeting in the local community "Kovilj". Beside theInstitute for Nature Conservation of Vojvodina province and theSecretariat for Environmental Protection and Sustainable Development, numerous stakeholders took part in it: representatives of the managers, Serbian Monastery of Holy Archangels in Kovilj, Associations of Stockbreeders "Dunav", local community "Kovilj", association of citizens"Ekofarmer", The Planning Institute of Vojvodina, Public company "Institute for City Development" and NGO "Arka".

The main questions about the management, use and promotion of protected areas are defined by the provisions of the Law on Nature Protection ("Sl. glasnik RS", 36/09, 88/10, 91/10). In the means of this Law, for every protected area a special act about the protection has to be done. This act defines the measures and the regimes of protection, and defines the legal entity, the manager of the protected area, who implements the regimes of protection and prepares a management plan.

The regimes and the measures of protection have been defined to protect water, marshy, meadow and forest flooded habitats as priority habitat types, aimed to conserve the protected species characteristic for those habitats (Panjković *et al.*, 2010). According to Puzović et al., the main objectives and methods of conservation in the "Kovilj –Petrovaradin marshes" are:

- Preservation and enhancement of natural resources by using active protection measures;
- Restoration and conservation of natural habitats and their mosaic layout;
- Ensuring of flooding of fish habitats and supply of the marshes with fresh river water by maintaining the channels and backwaters;
- Revitalisation and maintenance of sensitive habitats of ponds, wet meadows, pastures and swamp forests;
- Traditional using of wet meadows and pastures, encouraging grazing and mowing;

- Increase in forest area of autochthonous tree species, with reduction of the share of clonal plantations of poplars and willows, and invasive tree species;
- Preservation of trees, and groups of trees with pedunculated oak, narrow-leafed ash, elm and black poplar, as edificator species in natural forests of the marshes;
- Repression and prevention of the spread of invasive species;
- Development of a program of ecological education and promotion of the protected area.

Picture 1 Panorama of the wetland[1]

Picture 2 Panorama of the wetland[2]

Since the protection was proclaimed, numerous projects included in the multi-annual programs have been carried out. They were oriented on site and species protection, on improvement on water regime, construction of infrastructure for education, recreation and promotion of the protected area. These activities have made significant contribution to the improvement of natural resources and to strengthening ecosystem services of this protected area (Stojnić *et al.*, 2015.).

Puzović *et al.*, (2015) highlights some activities as major ones since the protection was proclaimed. These are dredging of the canals of the old Danube, ecological restauration of wet habitats on the Kurjačka beam (a natural rise in the wetland), revitalization of wet and swamp habitats of Šlajz-Tikvara location and grazing and promotion on Krčedinska island.

Conclusions

Special Nature Reserve "Kovilj-Petrovaradin Marshes" is a spacious flooded area by the River Danube which spreads on 5.895 ha, managed by the Public company "Vojvodinašume".It presents the biggest preserved wetland complex by the Danube in Serbia, which spreads in the inundation area and is in direct influence of the water level of the river. Mosaic of aquatic, marshy, wetland, meadow and forest ecosystems is the main characteristic of this area. Depending on the relief and water regime, a variety of wildlife has been developed; more than 70 habitat types have been identified to be important for protection on national and international level.

The first recordings about the history of protection of Kovilj-Petrovaradin marches dates from 1970, when a scientific research reserve "Kozjak" has been established on 43,66 ha. In 1971 the Institute for Nature Conservation of Vojvodina province made an elaborate about the valorisation of the area and the natural values of it with the aim to protect the whole area of Kovilj-Petrovaradin marshes. Since it wasn't accepted, they have done a review first in 1979/80, then in 1989/90 years. In 1994 the Institute for Nature Conservation of Vojvodina province issued a Rescript on previous protection of Kovilj-Petrovaradin marches. Finally, the

[2] Source:http://goo.gl/yhdex9, accessed June 2016.

Statute about the protection of Special nature reserve “Kovilj-Petrovaradin marches” has been proclaimed in 1998.
Great number and different stakeholders, such as state institutions, managers and users of the protected area, associations and NGOs are interested in the use of the area of the reserve so it can serve as an example for examination of the harmonisation of their goals and needs.
The regimes and the measures of protection have been defined to protect water, marshy, meadow and forest flooded habitats as priority habitat types aimed to conserve the protected species characteristic for those habitats. Since the protection was proclaimed, numerous projects oriented on site and species protection, on improvement on water regime, construction of infrastructure for education, recreation and promotion of the protected area have been carried out. These activities have made significant contribution to the improvement of natural resources and to strengthening ecosystem services of the protected area.

THE EFFECTS OF ENVIRONMENTAL IMPACT ON CONIFEROUS FORESTS OF THE WESTERN PART OF LATVIA

Oskars ZAĻKALNS[1,2*], Imants LIEPA[1]

[1]Department of Silviculture, Forest Faculty, Latvia University of Agriculture, Latvia

Abstract

The quality of Latvia's environment is influenced by many natural and anthropogenic factors whose proportions and intensity depends on local and global processes. Effective and quick evaluation of environment's quality with bioindication methods allows obtaining a concept of the real situation that derives from a sum of factors affecting the environment. Therefore nowadays not only felling of trees and recreation are affecting forest ecosystems, but also changes of environmental conditions, including chemical and physical factors. It must be emphasised that environmental factor impact on forest ecosystems is accumulating gradually and visually it is difficult to be discovered. The territory of the research covers Kurzeme region, which is located in the west part of Latvia or in the east of the European Union. Previous researches in this field in Kurzeme have fragmental features – they include impact evaluation of separate factors in separate stands. The analysis of environmental impact on forest ecosystems has theoretical and practical characteristics. Additional increment has been used to evaluate how stand has formed in a specific period of time. To demonstrate the accumulation course of environmental impact (or impact trend) the additional cumulative volume increment m^3m^{-2} per year has been used, which allows comparing different component and stand densities, or their parts. Total impact of environmental factors were evaluated in two categories: in the first category are those impact parts that can be explained with a common parameters for all sample plot stands. Second category is represented by only specific (local) factor impacts of each sample plot stands. A pronounced both category fluctuation of environmental impact in the territory of Kurzeme has been observed. The economic losses that results from the wood losses estimates 198 EUR ha^{-1} per year on average.

Keywords: *environmental impact, Norway spruce, dendrochronology, volume increment.*

Introduction

There are only few places in Latvia where forests are not growing. But without an anthropogenic impact these wooded areas would have been much greater. The highest forest cover percentage in Latvia was reached approximately nine thousand years ago when forests covered 90 % of the present day national territory. Humans have increased their material welfare with the use of forest resources. At the beginning forest was used with explicit restrictions, but with time the sphere of activities has increased. The environmental diversity of Latvia depends on the impact of not only Latvian, but also transboundary pollution, climate and other global process activities.

Environmental quality, including air quality, in Latvia is affected by stationary and mobile emission sources of pollutants, and also transboundary air pollution, which by its volume can be compared to the local pollution created in the territory of Latvia. The quality of air, chemical composition of precipitation, and sedimentation of substances on soil and in water are impacted by the composition and concentration of pollutant substances. Air pollution is

causing or favouring such environmental phenomenons as acidification, eutrophication, air-ground ozone formation and accumulation of dangerous chemical substances in living organisms.

Therefore nowadays not only tree felling and recreation are affecting forest ecosystems, but also changes of environmental conditions, including chemical and physical factors. It must be emphasised that environmental factor impact on forest ecosystems accumulates gradually and is visually hard to detect. When the visual signs of destruction appear (discoloration, defoliation, dieback of tree tops and branches) most likely it is too late to do something in the context of forest protection. The dendroindication has an advantage – impact effect is accumulating in the annual growth rings of a tree and it is possible to estimate impact volume of environmental changes starting from its first years. Electromagnetic radiation (high–voltage power lines, mobile communication transmitters, different types of radio transmitters) and radioactive radiation belongs to the physical factors, but air pollution with such dangerous impact sources as heavy metal, sulphur, nitrogen and other compounds are known as chemical factors. Sulphur and nitrogen compounds in a moist (with precipitation) and dry (aerosol) form produce sediments that change the reaction of precipitation and pH, thus, affects ecosystems (soil, surface waters, forests), and also buildings and cultural objects.

The method of environmental parameters provides a value determination of the assessed environmental factors and their comparison with critical or normative values. In most of the cases the normative values are adopted by the national parliament or government, surely, if possible, taking into account the statements of ecological studies. It must be noted, that not always they reflect the real situation. Furthermore, significant role is to the subjective option of decision makers, namely, with the increase of the level of normative values it is possible to manipulate with the evaluation of environmental quality, when hazardous environments are "made" safe. Secondly, the intercorrelation of the numerous environmental factors is very important. In the result, the same level of a factor in one growing conditions can show a different impact in other conditions. It must be taken into account when assessing territorially wider regions. Thirdly, one of the specific characteristics of environmental factors is their dynamics; complexes of factors and the impact level of separate factors are changing over time. Thus, once adopted normative values cannot be permanent. The usage of environmental parameter methods is limited by the second component – the accuracy of determination of environmental factor value, which, despite the use of standard procedures, cannot entirely exclude the stochastic nature of ecological factors (Лиепа, 1980).

The results of all the environmental factors are present in Kurzeme, furthermore, they have pronounced features of territorial and temporal fluctuations. Previous studies in this field in Kurzeme have a fragmentary character – they include assessment of factor impact in separate forest stands. The research of this study is connected to a development of a continuous network of bioindication stands and assessment of the complex impact of environment in the territory of Kurzeme in the period from 1989–2008. The analysis of environmental impact on forest ecosystems has a theoretical (ecological aspects) and practical (silvicultural and economical assessment) nature. Such problems affect many countries. When dealing with these common problems, solutions that were obtained in relation to the impact of changes of environment and its diversity in Kurzeme, has an informative value for interpreting the condition of the European forest ecosystems.

Materials and methods

The territory of the research covers Kurzeme region, which is located in the west part of Latvia or in the east of the European Union. It borders with the Baltic Sea in the west and with the Gulf of Riga in the north and northeast, with Zemgale and Riga region – in the east, and with Lithuania in the south. Territory of the region is 13 607 km^2 or 21% from the territory of Latvia[1].

Forests stands, which contain bioindication plots, are located in Kurzeme and some of them are located in the northwest of Zemgale. Sample plots are located both in maritime lowlands and Kurzeme highlands reaching the tilt of the middle of Latvia (Fig. 1.1).

In Kurzeme the dominant wind direction changes depending on the season. Such wind directions can ensure the transfer of air pollution from industrial objects (in Liepāja, Mažeikiai) to forest stands in the research territory. The dominant tree species in forests of Kurzeme, according to the State Forest Service data (CD 2010)[2] is pine (*Pinus sylvestris* L.) which grows in 45% of the total forest area, second most common species is birch (*Betula* sp.) 26%, and third most common species is Norway spruce with 18%.that most of the plots are established in the most suitable type for spruce – *Oxalidosa* (36%). Then follows the *Hylocomiosa* forest site type with 30% of plots. Other forest site types in total cover 34% from all the sample plots of the study. After assessment of existing industrial objects that could discharge pollution into environment (Tabors et al, 2001; Nikodemus et al., 2004) and also cause a pollution impact on trees, a data about these industrial objects were collected from public data basis, where companies have decelerated them. After analysing these data, and also the experience of other scientists (Ashby, Fritts, 1972; Ловелиус, 1979; Скудра, 1982; Шевякова, Кузнецов, 2000; Tabors et al, 2001; Pärn, 2006), the potential impact of pollutants on the environment in Kurzeme forest stands can be analysed. Special attention has been turned to the amounts of NO_x and SO_2 emissions. These chemical substances are active participants in the processes of photosynthesis and are affecting plants directly.

In the region of this study the major air pollution with SO_2 is produced by Mažeikiai oil refining factory. Considerably smaller SO_2 emission amounts are produced by Brocēni cement producer Cemex Ltd. and JSC Liepājas metalurgs. Some of the stands that are included in this study are exposed to the impact of SO_2 emissions, which are brought by the dominant winds.

Sample plots were created in the summer–autumn period of year 2008 and the spring of year 2009. To represent all Kurzeme region – two transects were chosen with 15 sample plots on each of them (Fig.1). The area of each sample plot is 400 m^2 (20x20 m) with a condition that there are at least 20 bioindicator sample trees in it (overstory trees with no visual signs of damage), if the number of trees is insufficient, then size of sample plot was increased so that the needed number of trees would be included. The centres of the sample plots were selected so that they would represent larger variety of stand densities.

Height measurements were performed with Suunto type clinometer with a precision of ±0.5 m, and with a 20 m measurement base, giving a higher probability to avoid errors. Samples were extracted at 1.3 m height above root collar. Boring was performed from S or SW direction, perpendicular to the stem growth axis in the direction to pith, additionally marking trees with signs of rot. In total, 655 core samples were collected. For each bioindication sample plot one common reference stand was selected (coded with symbol K) with similar growth conditions and without deformation, defoliation and wind damage signs. In this research, the last 40 annual rings from year 1969 to 2008 were used, which correspond to 20 years of assessment and 20 years of retrospection period. To evaluate the environmental impact – the Norway spruce response reaction was used and expressed with cumulative and current additional volume increments.

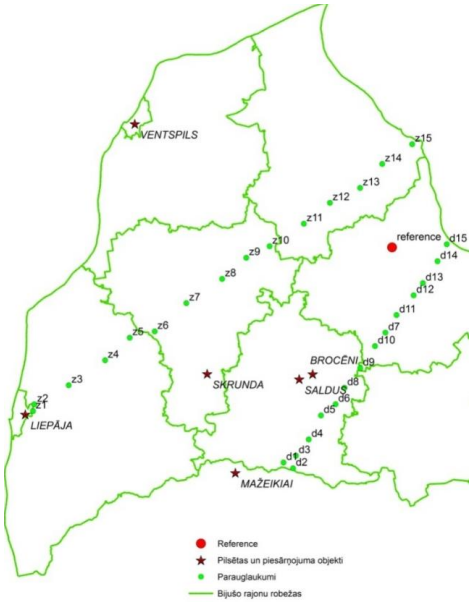

Fig. 1 Location of sample plots

.The additional volume increment is understood as an increase or loss of growing stock, which has originated in the influence of the researched factor (Liepa, 1996). Thereby, in the increase of tree or stand taxation parameters two components can be divided: uninitiated increment, which would have been produced even without the realisation of the assessed impact, and additional increment, which has been produced exactly due to this factor's impact. Only additional increment reflects the characteristics and magnitude of the assessed impact. The sum of both – components or the integral increment gives incomplete information, because natural fluctuations are partially evening out the impact effect of a factor.

Results and discussion

To demonstrate the accumulation rate of environmental impact (or impact trend) the reduced cumulative additional increment m^3m^{-2} has been used, but to reflect the annual changes of impact – the reduced current additional increment m^3m^{-2} per year was used, which allows to compare stands (or parts of stands) of various composition and stand densities.

Forest stands with various age, composition and stand densities can be compared with the usage of reduced current and reduced cumulative additional increments. It is possible, because additional increments are attributed to 1 square meter of stand's basal area. For example, Figure 2 shows the accumulation rate of reduced additional increment of five different stands in a 20–year period.

Environmental factors can either improve or aggravate the physiological condition of a tree, and that shows in the tree reaction. Researched stands according to the characteristics of spruce response reaction trend can be divided into three groups: positive, negative and neutral. The positive response reaction of stand shows a positive impact of the researched factor, but negative value indicates to a decreased biomass production. If the value is zero, then the impact is equal to the background level (Liepa, 1996). The Figure 2 shows previously mentioned groups. What could affect the growth and development of spruce stands in Kurzeme? Firstly, it could be air pollution that can enter the atmosphere from industrial companies in Latvia and Lithuania.

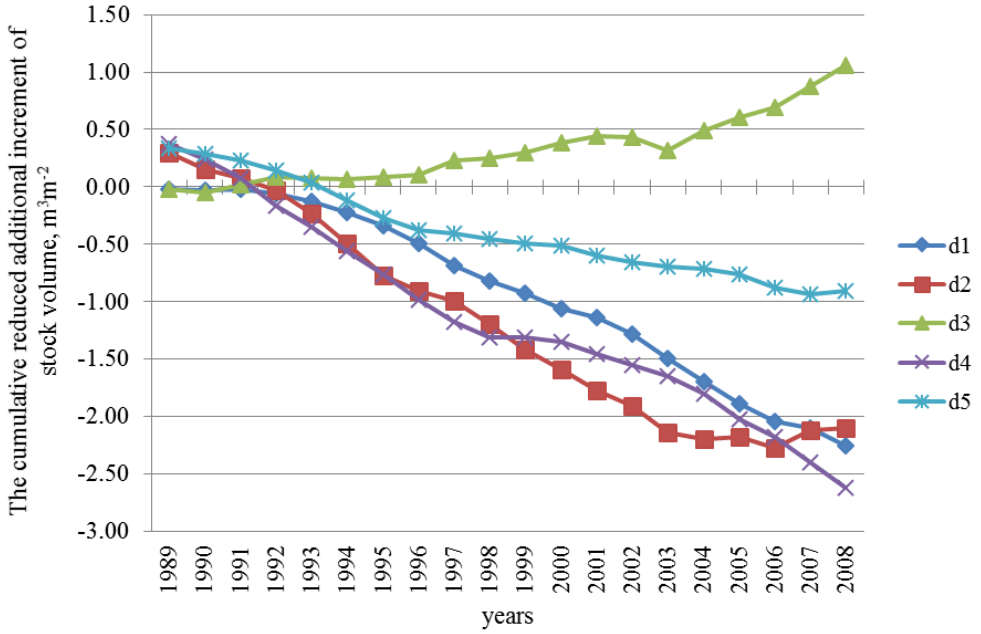

Fig. 2 Changes of cumulative reduced additional increment in a 20-year period

The impact of these and other abiotic factors on coniferous tree stands and their mineral supply has been researched also in Estonia, (Pärn, 2006), Lithuania (Stravinskiene, Erlickyte, 2009), Russia (Шевякова, Кузнецов, 2000), and other countries. The response reaction of coniferous trees is similar to the control trees, or even showing some fertilisation effect from cement dusts (Lukjanova et al., 2010). This impact has to be taken into account when analysing the impact of air pollutions in Kurzeme – due to the Brocēni cement factory – not taking into account that closest spruce stands are located more than 10 km away from this factory (the closest sample plot from Brocēni cement factory is d8 with a distance 11.5 km from factory). P. Skudra in his research, already, in 1960s–1970s has observed similar tendencies. In the planning of the research, an idea about the substantial impact of polluted air from industrial objects, which are located near Mažeikiai, Liepāja and Brocēni, was considered. If that is the case, the values of cumulative additional increment should show a trend dependency on the location of plot with the distance from the pollution source. There is dependence, but not a trend, which clearly shows its local origin with intensifications.

The economic effect assessment of the total environmental factor impact in monetary terms has been reflected show the gained or lost value of wood of separate stands in the whole assessment period in total and as an average value of loss per year. The average wood prices of year 2009 and 2012 in Kurzeme were used for the evaluation; prices are presented in data bases of Central Statistical Bureau. Since wood prices of separate years can differ greatly, then prices of two years were used in the economic calculations. The prices of 2009 were selected because 2008 is the last year of assessment period, however, 2012 was selected because it is the most recent information available in the data bases. Such solution is better compatible with the assortment outcome.

Losses, estimated by the prices of 2012 for the not produced wood due to various environmental factors in transect “D” in 20 year period on average comprises -3877.83 EUR ha^{-1} or -193.89 EUR ha^{-1} per year. In the same time, the average losses of transect “Z” in 20 years comprises -4011.80 EUR ha^{-1} or -200.59 EUR ha^{-1} per year.

Conclusion

1. The spruce stands included in the research, they are located in different edaphic, orographic and of other abiotic and biotic conditions. The dendroindication method was used for evaluation of total environmental impact. The response reaction of spruce to the impact of environmental change in a 20 year period (1989–2008) was expressed with the cumulative and current additional increments.
2. Total impact of environmental factors were assessed in two categories: first category consisted of those impact parts that can be explained with parameters common for all sample plots. The impact of these parameters was expressed with a multiple linear regression. Second category is represented by only specific (local) impacts of each sample plot.
3. According to response reaction the spruce stands of Kurzeme can be divided into three groups: with a positive impact trend; with negative impact trend; stands with a background trend.

Abstract

Defining growing space is one of the basic elements of the plantations of fast growing tree species, such as poplars, because of it depends on the length of the production cycle, the dimensions of the trees and the economic profitability of plantations. The paper shows possibility of using the area potentially available (APA), as an expression of growing space of trees, in the poplar plantation of clone B-229 which has been established in planting space of 5 x 5 m and where in a part of plantation after 8 years thinning has been performed. The experiment was established in a block design with three replications with the control and the experimental sample plots each of 0.1225 ha, or total of 0,735 ha, where diameters at breast height of all trees were measured after 8 and 11 years, as well as the elements of the spatial position of the trees. Area potentially available is defined as a polygon that is determined by the position and diameter of the tree and its neighbors by the method of Moore et al (1973). The results showed that area potentially available was an average of 26.6 m^2 in the part of plantation where thinning operation has not been implemented and 52.1 m^2 in the part where thinning was conducted. Correlation of diameter and basal area increment with area potentially available on the control plot is positive and highly significant, ie. 0.7 and 0.76, respectively. However, the correlation is very low (0.2 and 0.35) and not significant in the experimental plot

.

Introduction

Competition among individual trees is a fundamental ecological process that shapes plant growth, plays a major role in population dynamics, survival, growth and species replacement and provides the basis for density management of tree plantations (Peet & Christensen, 1987; Vanclay et al, 2013). Competition may be defined as an interaction between individuals, leading to a reduction in the survival, growth and reproduction of the competing individuals (Begon et al, 2006) and is summarized as the action on, and reaction to, their living environment (Ford & Sorrensen, 1992). Tree compete for a variety of resouces including light, water, nutrients and physical space. As trees grow, they modify their surrounding environmnet and alter the ability of their neighbors to acquire resources (Weiskittel et al, 2011).

Competition processes have been defined according to two basic models: symmetric/asymmetric and one-sided/two-sided competition. In two-sided competition resources are shared (equally or proportionally to size) by all the trees while in one-sided competition larger trees are not affected by smaller neighbours. When there is perfect sharing relative to size, competition is symmetric (Soares and Tome, 1999)

The effect of local neighbors is usually expressed by some mathematical fomulation, commonly referred to as a „competition index“, representing how much each tree is affected by its neighbors (Burkhart and Tome, 2012).

Such an index should properly account for the size of the subject tree and size and spatial pattern of neighboring trees, and it should both reflect the current competitive status of the subject tree and changes in that status over time. According to Nance et al (1983), such index exist in the form of „area potentially available“ (APA).

Brown (1965) introduced a measure, termed area potentially available (APA), that partitions the total stand area (and, thus, associated resources) into that potentially available for each tree (Daniels et al, 1986). This involves computation of the Dirichlet-Thiessen tesselation, as a special way of defining neighbourhoods, which involves „tiling“ the plane according to the position of plant individuals, so that each of them has a polygonal area around it. Polygon determined in this way, also called a Voronoi polygon, is a set of points closer to that focal individual than to any other (Czaran and Bartha, 1992). Polygons are mutually exclusive and collectively exhaustive of the total area. Thus, the individual polygon areas sum to the total area (Daniels et al, 1986).

The Dirichlet tessellation assumes equal weighting of individuals, since the boundary between any two points is a perpendicular bisector. When individual plants in a population vary in size, however, interest may focus on methods to weight the polygons to account for size differences. Moore et al. (1973) developed a competition index for use in forestry based on a weighted polygon model. Their model has the following properties: (a) like Dirichlet tiles, weighted polygons are mutually exclusive; and (b) the weighting is proportional to the relative size of neighbouring trees. As a weight authors used basal area of trees. A given polygon border is perpendicular to the line joining two individuals, but passing through the weighted distance instead of the bisector. The resulting tessellation has the undesirable property of not being space-exhaustive: there remain areas which are not assigned to any individual. Polygon overlap is avoided by having lines nearest the target individual take precedence over those further away (Kenkel, 1991).

Poplars, as a light demanding tree species, strongly react to density of plantation, ie. a space for tree growth, which allows the establishment of plantations with different densities for different purposes. Plantation density is the main element which conditions the purpose of production and targeted assortment, and thus the quantity and quality of timber volume and length of rotation. Thinnings are carried out in poplar plantations, as one of main silvicultural measure, with the aim of obtaining the previous yield in the form of pulpwood or thinner technical assortments, and it is expected that the remaining trees in the longer rotations achieve more quality assortments.

The aim of this work is to examine the possibility of using area potentially available in poplar plantation with different thinnig regimes (with and without thinning) by finding a correlation of current increment of trees, as one of the reliable criteria of competitive relations in plantation, and the area potentially avilable of the same trees.

Materials and methods

Researches were conducted in an experimental plantation of the clone "Bora" (*Populus deltoides* Bartr. Ex Marsh.), working name B-229, which was established with one year old plants type 1/1 at planting distance of 5 × 5 m. Plantation is located in Forest holding „Sremska Mitrovica“ (Serbia), Management unit „Čenjin – Obreške širine“, in department 13 (N 44^{o}42', E 19^{o}57'). In the first eight years, before establishment of experimental plots, in the plantation were performed usual tending measures: the row disking was done every year, and filling in and hoeing area with a width of 1 m around the plants was done two years after planting. The pruning of lower branches to the height of 6 m was also carried out in plantation, in order to obtain the best quality assortments at the end of the production cycle.

The experimental field is in the form of three blocks with two experimental plots, each the size of 0.1225 hectares, which are separated by a so-called „protective“ row. In each block on

an experimental plot the selective thinning was carried out (experimental plot - EP), by defining and marking so-called „perspective trees“, approximately uniformly distributed over the area with an average distance of 7 × 7 m, ie. 204 trees ha^{-1}. All remaining trees in the experimental plot were removed. The remaining three plots were control plots (CP).
On the experimental and control plots all trees were numbered, and after 8 and 11 years their two cross diameter at breast height were measured, with an accuracy of 1 mm, as well as the elements of the spatial position of the trees.
Area potentially available is defined as the area of an irregular polygon constructed around a subject tree. The polygon is formed by intersecting lines (influence lines) that are located between and perpendicular to the lines connecting the subject tree and each of its competitors (Nance et al, 1983).
Computationally, the construction of Voronoi polygons is quite complex (Green and Sibson, 1977). Basically, the computations consist of two tasks: the location of a set of nearest neighbors for each tree, and the construction of the edges or sides of each polygon. In establishing the location of each edge, lines connecting the subject tree with each of its nearest neighbors are established, and perpendicular lines are then formed to cut these connecting lines. The intersecting perpendiculars form the sides of the polygon. We use weighted tesselation, so the perpedicular bisectors are displaced away from the larger tree and closer to the smaller tree by an amount proportional to their diameter difference.Computations were performed using a program developed by the authors.
For a construction of area potentially available only inner trees were used, so size of each plot is 0.0625 ha.Descriptive statistics, regression analysis and t-test were used in the data processing.

Results and discussion

The area potentially available (APA) of poplar clone B-229 trees on the sample plots is shown in Figure 1, while Table 1 shows their descriptive statistics. On the control plots (CP) an area potentially available ranged from 10.4 to 39.6 m^2, an average of 26.65 m^2, while on the experimental plots (EP), where the thinning operation was performed, ranged from 34.2 to 109.7 m^2, an average of 52.13 m^2. On the control plot is determined two time less standard deviation of APA in comparison to experimental plot, while the coefficiet of variatiuons was 26-28%. The asymmetry of the distribution of APA is negative and leptokurtic on both, the CP, and the EP.

Table 1. Descriptive statistics of an area potentially available for research plots.

Plot	n* [trees]	mean [m^2]	min [m^2]	max [m^2]	sd [m^2]	cv [%]	skew	kurt
CP	69	26.65	10.38	39.65	6.94	26.0	-0.310	-0.367
EP	42	52.13	34.16	109.68	14.71	28.2	1.871	4.868

**n* – number of trees in plots; *mean* – arithmetic mean; *min* – minimum; *max* – maximum; *sd* – standard deviation; *cv* – coefficient of variation; *skew* – skewness; *kurt* – kurtosis.

On the EP is determined twice the mean size of the APA as a result ofthinning operation, which reduced 45% of the number of trees (Andrašev et al, 2011).While the trees in the inner part of the EP had less APA with slight differences in the length of sides of polygons, the other trees had great sides of polygons in parts of sample plot where competitors are removed (Figure 1).

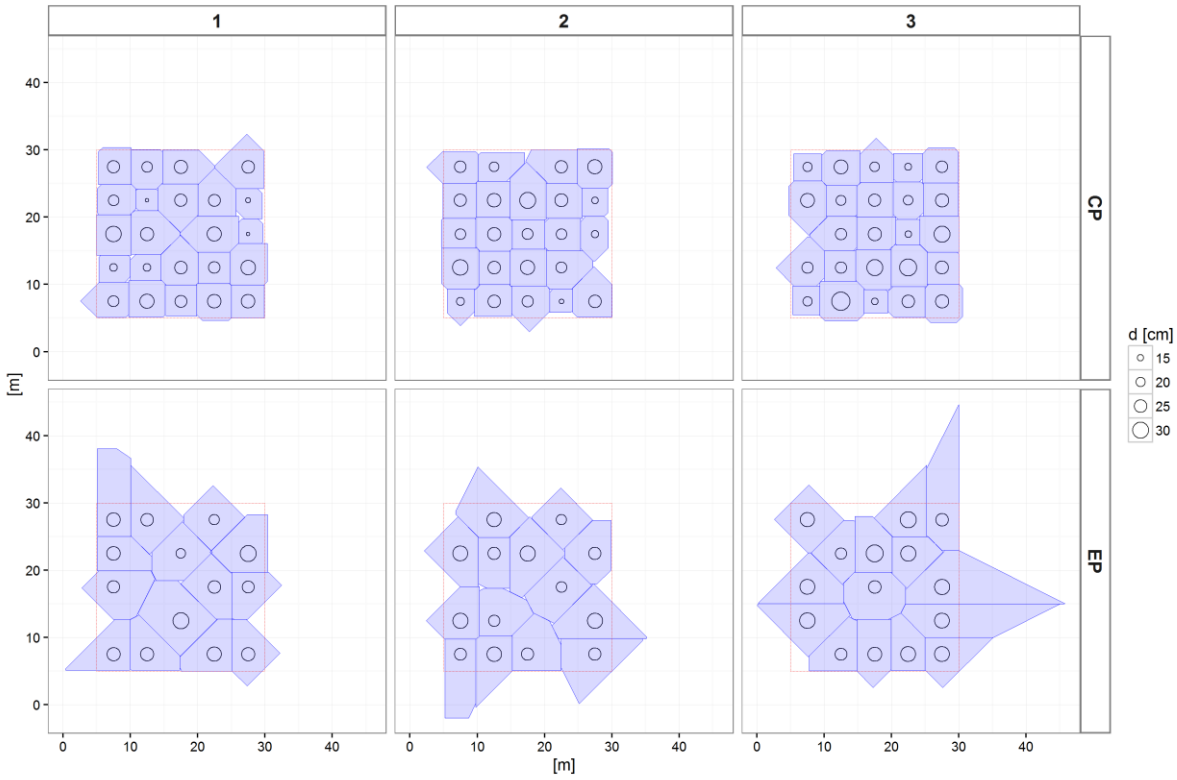

Figure 1. Area potentially available for the research plots.

Correlation of the current diameter increment over the next three years (from 8 to 11 year) with the APA defined in the eighth year shows high significant positive correlation of 0.7 on the CP. On the EP correlation is 0.2, and is not significant (Figure 2, Table 2).
Correlation of the current increment of the basal area of trees is also positive and highly significant, and higher (0.76) compared to the correlation of the diameter increment. However, the correlation on the EP was not significant (Figure 3, Table 2).

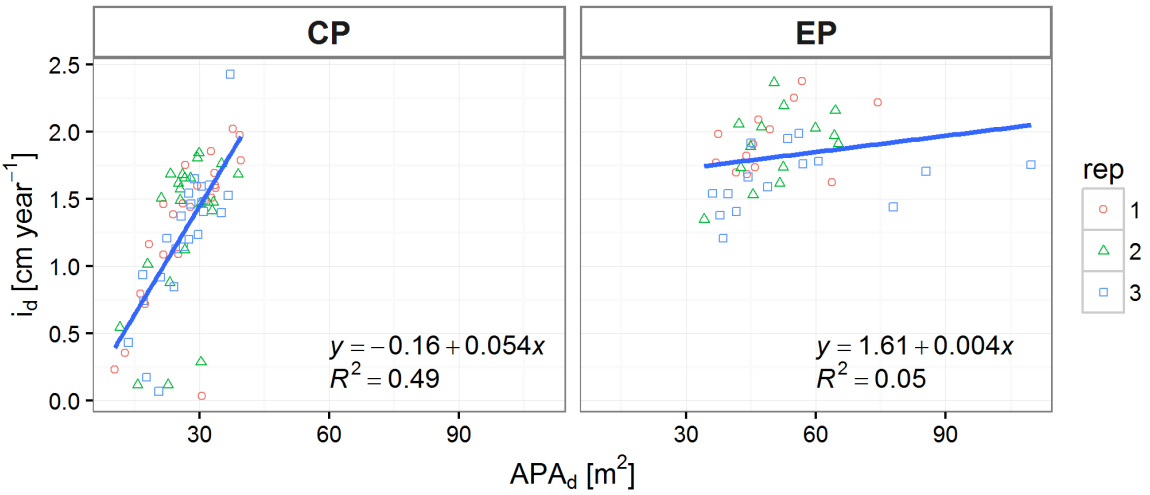

Figure 2. Relationships between current diameter increment and APA for researched experimental (EP) and control plots (CP).

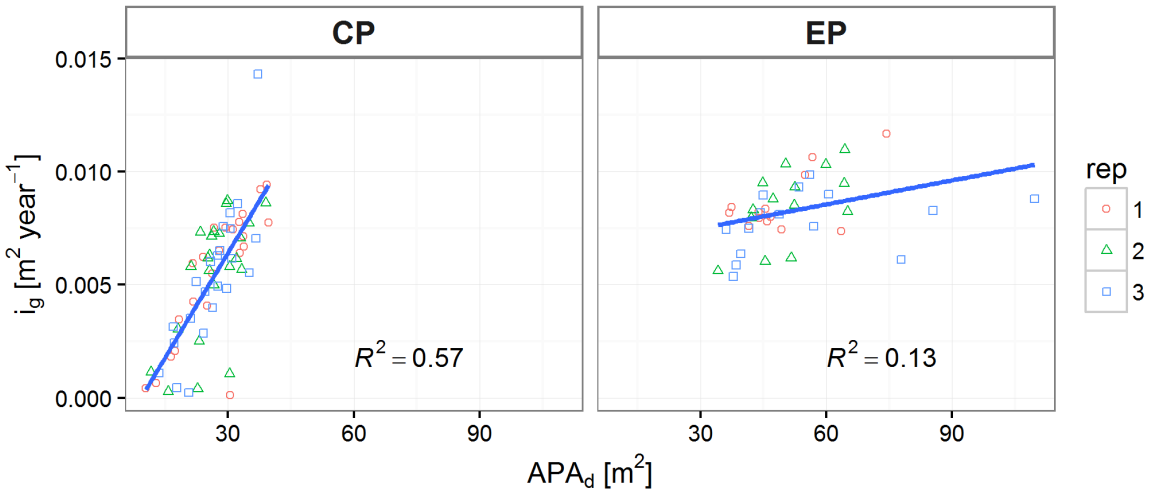

Figure 3. Relationships between current basal area increment and APA for researched experimental (EP) and control plots (CP).

