Private Rheumatology Practice, Colombes; Private Rheumatology Practice, Bois-Colombes; Private Rheumatology Practice, Ciamart, Private Rheumatology Practice, Antony, France

Background: Life quality issues in rheumatoid arthritis (RA) are often spontaneously mentioned by patients or identified by rheumatologists. Besides classic follow up parameters like DAS28, we have to consider those issues to improve our patients life quality.

Objectives: Explore and quantify the impact of RA on life quality via everyday life and psychological items and the effect of treatment on them.

Methods: RA cases were collected by 2 groups of 20 private practice rheumatologists in the Paris area. Basic information about the patient and his disease were provided by his rheumatologist. Questionnaire including 12 themes and 41 items was filled in by the patient.

Results: 167 cases collected: 82% women, mean age 57 years, 56% moderate and 14% severe disease, 76% ACPA positive, 73% structural damage. Initial DAS28 4.7. Post treatment DAS28 2.7. Drugs: classic DMARDs 95%, corticoste-roids 73%, biological DMARDs 22%, combination therapy 76%.

Life quality issues are spontaneously mentioned by 55% of the patients.
Before treatment, psychological well-being and housework ability are altered in more than 50% of the patients. Impact on economy, food and social life occurs in less than 25% of the cases.

Life quality is mostly altered by pain (85%), then fatigue (75%) and handicap (58%).

We find a correlation between the severity of RA and the importance of the impact on psychological well-being, sexual life and hobbies.

After treatment, psychological well-being improves in 53% of the patients, and social life, work, getting about and sexual life in 45%–32%.

Items improved around 50% of the patients in order: sleep, relation to other people, feeling excluded, social life, depression, sick leave, concentration problems, anxiety and shopping.

We find and improvement in a third of cases in house-keeping, going out, sports and libido.

72% of the patients feel a lack of listening by their families, even under treatment.

Conclusions: Treatment of RA, including drugs and associated measures, reduces the frequency of negative impact on life quality.

We observe that, when DAS28 drops by 43%, the frequency of RA related repercussions diminishes by 31% (14%–50%) on the chosen items. All the items are impacted by RA before treatment and stay impacted after treatment, but less frequently, except family relations. More than one patient of 2 gains correct sleep and almost half of them aren’t depressed or anxious anymore. Impact on social activity and house-keeping activity are less frequently improved.

Regarding these facts, the rheumatologist has to accomplish a tight follow-up and suggest, besides drug treatment, associated measures like physiotherapy, professional activity and environment adaptation and rest among others.

A qualitative evaluation of the improvement will be the subject of a further study.

AB0321  NEGATIVE CORRELATION OF THE ABSOLUTE NUMBER OF CD4+CD25+FOXP3+REGULATORY T CELLS TO THE LEVELS OF RHEUMATOID FACTOR IN PERIPHERAL BLOOD OF NEW ONSET PATIENTS WITH RHEUMATOID ARTHRITIS

X. Jianfang1, C. Gao2, X. Li1, G. Liu1. 1Second Hospital of Shanxi Medical University, Taiyuan, China; 2Pathology, Brigham and Woman’s Hospital, Boston, USA

Background: Rheumatoid arthritis (RA) is a progressive immune-mediated disease that can culminate in joint destruction and early mortality. High levels of serum RF are associated with a worse prognosis in RA. The role of is not fully understood. Recently, Our studies have found that the absolute number of peripheral CD4+CD25+Foxp3+ regulatory T (CD4+Treg) cells decreased in RA patients.

Interestingly, regulatory T cell epitopes (Tregitopes) in IgG have been reported as the main component of intravenous immunoglobulin therapy (IVIG) and provide one explanation for the expansion and activation of Treg cells following IVIG treatment. We hypothesise that RF joins with IgG to form large molecular complexes, which interrupts the production of Tregitopes in antigen presenting cells as a cause of reduction of CD4+Treg cells.

Objectives: The aim of this study is to investigate whether the absolute number of CD4+Treg cells is associated with the titers of auto-antibodies in blood of new-onset diagnosed patients with RA.

Methods: A total of 57 new-onset diagnosed patients with RA were enrolled and healthy donors as control. The absolute number of peripheral CD4+ Treg cells was detected by multicolor flow cytometry combined with an internal microsphere counting standard. 46 of new-onset cases were tested the levels of RF and anti-CCP with ELISA method. IIF method was used to detect APF and AKA. Low titers group and high titers group around with the value 1:80. All data was analysed by SPSS 22.0.

Results: The absolute number of CD4+Treg cells in peripheral blood of new-onset patients with RA was significantly lower than in healthy controls [25.1 (16.01, 40.75) vs 33.0567 (22.9, 43.18), p<0.05]. Interestingly, the reduction of peripheral CD4+Treg cells was negatively correlated to RF titers (correlation coefficient –0.488, p<0.01) but not to other auto-antibodies against CCP, APF and AKA. The absolute number of CD4+Treg cells in high titers RF group was lower than in low titters RF group [20.5 (14.0,40.0) vs 34.0 (29.7,44.6),p<0.05]. There was statistically significant difference in two titers groups.

Abstract AB0321 – Figure 1. The absolute number of CD4+ Treg cells were reduced in peripheral blood of the all enrolled new-onset RA patients (n=57) (A). The reduction of peripheral CD4+ Treg cells from new-onset patients were negatively correlated with the levels of RF tested in these subjects (B). There was statistically significant difference in two titers groups of RF (C).

Conclusions: The absolute number of CD4+Treg cells in peripheral blood of new-onset patients with RA was significantly decreased compared with that in health controls. Furthermore, the reduction of peripheral CD4+Treg cells was negatively correlated to the titers of RF, suggesting that RF contributes to the reduction of CD4+ Treg cells. The correlation of decreased CD4+Treg and RF may be involved in the pathogenesis of poor prognosis in RA.

Shanghai Gothic Internet Technology Co., Ltd., Shanghai; 14. Suzhou Antiinflammatory Research Institute, Suzhou, China

Background: Combination therapy with DMARDS for treating RA is considered as standard of care. However, certain rates of adverse events (AEs) are unavoidable. The stigma is which drug should be stopped first once AEs emerge. The application system (App). The patients can input medical records and perform self-evaluation via App. The data synchronises to the mobiles of authorised rheumatologists through cloud and advices can be delivered. In order to develop the master algorithm, abnormal white blood cell (WBC) counts in blood were first targeted. WBC and medication data was collected, extracted, validated, and then based on Bayesian networks, data mining, modelling, calculating, analysing were performed. WBC under 4,000/ml is defined as leukocytopenia (LP), and over 10,000/ml as infection predisposing (IP).

Methods: SSDM is an interactive mobile disease management tool, including the doctors’ and patients’ application system (App). The patients can input medical records and perform self-evaluation via App. The data synchronises to the mobiles of authorised rheumatologists through cloud and advices can be delivered. In order to develop the master algorithm, abnormal white blood cell (WBC) counts in blood were first targeted. WBC and medication data was collected, extracted, validated, and then based on Bayesian networks, data mining, modelling, calculating, analysing were performed. WBC under 4,000/ml is defined as leukocytopenia (LP), and over 10,000/ml as infection predisposing (IP).

Results: From Jun 2014 to Jan 2018, 24,731 RA patients from 486 centres registered in SSDM. 6099 male and 18 632 are female with mean age of 49.28 ±16.08 (18 to 99) years. 19 different drugs and 126 types of combination therapies are identified. Lab test results showed LP happened in 87 and IP in 123 treatment regiments. Among them we selected prednisone (Pred), leflunomide (LEF), methotrexate (MTX) and hydroxychloroquine (HCQ) as an example to develop a master algorithm based on Bayesian networks and learning model. Figure 1 shows Bayesian network and data processing, in which, quartet are correlating with 15 different regiments. Based on Bayesian method and network data, the calculation for LP and IP probabilities is generated through 32 modelling, and the algorithm for drug withdrawal strategies are generated. Drug withdrawal sequence for LP is HCQ, then LEF and then Pre, and the risks of LP are reduced by 64%, 52% and 26%, respectively. For IP, withdrawal sequence is Pred, then MTX and then LEF, and the risks of IP are reduced by 57%, 63%, and 14%, respectively.

Pred: prednisone; HCQ: hydroxychloroquine; MTX: methotrexate; LEF: leflunomide; LP: leukocytopenia; IP: infection predisposing

Conclusion: Big data system can be built using SSDM via empowering patient. Through data mining, networking, modelling, and Bayesian calculation, a master algorithm for drug withdrawal strategy in reduction of adverse events with combination therapy is developed, which can be applied on the other AEs in SSDM and may replicated in other diseases. Following the continuing data inputs and machine learning, an artificial intelligent system in assisting clinical decision making may be achieved.

Limitations: This study only focus on rate of AE without considering the efficacy, without stratifying dosing.

AB0323
RELATIONSHIP BETWEEN SERUM LEVELS OF LEPTIN & HOMOCYSTEIN IN RHEUMATOID ARTHRITIS PATIENTS WITH OR WITHOUT EXTRA ARTICULAR MANIFESTATIONS

Y. Hussein Gazar. Rheumatology Department, Al-Azhar University, Cairo, Egypt

Background: Rheumatoid arthritis (RA) is a chronic, systemic disorder with unknown etiology, which is characterised by involvement of hand joints and deformations. Rheumatoid arthritis is characterised by synovial inflammation and hyperplasia. chronic inflammatory process of the joints that progresses through different stages of increasing severity characterises rheumatoid arthritis.

Objectives: In this study we aimed to determine the relationship and correlation between serum homocystein and leptin levels in patients with rheumatoid arthritis (RA) without extra articular manifestation (non Ex RA)GROUP-A) and RA patients with extra articular manifestation (ExRA) (GROUP B) and disease progression.

Methods: 80 patients diagnosed as rheumatoid arthritis (according TO ACR/ EULAR 2010 classification criteria) (according TO ACR/EULAR 2010 classification criteria) and selected as follow: (Group A) 40 patients without extra articular manifestation (nonExRA) and (Group B) 40 patients with variable extra articular manifestation (ExRA), CONTROL GROUP (C)

Another 40 apparently healthy persons as controls. RA patients were divided into three groups based on Disease Activity Scores in 28 joints (DAS28) as low disease activity, moderate disease activity, and high disease activity groups. Of the patients (non Ex RA), 11 (27.5%) had low disease activity (DAS28=2.6–3.2), 15 (37.5%) had moderate disease activity (DAS28=3.2–5.1), and 14 (35.0%) had high disease activity (DAS28 ≥5.1). Laboratory investigations were performed for all patients, including determination of haemoglobin concentration (Hb), erythrocyte sedimentation rate (ESR), and C-reactive protein. Serum concentrations of tumour necrosis factor-alpha (TNF-α), IL-6, Homocystein and Leptin were measured.

Results: Significant differences were found between RA patients (group A+group B) and controls healthy group (group C) with regard to the mean levels of Hb, ESR, TNF-α and IL-6 (p<0.05).

As regards to serum leptin, non significant level differences between healthy control group (20.43±7.73 ng/ml) and patient groups (group II and III) (22.43±7.73 ng/ml).

Conclusions: Serum leptin, non significant level differences between healthy control group (20.43±7.73 ng/ml) and patient groups (group II and III) (22.43±7.73 ng/ml). While A statistically significant higher mean level serum Homocystein concentration (p<0.05) was found in patients (group A and B) (11.79±8.72 μmol/L) than in control (group C) (8.6±1.58 μmol/L).

Significant differences were found between non ExRA (group A) and ExRA (group B) with regard to the mean levels of Hb, ESR, TNF-α and IL-6 (p<0.05). A statistically significant differences in mean level of serum Homocystein concentration (p<0.05) was found in group A (22.43±7.73 ng/ml) and in group B (24.43±5.73 ng/ml).

While a significant mean level of serum Homocystein concentration (p<0.05) was found in group B patients (19.43±1.06 μmol/L) than in group A (11.79±13.05 μmol/L) (p<0.05).

Positive significant correlations were detected between serum Homocystein and ESR, TNF-α, IL-6, and DAS-28 (p<0.05) in group B

Multiple linear regression analysis showed that DAS-28 and ESR were the main variables associated with serum Homocystein in RA patients (p<0.05).

Conclusions: Serum leptin cannot be considered of value as an inflammation marker in monitoring RA patients. Serum homocystein can be used as a marker for probability of extra articular complication of RA.

AB0324 DISTRIBUTION AND CLINICAL SIGNIFICANCE OF ANTI-HETEROGENEOUS NUCLEAR RIBONUCLEOPROTEIN A2 ANTIBODY IN CONNECTIVE TISSUE DISEASES

Methods: Serum anti-hnRNP-A2 antibody level was measured by solid-phase enzyme linked immunosorbent assay (ELISA) in 1464 patients with RA, 209 patients with SLE, 204 patients with ankylosing spondylitis (AS), 63 patients with mixed connective tissue disease (MCTD), 133 patients with undifferentiated connective tissue disease (UCTD), 60 patients with Sjogren syndrome (SS), 47 patients with polymyositis/dermatomyositis (PM/DM), and 45 patients with systemic sclerosis (SSc). The positivity rate of anti-hnRNP-A2 antibody was compared among various patient groups, and its correlation to clinical and laboratory parameters and its diagnostic significance were analysed.

Results: The positivity rate of anti-hnRNP-A2 antibody was 38.0% (556/1464), 6.7% (22/209), 3.5% (6/204), 3.5% (7/63), 24.6% (32/133), 20.0% (12/60), and 16.7% (7/45), respectively. The rate differed insignificantly between the RA, SLE, and MCTD groups (p>0.05), but was significantly higher than in other disease groups (p<0.001). The titers of anti-hnRNP-A2 antibody were significantly higher in the RA, SLE, MCTD groups than in other disease groups (p<0.01), but differed insignificantly between the RA, SLE, MCTD groups (p>0.05). In RA patients, anti-hnRNP-A2 antibody weakly correlated negatively to anti-Cyclic citrullinated peptide (CCP) antibody (r=0.135, p<0.01), but correlated insignificantly to age, course of disease, time of morning stiffness, erythrocyte sedimentation rate, C reactive protein, rheumatoid factor (RF), anti-keratin antibody (AKA) and glucose phosphatase isomerase (GPI) (p>0.05).

Conclusions: Anti-hnRNP-A2 antibody can be found in various connective tissue diseases, and its positivity rate is relatively high in RA, SLE and MCTD. It is not a RA-specific antibody. In RA, anti-hnRNP-A2 antibody does not coincide with other RA-related serological indicators; hence, it may serve as an adjunctive indicator for RA diagnosis.

AB0325 CLINICAL OUTCOME OF 2 YEARS TREATMENT OF THE EARLY PHASE RHEUMATOID ARTHRITIS

Background: Few studies have reported long term clinical outcome of patients with early phase rheumatoid arthritis (RA).

Objectives: The objectives of this study were to investigate outcome of 2 years treatment for RA which was started less than 12 months after RA symptoms first appeared and to evaluate prediction factors of poorly controlled patients at 2 years.

Methods: From a total of 1663 RA patients registered in the Akita Orthopaedic Group on Rheumatoid Arthritis (AORA), 66 patients were treated within the first year of RA appearance, and enrolled in this study. Sex, age, RA disease duration, Steinbrocker’s stage, Steinbrocker’s class, medications and DAS28-CRP at the baseline and 2 years post-treatment were evaluated. Furthermore, we compared the group of remission (REM) or low disease activity (LDA) with the group of medium disease activity (MDA) or high disease activity (HDA) at 2 years.

Results: At the baseline, the patients included 13 males and 53 females. Mean age and RA disease duration were 59–65 years and 7–11 months, respectively. Fifty-four, 8, 4 and 0 patients were classified into Steinbrocker’s stage I, II, III, and IV, respectively. Thirty-nine, 25, 2 and 0 patients were classified into Steinbrocker’s class I, II, III, and IV, respectively. Thirty-seven (56%), 24 (36%), and 15 (24%) patients were treated with MTX, DMARDs, and PSL, respectively. In DAS28-CRP, 19 (29%), 13 (20%), 32 (48%), and 2 (3%) patients showed REM, LDA, MDA, and HDA, respectively. Forty-four patients were followed-up for 2 years. At 2 years, 30, 7, 5, and 2 patients were classified into Steinbrocker’s stage I, II, III, and IV, respectively. Thirty-one, 12, 1, and 0 patients were classified into Steinbrocker’s class I, II, III, and IV, respectively. In DAS28-CRP, 33 (75%), 4 (9%), 7 (16%), and 0 (0%) patients showed REM, LDA, MDA, and HDA, respectively.

Conclusions: At 2 years, 75% of patients with early phase RA achieved REM. Older, higher Steinbrocker’s stage and higher DAS28-CRP at the baseline could be prediction factors of poorly controlled patients at 2 years.

AB0326 MATRIX METALLPROTEINASE-3 IS A GOOD PREDICTOR FOR JOINT DESTRUCTION ONLY IN MALE PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Yamada1,2, K. Iinui1, T. Okano1, K. Orita3, Y. Sugikawa1, K. Mamoto4, T. Koike1,3, M. Tada1, H. Nakamura1.

Objectives: The purpose of this study is to investigate a relation between radiographic progression, MMP-3 and other factors such as ultrasonography (US) findings.

Methods: 259 patients (213 women) with RA were enrolled in this study. Their baseline data such as age, sex, disease duration, use of glucocorticoid (GC) or DMARDs, disease activity (DAS28), laboratory data (MMP-3, CRP, RF and ACPA), and the Power Doppler (PD) score at digits and wrists by US were collected. The modified total Sharp score (mTSS), erosion score (ERN) and joint space narrowing (JSN) were examined at baseline and 1 year. Changes from baseline to 1 year (Δ) were calculated. Relationship between baseline MMP-3 and other variables was examined. Predictors for joint destruction was investigated by multiple regression. Statistical analysis was separated by sex because upper limit of MMP-3 is different between men and women.

