

# Regional scale simulation of the forest resources evolution in Southern Belgium (Wallonia)

PERIN J.<sup>1</sup>, PITCHUGIN M.<sup>1</sup>, LEJEUNE P.<sup>1</sup>, HÉBERT J.<sup>1</sup>

IUFRO 125<sup>TH</sup> ANNIVERSARY CONGRESS

18 - 22 September 2017 – Freiburg, Germany

## **Developping methods and tools to :**

- 1) Assess the current forest resources with accuracy**
- 2) Study the likely outcome of changing forestry**
- 3) Predict forest resources evolution**

## **Cover 1/3 of Wallonia :**

- 450 000 ha of productive forest stands  
    ≈ 50 % public managed forest (DNF)

## **Small-scale intensive forest management :**

- Highly fragmented forest
- Generally thinned every 6 to 12 years
- Main harvesting method = clearcutting

## **Undergoing transformation to deal with :**

- Climate change and forest disturbances
- New environmental regulations
- New economic opportunities

**Question : What impact on wood industry supply?**

**➔ Need updated data and simulation tools**

## Permanent Forest Inventory of Wallonia (FIW)

- Systematic sampling : 0.1 ha every 1000 \* 500 m

- 11 000 PSP in forest land
- ± 10 % monitored / yr
  - First monitoring : 1994-2008
  - Second in progress : ≈ 50% done

➔ Fast composition changes underway

		Estimated area (ha)		Variation (ha/yr)	
		2001	2012		
Softwood	Species				
	Norway spruce	167 000	141 000	-2 364	-15%
	Douglas-fir	20 000	27 500	682	+38%
	Other	26 000	24 000	-182	
<b>Total</b>		<b>212 500</b>	<b>192 500</b>	<b>-1 818</b>	<b>-9%</b>
Hardwood	Oak	108 000	109 000	91	
	Beech	59 500	65 500	545	
	Other	71 500	81 500	909	
	<b>Total</b>		<b>239 000</b>	<b>255 500</b>	<b>1 500</b>