Table 2. Test of correlations between diameter and basal area increment, and area potentially available (APA) in research plots.

	Plot	n*	R^2	R	t	p
i_d [cm yr^{-1}]	CP	69	0,49	0,70	8,07	0,0000
	EP	42	0,05	0,20	1,38	0,1755
i_g [m^2 yr^{-1}]	CP	69	0,57	0,76	9,51	0,0000
	EP	42	0,13	0,35	2,39	0,2015

*n – number of trees in plots; R^2 – coefficient of determination; R – coefficient of correlation; t – result of t-test;p – p-value.

The high correlation of the current increment of the diameter and basal area with the APA were found in Daniels et al (1986) for loblolly pine trees, Tome and Burkhart (1989) and Soares and Tome (1999) for eucalyptus plantations, and Wimberly and Bare (1996) for Douglas fir and western hemlock basal area growth following silvicultural treatment.Wimberly and Bare (1996) stated that the strength of APA lies in the fact that they contain unique information about the spatial pattern of a given tree with respect to its neighbors, which cannot be captured by the non-spatial indices. In addition, tessellation-based indices are the only spatial indices that capture the influence of interactions between competitors on the subject tree (Kenkel, 1991).

Conclusion

Area potentially available, obtained as the weighted polygons, in the poplar plantation of clone B-229 at the age of eight years was an average of 26.6 m^2 in the part of plantation where thinning operation has not been implemented and 52.1 m^2 in the part where thinning was conducted.Current increment of diameter and basal area of trees for a period of three years and area potentially available on the control plot is in the high correlation indicating the possibility of using the APA in making growth model.In the experimental plot correlation of current increment of diameter and basal area of trees with the APA was not significant, indicating that the APA on the experimental plot, where the thinning operation was carried out, is not reliable regressor.

Abstract

Aphid feeding effect on poplar leaves has been studied by three physiological characteristics. Different clones of *Populus deltoides* and *Populus alba* have been tested. Investigations were carried out on a fully formed uncolonized and colonized leaves with three aphid species: *Chaitophorus leucomelas*(poplar aphid), *Chaitophorus populialbae* (white poplar leaf aphid) and *Chaitophoruspopulieti* (poplar shoot aphid). The studies of net photosynthesis, dark respiration were carried out using completely developed leaves of one-year-old plants of *Populus deltoides* cl. 101-1 and Populus alba 'L-12'. Net photosynthesis and dark respiration were determined polarographically. Stomatal diffusive resistance was measured by Li-600 in leaves of two Eastern cottonwood clones (*Populus deltoides*) 'S1-8' and '181/82' on adaxial and abaxial leaf surface, in both colonized and uncolonized leaves. In plants colonized with aphids the a decrease of the photosynthesis in the range of 25-75% depending on the aphid species, cultivars and age (leaf) was recorded. Dark respiration was considerably higher, as well as stomatal diffuse resistance in the leaves colonized with aphids. The results indicate that aphid colonization reduced the stomatal conductance and then photosynthesis, probably resulting in negative effect on assimilation, biomass accumulation and other important physiological processes.

Key words: *aphids, poplars, net photosynthesis, respiration, stomatal diffusive resistance*

Introduction

Aphids (*Aphididae,Hemiptera*) have long been the subject of interest of entomologists and experts engaged in plant production due to the abundance and distribution of the species, the number of plant species they colonize, specific development and the way of life, specific morphological and anatomical characteristics and the consequences of feeding on the host plants.

Numerous aphid species developing and feeding on different forest tree species, with their harmful effects particularly emphasized, has been cited in the literature. According to the available literature data the effect of the presence of aphids on growth elements, which are certainly economically the most important, has not been quantified up to date. Elements of growth (diameter at breast height and plant height) used to determine the degree of negative influence of aphids feeding on plant host are just not reliable enough due to their dependence on other external and internal factors, such as site conditions (presence and absence of nutrients and water in the soil, temperature, light), human interventions (soil preparation, weed and pest control, tending operations, sanitation), host resistance (specific genotype traits for particular conditions), respectively biotic factors (defoliators, bacteria, fungi), etc. All

these factors may exert strong influence on host plant and therefore "mask" the negative influence of aphid feeding. Hence it is necessary to study and to bring into direct connection the influence of aphids on the processes of photosynthesis, the respiration and transpiration, and by using the degree of disturbances of these processes to determine the degree of harmful effect of the aphids.

Previous studies have shown that aphids are responsible for changes in plant physiology in a number of agricultural crops, but little is known about how aphids elicit these changes and the physiological mechanisms associated with injuries (Macedo et al. 2003). The synthesis and accumulation of organic matter is achieved by the process of photosynthesis. Therefore, researchers have focused on the influence of aphids feeding on photosynthetic potential which may consequently affect plant productivity in plant species of economic importance, such as soybean (Macedo et al. 2003), wheat (Rafi et al. 1997, Haile et al. 1999, Macedo et al. 2003), and sugar beet (Hurej et al. 1993). Photosynthesis can be limited by a series of factors, due to the direct action on photosynthetic processes or to a reduction of stomatal conductance or both (Hajji et al. 2009). Haile et al. (1999) reported that limitations in photosynthetic efficiency of wheat injured by Russian wheat aphid, *Diuraphis noxia*(Mordvilko), were not related to the CO_2 assimilation phase, indicating that inhibitions occur before CO_2 assimilation with Rubisco (ribulose-1,5-bisphosphate carboxylase). Aphids cause direct injury to the host plant by the removal of the plant sap, which contains essential food materials that promote aphid and plant growth. Because phloem sap is richer in sugars than amino acids, which aphids need for growth, much of the sap is excreted as honeydew, which can cover the leaf surface, and consequently reduce the efficiency of respiration and photosynthesis (Shannag 2007). Aphids can also alter light interception and photochemistry *via* changes in chlorophyll content and metabolism leading to limitation in light-driven electron fluxes (Burdand Elliott 1996), Ni et al. (2002), Wang et al. (2004). Reduced photosynthetic rates were also observed following aphid feeding on soybean [*Glycine max* (L.) M.], wheat (*Triticumaestivum* L.), and cotton (*Gossypiumhirsutum* L.) (Shannaget al. 1998, Macedo et al. 2003). Furthermore, aphid feeding may hinder normal phloem transport, which interferes with the delivery of nitrogen to cells and disrupts the flow of assimilates (Peterson and Higley 1993).

Foliar pathogens often alter leaf stomatal conductance, and these changes could affect photosynthesis and water regime of infested plants. Riedell (1989) reported that barley leaves previously infested with aphids had lower relative water content, reduced stomatal conductance, more negative water potential and lower levels of chlorophyll than corresponding leaves from uninfested plants. However, stomatal conductance and transpiration were enhanced considerably by aphid feeding on broad bean plants (Shannag 2007). The authors concluded that an increase in transpiration may result from increasing the size of stomatal apertures rather than from damage of the leaf tissues. Such inconsistent results among plant species infested by aphids suggest species specific responses to colonization of these pests.

This paper presents the results of investigations of feeding effect of three aphid species (*Chaitophorus leucomelas, Chaitophorus populeti* and *Chaitophorus populialbe)* on some physiological parameters (net photosynthesis, dark respiration and stomatal diffusive resistance) of two different poplar species (*Populus alba* and *Populus deltoides)*.

Material and method

Net photosynthesis and dark respiration

The studies of net photosynthesis and dark respiration were carried out using fully developed leaves of one year old plants of *Populus deltoides* cl. 101-1 and *Populus alba* 'L-12' grown at the field trial of the Institute of Lowland Forestry and Environment. Plants of *Populus deltoides*'101-1'were colonized by aphids of *Chaitophorus leucomelas*, and those of *Populus alba* 'L-12' by *C. populialbae*. Net photosynthesis and dark respiration were determined polarographically, using the Hansatech DW1 electrode (Jones & Osmond 1973, Walker 1987). The rate of photosynthesis was evaluated by the quantity of released oxygen ($\mu molO_2cm^{-2}h^{-1}$), while the rate of dark respiration was determined by the rate of oxygen uptake in the dark ($-\mu molO_2cm^{-2}h^{-1}$). Leaf segments used for analysis were taken from both infested and healthy leaves, avoiding main veins, and suspended in the buffer pH 7.6-7.8 containing 10 mM $NaHCO_3$. The process of photosynthesis in the samples was carried out under complete saturation with white light produced by quarts-iodine lamp (Stanković & Wolker 1977), while the rate of respiration was observed in dark.The measurements were performed at three different plants per host x pest combination and on each plant were measured physiological paremeters.

Stomatal diffusive resistance

Measurements of stomatal diffusive resistance were made by LI-600 in leaves of two Eastern cottonwood clones (*Populus deltoides*) 'S_1-8' and '181/82' at adaxial and abaxial leaf surface, in both colonized and uncolonized leaves on the leaf spots with the highest aphid densityof the species *Chaitophorus leucomelas*.The measurements were performed at three different plants per host x pest .

Results and discussion

Two aphid species were found at adaxial leaf surface as follows:

- on *Populus deltoides* '101-1', 'S_1-8' and '181/82': *Chaitophorus leucomelas*;
- on *Populus alba* 'L-12': *C. populialbae*and *C. populieti*.

The results of respiration and net photosynthesis in leaves colonized and uncolonized by aphids are shown in Table 1. The results showed that aphids affected the process of respiration and photosynthesis by their presence i.e. feeding practice, as the values obtained in colonized and uncolonized leaves differed. It can be observed that in all cases mentioned in table 1. the photosynthesis was lower and respiration was higher in leaves colonizeded by aphids regardless of poplar clone, and of aphid species. The results showed that *Chaitophorus leucomelas* had greater influence on decreased intensity of photosynthesis in leaves of *Populus deltoides*'101-88' (59.22%), and lesser on increased respiration intensity (16.36%). *C. Populialbae* with its feeding practice on leaves of *Populus alba*'L-12'caused the greatest change in intensity of respiration and photosynthesis. The respiration intensity was higher by 56.77%, and that of photosynthesis by 76.63% (Table 1). At the same time this aphid caused increased respiration intensity and somewhat lesser decrease in photosynthetic rate of older leaves of the same clone (respiration intensity was increased by 15.74% and that of photosynhesis by 28.57%).

C.populeti caused increased respiration by 21.31% and decreased photosynthesis by 25.71%.

Table 1. Average values of respiration and photosynthesis, percentage of increased respiration values and decreased intensity of photosynthesis

Clone	Aphid species	Respiration µmol $CO_2m^{-2}h^{-1}$	Increased respiration* %	Photosynthesis µmol $CO_2m^{-2}h^{-1}$	Decreased photosynthesis* %
P.deltoides'101-88	-	10.27		6.45	
P. deltoides'101-88'	*C. leucomelas*	11.94	16.36%	2.63	59.22
P. alba'L-12'	-	6.64		6.89	
P. alba'L-12'	*C. populialbae*	10.41	56.77%	1.61	76.63
P. alba'L-12'	-	7.18	21.31%	7.00	25.71
P. alba'L-12'	*C. populeti*	8.78		5.02	

* Change between colonized and unclonized leaves related to the value obtained on unclonized leaves

The results of measurementof stomatal diffusive resistance were showed in fig. 3. It can be observed that stomatal diffusive resistance was always higher in leaves colonized by aphids of *Chaitophorus leucomelas* regardless of clone or side of the leaf. This indicated that the presence of aphids caused increased stomatal diffusive resistance, i.e. reduced conductance.

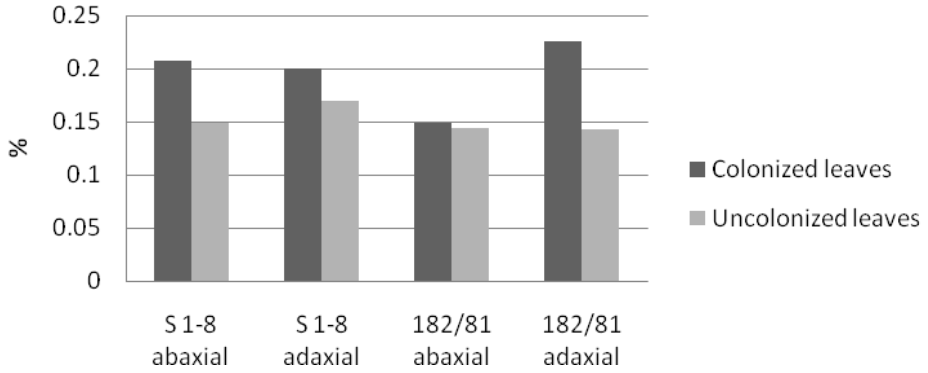

Figure 1. Diffusive stomatal resistance in colnized and uncolonized leaves

If we compare stomatal diffusive resistance (Figure 1) in clone 'S_1-8' and clone '182/81' only in the colonized leaves, we can observe that the difference in stomatal diffusive resistance on the adaxial and abaxial sides in clone '182/81' was higher in comparison to clone 'S_1-8'. These differences were probably due to differences in number of stoma. Values of stomatal diffusive resistance in uncolonized leaves in both clones were approx. at the same level on both the adaxial and abaxial sides of leaf.

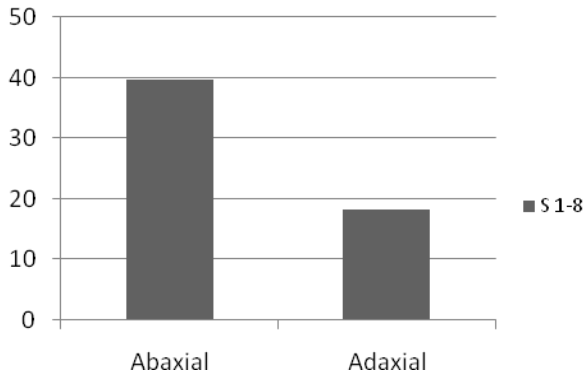

Figure 2. Ratio of adaxial to abaxial stomatal diffusive resistance in colonized and uncolonized leaf of *P.deltoides* cl. S1-8

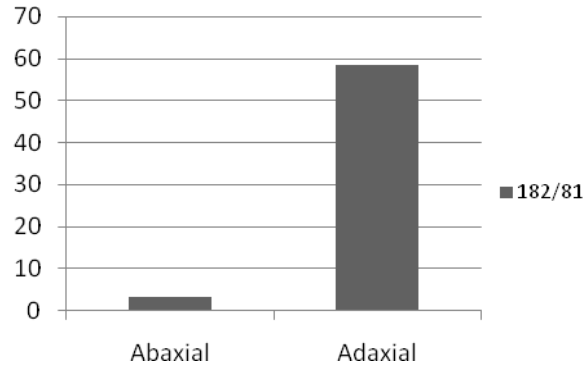

Figure 3. Ratio of adaxial to abaxial stomatal diffusive resistance in colonized and uncolonized leaf of *P. deltoides* cl. 182/81

The ratio of adaxial to abaxial stomatal diffusive resistance of leaves colonized and uncolonized by aphids was specific for clone 'S_1-8', on the one hand and clone '182/81', on the other hand (Figures 2 and 3). It was much higher in clone '182/81'. The ratio of stomatal diffusive resistance in colonized and uncolonized leaves in clone '182/81' was much higher on the adaxial in relation to abaxial side of leaf, while that difference was less pronounced in clone S_1-8. In this case it was clear that there were differences among clones and that it may result in varying degree of tolerance to negative influence of aphids on plant transpiration, or in response to water loss. The differences in stomatal diffusive resistance values in studied clones could be caused by a higher degree of predelection of *Chaitophorus leucomelas* for one of the clones with better feeding, growth and development conditions.

Plant productivity largely depends on the intensity of photosynthesis since the synthesis of organic substances takes place during this process. Variability within the genus *Populus* represents an important factor in selection of fast-growing, i.e. genotypes with high biomass accumulation. Therefore, it is essential to define the individual cultivars according to their physiological traits like net photosynthetic rate per unit leaf area, stomatal conductance, chlorophyll content, and total leaf area, particularly when a significant correlation between the photosynthetic rate x total leaf area and growth traits in trees is known (Mebrahtu and Hanover 1991). A survey of variability of these characters is focused on selecting genotypes with desirable traits as one of breeding tasks. Photosynthetic response of colonised leaves may answer questions related to plant tolerance and productivity. The results obtained in this study revealed the reduced rate of photosynthesis in plants infested by aphids, which was consistent with the studies of other authors. In soybean, photosynthetic rates of leaves infested by *Aphis glycines* were considerably lower than the rates of uninfested leaves (Macedoet al. 2003). Reductions in photosynthesis may be caused by stomatal limitations in CO_2 availability or mesophyll limitations (Macedoet al. 2003). Stomatal diffusive resistance in our study was increased in the presence of aphids in both two clones, which indicated that the reduction in photosynthetic rate was at least partially caused by stomatal limitations. Cotton aphid populations of approximately 300 per leaf did not significantly alter photosynthesis of cotton leaves (Gomez et al. 2006) while Godfrey et al. (1997) reported that aphid infestations of 400–550 per leaf reduced photosynthesis by 6.4% compared to the uninfested leaves. Shannaget al. (1998) also showed that photosynthetic rates in cotton were reduced in proportion to the number of aphids and the length of infestation period. Reduced photosynthetic rates were also observed following aphid feeding in wheat (Macedo et al. 2003~~b~~).

The plant tissue becomes mechanically damaged by the stylet protrusion, and later on saliva secreted during stylet penetration is forced out through salivary canal and further damages the tissues during feeding. Aphid saliva is composed primarily of plant hormones, phenolic substances and enzymes influencing the plant metabolism (Miles 1965). Plants respond to these injuries by accumulation of phenolics which are transferred to toxic quinones during oxidative process (Miles 1987). An investigated physiological parameters are the major indicators of plant physiological condition and are the part of the complex process of photosynthetis. Even the smallest change in some of the tested parameters may diminish, and in extreme cases stops the process of photosynthesis. Results and values of the tested physiological parameters obtained in uninfected plants of poplar clones were consistent with those obtained by Orlović (1996) and Ceulemans and Saugier (1991). Results obtained by testing the net photosynthesis, respiration and stomatal diffusive resistance revealed regularity in terms of plant responses to aphid colonization. The results of these studies are consistent with the studies regarding the influence of *Pemphigus bursarius* and *Pemphigus spyrotecae* on photosynthesis, respiration, and transpiration obtained by Cichocka et al. (1992). Intensity of photosynthesis in studied clones was higher in leaves with no colonization, while the intensity of respiration was lower. The influence of aphids on plants depends on plant variety, plant age and developmental stage of aphids. It is certain that abundance of aphids affects the plant physiological state, and it is well known that even the slightest change in plant water regime affects the process of photosynthesis. According to available data a small number of researchers were engaged in studying the influence of plant aphids on some of the basic physiological processes in plants.

In plants infected by aphids the reduction in the rate of photosynthesis of 25-75% was observed, depending on aphid species, variety and plant (leaf) age, which was consistent with the findings of Miles (1968). At the same time the respiration was higher in infected plants by 15-56.77%. Stomatal diffusive resistance was higher in leaves with aphids indicating that the presence of aphids reduced stomatal conductance, and hence the other physiological processes as well. It can be assumed that altered values of studied physiological parameters affected the growth elements and plant vigor as well.

Conclusion

The tested physiological parameters are important indicators of the physiological status of the plant and are an integral part of the complex process of photosynthesis. The slightest change in any of the examined parameters can highly reduce and even block the process of photosynthesis. The results obtained for examined parameters showed regularity in terms of plant response to the aphids colonization. Stomatal diffusive resistance is an indicator of the water regime in plants or leaves. It can be also represented as the reciprocal of the stomatal conductance. The impact of aphids on the plant depends on the cultivar, plant age and developmental stage of plant. It is certain that a high number of aphids affect the physiological state of the plant, a well-known fact that the slightest change in plants water regime lead to reduction the process of photosynthesis. In plants colonized with aphids we recorded a decrease of the photosynthesis of 25-75% depending on the aphid species, cultivars and plant age (leaf). At the same time processes of respiration are higher from 15 to 56.77%. Changes in stomatal diffuse resistance is an indication of a specific water regime of plants or leaves of the investigated clones. This parameter was higher in the leaves colonized with aphids. The results indicate that aphid colonization reduced the stomatal conductance and thus probably other physiological processes.

*Corresponding author: inga.straupe@llu.lv

Abstract

The objective of the research is to compare grey alder's (*Alnus incana* (L.) Moench) vegetation on abandoned agricultural lands and riparian forests. Grey alder occupies 7 % of total forest area in Latvia. It has an essential ecological role in forest: it grades soil and enables succession of forest but the most valuable forest habitats of grey alder develop in riparian forests. Total of 12 sampling plots (each - 0.04 ha) have been conducted in grey alder's stands. The type of forests' growing conditions is rich deciduous forest *Aegopodiosa*. The inventory of growing trees, dead wood and vegetation is carried out in each sampling plot. The average volume of growing trees on abandoned lands is 318.8 m^3 ha^{-1}, and in riparian forests – 399.4 m^3 ha^{-1}. The average volume of dead wood is accordingly 14.4 m^3 ha^{-1} and 85.8 m^3 ha^{-1}. In total, 196 species of vascular plants and bryophytes are listed: 16 species – in the tree layer, 15 – in shrub layer, 116 – in herb layer and 27 – in the moss layer. The average projective cover of vegetation in grey alder's forests on abandoned agricultural lands is bigger than it is in riparian forests. Plant species of nemoral forest group characterize stands of grey alder: the most common species are *Alnus incana*, *Fraxinus excelsior* L., *Padus avium* Mill. and *Corylus avellana* L.

Keywords: *Alnus incana*, vegetation, dead wood, abandoned agricultural lands, riparian forests.

Introduction

During last few decades the changes in political and economic conditions in many countries of Europe, also in the Baltic States, the agriculture lands have shifted to abandoned and overgrown with forests. For instance, in Latvia abandoned agriculture lands make up approximately 300, 000 ha (Liepins et al., 2008), in Estonia - 300,000 ha (Astover et al., 2006). A major part of such abandoned agricultural lands consists of deciduous tree species, including *Alnus incana* (L.) Moench which is commonly abundant on former agricultural lands. The growth of *A. incana* on former agriculture lands has been studied in Latvia (Liepins et al., 2008) and also in several countries such as Estonia (Uri et al., 2002), Lithuania, Sweden, Finland and Russia (Shvidenko et al., 1997). *A. incana* is fast-growing species with short rotation period, and it can reach their biological age until 60 years, but it is suggested to fell until age of 30 years. After this age *A. incana* develops wood decay fungi (Daugavietis, 2006).

Riparian zones in forest facilitate high biodiversity as transition zones between terrestrial and aquatic ecosystems (Gregory et al., 1991). *A. incana* is also a common tree species in riparian buffers which can transform nutrient fluxes from adjacent arable lands (Mander et al., 1997). Riparian forests are periodically flooded, where understorey plant species tolerates such disturbances. Riparian forest canopies are relatively rich with species and are commonly dominated by deciduous tree species. Only in riparian zones *A. incana* can form persistant

stands, but due to the channelizing of streams in areas of *A. incana*, forests has decreased in the region.

There is a lack of studies on vegetational diversity in *A. incana* forests. Grey alder forms river floodplain habitats rich in biodiversity. They fall into the category of European nemoral broadleaved forests.

The aim of the study was to analyse how the vegetation on abandoned agricultural lands and riparian forests deviates between different stand ages in forest stands dominated by *A. incana*. We focus on forest structural characteristics and vegetation in moss, herb, shrub and tree layers, with the following specific objectives:

1. To compare the changes in forest structural characteristics on abandoned agricultural lands and riparian forests with different stand ages.
2. To compare the changes in plant diversity on abandoned agricultural lands and riparian forests with different stand ages.

Materials and methods

Research was conducted in forests dominated by *A. incana* on abondaned agriculture lands and riparian zones in eastern Latvia (Fig.1.). All study plots where conducted in *Aegopodiosa* forest type, which grows on the richest mineral soils in the region (Skudra and Dreimanis, 1993). In forest, formed on abandoned agriculture lands, a permanent sample plots with size 20×20m (400m^2) were located randomly, avoiding edge effects, while in riparian forests three types of transects were established. The distance between these transects was 1 km and on each transect one or two permanent sample plots where established with size 20×20m (400m^2).

Fig.1. Location of study areas in eastern Latvia (1 - Viesīte municipality; 2 - Jēkabpils municipality).

Stand structure. Properties of each tree in a stand were measured in all sample plots. Trees, snags and stems (≥ 6 cm diameter at breast height, breast height=1.3m), where measured in all sample plots and also we recorded species, diameter at breast height and the height of the tree. In addition, the stage of decay was recorded for snags and stems. Diameter, length, species and decay stage were noted for all pieces of downed logs. Decay stages were rated from 1 to 5

according to Siitonen (2001). Volume of living trees and coarse woody debris was calculated for each of tree species using the volume calculation followed by Liepa (1996).
Vegetation survey. Projective cover (%) for each species and in total was measured using Braun-Blanquet approach (Braun – Blanquet, 1964; Mueller-Dombois and Ellenberg, 1974) in moss, herb, shrub and tree layers. The nomenclature for vascular plants followed Gavrilova and Šulcs (1999) and that for mosses – Āboliņa (2001). Plant functional characteristics were chosen to show the differences in plant communities between *A. incana* forests on abandoned agricultural lands and riparian forests. To test whether there are PFTs features that react to differences between two types of *A. incana* forests, species were grouped by plant type characteristics. For the analysis we used plant geographical distributions and Ellenberg indicator values. The classification of PFTs was obtained from Flora Database of Central Russia (www.jcbi.ru) – for Ellenberg indicator values: light, moisture, nitrate and soil pH. First, we used projective coverage (%) in analysis and results. We calculated the mean coverage and species richness ± standard deviation to show the differences between vegetation layers. Ellenberg indicator values for light, moisture, nitrogen and soil pH were calculated separately for each species in each sample plot. Second, we used species richness for each vegetation layer to find differences between two types of *A. incana* stands. We also calculated mean values for each vegetation layer including ± standart deviation. Since forest structural characteristics, species cover and richness per vegetation layers followed normal distribution, we used ANOVA to test for significant differences in living trees, dead wood, species cover and species richness, Ellenberg indicator values and plant geographical distribution. Tukey's HSD post-hoc test was used to find differences between treatments (abandoned agriculture lands versus riparian forests) in each age category (32-42 and 53-63 years). Differences were considered significant when $P \leq 0.05$. All statistical analyses were performed in R (R development core team, 2013).

Results and discussion

Stand structural characteristics. In all studied sites the largest part of stand structural characteristics comprise living trees, but small proportion are dead wood (Fig.2.). The total abundance of living trees varied notably between two types of grey alder stands, respectively on average 318.8 m^3 per 1 ha in sites on abondaned agricultural lands and 399.4 m^3 per 1 ha in riparian forests. Riparian forests have more diverse composition with different tree species, which benefits timber volume in a stand. In younger grey alder stands (32-42 years old) on abandoned agricultural lands timber volume is 234.8 m^3 per 1 ha, but in older ones (53-63 years old) it reaches 402.7 m^3 per 1 ha. In riparian forests these numbers are 311.2 m^3 per 1 ha and 487.6 m^3 per 1 ha respectively. In younger stands on abandoned lands other tree species are almost absent, but in older stands this admixture can reach 20-44%, mostly *Betula pendula* Roth., *Populus tremula* L., *Alnus glutinosa* L. and *Picea abies* L. This is in line with the theory that *A.incana* is a successional species which colonizes agricultural lands and create favourable growing conditions for other species (Miezite, 2008). However, in younger riparian forest stands is 43-66%, but in older ones – 9-52%. This confirms that *A.incana* overshadows weeds and thus facilitate the development of other tree species (Miezite, 2008).

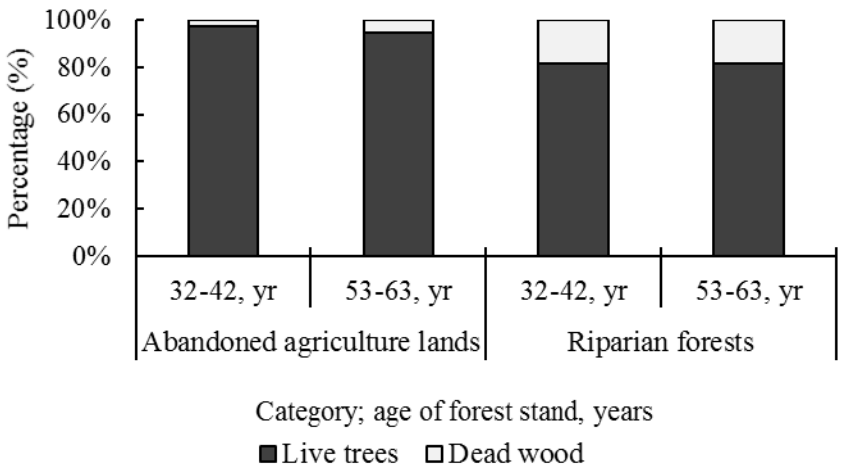

Fig.2. The proportion in percentage (%) of live trees and dead wood in the *A.incana* forests on abandoned agriculture lands and riparian forests within different age 32-42 years and 53-63 years.

Dead wood. The average amount of dead wood exceeded 14.4 m^3 per 1 ha in studied sites on former agricultural lands and 85.8 m^3 per 1 ha in riparian forests. Species diversity of dead wood was low and the main species was *A. incana* (98 % on abandoned agriculture lands and 73% in riparian forests). Other species are *B. pendula*, *P. abies* and *Salix alba* L. Average dead wood volume in study sites on former agricultural lands was 6 m^3 per 1 ha at stand age of 32-42 years and 22.7 m^3 per 1 ha - at the age of 53-63 years. These differences can be explained with the fact that at the age of 40 the majority of trees have a rot and they are gradually dying (Daugavietis, 2006). In riparian forests the average volume of dead wood was 61.9 m^3 per 1 ha at the age 32-42 years, and 109.6 m^3 per 1 ha in sites at the age of 53-63 years. However, the mean volumes of dead wood were much smaller in studied sites at the age of 32-42 on former agriculture lands, but significantly higher at the age 53-63 in riparian forests. Complex structural diversity such as uneven stand structure, diversity of dead wood and species composition provided by small-scale disturbances is characterized by gap dynamics. Canopy gaps plays an important role in maintaining biodiversity and providing long-term ecosystem functioning (Peterken, 1996).

Vegetation survey. The mean number of species in vegetation layers was affected by stand age, but did not differ between forests on abandoned agricultural lands and riparian sites. The largest species number was detected in riparian forests – 82 species, but number of species in the study sites on former agriculture lands was 78. In total 12 species at moss layer, 54 species at herb layer, 16 species at shrub layer and 7 species at tree layer were found in sample plots within *A. incana* forests on riparian zones of abandoned agricultural lands.

Moss layer. The lowest coverage of mosses was detected in riparian sites at the age of 53-63 years. The mean number of species was being rather similar in both riparian forests and on former agricultural lands (Fig.3.). Data analysis showed no differences between the studied sites and different age classes. The most abundant species was *Brachythecium oedipodium.*

Herb layer. The mean number of species in herb layer did not differ between study sites in both former agricultural lands and riparian forests, but it was lower at the age of 32-42 on abondaned agriculture lands (Fig.3.). The coverage of herbs was different between age of grey alder stands, but the effect was rather small, and no significant diferences were found between treatments and different age classes. The abundance of nemoral herb layer with species dominated by *Aegopodium podagraria* L., *Urtica dioica* L., *Geum rivale* L. were detected in all studied sites. The coverage of nemoral species in grey alder stands on abandoned agricultural lands and riparian forests is similar and thus the succesion of broad-leaved forest

is possible. However, the significant amount of boreal species occured in riparian forests with stand age of 53-63 years. The coverage of swamp forest species was higher in grey alder stands on abondaned agriculture lands at the age of stand 32-42 years, but suprisingly decreased in riparian forests at the age of stand 53-63 years. Environmental condition according to Ellenberg (1992) in all studied sites were similar and calculated values expressed: warm half-shade and moist, pH-neutral soil rich in nitrogen.

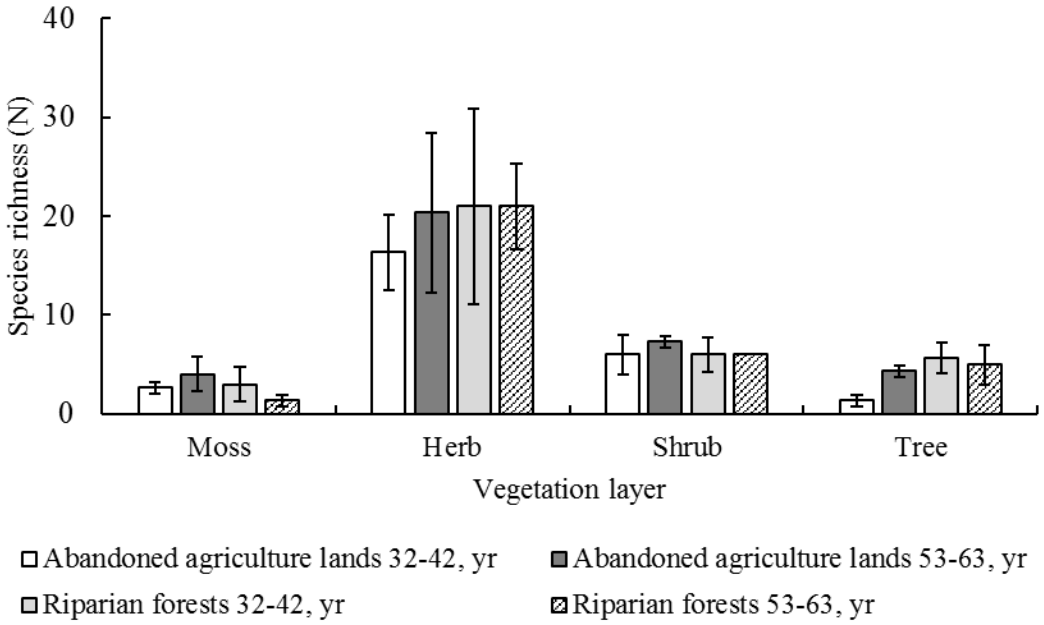

Fig.3. Numbers of species in different vegetation layers in the *A.incana* forests on abandoned agriculture lands and riparian forests within different age 32-42 years and 53-63 years. Values are means ± standart deviation.

Shrub layer. The number of of shrub species was similar in *A. incana* forests on abandoned agricultural lands and riparian forests (Fig.3.). We found that there were no statistically significant differences between the number of species and coverage in shrub layer in *A. incana* forests on abondaned agricultural lands and riparian forests.The high abundance of species in shrub layer with *Padus avium* L., *Corylus avellana* L. and *Sorbus aucuparia* L. were detected in all studied sites.