Results: MMP-3 showed no correlations with GC use, DAS28, CRP or mTSS. MMP-3 was correlated with ΔmTSS only in men, but PD score only in women (table 1). Multiple regression analysis revealed that MMP-3 was correlated independently with ΔmTSS only in men, whereas PD score was correlated independently with ΔmTSS in women. PD score, but not MMP-3, could predict joint destruction at 1 year in women (table 2).

Rheumatoid arthritis – comorbidity and clinical aspects

AB0327 CLINICAL SIGNIFICANCE OF HORMONE-RELATED (ISOLATED) AMYLOIDOSIS OF THE ISLETS OF LANGERHANS – A POSTMORTEM CLINICOPATHOLOGIC STATISTICAL STUDY OF 234 RHEUMATOID ARTHRITIS PATIENTS

A. Apáthy1, M. Bény2. 1Department of Rheumatology, St. Margaret Clinic; 2Department of Pathology, Hospital of the Order of the Brothers of Saint John of God in Budapest, Budapest, Hungary

Background: "All forms of amyloidosis related to the circulation of blood are systemic, and all forms of amyloidosis not connected to the circulation are isolated (localised)". Systemic AA amyloidosis (AAa) – characterised by amyloid A deposition – is one of the most frequent complications of rheumatoid arthritis (RA), in most of the cases leading to renal and less frequently to cardiac insufficiency and death. Islet amyloidosis (IA) (islet amyloid polypeptide – IAPP – prohormone fragment deposition localised to islets of Langerhans) is an isolated (localised) form of amyloidosis of clinical (diagnostic) significance in adult type II diabetes mellitus (DM).

Objectives: The aim of this study was to determine the prevalence of AAa and IA in RA, to analyse the relationship between them, furthermore to evaluate the possible role of IA in DM in RA patients.

Methods: At the National Institute of Rheumatology 11 558 patients died between 1969 and 1998; among them 234 with RA, and all of them were autopsied. RA was confirmed clinically according to the criteria of the ACR. The diagnosis of DM based on clinical data. Tissue samples of pancreas were available for histologic evaluation in 150 of 234 patients. AAa and IA were diagnosed histologically, amyloid A and IAPP deposits were confirmed histochemically. The relationships between AAa and IA further more between IA and DM were analysed by Pearson’s chi-squared test.

Results: AAa complicated RA in 32 (21.3%) of 150 patients. Hormone-related IA localised to the islets of Langerhans was observed in 15 (10.0%) of 150 patients. Clinically diagnosed DM was associated with RA in 31 (20.66%) of 150 patients. AAa was associated with RA in 2 (6.45%) of 31 cases. The relationship between AAa and IA was not significant, even the association’s coefficient was negative: –0.2381, χ²=0.785, p=0.77). IA associated with clinically diagnosed DM in 8 (53.3%) of 15 patients. There was a positive and significant correlation between clinically diagnosed IA and DM (association’s coefficient: 0.6893, χ²=10.947, p=0.0009). IA was present without the clinical diagnosis of DM in 2 (46.7%) of 15 patients. The relationship between IA and clinically not diagnosed DM was also positive and significant (association’s coefficient: 0.6037, χ²=6.8717, p=0.008).

Conclusions: Systemic or localised types of amyloidosis may exist simultaneously side by side or may be present independently from each other. AAa and IA are independent phenomena based on the negative association’s coefficient and not significant relationship between them, and may coexist in RA. According to our interpretation the early stage of IA (involving only a few islets with minimal IAPP deposits) represents a clinically latent DM and the advanced stage of it is clinically manifest DM. The strong positive and significant correlation between IA and clinically manifest DM suggest close relationship between them. Based on the positive and significant correlation between IA and clinically not diagnosed DM, the IA may be a good indicator of potential DM in the latent stage of disease. This correlation may help recognise DM in its early stage. For this reason we recommend that all biopsy material and surgical specimens of pancreas to be tested for IA or IAPP deposition.

AB0328 CARDIOVASCULAR RISK EVALUATION IN LONG STANDING RHEUMATOID ARTHRITIS: REAL CLINICAL DATA

A. Babaeva1, E.V. Kalinina1, N.S. Zvonorenko1, K.S. Solodenko2, M. A. Osadchuk3. 1Volgograd State Medical University, Volgograd; 2I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: According to recent national and EULAR recommendation cardiovascular risk (CVR) in pts with RA should be evaluated using modified SCORE system. But a lot of investigations and real clinical data demonstrate that this system commonly down-estimates CVR in RA pts.

Objectives: Aim of our study was to compare standard CVR assessment and additional CVR evaluation on the basis of specific disease-associated risk factors (RF) and CV system investigations in long standing RA.

Methods: 118 pts (96 female, 22 male) aged from 34 to 74 years old (mean age 59.51±5.21) with long standing RA (duration >5 years) were observed. In all pts CVR was stratified according to modified SCORE. We have analysed pts medical cards and standard examination data to determine clinical features of RA and associated conditions to verify severity of CVR. In term to reveal asymptomatic CV disease pts had undergone additional investigations (echocardiography, Dopplerography of carotid arteries, ECG-monitoring).

Results: Conventional CVRF were registered in 110 (93.22%) pts. Age>45 (male),<50 (female) was in 85 (72.03%) pts, BMI<25 kg/m² in 10.17%, elevated cholesterol level and/or dyslipidemia in 41.52%, AH with target organ damage was detected in 49.76%, T2DM and 11.8% CHD, stage 1 in 10.17%, history of MI was in 2 (1.69%) pts. According to modified SCORE for RA very high, high, moderate and low CVR was detected in 17.80%, 47.46%, 18.64%, 10.16% cases respectively. High activity of RA was diagnosed in 61.02%, and erosive arthritis in 84.75% pts. Inadequate disease-modifying treatment was qualified in 15.26% cases. Majority of pts (59.32%) received systemic glucocorticoids (GC) in daily doses from 2 to 12 mg of methylprednisolone, among these pts 14 (11.86%) have been taken GC in moderate and high dose for a long period. On the basis of instrumental data asymptomatic atherosclerosis of aorta and/or aortic valve and/or carotid arteries was detected in 44 pts (37.29%). Silent ischemia was revealed in 3 pts (2.54%). High disease activity and long term systemic GC treatment were associated with significantly high CV events in observed pts (p<0.05). Using obtained results we reassessed CVR in studied cohort. Revisied data of CVR stratification suggest that 49 (41.53%) pts were in VH-CVR, 41 (34.75%) – in H-CVR, 16 (13.56%) in M-CVR and only 12 (10.17%) in L-CVR. The difference in pt ratio for CVR stratification was significant in accordance with χ² criterion.

Conclusions: Obtained data suggest that modified SCORE is not absolutely reliable tool for precise CVR stratification in long standing RA. Additional investigations to define asymptomatic atherosclerosis and coronary artery disease are required in term to prevent CV complications especially in pts with high active erosive RA treated with systemic GC.

AB0329 THE METHOD OF EVALUATION OF CAR Di ORES P A R Y S TIM SYSTEM NEUROVEGETATIVE REGULATION IN RHEUMATOLOGIC PATIENTS

A. Lebedeva, V. Marchenko, I. Mozhaev. Department of Research Institute of rheumatology and allergy, Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation

Objectives: To study the characteristics of cardiorespiratory system (CRS) neurovegetative regulation disorders and to define the correlation with disease activity.

Methods: 40 rheumatoid arthritis (RA) patients (14 m:30 f; median age 45±2.32), 18 ankylosing spondylitis (AS) patients (m:13 f:5; m.a. 39,6±2,44), 17 osteoporosis (OP) patients (m:3 f:14; m.a. 55,5±1,47), 50 healthy persons (HP, 25 m:25 f; m.a. 23,6±0,84) were studied. The diagnosis of RA, AS, OP were established by the current diagnostic and classification criteria. The cardiorespiratory system neurovegetative regulation was studied with the use of
Sporoarteriocardiographimorphograph, that was able to synchronously analyse the variability of heart rate (HR), respiration (R), systolic (S) and diastolic (D) arterial pressure, resiphr/O-phase structure, baroreceptor sensitivity and some other cardiohemodynamics parameters. Following parameters were calculated: spectrum of fluctuations total power (TP), the activity of suprasegmental (VLF), sympathethic (LF), parasympathetic (HF), cortical (IC) and subcortical (SNCA) contours and sympatho-vagus balance parameters (LF/HF) in regulation HR, R, S, D, baroroeceptor sensitivity (BR), inhale (Ti) and exhale (Te) time (V. Marchenko, 2004).

Results: Different severity dysregulation of CRPS at all levels is typical for the AS patients, which expresses in decrease of the variability of the basic contours of regulation of heart rate, respiration, systolic and diastolic blood pressure with a shift of sympatho-vagal balance in favour of parasympathicotonia, reduction baroroeceptor sensitivity. The heterogeneity of the analysed groups according to the parameter LF/HFHR is shown. The ratio of patients with parasympathotony, normotony, sympathotONY in groups made up, respectively, in HP (34:48:18), RA (23:54:23), AS (55:28:17), OP (29:53:18). It is established that a significant number of AS patients had parasympathetic type of regulation, and the rest of the groups were dominated by patients with normotonic type of regulation. It is shown that in groups of patients neurovegetative regulation system was more stringent, as evidenced by the increase in their number of reliable correlations compared with the group of healthy individuals. The features of disregulation in each analysed group were established, the nature of which requires further analysis. Significant correlations (r >±0,45; p=0,029) between the parameters of the neurovegetative regulation of cardiorespiratory system on the one hand and the clinical and laboratory parameters of inflammatory activity (in the first place, DAS28, CRP, ESR) on the other hand in patients with RA; with parameters BASDAI, the activity of the inflammatory process (ESR, CRP) in patients with AS; denositometric parameters in patients with OP were identified. The close connection between vascular component and the activity of the inflammatory process is shown, which may be a manifestation of endothelial dysfunction.

Conclusions: Thus, the method of variability of cardiorespiratory allows to detect the neurovegetative dysregulation of the cardiorespiratory system in rheumatologic patients and can be recommended for the evaluation of the system of regulation in general, the possible role of its disorders in the pathogenesis of clinical manifestations of diseases, and assessing the dynamics of regulatory processes in the treatment of patients.

OSTEOPOROSIS, SARCOPENIA AND OSTEOSARCOPENIA IN WOMEN WITH RHEUMATOID ARTHRITIS

A. Feklistov, N. Demin, N. Toroptsova. Nasorova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease associated with polyarthritis, progressive joint damage, and physical impairment that can lead to osteoporosis and sarcopenia, increasing the risk of fractures and leading to a greater loss of autonomy in RA patients.

Objectives: To assess frequency of osteoporosis, sarcopenia and osteosarcopenia in women with RA.

Methods: 40 female patients with RA (mean age 63±7 years) and 40 female controls without RA (mean age 64±9 years) were enrolled in this study. Body composition and bone mineral density (BMD) in lumbar spine and proximal hip were assessed by using dual X-ray absorptiometry (DXA, Hologic Discovery A). Sarcopenia in women was defined as a skeletal muscle index (SMI) ≤5.67 kg/m² and osteosarcopenia – if sarcopenia and low BMD were present together. The particpants performed Short Physical Performance Battery (SPPB) and handgrip strength was measured. Body mass index (BMI) and Disease Activity Score (DAS28) were calculated.

Results: Low BMD at least in one of measured area was found out in 19 (48%) RA persons and in 18 (45%) controls. Sarcopenia occurred in 10 (25%) RA patients and in 5 (12.5%) people without RA (p<0.05). Among them osteosarcopenia was found in 6 (15%) RA women and 2 (5%) controls. Skeletal muscle index (SMI) was lower in patients with RA (6.43±0.978) than in controls (7.01±1.064, p<0.05). In RA patients SMI had a positive correlation with BMI (r=0.58, p<0.05) and handgrip strength (r=0.34 for right, r=0.30 for left, p<0.05 for both). Sarcopenia was more common in RA patients who were overweight or obese according to their BMI (p<0.01). There was no correlation between SMI and DAS28, drug use, frequency of falls during the last year, SPPB in the RA group

Conclusions: In RA patients 48% had osteoporosis and 25% – sarcopenia, among them 15% women – osteosarcopenia. The risk of sarcopenia and osteosarcopenia was higher in nonobese patients.

INCIDENCE OF MALIGNANCY IN PSORIATIC AND RHEUMATOID ARTHRITIS PATIENTS LIVING IN NEWFOUNDLAND AND LABRADOR

A.F. Lewis1, I. Landells2, G. Mugford3, M. Khrasha1. 1Clinical Epidemiology; 2Dermatology; 3Rheumatology, Memorial University of Newfoundland, St. John’s, Canada

Background: Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) are reported to be associated with an increased risk of malignancy. Newfoundland and Labrador (NL) has one of the highest cancer rates in Canada. There is a paucity of literature on the prevalence of malignancy in NL patients with PsA and RA.

Objectives: Evaluate the incidence of malignancy in a cohort of PsA and RA patients and compare rates with the general population. Evaluate the impact of therapy of these two diseases.

Methods: Data was extracted from the charts of 200 PsA and 500 RA patients seen at a rheumatology clinic in St. John’s between 2011 and 2014. Statistical analyses were performed using SPSS version 21.0 for Windows (IBM Inc.). Person-time Rate (PYs) per 100,000, stratified by age and gender, were used to estimate overall cancer risk and proportions between the two cohorts. Observed rates were compared with Statistics Canada reported general NL rates.

Results: We identified 37 (5.3%) malignancies; 34 (9.1%) solid and 3 (8.1%) hematologic. Mean (SD) age was 58.4 (12.28) and age at diagnoses of disease was 46.8 (12.88). Four hundred and eighty (86.6%) were females. No difference was observed in rates between the study population and the NL general population (p>0.3217). The most common solid tumours were breast 8 (21.6%) and skin 8 (21.6%), followed by five bowel and lung cancers in equal proportions (13.5%). Distribution of cancers between the two cohorts were similar.

Conclusions: The results suggest there is no difference in the cancer rate between our cohorts and the NL general population. We acknowledge study limitations related to shorter duration of follow-up and lower sample size.

COMORBIDITIES PREVALENCE AND CHARLSON INDEX IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS

Background: The Charlson comorbidity index (CCI) is a prognostic scale, which gives a numerical value that indicates the burden of comorbidities in a patient. This index is obtained from the sum of 19 medical conditions that have been related to mortality and has been validated in several studies. Patients with rheumatoid arthritis (RA) are more at risk than the general population of developing comorbidities. However, these often go unnoticed despite the impact on the disease activity and to treatment response, as shown by different studies such as COMORA.

Objectives: To determine the prevalence of comorbidities in a cohort of patients with RA and estimate CCI.

Methods: Cross-sectional descriptive study, patients diagnosed with RA according to the EULAR/ACR 2010 classification criteria were included. All patients were followed up in a rheumatology service in a tertiary hospital. Comorbidities were obtained from the medical records. To measure comorbidities, CCI was calculated, the diagnosis of RA was not included in the index. We defined three categories of comorbidity according to CCI: 0 (no comorbidity, applied to patients with no previous record of conditions included in the CCI), 1 to 2 (moderate) and 3 or more (severe). Others comorbidities not included in CCI, such as hypertension (HTN), dyslipidemias (DLP), thyroid disease (TD), osteoporosis (OP) were collected.

Results: 130 patients (103 women) were analysed; mean age was 58.6±12.9 years and disease duration of 6.0±4.4 years. 82.8% were seropositive for rheumatoid factor (n: 83) and/or anti-CCP (n: 97). 44.6% had previous smoking history, and 35.4% Charlson index (93%). Five patients with a history of tumour (2 metastases) and 2 lymphoproliferative diseases included TD (18.5%), OP (17.7%), diabetes mellitus (9.2%) and liver disease (32.3%; 6.9% Stage III) and chronic lung disease (23.8%). Other diseases included TD (18.5%), OP (17.7%), diabetes mellitus (9.2%) and liver disease (9.2%). Five patients with a history of tumour (2 metastases) and 2 lymphomas in the last 5 years. Four patients had a heart disease, in 3 as an ischaemic event.

According to CCI, 20.8% of the patients had a Charlson 0, 43.8% Charlson 1–2, and 35.4% Charlson >3.

Conclusions: In our cohort, despite being a relatively young population, the presence of comorbidities and cardiovascular risk factors is relatively high, in agreement with what has been observed in other studies. 1 out of 3 patients has a severe comorbidity burden.

ANALYSIS OF THE ASSOCIATION OF COMPOUND INDICATES OF DISEASE ACTIVITY AND QUALIFICATIONS OF FUNCTIONAL CAPACITY AND QUALITY OF LIFE RELATED TO HEALTH IN PATIENTS WITH RHEUMATOID ARTHRITIS

B.F. Altradi1, I.A. Pereira2, T. Fontana1, Y. Altaro2, C.J. Ferreira1 1Medicina, 2Universidade do Sul de Santa Catarina, Florianópolis, Brazil

Background: The correlation analysis of ICADs with questionnaires of functional evaluation and quality of life is essential, since it is the outcomes that matter to the patients.

Objectives: To evaluate the correlations between ICADs with questionnaires of functional capacity (HAQ) and health-related quality of life (SF12).

Methods: Cross-sectional study with 100 out-patients of Santa Catarina, participants of a multicenter cohort, followed between August 2015-January 2016. Evaluated ICADs were: DAS28 VHS, DAS28-PCR, SDAI, CDAI, RADAI. The questionnaires were: HAQ and SF12. Tests Qui Square, test t Student, prevalence ratio and Pearson’s correlation were used, with reliability interval 95%.

