BAMST Symposium: 'Meet the Belgian meat researchers' Melle, 7th December 2017

INTRODUCTION

Foodborne disease outbreaks are one of the leading causes of infections, hospitalisations and deaths provoked by pathogenic bacteria.

These diseases remain a global public health challenge.

Besides the application of good hygiene practices, the development of new hurdles and processing methods could help to maintain the proper quality of food.

INTRODUCTION

Biopreservation: use of controlled microorganisms or its metabolites

to preserve food and extend its shelf-life

Carnobacteria:

- ubiquitous lactic acid bacteria
 - part of the natural flora from meat

©INRA-ONIRIS

- can inhibit pathogenic and spoilage microorganisms

OBJECTIVE

This study aims to evaluate *in vitro* the <u>bioprotective potential</u> of <u>Carnobacterium maltaromaticum</u>* against major food pathogens:

- Escherichia coli O157:H7
- Listeria monocytogenes
- Salmonella Typhimurium

EXPERIMENT 1

Evaluation of the antimicrobial effect of C. maltaromaticum in cocultures

EXPERIMENT 1

E. coli and S. Typhimurium were not inhibited when in coculture with C. maltaromaticum at any temperature.

<u>At -1°C and 4°C</u>, the three strains of *C. maltaromaticum* showed an inhibition effect against *L. monocytogenes*.

This experiment confirmed the antilisterial activity of the *C. maltaromaticum* strains at low temperatures. This activity might be related to competition for nutrients or to a possible production of organic acids and/or bacteriocins.

EXPERIMENT 2

Evaluation of the antimicrobial effect of *C. maltaromaticum* in cocultures with the addition of EDTA

EXPERIMENT 2

A weak, but significant, inhibition effect against all pathogenic bacteria tested was observed.

EDTA possibly interacted with the outer membrane of gram-negative bacteria, allowing *C. maltaromaticum* and its metabolites to act against these bacteria.

Tests in lower temperatures could have produced higher inhibition effects.

EXPERIMENT 3

Evaluation of the antimicrobial effect of the cell-free supernatant of *C. maltaromaticum*

O *C. maltaromaticum* culture and cell-free supernatant preparation

EXPERIMENT 3

No inhibition effect of the supernatant against the pathogenic bacteria tested was observed.

E. coli

L. monocytogenes

S. Typhimurium

The three *C. maltaromaticum* strains are likely not to produce bacteriocins under the studied conditions.

CONCLUSIONS

The three *C. maltaromaticum* strains tested showed an antilisterial potential, which was greater $\underline{at - 1^{\circ}C}$ and $\underline{4^{\circ}C}$ than at 25°C.

The combination of two hurdles (refrigerated storage and bioprotective cultures) shows great potential to improve quality and food safety.

The behaviour of these strains, as well as their effect against pathogenic and spoilage bacteria, will be studied in meat products.