Tree layer. The number of species were significantly lower in the *A.incana* forests at the age 32-52 years, but number of species increased within the age of forest stands. The mean number of tree species in all studied plots was 4.1. (Fig.3.). The most abunadant species in tree layer was *A. incana*, *Fraxinus excelsior* L. and *Quercus robur* L. The projective cover of tree was not influnced by treatments and different age classes of forest stands. The highest projecive coverage values were found in *A.incana* forests on abondaned agriculture lands (average 90%), but in riparian forests – average 80%.

Conclusion

The present results show that there are minor diferences between grey alder stands on abandoned agriculture lands and riparian forests within different age of stand. The average volume of grey alder stands on abandoned agricultural lands is 318.8 m^3 per 1 ha, riparian forests – 399.4 m^3 per 1 ha. These diferences can be explained by greater tree species diversity in riparian forest sites. *A.incana* is fast-growing tree species, occupying 7 %

(207,000 ha) of total forested area in Latvia. It have an important ecological role as European floodplain broadleaved forests. The average volume of dead wood on abandoned agricultural lands is 14.4 m^3 per 1 ha, but in riparian forests it is almost six times larger – 85.8 m^3 per 1 ha. When comparing *A.incana* stands with different age it is evident that wider representation among habitat groups is found in riparian forests. In total, 107 species of vascular plants were found in *A.incana* stands: 12 in tree layer, 19 in shrub layer, 79 in herb layer and 15 in moss layer. In *A.incana* stands on abandoned agricultural lands 78 vascular plant species were found; on riparian forests – 82 species. The average projective coverage for all layers of vegetation was higher in grey alder stands on abandoned agricultural lands compared to riparian forests. In general the species in grey alder stands belong to nemoral and nitrophyle groups.

Abstract

The paper shows elements of growth and structure of mixed black locust and common hackberry stands, 28 years old and mixed origin in the area of Subotica-Horgos sands (Serbia) by measuring of all trees on three experimental plots, each of 0.0625 ha (25 x 25 m). Black locust trees in the stand are predominantly of coppice origin, and common hackberry trees are predominantly of seed origin. On the experimental plots 5000-6380 trees per hectare were determined, with the dominant share of black locust with 3100-4200 trees per hectare, or 62-71%. Basal area is 32.2 m^2ha^{-1} and wood volume is 200 m^3ha^{-1} on average, where black locust account for 73-80%. The dominant height of the black locust is 13.4-16.0 m and common hackberry is 14.8-15.9 m, while the mean height of black locust and common hackberry are approximately identical in all experimental plots and amount 11.4-12.8 m, indicating that stands belong to the V site class by Redei et al, (2014). The mean diameter of black locust trees ranged from 8.6 to 9.9 cm and the dominant from 16.8 to 19.3 cm, while the mean diameter of the common hackberry trees ranged from 70 to 94%, and dominant 92-122% of the black locust trees. Having in mind achieved heights of common hackberry trees, its abundance in the stand and representation in all crown classes, as well as its biological properties to a greater extent tolerated shading compared to black locust, it is estimated its dominance in the future of mixed black locust and common hackberry stands in the area of Subotica-Horgos Sands. Accordingly, it is necessary to adjust silvicultural and management measures in these stands, having in mind the natural succession of species and different planned orientations with them in the management plans in this area.

Keywords: *black locust, common hackberry, mixed stands, growth elements, stand structure*.

Introduction

Subotica-Horgos sands located in the northern part of Backa plain and in the wider area surround the city of Subotica (Serbia) on the north side, to the border with Hungary. It was created during the the younger Pleistocene (Diluvium) at the time of glaciation, when the rivers brought sand and mud from the Alps and the Carpathian mountains in summer, while when the river retreated to its riverbed in winter the wind diffused this material and deposited it in the form of sand or loess on the terrain of the existing sands and loess plateaus.In this way various forms of sands were formed: gray-yellow sand, brown sand, black sand, black-loamy sand and salinated sand.On these lands, primarily black sands and in the ravines, there were natural forests of oak and white and black poplar, while other parts were covered with grass vegetation (pastures) or barren land, so-called. "live" sands and caused wind erosion in a wider area with negative effects on the agricultural land and settlements (Pavićević and Stanković, 1962; Šijak, 1980).

At the end of the eighteenth century the first work on the binding of sand were begun with species of trees that grow rapidly: willow, poplar, linden, black locust and tree of

heaven.Initial establishment of forest stands was done with more or less success, due to inadequate choice of tree species or inappropriate technique of establishment. Milestone represented 1870 year when introduction of black locust with prior trenching terrain was begun mainly on the gray-yellow sand where could not grow any other species.After the First World War predominance in afforestation is given to Austrian pine (Peruničić, 1956).
In the 1969 year black locust was the tree species that was the most distributed in the area of Subotica-Horgos sands and occupied an area of 2450 ha of 3500 ha how occupied forests and forest plantations.Other tree species were: poplars on 470 ha, Austrian pine on 500 ha, oak (pedunculate and Turkey) on 42 ha and other broadleaves on approximately 140 ha (Šijak, 1980).
Today (inventory in 2009), black locust stands are represented with about 1750 ha, of which pure black locust stands account for nearly 600 ha, and the rest are mixed stands with black locust and other tree species.Having in mind the limitations of the methodology of allocation and measurements of stands by the inventory, especially in young coppice of black locust, which in inventory of the management unit "Subotica forests" in 1999 were allocated as pure coppice stands of black locust on the area of over 2100 ha, it is evident that these data indicate introduction and succession of species, especially common hackberry, which in inventory in 2009 was recorded that builds pure stands on an area of over 620 ha (16.6%), and in inventory in 1999year an area of pure common hackberry standswere 88.8 ha (2.5%).Based on the existing relationship the largest share by volume of all species recorded in this management unit has an Austrian pine with 33.8%, followed by black locust with 22.7% and common hackberry with 10.6%.
Cited literature does not mention the planned, artificial introduction of common hackberry on the area of Subotica-Horgos sands. Common hackberry (*Celtisoccidentalis* L.) is a non-native tree species that has introduced into Europe in 1636 year, and on area of the Pannonian Plain (Hungary) is assumed to be introduced in the first half of the XIX century, first as a park tree species in settlements. At the beginning of XX century common hackberry is used for afforestation in the wider area of Hungary (Bartha & Csiszar, 2008).Having in mind that the area of Subotica-Horgos sands in the early twentieth century belonged to Hungary (Austria-Hungary), it can be assumed that it is used for afforestation in sands, as has proved to be very resistant to drought (Tiborcz et al., 2011). Unlike common hackberry, black locust (*Robiniapseudoacacia* L.) is a widely cultivated species in Serbia and represents an important tree species for forest management, which has wide utility value (Banković et al, 2009; Andrašev et al, 2014).
The aim of the research is to examine stand structure and emphasize mutual relationships in the growth of represented tree species in mixed stands of black locust and common hackberry in the area of Management unit (MU) "Subotica forests".

Materials and methods

The structure of mixed stands of black locust and common hackberry has been studied at three permanent sample plots, sized of 0.0625 ha (25 × 25 m), in autumn 2014, when the stand(MU „Subotica forests", department 59)was 28 years old.Black locust trees in the stand are predominantly of coppice origin, and common hackberry trees are predominantly of seed origin.The study stands are with special purpose and have a priority function of soil protection of the first degree, because they represent the forest ecosystems in the habitat that is subject to erosion.The most represented species in the stand is black locust, and common hackberry is mainly in understorey leyer.
Two cross diameters at breast height with an accuracy to 1 mm were measured on all trees in the experimental plots, and heights were measured on a certain number of trees in all diameter degrees with altimeter type Vertex III (Haglof). During the measurement, crown class (CC)

was estimated for every tree based on the classification by Assmann (1970): (1) tree crown is in upper storey, (2) tree crown is in middle storey, (3) tree crown is in lower storey.
Data analysis included standard procedure for processing the experimental plots in order to obtain the quadratic mean diameters (d_g), the dominant diameters (mean diameter of the 100 thickest trees per hectare, D_{100}), mean height by Lorey (h_L) and dominant (top) height (mean height which corresponds to the diameter of the 100 thickest trees per hectare in the plantation, H_{100}) for each studied tree species. The function of Mihajlov was used for the construction of height curves ($h=a\cdot e^{-b/dbh}+1.3$). Stand volume was obtained using constructed height curves and volume table for black locust (Cestar and Kovačić, 1982).

Results and discussion

In the studied mixed black locust and common hackberry stands was determined high number of trees, on average over 5,700 trees per hectare, as a result of lack of tending measures.Total basal area amounted 32.19 m^2ha^{-1}, and total volume 200 m^3ha^{-1}.Number of black locust trees amounted 3100-4200 per hectare, or an average twice than the common hackberry trees, while the total basal area and volume of black locust are3 times higher (Table 1).

Table 1. The basic growth elements of black locust and common hackberry trees in the stands.

Tree species	Exper. plot	H_{100}*	h_L	D_{100}	d_g	N	G	V
		[m]	[m]	[cm]	[cm]	[trees ha^{-1}]	[m^2 ha^{-1}]	[m^3 ha^{-1}]
black locust	EP-1	15.99	12.57	18.7	8.9	4224	26.08	166.00

*__Legend__: H_{100} – mean height of the 100 tickest trees in the stand; h_L – mean height by Lorey; D_{100} – mean breast height diameter of the 100 tickest trees in the stand; d_g – mean quadratic breast height diameter; N – total number of trees in a stand per hectare; G – total basal area per hectare; V – total wood volume per hectare.

The mean diameter of black locust trees is 9.1 cm and is significantly greater than the common hackberry trees.However, the dominant diameter of common hackberry trees is greater than the black locust, but without significant difference.Mean heights of black locust and common hackberry trees are similar and amount 12.3 to 12.4 m, and dominant height is also close and amount 14.9 to 15.3 m (Table 1). Achieved height at the age of 28 years indicates that stands belong to the V site classes of black locust by Redei et al (2014).
Height curves, obtained by the function of Mihailov, show good agreement for both tree species. The coefficient of determination is slightly higher in common hackberry compared to black locust and indicates a better fit of empirical values with the model (Table 2, Figure 1). Height curves of black locust and common hackberry are very similar on all three experimental plots, have a greater curvature in thin diameters and indicate the presence of trees with smaller diameters and heights (Figure 1).This indicates similar height and diameter growth of these two tree species on sandy habitats in Subotica-Horgos sands.

Table 2. The parameters of the height curve models and the elements of model assessment.

Experimental plot	Tree species	Model: $h = a \cdot e^{-b/dbh} + 1.3$		Model assessment		
		a	b	R^2	s_e	n
EP1	black locust	22.02823	6.977001	0.846	1.232	34

EP1-3	black locust	18.38385	5.350667	0.824	1.161	95
	common hackberry	16.59348	4.433145	0.909	1.124	37

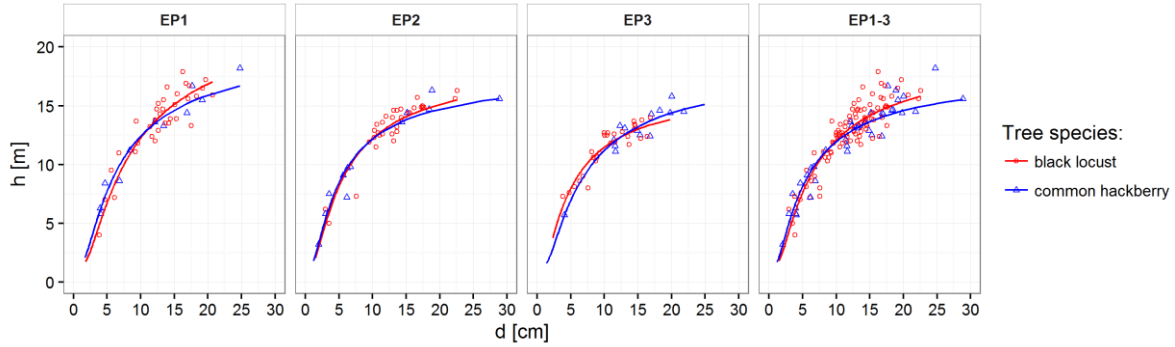

Figure 1. Height curves in experimental plots.

Diameter distribution is unimodal, with an expressed right asymmetry on all three studied plots.The largest number of trees are in the diameter degree of 5-10 cm, from 2000 to 2800 trees per hectare, followed by the thinnest trees with breast height diameter under 5 cm from 1700 to 2350 trees per hectare (Figure 2).

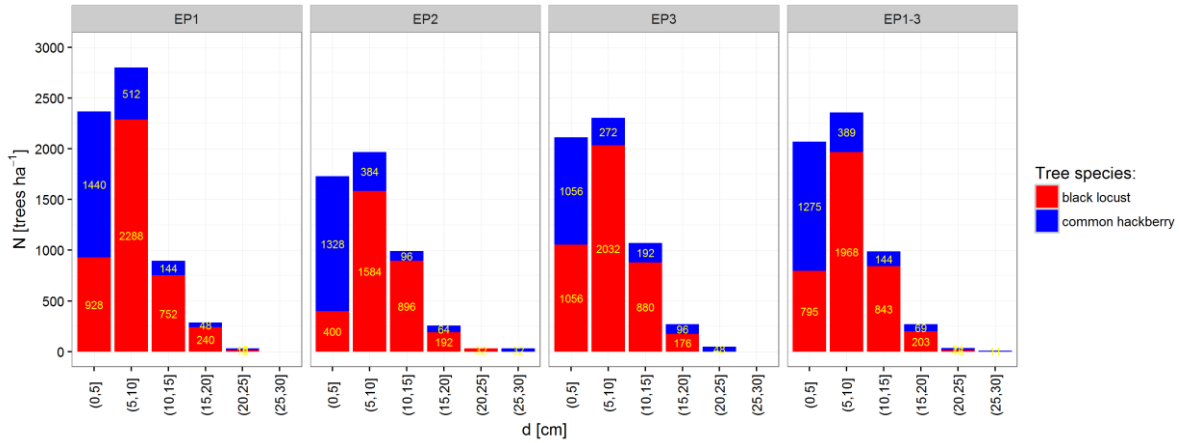

Figure 2. Diameter distribution.

Black locust trees dominated in the diameter degree of 5-10 cm, from 1580 to 2280 trees per hectare, while common hackberry trees are the most numerous in the thinnest diameter degrees, from 1050 to 1440 trees per hectare. On all three experimental plots there are a smaller number of trees with a diameter larger than 20 cm in both tree species (Figure 2).
The number of trees in crown class I amount 1,259 per hectare, or 22%, while the most numbered were trees in crown class III, with 3500 trees per hectare or 61.2%. The largest

number of trees which crown is in upper storey were black locust trees and consists of over 1,000 trees per hectare, as well as trees which crown is in middle storey with 780 trees per hectare, what is significantly higher than the number of common hackberry trees in the aforementioned storeys.In the crown class III were almost 2,000 black locust trees and over 1,500 common hackberry trees per hectares. Statistical t-test showed no difference in the number of black locust and common hackberry trees which crowns were in lower storey (Table 3, Figure 3).

Table 3. Number of trees in different crown classes per hectare and results of t-test.

Tree species	Measurement unit	Crown classes (CC)		
		CC-1	CC-2	CC-3
Total	[trees ha^{-1}]	1259	965	3509
black locust	[trees ha^{-1}]	1067	784	1973
common hackberry	[trees ha^{-1}]	192	181	1536
ratio		5.56	4.32	1.28
t-test		7.05	8.01	1.14
p-value		0.0081	0.0094	0.3382

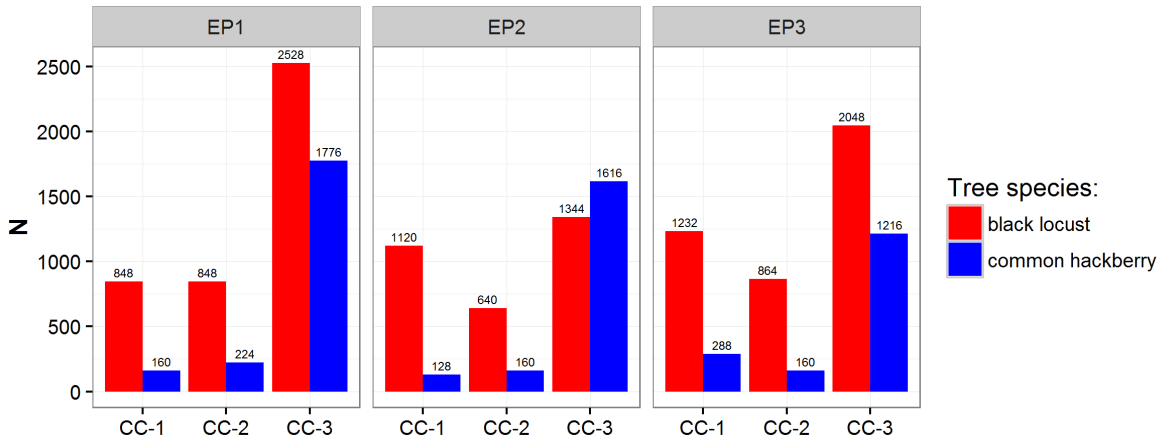

Figure 3. Number of trees in different crown classes per hectare.

Conclusion

The results show that on research sandy habitats black locust achieved lower productivity (V site class), and that a high number of trees per hectare may arise from lack of tending measures.

Common hackberry trees on average account for 1/3 of the number of trees, and for 1/4 of basal areas and volume of stands.Achieved mean and dominant heights were at the level of height of black locust trees, participating in all crown classes, and most of them were in a lower storey.

Having in mind achieved heights of common hackberry trees, its abundance in the stand and representation in all crown classes, as well as its biological properties to a greater extent tolerated shading compared to black locust, it is estimated its dominance in the future of mixed black locust and common hackberry stands in the area of Subotica-Horgos Sands.

Accordingly, it is necessary to adjust silvicultural and management measures in these stands, having in mind the natural succession of species and different planned orientations with them in the management plans in this area.

Abstract

The effect of initial medium pH on shoot growth and development of five white poplar (*Populus alba* L.) genotypes was tested. After 35 days of culture *in vitro* following characters were measured: shoot height, number of new shoots, percentage of survival and percentage of multiplication, fresh mass of shoots, dry mass of shoots, and shoot moisture content. The effect of four media buffered with sodium citrate buffer with following initial pH: 3.0, 4.0, 5.5 and 7.0, as well as of standard multiplication medium with pH 5.5 with no citric acid added were tested. In order to achieve agar solidification in medium with pH 3.0 media were sterilized in microwave oven. Results of analysis of variance indicated that there is significant effect of the media pH on the most of examined characters. There was no significant effect of interaction clone x medium pH, but according to LSD test, clones significantly differed in their reaction on medium with pH3 in relation to medium with pH5.5, especially by shoot height and fresh shoot mass. Generally, significantly lower values of the shoot height, number of new shoots, percentage of multiplication, fresh and dry shoot mass were recorded on a medium with initial pH 3.0 and pH 4 compared to the medium with pH 5.5. Most of the examined white poplar genotypes had a significantly lower percentage of the multiplication on low pH medium than on the control medium and medium with a higher pH values. Medium with initial pH 7.0 achieved inhibitory effect on fresh shoot mass and shoot moisture content.

Keywords: *Populus alba, micropropagation, acidity, microwave sterilization*

Introduction

White poplar (*Populus alba* L.) is a tree species that, in spite of its high adaptability, is considered to be a threatened species and an indicator of biodiversity (Kovacevic *et al.*, 2010b). Beside its use for wood and biomass production, this species has a wide implementation in horticulture and landscaping, especially the genotypes with a pyramidal tree shape (Eggens *et al.*, 1972; Kovacevic *et al.*, 2010a). In addition, white poplar (*Populus alba* L.) is one of the most interesting model tree species in biotechnology, where the tissue culture is an important propagation technique (Confalonieri *et al.*, 2000). It is known that different genotypes of the same species differ in their requirements for growth in *in vitro* conditions Kovacevic *et al.*, 2013).

Medium pH is an important factor of physicochemical environment during the development of plant tissues *in vitro* (De Klerk *et al.*, 2008). However, the most effective pH value is specific to the individual plant species and even cultivars, and has to be determined experimentally (Ostrolucká *et al.*, 2010; Ruzic and Cerovic, 2001).

Tissue culture has been extensively used to evaluate the abiotic stress tolerance of many species. It is a good tool to test the *in vitro* ability of the species to form roots and growth in

the low pH conditions as most of the factors affecting *in vitro* growth are similar to those limiting the growth *in vivo* (Kovacevic *et al.*, 2013).
In this research, the growth and development of shoots of five different white poplar genotypes were observed in order to optimize the procedure of testing and test white poplar genotypes on grow *in vitro* on media with different initial pH.

Materials and methods

Plant material

Five white poplar genotypes, interesting for wood production, horticulture and landscaping were examined: widespread Italian selection "Villafranca", and Serbian selections in experimental phase: L-12, L-80, LBM and LCM.
Shoots of all five tested genotypes were multiplied by culture of axillary buds, as described by Ahuja (1984). The cultures were sub-cultured at 4-week intervals and kept at 26±2 ºC, under a 16 h photoperiod (cool white fluorescent lamps, 3500 lx), till their use in the experiment.

Media preparation

Sterilization was provided by microwave oven. The media were treated until they reached boiling point, and then poured in sterilized jars in laminar chamber. In this way the jellification potential of agar was preserved in media with pH3 and pH4 (Kovačević et al., 2013). Mineral growing medium ACM (Aspen Culture Medium) described by Ahuja (1984), supplemented with $9gL^{-1}$ agar, $20gL^{-1}$ sucrose and with no growing hormones in it, was used in the experiment. The pH of the medium was adjusted to 3.0, 4.0, 5.5 or 7.0 before sterilization. Citric acid/Na-citrate buffer was used in order to provide pH stability of media (Skirvin et al., 1986). This buffer system provided us relatively wide pH spectrum for testing.

Influence of medium pH on shoot growth and development

In order to investigate the effect of medium initial pH on shoot growth and development of tested genotypes, 1.0-1.5 cm long shoot tips of the previously multiplied shoots were placed on media with different initial pH: pH 3.0, pH 4.0, pH 5.5, pH 7.0 and control (standard medium for multiplication, without citric acid and with pH 5.5). Five shoot tips were cultured per 190 ml jar with 25 mL of culture medium. There were three jars per examined medium within a genotype. The cultures were kept at 26±2 ºC in the white fluorescent light (3500 lx) with a 16-hour photoperiod. After 35 days of culture, the shoot growth and development was assessed by the shoot height (SH), number of new shoots (SN), percentage of survival (PS) and percentage of multiplication (PM), fresh mass of shoots per jar (FM), dry shoots mass per jar (DM), as well as the moisture content of shoots (CM).

Statistical analysis

Examined characters were measured either per jar (FM, DM, PS, PM and CM) or the average value per jar was calculated after the measurement of individual plants (SH and SN). There were three repetitions within each genotype for each tested initial pH. The design of the experiment was totally randomized. Number of new shoots was transformed by square transformation ($\sqrt{X+1}$), while the percentage of survival and multiplication of the percentage of transformed arcsin transformation ($\arcsin\sqrt{X}$) in order to meet normal distribution of frequencies. The obtained data were analyzed by two-way ANOVA and LSD test with STATISTICA 10 (StatSoft Inc., 2012) statistical program.

Results and discussion

The research of the influence of low pH on growth and development has mainly been limited by the problems in jellifying of agar on low pH, especially on pH 3 and lower. That was

mainly resolved by sterilization of media with lo initial pH in microwave oven (Kovacevic et al., 2013). While Kovacevic et al. (2013), worked on the examination of growth and development of rooted white poplar shoots *in vitro* on medium with low pH, in this work we attended to examine the influence of media with initial pH ranging from pH3 up to pH 7 on shoot tip explants. Also, considering that tissue culture is poorly buffered (De Klerk *et al.*, 2008) and that plants tend to buffer the medium during the cultivation (Kovacevic et al. (2013), we used sodium citrate buffer in order to stabilize desired medium pH until the end of cultivation.

According to the results of analysis of variance, the strongest influence of examined morphological and biomass characters was made by the initial pH of the media. All characters, except of percentage of survival and shoot moisture content were significantly affected by this factor. There were no significant effect of the interaction Clone x Initial pH; while the effect of Clone was significant only for shoot height and fresh shoot mass (Table 1).

Table 1. The results of two-way analysis of variance for examined white poplar genotypes and initial pH [a)]

Character	F-test		
	Clone (A)	Initial pH (B)	Interaction A × B
Shoot height	4,96 **[b)]	19,69 **	1,49
Shoot number	1,26	8,80 **	0,64
Percentage of survival	1,45	1,34	1,21
Percentage of multiplication	0,91	29,88 **	0,52
Fresh shoot mass	3,669 *	8,756 **	1,333
Dry shoot mass	0,952	7,958 **	1,095
Shoot moisture content	1,045	1,354	1,044

[a)] Degrees of freedom for genotype was $DF_A = 4$, degrees of freedom for pH $DF_B = 4$, degrees of freedom for interaction genotype × pH $DF_{A\times B} = 16$, degrees of freedom for error $DF_{ERR} = 43$ and degrees of freedom for total $DF_T = 67$.

[b)] Labels for F-test: * - significant at the level α=0,05; ** - significant at the level α=0,01

Results of the Least significant difference test (LSD) showed that there was almost no significant effect of addition of citric acid in the medium, as the difference between Control (no citric acid and pH 5,5) and pH5,5 (with citric acid and pH5,5), except for number of new shoots. In that sense, it could be assumed that differences between treatments are almost solely due to differences in the pH of the medium and quantity of sodium ion (Table 2 and 3). The most significant differences in shoot height are due to the highest shoots of "Villafranca". Difference in fresh shoot mass between the same clone (that had the lowest fresh mass accumulation) and others also contributed to the significant effect of factor clone for this character. Despite the fact that the effect of interaction Clone x Initial pH was not significant, some results of LSD test suggest that there could be detected differences in reaction of examined clones on Initial pH treatments. Generally, the highest inhibitory effect was achieved by medium with initial pH3, but some genotypes did not reacted as strong. This is not in concordance to the results of Kovačević et al. (2013) who found stimulant effect of medium with initial pH3 on growth of rooted shoots of white poplar genotypes. However, they did not use any means to enforce buffering capacity of their medium. It seems that in their experiment the low pH was provided for just a limited time during cultivation, and in this case produced even stimulant effect on shoot growth. However, the presented obtained results suggest that method described in this work would bi more appropriate for further studies and tests on low pH tolerance.

[a)] The differences among values of particular characteristic marked with the same letter are not significant at the level $\alpha_{0.05}$.

The most sensitive clone appeared to be clone L-12 as it achieved the lowest percentage of multiplication (20 %) and shoot height that was almost 2.5 times lower then in Control. Also, number of new shoot was almost half of the number of new shoots that appeared in Control, which was the case with all other clones except "Villafranca". On the other side, the most tolerant was the clone "Villafranca" that achieved more then 50% of percentage of multiplication, and relative mild decrease of shoot height growth, while the number of shoots on pH3 did not differed significantly from that of Control. Almost the same situation was for

fresh and dry shoot mass, where the severe decrease of biomass accumulation on pH3 was found for L-80, LBM and LCM, and relatively mild reaction of "Villafranca".

[a)] The differences among values of particular characteristic marked with the same letter are not significant at the level $\alpha_{0.05}$.

On the other side, although the effect of shoot moisture content was not under significant effect of differences between initial ph treatments, the LSD test suggest significantly lower shoot moisture content on the medium with pH7, then on pH5.5.This effect was particularly obvious in clone L-80, although the effect in this case was not statistically significant. Our assumption goes to the positive influence of high pH of the xylem sap on the aperture of stomata and reduced ABA sequestration ability of epidermis and mesophyll cells described by Wilkinson and Davies (1997). However, this effect was not noticeable in other clones, suggesting higher reaction of clone L-80 on rise of xylem sap pH.

Conclusions

The effect of initial medium pH on shoot growth and development of five white poplar (*Populus alba* L.) genotypes was tested. There is significant effect of the initial media pH on the most of examined characters, but not on interaction clone x medium pH. However, according to LSD test, clones significantly differed in their reaction on medium with pH3 in relation to medium with pH5.5, especially by shoot height and fresh shoot mass. Media with initial pH3.0 and pH4.0 achieve inhibitory effect on the most of examined characters compared to the medium with pH 5.5. Most of the examined white poplar genotypes had a significantly lower percentage of the multiplication on low pH medium than on the control medium and medium with a higher pH values. Medium with initial pH 7.0 achieved inhibitory effect on fresh shoot mass and shoot moisture content.

COMPARISON ON THE DENDROMETRIC PROPERTIES OF SILVER BIRCH *BETULA PENDULA* ROTH AND DOWNY BIRCH *B. PUBESCENS* EHRH. GROWING IN THE SIMILAR CONDITIONS

Imants LIEPA, Olga MIEZĪTE, Dagnija BĒRZIŅA, Aigars INDRIKSONS*, Linards SISENIS

Latvia University of Agriculture, Jelgava, Latvia
*Corresponding author: aigars.indriksons@llu.lv

Abstract

Both of these commercial birch species are present in Latvia, growing as mixed forest stands, often without the admixture of other tree species. Birch groves occupy 28% of the Latvian forest area. It is believed that the silver birch is more common in fertile and mesic mineral soils, but downy birch prefers wetlands and nutrient-poorer areas. Often birch groves are characterized by spruce second floor and undergrowth. From dendrological point of view silver birch and downy birch are two separate tree species. But in forestry practice these ideas are ignored. This is evidenced, for example, by the fact that in forest inventory to determine parameters of individual trees and forest stands for both species are used common regulations (tables, formulas, coefficients). Another case shows the round timber market with similar prices for both species timber assortments. Objective of this research is to analyze the dendrometric differences between both birch species growing in the same environmental conditions. The empirical material was collected in the two naturally regenerated forest stands represented by two birch species. For every tree of each plot has been assessed: species belonging, tree height, the first green branch height, trunk diameter at the height of 1.3 m above the root collar, stem sinuosity. To determine tree age and course of tree growth the increment cores were obtained by using Presler's increment borer. The main dendrometric parameters including annual increment dynamics for both birch species are found to be statistically different.

Key words: *silver birch, downy birch, dendrometric parameters.*

Introduction

Four species of genus *Betula* L. are found in Latvia territory: silver birch *Betula pendula* Roth, downy birch *B. pubescens* Ehrh., low birch *B. humilis* Schrank., dwarf birch *B. nana* L. Of these the first two species have commercial importance (Mauriņš, Zvirgzds, 2006). Both of these tree species take up to 28% of the total Latvian forest area. It is believed that the silver birch make up the best site indexes stands on the loose, evenly moist and humus-rich mineral soils, while the downy birch is more common in more wet and nutrient-poor places - terrain depressions and even fens. Silver birch also demands slightly more summer warmth than does downy birch (Niemistö, 2013). However, the two species are usually found in one place, forming of mixed stands with the Scots pine *Pinus sylvestris* L., Norway spruce *Picea abies* (L.) Karst. and aspen *Populus tremula* L. On mineral soils birch stems in mixed stands are slightly larger than those in pure birch stands. On peatlands, however, birch stems in pure stands are larger than those in mixed stands. The average stem form of silver birch was straighter than that of white birch (Heräjärvi, 2001). Often, birch groves are characterized by spruce second floor and undergrowth.

From dendrological point of view silver birch and downy birch are two separate tree species. But in forestry practice this idea is ignored. This is evidenced, for example, by the fact that in

forest inventory to determine parameters of individual trees and forest stands for both species are used common regulations (tables, formulas, coefficients). The round timber market with similar prices for both species timber assortments shows another case. In addition, such attitude can raise some questions, the answers to which could lead to reconsider the current practice. According to the article topic here just we note some informative dendrometric uncertainties. Are there statistically significant differences between the two species parameters (stem and forest stand volume, stem quality, current and mean increment of volume, the reference reaction to the management regime change and to various natural risk factors)? Failing that, two birch species practical use as one species is considered to be correct. Otherwise, it would assess the economic effect of this difference.

Materials and methods

The empirical material was collected in 2015 in two naturally regenerated forest stands near City Jelgava in Latvia composed by two birch species with small admixture of Scots pine (*Pinus sylvestris* L.). Medium thick and 2 to 3 m tall brushwood consisted of the alder buckthorn (*Frangula alnus* Mill.), bird cherry (*Padus avium* Mill.), rowan (*Sorbus aucuparia* L.) and common hazel (Corylus avellana L.). Ground vegetation was dominated: in the first forest stand - by bilberry (*Vaccinium myrtillus* L.), *Calamagrostis arundinacea* (L.) Roth, purple Moor-grass (*Molinia caerulea* (L.) Moench) and bracken (*Pteridium aquilinium* (L.) Kuhn); in the second forest stand – by purple small-reed (*Calamagrostis canescens* (Weber) Roth), wood small-reed (*C. epigeios* (L.) Roth) and purple moor-grass (*Molinia caerulea* (L.) Moench). The research forest areas were drained twice (the previous century thirties and sixties) as a result, have developed drained mineral soils with up to 20 cm thick layer of well decomposed peat. According to Latvian forest typology (Liepa et all., 2014) currently the forest stands belong to forest site type *Myrtillosa mel*. The analysed trees grow in the municipal forests of city of Jelgava (Latvia). First forest stand coordinates: lat. 56.6217, lon. 23.7191; the second forest stand coordinates: lat. 56.6233, lon. 23.7098.

One rectangular sampling plot with an area of 0.18 and 0.20 ha respectively has been established in each stand. For each tree were collected dendrometric indicators: height, diameter at breast height, the first green branch height, rugged bark height for *B. pendula*. The seperate tree trunk quality (stem sinuosity, double wooden top, branching, pest and disease injuries) and forest stand general sanitary state were visually assessed. From each tree was taken woody core 1.3 m above the root collar. The cores were sampled randomly with a Pressler's increment borer. For every cored sample ring width measurements were performed within 0.01 mm accuracy using measuring equipment Lintab4 (Schweingruber, 1996). Values at forest stand level were calculated accordingly to dendrometric algorithms, the analysis and interpretation of results were performed by graphical and statistical methods (Liepa, 1996; Philip, 1994).

Location of trees for both forest stands totally and for individual birch species separately was established randomly and evenly. The dominant tree species at the first forest stand was silver birch which according to number of trees comprised 64.0%, but regarding growing stock 81.3% (58.7% and 69.6% respectively at the second forest stand). These results corresponded with publications of other authors (Liepiņš et. al., 2013), who pointed out the similar data. Research forest stands survived intensive self-thinning process, which resulted in developing to medium stocking level (0.58 and 0.54 respectively) in the age of 65 years.

We draw attention to the fact that the thinning for silver birch has been faster. This was indicated by the tiny values of number of trees (growing stock) in the smaller diameter classes, when compared with downy birch. (Fig. 1).

Results and discussion

The calculated data for mean values of established sample plots are shown in table 1.

Table 1. Characteristics of the studied forest stands

Notes: Bs – Silver birch, Bd – Downy birch, P –Scots pine, Am – *Vacciniosa mel*., As – *Myrtillosa mel*.