Results: Moderate correlation between ICADs and HAQ (variation r 0.52–0.65), Weak correlation between ICADs and SF12 (Physical: variation r 0.15–0.24 and Mental: variation r 0.40–0.45).

Conclusions: ICADs correlate poorly with quality of life, assessed by SF12, but moderately with functional limitation, assessed by HAQ.

NEOPLASM RISK IN A RHEUMATOID ARTHRITIS COHORT: A RETROSPECTIVE STUDY

C. Ámbrósio, A. Barcelos. Rheumatology, Hospital Infante D. Pedro-Aveiro, Aveiro, Portugal

Background: It is well known that the risk of neoplasms is increased in rheumatic patients, especially in Rheumatoid Arthritis (RA), SLE and inflammatory myopathies. Although the relationship between neoplasms and some factors involving the pathophysiology and immunomodulatory therapy of this diseases is well known, we still don’t know all the mechanisms underlying this process. Thereby, this theme has been of ongoing interest and research.

Objectives: To determine whether the incidence of neoplasm is increased in patients with RA compared to a matched comparison cohort and to identify risk for any individual malignancy in RA.

Methods: A cohort of 243 RA patients, who fulfilled 1987 ACR criteria for RA and a comparison cohort, sex and age matched without RA (non-RA) were evaluated retrospectively for cancer occurrence. Demographic, epidemiological, clinical, laboratorial and imaging data were collected through medical record review. All paraneoplastic cases were excluded. Descriptive statistics were used to summarise data of the RA and comparator group.

Results: 243 RA patients (mean age 62.9y, 68.7% female, mean disease duration 10.6 y) were enrolled. 148 RA patients had rheumatoid factor (RF) present.
ARE EULAR RHEUMATOID ARTHRITIS (RA) MANAGEMENT RECOMMENDATIONS APPLICABLE AT THE COUNTRY LEVEL? SIMILARITIES AND DIFFERENCES WITH THE RECENT FRENCH RA MANAGEMENT RECOMMENDATIONS

C. Hua1,2, A. Daëna1, C. Gaujoux-Viala1,2, A. Cantagrel3, M. Dubremetz4, M. Dougados3, B. Fautrel3, X. Mariette5, N. Nayral5, C. Riché6, A. Saraux7, G. Thibaud8, D. Wendling9, L. Gossec10, B. Combe10, Nîmes University hospital, EA2415, Montpellier University, Nîmes; 2SFR Recommendations Working Group, Paris, France

Background: Recently, EULAR updated the rheumatoid arthritis (RA) management recommendations. 1 In 2018, the French Society of Rheumatology (SFR) updated their recommendations regarding the management of RA. 2 This gave us the opportunity to compare the recommendations.

Objectives: To update the 2014 French recommendations for the management of RA and to compare them to the EULAR recommendations.

Methods: The SFR approach was based on the literature and on expert opinion. A systematic literature review (SLR) was performed by 2 fellows, collecting data to answer 11 questions. The previous (2014) recommendations were updated by a committee including 11 rheumatologists, 2 patients and 1 healthcare professional, during a 1 day meeting in January 2018. The recommendations were compared to the recently issued EULAR recommendations.

Results: The SLR included 137 papers. The consensus process led to 4 over-arching principles and 15 recommendations. The overarching principles emphasise the need for shared decisions between the rheumatologists and the patient and the importance of a global approach of RA including pharmacological and non-pharmacological management. The recommendations address the diagnostic phase of RA, early initiation of disease-modifying antirheumatic drugs (DMARDs) and the usefulness of regular disease activity assessments through validated composite indices with a target of clinical remission or low disease activity. As first strategy, the expert committee recommends methotrexate (MTX). In case of intolerance or inadequate response to MTX, treatment must be optimised. If unfavourable prognostic markers are present, adding a targeted treatment (either biologic or synthetic) can be proposed, at best in combination with MTX; if not, switching to another conventional synthetic DMARD (csDMARD) or combined csDMARDs therapy can be proposed. While waiting for csDMARDs efficacy, short term (< 6 months) glucocorticoids (GC) can be proposed. Second-line and further treatments and management of remission are also addressed, as well as the importance of managing comorbidities and of non-pharmacological measures.

Conclusions: These recommendations are designed to improve the management of RA and are concordant with the recent EULAR recommendations on several items. Main differences concern the place of GC and of combined csDMARD therapy, as well as additional points on diagnosis, non-pharmacological measures, comorbidities and the importance of a global approach.

HEPATITIS B VIRUS REACTIVATION IN RHEUMATOID ARTHRITIS PATIENTS WITH HBsAG-NEGATIVE/ANTI-HBc-POSITIVE STATUS

C.-H. He1, M.H.A. Leung2. 1Department of Medicine; 2Queen Elizabeth Hospital, Kowloon, Hong Kong

Background: Hepatitis B virus (HBV) reactivation in rheumatoid arthritis (RA) patients with positive hepatitis B surface antigen (HBsAg+) is one of the treatment-related complications. The risk of reactivation in patients with negative hepatitis B surface antigen but positive anti-hepatitis B core antibody (HBsAg+/anti-HBc-) is less well defined compared to their HBsAg+ counterparts.

Objectives: This retrospective, single centre study aimed to study the prevalence of HBV reactivation (defined as HBV DNA becoming detectable) among RA patients with HBsAg+/anti-HBc+ and, to investigate any factors predicting reactivation.

Methods: RA patients attending the rheumatologist specialist clinic in a local tertiary hospital between 1st January 2011 and 31st December 2016 were included if they had HBsAg+/anti-HBc+ status and undetectable HBV DNA at baseline. Demographic data, clinical parameters including treatments for RA and any use of antiviral prophylaxis, and laboratory results including anti-hepatitis B surface antibody (anti-HBs) and serial HBV DNA levels were obtained. Chi-square (or Fisher exact test if number was less than 5) was used for analysis of categorical variables. Student’s t-test and Mann Whitney test were used for analysis of parametric and non-parametric continuous variables respectively.

Results: Majority (80%) of the 107 included patients included were female and the mean age was 62.5-year-old (SD 12.09). All the patients were receiving disease-modifying anti-rheumatic drugs (DMARDs), 43% of which (n=46) were on biological therapy (with or without concomitant synthetic DMARDs) and the remaining (n=61) were only on conventional synthetic DMARDs (B or monotherapy, 53 on combination therapy). As antiviral prophylaxis was not mandatory in HBsAg+/anti-HBc+ patients according to local guideline, only 13 patients (12.1%) were on antiviral cover (12 on entecavir and 1 on lamivudine). Ten patients (9.3%) experienced HBV reactivation during their disease course. Three of them were on antiviral prophylaxis and four had positive anti-HBs. All of these reactivations were only transient low-grade viraemia with HBV DNA level <20 IU/mL. Spontaneous resolution of viraemia in less than 12 months’ time were observed in all of these patients. None of the reactivation resulted in any adverse clinical event including acute hepatitis, hepatic failure or mortality. Among all synthetic and biological DMARDs, only the use of methotrexate was found to be a significant predictor of HBV reactivation (p<0.05). Other parameters including age, the lack of antiviral prophylaxis, negative anti-HBs status and anti-HBs titre did not predict HBV reactivation.

Conclusions: HBV reactivation among RA patients with HBsAg+/anti-HBc+ status and undetectable HBV DNA at baseline was infrequent. Reactivation may occur in patients with positive anti-HBs or on antiviral prophylaxis, but was unlikely to be associated with adverse clinical outcomes. The use of methotrexate was a predictor of HBV reactivation in these patients.

ASSESSMENT OF NUTRITIONAL STATUS IN WOMEN WITH RHEUMATOID ARTHRITIS MEASURED BY DUAL ENERGY X-RAY ABSORPTIOMETRY

D. Reing1, C. Gómez Vaquero2, J.M. Nolla3. 1Rheumatology, Consorci Sanitari Integral; 2Rheumatology, Hospital Universitari de Bellvitge, Barcelona, Spain

Background: As many other chronic diseases, rheumatoid arthritis (RA) has been related to an impairment of the nutritional status of multifactorial etiology. Even if Body Mass Index (BMI) has traditionally been used, it is not always a valid method, and there are still lots of questions without answer in how to evaluate ideally the nutritional status in these patients. Only very few studies had evaluated it by Dual Energy X-ray Absorptiometry (DXA).

Objectives: 1) To evaluate the nutritional status in women with RA and to compare with a population of same age women without RA using DXA for the analysis of whole body composition; 2) differences between the prevalence of alterations of the nutritional status measured by DXA and by the classical methods used in clinical care, 3) relation of RA time of evolution, inflammatory activity, physical function and dietary intake on altered nutritional status measured by DXA.

Methods: Case-control study including 89 patients that were diagnosed with RA and a control group (100) composed by patients affected by other non-inflammatory rheumatic diseases as soft tissue diseases. All the clinical charts were revised in order to record the following data: age, BMI, RA duration, history, activity and disability, serum albumin, Dietary intake, Whole body DXA assessment and Skeletal muscle index (SMI).

Results: Mean age of patients was 62±8 years. Mean duration of RA was 13.7 ±9.3 years. Mean DAS28 was 3.7±1.4 and mean Health Assessment Questionnaire was 0.88±0.77. BMI of the patients was 27.4±5.16 and 27.7±5.98 in controls (p<0.05). Albumin was within normal range in all patients. RA patients presented a statistically significant lower lean mass than controls in all locations and lower fat mass in limbs, along with a higher fat trunk. RA duration was found to be inversely correlated to BMI and lean mass and directly correlated with fat mass.

Neither BMI nor albumin correlated with DXA parameters. RA patients fulfilled criteria of sarcopenia in 44% of the cases vs 19% of controls (p<0.001). In RA patients, regarding SMI, BMI showed a high specificity to detect sarcopenia (94% of the patients with low BMI had sarcopenia) but low sensitivity (47% of the patients with normal or overweight BMI had sarcopenia).

Conclusions: RA patients have an impairment of nutritional status associated to time of evolution that resembles sarcopenia and that is not predicted by BMI.

AB0338

CLINICAL CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO USED COMPUTER TERMINALS FOR SELF-ASSESSMENT OF DISEASE ACTIVITY AND QUALITY OF LIFE

E. Pogozheva, V. Amirdzhanova. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Objectives: To present the clinical features, pharmacotherapy, activity and quality of life in pts with rheumatoid arthritis (RA) who used computer terminals for self-assessment of pts with rheumatic diseases.

Methods: The study included 976 RA patients from the cohort of “TERMINAL” multicenter study, envisaging pts self-assessment of disease activity and quality of life using a designated computer system (“Computer terminals for self-assessment of pts with rheumatic diseases”) before the visit to the rheumatologist. Mean age 52.3±13.3 years, mean disease duration 10.2±8.5 years, 85% female. Base-line clinical parameters and pharmacotherapy were assessed, as well as disease activity (using DAS 28 and RAPID-3), and quality of life (using HAQ and EQ-5D).

Results: 83% of pts were RF positive, and 60% ACCP positive. Almost all (91.2%) pts received conventional DMARDs. 70.2% of them received methotrexate: 56.7% 15 mg/week and 13.5% >15 mg/week (from 17.5 to 40 mg/week). 20.5% pts were treated earlier with low doses of glucocorticoids. 6.6% pts received Infliximab, 16.4% – Rituximab and 9.8% pts were treated with more than 1 biological agent in anamnesis. 46.2% of pts had high disease activity, 40.9% moderate, 4.5% low and 1,5% pts achieved clinical remission (mean DAS28 score 4.2±1.8, RAPID 13,6±3.6). Only 14.3% pts achieved general population HAQ values. The remaining showed significant reduction in the quality of life (mean HAQ 1,7±0.9, EQ-5D 0.6±0.2), 7.4% of the pts had prosthetic joints.

Conclusions: In the studied population almost all patients were treated with DMARDs (mostly methotrexate), and about 30% received biological agents. High to moderate disease activity and reduction in quality of life were typical for this population. Persistence of disease activity and functional insufficiency in pts who received DMARD therapy may be explained by poor monitoring in real clinical practice. The introduction of computer system for self-assessment of disease activity and quality of life in the out-patient facilities will improve the interaction between doctors, nurses and patients, providing better control of therapy efficacy in RA patients.

AB0339

SARCOPENIA AND EARLY FRAILTY SYNDROME IN RHEUMATOID ARTHRITIS

E. Trujillo1, M.R. García-Marreño2, M.I. Fuentes2, M.D.M. Trujillo2. 1Servicio de Reumatología, Hospital Universitario de Canarias, la laguna; 2Gerencia de Atención Primaria, Tenerife; 2Funcanis, Fundación Canaria de Investigación, Canarias, Spain

Background: Sarcopenia and frailty are common in older persons and pose particular challenges for health and social care systems. Sarcopenia, the loss of skeletal muscle mass, is a core component of physical frailty that together impact negatively on an individual’s capability to live independently.

Frailty is defined as a syndrome of physiological decline in late life, characterised by marked vulnerability to adverse health outcomes. Frail adults are less able to adapt to stressors such as acute illness or trauma than non-frail adults. This increased vulnerability contributes to increased risk for multiple adverse outcomes, including procedural complications, falls, institutionalisation, disability, and death.

Rheumatoid arthritis (RA) is a chronic disabling disease, which leads to functional limitations and diminishes health-related quality of life. The presence of comorbidity and polypharmacy are both related to RA severity.

Objectives: The aim of this study was to assess the prevalence of sarcopenia and frailty syndrome in patients with RA.

Methods: Cross-sectional, observational and descriptive study in patients with RA (ACR criteria) older than 50 years.

Sarcopenia was defined as per the European Working Group on Sarcopenia in Older People definition as Skeletal muscle mass index (SMI) ≤8.87 kg/m² in men and ≤6.42 kg/m² in women. Body composition analysis was performed using bioelectrical impedance analysis (BIA). Frailty was measured according to the 5 criteria proposed by Fried, using the Frail scale, and it was considered fragile to the patient who met at least 3 and frail to those who met at least 2.

FRAIL SCALE
Did you feel worn out? or Did you feel tired?
Ability to climb one flight of stairs
Self-report of >5% wt loss
≤5 of: dementia; heart Disease; depression; arthritis; asthma; bronchitis/emphysema; diabetes; hypertension; osteoporosis; stroke.
Mean number of comorbidities was 1.48, with systemic hypertension and obesity as the most frequent ones (33.8% and 26.4%, respectively). Polypharmacy was found in 96.8% and 64.7% received more than five drugs simultaneously. 31% presented some degree of sarcopenia. 21.5% met frailty criteria (42% in >65 years old patients).

Conclusions: Prevalence of sarcopenia and frailty syndrome in this study was high. Rheumatologists should make an early detection of signs of frailty.

The screening and early detection of frailty can spur reforms to make routine care less hazardous, can focus on outcomes most relevant to patients and can aid in understanding effectiveness of health care interventions, including at the population level.

Disclosure of Interest: None declared

ASSOCIATION BETWEEN MICROALBUMINURIA AND METABOLIC SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Baraka1, S. Abdel Moneim1, R. El Tanawy1, A. Shoshan2, Y. Ismail2. 1Rheumatology, Rehabilitation and Physical medicine; 2clinical pathology, Benha Faculty of Medicine, Benha University, Cairo, Egypt

Background: Rheumatoid arthritis (RA) is an autoimmune, symmetrical polyarticular disease characterised by chronic inflammation of the synovial joints. Microalbuminuria (MA) occurs as a leakage of small amounts of albumin into the urine. Metabolic syndrome (MetS) describes risk factors for cardiovascular diseases such as dyslipidaemia, obesity, hypertension and diabetes.

Self-report of >5% wt loss
≤5 of: dementia; heart Disease; depression; arthritis; asthma; bronchitis/emphysema; diabetes; hypertension; osteoporosis; stroke.
Mean number of comorbidities was 1.48, with systemic hypertension and obesity as the most frequent ones (33.8% and 26.4%, respectively). Polypharmacy was found in 96.8% and 64.7% received more than five drugs simultaneously. 31% presented some degree of sarcopenia. 21.5% met frailty criteria (42% in >65 years old patients).

Conclusions: Prevalence of sarcopenia and frailty syndrome in this study was high. Rheumatologists should make an early detection of signs of frailty.

The screening and early detection of frailty can spur reforms to make routine care less hazardous, can focus on outcomes most relevant to patients and can aid in understanding effectiveness of health care interventions, including at the population level.

Disclosure of Interest: None declared
Objectives: The aim of this study was to detect the prevalence of MA in patients with RA and study its correlation with disease activity and severity. Our aim extends to identifying differences in MA with MTPs in rheumatoid arthritis.

Methods: This study was carried out on 30 adult RA patients, 30% male patients and 70% female patients (mean ± SD: 42.27±10.99 years). Their mean disease duration was 12.8±7.06 years. Twenty apparently healthy adults of matched age and sex were selected as a control group. All the patients were subjected to full history taking, full clinical examination, laboratory investigations and assessment of disease activity using DAS 28 Score. Urinary microalbumin level was measured in all subjects in early morning samples by the immunoturbidimetry method. MetS was assessed in all subjects according to Grundy’s criteria.

Results: The RA patients’ group had significantly (p<0.001) elevated mean values of urinary microalbumin and urinary albumin to creatinine ratio compared to the control group (63.9±2.57 mg/dl vs 21.95±13.88 mg/dl, 46.6 ±95.28 ug/min vs 14.9±11.45 ug/min respectively). The frequency of the metabolic syndrome according to Grundy’s criteria was 60% in the RA patients’ group. This frequency was highly statistically significantly different (p<0.001) compared to the control group (10%). The MetS was prevalent in 13/15 (87%) of RA patients with microalbuminuria (MA), while 5 normo-albuminuric RA patients (33%) had the MetS. A statistically significant difference was observed among these groups (p<0.05). On the other hand, 13/18 (72%) of RA patients with MA had MetS.