➔ A better time resolution is required

## FIW data were updated using aerial photographic cover :

**Photo interpretation  
on PSP coordinates  
(11 079 plots)**

**Working pace :**  
≈ 400 plots / hour

**→ 1 213 CC identified**

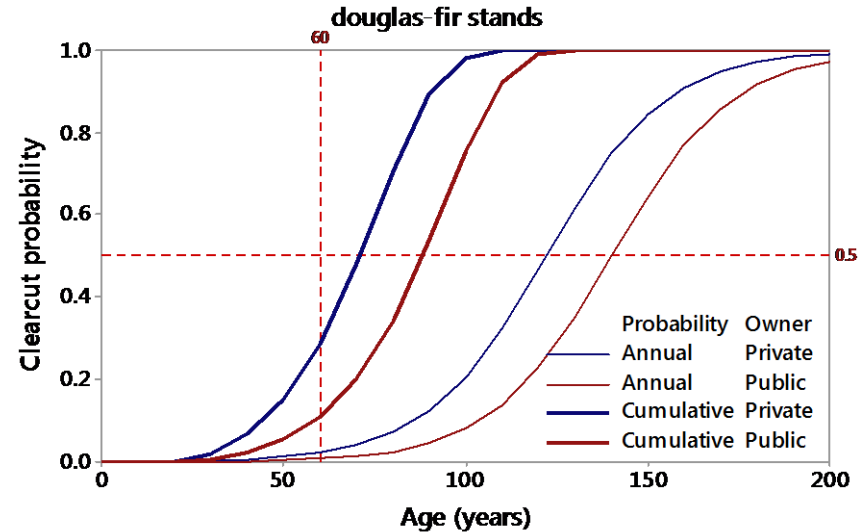

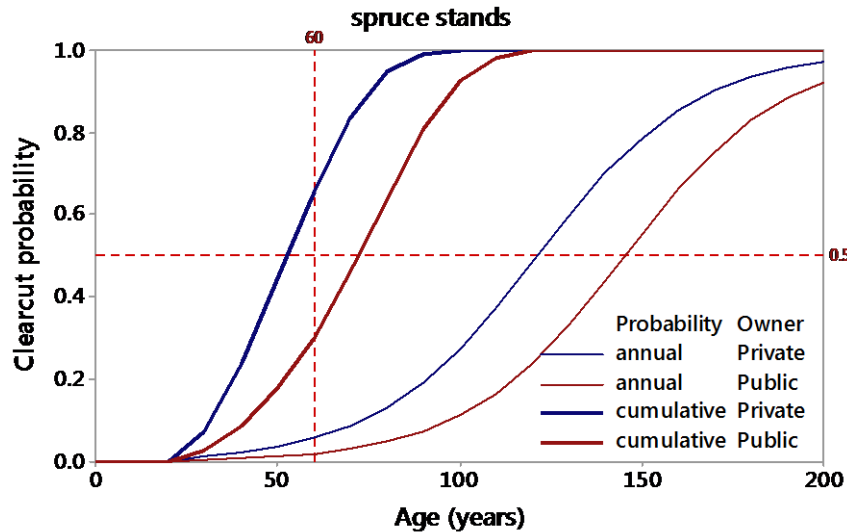

*In example :*  
41 years spruce stand  
sampled in 1998

## Photo interpretation results analysis :

- Clearcut area  $\approx$  4 500 ha/yr (80% in softwood)
- Clearcut probability = f(species, owner, age, SI)

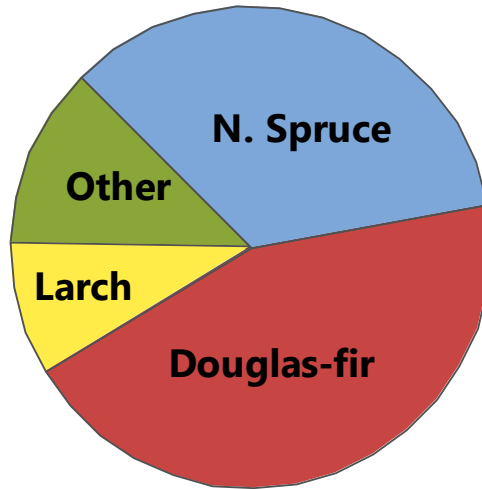

## Reforestation survey in recent clearcuts (N = 529) :

- Total reforestation rate  $\approx 92\%$
- Reforested species in softwood stands :

- Low productivity softwood  $\rightarrow$  hardwood

## **Development of a forest simulation software :**

- Integrated in the CAPSIS<sup>1</sup> platform (java)
- From the tree level to the regional scale

## **First version fully functional (GYMNOS)**

- For pure even-aged softwood stands

## **New version in development (SIMREG)**

- Expansion to other species and structures

<sup>1</sup>Computer-aided projection of strategies in silviculture (<http://www7.inra.fr/capsis/>)

## Operating of GYMNOS

- Virtual stand creation from basic variables
  - Nha, Age, Hdom, Cg, Stdev
- Integrate latest growth and allometric models
  - Tree level distance independent
- Several thinning procedures available
  - Type and intensity are perfectly configurable

Modelling the top-height growth and site index of Norway spruce in Southern Belgium