It establishes a presumption that 65 years ago the two birch species were similar represented because seed trees in the surrounding mixed forest stands have been always richly found, but thinning have never been performed. Slenderness ratio i.e. h, m/d, cm between two species was markedly different (Fig. 2). This could be indicated that the downy birch on drained soils might be more sensitive to windthrow in the newer forest stands, but silver birch - in older stands.

The growing intensity of both birch forest stands have been compared using the last 30 years annual tree ring width (Fig .3). Trees were aged (35-65 years), when the radial growth had culminated and it continued to gradually decline. Except for a temporary period from 1989 to 1993 years, silver birch was indicated markedly greater increment values. This was especially true of the three time intervals: 1986 - 1989, 1994 - 2002 and 2006-2014. It is possible that this was due to a different distribution of rainfall. As is known, the two species of birch reference reaction to humidity has been partially reversed (Hynynen et. al., 2010). Moreover, the interpretation of the data have been complicated by the fact that in the neighborhood of second forest stand since the last century sixty years well functioned repeatedly renovated deep ditch.

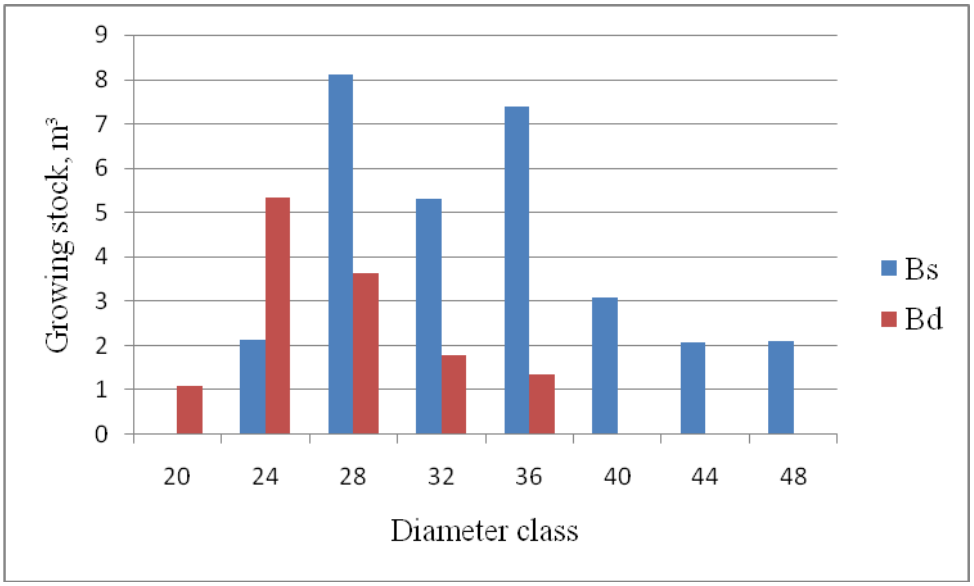

Fig. 1. The growing stock distribution among the diameter classes (second plot).

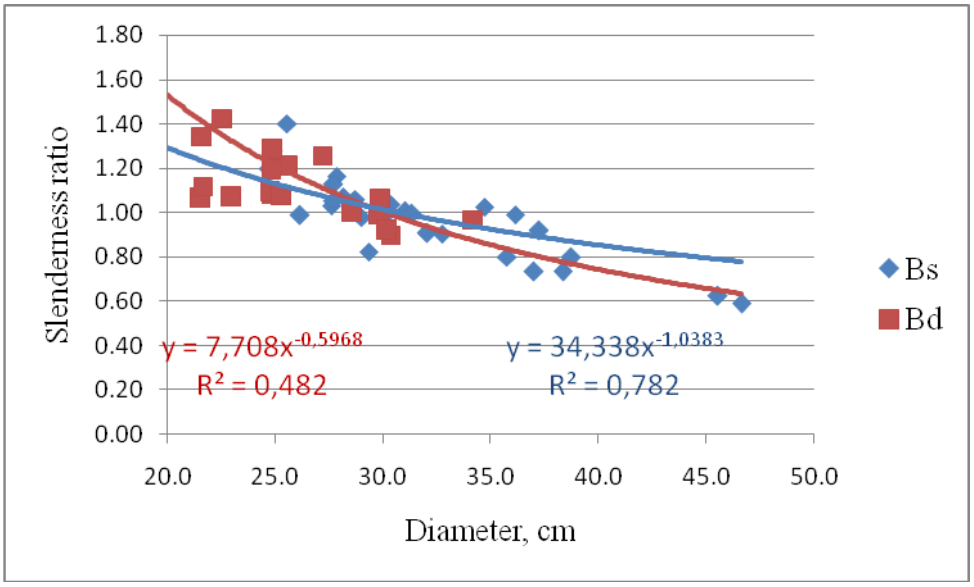

Fig. 2. The change of slenderness ratio along the tree diameter (second plot).

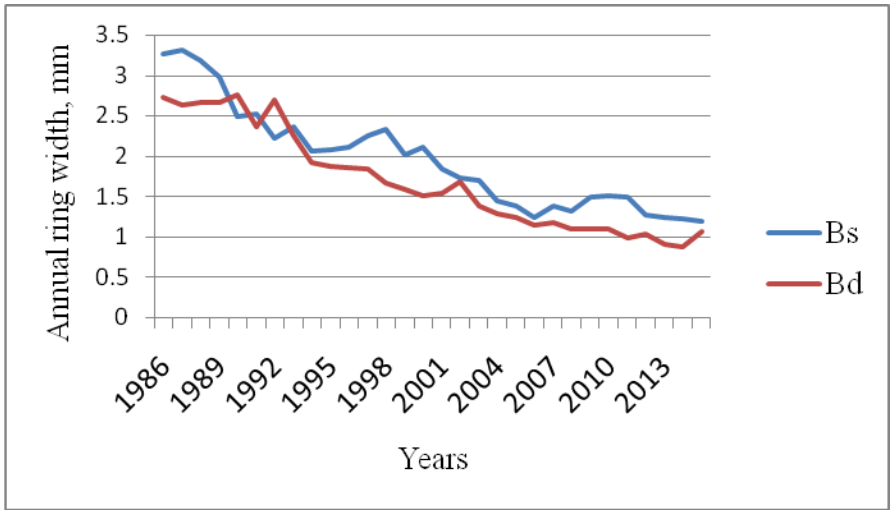

Fig. 3. Dynamics of annual tree ring width in the last thirty years, mm (second plot).

Conclusion

Our study showed that dendrometric properties between to birch species - silver birch *Betula pendula* Roth and downy birch *B. pubescens* Ehrh. growing in the similar environmental conditions (on the same places) in Latvia were remarkably different. These conclusions were not ecological and silvicultural novelty, but only proof that it is in sight to carefully decide evaluation aspects related to forest inventory. Of course, in the context of the rational use of forest resources the more important is to compare the wood mechanical and chemical qualities of two birch species.

Abstract

The paper presents the results of the research into the intra and inter-population variation in the morphological characteristics of the fruits and seeds of five populations of wild cherry (*Prunus avium* L.) in the Entity of the Republic of Srpska. The fruits and seeds were collected from 10 trees of five wild cherry populations in municipalities of Kalinovik, Višegrad, Milici, Ribnik and Prnjavor in the summer 2015. The studied morphological properties were: fruit length, fruit width, seed length, seed width and petiole length. The population "Ribnik" was characterized by the highest coefficient of variation regarding petiole length (10.6%). On the other hand, the lowest variation coefficient was observed in the population "Milici" for seed width (3.9%). The ANOVA showed that the variation between populations as well as the variation between the genotypes within the populations were highly significant ($p<0.001$) for all of the analysed traits. Statistically significant correlation was observed between fruit and seed traits studied, as well as between petiole length and fruit length. The conducted research can serve as a starting point for further researches when it comes to breeding wild cherry in the Republic of Srpska and beyond.

Key words: *wild cherry, population, half-sib lines, morphology, the Republic of Srpska*

Introduction

Wild cherry (*Prunus avium* L.) is one of many wild fruit trees that can be found in the forests of the entity of Republic of Srpska (RS), Bosnia and Herzegovina (B&H) (Mataruga et al., 2013). The tree usually grows up to 20 m high, and it is rarely bigger than 50 cm in diameter. It belongs to the fast-growing species with life span of 40 to 60 years. It produces rich blossom early in spring, with prominent white blossoming due to which trait it is present in bee keeping. The fruit is small, 1 cm thick, of roundish shape (Jovanovic, 2000). Edible fruits ripen from June to August and are red or black, often distributed by birds and small mammals (Pilipovic et al., 2011). Wild cherry (*Prunus avium* L.) has manifold significance for the economy of the RS. Back in 1954, it was proclaimed the "Tree of the Future" (Bejdl, 1954), but this species was not given sufficient attention in our areas. The Law on Forestry forbade cutting of wild fruit trees, wild cherry included, but in the post-war period, from 1996 to 2000, all wild cherry trees that could be used for processing were cut down in B&H (Ballian et al., 2007). The first researches of variability of wild cherry in B&H started in 1990. Plentiful material was collected and *half-sib* posterity grown to over 200 families. The researches were stopped because of war activities in B&H, while data and grown/bred posterity destroyed. In the post-war period, the lack of resources prevented extensive studies of the wild cherry, but local researches of morphological and genetic parameters were undertaken (Ballian, 2000, 2004). Among the great number of species having stone fruits, wild cherry excels as the most significant one with great economic value. Branches produced by the form of smooth crust, small, bitter and black fruits that ripen late (Ballian et al., 2007).

Use value of the wild cherry trunk as raw material for wood-processing industry and pomology significance should be directed towards raising progeny tests, while seed material shall serve for raising dedicated cultures for the purpose of production of raw materials for food processing industry, pharmaceutical and chemical industry.

In order to preserve the wild cherry genetic resources, the primary aim is to determine the richness of its gene pool as the basis for the conduct of measures of preserving, measures of breeding and commercial use (Nonić et al., 2013). This research focuses on studying the morphological parameters of the fruit and seed of wild cherry originating from five natural populations in the RS. The main aim of the research is to determine variability of studied characteristics within the population and among the populations, as well as the level of connectivity between the studied characteristics The researches have been conducted with the aim of preserving the wild cherry on the territory of the RS and beyond.

Material and method

Material for the morphological analysis (fruits and seeds) of the fruit and the seed was collected from five natural populations in the RS: Kalinovik, Višegrad, Milići, Ribnik and Prnjavor municipalities. At each of these locations, 10 trees were selected, and thirty healthy, normally developed and ripe fruits with petioles were collected from each fruit tree. The trees were selected on the basis of phenotypic characteristics and the volume of fruiting (Isajev et. al., 2011). Fruits and seeds were collected during the month of June and July 2015, depending on the altitude where the above indicated populations are found. The first fruits for the research were collected in the middle of June, from the population Prnjavor, which is at the altitude of 185 m, while the fruits that were last collected were collected from the population Kalinovik (1070 m above the sea level), in the end of July. Measuring of the fruits was done by nonius with accuracy of 0,01 mm.

Morphometric analyses comprised the following parameters: fruit length (FL), fruit width (FW), seed length (SL), seed width (SW) and the fruit petiole length (PL). The measured morphological characteristics are described through descriptive statistical indicators: mean value ($\overline{x}$), standard deviation (SD), coefficient of variation(CV). In order to determine intra and inter-population variability of the wild cherry, Nasted ANOVA. The analysed variability factors were “population” and “tree” (tree factor nested inside of population factor). Correlation among studied characteristics was determined using Pearson's correlation ($p<0.05$). Collected data were processed by means of statistical programme Statistica 10.0 (StatSoft, Inc.).

Results and discussion

Results of descriptive statistical analyses indicated that the mean value of the fruit length varied from 9.4 mm in the population Kalinovik up to the maximum of 12.2 mm in the population Višegrad. The lowest variation in the fruit length characteristics was found in the wild cherry from the population Višegrad (5.5%), while the population Kalinovik indicated the highest variation in the fruit length (6.9 %).

When it comes to the fruit width characteristic, the mean value varied from 8.6 mm in the population Kalinovik up to 11.9 mm in the population Višegrad. Variation coefficient for the fruit length characteristic showed that the lowest variability of this studied characteristic was observed with the population Višegrad (6.3%), while the highest variability was observed with the population Ribnik (8%).

Results of the descriptive analysis for the seed length characteristic indicate that the mean value of the seed length varied from 5.9 mm in the population Kalinovik, up to 6.6 mm in the population Višegrad. Minimum length of seeds was recorded in the population Ribnik and amounted to 5.0 mm, whereas the maximum length of seeds was recorded in the population

Višegrad and amounted to 7.2 mm. Average deviations by population varied from the minimum of 0.30 mm for the population Milići up to the maximum of 0.40 mm for the population Ribnik. The lowest variability in the seed length was recorded in the population Višegrad and amounted to 4.6%, while the highest variability was recorded in the population Ribnik and amounted to 6.8%.

The mean value in the seed length characteristic varied from 4.8 mm in the population Kalinovik up to 5.5 mm in the population Prnjavor. Variability coefficient for this studied characteristic indicates that the lowest variability was observed in the population Milići (3.9%), while the highest one was observed in the population Kalinovik (6.5%).

For the petiole length characteristic, the results of descriptive statistics showed that the mean value of petiole length by population varied from 34.7 mm in the population Kalinovik up to 39.9 mm in the population Prnjavor. The lowest variability coefficient of the petiole length was recorded in the population Višegrad (8.0 %), while the highest one was recorded in the population Ribnik (10.6 %). Results of descriptive statistics for average mean values and variations are presented in Table 1.

Table 1. Descriptive statistical analysis of studied fruit and seed morphological traits. Means followed by the same letters within a variable are not significantly different ($p<0.05$).

Trait	Parameter	Kalinovik	Milići	Prnjavor	Ribnik	Višegrad	All populations

	CV (%)	6.5	3.9	5.1	6.0	4.9	5.3

The research results show high level of variability of studied characteristics. Analysis of variance (ANOVA) indicated highly significant differences ($p<0.001$) for all studied characteristics, both between the populations of wild cherry and between the genotypes within the populations (Table 2).

Table 2. Results of Nested designed ANOVA analysis for investigated fruit and seed characteristics.

		df	PL	FL	FW	SL	SW
Between populations	*F*	4	117.0	671.6	861.9	240.8	269.5
	p (<)		0.001	0.001	0.001	0.001	0.001

Legend:
PL- petiole length, FL- fruit length, FW-fruit width, SL-seed length, SW-seed width

The results showed that the size of fruit and seed were in accordance to the values found by other authors. Ballian (2000) states that the mean of length of seeds of selected trees amounts to 8.63 mm, and the seed width is 7.15 mm, Nonić et al. (2013), state the results of their researches indicating that the length of the seed varies from 6.48 to 8.31 mm. Jovanović (2000) and Šilić (1983) state that dimensions of the fruit vary by around 1 cm for the fruit petiole length characteristic. Noćajević et al. (2012) found that the fruit petiole length varied from 33.6 mm to 42.3 mm (results for the year 2006), and also from 36.3 to 53.3 mm (results for the year 2007). Analysis of morphological characteristics of fruits and seeds in five natural populations of wild cherry in the Republic of Srpska (Bosnia and Herzegovina) was conducted with the aim of determining intra- and inter-population variability which would presents the grounds for further work on breeding of this species. Results of the research indicate that the highest mean length of fruit petiole was recorded in the population Prnjavor, and that this population significantly defers when compared to the populations Kalinovik and Ribnik, unlike other populations, that are similar. Study of the fruit length indicated that the populations Višegrad and Kalinovik differ between each other significantly, as well as that these populations differ when compared with other populations. Also, similarity of this

studied characteristic is found among the populations Milići, Prnjavor and Ribnik. For the fruit width characteristic, the results of the research indicated that the populations Kalinovik, Višegrad and Ribnik differ among each other as well as that these populations differ in relation to the populations Prnjavor and Milići, among which there is a similarity. The research conducted for the seed length characteristic indicated that the populations Milići, Prnjavor and Višegrad significantly differ in relation to the populations Kalinovik and Ribnik. The study of the seed width characteristic showed that the populations Višegrad and Prnjavor significantly differ in relation to the populations Kalinovik and Ribnik. Results of this research proved that there are significant differences in all studied characteristics, both among the populations of wild cherry and between genotypes within the populations. Similar results were also reached by Ballian (2000); Ballian (2007); Ballian (2013). The conducted research studies indicate that statistically significant differences were found between analysed populations and genotypes within the same populations. Statistically significant differences that appeared between genotypes and populations indicate the impact of both the genotypes and the environmental factors. Namely, when the above stated results are analysed, they show that there is a similarity between the populations Ribnik and Kalinovik in all three studied characteristics (the fruit petiole length, seed length and width), as well as that there is a similarity between the populations Milići and Prnjavor in all studied characteristics. Namely, the populations Ribnik and Kalinovik are found at higher altitudes that vary by above 500 m of altitude compared to the populations Milići, Prnjavor and Višegrad.

Conclusion

The analyses of variance indicated highly significant difference ($p<0.001$) in all studied characteristics, both between the genotypes within the populations and among the populations of wild cherry.

Results of morphometric analysis indicate that the fruit petiole length (PL) is the most variable characteristic; the lowest coefficient of variance for petiole length was recorded in the population Višegrad (8.0 %), while the highest one was recorded in the population Ribnik (10.6 %). According to the variation coefficient value, the lowest variance was found in the seed width (SW), and it was found in the population Milići (3.9%).

The lowest average means for all studied characteristics (fruit length, fruit width, seed length, seed width and the fruit petiole length) was found in the population Kalinovik.

For the petiole length and seed width characteristics, the highest mean values were found in samples taken from the populations from Prnjavor, while the population from Višegrad indicated the highest mean values for the length and width of the fruit, as well as for the seed length.

The lowest deviations from the mean value was found in the population Milići (0.21 mm) for the seed length characteristic, while the highest deviation was found in the population Ribnik for the petiole length characteristic (3.70 mm).

Statistically significant correlations were recorded between the fruits and the seeds for all studied characteristics, as well as between the petiole length and the fruit length.

The following phase in our researches shall be to establish the tests of wild cherry posterity by collecting seeds from the populations that have been the subject of our research presented in this paper. Better knowledge of genotypes and production of seedlings at the level of half-sib lines would help us achieve the set aims in terms of raising cultures for special purposes at various habitats.

Acknowledgement

This paper has been produced within the project "Genetic diversity and variability of wild cherry (*Prunus avium* L.) in the Republic of Srpska", financed by the Ministry of Science and

Technology of the RS. We are also grateful to the Public Enterprise "Forests of the Republic of Srpska" (JPŠ „Šume Republike Srpske") for their support during the field work.

FOREST AREAS AS KEY INDICATOR FOR SUSTAINABLE FOREST MANAGEMENT IN SERBIA

Zvonimir BAKOVIĆ[1]*, Branko STAJIĆ[2], Vladimir VASIĆ[1]

[1]State enterprise (SE) "Srbijašume" Belgrade, Department for Silviculture, Serbia

Abstract

Forests and forest land belong to the most important natural resources in Serbia. The area under forest represents one of the key indicators of sustainable forest management. Forests in Serbia are spread over a surface area of 2,252,400 ha. One of the main problems related to the state of forests and forest land and their sustainable management in Serbia is the inadequacy of its forest coverage (29.1%) in relation to the optimum level of 41%. From the global point of view, it is close to the world's average forest cover of 30%, but drastically lower than the 46% in Europe (TBFRA 2000). The forest cover in Serbia needs to be raised to its optimum level by year 2050. Sustainable forest management has its own requirements that can be fulfilled only if we provide certain preconditions. As regards the forest cover, the goal is to increase it by afforestation. According to the provisions of the Spatial Plan, the operational objective of the Republic of Serbia implies that, with respect to global space regionalization and categorization, 450 km^2 of new forests were to be established in the period 2010 - 2014. Operational objectives are by nature specific, measurable, time-framed, "real" and susceptible to analysis. In this context, two main objectives are contained in this paper. Based on the data available, the first objective is to do an analysis on the area size of new forests in Serbia that were established through afforestation of barren land in the period 2010 - 2014. In this regard, an assessment will be made of whether the afforestation level and trend represent a sufficiently secure framework to ensure sustainable forest management in Serbia. The second objective of this paper is to analyze the resources of the Budgetary Fund for Forests of the Republic of Serbia allocated for the purpose of afforestation on barren lands for the period 2010 - 2014. For this purpose, an analysis will be carried out (growth / decline trend) of allocated funds and the by-laws related to the conditions for their granting, allocation and justification. The paper shall give specific recommendations on how to improve the current situation in this field, given the conditions in Serbia.

Keywords: *afforestation, sustainable forest management, Serbia*

Introduction

Intense exploitation and partial "degradation" of forests in Serbia and most of South-East Europe began as early as the 18th century, especially in the 19th century (Stajić et al. 2009), which may explain a significant part of the total anthropogenic impact on forests. Forests in Serbia play a very important role in environmental protection, with a large number of regulatory and protective functions (protection of waters and water supply, protection against erosion, improving soil hydrological properties, balancing the hydrological cycle, biodiversity protection, etc.) (Aleksić et al. 2013).

Based on the provisions of the Draft Spatial Plan of the Republic of Serbia (RS), "*the assessment of the conditions relating to spatial development of Serbia has been carried out according to the integral method which involves understanding of interinfluence among economic, social and physical-environmental development*". According to this draft, and in

the spirit of sustainable development, the top-priority should be conservation of nature (forest ecosystems) and the environment.
Forests are one of the most important natural resources in the RS. Primarily, environmental quality depends largely on the forest cover. The preservation and improvement of the current forest conditions are directly related to the quality of the living environment. Increasing the forest area in a sustainable manner in order to increase biomass (green and wood), and their correct spatial zoning represent a challenge for both the state and profession.
The forest coverage of the RS is 29.1%, which is below expectations as compared to the plans. The planned optimal forest cover for the RS is 41.4%, and it is to be reached by the year 2050.
Important prerequisites to reach the required / planned percentage of forest cover are: the harmonization of the legal framework and planning provisions, development and adoption of the National Forestry Action Programme (NFAP) and securing the necessary funding for the establishment of new forests.
One of the key indicators for assessing the sustainability of forest management is the forest surface area, i.e. whether it decreases or increases over time.
This paper has two main operational objectives. The first objective is to analyse the area size of new forests in Serbia that were established through afforestation of barren land in the period 2010 – 2014, and the second one is to analyze the resources of the Budgetary Fund for Forests of the Republic of Serbia allocated for the purpose of afforestation on barren lands for the same period.

Materials and methods

Background
In order to realize the set goals, different empirical (statistical) data on the forest conditions were used (see their overview by surface area). In some depictions, there are certain differences in relation to the data of the National Forest Inventory of the Republic of Serbia (NFIRS), in terms of both methodology and time.
The data on the establishment of new forests has been obtained on the basis of records of performed work kept by the users. Through grouping, the data is presented in tables and analyzed using graphs, aiming at full comprehension.

Method of work
Acknowledging the stated research problem, the methodological procedure used in the preparation of this paper has been basically analytical-synthetical in its character. International and national professional literature relating to the field of interest has been used.
The most frequently used scientific methods in research have included: the method of analysis and synthesis, comparative method and, lastly, method of induction and deduction.

Results and discussion

Forests and forest lands in Serbia
Prior to the presentation on the conditions of forests and forest land in the RS, an overview of area structure according to land type (land use model) is given in Table 1 below.

Table 1. Area Structureby Land Type (Land Use Model)

Land Type (Land Use Model)	Area	
	ha	%
Forest	2,252,400.00	29.10
Other Forest Land	382,400.00	4.90
Barren Land	92,000.00	1.20
Agricultural Land	3,594,800.00	46.40
Meadows and Pastures	1,029,600.00	13.30
Urban Land	312,000.00	4.00
Water Surfaces	85,200.00	1.10
Total	**7,748,400.00**	**100.00**

Source: NFIRS (2009)

Considering the data presented in Table 1, we may conclude that the forest coverage of the RS is 29.1%.

Se "Srbijašume" – condition of forests and forest land

SE "Srbijašume" manages forests and forest land in a total area of 896,266.06 ha, of which 767,523.87 ha of wooded area and 128,742.19 ha of unwooded area (Table 2). The ratio between wooded (under trees) and unwooded areas (forest land) at SE "Srbijašume" is 86% : 14%, which can be assessed as relatively favourable. SE "Srbijašume" manages 40% of a total of 2,252,400 ha (Banković et al. 2009) under forests in Serbia.

Table 2. Area Conditions at the Level of SE "Srbijašume"

Source: Internal database of SE "Srbijašume" – Belgrade, as of 31st Dec. 2014; data taken from forest stand inventory of SE "Srbijašume".

SE "Srbijašume" performs professional-advisory activities in forests under private ownership - private forests over an area of 1,176,139 ha, covering about 3.5 million cadastral parcels and about 1,000,000 owners. Professional-advisory activities acc. to the Forest Law, include as follows: registration, tree marking for harvest, issuing logging permits, issuing shipping documentation for wood assortments, organizing activities on forest protection, training of forest owners etc.

SE "Srbijašume" manages forests and forest land owned by the state and performs professional work in private forests in the total area of 2,072,405.06 ha, which make up 92% of the total forest area in the RS (2,252,400 ha).

Condition of forests and forest land in Central Serbia (other users)

The condition of forests and forest land, owned by the state on the territory of Central Serbia, without Autonomous Province of Vojvodina (APV) and Autonomous Province of Kosovo and Metohija (AP K&M) is shown in Table 3 below.

Table 3. Condition of Forests and Forest Land,Central Serbia without SE "Srbijašume" – State Owned

Condition of forests and forest land - AP Vojvodina

On the territory of the Autonomous Province of Vojvodina, forests and forest land occupy a total area of 174,413 ha, of which 140,718 ha of wooded area and 33,696 ha of unwooded area (Table 4). The ratio between wooded and unwooded areas in AP Vojvodina is 93.5% : 6.5%, which can be assessed as extremely unfavourable.

Table 4. Area Conditions at the Level of APV

User	Area (ha)	Share of total Vojvodina Land Area (%)
SE "Vojvodinašume"	130,589.00	6.10

Forests under private ownership - private forests

The State of Serbia, through its Ministry of Agriculture and Environmental Protection (MAEP) - Forest Directorate has entrusted the expert-advisory affairs in private forests to state enterprises for state forest management by forest areas and state enterprises - national parks on the territory of which the private properties are found. The forest owners themselves are responsible for the management of private forests in Serbia. Private forest area in RS without AP K&M is given in Table 5 below.

Table 5. Private Forest Area by Competent Institutions

Institution	Area under Forest	
	ha	%
SE "Srbijašume"	1,176,139	95
SE "Vojvodinašume"	5,567	0.5
SE National Parks*	25,000	2.0
SE National Parks "Tara"**	25,725	2.1
PUC Borjak	4,000	0.3
Private Forests - Total	**1,236,431**	**100**

Source: Internal database PE (2008), SE "Srbijašume" (2016).
*SE National Parks: Data from 2008; Internal documentation without NP "Tara";
**Database NP "Tara" – Development Plan for the Tara National Park (2012-2021).

Based on Table 5, we conclude that SE "Srbijašume" performs professional-advisory activities in approximately 95% of the private forest area, while all other enterprises perform these tasks in the remaining 5% of the area. The entrusted professional-advisory activities in private forests are financed from the Budget of RS at MAEP – Forest Directorate.

Afforestation 2010 – 2014; PLAN: implementation report

Observing the forest conditions in the Republic of Serbia, it is assessed that the forest cover insufficiency (29.1%) compared to its optimum percentage (41.4%) represents the leading problem of Serbian forestry.
One of the basic assumptions of sustainable forest management is to increase the forest area through afforestation. According to the provisions of the Draft Spatial Plan of the Republic of Serbia (DSPRS) 2010-2014-2021, respecting the global zoning and space categorization, afforestation from 2010 to 2014 was to include 450 km^2 or 45,000 ha (Table 6).

Table 6. Forest Surface Area, Forest Cover & Afforestation Plan by 2014 in RS

Area / Province	Total Area Surface	Forest Area	Forest Cover	Optimal Forest Cover	Forest Area 2014
	km2	ha	%	%	ha
Serbia without AP K&M	77,474	2,252,400	29.1	41.4	2,297,400
AP Vojvodina	21,506	154,000	7.1	14.3	171,600

***** Data on the establishment of new forests in the period 2010-2014 by users managing forests in AP Vojvodina (Table 4) were not available.

Based on the data in Tables 6 and 7, drastic deviation is evident from the afforestation plan and its implementation for the period 2010 - 2014. For the space of Serbia without APV and AP K&M the difference is -23,170 ha, which means the fulfillment of the plan is 13.9%. If this trend in establishing new forests continues, by year 2050, on the territory of Serbia without APV and AP K&M there will be 26,266 ha of new forests or a forest coverage of 37.9%. Viewed through this model, the optimal forest cover of Central Serbia following this afforestation trend will be reached in several centuries from now. Considering that this is the area comprising 93% of the total forest area in the RS, this projection can be transferred to the entire RS land area with great certainty. The problem of plan non-conformities in the establishment of new forests within the conditions in Serbia is very complex and particularly noticeable.

Budgetary funds for Serbian forests

In the period 2010 - 2014 the assets of the Budgetary Fund for Forests of the Republic of Serbia (BFFRS) allocated to afforestation varied in the unit price and amount, as well as by types of work. Types of afforestation work, for which the assets were allocated by regulations and through competitions, are as follows: (I) afforestation of barren land (2010-2014), (II) raising (intensive) plantations (2010-2014, except for 2011), (III) afforestation of barren land in private forests - distribution of forest seedlings to individuals (2010 -2014), (IV) rehabilitation of surfaces through afforestation (2010-2013), (V) reforestation (2013), (VI) reclamation of degraded forests (2010-2013) and (VII) recruiting/repair planting (2013).

The amount of funds allocated to afforestation also varied, and in certain years it was not defined for each work type separately. Bearing this in mind, the fund total amount allocated to afforestation was taken into account for the purpose of analysis.

Since SE "Srbijašume" manages state-owned forests and forest land and performs expert tasks in private forests on a surface that makes up 92% of the total forest area in the RS, SE "Srbijašume" database was used in the analysis of the contract funds. Each year, during the said period, the contracted scope of work was lower than anticipated.

Since 2013, unit prices have increased (e.g. unit price for afforestation of barren land before 2013 was 110,000 dinars/ha, since 2013 - 120,000 dinars/ha). However, if one takes into account that the average price for afforestation in 2014 amounted to 236,885.46 dinars/ha, it can be concluded that the share of BFFRS assets in the overall price of afforestation of barren lands per hectare was approx. 51%. It is also necessary to point out that in 2014 the BFFRS Regulations (Regulations on detailed terms, method of allocation and use of assets from the Annual Programme for the use of the Budget Funds) were applicable, which provided an addition to the afforestation prices in terms of tending measures up to 5 years of age. Considering the above mentioned, it can be concluded that the share of the unit price in the total price of afforestation per one hectare of barren land was not 51% but 45%. When talking about raising plantations and intensive plantations, this ratio was far more favourable. The unit price of 120,000 dinars/ha was about 91% of the calculated average price (131,774.13 dinars/ha). When tending measures up to 5 years of age are added to the average price, the participation of the unit price was around 77%. Since 2016, by entering into force of amendments to the BFFRS Regulations, the situation has been somewhat better. Namely, by the above amendments, it was defined that the tending measures up to 5 years of age were to be financed separately from afforestation.

The scope of work allocated to afforestation varied from year to year, but from 2012 to 2014 a drastic downward trend was noticeable. It should be noted that in 2014 no contract was signed for afforestation of barren lands in private forests - distribution of forest seedlings to individuals, yet these works were contracted during 2015. Also, in 2014 the contracted amount of 5,817,600 dinars was related to the works carried out in 2013. The competition in 2014 did not anticipate the funding of afforestation in state forests which was included within the works agreed for the year 2015.

Table 8 shows the financial assets allocated by regulation, as well as financial assets contracted in the period 2010 - 2014.

Table 8. Allocations & Contract Funding

Year	Total by Regulation	Afforestation Anticipated by Regulation	Contracted
	din	din	din
2010	462,681,863	amount not defined separately	80,894,011
2011	577,969,400	199,570,000	106,330,184
2012	1,500,000,000	379,500,000	54,080,255
2013	809,998,929	46,000,000	18,120,493
2014	510,000,000	8,681,053	5,817,600

A lack of financial resources can be cited as one of the main reasons for the above stated. When talking about the assets of the BFFRS, it should be noted that, when compared to 2013 and 2014, there has been a considerable increase in asset allocation to afforestation by regulations in the last two years. Also, an increase in contracted assets for afforestation works has been noticed.

Conclusions

The area under forest represents a major indicator of sustainable forest management. This fact is gaining in importance in the times of current climate changes, especially when viewed through the prism of the conclusions from the Paris Conference COP 21, the Conference of the Parties (COP 21) to the United Nations Framework Convention on Climate Change.

The forest area in the Republic of Serbia (without AP K&M) is 2,252,400 ha, which means that it is close to the world's forest cover of 29.1%.

The Spatial Plan of the Republic of Serbia anticipates 41.4% of forest cover by 2050. Five-year operational plans (DSPRS) for the period 2010 – 2014 envisaged the establishment of 450 km^2 of new forests. These were to be established through: protection forests (against erosion = 100 km^2, protection of roads = 10 km^2, emissions reduction = 23 km^2, protection of agricultural crops = 20 km^2, water protection = 135 km^2, rehabilitation of tailing ponds = 18 km^2) afforestation on degraded lands (6^{th} and 7^{th} land capability class) on a total area of 119 km^2 and planting of new forests in suburban zones on a total area of 25 km^2.

Initial afforestation activities in Serbia started back in 1818. The technologies and requirements for the establishment of new forests in Serbia have been changing during its 200-year-long tradition.

When it comes to the extent of afforestation in Serbia, the "golden" period is linked to the end of the 20^{th} century. The afforested areas by periods were as follows: 1975 – 1980 = 18,930 ha; 1980 – 1985 = 15,150 ha; 1985 - 1990 = 8,720 ha. There has been a declining trend ever since.

In the period 2010 – 2014, on the territory of Serbia (without APV and AP K&M, which represents 97% of the total forest area), a total of 3,752.36 ha of new forests was established, i.e. the plan fulfillment was 13.9%. If this trend continues, Central Serbia will reach its optimal forest cover of 49.8% in several centuries from now. Viewed through this perspective, the trend can be assessed as highly unfavourable.

For the purposes of establishing new forests in Serbia, mostly the assets from the Budget Fund for Forests of the RS are used. In the period 2010 - 2014 the assets allocated to afforestation varied in the unit price and amount, as well as by types of work. The share of BFFRS assets in the overall price of afforestation of barren lands per hectare was in the range between 45% and 51%. The difference up to the full price was covered by the users from their own resources. Asset allocation is defined by the Regulations. According to the regulations, in the observed period tending measures up to 5 years of age were to be added to the price of afforestation. The amount of assets for the purpose of establishing forests in Serbia in the observed period can be assessed as insufficient.