Although RA patients with MA had increased mean values of disease duration, body mass index, waist circumference, fasting blood sugar, triglycerides, high density lipoprotein, DAS 28 and Larsen’s score, they had no statistically significant differences compared to normo-albuminuric patients. RA patients with the MA had a statistically significantly higher mean disease duration (p=0.004) than patients without the MetS. There were highly statistically significant positive correlations (p<0.001) of urinary microalbumin levels with disease duration, duration of morning stiffness, number of tender joints, number of swollen joints, ESR 1st hour, C-reactive protein, Larsen’s score, DAS 28, and A/CR.

Conclusions: MA and MetS are frequent in RA, particularly in those with long standing disease. The early detection of MA in RA in early intervention could strongly reduce the risk of major complications and chronic sequelae that may result in severe disability and premature mortality. The erosions seen in RA differentiates it from other rheumatological diseases.

AB0342 THE CHRONIC HAND PAIN IN RHEUMATOID ARTHRITIS, OSTEARTHRITIS, AND FIBROMYALGIA: THE ROLE OF CENTRAL SENSITISATION

F.F. Aytan1,2, M.A. Güler1, Ö. F. Celik1, 1. Department of Physical Medicine and Rehabilitation, Divisions of Rheumatology, Pain Medicine, Health Science University, Ankara Health Research and Training Hospital, Ankara, 2. Department of Physical Therapy and Rehabilitation, Usak University, High School of Health Sciences, Usak, Turkey

Background: Modern pain medicine divided chronic pain as nociceptive, neuropathic, central sensitisation (CS) and mixed pain. CS syndromes are a group of disorders characterised by chronic non-neuropathic and non-nociceptive pain.1 Central sensitisation inventory (CSI) suggest the tool generates reliable and valid data that quantify the severity of some symptoms of CS.2 Objectives: Hand pain in RA, OA, and FMS have different features. The aim of this study was to show the role of CS pain in these patients.

Methods: Totally 151 patients with chronic hand pain (56 RA, 45 OA, and 50 FMS) were included. CSI was used for evaluation of CS.3,4 CSI consists of 2 parts: CSI-A scoring 0–100 and CSI-B including 10-CS related syndromes (restless leg, chronic fatigue, fibromyalgia, temporomandibular disorders, migraine/tension type headache, irritable bowel, multiple chemical sensitivity, whiplash, anxiety/panic attack, and depression).

Results: Sixteen patients (28.57%) had active (DAS28 ≥2.6) RA. Disease activity was not related with CSI-A and CSI-B scores. Rheumatoid hands was less painful compared with them of OA and FMS (p<0.001). The CS pain was detected in most of the patients with FMS, compared with OA and RA patients (p<0.001). Similarly, CSI-A score was the highest in patients with FMS group (p<0.001) and similar in both OA and RA groups (p>0.05). CS-related syndromes were also detected in both RA and OA groups, but less than FMS group (p<0.005). The numbers of CS syndromes were similar in both RA and FMS (p=0.084) and higher than OA group (p=0.036). Table 1 shows the demographic and pain parameters in all groups. CSI-A score was correlated with VAS-pain score (r=0.364, p<0.001).

Conclusions: Central sensitisation should be considered in patients with chronic persistent pain, not only having FMS, but also half of the patients having RA and OA. It is not a rare phenomenon and if it is exists, effective pain management strategies could be needed in addition to the specific pharmacologic treatment.

MYOCARDIAL INVOLVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS EVALUATED BY TWO-DIMENSIONAL SPECKLE TRACKING ECOCARDIOGRAPHY BEFORE AND AFTER 18 MONTHS OF TREATMENT WITH ANTI-TNF DRUGS
F. Atzeni1, L. Gianfanco1, L. Boccardi2, P. Sarzi-Puttini2, M. Turie2.
1Rheumatology Unit, University of Messina, Messina; 2Cardiology Unit, Beato Matteo Hospital, GSD Hospitals, Vigezzano (PV).

Background: Cardiovascular (CV) mortality and morbidity is increased in rheumatoid arthritis (RA). Studies found a more than two-fold higher prevalence of ischaemic heart disease in RA patients compared to controls. However, a number of studies indicate that RA is also associated with various non-atherosclerotic CV manifestations. The inflammatory processes in RA may affect different structures of the heart: the most characteristic lesions are conduction defects, cardiomyopathy and valve disease.

Objectives: The aim of this study was to evaluate left ventricular myocardial function with two-dimensional speckle tracking echocardiography (STE), in addition to conventional Doppler and tissue Doppler echocardiography, in order to detect subclinical left ventricular myocardial dysfunction in patients with RA.

Methods: The study involved 30 outpatients who fulfilled the 2010 ACR/EULAR criteria for RA (11 males and 19 females; mean age 54.62±9.36 years, median disease duration 2 years), at baseline and after 18 months of treatment with anti-TNF drugs and 30 healthy controls matched in terms of age, gender and other anthropometric characteristics. All patients underwent a complete physical examination and routine laboratory analysis. CV risk profiles were assessed by means of standard ECG, conventional and stress trans-thoracic echocardiography with the measurement of CFR, cardiac ultrasonography and pulse wave velocity (PWV). Two-dimensional echocardiographic images were obtained using the apical 4-chamber view at a high frame rate of 70–80 frames/s, and three cardiac cycles were stored in cine-loop format for off-line analysis using commercially available QLAB 9 software (Philips Medical System, USA) in order to assess global longitudinal strain (GLS).

Results: None of the patients showed any signs or symptoms of CV disease, pulmonary involvement, or any other complication. The results of the speckle tracking analysis were significantly different between the two groups, with GLS being significantly lower in the RA patients compared to healthy controls (GLS%: 18.51±9.63 vs 20.23±2.71; p<0.05). Right and left PWV (PWV right, m/sec: 7.52±1.64 vs 6.85±2.02; p=0.06 and PWV left, m/sec: 7.56±1.60 vs 6.88±2.11; p=0.07) and right and left coronary intima media thickness (cIMT) (cIMT right mm: 0.90±0.22 vs 0.75±0.13; p=0.05 and cIMT left, mm: median 0.89±0.18 vs 0.75±0.09; p<0.05) values were all higher in the RA patients and the differences of cIMT were statistically significant. Furthermore, a significant improvement in GLS in RA patients at 18 months of anti-TNF treatment was observed (GLS%: 18.51±9.63 vs 19.09±9.72 p<0.01).

Conclusions: GLS measured by means of speckle tracking echocardiography was impaired in RA patients in the absence of any clinical evidence of CV disease and echocardiographic evaluations negative. This data suggests an early myocardial alteration.

DOES THE PRESENCE OF ILD INFLUENCE THE CHOICE OF DMARD AND BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS?
F. Coelho1, A. Siddiqui2, A. Yamashita3, A. Bharadwaj3, S. Dubey2, F. Hayes1, G. Kodu1, 1Rheumatology, Southend University Hospital, Westcliffe On-Sea; 2Rheumatology, University Hospital Coventry and Warwickshire, Coventry; 3Rheumatology, Basildon University Hospital, Basildon, UK

Background: Interstitial lung disease (ILD) is a progressive fibrotic disease of the lung parenchyma. It is the only complication of rheumatoid arthritis (RA) reported to be increasing, accounting for around 7% of all RA deaths.1 Prognosis of patients with RA-ILD is reported to be poor, with usual interstitial pneumonia (UIP) being the predominant pattern associated with poor survival.2 It is a challenge to determine specific pattern of ILD and formulate an appropriate treatment plan to achieve stabilisation. Early use of Methotrexate (MTX) and biologics in RA has improved outcomes and quality of life. However, this causes difficulty when RA patients develop ILD. There are reports of ILD with biologics and DMARDs, although it is difficult to establish a causal relationship or if an exacerbation of pre-existing ILD. There are no evidence based guidelines regarding introducing biologics in such patients and clinicians face a dilemma as to whether they should be denied.

Objectives: The aim of this retrospective study is to:
- Check the overall management of RA and ILD.
- Examine whether ILD diagnosis influences treatment of RA.

Methods: We reviewed 37 patients with RA-ILD from 3 hospitals (2001–2017). We collected data on demographics, clinical, Pulmonary function tests, imaging, time from diagnosis to treatment and outcomes.

Results: The majority developed ILD after RA except for 3 patients. Mean age at onset of RA was 67 years, 22 (60%) were female. 32 (87%) were RF or ACPA positive, 25 (68%) patients smoked. 29 (78%) patients had baseline PFTs. HRCT showed 13 had NSIP, 20 UIP and 4 were unclassified. Following the diagnosis of ILD, MTX was stopped in 16 patients, reduced in 3 and unchanged in 2. Leflunomide was stopped in 4 and SLZ stopped in 4, of which 1 had definite alveolitis. Infliximab was stopped in 2 patients.

Specific Treatment for ILD: 12 patients received Rituximab, of those 8 were for ILD and 4 for RA. 4 Patients continued Anti-TNF. 26 patients received steroids, 4 received MMF and 2 Cyclophosphamide. 2 received Abatacept for ILD with active RA and one received Etanercept. 3 were on Carbocysteine, 2 on NAC and 3 on oxygen.

Outcomes: 20 ILD patients were stable and 8 (21%) progressed and died despite treatment. RA disease activity was low to moderate in 23 patients. RA progressed in 8 patients and 1 who received Etanercept was in remission. MTX was stopped in the majority of patients. Steroids were the commonest treatment for RA in the presence of ILD. Rituximab was the drug of choice for RA with severe ILD, followed by MMF and Cyclophosphamide. DMARDs such as HCQ, Leflunomide and SLZ were used for RA in milder ILD and biologics were generally avoided.

Conclusions: There appears to be significant variation in the treatment of RA in the presence of ILD. However Rituximab seems to be the preferred option for severe ILD. There is a need for stratified and standardised guidance for management of RA-ILD.

DOES IRON DEFICIENCY CONTRIBUTE TO FATIGUE OF PATIENTS WITH RHEUMATOID ARTHRITIS WITHOUT ANAEMIA?
F. Vidal1, A. Gillibert2, M. Quillard3, P. Fardellone3, S. Poupill3, D. Vitezco4, T. Lequerre5. 1Rheumatology; 2Biostatistics; 3Biochemistry, Rouen University Hospital, Rouen; 4Rheumatology, Amiens University Hospital, Amiens, France

Background: Iron deficiency (ID) without anaemia is a cause of fatigue, which is itself a recurring complaint of patients with rheumatoid arthritis (RA).

Objectives: The objective of the study was to determine the prevalence of ID in patients with RA without anaemia and to analyse the relationship between ID with fatigue, disease activity and depression.

Disclosure of Interest: None declared
INVESTIGATION OF ALEXITHYMIA IN PATIENTS AFFECTED BY RHEUMATOID AND PSORIATIC ARTHRITIS: CROSS-SECTIONAL OBSERVATION

G.L. Fordi, M.S. Chimenti, P. Conigliaro, J. Hitaj, M. Galluzzo, M. Talamonti, B. Kroegler, E. Greco, R. Pericione. Policlinico Tor Vergata, Rome, Italy

Background: Rheumatoid arthritis (RA) and Psoriatic arthritis (PsA) are chronic inflammatory diseases that lead to an overthrow of articular structure, functional limitation and disability. Alexithymia is a personality trait characterised by deficits in cognitive processing and regulation of emotions. A broad association between alexithymia and symptoms as depression, inflammation and pain has been demonstrated.

Objectives: to evaluate the prevalence of alexithymia in patients affected by Rheumatoid and Psoriatic arthritis.

Methods: We prospectively enrolled, from January to December 2017, patients affected by RA diagnosed according to the ACR revised criteria and PsA diagnosed according to the CASPAR criteria referred to the out-patients clinic of the Rheumatology Unit of Policlinico Tor Vergata, Rome. The 20-item Toronto Alexithymia Scale (TAS-20) was used to assess alexithymia. Disease activity, function and quality of life, clinimetric tests as well as ESR and CRP were assessed. Statistical comparisons were performed using Pearson’s Coefficient of Skewness, the unpaired t-Test and Mann-Whitney test.

Results: A total of 50 RA patients and 51 PsA patients were enrolled (table 1). The TAS-20 score showed that 38.6% (39/101) of patients had alexithymia, 26.7% (27/101) patients were in the borderline of alexithymia and 34.7% (35/101) patients had not alexithymia. A statistical significant association was observed between alexithymia and inflammatory indices (ESR: p=0.029, CRP: p=0.043, figure 1 and 2) and also between alexithymia and clinimetrics parameters (pVAS, pVAS GH, p<0.0001 for all comparisons). No correlations were observed between alexithymia and disease duration, gender, therapies with bDMARDs. A significant trend has been demonstrated between alexithymia and corticosteroidal therapy.

Disclosure of Interest: None declared

BODY COMPOSITION IN PATIENTS WITH RHEUMATOID ARTHRITIS KAZAKH NATIONALITY

G. Gabdulina, A. Tokarev, D. Mussababaeva. Kazakh Medical University, Almaty, Kazakhstan

Background: Chronic inflammation in rheumatoid arthritis (RA) leads to a decrease in fat and muscle mass (Baker J.F., Von Feldt J. Mostoufi-Moab S. et al., 2014) Low muscle mass in RA is considered as the main criterion of sarcopenia. Recently, much attention has been paid to various phenotypes of sarcopenia, among which osteopenic sarcopenia, sarcopenic obesity and osteosarcopenic obesity (most unfavourable in terms of functional disorders) are distinguished. In the modern literature there are works devoted to changes in the composition of the body in the aspect of abdominal obesity and its influence on cardiovascular risk in RA (Crowson C.S., Myasoedova E., Davis J.M., 2011). Studies with the evaluation of muscle mass and sarcopenia in RA are few. In Kazakhstan, the composition of the human body was not studied.

Objectives: The purpose of the study was to study the body composition (muscle and fat mass) of patients with RA of Kazakh nationality using bioelectrical impedance analysis.

Methods: In our study we used Bioimpedance analyzer 101 (BIA 101, Italy). Bioimpedanometry was performed in 585 participants, including 295 patients with RA and 290 of their siblings.

Results: In patients with RA, in contrast to the comparison group (sibs), BMI (probands – 25.3±4.1, siblings – 24.8±4.45), the girth of the waist and hips were slightly higher than those of the siblings. The ratio of RT:OB in both groups was virtually the same. At the same time, a decrease in the lean mass was found.
Grip power and independent daily living in the oto-rhino-laryngological manifestations of rheumatoid arthritis

AB0348

Grip power and independent daily living in the patients with rheumatoid arthritis

H. Ishikawa1, A. Abe1, T. Kojima2, M. Kojima2, N. Ishiguro2, S. Ito1, A. Murasawa2.
1Rheumatology, Niigata Rheumatic Center, Sibita city, Niigata; 2Orthopedic Surgery, Nagoya University Hospital, Medical Education, Nagoya City University Graduate School of Medicine, Nagoya city, Japan

Background: Grip power is known to be a simple and useful objective index that can be used in the self-assessment of disease activity in patients with rheumatoid arthritis (RA)1). However, the clinical significance of this physical function is unknown.

Objectives: The objective of this study was to clarify the relationship between the grip power and the level of activities of daily living (ADL).

Methods: The grip power was measured in 221 inpatients of our hospital with RA using a mercury dynamometer. The independence level (0: impossible, 1: incomplete but possible, 2: complete) was investigated for each item. For each patient, the site with the problem (shoulder, elbow, forearm, wrist, thumb, fingers, lower extremity and trunk) and cause of disability (pain, loss of power, decreased range of motion, abnormal prehensile pattern and fatigue) were investigated by interviewing the patient. There were 33 male and 188 female patients. The average age of the patients was 64.6 years, and the average duration of the disease was 13.3 years. Biological therapy had been given to 23% of the patients. The average grip power of the right and left hands was used.

Results: There were 14 items requiring others’ assistance (level 0 or 1) in more than 10% of patients. For these 14 items of ADL, the grip power increased with the increase in the independence level (p<0.001)2. The site with a problem was, in order of frequency, the fingers (26.1%), wrist (14.8%) and lower extremity (14.0%). The cause of disability was, in order of frequency, pain (38.8%), loss of power (32.8%) and a decreased range of motion, abnormal prehensile pattern and fatigue) were investigated by interviewing the patient. There were 33 male and 188 female patients. The average age of the patients was 64.6 years, and the average duration of the disease was 13.3 years. Biological therapy had been given to 23% of the patients. The average grip power of the right and left hands was used.

Discussion: This study showed that grip power is correlated with the level of activities of daily living in patients with RA. The factors affecting grip power are pain, loss of power and decreased range of motion.

OTO-RHINO-LARYNGOLOGICAL MANIFESTATIONS OF RHEUMATOID ARTHRITIS

S. Zrou1, H. Mouanaa2, N. kolsi2, H. Hacht3, A. Arta1, M. Jigou1, I. Beija2, T. Mongi1, M. Youness1, J. Koubaa3, N. Bergaoui1. 1Rheumatology Department of Monastir University Hospital, Monastir; 2Rheumatology Department of Mahdia University Hospital, Mahdia; 3ENT Department of Monastir University Hospital, Monastir, Tunisia

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disorder that can damage a wide variety of body systems. Ear, nose and throat (ENT) involvement is frequent but not often reported. The purposes of our work are to determine the prevalence of ENT involvement during RA and to evaluate its correlation with RA disease activity.

Objectives: The purposes of our work are to determine the prevalence of ENT involvement during RA and to evaluate its correlation with RA disease activity.