## Operating of GYMNOS at the regional scale

**INPUT = regional forest inventory data**

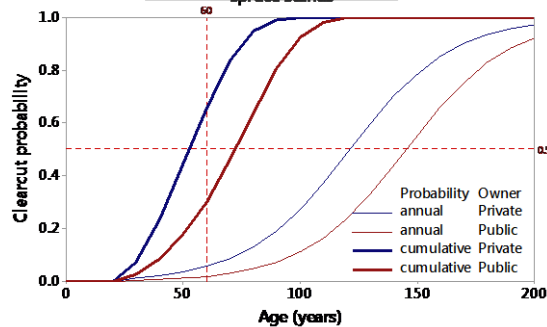

- Each sampled plots → several virtuals stands

**Forest management calibrated with 3 process :**

Thinning

Clearcut

Reforestation

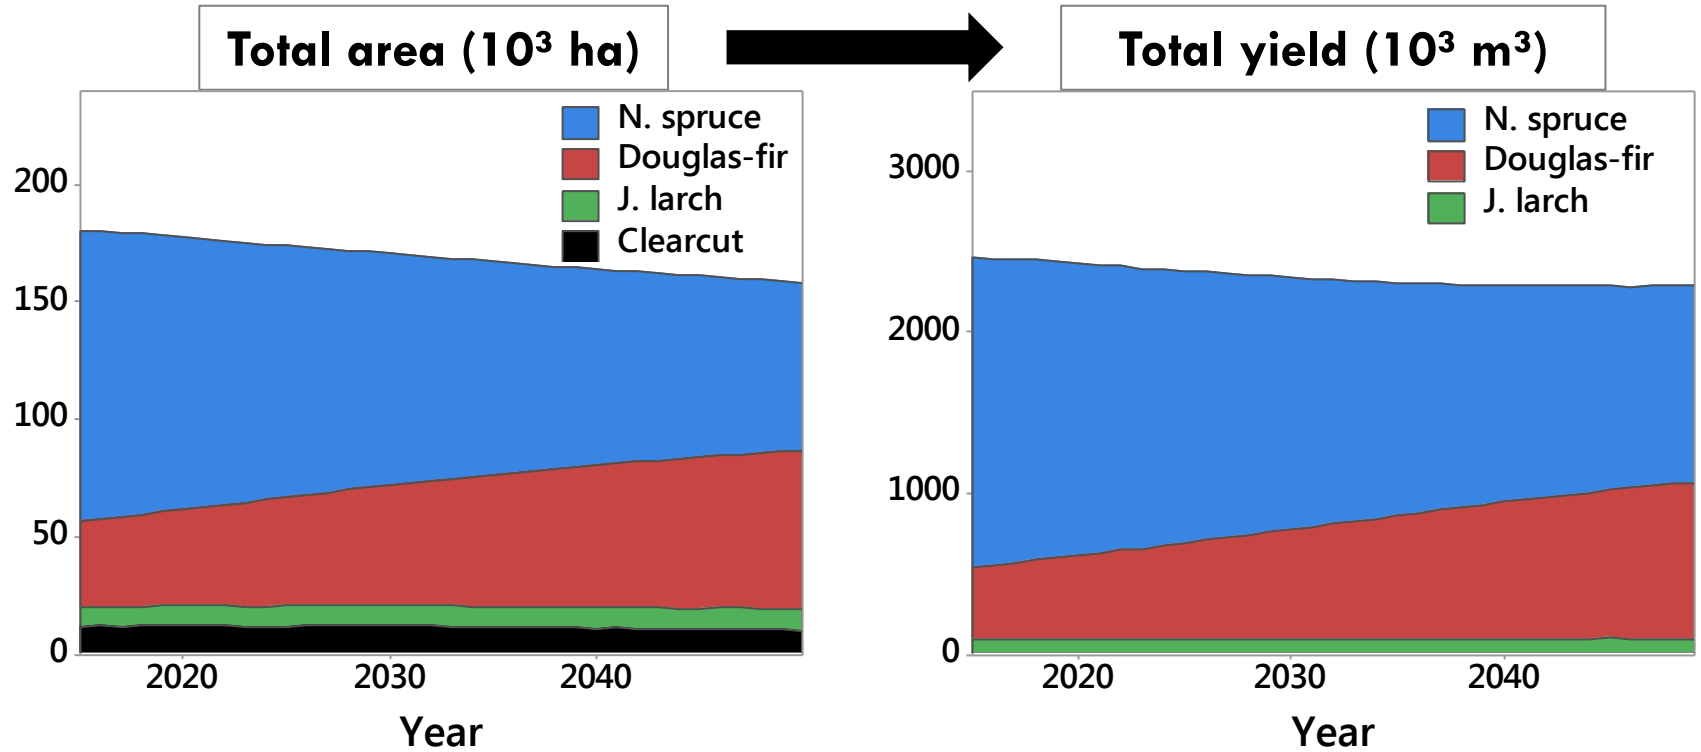

## Operating of GYMNOS at the regional scale

### Performances

- 200 000 ha for 50 years  $\approx$  90 min  
→  $1.2 * 10^6$  annual tree growth /s

# Simulation of Wallonia softwood evolution

## **Conclusions :**

### **Unsustainable harvesting rate**

- $\approx 1.2 * \text{yield}$

### **Partially offset by high yield of douglas-fir**

- DF yield  $\approx 1.3 * \text{NS yield}$

**➔ Possible solution : ↗ douglas-fir reforestation**

## **Automatic detection of clearcuts :**

- With Sentinel-1 and Sentinel-2 data

## **Improvement of the simulator :**

- Expansion to other species and structures