The general conclusion is that the afforestation for the observed five-year period has not satisfied the SMART matrix. To be more precise, the afforestation plan has met the test requirements of this matrix in the first part (**S**pecific - clear and defined; **M**easurable - can be estimated on the basis of quality, timing, quantity or resources). However, it has failed in the second part of the matrix (**A**ttainable; **R**ealistic – the society, institutions and individuals should have control / direct responsibility and the opportunity to achieve the planned level of afforestation; **T**imely – the planned goal of afforestation should include clear deadlines for implementation).

The problem of plan non-conformities in the establishment of new forests within the conditions in Serbia is very complex and particularly noticeable.

With the adoption of amendments to the Forest Law in 2015, and the new Regulations in 2016 the situation has slightly changed for the better. The very regulatory amendments have introduced the provision according to which the tending measures up to 5 years of age are to be financed separately from afforestation. Also, an increase in contracted assets for afforestation works is noticeable, which is an encouraging sign and announces a new era in afforestation in Serbia. This will ensure a considerable increase of the forest area in Serbia, which is one of the key indicators of sustainable forest management.

HYDROLOGICAL PROPERTIES OF EUGLEY SOIL IN THE MIDDLEDANUBE BASIN

Saša PEKEČ[1*], Marina KATANIĆ[1]

[1] Institute of Lowland Forestry and Environment, University of Novi Sad, Antona Cehova 13, 21000 Novi Sad, Serbia
*Corresponding author. pekecs@uns.ac.rs

Abstract

The paper presents hydrological characteristics of eugley soilin the middle basin of the Danube river. Eugley soilwas analyzedat three sites within the part of the alluvial plain, which is protected from flood waters and wetting of this soil is under the influence of groundwater. The level of groundwater in the first profile ranged from 130 to 230 cm below the soil surface, in the second profile movement of groundwater amounted from 90 to 240 cm, while the third profile had amplitude varying from 95 to 185 cm below the soil surface. During the measurement of soil moisture at the depth of 10 cm it was noted that moisture values ranged from 8.96 to 72.65% vol., at the measurement depth of 40 cm soil moisture ranged from 12.24 to 47.74% vol., while at a depth of 70 cm soil moisture was in the range from 13.83 to 54.80% vol.. The measurement results show that the highest value of soil moisture is in the surface horizon at 10 cm depth, while soil moisture valuesat 40 and 70 cm areperiodically increased due to the influence of groundwater capillary rising,especially in dry summer months.

Key words: *Soil moisture, Ground water, Eugley, Soil*

Introduction

In the area of distribution of alluvial plains greatest impact on the water regime of soilhave water levels of nearby rivers. Part of the soil located behind embankment has totally different hydrological characteristics because moisteningoccurs only by underground water and rainfall, in relation to the part that is not protected by an embankment and where moistening, in addition to these two ways, takes place through floodwater. On the hydrological characteristics of the soil in this protected part the underground water has the greatest impact, and its variations during the year, while on the variation of groundwater in the protected part influence has the nearby river water stream. These soils are found at the lowest parts of the preterrace part of the alluvial plain as a representative soil from hydromorphic order (usually Gleysols acording to WRB, 2006). Bearing in mind that the soilsof type eugley found in preterrace part of alluvial plain are the furthest from the river bed and are located at the lowest forms of relief and depressions according to Antić et al (1968), their hydrological characteristics depend on direct moistening of profile with groundwater and indirect influence or capillary rising of groundwater through various horizons and layers of soil. These eugley soils are classified by Miljković (1996) in gley or hypogley soilsaccording to the way of wetting.Given the depth of groundwater, in these soils due to the reduction phase and moistening of the bottom of the profile, gley horizon is located at different depths according to Antić et al. (1969). The greatest impact on pedogenetic processes and properties of eugley soilsstudied in this area has groundwater regime (Pekeč, 2010). Sincethese are floodplain soils, they have a pronounced variability of granulometric composition, which together with the variability of relief forms on which they are located, give a very variable productive values (Pekeč and Katanić, 2015)

Material and method

Research of eugley soils was carried out in 2012.on the left bank of the middle course of the Danube in an area protected with the embankment from the flood waters. At three selected sites piezometerswere placed to measure the depth of groundwater. The level of groundwater was measured once per month. Along with the measurementof groundwater, soil samples were taken monthly in disturbed condition to measure soil moisture. Samples of soil were taken from a depth of 10, 40 and 70 cm, measured in wet condition, dried in the oven at 105 °C, and measured in dry condition.

Results and discussion

The analysis of thegroundwater level ofeugley soil presentby profile 1 (Fig. 1), showed that the highest level of ground water was130 cm below ground, while the lowest level was 230 cm. The level ofgroundwater rose toApril, then declined until June after that was noticed a slight increase in its level.

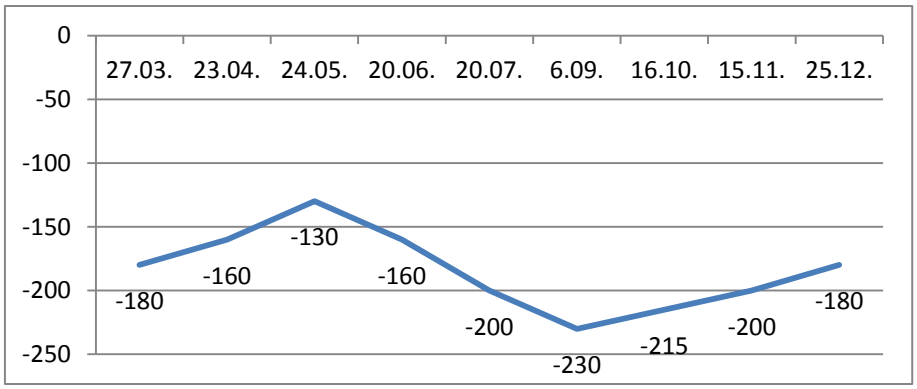

Figure 1 The level of groundwater in profile P1

The analysis of soil moisture in profile 1 (Fig. 2) showedthat moisture value wasthe highestat a depth of 10 cm and ranged from 16.56 to 72.65% vol.. Lower values of moisture content were recorded at the lower depths. The soil moisture value at the depth of 40 cm was in the range from 13.77 to 45.67% vol.and at the depth of 70 cm from 19.98 to 40.80% vol. Trend of soil moisture movement at all three depths showed an increase in the moisture value until the end of May and decline until the beginning of September, after that it was noticed an increase in moisture value in the soil at all depths.

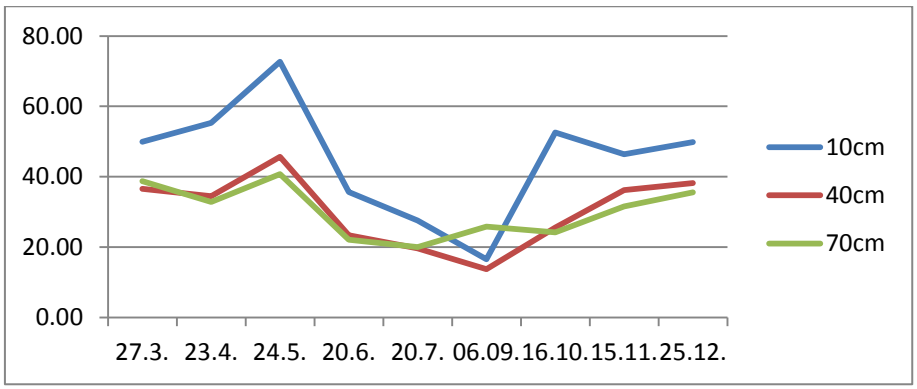

Figure. 2 The soil moisture in profile P1

In the eugley soil presentedby profile P2 (Figure 3) the ground water level was highest at 90 cm below ground level and the lowest at 240 cm. Trend of groundwater is such that the level of groundwater was in decline until mid-November, after that there was a decline.

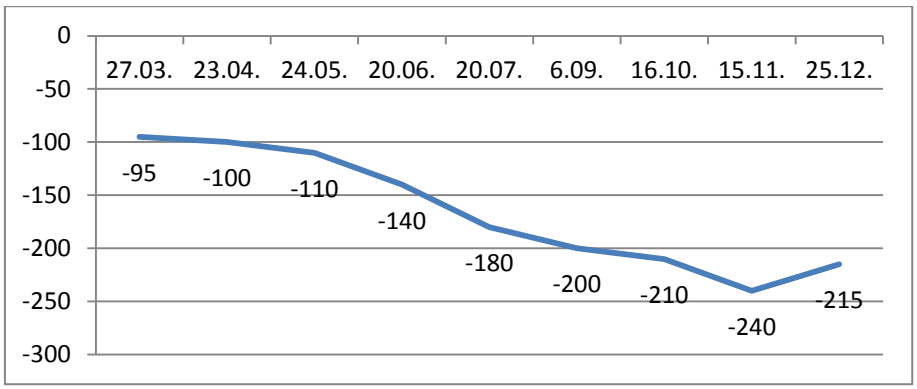

Figure. 3 The level of groundwater in profile P2

Analyzing the dynamics of soil moisturein profile P2 (Fig. 4) it was noticed that the level of soil moisture ranged from 8.96 to 54.80% vol.at 10 cm depth, from 121,24 to 47,74% vol.at 40 cm depth, and from 13.83 to 54.80% vol. at a depth of 70 cm. Soil moisture significantly increased in period from the beginning of the yearto the end of May, especially in the deeper parts of the profile, thendeclined until the beginning of September, after thatwas increased until the end of the studied period.

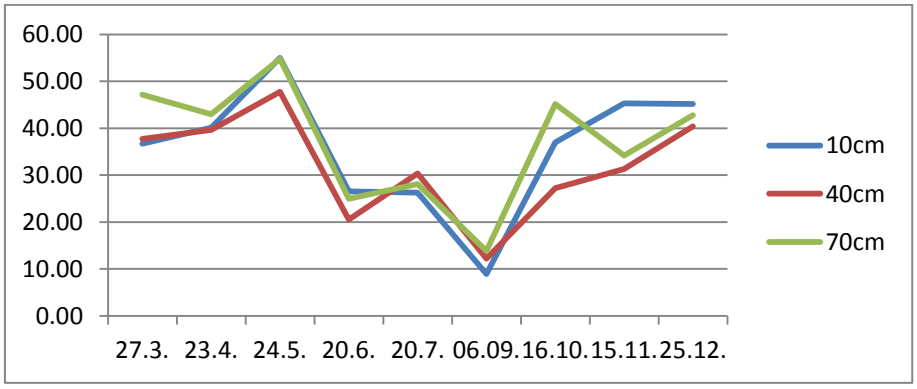

Figure 4 The soil moisture in profile P2

Groundwater level in eugley soil of profile P3 (Fig. 5) decreased until mid-November, after that increased slightly until the end of the measured period. The values of groundwater level ranged from minimum depth of 95 cm in the middle of the studied period up to 155 cm at the beginning and 185 cm depth below the soil before the end of the studied period.

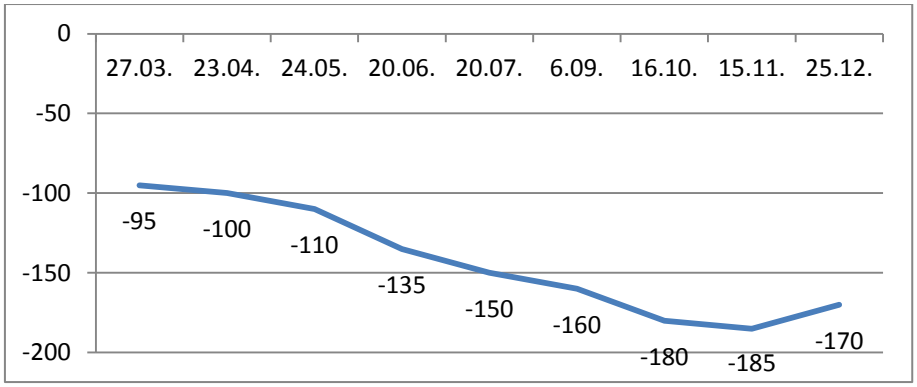

Figure. 5 The level of groundwater in profile P3

Soil moisture level in the profile P3 (Fig. 6)at 10 cm depth ranged from 15.06 to 51.58 % vol.. At a depth of 40 cm, soil moisture was in the range from 18.68 to 43.43% vol.while at a depth of 70 cm it was oscillated from 18.68 to 42.12% vol..At all depths there is a noticeable increase ofsoil moisture until the end of May, thenadecline until the beginning of September, and after that the value of moisture level increased again until the end of the measured period.

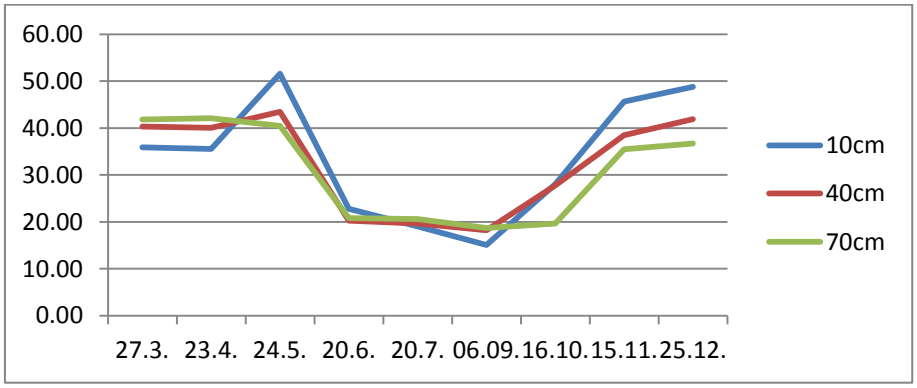

Figure 6 The soil moisture in profileP3

It was noted that the level of groundwater in the first profile ranged from 130 to 230 cm below the soil surface, in the second movement of groundwater amounted from 90 to 240 cm, while the third profile had amplitude varying from 95 to 185 cm below the soil surface. Pekeč et al (2011) recordedthat in eugley soilduring 2006 the groundwater level was in the range of 20 cm above the soil surface to 137 cm below the soil surface, while in 2007 the groundwater level was lower and 1 cm above the soil surface to 180 cm below ground level. In terms of soil moisture it can be seen that the highest humidity was still at a depth of 10 cm within profile P1 and P3, which can be connectedto precipitation during the year. Looking at the three soil profiles of eugley soil can be seen that during the period of measurement soil moisture at 10 cm depth had values of 16.56 to 72.65% vol.in the first profile, 8.96 to 54.80 % vol.in the second profile, and 15.06 to 51.58% vol.in the third profile. In the mean of measurements at the depth of 40 cm, soil moisture ranged from 13.77 to 45.67% vol.in the first profile, 12.24 to 47.74% vol.in the second profile, and 18.68 to 43.43% vol. in the third profile. At a depth of 70 cm soil moisture ranged infirst profile from 19.98 to 40.80% vol., 13.83 to 54.80% vol.in the second profile, and 18.68 to 42.12% vol.in the third profile.

Pekeč et al. (2011) studied eugley soil for the cultivation of the black cottonwood and found movement ofimmediate moisture at the depth of 0-30 cm in the range of 54.77 to 63.54% vol., while at a depth of 30-60 cm in the range 56.35 to 77.90% vol.which was located in the zone accessible to plants during the entire measurement period. The movement of soil moisture in the measured period was in according to the movement of groundwater. In the profile P2, during the entire period the highest moisture content of soil was measured at a depth of 70 cm. In the same period the profile P3 had a moisture content of soil at 70 cm depth greater than at 40 cm until the beginning of September, which can be explained by the influence of groundwater at greater depth, or capillary rise of moisture in the lower parts of the profile.

It can be notedalso that the trend in soil moisture movement is almost identical at all three depths, where it rose until the end of May and then notable declined until the beginning of September, after thatincreased again the amount of moisture in the soil. The measurement results showed the highest value of soil moisture in the surface horizon at 10 cm depth, while volume of soil moisture at 40 and 70 cmperiodically increased, due to the influence of capillary rise of groundwater, especially pronounced in the summer dry periods. Increased

soil moisture at 10 cm depth can be explained by the influence of rainfall that increase the measured moisture at this depth.

Bearing in mind the manner of moistening in these soils, Skoric et al (1985), ranked these soils among the hypogley soils or soils where the humidification occurs exclusively by groundwater. Pekeč et al (2010) have noted that the dependence of the groundwater dynamics on water level dynamics is higher when the water level is higher.

Conclusion

The paper presents hydrological characteristics of eugley soil at three locations in the middle Danube basin. The soil was located in the zone of the alluvial plain which is protected by an embankment of the flood waters so the moistening of the studied area is only possible by groundwater. The values of soil moisture varied at different measureddepths. The measurement results show the highest value of soil moisture in the surface horizon at 10 cm depth, while periodically increased value of soil moisture at 40 and 70 cm was due to the influence of capillary groundwater particularly pronounced in the summer dry periods.

Acknowledgement

This paper was realized as a part of the project financed by the Ministry of Education and Science of the Republic of Serbia within the framework of integrated and interdisciplinary research for the period 2016-2019.

EDUCATIONAL PERSPECTIVES IN URBAN FORESTRY - OVERVIEW IN THE FEDERATION OF BOSNIA AND HERZEGOVINA

Selma HARAČIĆ-BERBIĆ[1], Senka MUTABDŽIJA BEĆIROVIĆ[1*]

University of Sarajevo, Faculty of Forestry, Bosnia and Herzegovina
[*] Corresponding author: senka.mutabdzija@gmail.com

Abstract

As relatively new concept in Western Balkan countries (WBC), urban forestry is facing with vast number of challenges that are stemming from both institutional and legislative shortages as well as poor human resource capacities. What is more, current situation of this sector in the Federation of Bosnia and Herzegovina (FBiH) arises an arguable question whether urban forestry can be treated as a separate sector or not. Scattered jurisdictions between public and private sector, lack of legislative framework that is strictly focused to urban forestry, small number of professionals with educational background in urban forestry and even an arguable definition of basic terms this sector operates with (i.e. "urban forest") can justify the fact that urban forestry is in its initial phase in this part of Bosnia and Herzegovina (BiH). On the other side, it is needless to speak about immense positive effects of urban forests to our society, both ecologically and socially.

Due to the complex situation in which the employees of enterprises responsible for urban forestry are operating, the goal of this paper is to identify main burning issues they are facing with. Identification of these problems could help in preparation of case-specific educational programs for professionals in urban forestry. Finally, it will lead to the improvement of overall conditions of urban forests and, consequently, it will increase the level of satisfaction of local population as users of urban forests.

Key words: *urban forestry, the Federation of Bosnia and Herzegovina, education, professional trainings*

Introduction

Urban forestry (UF) represents a relatively new concept for the WBC. Generally, UF is interpreted as a rather vague concept that has no common definition. One of the interpretations of this concept defines UF as the art, science and technology of managing trees and forest resources in and around urban community ecosystems for the psychological, sociological, economic, and aesthetic benefits trees provide society (Konijnendijk et al., 2006 in Hansmann et al., 2016). Onward, urban forest has been described as the sum of all woody and associated vegetation in and around dense human settlements, ranging from small communities in rural settings to metropolitan areas (Miller, 1997 in Hansmann et al., 2016).Urban forests accordingly comprise different elements, such as urban woodlands, parks, civic squares, green corridors and single trees (Hansmann et al., 2016).

Citizens usually consider that the main purpose of urban forests is to make nice and comfortable life-environment. Certainly, urban greenery mostly has nonmaterial, spiritual functions such as decorative-aesthetic, sanitary-hygienic and cultural-educational (LjujićMijatović and Mrdović, 1998 in Brajić et al., 2012b).Trees and forests are an essential part of urban development that contribute to vibrant cities, public health, and functioning ecosystems and watersheds, while mitigating risks of floods and landslides (Brajić et al., 2012b).

Most of the national and regional UF-related scientific and professional literature is focused on biological and ecological aspects of urban and peri-urban forests. Dendrological

characteristics of urban forests and its role in spatial planning (Janjić, 2002; Anastasijević and Vratuša, 2000; Anastasijević, 2002;Aničić and Rechner, 2004; Dobrilović, 2009; Turalija, 2005, Haračić-Berbić, 2015), health condition of urban greenery (Treštić, et al., 2003; Mujezinović et al., 2011;), spatial planning issues (Beus and Mekić, 2007; Hadžidervišagić, 2010; Brajić et al., 2012a; Brajić et al., 2012b) make cornerstones of national and regional scientific literature related to UF, urban forests and urban greenery. On the other hand,sociological approach to concept of UF and urban greenery have beenstrictly focused to phenomenon of sociological demands toward forests and urban forests (Avdibegović et al., 2006; Fazlić, 2010; Brajić, 2011; Polić, 2013; Hanić, 2014; Polić, 2015).

Despite of the indisputable importance of the urban forests, UF in the FBiH is facing with vast number of challenges that are stemming from both institutional and legislative shortages as well as poor human resource capacities. Scattered and highly decentralised jurisdictions between public and private sector and different governmental levels, lack of UF-focused legislative framework, insufficient number of professionals with educational background related to UF depict the current legislative and institutional environment for the implementation and further development of this concept in the FBiH. For example, in the Canton Sarajevo, as the most urban administrative unit of the FBiH, urban and peri-urban forests are governed and managed by following institutions: cantonal public utility enterprise "Park", cantonal public institution for protected areas, cantonal public forest enterprise "Sarajevo šume" as well as municipalities of Canton Sarajevo. Having in mind that urban forests are usually shaped and managed by professionals from different disciplines and public authorities (Pütz et al., 2015; Konijnendijk, 2011 in Hansmann et al., 2016), underdeveloped competent institutions in terms of insufficient human resource capacities makes governing and managing of urban forests more demanding and challenging.

Due to the complex situation in which the employees of enterprises responsible for UF are operating, the goal of this paper is to identify main burning issues they are facing with. Identification of these problems could help in preparation of case-specific educational programs for professionals in urban forestry. Finally, it will lead to the improvement of overall conditions of urban forests and, consequently, it will increase the level of satisfaction of local population as users of urban forests.

Materials and methods

As already emphasized, UF represents a rather innovative concept for the FBiH. Despite of its characteristic as being a concept that implies joint endeavour of various sectors and professions, specific socio-political and institutional occasions in the FBiH makes this concept rather decentralised. That is the reason why the survey conducted for the purpose of this paper was created in order to assess specific needs for professional trainings of the employees of the companies registered for maintenance, establishment and protection of urban forests and urban greenery. Having in mind particular institutional setup UF has been operating with, survey included enterprises that are, in any way, responsible for planning, management or usage of green areas for different purposes be it public or privately owned enterprises. Therefore, the research was conducted with representatives of following types of institutions: municipalities, utility companies, cantonal forest management enterprises, cantonal planning institutes, and privately owned project offices. Due to their specific concerns over urban greenery, it had been decided to contact representatives of coal mine from Kakanj municipality, tobacco factory Sarajevo and cement factory from Kakanj that are responsible for green spaces. The purpose of this questionnaire was to assess current needs of professionals responsible for urban forests and/or urban greenery for specific educational programmes.

Questionnaire is consisted out of two groups of questions. The first group of questions are socio-demographic ones (such as gender, age, and age of working experience, education and current job position). The second group of questions were created in order to assess burning issues of each identified enterprise which are related with UF, urban forests and urban greenery. Additionally, questions from this group had a purpose to assess the specific "enterprise's ethnography" and working ethics related to educational programmes and long life learning concepts. Research had been conducted in period April - May 2016. Finally, representatives of 15 institutions answered the questionnaire. Having in mind current situation in UF of the FBiH, such response rate is sufficient for making general conclusions over this issue.

Results and Discussions

UF in the FBiH falls into competences of various types of institutions and enterprises. This caused expected diversity of experiences, attitudes and opinions regarding the issue of educational perspectives.

In comparison to the male dominance in forestry sector (Mutabdžija, 2013), research showed significant domination of females in UF (64% females and 36% males). Concerning the age structure, it can be concluded that UF engages rather younger people (average age is 33 years). Consequently, years of working experience are rather small as well (average years of working experience is 8 years). Most of the respondents have university diploma. Yet, they have rather different educational background which can be concluded based on their working positions and specific reference to the UF and urban greenery.

When it comes to the assessment of current presence of professional development and educational programs within enterprises, 65% of the respondents answered that such mechanisms are underrepresented in their enterprises. On the other hand, 78% of the respondents stated that professional development and education plays very important role for accomplishment of their working tasks. Such discrepancies between needs and realisation of these activities indicate high demand for creation and implementation of appropriate educational programs for UF professionals in the FBiH. Yet, respondents' answers related to the influences of their professional improvements that will be obtained by attending the educational programs depict specific work ethics within enterprises responsible for urban forestry and urban greenery. Answers led to the conclusion that professionals lack motivation for further professional improvements. For example, 35% of the respondents stated that their additional education will not result in improvements of urban forests and urban greenery. Same percentage of respondents thought that their education will not contribute to change in citizens' perception of urban greenery. Surprisingly, around 20% of the respondents stated that their additional education will not help in increasing the competences of employees. Such results indicate two main conclusions - UF professionals do not have a bigger picture related to the influences of their institutions and their professional engagement on citizens as final beneficiaries of urban forests and urban greenery and UF is marginalised in portfolios of responsible enterprises.

In order to assess needs for preparation and realisation of specific educational programs, respondents were asked to rate the importance of various aspects related to planning and management of urban green spaces. These are the following aspects: urban greenery management, professional literature, guidelines for establishment, management and improvement of urban greenery, planning of urban greenery, cooperation with citizens and local communities, preparation of project applications, application of various tools and software solutions (e.g. GPS, GIS etc). These aspects can be grouped in following categories:

- Planning and management of urban green spaces
- Soft skills related to management of urban green spaces

- Funding opportunities in UF

Assessment of these aspects of UF helped in identification of bottlenecks in professional knowledge and competences of respondents. Respondents rated urban greenery management and guidelines for establishment, management and improvement of urban greenery with highest rates (only for these two categories, respondents gave the two greatest rates). On the other hand, in case of preparation of project applications, around 45% of the respondents thought it is not important aspect of UF. Having in mind the perspective of BiH as EU candidate country, this result indicates insufficient awareness of UF professionals regarding opportunities for additional funding that can be utilized for improvement of urban greenery.

Generally, one can conclude that variations of rates for different aspects of planning and management of urban green spaces depend upon the competences and authorities of the institutions that respondents represented. This can be concluded based upon the rates for importance of cooperation with citizens and local community. Successful cooperation with local community is a cornerstone of concept of UF. On the other hand, respondents rated its importance differently based upon their duties and responsibilities related to the planning and/or management of urban greenery. Same also holds for the application of various tools and software solutions - respondents rated its importance based on their frequent usage of such technical solutions in day-to-day professional activities. Still, professional literature has the biggest percentage of the lowest rates for its importance. Such rating indicates low awareness on importance of continuous professional improvement that can be achieved through constant updating on new achievements in area of expertise. That is crucial bottleneck of current professional ethics in UF in the FBiH. Future educational programs need to be created with purpose to increase professionals' awareness on importance and benefits from constant learning and updating related to their field of expertise and professional interests.

On the other hand, cross tabulation of these answers with those related to the questions on rating the importance of additional education revealed strong positive correlation of these two questions. Most of the respondents that rate importance of the additional education with highest rates also rated aforementioned aspects of planning and management of urban forests and urban greenery with highest rates. Such answers justify the actual need for preparation and implementation of appropriate educational programs for UF professionals.

Conclusion

Results of the research revealed need for preparation and implementation of appropriate educational programs for UF professionals in the FBiH. This was also concluded based on the respondents' needs for additional education and actual realisation of such activities in their enterprises.

Furthermore, results of this research brought up an important issue of overall work ethics and work environment within enterprises. Despite of their formal expression of educational programs as important aspects for their professional improvements, analysis of respondents' answers led to the conclusion that professionals actually lack motivation or further professional improvements. Such conclusions represent an important input for defining the strategy for advocating the importance of educational programs for UF professionals in the FBiH. Future educational programs need to be created with purpose to increase professionals' awareness on importance and benefits from constant learning and updating related to their field of expertise and professional interests.

Another important aspect of UF in the FBiH that was also brought up by results of this research can be described as "disconnectedness" of UF professionals from the final beneficiaries of urban forests and urban greenery. Such state of mind clearly indicates the

status of UF as recently introduced concept in the FBiH which is rather marginalised in portfolios of responsible institutions.

Onward, respondents expressed the expected predominance of technical expertise related to UF. It was concluded based upon their ratings of specific aspects of planning and management of urban forests and urban greenery. Most of them rated the aspects of planning and management of urban green spaces with highest rates while importance of soft skills and funding opportunities are insufficiently recognized. Having in mind overall strategic and socio-political trends in the FBiH as well as essence of UF as society-based concept of management of natural resources, these two aspects of planning and management of urban greenery and urban forests need to be particularly emphasized in future educational programs for UF professionals in the FBiH.

USING PINE (*Pinus*) AND SPRUCE (*Picea*) STUMP SURFACE PATTERNS FOR THE DETERMINATION OF FELLING TIME

Aleksandr ROMANOV*, Igor SMIRNOV

The Perm State Agricultural Academy 23 Petropavlovskaya, Perm 614990 Russia
*Corresponding author: moraposh@mail.ru

Abstract

To determine of the timeline of tree felling is one of a number of investigative leads of illegal logging and superfelling of the forest. The study of literature and electronic sources showed a lack of methodology for the study of these problems along with results of such research. From June through September 2015 an exploration of diagnostic capability for determining the timeline of tree felling using the pine and spruce stumps. For the study cutover areas of spruce shamrock forest were selected. The age of felled forests is upwards of 80 years. The felling was carried out in September (2014), December (2014), February (2015), May (2015) and June (2015). Stumps on permanent plots were selected from every cut over area. There are 40-47 stumps in each cut over plot. Research stumps have a diameter range from 20 to 60 cm. Every stump was photographed in July, August and September. Stumps were grouped by species, degree of decay, diameter and stump surface condition. The change of stump surface condition was determined by climactic factors during summer. There are resin, water-dissolved available nutrients and metabolites on a stump surface after pine and spruce felling. They form a characteristic pattern on the stump surface. As for the pine felled in June (2015) the stumps are characterized by a heavy resin discharge (70 % of the total number of stumps). The May (2015) felling promotes a discharge pattern of water-dissolved nutrients and metabolites along with pine resin. The spruce stump surface has a more complicated pattern depending on the felling time.

Keywords: *illegal logging, stump analysis, common pine, spruce, shamrock spruce forest.*

Introduction

Forests cover approximately 45 % of the territory of Russia. Therefore the felling and the utilization of wood are a traditional activity in our country. The large forest area incites individuals to illegal fell trees who wish to make a profit. The illegal felling comprises anywhere from 10 to 35 % of the total timber harvested in Russia depending on the region [1-2]. Permskii krai is heavily forested territory which has illegal felling problems as well. According to unpublished data of the Ministry of Natural Resources of Permskii krai, the have been 8295 occurrences of illegal felling from 2008 to 2015. The illegally cutover timber is 463000 m^3 with a loss that is more 3 million rubles.

In 2008 the detection rate of illegal logging was 39% and increased to 75% in 2015. The proceeding of these actions is difficult. The measures of an investigation may continue for 4-5 years. The cause is the imperfect tools for gathering evidence. A superfelling is another wrong that is proceeding in courts. It is illegal aggrandizement of a legal felling plot. In this case, the superfelling is incorreclty ascribed to an honest businessman and is perpetrated by illegal loggers or "black lumbermans". They fell a forest near a made timber road.

Initial attributes of illegal logging investigation are 1) a location of felling plot and a measurement of its area; 2) a location of cut trees (stumps); 3) a felled stand volume inventory and wood quality; 4) a felling time determination; 5) a tool and persons determination who performed this felling [1-2]. Reliable data of the first two attributes are provided by surveyors.

The felled stand volume inventory is calculated using stumps with specific volume tables [4]. A felling time determination isn't resolved at this time. Tool identification is difficult problem too. There are preliminary research results for felling time determination in this article.

Material and methods

Research was undertaken from June through September 2015. The cutover areas are in the Karagai forest district of Permskii krai (Russia). The aim of our research is an express-method explanation for felling time determination. The primary objective is a determination of the differences between patterns on stump surface that emerged based on the physiological status of trees at felling time. For the study cutover areas of spruce shamrock forest were selected.

Study objects are legal logging plots in forest compartments (numbers 22, 26 and 83) of Karagai forest district in Permskii krai (fig. 1). The subject of the study were surfaces of spruce and pine stumps remaining after different felling times. Pine stumps were studied in plots in which felling occurred in September (2014), May (2015) and June (2015). Spruce stumps were studied in plots in which felling occurred in September (2014), December (2014), February (2015), May (2015) and June (2015). Felled trees were aged more than 80 years. The plots had identical species composition of the stand (spruce – 50 %, pine – 30 %, fir – 20 %). The degree of density was approximately 0.6 or 60%.

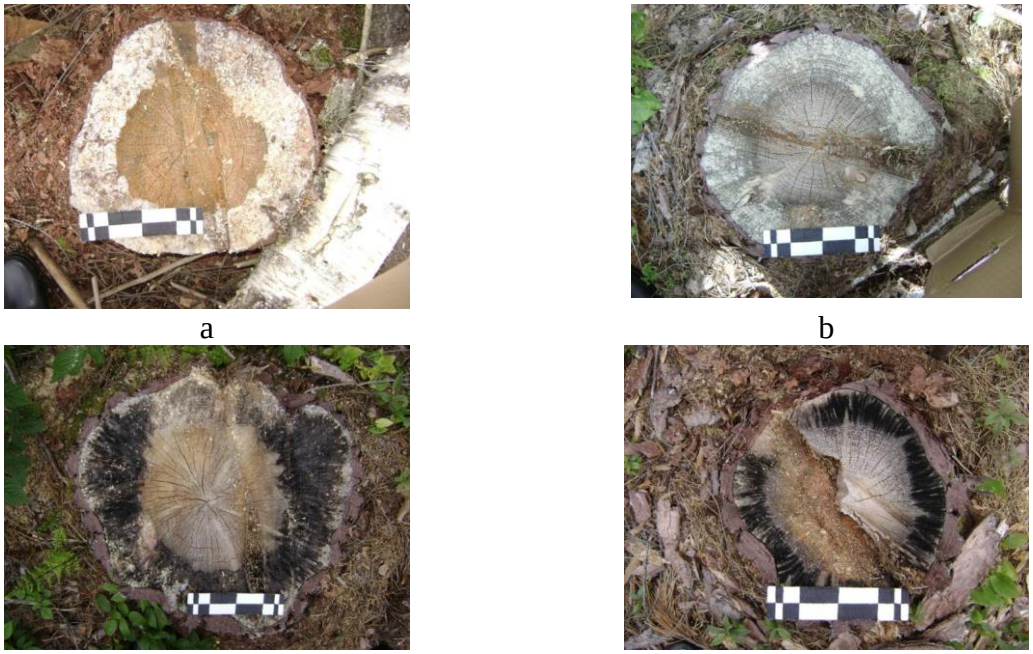
Pine and spruce stumps numbering between 45-59 were selected in each felling plot. Diameters of studied stumps were 20, 40 and 60 cm. The distribution of studied stumps on felling plots is in table 1. The photographs of the studied stumps were taken every month from July to September 2015. Each photograph was taken with the stump oriented to the north, it was protected with specific screen and was supplied the dividing rule. Then photographs were visually sorted by the pattern on the stump surface.