Methods: This is a cross-sectional study of 90 consecutive RA, followed at the Rheumatology department of Monastir Teaching Hospital in Tunisia, during 06 months (November 2016 to April 2017) and 46 matched volunteers. ENT clinical examination with tonal audiometry and thyroid tests (TSH, T4, anti-Thyperoxi-dase Ab (Anti TPO Ab) and Anti-Thyroglobulin Ab (Anti anti Tg) were performed.

Results: ENT involvement prevalence was 78%. The most frequent functional signs were intermittent dysphonia in 50% and dysphagia in 42% of cases. The neck examination revealed painful larynx mobilisation in 58% cases and cervical lymph nodes in 7% of cases. Indirect laryngoscopy, performed in the 67% of symptomatic patients, noted inflammatory mucosa in 38% of cases and decrease in vocal cord mobility in 8% of cases. Seventy percent patients had temporomandibular Joint (TMJ) involvement. Tonal audiometry revealed 42% of cases of deafness: 27% sensorineural deafness, 13% conductive deafness and 2% cases mixed hearing loss. The ENT manifestations significantly associated to RA compared to the witness group (p<0.01) were intermittent dysphonia, dysphagia, painful larynx mobilisation, inflammatory nasal mucosa, painful TMJ and deafness. Active disease (DAS 28≤3.2) is statistically associated with deafness (p<0.048) and TMJ involvement (p<0.009). Logistic regression study shows that RA duration over 10 years was associated to laryngeal dyspnea (OR=4.4, p=0.012, IC (95%) [1.377, 14.134]) and deafness (OR=3.8, p=0.03, IC(95%) [1.142, 12.882]). In the other hand, RA moderate functional handicap is a protective factor (OR=0.123, p=0.016, IC (95%) [0.076, 0.772]) of ENT involvement and biotherapy use was associated to thyroid involvement (OR=7.8, p=0.017, IC(95%) [4.31, 14.175]).

Conclusions: ENT involvement is a very common, usually asymptomatic extra-articular manifestation during RA. It is, mainly, TMJ involvement, deafness and dysphonia. The main relevant determinants are RA disease activity and duration.

AB0350 TEMPORO-MANDIBULAR JOINT INVOLVEMENT IN RHEUMATOID ARTHRITIS

S. Zou1, H. Mouana1, A. Arfa1, H. Hachfi2, M. Jguir1, I. Bejia1, T. Mongi1, M. Youness2, N. Bergaoui1. 1Rheumatology Department of Monastir University Hospital, Monastir; 2Rheumatology Department of Mahdia University Hospital, Mahdia, Tunisia

Background: Temporomandibular joint (TMJ) disorder in rheumatoid arthritis (RA) may be associated with significant osteoarticular destruction and may be responsible of significant functional impairment.

Objectives: We aimed in this study to determine the prevalence of TMJ involvement and its correlations with RA parameters.

Methods: We report a descriptive monocentric cross-sectional study of 90 consecutive RA, followed at the Rheumatology department of Monastir Teaching Hospital in Tunisia, during 06 months (November 2016 to April 2017) and 46 matched volunteers. Clinical assessment and stomatological examination were performed in all cases.

Results: Sixty-three RA patients out of 90 (70%) had TMJ involvement. TMJ pain, functional impairment, mastication difficulties, swollen TMJ, dental malocclusion and limitation of mouth opening were noted in 55 (81%), 49 (74%), 20 (30.3%), 19 (29%) and 8 (12%) of cases, respectively. Compared with the control group, painful palpation of TMJ (p<0.000) was significantly associated with RA.

Conclusions: Temporomandibular disorder is frequent in RA (70%). TMJ disorder is more common in adults between 40 and 60 years of age, patients with HAQ>0.5 and a high total Vander Heijde Sharp radiographic score (SS). TMJ painful mobilisation is significantly associated with increased body mass index (BMI). Swollen TMJ is significantly associated with age (more frequent in elderly subjects), increased BMI, high RA disease activity (high DAS 28 ESR and/or DAS 28 CRP) and HAQ>0.5. Limitation of mouth opening is significantly associated with age (more common in elderly subjects), overweight, high methotrexate dose (20 mg/day), leflunomide and biotherapy use. Dental malocclusion was significantly associated with high doses corticosteroids (more than 5 mg/day). Mastication difficulties are significantly associated with more than 10 year RA duration, HAQ>0.5 and radiological impairment.

AB0351 DIFFERENTIAL PERCEPTION ABOUT THE CSDMARDs ON DRUG-INDUCED INTERSTITIAL LUNG DISEASE BETWEEN RHEUMATOLOGISTS AND NON-RHEUMATOLOGISTS

H. Kobayashi1, 2, T. Okubo1, H. Oka1, A. Akoi1. 1Rheumatology, Tokyo Medical University Hachioji Medical Center, Tokyo; 2Internal Medicine, Aihara Hospital, Sagamihara, Japan

Background: As disease modified anti-rheumatic drugs (DMARDs) were the mainstay in the treatment of rheumatoid arthritis (RA), the opportunity for general physicians to also prescribe DMARDs has recently increased in Japan. After DMARDs were initiated by specialists, subsequent drug prescription by general physicians during remission should be expected. However, general physicians are more likely than rheumatologists to feel it difficult to accept patients taking even conventional synthetic (cs) DMARDs but not biologics and such discomforts may be potential barriers to cooperative management between specialists and general physicians. One of the reasons is because some csDMARDs such as methotrexate and leflunomide may induce pneumonitis or worsen RA-related pre-existing interstitial lung disease (ILD) as a rare but severe adverse event. To minimise the risk, rheumatologists may choose low-risk csDMARDs smartly when the patients are concomitant with risk factors on ILD.

Objectives: To measure the physicians’ perspective toward the risk of each csDMARDs on drug-induced ILD and their attitude in prescribing the csDMARDs to a pre-existing ILD case.

Methods: A questionnaire was given in an internet survey to registered physicians who take care of more than ten patients with RA in Japan. Topics covered were i) how is the risk of each csDMARD for drug-induced lung injury compared to methotrexate, ii) which csDMARDs should be applied to a case with mild pneumonitis on the chest CT. Cross tabulation analysis and χ2 test as a statistical analysis was performed.

Results: A total 184 physicians consisting of 66 rheumatologists (36%) and 118 non-rheumatologists (64%) responded. The physicians’ mean age was 45 years old. The rheumatologists tended to belong to rheumatology and take care of more than 200 RA patients per month in university hospitals. On the other hand, the non-rheumatologists tended to belong to general medicine and manage less than 50 patients per month in their clinics. The csDMARDs except for methotrexate were more significantly prescribed by the rheumatologists. All rheumatologists but 24% of non-rheumatologists had managed RA patients with exacerbated ILD. On physicians’ perspective toward the risk of each csDMARD, the rheumatologists considered that LEF was equal to or higher than MTX and that cyclosporine A (CyA), tacrolimus (TAC), salazosulfapyridine (SASP) was relatively safer (Figure A). In cases with pre-existing ILD, more rheumatologists agreed to use the csDMARDs except for methotrexate and leflunomide. (Figure B.)

CONCLUSIONS: We can find the gap of risk perception about each csDMARDs between rheumatologists and non-rheumatologist and the difference of attitude in prescribing to patients concomitant with risk factors. Considerable consensus and additional enlightenment to general physicians should be necessary.

AB0352 SIGNIFICANCE OF OCCULT INFECTIONS IN INFLAMMATORY ARTHRITIS PATIENTS RECEIVING BIOLOGIC THERAPIES IN EAST LONDON

Background: Chronic hepatitis B virus (HBV) infection remains a significant global health problem. In high endemic areas like African and Asian countries, most infections occur from vertical transmission, whilst in western countries HBV is primarily acquired in adulthood. Either way, HBV can persist in infected hepatocytes lifelong, even if undetectable in the serum, allowing reactivation during immunosuppression. HBsAg carriers, those with detectable HBV viral load, or receiving concomitant corticosteroids are at greater risk. Most guidelines recommend screening for occult infections prior to starting biologic treatment including trastuzumab, IVBV, HCV, HIV and TB infection.

Objectives: This study was carried out to estimate the prevalence of occult infections, particularly chronic HBV, in an East London rheumatology population receiving biologic therapies, and to evaluate the rate of HBV reactivation after starting treatment.

Methods: Inflammatory arthritis patients starting biologic therapies in Barts Health NHS Trust between August 2014 and August 2017 were identified from databases of Whips Cross and Mile End Hospitals. Health records were reviewed focusing on HBV core antibody (HBcAb), HBV surface antigen (HBsAg), HBV DNA, HCV and HIV antibody status. Latent TB tests included IGRA and ELISPOT assays.

Results: 757 patients were included in the study. Of those, 51 (6.7%) were HBsAg positive. Six patients (0.8%) were HBsAg positive and two patients had low level HBV viraemia with detectable DNA antibody at baseline. 61% (n=31) of those with detectable HBV DNA were treated for chronic HBV infection. Of the 31 patients, 29 (94%) were African or Afro-Caribbean black (n=15), and 18% white caucasian (n=6). The underlying rheumatological conditions included rheumatoid arthritis (59%), ankylosing spondylitis (33%) and psoriatic arthritis (8%). Fifteen patients (29%) received concomitant prophylactic anti-viral therapies (lamivudine, entecavir or tenofovir). After commencing biologic therapies, no HBV reactivation was noted in the HBcAb positive cohort. Intermittent mild transaminitis were detected on monitoring blood tests in 22% (n=11). The rate of latent TB infection was 11.5%; HCV IgG was detected in three patients, whilst HIV infection was absent in our cohort.

Conclusions: Approximately 50% of the patient population of Barts Health NHS Trust is coming from minority ethnic groups. Likely because of the diversity of the population, the prevalence of chronic HBV infection (HBsAg and HBcAb positives) in our East London rheumatology population receiving biologic therapies was higher than the national average (0.8% vs. 0.3%, respectively). No HBV reactivation was noted in our East London rheumatology population receiving biologic therapies, and to evaluate the rate of HBV reactivation after starting treatment.

AB0353 GENETICALLY PREDISPOSITION AND PRO-INFLAMMATORY DYSREGULATIONS – CONNECTING RHEUMATOID ARTHRITIS AND MENTAL DISORDERS
I.C. Filipescu1, L. Ghîb2, P. Juan Sainz3, C. Perez-Sanchez4, C. Lopez-Pedrera5, A. Escudero6, L. Damián7, L. Muntean8, E. Colllantes-Estevez9, S. Rednic1
1Rheumatology Clinic, University of Medicine and Pharmacy, Cluj-Napoca, Romania; 23GENYO Centre for Genomics and Oncological Research, University of Granada, Granada; 34Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), University of Cordoba; 4Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC); 5Reina Sofia University Hospital/University of Cordoba, Cordoba, Spain

Background: Depressive and anxiety disorders are reported as the more prevalent psychiatric comorbidities in chronic inflammatory diseases and their occurrence has been correlated with higher serum levels of cytokines and chemokines (IL-6, IL-1, IL-12, IL-18, TNF-α, and even TNF-R1 and TNF-RII). Some single nucleotide polymorphisms (SNPs) in TNF-α gene have been found to play a common part in pro-inflammatory alterations in patients with rheumatoid arthritis (RA) and depressive symptoms. Either way, it is an emerging field of research in mental disorders.

Objectives: To investigate the possible influence of four single-nucleotide polymorphism in the tumour necrosis factor receptor II (TNFRII) genes and development of psychiatric disorders in patients with active RA. The second aim was to evaluate some correlation between these SNPs, the level of four chemokines and the incidence of mental disorders.

Methods: We included 89 Caucasian patients with active RA treated in a tertiary Department of Rheumatology from Cluj-Napoca. All demographic, clinical, and biological data and RA comorbidities were completed. The presence of

AB0354 FACTORS OF THE POSITIVE OR NEGATIVE ANSWER ON THERAPY WITH DENOSUMAB IN WOMEN WITH RHEUMATOID ARTHRITIS AND OSTEOPOROSIS
I. Dudykina, K. Kovalenko, A. Smirnov, E. Nasonov. Narbonne Reumatologic Research Institute, Moscow, Russian Federation

Objectives: To define a contribution of factors: anamnesis, clinical/laboratory markers, glucocorticoids (GC) intake, etc. on the response to therapy with denosumab in women with rheumatoid arthritis (RA) and osteoporosis (OP).

Methods: 66 postmenopausal women (mean age 59,6±7,4) with RA (mean duration 14,0±6,1 years) and OP received s.c denosumab 60 mg every 6 months for 1 year. RF- positive were 72%, ACPA – 74% of patients. 34 (49%) continued GC. At baseline and after 12 months it was carried out the dual energy x-ray absorptiometry at 3 sites: lumbar spine (L1-L4), hip neck (HN) and distal forearm (DF) and x-ray of hand and feet (Sharpe/ van der Heijde (SVH) score). After therapy it was noted the increase of BMD in L1-L4 and HN, a tendency to increase in DF (p<0,0529) in DF. Positive dynamics (increase or stabilisation of BMD) was noted in 89% patients at L1-L4, 67% – at HN and 60% – at DF. The erosion score was increased in 12% (n=8) patients, the joint space narrowing score (JSN) – in 9% (n=5) (p<0,0117 and p<0,027, respectively). The Statistica 6.0 was used.

Results: Results of analysis of influence of statistically significant factors on the response to therapy in BMD showed that the negative response in L1-L4 was associated with GC intake (>3 months in anamnesis) (p=0,034) and the beginning of GC intake after menopause onset (p=0,023). In HN positive response was associated with higher concentration of the RF (initially and in dynamics) (p<0,05) and the beginning of menopause later than RA onset (p=0,024), the negative response – with GC intake (<3 months in anamnesis) (p=0,024). In DF positive response on therapy is associated with RF-positivity (p<0,02), the negative response back correlates with increase in erosion score and total SVH score: r= 0.360 (p<0,05).

In table 1 it is shown the most significant factors, which influence on SVH score dynamics (increase) after 12 months of denosumab therapy.

Abstract AB0354 – Table 1. The factors which influence on SVH score increase (n=66), p<0.05.

<td></td>
</tr>
</tbody>
</table>
Conclusions: There was established that positive response on therapy with denosumab in BMD in NH and DF is associated with RF-positivity. The particular concern was the negative response in L1-L4 and HF is associated with GC intake (previous intake more than 3 months in the anamnesis), purpose of the GC after menopause onset. There was note that the increase of erosion score is associated with either lower BMD in L1-L4 (at baseline and after treatment) or back correlation with BMD increase in DF. Also the higher cumulative GC dose and back correlation with BAP base level were observed at patients with increased erosion score. The only factors that we could reveal in patients with increased JSN score were surgical menopause in anamnesis and lower value of BMD dynamics (%) in DF after treatment. In general it was a direct correlation between erosion score and JSN score.

The SUPPORT OF MEDICAL CLERKS IN RHEUMATIC DISEASE CLINIC AIDS T2T PRACTICE FOR RHEUMATOLOGISTS AND IMPROVES DISEASE ACTIVITIES OF PATIENTS WITH RHEUMATOID ARTHRITIS

I. Matsushita1, H. Motomura1, T. Hiraoka1, S. Arai1, C. Ota2, T. Kimura3
1Orthopaedic Surgery, University of Toyama; 2Orthopaedic Surgery, Sainou Hospital, Toyama, Japan

Background: With treat-to-target (T2T), the physician always has to evaluate disease activity and joint damage of rheumatoid arthritis (RA) patients exactly to maintain the activities of daily living of the patient for the long term. However, the amount of work required by physicians to complete T2T can be onerous, so the cooperation of medical staff is necessary to practice T2T.

Objectives: The purpose of this study is to clarify the role and effectiveness of medical clerks (MCs) in a rheumatoid disease clinic. Methods: In our rheumatologic disease clinic, MCs have supported rheumatologists since April 2011. We individually evaluated 50 RA patients in May 2010 (before MC support) and 50 RA patients in April 2011 (1 year after the start of MC support; “early period”), April 2013 (3 years after the start of MC support; “middle period”), April 2015 (5 years after the start of MC support; “late period”) and April 2017 (7 years after the start of MC support; “last period”). We assessed the prevalence of T2T practice, disease activity, and drug use. When all components of the Simplified Disease Activity Index (SDAI) of patients had been listed in the medical record and radiography of hand and foot joints had been undertaken more than once a year, the medical examination was defined as “T2T practice”. Disease activity was assessed using the SDAI and Clinical Disease Activity Index (CDAI).

Results: Prevalence of T2T practice was 50%, 86%, 94%, 100% and 100% at preceding, early, middle, late and last periods, respectively. Prevalence of T2T practice increased after the start of MC support. Accordingly, disease activities improved gradually. SDAI remission was 30.8% in the preceding period, 28.5% in the early period, 30% in the middle period, 58% in the late period and 56% in the last period, respectively. CDAI remission improved towards the last phase, similar to that seen with the SDAI. The mean dose of methotrexate (MTX) increased gradually towards the last phase, but the prevalence of MTX use did not show a remarkable change. Prevalence of use of biological disease-modifying anti-rheumatic drugs did not increase during the study period.

Conclusions: MC support in rheumatologic disease clinics aids T2T practice for rheumatologists. The disease activities of RA patients can be improved by MC support.

PHENOTYPES OF SECONDARY SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Yatsyshyn, I. Stoks. Internal Medicine #1, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine

Background: Secondary sarcopenia may be caused by low physical activity, eating disorders, chronic inflammation. In patients with rheumatoid arthritis (RA), sarcopenia co-occurs with osteoporosis as well as obesity and, in most cases, both osteoporosis and obesity co-occur with sarcopenia. Therefore, 3 phenotypes of sarcopenia can be identified: sarco-osteoporosis, sarcopenic obesity, osteosarco-penic obesity.