Results and discussion

The different physiological condition of pines and spruces at felling time promotes a different pattern on the stump surface. This is due to the resin, water-dissolved available nutrients and metabolites exudation on a stump surface after pine and spruce felling. This allows the use of the stump surface pattern for the expert study of illegal logging. The pine and spruce each have unique features for the felling reaction. The resin exudation is distinctive on the pine stump surface. The spruce stump surface has a complex pattern. For description stump surface we use term "alburnum". The "alburnum" is peripheral part of wood (live wood or sapwood [3]) with moving resin and water-dissolved available nutrients.

The pine resin exudes on a stump surface is consistent with four types: I) the resin spreads over the entire alburnum zone (fig. 2a); II) the resin exudes by way of small droplets on each annual growth ring (fig.2b); III) the resin exudation covers a portion of alburnum zone (fig. 2c); IV) the resin exudation is absent (fig. 2d).

The June (2015) pine felling was accompanied the resin exudation for the first (I) type (70 %) and 30 % of studied stumps had the second (II) type (table 1). The resin covers the alburnum zone in a complete ring. The resin exudes by way of small droplets on each annual growth ring (II type) for the May pine felling (88-100 % of stumps). The resin exudation of third (III) type is indicative for the September pine felling (53-67 %).



a b c d

Figure 2 – Type of resin exudation on pine stump surface (see text for full description)

Table 1. Allocation of pine stumps based on the resin exudation type, %

Felling time	Type of the resin exudation			
	I	II	III	IV
September (2014)	0	28	62	10
May (2015)	0	94	4	2
June (2015)	70	30	0	0

Water-dissolved available nutrients and metabolites create specific pattern on stump surface as well. For the pine stumps we used four types of patterns: I) the alburnum zone has an unbroken black color (fig. 2c); II) the alburnum zone has an unbroken grey color (fig. 3); III) the alburnum zone has a radiating lines of black spots (fig. 2d); IV) the alburnum zone has a color of wood (fig. 2a and 2b). The allocation of pine stumps with color of alburnum zone is in table 2.

Table 2. Allocation of pine stumps based on coloration of alburnum zone, %

Felling time	Type of coloration of alburnum zone			
	I	II	III	IV
September (2014)	41	0	59	0
May (2015)	28	34	30	8
June (2015)	0	0	0	100

The specific view of pine stump surface for the June felling is in figure 2a. The stump surface for the September felling looks like figure 4 in more causes. The May pine felling has a specific resin exudation as the third type (fig. 2b) the view of alburnum zone may be different types.

Figure 3 – The view of alburnum zone for type number II

Figure 4 – The typical view of a pine stump surface for the September felling

There is a resin exudation on spruce stumps in any time of felling. Therefor the first position of our classification for spruce stump surface is characteristic of water-dissolved nutrients and metabolites exudation zone (fig. 5). We used four types of patterns for a spruce stumps: I) the alburnum zone has an unbroken black color (fig. 5-I); II) black spots have direction along annual growth ring (fig. 5-II); III) the alburnum zone has radiating lines of black spots (fig. 5-III); IV) the alburnum zone has a color of wood (fig. 5-IV).

The second position is the resin occupation density on water-dissolved nutrients and metabolites exudation zone. It has two types. Type “A” is a resin covers all surface of this zone. Type “B” is a resin covers fewer than half of one. But the verification shows both types took place for any felling time. This position is not the time index. There are five types of a resin exudation in the third position of our classification. Type “W” has all-round wide resin ring. Type “N” has all-round narrow resin ring. Type “G” has group resin exudation. Type “DW” is the resin exudes by way of small droplets on each annual growth ring. Type ‘DN” is the resin exudes by way of small droplets on each annual growth ring.

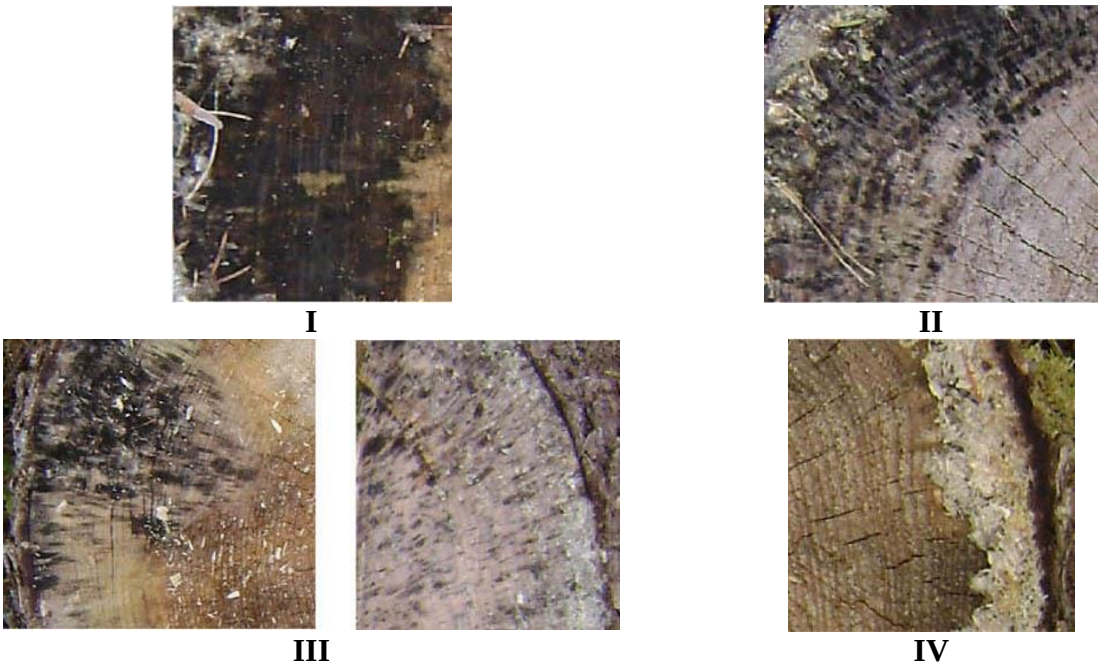


Figure 5 – Type of water-dissolved nutrients and metabolites exudation zone coloring on spruce stump surface (see text for full description)

The allocation of spruce stumps according the coloration of alburnum zone can be seen in Table 3. Radiating lines of black spots are the peculiarity for September, February and May felling times. Spruce stumps after December felling have I type of the alburnum zone coloration. In June the vertical moving of water-dissolved nutrients was weak in weather states of 2015. The alburnum zone does not have the coloration. Table 4 contains facts about resin exudation peculiarities for different spruce felling time.

Table 3. Allocation of spruce stumps based on coloration of alburnum zone, %

Felling time	Type of coloration of alburnum zone			
	I	II	III	IV
September (2014)	20	4	76	0
December (2014)	64	2	30	4
February (2015)	37	4	55	4
May (2015)	22	6	66	6
June (2015)	6	2	3	89

Table 4. Allocation of spruce stumps based on the resin exudation type, %

Felling time	Type of the resin exudation				
	W	N	G	DW	DN
September (2014)	27	51	17	0	0
December (2014)	45	44	8	2	1
February (2015)	24	44	16	9	7
May (2015)	13	19	7	43	18
June (2015)	21	58	6	9	6

Usually the spruce resin exudes as a narrow ring along the stump border (39-66 %). But the resin exudes produce a wide ring on the alburnum zone for December felling as well. In May the felling of spruce trees furthers to form the resin exudation as wide ring with small droplets on each annual growth ring.

Conclusions

1. Typical sign of June pine felling is the abundant resin exudation on the alburnum zone of stump surface. Water-dissolved nutrients and metabolites exudation is absent.
2. The resin exudation was weak and the alburnum zone coloring had many radiating black spots (53-67 %) or an unbroken black cover (39-43 %) for the September pine felling.
3. In pines felled in May, the resin exudes as a wide ring with small droplets on each annual growth ring (88-100 %).
4. Typical sign of June spruce felling is the absence of water-dissolved nutrients and metabolites exudation. The resin exudes usual as narrow ring.
5. The coloration of alburnum zone is black for the December spruce felling (51-81 %).
6. September, February and May spruce felling is dimly by stump surface. Researches need to continue.

Abstract

Considering that the pyramidal fir is of high conservation importance for Serbia forest diversity, the aim of this study was to determine, using SSR marker analysis, spatial genetic profile of the endemic and marginalised *Abies alba* population from Ogorijevac, Serbia. Leaf samples from nineteen *Abies alba* individuals from Ogorijevac site were collected, where nine of them were determined by morphological traits as *Abies alba* f. ´*Pyramidalis*´ and ten as a typical, silver fir, (*Abies alba* Mill.). PCR amplification was done with the 19 SSR primers in three multiplex mixes (16 EST-SSRs divided in 2 multiplexes and three genomic SSRs as a separate multiplex mix). Successful amplification was obtained for 17 out of 19 markers. Fragment analysis of PCR products was done on capillary electrophoresis automatic sequencer where, afterwards, scoring of resulted peaks was obtained using the GeneMarker V2.4.0 and MicroChecker software. Spatial genetic profile analysis was evaluated via BAPS software. The results of spatial BAPS showed the presence of two clusters (7/12) among 19 sampled individuals, indicating significant difference in genetic profile between selected silver fir (taxa) samples. Cluster differentiation within marginalised population of silver fir showed the results of such genetic profile which will be used as a platform for further molecular genetic research and conservation strategies of this endemic species. This research was done on STSM project within COST Action FP 1202 (MaP-FGR).

Keywords: *Abies, SSRs, genetic profile, spatial analysis*

Introduction

Silver fir is an ecologically valuable and indigenous tree species in many European mountain forests. It occupies a wide variety of ecological sites ranging from the East Carpathians to the Pyrenees and from the Beskides in Poland to the mountains of northern Greece (Larsen 1986**)**. In the course of several episodes of silver fir decline during the past century, its populations have decreased in size and number and currently are scattered throughout the entire European range (Konnert and Bergmann 1995).

Although silver fir in the Western Balkans area very rarely forms pure stands, it is the most important constituent element of mixed forests of fir and beech (*Abieti-Fagetum* s.l.) (Ballian et al. 2012). Its significance, but also its threatened status and decline caused by atmospheric and soil pollution, especially in the Slovenian Dinaric Alps, in Gorski Kotar (Croatia) and western Bosnia (Tikvić et al. 1995, Seletković and Tikvić 1996, Ušćuplić et al. 2007) has made it the subject of numerous studies (Ballian et al. 2012).

The first scientific observation and probably the first written record of the site with the excessively narrow habitus of silver fir in Ogorijevac were done by Tošić (1963). From the mid-nineteenth century, when the first case of the pyramidal variety of the *Abies alba* Mill. was described, only few individual specimens of this variety, whose habitus has a pyramidal shape, survived until today. Discovery of the population of this extremely rare variety of silver fir attracted the attention of scientists and the general public, followed by a several authors who have studied and described in details mainly morphometric characteristics of the variety (Tošić

1963, 1995, 1997, Matović et al. 1996, Tošić and Vilotić 1998). Ecological characteristics of the site were analysed too, giving the insight of possible influence of environment and its properties on development of the phenotype (Kiš et al. 2009, Ratknić et al. 2013). The main phenotypic characteristic of the variety is growth of lateral branches directional upward, at a relatively acute angle to the longitudinal axis of the trunk. This development resulted that the tree has an unusual narrow - pyramidal shape of crown which is developing with the age of the tree (Matović et al. 1996). Tošić (1995) observed that pyramidal fir has a slower growth than other tree species in the reserve, which is often overgrown by the surrounding trees. As one of the characteristics of the variety is the occurrence of multiple centres of apical dominance. According to this, pyramidal fir could possess some genes that induce morphogenesis due to surrounding conditions, similar to the genera *Cupressus* and *Juniperus* (Tošić 1995). According to terrain research data of Kiš et al. 2009, and Panjković et al. 2010, entire population of silver fir in Nature reserve "Paljevine" consists of 20 individuals in total, from which 14 are in juvenile and 6 in adult phase from which two are almost completely dry. We succeed to take enough vital plant leaf samples from 19 individuals. The aim of this study is to assess spatial genetic structure of small population of silver fir from Ogorijevac site, through simple sequence repeats (SSR) marker analysis.

Materials and methods

Sampling of the needles from 19 individuals belonging of two *Abies* varieties from Ogorijevac site, for the comparative genetic profile analysis has been done on 20th July 2013. All leaf samples were stored on silica gel in sterile safety bags until isolation of genomic DNA. One 50 mg of completely dried needles for every tree was homogenized in Retsch homogenizer (frequency=28, 90 seconds duration for homogenization of dried samples). Isolation of total, genomic DNA from collected plant material was done with STRATEC-INVITEK plant kit (for 250 samples). Quality and quantity control of total isolated DNA was done with the NanoDrop® ND-1000 spectrophotometer (with the following NanoDrop® ND-1000 Spectrophotometer user software) and on agarose gel electrophoresis on 1 % agarose. 1% agarose gel was prepared with 1g of agarose (GE Healthcare) in 100 ml of 1 X TAE buffer (Tris Acetate EDTA 1X, made from 50X stock). TAE buffer used in our analysis was consisted of 242 g Tris base (2-Amino-2-hydroxymethyl-propane-1,3-diol), 57.1 ml Acetic acid (100%) dissolved in 100 ml 0,5 M Na_2EDTA. PCR amplification was successful for all 19 SSR markers. Only for 17 SSRs (14 Expressed Sequence Tags-SSRs (EST-SSRs) and 3 genomic SSRs (gSSR)) we succeed to proceed with fragment analysis (Table 1 and Table 2). Information about all primers design and sequences are available in Postolache et al. (2014). It was impossible to correctly score the peaks for two EST-SSR markers, contig28516 and contig04529, resulted after capillary electrophoresis sequencer analysis. PCR was performed on PCR System 9700 GeneAmp machine (PE Applied Biosystems) in 3 multiplex mixes (Mix A: consisted of 8 EST-SSRs, MixB: consisted of 8 other EST-SSRs and Mix C: consisted of 3 genomic SSRs). PCR amplification for all multiplexes was proceeded due to the following protocol: 95^{0}C-5min, 95^{0}C-30sec, 57^{0}C (for genomic SSRs=59^{0}C)-90sec, 72^{0}C-30sec (30 cycles for those three temperatures repeated), 60^{0}C-30min, 4^{0}C-hold. PCR products were diluted 1:1, denatured at 95°C for 2 minutes with formamide and Liz 500 as internal standard. Fragment analysis of PCR products was performed on Applied Biosystems/HITACHI 3500 Genetic Analyser capillary electrophoresis automatic sequencer (hereinafter: AB 3500). Scoring of resulted peaks of analysed fragments was done with GeneMarker V2.4.0 and MicroChecker software. Population structure analysis was performed using spatial BAPS (Corander et al. 2008).

Results and discussion

The results of spatial BAPS (Figure 2) indicate the presence of two clusters (7/12) among 19 sampled individuals. For four out of seven analysed individuals in first indicated cluster, morphometric traits were showing that those are *Abies alba* var. *pyramidalis* (Carrière) Voss individuals (1, 2, 5, 18). Figure 1 and Figure 2 give geographical complementarity of BAPS genetic profile. This will additionally support efforts in conservation of this species, making a significant contribution to the selection of individuals for future breeding management and construction of genetic linkage map.

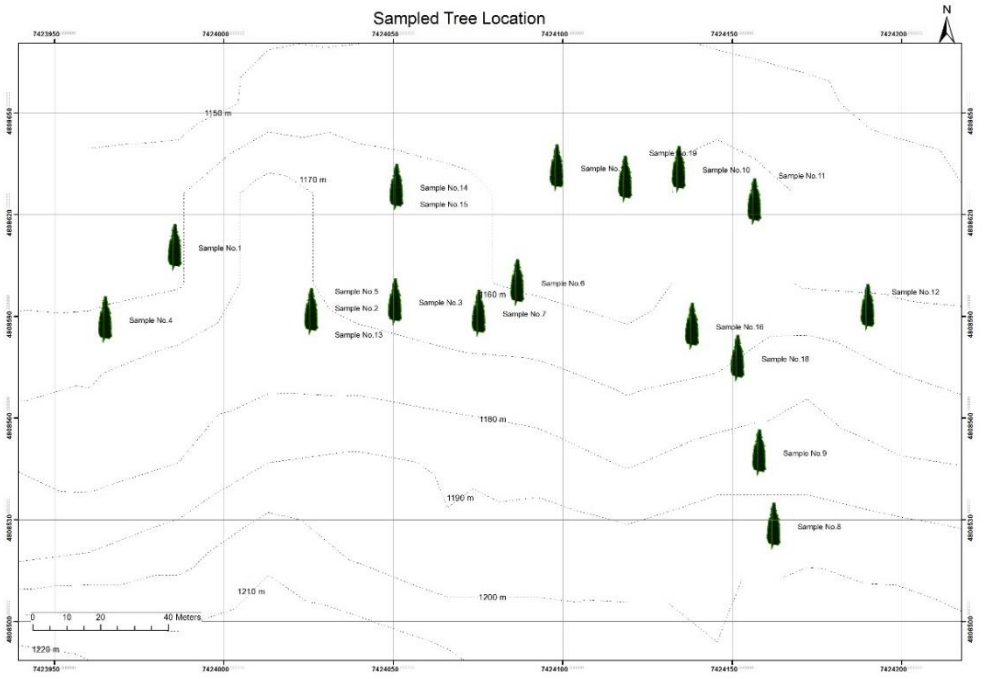

Figure 1. Spatial GPS map of sampled tree individuals

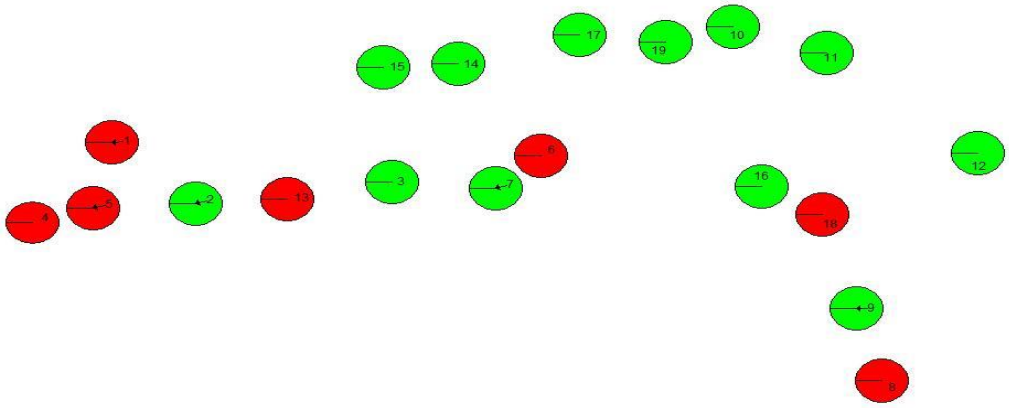

Figure 2. BAPS spatial genetic model analysis of *Abies* samples from Ogorijevac site. Two different colours clearly indicate existing of two *Abies* genetic clusters on the site. For better overview, while constructing this map, we separate individuals 2, 5, 13, 14 and 15 since they are on site physically very near each other, which is presented on standard GPS map (Figure 1)

Western Balkan countries are burdened with the problem of inadequate system of fir management, which significantly contributes to its rapid decline. This is the reason why it's urgent to investigate both the healthy and damaged fir stands (Ballian et al. 2012). Using the newly developed markers in ongoing studies, it would be possible to tackle the dynamics of genetic diversity in silver fir between closed stands and large-sized forest gaps in Serbia. Ballian et al. (2012) showed that some allele's characteristic of the Balkans occur in central Europe, and *vice versa*. Hence, they concluded that silver fir derived from the Balkan refuge may have been more widely distributed in the past, but is now constantly retreating, while the Apennines-derived silver fir takes its place, or, on the other hand, it may have reached southern Germany through past gene flow similar to the central Dinaric Alps. The finding of *Abies alba* var. *´Pyramidalis´* at Ogorijevac in Serbia is very specific regarding the habitat and stand characteristics. Also the range of distribution of pyramidal fir should be extended by afforestation**.** In order to successfully protect and preserve silver and pyramidal fir with *in situ* and *ex situ* methods, it is essential to have an in-depth knowledge of its genetic constitution. BAPS analysis gave us primarily insight in genetic variability of sampled individuals. Spatial model gave clear picture of two genetic clusters existing on that particular site. Further marker assisted analysis is needed to clarify the correlation between different genetic structure and phenotype difference.

Conclusions

For the future of pyramidal fir on the protected area, it is necessary to identify the tending and protection measures, which will favour the regeneration and development of its individual trees. This would include the following:

- Removal of competitive trees which disturb the regular development of pyramidal fir trees and the ensuring of the favourable biological position in all stages of development;

- For having fully reliable information on taxonomic determination of varieties, it is always needed to have both morphometric measurements and marker analysis. For further taxonomic research of confirming possibility of two different varieties of silver fir on this site, ITS region detection and sequencing will be preferable to be used;
- It is possible to increase the area of pyramidal fir if it would be provided a sufficient number of seedlings by producing seed and planting material of pyramidal fir in forest nurseries. Modern planting stock production techniques should be applied because it provide good results even with the small amount of seed obtained from regular crops. There are large areas in this region whose site conditions allow reforestation with the pyramidal fir.

Acknowledgement

This research was done during short term scientific mission: "Conservation platform of marginalized *Abies alba* and endangered peripheral *Quercus robur* from Serbia using DNA fingerprint and SNP analysis." It was supported within COST Action FP 1202 (MaP-FGR) "Strengthening conservation: a key issue for adaptation of showing marginal/peripheral populations of forest trees to climate change in Europe" and implemented from July 14th to August 18th, 2014, on hosting Institute of Biosciences and BioResources, Division of Florence, National Research Council, - Via Madonna del Piano, 10 - 50019 Sesto Fiorentino (Firenze), Italy. I would like to thank Giovanni Giuseppe Vendramin, Ilaria Spanu, Francesca Bagnoli, Dragos Postolache from CNR, Florence for their support during short term scientific mission.

Abstract

Knowing mycorrhizal community structure can provide valuable information about functioning of forest ecosystems. Beech forests make almost one half of forestry fond in Serbia and have important influence on environmental status.The aim of this study was to identify types of ectomycorrhizae in natural managed beech (*Fagus sylvatica* L.) stands from four different sites in Serbia: Homolje Mountains, Čemernik-Ostrozub, East Boranja and Fruška gora in two seasons: early winter and spring. Identification of fungal partner in ectomycorrhiza was obtained with morphological and anatomical characterization according to published descriptions and with molecular identification based on PCR amplification and sequencing of the ITS regions within nuclear ribosomal DNA.In all soil samples from investigated sites in two seasons total number of analysed fine roots was 54636 while total number of vital ectomycorrhizal roots was 8373. In examined beech stands 36 ectomycorrhizal types were recorded. Twenty seven types of ectomycorrhizae were identified with molecular methods from which 14 types to the species level, 4 types to the genus, 6 types to the family and 3 types to the ordo level. Genera *Russula* and *Lactarius* were the most species-rich genera, while type *Cenococcumgeophilum* was the most frequently found. Most of recorded ectomycorrhizalfungi are commonly found on beech.

Keywords: *ECM, Fagus sylvatica L., morphological-anatomical characterization, ITS rDNK, Serbia*

Introduction

In the most temperate forests, establishment, growth and survival of trees depend on colonization with ectomycorrhizal (ECM) fungi (Smith et Read, 2008).Mycelium of ECM fungi is the main component of forest ecosystems which links biotic with abiotic factors influencing sustainability, productivity and vitality of forests (Kraigher, 1996).

Ectomycorrhizal fungi successfully take water, organic and inorganic nutrients from soil and translocate them to fine roots of plants from which they obtain carbohydrates in return (Smith etRead, 2008).Functional compatibility and stress tolerance of ectomycorrhizae are species specific and depend on both partners, therefore the information on the ECM community structure can provide valuable information about physiology of forest trees and functioning of forest ecosystems(Kraigher et a1., 2007).

In Serbia beech forests make almost one half of forestry fond. They have important function in biomass production and significant influence on environmental status(Vučićević, 2004).Diversity of ECM fungi on beech in Serbia was firstly described on Stara planina (Katanić et al., 2011). Thentypes of ectomycorrhizae were preliminary described and identifiedwith morphological and anatomical methods in natural managed beech (*Fagus sylvatica* L.) stands from Homolje mountains, Čemernik-Ostrozub, East Boranja and Fruška gora in early winter 2011 (Katanić et al., 2012).

In this work, previous results were suplemented with molecular methods of identification and studies were repeated at the same sites in spring 2012.

Material and methods

Ectomycorrhizal types were analysed in four pure or mixed natural uneven-aged managed beech (*Fagus sylvatica* L.) standsin Serbia atHomolje Mountains (site Majdan Kučajna), Čemernik-Ostrozub (site Predejane), East Boranja (site Krupanj) and Fruška gora (site Iriški venac).Characteristics of studied sites were given in Katanić et al. (2012).Beech was main and dominant woody species at all sites, but at sites Krupanj and Iriški venac other tree species were found in minor percentage.

At selected sites soil samples were collected in December 2011 (early winter)and May 2012 (spring). A soil corer of 274 ml volume was used for taking standardized samples (Kraigher, 1999). The total number of samples was 24. Three samples were taken per each site in each season. Roots were carefully washed from soil and vital ECM root tips were separated from old, nonturgescent and nonmycorrhizal roots in water under a dissecting microscope. Types of ECM were analyzed and ECM fungi identified after morphological and anatomical characteristics with a binocular (light sourse Olympus Highlight 3100, daylight filter) and microscope Olympus BX 51 (enlargement 100-2000x) according to published descriptions (Agerer, 1987-2002; Agerer et Rambold, 2004–2016) and methodology described by Agerer (1991) and Kraigher (1996).

Identification of fungal partner in ectomycorrhiza using molecular methods was based on PCR amplification of fungal nuclear rDNA ITS region. Total genomic DNA was extracted from ethanol-stored ectomycorrhizal root tips by using a Plant DNeasy Mini Kit (Qiagen, Hilden, Germany). Amplification was performed with ITS 1f (Gardes et Bruns, 1993) and ITS 4 primer pair (White et al., 1990). PCR reaction was optimized in the way that the optimal quantity of DNA extract was determined in order to give the best product in the reaction. Amplification reaction was performed on GeneAmp® PCR System-u 9700 (Applied Biosystems) according to protocol described in Kraigher et al. (1995) and modified by Grebenc et Kraigher (2007). The amplification success was checked and selection of samples for further analyses wasperformed by gel electrophoresis (1.5% agarose). Amplified DNA samples were excised and separated from the agarose gel and purification was performed with Wizard SV Gel and PCR Clean-Up System, PROMEGA.Sequencing was performed in a commercial sequencing laboratory (Macrogen inc., Seul, Republic of Korea). Species, genus or family of ECM fungi were determined by comparing our sequence to the ones deposited in GenBank (http://www.ncbi.nlm.nih.gov/genbank/index.html) and Unite (Abarenkov et al. 2010) database.

Results and discussion

Average number of vital ECM roots per soil sample ranged from 95.3±6.1 (347.8dm^{-3}) recorded in Majdan Kučajna in spring to 757.7±224.3 (2783.9 dm^{-3})counted in Predejane in early winter (Table 1).These values aremuch lower than values recordedon beech grown at sites contaminated with Pb, Cd and S (4095.5-7288.5 dm^{-3} (Al Sayegh Petkovšek et Pokorny, 2006)) as well as in mature beech (5412.9 dm^{-3} (Mašek et Grebenc 2011)) and spruce stands (4309-6716 dm^{-3} (Kraigher 1999)) in Slovenia. However, they are comparable with values obtained in Germany under two-fold ozone fumigated beech trees (1.993 dm^{-3}) and in the control plot (1.266 $dm^{-3)}$ (Grebenc and Kraigher, 2007). Also, our results can be compared to the ones obtained on white poplar (1106 dm^{-3} -1570 dm^{-3}) (Katanić et al., 2015).

Number of vital ectomycorrhizal roots, old non-turgescent and non-mycorrhizal roots and total number of fine roots differed among sites, while percentage of vital roots differed between spring and early winter (data not shown). This value decreased in spring compared to

early winter which is in accordance to De Roman et De Miguel (2005) who found that the percentage of mycorrhizal tips reached a maximum in winter and a minimum in autumn.

Table 1 Average values (±standard error) for number of vital ectomycorrhizal (ECM) roots, old non-turgescent and non-mycorrhizal roots (ONN), totalnumber of fine roots and percentage of vital ECM roots per sample in beech stands from different sites in Serbia in two seasons. Fisher LSD test was used to assess differences among sites and seasons.

(IV=Iriški venac; MK=Majdan Kučajna; K=Krupanj; PR=Predejane; w=winter, s=spring)

In all (24) soil samples frominvestigated sites in two seasons total number of analysed fine roots was 54636 (24478 in winter and 30158 in spring) while total number of vital ECM roots was 8373 (4784 in winter and 3589 in spring). From all vital ECM roots, 36 ECM types were identified. With molecular methods 27 ECM types were identified from which 14 types to the species level, 4 types to the genus, 6 types to the family and 3 ECM types to the ordo level (Table 2).With morphological and anatomical methods 9 ECM types were identified (*Cenococcum geophilum* Fr., *Fagirhiza cystidiophora*, *Fagirhiza tubulosa*, *Geastrum fimbriatum* Fr., *Genea hispidula* Berk. &Br., *Genea verrucosa* Vitt., *Lactarius blennius* Fr., *Piloderma croceum* Erikss.&Hjortst., *Russula illota* Romagn). Detailed descriptions of these ECM types were given in Katanić et al. (2012).

Cenococcum geophilum Fr. was recorded at all studied sites, a few ECM fungi occurred at one site in both seasons (*Inocybe* sp., *Entolomataceae* sp. *Fagirrhiza tubulosa*,*Lactarius blennius* and *Lactarius camphoratus*), but the majority of them were characteristic for one site and were recorded only ones.

Most of recorded ECM types are commonly found on beech (Grebenc, 2005; Grebenc etKraigher, 2007; Kraigher et al., 2007). Genus*Lactarius*with three and *Russula* with five ECM species/types were most species-rich genera at investigated sites, which is in accordance with previous research (Grebenc, 2005; Grebenc et Kraigher, 2007). *Cenococcum geophilum* has a world-wide distribution with a wide range of plant partners (Smith et Read, 2008). Its mycorrhiza is very common on seedlings and mature trees but it is rarely dominant type on root system (Ingleby et al., 1990). However, *C. geophilum* is frequent and abundant on sites under the influence of stress factors (LoBuglio, 1999).Also, it is in known as an indicator of drought and ozone stress on beech and spruce (Kraigher et Al Sayegh Petkovšek, 2011). At investigated sites *C. geophilum*was frequently found butnot abundant, so it can be assumed that these sites were not affected by stress. *Hydnum rufescens* is suggested as pollution sensitive ECM species in beech forest, *Russula illota* as an indicator of ozone stress on beech and *Fagirhiza spinulosa* as an indicator of polluted air and drought on Norway spruce (Kraigher et Al Sayegh Petkovšek, 2011).Therefore, in future studies attention should be payed on these ECM types and their abundance.

Conclusion

This paper gives the information about diversity of ECM fungi on beech in Serbia obtained with DNA based methods. These results could behelpful in estimating site condition of particular stands and detecting their potential changes in future. In order to reveal potential disturbance of ECM fungal diversity on analysed sites, the ECM monitoring should be continued.

Abstract

Human beings tend to feel healthy and active in regions that have environmental conditions such as overall nominal temperature, precipitation, humidity, and wind within a range called the biocomfort threshold. Beyond the biocomfort threshold, people start to feel uncomfortable and want to move from the area. Hence, bioclimatic mapping of rural areas can help people find the best possible place for recreation. In this study, bioclimatic mapping of Bozkurt's rural areas was conducted with the aim of building upon similar studies in the rural areas of similar structures. To this end, Bozkurt's climatic data was collected from meteorological stations and used to produce biocomfort maps showing temperatures equivalent to the physiological index. The RayMan 1.2 program was used to evaluate the climatic data to determine a field's biocomfort structure, and the geographic information system (GIS) was used to produce thermal perception maps. Based on the psychological equivalent temperature, the most appropriate time and area for outdoor recreation activities were identified on the thermal perception maps.

Keywords:*Rural area, Bozkurt, biocomfort.*

Introduction

How people spend their leisure time has social, psychological and economic importance, especially in developing countries such as Turkey. Because economic and environmental pressures on people are increasing in this country, recreational activities can reduce the stress caused by difficult living conditions. Therefore, recreation can contribute positively to people's physical and mental health. Through such activities, people can also contribute to their personal and social development and share knowledge and experiences with others. In pursuing the health benefits of recreational activities during their leisure time, people can continue to be productive in their jobs and contribute to the economy through recreational spending. Thus, recreation has positive economic impacts in the field of business creation (Cetin, et al., 2010; Milne 2013; Cetin, 2015a; Cetin, 2015b; Cetin, 2015c; Olgyay 2015; Cetin & Zeren 2016).

However, the physical environment that people live in can limit outdoor recreational activities. Among environmental factors that have a huge impact on human activity are ever changing weather and climate conditions. For example, high humidity can prevent body sweat from evaporating, causing heat to be trapped in the body and raising body temperature. In high-temperature or low-temperature environments, dry throat and burning eyes can occur. Dust, smoke, pollen, and other harmful substances can pollute the air and cause difficulty breathing. A recent study describes the variables for bioclimatic comfort that ensure the comfortable breathing and well-being of human beings. According to the widely accepted research, people are comfortable within a certain range of temperature and humidity in a clean air environment. This range is called the comfort zone (Topay, 2012; Olgyay 2015; Cetin, 2015c; Cetin & Zeren 2016).

Construction and urban development can endanger the natural wildlife and ecosystem. An ecological corridor of landscape elements can help to link habitat areas. According to recent studies, Turkey has a richness of flora because of different geographical conditions in different regions (Cetin, 2015a; Cetin, 2015b; Cetin & Sevik 2016a; Cetin & Sevik 2016b; Cetin, 2016a, Cetin, 2016b). A study mentioned that some reasons for the destruction of the natural environment in Turkey include population growth rate, lifestyle, and cultural features. The study demonstrated that these factors were found to affect the formation of biomass. Furthermore, human actions affect ecosystems; thus, the environment in Turkey has been altered drastically (Cetin, 2015c; Cetin, 2015d; Cetin & Sevik 2016c; Cetin, 2016a, Cetin, 2016b).

In 2000, 47% (2.9 billion people) of the world's population lived in urban areas. It is predicted that 60% of the world's population will be living in cities in 2030. In Europe, more than two thirds of the total populations live in urban areas. Increasing population and industrialization has brought about air pollution, and in some cities, air pollution has reached levels that can threaten human health and has become one of the most important current topics of today (Cetin, 2015a; Cetin, 2015e; Cetin, 2016a, Cetin, 2016b).

Human health is adversely affected by air pollution. Carbon dioxide, CO_2, is one of the most common gases investigated in studies of global warming. Furthermore, the amount of carbon dioxide, particularly in areas that have had a population explosion, goes up as motor vehicle emissions rise, becoming a menace to human health in some cities (Cetin, 2015a; Cetin, 2015e; Cetin, 2016a, Cetin, 2016b).

To determine the bioclimatic comfort conditions such as temperature, relative humidity, and radiation, it is also necessary to determine and evaluate the wind conditions. In the evaluation of outdoor recreational activities, defining features include climate, topographic conditions, vegetation and animal life, which are limiting and controlling factors in these activities. In addition to these basic factors, the number of hot days, rainfall situation, emerging pests and diseases, and air pollution also affect human comfort. All of these factors can be used to determine the bioclimatic comfort status. This study uses the situation of Bozkurt as an example to determine the bioclimatic comfort zone.

In urban planning and design, the creation of a comfortable urban environment requires the consideration of thermal conditions for thermal comfort, and the evaluation of the effects of designated green areas in the outdoor environment. Because the urban environment can greatly change the natural landscape, the shading effect and open green spaces can offset the influence of climate elements by providing moisture to the environment, thereby preventing the formation of extreme hot and cold environments. In this study, an attempt has been made to investigate the influence of the landscape and climate on the urban design for recreational activities, and the effects of environmental factors on bioclimatic comfort.

Materials and methods

This study used the climate values of Bozkurt district as the main research material. Data from the township's meteorological station revealed Bozkurt's bioclimatic comfort status. A database of field information was created to produce maps for analysis to connect geographically referenced data and GIS data using ArcView and Rayman 1.2 software. Bozkurt, in the north of Turkey, is situated between 41° 57' North latitude and 34° 01' East longitude. Fig. 1 shows Bozkurt's global location.

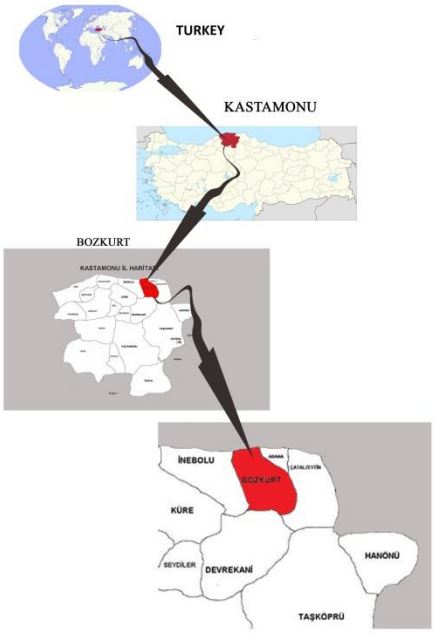

Figure 1.Bozkurt's global location

Bozkurt, Kastamonu province, Turkey, is a Black Sea port city with traditional domestic architecture. The town is situated two kilometers inland from the sea, and Ezine River flows through the valley. Abana is a town situated in the north, Devrekani in the south, Çatalzeytin in the east, and Inebolu in the West. The research area spans 296 square kilometers at an altitude of 30 meters. Ezine River and Ilisi River are the major rivers, Ezine River being 60 km long, and Ilisi River 40 km long.The major mountains are Yarali Goz (2018 meters) and Goynuk (1770 meters), and the main hill in the district of Belen, Hena, Yilmaz, is Karabalçık, where the peak reaches 1,300 meters (Municipality, 2016).

The average temperature in Bozkurt over many years was 17.1 degrees. For the extreme temperatures, the highest temperature occurred in August 1997 and was 32.3°C, and the lowest temperature occurred in February 1989 and was -7.4°C.The average annual rainfall of the county was around 989 mm. From the town center, rainfall usually continues to increase at higher altitudes despite falling snow. The melting of snow in the district would often last a few days. The most snowfall in the city was 133 cm in 1992. The average number of rainy days in a year is 134 days, and rainfall occurs mostly between December and March. Precipitation tends to be regular and heavy. The district saw 23 days of fog and 2 days of frost in a year. Of the number of days of precipitation, the number of days that had negative temperatures was 17. The dominant wind direction was south-southwest, and the average temperature of sea water was 12.5°C.

Higher temperatures dominate coastal areas. At altitudes of up to 210–330m, a combination of porphyry rock with some high scrub elements is common. Chestnut and oak woods can be found further inland on the plateau. Beech forests can be found in the northern plateau, while south oak is more common in the mountainous areas of the field. At higher altitudes, larch forests are common.

This study provides the most accurate map of the climatic data field. In the mapping formula, the universal option of linear kriging interpolation was performed using ArcView, Esri's GIS mapping software, and Rayman 1.2. Bozkurt and its climatic factors were compared, and the appropriate bioclimatic areas were identified in terms of assessed comfort levels. The meteorological station Turkish State Meteorology Affairs General Directorate in Bozkurt in the Western Black Sea (Meteorology 2016) (measured at 14:00) had records of the temperature and relative humidity data in 1981 and in 2016. In this study, higher temperatures

were compared to temperatures with humidity (air temperature was typically above 20°C). Eq. 1 (Steadman, 1979) calculates the conditions for bioclimatic comfort as follows.

$$Te = -42.379 + (2.04901523xT) + (10.1433127xRH) - (0.2247554xTxRH) - (6.83783x10^{-3}xT^2) - (5.481717x10^{-2}xRH^2) + (1.22874x10^{-3}xT^2xRH) + (8.5282x10^{-4}xTxRH^2) - (1.99x10^{-6}xT^2xRH^2) \quad (1)$$

Where Te is the effect of temperature, T is the ambient dry-bulb temperature (in degrees Fahrenheit), and Rh is the relative humidity (percentage value between 0 and 100).
According to the calculation of the formula for determining the suitable bioclimatic comfort areas, the comfortable temperature range is 15–20°C, relative humanity is 30–60%, and wind speed is 1–3 m/sn.
With the help of GIS, the bioclimatic comfort conditions in areas of intensive settlement were found to decrease in comfort, while a decrease in the density of settlements increased comfort. In some studies, data assessments were made on the average annual temperature, humidity, and wind. This study found a favorable environment in terms of bioclimatic comfort conditions and obtained limited results. The monthly average of the hourly sensed temperature values was obtained, and the average annual sensed temperature was obtained from the monthly sensed temperature maps. Thus, Bozkurt's residential areas are suitable considering the temperature sensed in the province.
With the development of software technology today, programs can perform easy-to-use calculations and estimates of many outdoor comforts. Based on formulas and indices created by comfort factors, programs also include the leading rail bearing (Matzarakis et al., 2007; Matzarakis et al., 2010).

Results and discussion

Design features and meteorological parameters for a new residential location were chosen as the materials for analysis and were examined using the GIS method. Thus, in this study of climatic elements, bioclimatic comfort parameters were determined by evaluating temperature, humidity, and wind speed. Data maps presented in Fig. 2, 3, 4, and 5 were prepared by applying the daily maximum temperature measurements observed at 14:00 in Bozkurt and its environment between 1981 and 2016 in Eq. 1.
Fig.2 shows the Annual Average Temperature Maps. In the creation of the climate maps, the ArcView software used the Kriging Interpolation extension of the Universal Linear option to provide the most accurate distribution area of climatic data.

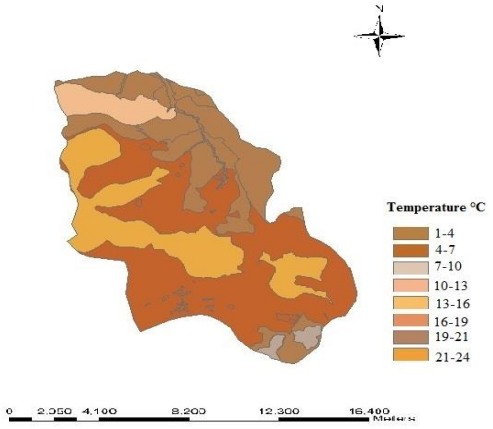

Fig. 2 Annual Average Temperature

According to this map of the study area, the resulting average annual temperature values range from 16–19°C. From the north to the south, the area shows that the average annual temperature values tend to decrease with the increase in other factors.
Fig.3 is annual average relative humidity map showing the relative humidity values obtained. The map of the study area shows that the relative humidity values vary between 49–58%. The percentage of relative humidity values tends to increase toward the south of the area because of the sea.

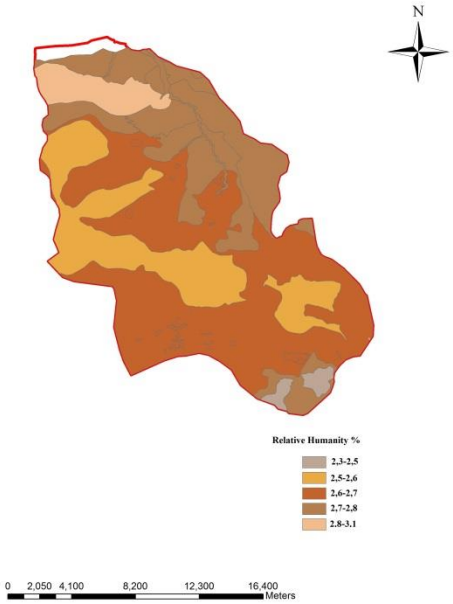

Figure 3. Annual Average Relative Humidity

The average wind speed map shows the field research values are 1.1–2.8 m/sec. The average wind speed values are increasing toward the northern and inland areas (Fig. 4).

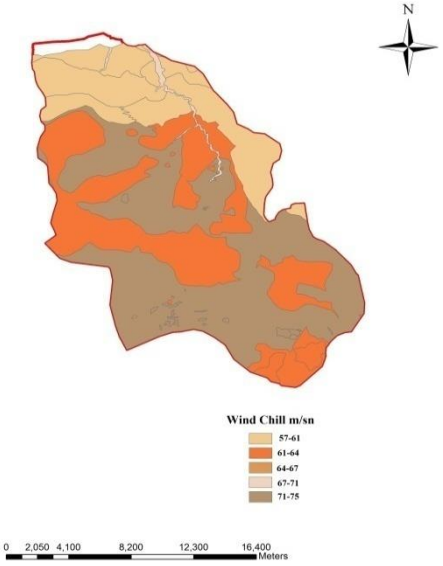

Figure 4. Annual Average Wind Speed Map showing the average wind speed values.

In this study of bioclimatic comfort, the value of each of the climatic elements is determined based on the most extensive range. The purpose of investigating Bozkurt district's bioclimatic comfort is also to investigate the surrounding areas. For this reason, climate maps of Bozkurt district were prepared. Fig. 5 shows the values in terms of bioclimatic comfort.

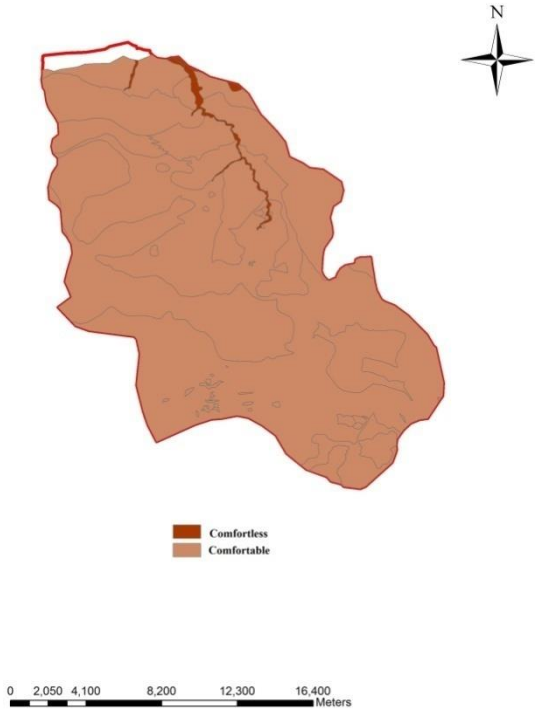

Figure 5.Biocomfort areas

According to the mapping of a large portion of Bozkurt, the town's location appears to be suitable for bioclimatic comfort. This area shows the distribution of more provinces in the eastern and northern parts. The areas suitable for bioclimatic comfort include part of Bozkurt's area of 296km^2, and the areas which are not suitable for bioclimatic comfort are located mostly in the northwest part of the province. The area covering 73 km^2 was found to be unsuitable for bioclimatic comfort, and the reason for this is that the relative humidity in the area is not within the range for bioclimatic comfort. In this study, the results showing Bozkurt's bioclimatic comfort zones can be used to facilitate furtherer development of the provinces around the Bozkurt region to construct comfortable limits, human settlements, recreation, and so on. A practical application of this study is to plan the most accurate distribution area for environmental sustainability and human comfort.

Conclusion

Studies on human bioclimatic comfort usually tried to make an annual distribution in terms of a comfort zone and recommend the appropriate periods in terms of comfort for human activities such as tourism and outdoor recreation. Exterior planning and design is an interest of modern landscape architecture disciplines. Another advantage of the knowledge of the period for bioclimatic comfort is that such knowledge can be used to lay out options for outdoor activities. In this way, space utilization can be tailored to the appointed period.

As can be understood from the study of human bioclimatic comfort conditions, they are affected by a lot of their own characteristics and parameters. Therefore, small changes in one of the variable parameters can affect the total result too much. Due to the characteristics of the people, it is impossible to fix the direction of outside intervention. Therefore, non-factors

affect the bioclimatic comfort conditions are kept under control through various measures and adjustments.

Bioclimatic comfort conditions can be improved with the implementation of the principles of landscape architecture and planning and design criteria. The plan and design in every area of bioclimatic comfort conditions in terms of landscape architecture and design is for a balanced distribution, and there is sufficient basis for the release of open green spaces. Adequate and appropriate plantation areas can produce shade effects, and water vapor spray can prevent heat stress in summer. The deciduous plants in winter can help to get rid of the cold stress field by not shielding the sun's rays. This and many other measures and arrangements should be considered in landscape planning and design. The wrong planning and design of bioclimatic comfort conditions may result in extremely adverse circumstances. The areas of heat or cold stress under natural conditions, due to the destruction of dense natural vegetation and bioclimatic conditions can become inappropriate in terms of comfort. Design in terms of planning and intensive land use with insufficient green areas produces a negative situation for bioclimatic comfort.

As a result, outdoor design is important in the creation of suitable areas in terms of bioclimatic comfort. Therefore, every step of the landscape planning and design should be done with great care and without compromising the conditions for bioclimatic comfort.

Abstract

Spiders are an important group of invertebrates in all terrestrial ecosystems. They are the most abundant with very high species richness. They are known to lodge various ecological niches. The aim of the present work is to study the ecology of the ground spiders in three different orchards (Medlar tree, Clementine tree and Fig tree) located in the hunting reserve of Zeralda (suburb of the city of Algiers in northern Algeria). The epigean spiders were collected using thirty pitfall traps, filled third with a formaldehyde solution (4%) as fixative. The traps were emptied monthly during 8 months between 2014-2015. A total of 354 individuals were collected belonging to 14 families. The Gnaphosidae were represented by 6 species, the Lycosidae and the Dysderidae with 5 species each. The other families were collected with less species number.Out of all sampled species, none of them was constant (frequency of occurrence). 6 species were considered as accessory, 9 as accidental and 23 were sporadic. The changes in richness and species diversity might be the results of the richness of the litter's flora. From our results we can consider the sampling sites as being organized according 2 abiotic factors: the soil humidity and the recovery rate of the herbaceous layer. However, this dual ordination did not explain the species distribution.

Keywords*:* *Spiders, richness, Ecology, orchards, Zéralda*.

Introduction

The biodiversity is part of the natural resources threatened by human and in particular by agriculture. In order to preserve and to encourage the species contributing to the agricultural outputs and healthy agricultural product, it is very important to well know the statute of the biodiversity in agro-ecosystems (Sarthou *et al*., 2013). Arthropoda are much diversified and the most numerous. In fact, approximately 80% of the known species belong to this phylum (Gambaiani, 1999). Among the Arthropoda, the Arachnida are the most widespread class, in which the order of spiders is the largest (Roberts, 2001), since it is the most abundant and the most affluent (Buschholz, 2009). The spiders are important in agro-ecosystems (Oberg *et al*., 2007), as they are used as indicators of the invertebrates diversity (Gravesen, 2000; Cardoso *et al.*, 2004). They are generalist predators and can be used as auxiliary in biological control in differents environments. In Algeria, some studies related to the ecology of spiders in various ecosystems were carried out (kherbouche-Abrous, 2006; Kherbouche *et al.,* 2008; Alioua *et al.,* 2012) and only one work is related to the agroecosystemes (Bouseksou *et al.*, 2015). The present work is an ecological study of Araneae group in three orchards of the hunting reserve of Zeralda (suburb of the city of Algiers in northern Algeria). This reserve was chosen for the diversity of the habitats, moreover, no preliminary arachnological data biotope are done. These three yards (Medlar tree, Clementine tree and Fig tree) were chosen

in order to compare the composition, the diversity and the abundance of spiders and have an idea on the impact of these diverse habitats on the spiders distribution.

Materials and methods

Sampling sites

The region of Zeralda is located at 40 km in the North-East of Tipaza and at 25Km North-West of Algiers (Suburb of the city of Algiers in northern Algeria) (Fig.1). The Zeralda hunting reserve (2°51'44.60"N-36°41'53.55") covers an area of 1034 ha
It is characterized by a Mediterranean climate (sub-humid bioclimatic to mild winter). Three orchards were chosen as study site, the name derives from the cultivated fruit tree. The following abbreviations were used: (i) FG: Fig tree (*Ficus carica*); (ii) CL: Clementine tree (*Citrus clemantina*) and (iii) NF: Medlar tree (*Eriobotrya japonica*).

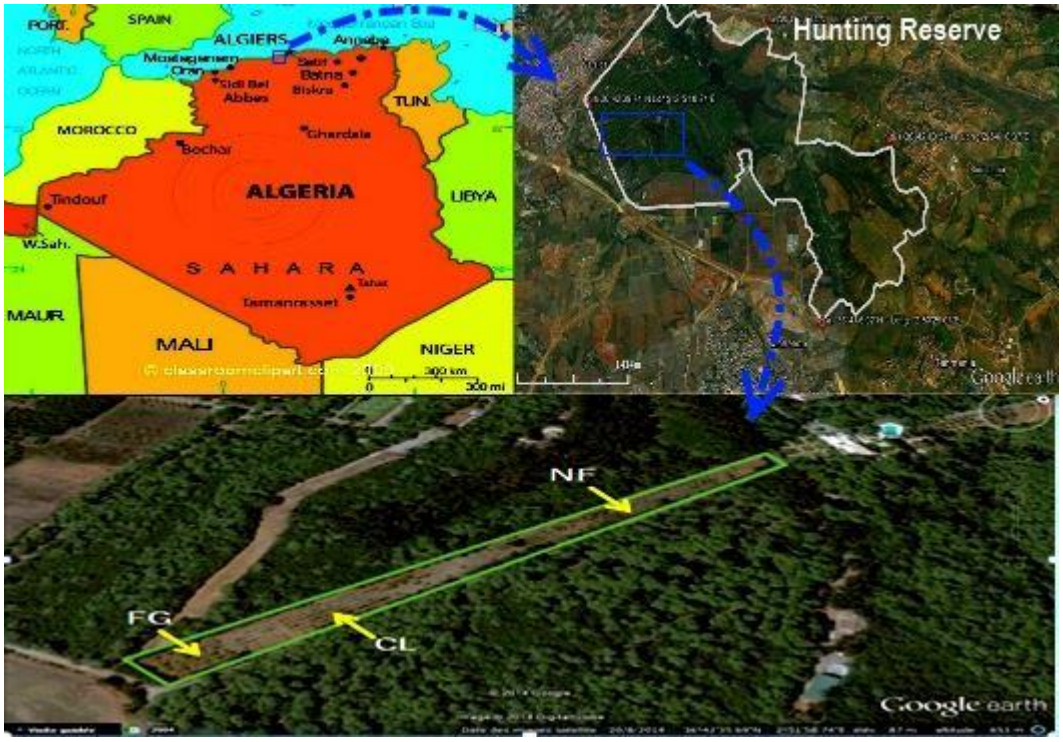

Fig.1 : Geographical location of the hunting reserve of Zeralda and the different sampling sites (FG, CL and NF)

Sampling method
To get an overall idea on the presence and the richness of the soil fauna, the appropriate sampling methods is very important (Southwood, 1978).
Pitfall Barber traps were used in the present study as it is the efficient method for collecting soil invertebrates (Coulson & Butterfield, 1985) and the main sampling method to study spiders community (Maurer & Hanggi, 1990). At each site, 10 trees were selected, around which was placed following the linear transect model. The traps consists of plastic containers (10 cm deep, 7.5 cm diameter) dug, leveled with the soil surface, and 1/3 filled fixative solution (4% formaldehyde). The traps were emptied monthly from April 2014 to April 2015.
The identification to species level was performed using Ledoux & Canard (1981), Bosmans & Abrous (1990), Bosmans & Abrous (1992) and Word Spider catalog (2015).
For specific diversity, the Shannon-Weaver index was used (Ramade, 2003).

Results and discussion

In total 1647 individuals belonging to different zoological groups were collected: 55% Isopoda, 26% Arachnida and 19% Myriapoda. The Araneae order represented 83% of the sampled Arachnida with 352 individuals, followed by the order Opiliones with 65 individuals (15%), and 7 individuals only for the order of Scorpionida (2%) (Fig.2).

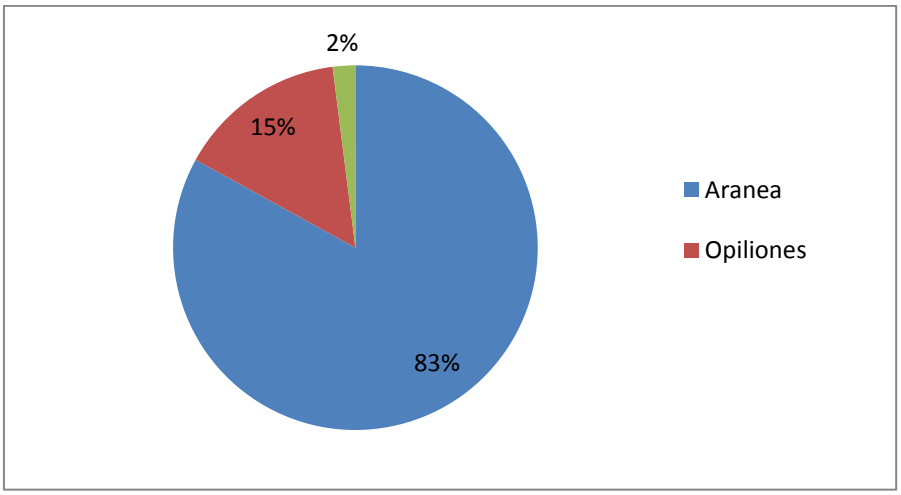

Fig.2: Percentage of different Arachnida in the three study sites.

From the whole 354 individuals spiders sampled 271 were adults and 83 juvenile. Only the adult are taken into account, since the identification of the juvenile spiders is impossible or at least extremely difficult (Valverde & Lobo, 2006; Zulka *et al*., 1997). Among 271 adults collected 190 were males and 81 were females. They belong to 14 families, 26 genus and 38 species.

		Zodarion ludibundum	5	1	6	6
Abundance			69	132	70	271

The results show that the males are more abundant than the females (190 individuals *versus* 81 individuals) with a sex-ratio of 2.34. No female were collected for 16 species, while for 6 others species no male were sampled.

Six species are considered as accessory and nine species as accidental. The 23 species over are considered as sporadic. The sporadic species is represented by a larger number of individuals is simply due to the randomly captures rather than the absence of the species.

Total abundance by site

The total abundance of 271 individuals varies between 69 and 132 individuals (Table 1). The orchard CL has a higher abundance (49%), this can be explained by the fact that the plant species are much more abundant than in the two other orchard (FG and NF), which provide a better ecological niche to the installation of a diversified fauna.

Species richness and Diversity

The total species richness is 38 species and it varies between 19 and 25. CL has the larger spcies richness (25) followed by FG and NF (23 and 19 respectively) (Table 2).

Out of the total collected species, 17 are considered as abundant, as the number of individuals is higher than the number of sampled habitats (Maelfait *et al*., 1990). Among the 38 sampled species, 18 are represented by a single individual. They are probably little active or rare, or the chosen sampling method seems inefficient for these species (Saadi, 2010). The specific diversity varies between 3.40 and 4.12 bit/individuals (Table 2). The stations ranked according to the increase order of diversity H' as follows CL, NF and FG.

Table 2: Species richness, diversity (H') and maximum diversity (Hmax).

Stations	FG	CL	NF
Specific richness (S)	23	25	19
Abundant species	6	6	5
H'	**4,12**	3,4	3,43
Hmax	4,52	4,64	4,24

Low diversity has an abundant population, and a strong diversity characterise by small population (Bachelier, 1978). Despite a low abundance and a low species richness in the Fig tree orchard (FG) compared to those found in Clementine tree (CL), FG orchard has the highest diversity index. This can be explained by the equal distribution between individuals from the different species. According to Uetz (1991), the structure of the vegetation can determine the differences between the spiders settlements. It can influence them through several biotic and abiotic factors, namely web structure, temperature, humidity, sunshine, abundance and the type of prey (Wise, 1993). The Lycosidae family is the most abundant; followed by the Gnaphosidae and Dysderidae. The comparison of the distribution of Araneofaune between the three orchards, allow us to conclude that the Clementine tree has most abundant and the largest species richness, followed by Fig tree and Medlar tree. The Fig tree site has the highest diversity index. The variations of species richness and diversity can be explained by the flora richness and the litter of the orchards.

Conclusion

Our work is a new knowledge of Aranea fauna in the hunting reserve of Zeralda, since no similar study has been done in this region yet. The chosen sites have a species richness lower than in similar ecosystems in our country.

Abstract

The hunting reserve at Zeralda (suburb of the city of Algiers in northern Algeria) is characterised by different type of habitats. Besides the natural ecosystems, the reserve has several agricultural ecosystems (cereal crops and orchards). This diverse environment is very favourable to different fauna in particular soil fauna. Terrestrial Isopoda (Arthropoda) were collected from 3 different orchards (Fig trees, Medlar trees and Clementine trees) in the hunting reserve. The Isopoda were sampled using the pitfall traps. Ten traps were used per sampling site for a period of 8 months between 2014 and 2015. A total of 903 specimens were collected of which 857 were mature (406 males and 451 females) and 46 were juveniles. Five families, 5 genera and 7 species were determined. *Armadillidium vulgare* and *Philoscia muscorum* were the most abundant species (82.93% and 11.84% respectively). No difference in species richness was found between the 3 different orchards, while the highest diversity was in the fig orchard. According to Kruskal-Wallis test, there is no significant difference between species activity in the 3 orchards. Also the biotopes have no effect on this activity.

Keywords: *Isopoda, Richness, Orchards, Ecology, Zeralda.*

Introduction

In Algeria, agriculture has become one of the most important factorsof economic growth leading to sustainable solutions to hunger and poverty and generating a consequent increase in the use of agricultural land. Soil is the principal habitat for plant's roots and a wide range of macroscopic and microscopic organisms which helpmaintainingthe balance and the productivity of agro-ecosystems (Paoletti and Hassall, 1999). According to recent investigations, the pedofaunarepresent up to 23% of the total divers organism known up to date (Decaens*et al*, 2006). The relationship between agriculture and soil isopods (Oniscoides) was studied by different authors: Paoletti (1987, 1988); Hassall (1996); Paoletti and Hassall (1999). Recently, other work was carried out on different types of semi-natural grasslands subjected to different types of farming(Souty-Grosset*et al*, 2005a, b;. 2008). No studies have been performed on the Isopoda in agro-ecosystems in Algeria. The present workinvestigated the structural heterogeneity and the ecological needs of Oniscoidesspecies by comparing the abundance and species richness in relation withthe selected crop type in the Zeralda hunting reserve.

Materials and methods

Zéralda hunting reserve which is represented by forests, land crops and maquis is located at 40 km in the North-East of Tipaza and at 25Km North-West of Algiers (Suburb of the city of Algiers in northern Algeria) (Fig.1). The Zeralda hunting reserve (2°51'44.60"N-

36°41’53.55”)is characterized a dry season from the end of May till the end of September with a subhumid to mild winter.
Three orchards sites were chosen in the reserve and names derivefrom the cultivated fruit tree.The fig Tree (*Ficuscarica*) which is dominant by low litter and abbreviated as FG. The second stite Clementine (*Citrus reticulate*)is characterize by the dominant physiognomically species and abbreviated as CL, and the third site Medlar tree (*Eriobotrya japonica)*abbreviated as NF, is covered by abundant litter.

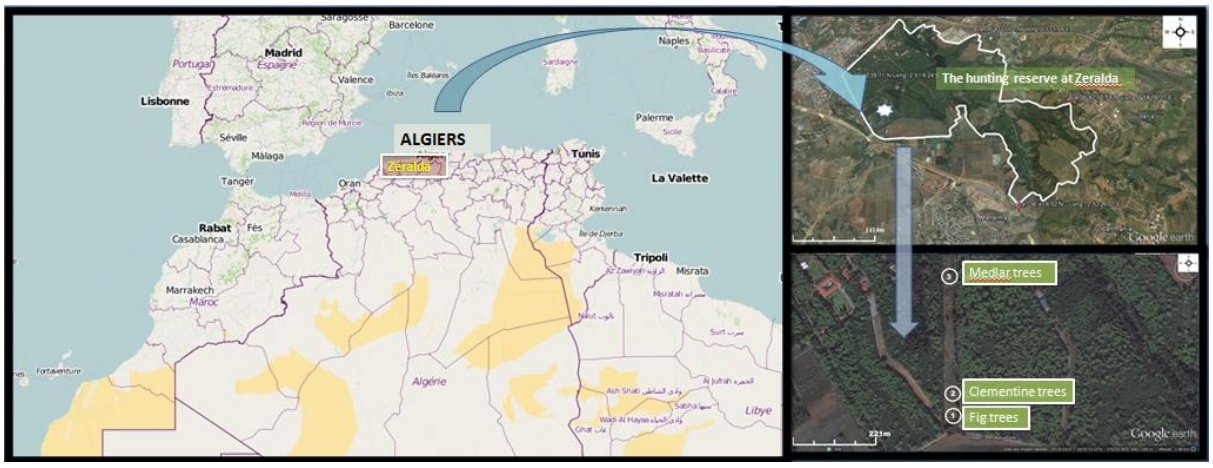

Figure 1: Geographical location of Zeralda hunting reserve and the sampling sites

Pitfall Barber traps (Barber, 1931) were used in the present study as it is the efficient method (Chergui F. & Abrous O. 1988) for collecting soil invertebrates. Ten (10) pitfall traps were used for eachselected habitats.
The traps consists of plastic containers (10 cm deep, 7.5 cm diameter) dug, levelled with the soil surfaceand 1/3 filled withfixative solution (4%formaldehyde).
The trapswere separated at least 3 meters from each other,and were operationalbetween April 2014 and April 2015 and monthly emptied. The collected Isopoda were separated from the rest and identified using a Streomicroscope, Hopkin (1991) determination key.
For ecological studies of harvested Oniscoides species, we considered the abundance and relative abundance (Ramade, 2003), distribution of individuals in their populations (Dajoz, 2006), species richness (Barbaut, 2008) the diversity index (Shannon) (Peet, 1974) and the index of equitability (Blondel, 1979; Magurran, 2004).

Results and discussion

Out of the 903 Isopoda specimenscollected,857were adults and 46juvenile. Onlythe adultsweretaken into account (406 males and 451 females).
The Figsite had the highest abundance(241 individuals) followed by the Clementine site(295 individuals) and the Medlarone (321 individuals). Taking into account the relative abundance of the sampled species *Armadillidium vulgare* is the most abundant species (82.93%), followed by *Philoscia muscorum*(11.84%), *Oniscus asellus*(2.36%), *Armadillidium sp.*(2.01%), *Porcellio dilatatus*(0.47%), *Oniscus sp.*(0.23%) and *Ligidium sp.*(0.11%)(Table 1).This abundance can be explained by the adaptation of *Armadillidium vulgare* and *Philoscia muscorum* to different types of habitat and to their low requirement with regard to the recovery and to the nature of the soil. However, the other five species (*Oniscus asellus*, *Armadillidium sp*., *Porcellio dilatatus*, *Oniscus sp.*, *Ligidium sp.*) are considered as rare species with more demanding and they are located in areas considered as not being their natural habitats.

Table 1: abundance of species collectedin the three sampling sites in Zeralda hunting reserve.

Families	Species	Fig trees	Clementine trees	Medlar trees	Total
Armadilidiidae	***Armadillidium sp.***	6	6	5	17
	Armadillidium vulgare	149	251	300	700
Ligiidae	***Ligidium sp.***	1	0	0	1
Oniscidae	***Oniscus asellus***	9	3	8	20
	Oniscus sp.	0	2	0	2
Philosciidae	***Philoscia muscorum***	62	34	4	100
Porcellionidae	***Porcellio dilatatus***	0	0	4	4
	Total	227	296	321	844

The homogenous species richness (index = 5) in the three orchards indicate the specific stability.The diversity index is variable with the highest one (1.26) recorded in the Fig tree site. This is due to the low trees density allowing a higher sun rays penetration and as results an increase in soil temperature, and poor litter. These conditions inhibit the isopods night activity. The medlar tree orchard has low diversity index (0.45). This can be explain by the high density of fruit trees, less sun penetrationleading to low soil moisture and thick litter. The Eveness(Table 2)of the three orchards indicates strong imbalances within the region.

Table 2: Species richness, diversity and evenness inthe three sampled sites in Zeralda hunting reserve.

Index	Fig trees	Clementine trees	Medlar trees
Species richness	5	5	5
H'	1.26	0.79	0.45
H'max	2.32	2.32	2.32
Evenness(H '/ H max) (H'/H'max)	0.54	0.34	0.2
	Strong	imbalance	imbalance

The Kurskal-Wallis test allows us to compare several averages for its simplicity and eco-efficiency. Since the calculated p-value (0.97) is higher than the significance level of alpha = 0.05, we can validate the null hypothesis: The samples are from the same population. We can then say that there is no significant difference between species activity in the three areas, that is to say the nature of the site has no effect on the species activity.

Comparing our results with similar studies in cultivated areas in some regions of the world, the species richness in the present work is low (5 species) in comparison to agro-ecosystems one located north of Africa but remains similar to the results obtained in Europe.
Recently, in the Maghreb region, Achouri et al. (2008) collected 12 species of Oniscoides in natural and uncultivated habitats. In a similar study Hamaied-Melkiet al. (2011), were able to identified 11 species Oniscoïdes. In Europe, three species were collected in a cultivated field (Paoletti and Hassall, 1999) and 7ones in grasslands (Souty-Grosser et al., 2005b).
Comparing the species abundance in relation to the type of habitat, the sampled species are present in the orchard wherethe litter is more important. Our study showed that the diversity of Oniscoides decreases with the less abundant litter. Severalstudies showed that the species

richness and the high diversity are much important in the agro ecosystems with low agricultural activity than in those with intensive one (Souty-Grosset et al, 2005a, b;. 2008). Isopods preferringhumidity andmainlyare present in the litter are more active during the night. According to Muchan et al. (2012) the diversity of macrofauna in farmland is less than in meadows and forests.