Objectives: The aim of the research was to study the features of sarcopenia and her phenotypes in patients with RA. There were examined 40 women with stage II-III RA, Rtg stage II-III, functional limitation stage II. The patients average age was 40.7±2.25 years.

Methods: The algorithm for diagnosing phenotypes of sarcopenia recommended by the European Working Group on Sarcopenia in Older People (2001) was used. Body mass index was determined. Dynamometry (the measurement of hand-grip strength using handgrip dynamometer) was performed and the evaluation of physical fitness. Serum levels of leptin and creatine phosphokinase MM (CPK MM) fraction were determined. The dual-energy X-ray absorptiometry DEXA (to calculate a T-score) was performed.

Results: According to the results of laboratory tests and methods of evaluating functional muscle disorders, 87.5% of patients were diagnosed with sarcopenia. The mean values of dynamometry were within 18.3±0.7 kg being significantly lower as compared to healthy individuals – 28.3±0.5 kg. After the evaluation of physical fitness, the average score was 7.9±0.7, while in healthy individuals, it was 11.3±0.4. The mean CPK MM concentration was 175±2.34 U/L, while in healthy individuals, it was 144.3±5.5 U/L. The average T-score were within the limit (~1.8±0.17) SD and was significantly lower than in healthy (~0.56±0.10) SD. After conducting studies in 17 patients were diagnosed with osteosarcopenic obesity in 11 – sarco-osteoporosis, 7 – sarcopenic obesity, 5 patients sarcopenia has not been diagnosed.

Conclusions: RA leads to muscle metabolism disorders which result in the development of secondary sarcopenia. Therefore, a high-protein diet, physical exercise, namely aerobic exercise (swimming, cycling) and medical preparations that improve muscle metabolism should be included in therapeutic measures and preparations of calcium.

CLINIC PROFILE OF PATIENTS WITH RHEUMATOID ARTHRITIS AND PULMONARY AFFECTION IN A COHORT FROM A UNIVERSITY HOSPITAL

I. Casañol Solé, J. A. Prior-Esparhol, S. Holgado, J. Roca, L. Mateo, Y. García-Miris, J. C. Atienza, L. Giné, A. Rivero, M. Martínez-Molillo, M. Aparicio, A. Olivé, Rheumatology, Epidemiology, Hospital Universitari Germans Trias i Pujol, Badalona, Spain

Background: Pulmonary affection is a serious complication in Rheumatoid Arthritis (RA) with an important impact on mortality and morbidity.

Objectives: To describe the clinical and radiographic characteristics of patients with RA in our centre, and specifically from those with interstitial lung disease (ILD).

Methods: Retrospective analysis of patients with RA and pulmonary affection from a University Hospital with a referral area of 85,000 inhabitants. Clinical, laboratory, imaging and pulmonary function test (PFT) data was recorded.

Results: Data from 85 patients, 37 (43.5%) male and 48 (56.5%) female, were recorded. The mean time from RA diagnosis to pulmonary disease was 9.2 years, with mainly erosive (58.8%) and seropositive (84.7%) disease. The positive rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) disease. The 56.5% of the patients were smokers or ex-smokers. PFT results were documented in 75.3% of the patients: diffusing capacity for carbon monoxide (DCLO) baseline values were over 60% in a 38.8% of cases and forced vital capacity (FVC) baseline values were over 50% in a 69.4% of patients. The most frequent High Resolution CT scan pattern was the presence of bronchiectasis (64.7%), followed by ILD (31.8%) and, specifically, the Usual Interstitial Pneumonia pattern (UIP, 66.6%); lung infections (25.8%), lung nodules (22.4%), pleural effusion (15.3%), lung tumours (9.4%) and bronchiolitis (5.8%). The presence of extra articular manifestations as rheumatoid nodules (27%), vasculitis (9.4%) was registered. The coexistence of Chronic Obstructive Pulmonary Disease (COPD) was recorded too (24.7%). Related to treatment, 84.7% of patients had received Methotrexate and in a 40% of cases, at least one biological disease-modifying antirheumatic drug had been administered. Though the causes were not registered, a 25.9% of deaths were documented. In parallel we did a subanalysis of ILD related to RA cases, summarised in table 1 (n=27):

Conclusions: Bronchiectasis is the most common pulmonary manifestation of RA patients in our area. The most frequent clinical profile is a non-smoker woman with seropositive disease. ILD affects approximately one third of RA patients in our area and is an undiagnosed entity. We consider that it is necessary to establish a screening program to diagnose and treat it early.

LEFT ATRIAL DILATION IS INCREASED IN PATIENTS WITH RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY

Background: Rheumatoid arthritis (RA) is a chronic, systemic inflammatory disease which mainly affects synovial joints. Heart structure abnormalities are more prevalent in RA-patients than in general population, such as pericarditis, increased left ventricle mass and valvular disease. Left atrial (LA) dilation predicts atrial fibrillation and congestive heart failure. It also increases the risk of developing thromboembolic events.

Objectives: The aim of this study was to determine the prevalence of LA dilation in RA-patients and compare it with matched controls.

Methods: An observational, cross-section, case-control study was designed. Patients who fulfilled 1987 ACR and/or 2010 ACR/EULAR classification criteria for RA, 40–75 years old, with no overlap syndromes or atherosclerotic cardiovascular disease were included. The control group was matched by age, gender and comorbidities. A standard transthoracic echocardiogram was performed by a board-certified cardiologist. LA structure alterations were evaluated according to the American Society of Echocardiography guidelines.

Results: A total of 63 RA-patients and 41 control subjects were included. Demographic characteristics are shown in table 1. LA dilation, defined as a LA indexed volume (LAIV) >34 ml/m², was found in 9 (14.3%) patients of the RA-group, whereas no control subjects presented that condition (p=0.011). Mitral regurgitation was detected in 39 (62%) RA-patients and 7 (17%) control subjects (p<0.001).

The impact of obesity in clinical and rheumatoid arthritis

Background: Obesity is one of the most frequent comorbidities among patients with rheumatoid arthritis (RA). It has been proposed as a risk factor of poorer response to treatment and lower likely chance of achieving RA disease remission.

Objectives: The objective of this study was to evaluate the effect of obesity on clinical and musculoskeletal ultrasound (MSUS) disease activity.

Methods: Cross-sectional clinical and laboratory data were collected on 44 RA patients. MSUS assessment of power Doppler (PDUS) and grey scale (GSUS) hypertrophy and effusion was performed on 11 joints of dominant hand (wrist, metacarpal, proximal interphalangeal 1–5) and PDUS and GSUS were scored semi-quantitatively on a scale of 0–3. The max score of the views obtained for each joint was computed and then was theses maximums were summed across all 11 joints to obtain total PDUS (range 0–33) and GSUS (range 0–33) scores. DAS28/ESR was calculated. Patients were categorised by BMI (kg/m²): ≤25 (group 1), 25–30 (group 2), and >30 (group 3). Demographic, clinical and ultrasonographic characteristics were compared across BMI groups.

Results: The overall cohort was 88.6% female, 43.2% ACPA positive and 63.6% RF seropositive with a mean age of 53.8 and disease duration of 12.9 years. The mean BMI was 28.6. Eighty two percent of patients were on sDMARD, 18.2% were on Biologics, and 68.2% of patients were on prednisone. There were no significant differences in these characteristics across the BMI categories. The overall median and interquartile ranges (IQR): 4.1 (1.3) for DAS28/ESR; 3.9 (4.1) for GSUS scores and 4 (5.1) for PDUS scores. The disease activity as measure was not significantly different across the BMI groups (p=0.61). Both GSUS and PDUS scores were not significantly different across BMI groups. Concerning GSUS score: the median (IQR) scores was 5.3 (5.4) for group1, 4.4 (4.3) for group2 and 2.6 (2.7) for group3 (p=0.41). For the PDUS scores the median (IQR) scores was 6 (8.6) for group1, 4.3 (4.1) for group2 and 2.3 (2.7) for group3 (p=0.37). There was no statistically significant correlation of BMI with ultrasound scores (r=−0.19, p=0.2 for GSUS score and r=−0.22, p=0.14 for PDUS score).

Conclusions: Our study didn’t proved differences in clinical or ultrasonic disease activity of RA among BMI. This finding doesn’t exclude the hypothesis suggesting that obesity is risk factor of refractory RA which requires a larger number of patients to confirm.

Factors associated with the development of arthritis in patients with arthralgias clinically suspected of evolving into arthritis: experience of a pre-arthritis clinic

L. Nurho, D. Peiteado Lopez, I. Monjo Henry, A. Villalba Yllan, M.E. Miranda Carús, P. Fortea Gordo, E. De Mendez Agüeta, A. Balsa Criad, Rheumatology, Hospital Universitario La Paz, Madrid, Spain

Background: Despite the fact that genetic and serological risk factors have been studied in rheumatoid arthritis (RA), the symptoms phase of preclinical RA is poorly characterised. Taking into account the importance of early diagnosis and effective treatment for the prevention of structural damage and long-term disability in RA, it is important to find clinical or image variables that identify patients with clinically suspected arthralgias at risk of developing a chronic arthritis (CSA).

Objectives: To identify baseline clinical, immunological and ultrasound variables in patients with arthralgias clinically suspected of progression to chronic arthritis.

Methods: Longitudinal prospective study of patients with CSA and follow-up from November 2015 in pre-arthritis clinics. Patients were assessed at baseline and every 6 months until 2 years, with clinical, laboratory and ultrasound data using standardised protocols. The criteria for eligible patients for inclusion in the study were ≤12 months of symptoms onset, inflammatory arthralgias (predominance in nights or mornings, improvement during the day or with movement, and morning stiffness of ≥30 min), and the involvement of small joints of hands or feet. Patients with clinical synovitis at baseline visit, patients with fibromyalgia or osteoarthrits were excluded.

Results: Twenty-six patients were recruited in 26 months of the study (1 male, 25 female), with an average baseline age of 44.7±12.6 years, an average delay time of symptoms to first visit of 8.7±3.3 months, a mean follow-up time of 7.7±8.1 months an average body mass index (BMI) of 27.7±7.2. Five patients had familial background of autoimmune diseases in first degree relatives (RA, psoriasis, inflammatory bowel disease), 6 (23.1%) were seropositive (RF and/or ACPA), 7 (26.9%) had increased baseline acute-phase reactants (PAR), and 11 (47.8%) were smokers or former smokers. Most of the patients reported a progression of the arthralgias (55%) and a subjective joint swelling at some point (70%). Of 24 patients, 8 (33.3%) developed clinical arthritis (7 RA, 1 undifferentiated arthritis), with a longer follow-up (15.7±7.4 vs. 7.5±7.2 months, p=0.016), greater baseline HAQ (11.8±8.3 vs. 3.9±4.8, p=0.033) and higher percentage of moderate inflammatory activity in the baseline ultrasound (83.3% vs. 8.3%, p=0.004), compared to patients that didn’t develop arthritis. There was a trend towards a higher seropositivity (37.7% vs. 18.8%), a higher patient global disease assessment (45.29 vs. 30±27 on a 100 mm scale), higher patient pain scores (using a visual analogue pain 100 mm scale) (58±41 vs. 34±23) among patients who eventually developed arthritis, although not statistically significant. No differences were found with PAR, BMI, age, smoking habit or painful joint count at baseline visit.

Conclusions: In our pre-arthritis clinics of patients with clinically suspicious arthralgias, 33% progressed to arthritis, underlying the importance of these clinics. Functional disability and ultrasound at baseline visit are especially useful in predicting future progression to arthritis. It is necessary to recruit more patients in order to obtain more robust conclusions.

Rheumatoid arthritis and sickle cell disease: clinical, biological, radiological and therapeutics specific aspects. A retrospective observational study

Background: Thanks to medical advances in sickle cell disease (SCD) treatments, practitioners have to be aware of new comorbidities, as rheumatoid arthritis (RA).

Methods: We conducted a retrospective, observational and monocentric study about clinical, biological and radiological specific aspects of RA in SCD patients and studied the impact of anti-rheumatic drugs, comparing the number of SCD admissions.

Disclosure of Interest: None declared

flares occurring six months before/after their introduction, using medical files and phone inquiry.

**Results:** Twenty-three patients were included in this study. Data about RA treatments and SCD flares could be collected for 15 patients. Middle age at RA diagnostic was 32.9 years-old, sex ratio was 4.75F/1M. 74% of the patients were RF positive, 65% were ACPA positive. 74% of the patients had articular damages. Among them, 100% had severe carpal which appears to be the major radiological expression of RA in SCD patients, occurring sometimes without finger bone erosion. 100% received at least one specific drug for RA, 35% a biotherapy. There was no significant difference in the number of crisis before and after methotrexate introduction (p=1) or anti TNF alpha drugs (p=0.35 IC95% [1.26:0.51]). Methotrexate had to be stopped for 3 patients because of acute chest syndrome, which did not occur with anti TNF. No infection was noticed.

**Conclusions:** In conclusion, in SCD, RA occurs sooner in life course and to be more severe with a particular pattern: carpal and tarsal without finger bone erosion. The use of biotherapies appears to be safe, with a close monitoring.

**RISK ASSESSMENT IN RHEUMATOID ARTHRITIS AND TYPE 2 DIABETES MELLITUS DEVELOPMENT RISK ASSESSMENT IN RHEUMATOID ARTHRITIS PATIENTS**

L. Kondratyeva, T. Popkova, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** The insulin resistance (IR) is the known risk factor of type 2 diabetes mellitus (DM) and potential cardiovascular complications. But it's not feasible in routine practice to calculate special indices to determine IR, as insulin levels monitoring is not a standard procedure in RA pts. Metabolic syndrome (MS) criteria and questionnaires designed to assess the risk of DM development can help to differentiate a subgroup of pts, requiring more accurate evaluation of their IR status.

**Objectives:** To determine how IR relates with MS and DM development risk assessment in RA patients.

**Methods:** A total of 46 RA pts (39 women, 7 men, 57 [39:64] years old) without established DM were enrolled in the study, including 14 pts with IR and 32 pts without IR, matched by age and sex. IR was defined as Homeostasis Model Assessment of Insulin Resistance (HOMA-IR) index >2.77. National Cholesterol Education Program/Adult Treatment Panel III (NCEP/ATP III) and International Diabetes Federation (IDF) criteria were used to confirm MS. The abdominal obesity was determined as waist circumference (WC) >80 cm for women and >94 cm for men (by IDF), and WC >88 cm for women and >102 cm for men (by NCEP/ATP III). If the total score of questionnaire Finnish Type 2 Diabetes Risk Assessment Form (FINDRISK) was >12, the DM development risk was considered as moderate or high.

**Results:** The body mass index was higher in pts with IR than in those without IR (28.5 [24.8; 32.5 kg/m² vs 22.4 [20.1; 25.4 kg/m², p<0.001]. Abdominal obesity was documented in 100% pts with IR and in 41% pts without IR by IDF criteria (p<0.002), in 64% and 22% pts, respectively, by NCEP/ATP III criteria (p<0.01). There were no differences in FAS28, CRP and ESR values and glucocorticoids users proportions, MS by IDF criteria was diagnosed in 57% pts with IR and 19% pts without IR (p=0.02), and MS prevalence by NCEP/ATP III criteria was similar in both groups (36% vs 16%, respectively, p=0.2). Higher rates of moderate and high risk for DM development were found in pts with IR compared to pts without IR (71.4% vs 31.2%, p=0.03).

**Conclusions:** The FINDRISK and IDF questionnaires, but not the NCEP/ATP III criteria of MS, can be helpful in selecting RA pts with potential IR. Abdominal obesity was the key factor indicative of IR in RA pts. On the other hand, IR may not be there even in the presence of several traditional DM risk factors. Therefore further clarification of potential contribution of RA-related risks is needed.

CLINICAL, EPIDEMIOLOGICAL CHARACTERISTICS AND COMORBIDITIES IN A COHORT OF PARAGUAYAN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Roman, S. Riquelme-Granada, J. Losanto, M. Duarte, S. Cabrera-Villaia. Reumatología, Hospital de Clínicas, San Lorenzo, Paraguay

Background: Rheumatoid arthritis (RA) is a chronic rheumatic inflammatory disease with a higher risk of developing some cardiovascular pathology compared to the general population. The presence of comorbidities in patients with RA represents an increase in the cost of care, work disability and hospital admissions.

Objectives: To describe clinical, epidemiological characteristics, frequency of comorbidities and their association with clinical and analytical characteristics in Paraguayan patients with rheumatoid arthritis.

Methods: Descriptive, cross-sectional study of a cohort of patients with established rheumatoid arthritis, followed in the Department of Rheumatology of the Hospital de Clínicas, epidemiological (i.e. sex, age, origin), clinical (i.e., comorbidities (i.e. HBP was defined as BP ≥140/90), obesity BMI ≥30, dyslipidemia according to lipid profile levels), time of evolution of the disease, DAS28, etc.), laboratory (i.e. RF, anti-CCP) and radiographic variables were recorded. Qualitative variables were expressed in frequencies and percentages and quantitative variables were characterised by their means and standard deviations. The comparison of clinical, epidemiological, serological variables was performed using the chi-squared test and the student test respectively for qualitative and quantitative variables. The statistical analysis was performed with the statistical program SPSS V.23.0.

Results: 177 patients with RA were included, 82.5% were women, with a mean of age of onset of 44.8±13.8 years, mean disease duration of 8.6±8.3 years, 68.3% came from Asunción and Gran Asunción, 44.6% of the patients were married, 54.5% were housewife, and only 11.9% had a university degree. Only 15.3% had extra-articular manifestations, mainly rheumatoid nodules. The average body mass index was 29.6±12.7, 75.9% were RF positive, with a mean of level of 436.7±301 UI/L and 85% were anti-CCP positive, with a mean of level of 2247±201 UI/L. Methotrexate was the most frequent treatment (87%), 57.7% were using prednisone, with a median dose of 7.9±4.8 mg. 40.9% had erosive disease, 38% presented hypertension, 11.9% had dyslipidemia, 5.3% type-2 Diabetes Mellitus, 39.4% were obese and 35% were overweight. Only 5% were smoker, and 16.5% had osteoporosis. When comparing the presence or absence of comorbidities with the clinical, epidemiological, serological and radiological characteristics, we did not find significant differences between them.

Conclusions: In this cohort of patients with established RA a little more than half received a monthly income less than or equal to the minimum salary, and only the minority had university studies. The most frequent comorbidities were obesity, hypertension and dyslipidemia. One third of patients were in clinical remission, 57.7% were using prednisone, with a median dose of 7.9±4.8 mg. 40.9% had erosive disease, 38% presented hypertension, 11.9% had dyslipidemia, 5.3% type-2 Diabetes Mellitus, 39.4% were obese and 35% were overweight. Only 5% were smoker, and 16.5% had osteoporosis. When comparing the presence or absence of comorbidities with the clinical, epidemiological, serological and radiological characteristics, we did not find significant differences between them.

"THE STRUCTURAL INDEX SCORE – SIS" FOR RHEUMATOID FOOT AND ITS RELATION TO FOOT FUNCTION, DISABILITY AND PHYSICAL PERFORMANCE TESTS

J.Z. Gainé, M.B. Bertolo, C.S. Nunes, C.M. Barbosa, Z. Sachetto, M. Davit, E.D.P. Magalhães, UNICAMP, CAMINHAS, Brazil, Rheumatology, UNICAMP, CAMINHAS, Brazil

Background: Feet are involved in 90% of Rheumatoid arthritis (RA) patients. The Structural Index Score(SIS) is a score that evaluates forefoot and rearfoot aspects. Although it has been used as a clinical tool to quantify foot deformities in RA, its relevance in clinical practice is uncertain.

Objectives: The aim of this study was to evaluate the relation of SIS with foot function, disability and physical performance tests in RA.

Methods: 104 RA patients of the outpatient clinic of Rheumatology/Unicamp were evaluated for SIS total, forefoot, rearfoot and its items (hallux valgus, metatarsalphalangeal (MTP) subluxation, 5th MTP exostosis, claw/hammer toe deformities), calcaneus varus/varus angle, ankle range of motion (ARM) and plan cus/cavus foot deformity). Subjects also performed Foot Function Index (FFI), Health Assessment Questionnaire Disability Index-HAQ-DI, lower limb HAQ-LL-HAQ and physical tests: Berg Balance Scale-BBS, the Timed Up and Go-TUG and the 5-time sit down-to-stand up-SST5 tests.SIS items were compared with HAQ, LL-HAQ, FFI and physical tests through Kruskal- Wallis test and Spearman correlation coefficient with a 5% level of significance.

Results: SIS Forefoot score did not correlate with any variables. Among the SIS-forefoot items, hallux valgus was associated with FFI-pain (p=0.007), FFI-disability (p=0.005) and FFI-total (p=0.016); MTP subluxation was weakly correlated with FFI-disability (r=0.196) and 5th MTP exostosis was associated with FFI-pain (p=0.018). SIS Total, SIS Rearfoot and its associated and correlated items are shown in table 1.

* Mann-Whitney’s test, ** Spearman’s rank correlation coefficient significant p-value

Conclusions: It is not clear if the use of SIS may be related to function and disability in RA. Forefoot SIS did not show correlation although hallux valgus, MTP subluxation and 5th MTP exostosis may be related to foot function. Rearfoot SIS and its items seem to be most correlated with function and disability in RA.

THE OCCURRENCE OF ANTIBODIES DEPENDING ON THE DURATION OF RHEUMATOID ARTHRITIS

M. Volkova, BeMAPGE, Minsk, Belarus

Background: Recently heterogeneous nuclear ribonucleoproteins (hnRNPs) were identified as antigenic targets for autoantibodies in RA. Autoantibodies to RNP B1, B2 and heterogeneous complex A2/b are the most studied and are referred to as “antigen RA33”. Clinical value of anti-RA33 in RA continues to be studied, so the question is about the diagnostic and pathogenic significance of these autoantibodies in patients with RA remains open.

Objectives: The aim of this study was to investigate the frequency of occurrence of anti – RA33p with RA and compare them with clinical manifestations and immunological parameters of disease.

Methods: The study included 139 patients with RA. The diagnosis was verified according to the classification criteria of ACR/EULAR 2010 Autoantibodies to RNP B1 IgG was assessed in samples of blood serum by enzyme immunoassay (ELISA; Medigan AG, Germany). A recombinant human RNP antigen B1 was used as the antigen, which was synthesised in the E. coli. system of the protein production. Anti-C-CP, RF and antibodies to Sa-antigen (anti-Sa) was evaluated by ELISA according to the manufacturer's instructions (Euroimmun AG company, Germany). The results were expressed in relative units (U/ml). Statistical data processing was carried out using the software Statistica 7.0 (StatSoft, USA) and
ADULT-ONSET STILL’S DISEASE TREATMENT PREDICTORS AT 1-YEAR FOLLOW-UP IN A SINGLE RHEUMATOLOGY CENTRE EXPERIENCE

M. Giannotta, F. Cacciapaglia , M. Giannini, M. Nivuori, R. Fanizzi, G. Lopalco, G. Laselva, C. Scioscia, F. Iannone. Department of Emergency and Organ Transplantation, Rheumatology Unit University of Bari, Bari, Italy

Background: Adult-onset Still’s disease (AOSD) is a rare systemic inflammatory disorder mainly characterised by persistent high spiking fevers, evanescence rash, and joint involvement. Data on the efficacy of biologic therapy in the management of AOSD1 is increasing and represents a breakthrough in the management of patients with AOSD refractory to corticosteroids (CS) or conventional (c) DMARDs.

Objectives: We aimed to evaluate possible predictor on the need to use a biologic agent in the management of AOSD patients.

Methods: In this retrospective monocentric study we evaluated AOSD patients followed in our outpatient’s clinic since 2010 with at least 1 year follow-up. Clinical manifestations, joint involvement, CS and c- or bDMARD use were main outcome measures. T-test or ANOVA and Chi-squared were used to compare continuous or categorical data, when appropriate, and the odds ratio (OR) for which condition had an influence on clinical outcome was calculated.

Results: We evaluated 28 AOSD patients (mean age 43±14 years; median disease duration 3 (95% CI 2.5–17.3) months). All patients at baseline were treated with a median of 18.7 (95% CI 14.3–24.8) mg/die prednisone equivalent dose, and median methotrexate (MTX) dose of 15 (95% CI 13.4–16.28) mg/week. After 1 year follow-up, in the 8 patients (28.6%) that needed to start a bDMARD (4 anti-IL1; 3 anti-IL6 and 1 anti-TNF), we observed that baseline joint involvement was the more prevalent manifestation of the disease with higher DAS28 compared to those patients still on CS +MTX (DAS28 3.8±1.2 vs 2.8±1.1, respectively (p<0.03)). Moreover, we showed that clinical manifestations of systemic involvement (i.e. fever, rash, organomegaly and anaemia) were associated with a protective risk to start a bDMARD at 1 year (OR 0.4 95% CI 0.2–0.76). Consistently, in those patients with concomitant elevated ESR (>20 mm/h), CRP (>15 mg/L) and ferritin (>250 ng/ml) levels at baseline, we observed a low risk to start a bDMARD at 1 year follow-up (OR 0.4 95% CI 0.18–0.87).

Conclusions: In our cohort about one third of AOSD patients required to be treated with a bDMARD at 1 year follow-up, mainly if joint involvement was the predominant clinical manifestation at disease onset. Systemic manifestations of the disease seem to benefit from high dose CS+MTX combination therapy. Further studies with more extensive cases are necessary.

LOW SERUM IGF1 IS ASSOCIATED WITH HIGHER CARDIOVASCULAR RISK IN THE MIDDLE-AGED WOMEN WITH RHEUMATOID ARTHRITIS INDEPENDENTLY OF THE DISEASE RELATED PARAMETERS

M.C. Erlandsson1,2, S.T. Silversward3, M. Nadali4,2, R. Pullert5, M. Bokarewa1,2,3,4,5

1,2, Rheumatology and Inflammation Research, GOTHENBURG UNIVERSITY; 3Rheumatology Clinic; 4Department of Clinical Immunology and Transfusion Medicine, Sahlgrenska university hospital, Gothenburg, Sweden

Objectives: To analyse the relation between serum levels of IGF1 and cardiovascular risk (CVR) in women with rheumatoid arthritis (RA).

Methods: The risk of dying of CV disease within 5 years was calculated using the strategy proposed by Pocock et al. BMJ 2001 in 185 women with RA (mean age 51.7 years) with no previous history of CV events. The CVR and characteristics related to it were analysed with respect to serum IGF1. IGF1 levels below the median of the total cohort were considered low.

Results: The RA women with low IGF1 (n=91, mean 104 pg/ml) had significantly higher CVR compared to those with normal IGF1 (n=94, mean 194 pg/ml) with the predicted risk of 0.51% and 0.17%, respectively (p<0.05). Among the traditional CVR factors, the low IGF1 group was 10 years older (mean 56.8 vs. 46.9, p=0.05), lower height (165 vs. 168 cm. p=0.013, 21% of the patients being <160 cm) and had high prevalence of hypertension (24% vs. 8.5%, p=0.004), while current smoking was similar between the groups (15% vs. 14%).

The low IGF1 group displayed the unfavourable metabolic profile with higher BMI (p=0.002) and obesity in 22%, higher predicted body fat content (mean 39.5 vs. 35%, p<0.05), and higher total and LDL cholesterol (p=0.0014 and p=0.0053, respectively). The levels of adiponectin (p=0.032) and HDL-cholesterol (p=0.025) tended to be higher in the low IGF1 group, which resulted in the comparable total cholesterol to HDL ratio between the groups. This could also explain that the prevalence of diabetes mellitus and metabolic syndrome were low. With exception of the disease duration, the groups displayed no significant difference in the RA-related CVR factors such as the disease activity measured by DAS28 (3.29 vs 2.99), systemic inflammation measured by serum IL6 (mean 8.46 vs. 5.99 pg/ml) and IL1β (mean 19.47 vs. 23.1 n/ml), and the prevalence of sero-positivity (91% vs. 92%). The prevalence of treatment with MTX monotherapy was higher in the low IGF1 group (56% vs. 39%, p=0.024), while the use of TNF-inhibitors and other biologic and synthetic anti-rheumatic drugs was similar within the groups.

Conclusions: Serum IGF1 levels in the low range are associated with higher CVR in RA female patients. This increase in CVR seems to be independent of the RA-related characteristics. The combination of low height and hypertension argues for the important role of congenital factors in defining serum IGF1 levels in the studied RA women.

THE EFFECT OF CUMULATIVE EXPOSURE TO CIGARETTE SMOKING ON VASCULAR DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Aguilar-Zamora1, M. Robustillo-Villarino1, L. Montolivo Chiva1, A.V. Orenes Vera1, Á. Martínez-Ferrer1, E. Valls. Pascual1, D. Ybáñez García1, Á. Sendra García1, I. Torner Hernández1, V. Núñez Monje1, J.J. Alegre-Sancho1,2

1Rheumatology, Hospital Universitario Dr. Peset; 2Foundation for the promotion in health and biomedical research (FISABIO), Valencia, Spain

Background: Smoking is described as a classic cardiovascular (CV) risk factor and we also know the beneficial effect on the CV system of smoking cessation. However, there is contradictory data about its effect on patients with rheumatoid arthritis (RA). It is possible that the measure of cumulative exposure to tobacco expressed in pack-year gives us more information than the smoking status.

Objectives: To explore the relation between smoking exposure, measured in pack-year, and subclinical vascular damage, mortality and vascular events in patients with RA.

Methods: Observational ambispective study. We included, consecutively, RA patients controlled in a tertiary hospital. We gathered demographic (sex, age, body mass index [BMI], clinical [characteristics of RA, classic CV risk factors and history of vascular events] and analytical variables [CRP, ESR]). We estimated the modified SCORE. We explored the extracranial branches of the carotid artery

Disclosure of Interest: None declared

with an Esato MyLab70XVG ultrasound device with a linear probe (7–12mHz) and an automated program measuring intima media thickness (IMT) by radiofrequency ("Quality intima media thickness in real-time, QMIT"), and registered the presence of atheroma plaques (per Mannheim consensus). We determined pulse wave velocity (PWV) by a validated MobilOGraph device. We considered as pathological an IMT >900 μ and a PWV ≥10 m/s and the presence of plaque and/or pathological IMT. We prospectively collected mortality and the development of new vascular events over four years and the current smoking status and exposure calculated in pack-year. Statistical analysis was performed using SPSS 17.0 software.

Results: We included 198 patients, excluding 15 because of previous CV events. The mean age was 66.5 years (SD 13.44) 76% were women and the mean BMI was 27.35 (SD 4.82), 31.1% were smokers, 43.2% hypertensive, 47.5% dyslipidemic and 10.4% were diabetic. The mean duration of RA was 19.95 years (SD 11.88), 76.5% of patients were seropositive and 75.4% had erosions. The mean CRP and ESR were 9.51 mg/L (SD: 32.29) and 13.83 mm/h (SD: 14.26), respectively. The mean modified SCORE was 1.81 (SD: 1.81). Regarding the vascular study, 48.1% had atheroma plaques, 32.2% a pathologic PWV [mean value of 9.13 (SD 2.12)], and 16.7% had a pathologic IMT [mean value of 748 μ (DE 188.73)].

31.1% of the patients (57) were smokers or former smokers. The average pack-year was 24.17 (SD: 21.37). No relation was found between current or previous use of tobacco and any of the outcome measures described. However, when considering cumulative exposure to tobacco, there was a trend to correlate with higher values of PWV (p=0.07) and a higher plaque presence (p=0.089) was detected. After 4 years of follow-up, 3 deaths were recorded among smoking patients, but a higher incidence of CV events was not detected in relation to cumulative exposure to tobacco (p=0.09).

Conclusions: The quantification of the exposure by pack-year of cigarette smoked could give us more information about vascular damage in patients with RA. The limitation of our study is the small number of smokers in the time they smoked could give us more information about vascular damage in patients with RA. The limitation of our study is the small number of smokers in the time they could give us more information about vascular damage in patients with RA.

LEFT ATRIAL FUNCTION IN RHEUMATOID ARTHRITIS PATIENTS

M. Fawzy, S. bahoom, A. Ashour, M. sheik, kaser el Ani, giza, Egypt

Background: Rheumatoid arthritis (RA) is a common autoimmune systemic inflammatory disease affecting approximately 1% of the worldwide population. The interaction of genetic and environmental factors results in a cascade of immune reactions, which ultimately lead to the development of synovitis, joint damage, and structural bone damage.

The importance of the left atrium in cardiovascular performance has long been acknowledged. Quantitative assessment of left atrial (LA) function is laborious, requiring invasive pressure-volume loops and thus precluding its routine clinical use. In recent years, novel non-invasive echocardiographic techniques have emerged, providing a complementary approach for the assessment of the left atrium. Atrial strain and strain rate obtained using Doppler tissue imaging or tissue Doppler imaging (TDI) and strain (S) and strain rate (SR) analysis by two-dimensional speckle-tracking echocardiography have proved to be feasible and reproducible techniques to evaluate LA mechanics.

Objectives:
1. To screen cardiac affection in rheumatoid arthritis patients
2. To assess subclinical echocardiographic affection in RA patients

Methods: 30 healthy control, and 45 RA patient subjected to full clinical assessment, DAS 28 ESR score, full laboratory evaluation, conventional and tissue Doppler imaging (TDI) and strain (S) and strain rate (SR) analysis by two-dimensional speckle tracking of the left atrium.

Results: We found statistically significant difference in 2 Left atrial PEF, 2 Left atrial, 2 Left atrial TEF, TDI mitral lateral anulus e, TDI mitral lateral anulus 5, Average SR E 1/s between patients and controls, and negative correlation between TDI mitral lateral e, TDI mitral lateral s, and Strain rate e and rheumatoid factor. There was negative correlation between 2LA PEF, 2LA E, and 2LA TEF. Rheumatoid factor is correlated to strain rate e, and negatively correlated with left atrial passive emptying

Conclusions: RA had alteration in left LV longitudinal myocardial function, left atrial expansion volume can be a predictor of AF in RA. RA patient had more left atrial stiffness. Our study concluded cardiac affection is more in seropositive RA patients.

AB0373

SARCOPEenia CUnOT PREDICT FALLS IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM THE CHIKARA STUDY

M. Tada1, Y. Yamada2, K. Mandai2, N. Hidaka1, 1Orthopaedic Surgery, Osaka City General Hospital; 2Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan

Background: The falls ratio is higher among patients with sarcopenia than among healthy individuals. We reported that the prevalence of sarcopenia was 28% and neurological syndrome (locomo) was 52% in patients with rheumatoid arthritis (RA)1. Whether patients with RA complicated by sarcopenia show a higher ratio of falls compared to those without sarcopenia remains unclear.

Objectives: We investigated events of falls and fractures, and predictors of those events in patients with RA.

Methods: We used data from a prospective observational study (CHIKARA study, UMIN000023744) started in 2016. Sarcopenia was diagnosed using the criteria of the Asia Working Group on Sarcopenia2. We counted the number of patients and events of falls and fractures they had per year[1], and investigated correlations between those events and disease activity, body composition and sarcopenia. Predictors at baseline influencing those events were analysed by uni- and multivariate analysis.