Conclusion

Isopods are very important pedofauna in the agro-ecosystems, their roles as bio indicatorsis not to be underestimated. The present study is the first on soil Isopoda in Algeria. Six species have been recorded in Zeralda hunting reserve, they are in close relationship to the diversity of the vegetation and the ecological conditions.

COENOLOGICAL ADAPTABILITYAND VITALITY OF ARTIFICIALLY ESTABLISHED BROADLEAFSTANDS IN HUNGARIAN OAK AND TURKISH OAK FOREST TYPE IN LIPOVICA NEAR BELGRADE, SERBIA

Rajko MILOŠEVIĆ, Marijana NOVAKOVIĆ-VUKOVIĆ

University of Belgrade Faculty of Forestry, Serbia
*Corresponding author: rajko.milosevic@sfb.bg.ac.rs

Abstract

The paper presents the results of a research of coenological adaptability and vitality, and in those terms the planning of sustainability of species in artificially established stands on the forest type of Hungarian oak and Turkish oak (*Quercetumfarnetto-cerris* Rud.1949), on brown forest soil in the forest complex ofLipovica near Belgrade. The research results clearly confirm that it is justified to introduce some individual species into this site, because they show markedcoenological flexibility and vitality, and accordingly apply the regular planning process. These are primarily pedunculate oak, largeleaf linden and white ash. The coenological inadaptability and unsustainability under the site conditions of the Hungarian oak and Turkish oak (*Quercetumfarnetto-cerris* Rud.1949) forest typeon brown forest soil is primarily shown by green ash, which is ecologically and coenologically unsustainable in this site, as well as maple and black locust. Guided by the priority objectives of forest management in the complex "Lipovica" and in order to ensure biological stability and multifunctional contents, these species should primarily be substituted either by the species of the primary typological composition (Hungarian oak, Turkish oak) or the ones which have shown coenological stability and vitality (largeleaf linden, white ash and oak).

Key words:*artificially established broadleaf stands, vitality, Hungarian oak and Turkish oak forest type, Serbia*

Introduction

Artificially established stands in Serbia cover areas that primarily belong to a number of different types of forests and consequently show different ecological-coenological adaptability to specific site conditions, which further affects the overall production and protective effectsand overall site potentials.

Artificially established stands cover primary and secondary sites (Milošević, 2011, Milošević, 2012a) with a different organic-coenological optimum. That further has an effect on planning and the planning process, i.e. rotation and finally the conservation and sustainability of the overall functional resources and biodiversity structure, althoughin recent years there have been different opinions on the impact of artificially established stands on the conservation of biodiversity (Bremer, L.L., Farley, K.A., 2010).

Artificially established stands account for 6.1% ofthe total forest area in Serbia, with an average volume (conifer and broadleaf plantations) of 127 m^3 ha^{-1} (Banković et al., 2009).

In the area of Belgrade, artificially established stands and plantations are located on a total area of 6795.42 ha, which represents 42.2% of the total forest covered area (Milošević, 2012b).

In the forest complex "Lipovica" artificially established stands are present on the total area of 127.85 ha, or 11% of the total area (Bićanin, 2015).

The largest area is covered by artificially established broadleaved stands of pedunculate oak, white ash, largeleaf linden and locust (Milošević, 2012b).

Broadleaved species represented in the artificially established stands have different bio-ecological characteristics in relation to the ecological conditions of the primary forest type, that is, in the conditions of the Hungarian oak and Turkish oak forest type (*Quercetumfarnetto -cerris)*on brown forest soil, which affects their stability and coenological vitality. The determination of coenological flexibility and vitality of the broadleaved species to the forest type Hungarian oak and Turkish oak (*Quercetumfarnetto -cerris)*forest on brown forest soil in the Lipovica forest complex will provide a realistic basis for management plans related to this category of stands in terms of dynamics and periodicity of management procedures (management objectives, ecological and coenological assessment of the current state in relation to the priority functional objective of the forest complex "Lipovica", silvicultural and management measures, rotation, etc.). This will serve to estimate the justification of retention of certain broadleaved species that build the artificially established stands or their restitution with the species of the primary typological composition or the existing species that in the concrete conditions of the primary forest type, proved to becoenologically more stable and more vital.

Material and method

The "Lipovica" forest complex is located in the central part of Serbia, 20 km away from the capital city, Belgrade. It is located at an altitude between 160-290 m. The basic exposure is southwest, while a significant part of the terrain consists of creek banks and landforms with northern and eastern exposures.

The mean annual air temperature in the submontane belt (200 m altitude) of forests in Serbia, including Lipovica is 11.0 ° C. In the warmest month of July, the average temperature is 20.8 ° C. In the vegetation period, the air temperature ranges from 11.2 to 20.8 ° C (Krstić et al., 2013). In the area of Lipovica forest the parent rock in the highest percent consists of clays and sands followed by limestones, dolomites, green sandstone, sandy limestone and Upper Cretaceous flysch (Kanjevac, 2015). Two soil types were described: brown acid soils andlessive brown forest soil. In the area of Lipovica theclimatogenic community of Turkish oak and Hungarian oak (*Quercetumcerris-farnetto*Rudski 1949)is the most common. It is mainly of coppice origin and beech forests in the form of groups of ecological units of submontane beech forests (*Fagetummoesiacaesubmontanum*B.Jov . 1967) account for a smaller percentage.

The research investigated artificially established stands of pedunculateoak (*Quercusrobur* L.) largeleaf linden (*Tiliaplatyphyllos*Scop.), White ash (*Fraxinus excelsior* L.), maple (*Acer pseudoplatanus*L.), green ash (*Fraxinuspennsylvanica*Marsch.), black locust (*Robiniapseudoacacia* L.) aged 50 years on the forest type of Hungarian oak and Turkish oak forest (*Quercetumcerris-farnetto* Rud.1949.) on brown forest soil in FMU "Lipovica".

A total of 14 phytocoenologicalreleves taken from literaturewere used for the analysis of the floristic composition of the investigated areas using the standard Braun–Blanquetmethod (Braun-Blanquet, J. 1964). Five phytocoenologicalreleves were madein a natural forest of Hungarian oak and Turkish oak -*Quercetumfarnetto-cerris*Rud. 1949(Novaković- Vuković, M. Perović, 2014), and nine in artificially established broadleaf stands established in the site of the Hungarian oak and Turkish oak forest type (*Quercetumcerris-farnetto*) on brown forest soil in FMU "Lipovica" (Bićanin, M.).Syntaxa names were given after Tomić (2004). DCA vegetation data analysis was performedusing the CANOCO 4.5statistical software (Leps, J., Šmilauer,2002).

Results and Discussion

Figure 1. shows that the majority of species grouped in the right part of the figure belong to the group characteristic for the orderQuercetaliapubescentis: Quercus frainetto, Fraxinus ornus, Quercus cerris, Crataegus monogyna, etc. Going down towards the left corner of the coordinate system,we can see that mesophilic species characteristic of the orderFagetalia sylvaticae and class Querco-Fagetea: Carpinus betulus, Melica uniflora, Tilia platyphyllos, etcstand out. Such grouping of species clearly indicates that the phytocoenologicalreleves that approach the left side of the coordinate system differ a lot by their floristic composition from the natural Hungarian oak and Turkish oak forests, i.e. they are characterized by a significant presence of species that are indicators of mesophile site conditions. The greatest deviation from the forest of Hungarian oak and Turkish oak was found in the artificially established stands ofpedunculate oak, white ash, largeleaf linden.

The dominance of species typical of Hungarian oak and Turkish oak forests is particularly pronounced in artificially established stands of green ash (phytocoenologicalrelevé10), black locust (phytocoenologicalrelevé6) and maple (phytocoenologicalrelevé8) (Figure 1).

Artificially established stands of pedunculateoak (phytocoenologicalrelevés 2, 9) (Table 1) are characterized by a significant presence of species that are indicators of mesophile site conditions (Cornus sanguinea, Circaea lutetiana, Carpinus betulus, Ajuga reptans, etc.), i.e. species characteristic of pedunculate oak forest types, while the share of species typical of the forests of Hungarian oak and Turkish oak is reduced.

Artificially established stands of largeleaf linden (phytocoenologicalrelevés1, 4, 5) (Table 1) with respect to representation and differentialityshow even more pronounced mesophile character and coenological stability and adaptability to specific site conditions compared to the artificially established stands of pedunculateoak (Figure 1). In all the storeys of these stands, the presence of mesophilic species (Tilia platyphyllos, Fraxinus angustifolia, Sanicula europaea, Asperula odorata, Mycelis muralis, etc.) issignificant, i.e very large deviationsare noticeablyfrom Hungarian oak and Turkish oak forests (Quercetum farnetto-cerris) on brown forest soil.

Artificially established stands of white ash (phytocoenologicalrelevé7) (Table 1), on thetype of Hungarian oak and Turkish oak forest(Quercetum farnetto-cerris) on brown forest soil, show a very strong coenological stability and vitality (Figure 1). They show a significant difference in terms of their distinct mesophile character from the characteristic set ofthe primary forest type. White ash is dominant in the first storey, has a preserved canopy and also appears in the third floor (Table 1).

Coenological stability of white ash in site conditions of the forest type of Hungarian oak and Turkish oakforests (Quercetum farnetto-cerris) on brown forest soil in FMU "Lipovica" has also been found in previous research (Bićanin, M., Milošević, R., 2015).

A significant difference in terms of coenological relations in the forest type of Hungarian oak and Turkish oak forests(Quercetum farnetto-cerris)on brown forest soil in FMU "Lipovica" is shown by artificially established stands of green ash, black locust and maple as compared to previous species in the artificially established stands (Figure 1).

The floristic composition of these stands contains species typical of forests of Hungarian oak and Turkish oak and the orderQuercetaliapibescentis: Quercusfrainetto, Fraxinusornus, Quercus, Crataegusmonogyna et al. (Figure 1).

In those terms, artificially established green ash stands (phytocoenologicalrelevé10) (Table 1)show a very strong coenological instability and vitality under the given site conditions(Figure 1). In the first storey of the 50-year-old stand, only individual specimens of this species were found, while they are entirely absentfrom the second and third storey. Species that are typical representatives of Hungarian oak and Turkish oak forests were

recorded within these stands, includingQuercus cerris, Fraxinus ornus, Acer campestre, Rosa arvensis, Tamus communis, Helleborus odorus, etc.
Coenological - ecological inadaptability and poor vitality of green ash in the forest type of Hungarian oak and Turkish oak forest (Quercetum farnetto-cerris)on brown forest soil has also been found in previous research (Bićanin, M., Milošević, R., 2015), where this species could not survive under the specific site conditions. Identical coenological relations and coenological stability in the forest type of Hungarian oak and Turkish oak forest (Quercetum farnetto-cerris)on brown forest soil was shown by the artificially established stands of black locust and maple (phytocoenologicalrelevés6 and 8). They are not significantly different from the characteristic set of the primary type, i.e. their floristic composition contains typical representatives of the alliance Quercion farnetto: Quercus cerris, Acer campestre, Lonicera caprifolium, Rosa arvensis, etc.

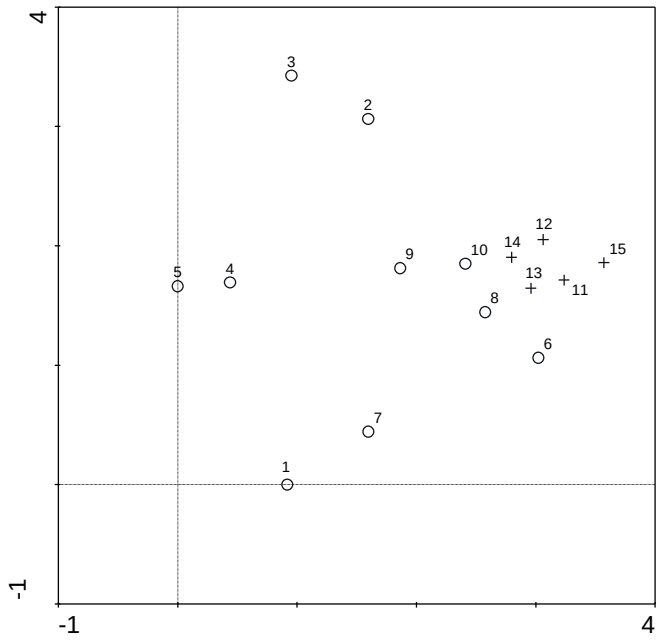

Figure 1: DCA ordination biplot+ -phytocoenologicalrelevés in the natural forest of Hungarian oak and Turkish oak; ○ -phytocoenologicalrelevésin the artificially established stands 2,9-pedunculate oak; 1,4,5, -largeleaf linden, 6- black locust; 8-maple ; 7-white ash, 10- green ash;

Conclusion

Under the site conditions of the forest type of Hungarian oak and Turkish oakforest (*Quercetum farnetto-cerris)*on brown forest soil in the forest complex "Lipovica" near Belgrade, broadleaf species in artificially established stands show different ecological-coenological vitality and adaptability.

Very high ecological-coenologicaladaptability, vitality and stability in artificially established stands in the specific site conditions was shown by pedunculate oak, largeleaflinden and white ash, which cover the largest areas and are the most common in the artificially established stands. This enables a realistic planning approach in terms of justification, planning treatment and regular management planning related to these species.Coenological inadaptability and unsustainability in the site conditions of the given forest type of Hungarian oak and Turkish oakforests (*Quercetum farnetto-cerris)*on brown forest soil is primarily shown by green ash,as well as maple and acacia, which are environmentally and coenologicallyunsustainable in this site.

Guided by the priorityforest managementobjectives in the forest complex "Lipovica" and in order to ensure eco-coenological vitality, stability and multifunctionality, green ash, maple and black locust need to be restituted withthe species of the primary typological composition (Hungarian oak, Turkish oak) or species that have showncoenological stability and vitality in the specific site conditions of the forest type of Hungarian oak and Turkish oak forest(*Quercetum farnetto-cerris)*on brown forest soil (largeleaf linden, white ash and pedunculateoak).

ECOLOGICAL-COENOLOGICAL RELATIONS OF BLACK PINE IN SITE CONDITIONS OF DIFFERENT FOREST TYPES IN THE VICINITY OF BELGRADE, SERBIA

Rajko MILOŠEVIĆ

University of Belgrade, Faculty of Forestry, Serbia
*Corresponding author: rajko.milosevic@sfb.bg.ac.rs

Abstract

The distribution and share of black pine in the growing stock of Serbia is related to its primary and secondary sites. According to the typological classification of forest sites in Serbia, black pine sites are natural finds of black pine in which black pine is at its coenological optimum, i.e. biological black pine characteristics are adaptable to specific extreme site conditions. However, considerable areas in artificially established stands in sites of different forest typesare occupied by black pine. Most commonly those are areaswhose primary ecological and stand structure is endangeredor areas of priority purpose and planned zoning (protective forest belts and various other purpose units).Depending on the typology of black pine sites black pine shows different ecological and coenological flexibility and vitality in artificially established stands under the site conditions of different forest types. This is further reflected in its functional sustainability and overall multi-functional effects.In the vicinity of Belgrade, black pine covers significant areas in the sites of various forest types of different multifunctional purposes.Therefore, the analysis and study of vitality and ecological and coenological stability gives full importance to the management, i.e. realistic assessment of planning procedures, when this species under specific site and typological conditions is at issue.In the Hungarian oak and Turkish oak forest type (*Quercetumfrainetto-cerris*)on brown forest soil, black pine achieves significantly higher production effects at the age of 50 years, compared to site conditions of the forest ofpedunculateoak and white linden (*Tilio-Quercetumcrassiusculaetypicum*Slavnić 1952) on medium deep to deep carbonate chernozem, also being morecoenologicallystable. Actually, even in artificially established stands biological characteristics of black pine have been manifested under the specific site conditionsof different forest types.

Keywords:*black pine, typology of sites, ecological and coenological stability, forest types, Serbia.*

Introduction

Artificially established stands in Serbia are located in sites of different forest types. For this reason, they are characterized by different eco-coenological adaptability depending on the typology of sites and bioecology of species used for afforestation, which further has an impact on the management plans and finally the sustainability of overall functional potentials.

Artificially established stands account for6.1% of the total forest area in Serbia(Banković, S. et al., 2009).Most commonly, protective forest belts in urban areas are located in secondary sites, i.e. their afforestation was carried out without a prior typological classification of sites and therefore the selection of tree species is inappropriate for the current typological (at this stage of typological classification ecological) definition of the given site conditions. Protective belts in secondary sites are coenologically unstable and less vital in terms of the complex of environmental factorsfalling out of the scope of the coenological and ecological optimum (Milošević, R. 2012).In the area of Belgrade, artificially established stands and

plantations cover a total area of 6,795.42 ha, which accounts for 42.2% of the total forest covered area (Forest management plan of FE "Beograd" - Belgrade).In the vicinity of Belgrade, black pine can be found in artificially established stands, covering large areas of forest complexes with different ecological and protective functions. In addition, black pine in artificially established stands in the Belgrade area covers a variety of areas in terms of the ecological and typological affiliation of theirsite conditions, i.e. forest types ranging from the most xerothermic to more mesophile site conditions.Therefore, considering the biological characteristics of black pine, its typological affiliation and ecological-typological characteristics of forest complexes in the vicinity of Belgrade, i.e. the typology of sites where black pine stands are located,this species is expected to show different ecological and coenological relations and ecological-coenological vitality and stability.

The research of ecological- coenological vitality and adaptability of black pine in site conditions of different forest types will further serve to make a realistic assessment of the justification of keeping this species in the particular foresttype, particularly bearing in mind the need for a multifunctional sustainability of forest complexes in urban areas and the need to ensure the planned priority function of the area.

Materials and method

The research was conducted in artificially established stands of black pine in the area of forest complex "Lipovica" and in the protective forest belt along the"Belgrade-Zagreb" highway. The artificially established stand of black pine in the forest complex "Lipovica" is aged 50 years, characterized by a closed canopy (0.7), good health condition and a share of otherbroadleaf species. The terrain is flat, and the parent rockisclay substrates. The artificially established stand of black pine in the protective forest belt along the "Belgrade-Zagreb" highwayis 50 years old, has a canopy closure of 0.6-0.7, good health condition and mostly contains species of the primary typological composition.The terrain is flat, and the parent rock is loess. Site typology was definedusing the standard methodological procedure appropriate for the methodology of typological definition of artificially established stands (Jovic, N. et al., 2009, Milošević, R., 2012). The artificially established stands of black pine in Lipovica are located in the forest type of Hungarian oak and Turkishoak forest(*Quercetum frainetto-cerris*) on brown forest soil (Bićanin, M., 2015). The artificially established black pine stand along the "Belgrade-Zagreb" highwayis in the forest type(ecological unit) of pedunculate oak forest(*Tilio-Quercetumcrassiusculaetypicum* Slavnić 1952.) on deep to medium deep carbonate chernozem (Milošević, R. 1996; Milošević, R. 2011).

The actual current production effects (current state) of the artificially established stands of black pine in these forest types at the specified age and their adaptability to the specific ecological and typological site conditions, as well as ecological vitality were expressed through taxation indicators. Taxation indicators were determined by the standard dendrometric method. The statistical analysis of data was performed using the SPSS Statistics 17.0software package. The correlations between the achieved values of mean stand heights of black pine in these forest types were examined using the Pearson's coefficient of linear correlation.

Results and discussion

Site conditions in the artificially established black pine stands in the Lipovica forest complex near Belgrade are ofextremely xerothermophile character in terms of expressed synergistic effect and reciprocity of environmental factors of the primary forest type.In this sense, according to the typological classification of forests of Serbia (Jović, N. et al., 2009)the foresttype of Hungarian oak and Turkish oak forest (*Quercetum frainetto-cerris*)on brown forest soil (Bićanin, M., 2015) belongs to the complex xerothermophile Hungarian oak and Turkish oak and other forest types, i.e. the coeno-ecological group of forest types of Hungarian oak and Turkishoak (*QuercionfrainettoHorv. 54*) on brownand lessive soils, whichoccupy the largest area in the Lipovica forest complex.Black pine in the artificially established stand in the protective forest belt near the "Zagreb-Belgrade"highway is located in completely different site conditions concerning the expressed synergistic effect and correlation of environmental factors of the primary forest type. More precisely, the research standof black pine is located in the forest type (ecological unit) of pedunculateoak forest(*Tilio-Quercetumcrassiusculaetypicum* Slavnić 1952.) on medium deep to deepcarbonatechernozem (Milošević, R. 1996; Milošević, R. 2011).According to the typological classification of forests (Jovic, N., et al., 2009), this type belongs to the complex of xerothermophileHungarian oak and Turkish oak and other forest types, i.e. the coeno-ecological group of forest types of pedunculate oak and tatar maple (*Aceri tatarici-Quercion* Zolyomi & Jakucs 1957) onchernozem, pararendzina on loess, brown forest soils and lessivebrown forest soils. This coeno-ecological group of forest types spatially borders with the flood-pronepedunculateoak forests, but takes slightly higher positions, out of the reach of high water on the edges of loess plateaus (Tomić, Z., Rakonjac, Lj. 2013).

Chernozems belong to the class of humus accumulative soils which include all soil types with a characteristic A horizon which transforms to a substratevia the A /C horizon or directly(Škorić, A. et al., 1985).Chernozems are soils with a very high-production potential (Antić, M. et al., 2007).

This soil type is characterized by very favorable physical and chemical characteristics and a very high organic-production potential. In terms of texture and mechanical composition of the soil, it belongs to clay loams (clay content + powder ranges from 58 to 62%). $CaCO_3$ contentis present in the whole profile andgets increased with depth. This is accompanied by an increase in pH value ranging from 8.18 to 8.55 (Milošević, R.1996).Different typology of sitesin which black pine is foundin artificially established stands in the study sites in the vicinity of Belgrade affected the eco-coenological relations and vitality of black pine in the specific site conditions (belonging to a specific forest type).

The currently (recorded) achieved production effects and in that respect ecological adaptability and coenological vitality are expressed throughtaxation indicators. Black pine in the artificially established stand in the forest type of pedunculate oak (*Tilio-Quercetumcrassiusculaetypicum*)on medium deep to deep calcareous chernozemaccounts for 48.7%of structural composition, while the rest are various species of both primary typological composition and other broadleaf species with different adaptability to specific site conditions and pioneering character. In this sense, and considering the age, black pine shows very little coenological adaptability to specific site conditions.

Mean stand heights can be used as a reliable indicator of differentiation of the eco-production potential of a site (Milošević, R. 2006; Milošević, R. 2012) and the assessment of ecological and typological adaptability of a species to specific site conditions(Stamenkovic, V., Miscevic, V. 1979). Mean stand heightsfor black pine on the type of pedunculate oak forest (*Tilio-Quercetumcrassiusculaetypicum*) on medium deep to deep carbonate chernozem were significantly lower than the mean stand heights of the species that builds the primary coenological typological structure, i.e. pedunculate oak and the species of more mesophile

bio-ecological features, which is an indicator of a more marked eco-coenologicalvitality and adaptabilityof these species compared to black pine (Table 1).

Table 1. Taxation indicators of the artificially established black pine stand in the site of pedunculateoak(*Tilio-Quercetumcrassiusculaetypicum*) forest type (ecological unit) on medium deep to deep calcareous chernozem-protective forest belt of the "Belgrade-Zagreb" highway.

In total		**568**	**18,4**			**158,4**	**100**	**6,1**	**100**

Depending on the environmental and typological affiliation of site conditions (the primary forest type) black pine shows different eco-coenological adaptability. Actually,black pine achieves higher total-production effects and iscoenologically more stable in the type of Hungarian oak and Turkish oak forest (*Quercetumfrainetto-cerridis* Rudski 1949)on brown forest soil (Table 2) at the stand age of 50 years in the Lipovica forest complex, i.e. in more xerothermic site conditions.

Mean stand heights of black pine in the forest type of Hungarian oak and Turkish oak forest (*Quercetumfrainetto-cerridis*)on brown forest soil are 19.1 m, while in the pedunculate oak forest type(*Tilio-Quercetumcrassiusculaetypicum*) on medium deep to deep carbonate chernozem at the identical age they are 17.1 m.

Table 2.Taxation indicators of the artificially established black pine stand in the site of forest type of Hungarian oak and Turkish oakforest (*Quercetum frainetto – cerridis* Rudski 1949)onbrown forest soil - forest complex "Lipovica"

Tree species	t	N	g	dg	hg	V	V	I_{vt}	I_{vt}
	years	pieces	$m^2 \cdot ha^{-1}$	cm	m	$m^3 \cdot ha^{-1}$	%	$m^3 \cdot ha^{-1}$	%

Largeleaf linden		55	2,35	16,0	17,3	10,9	3,87	0,4	3,88
White ash		32	2,23	19,0	15,6	11,3	4,01	0,4	3,88
Field maple		20	1,85	34,0	20,2	21,3	7,56	0,4	3,88
Norway maple		17	0,53	20,0	19,2	6,6	2,34	0,2	1,94
Hungarian oak		5	0,41	33,0	21,2	4,6	1,63	0,1	0,97
Turkish oak		9	0,99	38,0	21,8	8,3	2,95	0,2	1,94
Hornbeam		6	0,17	18,2	13,6	0,9	0,32	0,0	0,0
Maple		25	2,01	18,7	14,5	17,0	6,04	0,5	4,85
In total		**784**	**36,94**			**281,6**	**100**	**10,3**	**100**

Mean stand heights of black pine in the forest type of Hungarian oak and Turkish oak forests (*Quercetumfrainetto-cerridis*) on brown forest soil at the identical age (50 years) are significantly higher than the mean heights of black pine in the pedunculateoak forest type(*Tilio-Quercetumcrassiusculae*subass.*typicum*)onmedium deep to deep calcareouschernozem, which is represented by a strong positive correlation, r = 0.54 (Table 3).

The share of black pine in the structural composition of the forest type Hungarian oak and Turkish oak forest (*Quercetumfrainetto-cerridis*)on brown forest soil is significantly higher and accounts for 63.3% (Table 2). In addition, (Bićanin, 2015) mean stand heights of black pine in the forest type of Hungarian oak and Turkishoak(*Quercetumfrainetto- cerridis*) forest on brown forest soil in the forest complex "Lipovica" are closer to the mean stand height of edificators of the primary forest type (Hungarian oak, Turkish oak) compared to the mean stand heights of black pine and pedunculate oak in the pedunculate oak forest type(*Tilio-Quercetumcrassiusculaetypicum*) onmedium deep to deep carbonate chernozem. All this points to different ecological-coenological black pine adaptability depending on the typological affiliation of forests where this species is found in artificially established stands.

The research Vučkovic, M. (1989) suggestsa different dynamics of development and productivity of black pine in artificially established stands in different environmental conditions and ecological and productive site potentials. Accordingly, the author concludes that a rotation with a maximum production volume in sites of high ecological value should not be below 80 years, and that in well stocked stands in weaker sitesit should be considerably longer, reaching about 120 years.

Considering that recently there have been different opinions on the impact of artificially established stands on biodiversity conservation(Bremer, L.L., Farley, K.A., 2010),and

fulfillment of multiple functional needs in urban zones, eco-coenological stability and vitality of species that build protective belts, i.e. species in sites of other forest types are of great practical importance in terms of ensuring multifunctionalsustainability and stability expressed through management plans. In this sense, black pine in artificially established stands shows different eco-coenological stability and vitality depending on the type of forest in which it is located and the typological conditions of the site.

Table 3.- Pearson's coefficient of linear correlation

		Protective belt	Lipovica
Prot. belt	Pearson Correlation	1	,541
	Sig. (2-tailed)		,107
	N	40	40
Lipovica	Pearson Correlation	,541	1
	Sig. (2-tailed)	,107	
	N	40	40

Conclusion

Black pine in the artificially established stands in the vicinity of Belgrade shows various ecological and coenological stability and vitality. In this sense, ecological-coenological vitality and stability of black pine in artificially established stands is correlated with the site conditions of the primary forest type. The typological affiliation of theprimary forest type has an impact on the overall ecological and coenologicaladaptability of black pine in specific site conditions. Black pine in artificially established stands on the forest type of pedunculateoak forest (*Tilio-Quercetumcrassiusculaetypicum)*on deep to medium deep carbonate chernozem in the protective forest belt near the Belgrade-Zagrebhighway has a significantly reduced ecological and coenological vitality and adaptability and biological stability compared to the site conditions in the forest type of Hungarian oak and Turkish oak forest(*Quercetumfrainetto-cerridis*)on brown forest soil in the forest complex "Lipovica".

Ecological and coenological vitality under specific site conditions also affected the overall production effects of black pine.Mean stand heights are an indicator of production differentiation of a site in the typological classification of forests and the overall assessment of production effects of forest types. The mean stand heights of black pine in artificially established stands in the site of forest type of Hungarian oak and Turkish oak forests (*Quercetumfrainetto-cerridis*)on brown forest soil in the forest complex "Lipovica" are significantly higher than the mean stand heights of black pine in the artificially established stands in the pedunculate oak forest type(*Tilio-Quercetumcrassiusculaetypicum)*on medium deep to deep carbonate chernozem in the protective forest belt near the Belgrade-Zagrebhighway.

Different ecological-coenological adaptability of black pine depending on whether the site where the artificially established stands are located belongs to the primary forest type affects the overall planning and management measures given the need to ensure the multi-functional contents and their ongoing sustainability when forests and forest complexes in urban areas are concerned.

SWG RRD

Regional Rural Development Standing Working Group

Regional Rural Development Standing Working Group (SWG) in Southeastern Europe

Introduction to SWG GIZ project

What is the SWG? The "SWG" stands for Regional Rural Development Standing Working Group in South Eastern Europe. It is an International Intergovernmental Organization consisted of governmental institutions responsible for agriculture and rural development in respective countries and territories. It is a platform for networking and regional co - operation among the SEE countries and territories in the field of agriculture and rural development. It was founded on the basis of a common wish to establish an organization for sustainable rural development in SEE. As an organization the SWG is a non-political body, acting in a spirit of friendship and good neighborliness and enhances mutual respect and confidence, dialogue and cooperation among the Member Institutions.

Vision: Innovative and sustainable agriculture and rural development through cohesive regional co-operation for improvement of rural livelihoods in the SEE countries

Mission: To increase horizontal collaboration among respective countries and territories of SEE, coordinating regional initiatives related to agriculture and rural development and support the process of economic development in rural areas of Southeastern Europe

General Objective: To facilitate close cooperation among the Ministries of Agriculture and other stakeholders in the field of agriculture and rural development and to support the EU integration

Specific Objectives:

- To improve the common understanding of EU agriculture and rural development policies;
- To assist the improvement of implementation structures and systems for agriculture and rural development in rural areas, with specific emphasis on cross border cooperation;
- To improve the understanding and use of implementation tools for agriculture and rural development;
- To identify and share information and application of good practice in agriculture and rural development to broaden the rural agenda**.**

DEUTSCHE ZUSAMMENARBEIT

Rural Development through Integrated Forest and Water Resources Management in Southeast Europe LEIWW

The regional project includes the countries Albania, Bosnia and Herzegovina, Kosovo, Macedonia, Montenegro and Serbia. LEIWW is a joint project of the Standing Working Group for Regional Rural Development in South Eastern Europe (SWG) and the Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ).

Context

The rural population of Southeast Europe is strongly dependent on the preservation and sustainable use of soil, forests, water and biodiversity. Degradation due to unsustainable management practices and climate change is threatening the bases of income generation, employment and development in rural areas, which in turn affects development opportunities and migration. In light of the encounter between the use of natural resources and efforts to conserve them, there is a need for an integrated approach as well as coordination between the important sectors and institutions.

Accession to the European Union (EU) is a declared policy goal in all the countries of Southeast Europe. To achieve this they need to harmonise their strategies, policies and legislation with those of the EU, and to put in place necessary conditions for their implementation.

Natural resources management is a cross-border issue and the process of EU accession provides a common framework for it. In addition to their own national challenges related to sustainable rural development, the countries of Southeast Europe are now also required to cooperate and coordinate their actions across national borders.

Objective

The overall objective of the project is to strengthen regional capacities for rural development and natural resources management in Southeast Europe.

Project name	Rural Development through Integrated Forest and Water Resources Management in Southeast Europe (LEIWW)
Commissioned by	Bundesministerium für wirtschaftliche Zusammenarbeit und Entwicklung (BMZ)
Project region	Southeast Europe: Albania, Bosnia and Herzegovina, Kosovo, Macedonia, Montenegro and Serbia
Lead executing agency	Standing Working Group for Regional Rural Development in South Eastern Europe (SWG)
Duration	01.01.2015 – 31.12.2017

Approach

The project contributes to the improvement of technical, methodological and implementation competencies for the management of natural resources and for the use of their economic potential in rural areas.

The cooperation between the SWG and GIZ contributes structurally to rural development, the promotion of agri-businesses and the sustainable use of natural resources.

giz Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ) GmbH

South Eastern Europe SWG RRD Regional Rural Development Standing Working Group

The project operates in three areas:

Improving coordination between the environment, forestry, water sectors and rural development / agriculture

SWG introduces positions to the regional dialogue that have been developed by its member institutions, working groups and networks. This entails coordination of the competent ministries, departments and authorities in the Southeast European countries. The topics addressed include the EU directives and their implementation in the context of the EU Common Agricultural Policy and the protection of natural resources. Results and solutions are taken back to the member institutions.

Integrating environmental objectives in rural development and agricultural policies

Here, the aim is to develop inputs that support evidence-based and EU-compliant policymaking for the integration of environmental objectives in agricultural and rural development policies. To this end, the project uses the capacities of the SWG networks to develop practically applicable policy recommendations. This process involves expert staff from various ministries, as well as academics and practitioners; and it includes the private sector and non-governmental organisations.

The regional composition enables fruitful exchanges and learning, particularly since the countries find themselves at different stages of the EU accession process.

Planning and implementing measures for rural economic development and natural resource management in cross-border regions

In four pilot regions across all countries (Drina-Sava, Drina-Tara, Prespa and Sharra), the project supports measures for integrated natural resources management that reconcile the conservation and use of natural resources.

Examples include grants for income generation and natural resource management to contribute to nature conservation while generating incomes. For example through so-called green value chains or through rural tourism. These measures pay special attention to the economic activities of women.

Further education and training as well as on-the-job consulting are provided for policy and administrative actors, as well as the private sector and civil society. This equips them to implement measures, use EU support mechanisms and develop models for sustainable rural economic development.

By working with the media, holding events and organising people to people activities, the project raises awareness among the general public, decision makers, the private sector and civil society regarding the importance of forests, water and biodiversity to sustainable development.

The SWG

"SWG" stands for Regional Rural Development Standing Working Group in South Eastern Europe and is an International Intergovernmental Organization, consisted of governmental institutions responsible for rural development in respective countries and territories.

SWG is working to empower and promote sustainable principles on rural development, through networking and permanent cooperation between all stakeholders of rural development in SEE region.
It acts as independent agency for coordination and implementation of joint projects, as well as for carrying out project activities. Through them, the SWG serves as the facilitator in the process of strengthening regional institutions necessary to support long-term agricultural and rural development.

Moreover, the teamwork by SWG members reinforces their individual efforts to mainstream or incorporate regional rural development concerns into all of their policies and programs.