Results: Participants comprised 100 patients with RA (females, 78%; mean age, 66.1 years). Falls occurred in 21 patients (19 women), as 33 events (mean, 2 times/patient). Fractures occurred in 4 patients (4 women), as 5 events. Table 1 shows predictors for falls, with positive correlations for bone mass index, obesity level, fat percentage, and lomoco, and negative correlations for height, trunk muscle mass, and grip strength. No relationships were seen between falls and CRP, DAS28ESR, skeletal muscle mass, and sarcopenia. Height (odds ratio, 0.912; p=0.003) and obesity level (odds ratio, 1.04; p=0.006) were independent predictors of falls by multivariate analysis (table 1). In terms of fracture events, falls was the only predictor (r=0.469, p=0.001).

Conclusions: Falls have been reported as significantly more frequent with sarcopenia. However, no relationship was seen between fall events and sarcopenia in this study. We may need to evaluate not only skeletal muscle mass, but also muscle function to predict falls.

NONTUBERCULOUS MYCOBACTERIUM INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTRE EXPERIENCE IN JAPAN

M. Hayashi, K. Funamura, M. Maeda, T. Kanamoto, Departments Of Orthopedics Surgery And Rheumatology, Nagano Red Cross Hospital, Nagano, Japan

Background:
Objectives: Nontuberculous mycobacteria (NTM) infection has been increasing in both general population and immunocompromised patients in Japan. This study aimed to identify the incidence and clinical characteristics of NTM infections in patients with rheumatoid arthritis (RA).

Methods: We performed a cross-sectional analysis and assessed 11 RA patients, who were all female, complicated with NTM (mean age, 66.6 years) at our institute. We examined Steinbrocker Stage and Class, disease duration, positivity of anti-CCP antibody and rheumatoid factor, HAQ-DI, DAS28-ESR, NTM species, radiological features, methotrexate use and dosage, prednisolone use and dosage, biological agent use, and anti-NTM therapy.

Results: Average values obtained with SD were as follows: age (years), 66.6 ± 8.0; Steinbrocker Stage I, 1; II, 0; III, 1; and IV, 9; Class 1, 2; 2, 5; 3, 4; and 4, 0; disease duration (months), 274.5±126.9; positivity of anti-CCP antibody, 80.0%; positivity of rheumatoid factor, 100%; HAQ-DI, 1.35±0.72; DAS28-ESR, 3.61 ± 0.90; detection by sputum culture, 81.8%; NTM species, M. avium 8 cases and M. intracellulare 3 cases; bronchiectasis, 90.9%; interstitial pneumonia, 0%; methotrexate use and dosage (mg/week); 63.6% and 7.4±3.4; prednisolone use and dosage (mg/day); 81.8% and 4.3±3.2; biological agent use, 45.5%; and anti-NTM therapy, 36.4%.

Conclusions: At our institute, RA patients complicated with NTM were long-standing, had high disease activities and worse HAQ-DI. In all five patients (45.5%) who were treated with biologics, 3 who had preceding episodes of NTM infection were treated with anti-NTM therapy before treatment with biologics, and the other 2 who had asymptomatic NTM infection after treatment with biologics were not treated with anti-NTM therapy thereafter. In RA patients who are treated with biologics, it is necessary to perform sputum cultures constantly to detect possible NTM infections. This finding is important in the management of RA complicated with NTM.

A SYSTEMATIC LITERATURE REVIEW OF OMEGA 3 IN THE TREATMENT OF RHEUMATOID ARTHRITIS

M. Prince1, M. Bukhari2. 1Lancaster Medical School, Lancaster University; 2Rheumatology, Royal Lancaster Infirmary, Lancaster, UK

Background: Many different elements and variations of diet in the management of rheumatoid arthritis (RA) have been studied over the years such as vegan or Mediterranean diets.

Objectives: This systematic literature review covers one food stuff, omega-3 polyunsaturated fats efficacy in the management of RA alongside or independent of conventional DMARD therapy.

Methods: A systematic review of the literature between 1966–2017 was conducted using MEDLINE, CINAHL and EMBASE databases, with key words ‘RA’ and ‘omega-3’ for English-language articles producing 209 hits. We then refined the search to publications within the last 10 years, giving 96 results. Only including clinical trials gave 12 hits pertaining to 8 trials.

Results: The table above shows a summary of the evidence found. In total, 751 participants in 15 trials were exposed to omega-3 versus 1733 controls with the smallest study being an RCT involving 13 people and the largest a case-control study with 1569 participants. A notable difference between these studies was the use of DMARD therapy as part of the inclusion or exclusion criteria. Another difference noted was the RA stage eligible for a trial. Some studies required a diagnosis of RA of <12 months whereas most required stable RA ongoing for >12 months.

Conclusions: This review concludes that omega-3 leads to clinical and statistically significant improvements in RA. There was a significant heterogeneity in the trials published with different inclusion criteria especially regarding disease duration and concomitant DMARD therapy. It would seem prudent to include dietary advice in our advice to patients when treating RA. Possible reasons for this evidence would include altering the microbiome.

AB0376
RAPAMYCIN INDUCES REMISSION IN PATIENTS WITH NEWLY DIAGNOSED RHEUMATOID ARTHRITIS

M. Chen1, Z. Li1, H. Yao1, F. Hu1, J. Liang2, N. Yan1, H. Ni3, C. Gao2, X. Li3, C. Wang1. 1Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; 2Pathology, Brigham and Women’s Hospital, Harvard Medical School, Boston, USA

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterised by chronic inflammation of the joints. We found that there was an imbalance between Th17 and Treg cells in the patients with active refractory RA, reduced absolute number of Treg cells was found in these patients.

Objectives: To observe the medium-term curative effect of rapamycin in the treatment of 25 cases newly diagnosed rheumatoid arthritis.

Methods: Collecting 25 patients of newly diagnosed rheumatoid arthritis, which accorded with RA diagnosis standard of ACR in 1987. The patients were treated with rapamycin at a dose of 0.5 mg every 2 days for 24 weeks, then we observed the change of clinical improvement and immunological assessments after 24 weeks.

Results: There was 25 patients enrolled. After rapamycin treatment for 24 weeks, the mean DAS28 of them was decreased from 5.36 [1.42] to 3.45 [1.29](p<0.001). The absolute number of TregCD4+CD25+Foxp3+cells significantly higher than baseline - line (30.24 [14.44,46.64 [27.54],p<0.025). The absolute number of Th17 cells was not significantly different (6.40 [4.46,7.03 [5.60],p>0.05), and the same as the ratio of Th17/Treg cells (0.25 [0.18,0.19 [0.16],p<0.05). Meanwhile, the mean dose of prednisone was decreased form 11.25 mg/d to 9.6 mg/d.

Conclusions: Rapamycin could induce the balance of Th17 and Treg cells, especially up-regulate the absolute number of Treg cells, thus induce remission in patients with newly diagnosed RA.

ARE CO-MORBIDITIES DURING RHEUMATOID ARTHRITIS DIFFERENT FROM THOSE IN ANKYLOSING SPONDYLOARTHITIS?

Background: Patients with inflammatory rheumatic diseases are certainly not unscathed from a lot of comorbidities which may be due to the systemic inflammatory activity of rheumatic diseases themselves, immune dysfunction, or iatrogenic, they may also occur independently. Cardiovascular morbidity remains one of the most important to detect and is increased during these diseases.

So are there significant differences between co-morbidities associated with rheumatoid arthritis (RA) and those with ankylosing spondylitis (AS)?

Methods: This is a retrospective study of 111 patients followed for RA ACR 1987 criteria, and 60 patients followed for AS, compiled between January 2005 and December 2016.

Results: The mean age of patients with RA was 51.04 years [18–80 years] with a sex ratio (M/F) of 0.18. The average duration of disease progression was 6.54 years [0–29 years]. The mean age of patients with AS was 40.4 years [18–61] with a sex ratio (M/F) of 19. The average duration of disease progression was 16.8 years [1–45 years].

About cardiovascular comorbidities, 16.2% of patients with RA and 5.1% with AS were diagnosed with high blood pressure. Dyslipidemia was found in 2.7% of patients with RA and in 0% with AS. Ischemic heart disease was found in 3.1% with RA and in 0% with AS. In both diseases, obesity and overweight was obesity and was illustrated in 22.5% of RA and 11.7% of AS.

Heart and coronary failure were documented in 5.4% of RA and 1.7% of AS. Likewise renal failure in 3.6% of RA and 3.4% of AS. Diabetes was found in 18% of RA and 10% of AS. Hypothyroidism in 5.4% of RA and 1.7% of AS. Gout attack in 0.9% of RA and 0% with AS and osteoporosis in 21.3% of RA and 40% of AS.

Conclusions: Our study concluded at the frequency of comorbidities and mostly cardiovascular in rheumatoid arthritis compared with AS. Osteoporosis is also more common in our studied population with RA, although not rare with our patients with AS. This can be explained by the prescription of corticosteroid therapy in RA.

Disclosure of Interest: None declared

MUSCULOSKELETAL INVOLVEMENTS IN GIANT CELL ARTERITIS

M. Tououri; T. Ben Salem, M.S. Hamdi, M. Lamloum, I. Ben Ghorbel, M. H. Houman. Internal medicine, RABTA HOSPITAL, Tunis, Tunisia

Background: Joint involvement is frequent in Giant cell arteritis (GCA), mostly polymyalgia rheumatica (PMR). The aim of this study was to describe clinical features of joint involvement in GCA.

Objectives: To compare patients according to the presence or not of PMR.

Methods: A retrospective and descriptive study of 96 patients with GCA diagnosed between 2000 and 2015. ACR 1990 criteria were used for the diagnosis of GCA. Clinical, biological and histological features were recorded and analysed.

Results: Joint involvements were noted in 67 patients with GCA (69.8%); 34 women and 33 men. Mean age at diagnosis was 72.4±6.36 years. PMR was diagnosed in 45 patients (46.8%) and revealed the disease in two patients. Neck pain was noted in 48 patients. Twenty one patients (21.8%) complained of peripheral arthralgias which revealed GCA in five cases. Joint manifestations were associated to cardinal symptoms of GCA: headache (97%), jaw claudication (62%), scalp tenderness (49.3%) and ophthalmologic manifestations (36.9%). Erythrocyte sediment rate and C-reactive protein were high in 89.2% and 82.7% of cases respectively.

Constitutional symptoms (60% vs 39.2%; p=0.042), jaw claudication (62.2% vs 47.1%; p=0.038) and neck pain (62.2% vs 39.2%; p=0.024) were significantly more frequent in patients with PMR. Peripheral arthralgias (29.8% vs 15.7%) were more frequent in patients with PMR without significant differences. Giant cell vasculitis on temporal arterial biopsy was more frequent in patients with PMR (57% vs 30%; p=0.037).

Corticosteroids were given in 97% of patients while methotrexate was used in 20.9%.

Conclusions: PMR in patients with GCA seem to be associated to different joint manifestations.

PULMONARY AFFECTION IN EGYPTIAN PATIENTS WITH RHEUMATOID ARTHRITIS

M.S. Abdel-Baky1, F.D. Mohamed1, S.H. Hamza2, D.A. El-Sherbiny1, M. Rezk1, A. A. Gomaa2. 1Department of Medicine Division of Rheumatology; 2Department of Chest diseases, Ain Shams University, Cairo, Egypt

Background: Rheumatoid arthritis (RA) is a disabling autoimmune systemic inflammatory disease. It manifests as peripheral symmetric inflammatory polyarthritides and produces a wide range of extra-articular manifestations. Interstitial lung disease (ILD), a diffuse progressive disease of the lung parenchyma, is the most serious manifestation of RA lung affection, it remains as a significant source of morbidity and mortality.

Objectives: To evaluate the frequency and pattern of pulmonary affection in a cohort of Egyptian rheumatoid arthritis (RA) patients and the relation to disease activity and severity.

Methods: Seventy RA patients who fulfilled 2010 (ACR/EULAR) classification criteria underwent full clinical assessment, plain X ray chest, chest high-resolution computed tomography (HRCT) with assessment of the extent and severity of pulmonary affection by Warrick score. Pulmonary function tests (PFTs) including diffusion lung capacity for carbon monoxide (DLCO) were done. Transthoracic echocardiography to screen for pulmonary hypertension (PH). Assessment of disease activity by DAS28 score and of radiographic joint damage by modified Larsen score.

Results: The mean age of the patients was 44±10.8 years; females (87.1%) and males (12.9%), mean disease duration 7.3±6 years. PFTs were abnormal in 45.7% with restrictive pattern in 24.3% of patients followed by small airway affection in (10%), mixed pattern in (8.6%), the least is the obstructive pattern in (2.8%) of patients. DLCO was abnormal in (72.86%) with mild affection in (48.57%), moderate in (15.7%) and severe affection in (8.6%) of patients. HRCT abnormalities were found in 30 patients (42.85%). Interstitial abnormalities were detected in (35.7%), Septal or reticular lines, ground glass appearance, pleural irregularities and bronchiectasis were the most common findings. Most common HRCT pattern was nonspecific interstitial pneumonia (NSIP) in 12.8% (9/70), usual interstitial pneumonia (UIP) in 5% (5/70), organizing pneumonia (OP) in 1.4% (1/70) and indeterminate subtype in 14% (10/70). HRCT total score (Warrick score) was correlated with age, disease activity (DAS ESP 28), ESR, modified Larsen score, FVC, FEV1 and DLCO. Age, dyspnea and DLCO impairment were significant predictors for development of HRCT chest abnormalities. Pulmonary hypertension(S/PAp >30 mmHg) was detected in (14%) of patients.

Conclusions: Pulmonary abnormalities are common in Egyptian RA patients. HRCT and PFTs including DLCO can be used effectively for early diagnosis and monitoring of pulmonary affection in RA patients. DLCO can detect pulmonary abnormalities early in clinically asymptomatic patients. Age, disease activity and severity, PFTs and ESR are correlated with the pulmonary affection in RA. Age, dyspnea and DLCO impairment are significant predictors of pulmonary affection in RA patients. Echocardiography can be used as a screening tool for detection of pulmonary hypertension.

Disclosure of Interest: None declared

DELAY IN TIME TO DIAGNOSIS INCREASES THE RISK OF SUFFERING CLASSIC CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Robustillo Villarino1, A. Sendra Garcia1, J.J. Alegre Sancho1. 1Rheumatology, Hospital Universitari Dr Peset i Alexandre; 2Rheumatology, Foundation for the Promotion of Health and Biomedical Research of Valencia (FISABIO), Valencia, Spain

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that constitutes an independent cardiovascular risk factor (CVRF). In addition, patients with RA have a higher prevalence of CVRF than the general population.

Objectives: To assess whether delay in time to diagnosis of the disease may increase the risk of CVRF in patients with RA.

Methods: Patients diagnosed with RA, according to the EULAR/ACR 2010 classification criteria, were consecutively selected and recruited for a period of 12 months. Delay in time to diagnosis was calculated as the interval between the beginning of first joint symptoms and the diagnosis of RA with start of specific treatment. Furthermore, the presence or absence of arterial hypertension (AHT), dyslipidemia (DL) and diabetes mellitus (DM) were recorded. Whether its diagnosis was prior or subsequent to the diagnosis of the inflammatory disease was also recorded. SPSS version 17.0 software was used for statistical analysis, considering statistical significance for p<0.05.

Results: A total of 244 patients were studied, 73.8% (180) of whom were women and 26.2% (64) men. The mean age was 60.42 years (SD 13.24). Mean Delay in time to diagnosis was 2.1 years (SD 5.5). Mean age at diagnosis was 48.9 years (SD 15.7). Regarding classic CVRF, the percentage of patients with AHT, DL and DM before RA diagnosis were 17.6% (43), 6.1% (15) and 6.1% (15), respectively,
CLINICAL AND RADIOGRAPHIC CHARACTERISTICS OF AIRWAY DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Kondi1,2, Y. Katsumata3, Y. Sato1, M. Hasegawa1, S. Sakai1, H. Katsura4, H. Yanama4, 1Institute of Rheumatology, Tokyo Women’s Medical University, Tokyo; 2Division of Rheumatology; 3Division of Respiratory Medicine; Tokyo Women’s Medical University Yachiyo Medical Center, Chiba; 4Department of Diagnostic Radiology, Saitama International Medical Center, Saitama Medical University, Saitama, Japan

Background: Airway disease (AD) has drawn attention both clinically and etiologically in rheumatoid arthritis (RA), but is still poorly understood.

Objectives: We aimed to elucidate the clinical and radiographic characteristics of AD in patients with RA.

Methods: We retrospectively reviewed high-resolution computed tomography (HRCT) images and clinical data of 131 consecutive RA patients in whom HRCT were scanned for clinical purposes and screening. Overlap patients with other collagen tissue diseases and patients complicated with active infection or lung cancer were excluded. Patients who had a history of drug-induced lung disease, thoracic radiation, or exposure to dust were also excluded. HRCT images were reviewed independently by a pulmonologist and a radiologist in blind fashions, and cases of disagreement were discussed to reach a final consensus. AD was radiographically sub-categorised into 3 sub-groups: central AD, small AD, and middle lobe and lingular bronchiectasis. The associations between AD and interstitial lung disease (ILD) and each pair of the subtypes of AD were analysed by Fisher’s exact test. The risk factors for AD and subtypes of AD were identified by multivariate logistic regression analyses.

Results: The mean age of the patients was 65 years old, the mean disease duration of the patient was 123 months, 69% of the patients were women, and 42% of the patients had past/current histories of smoking. The mean Disease Activity Score 28 (DAS28)-erythrocyte sedimentation rate (ESR) value was 2.87, AD and ILD were observed in 53 (40%) and 36 (27%) patients, respectively, and both in 19 (15%) patients. AD and ILD were not significantly associated (p=0.11). By multivariate logistic regression analyses, rheumatoid factor (RF) was identified as risk factors for whole AD (odds ratio [OR] 2.7; 95% confidence interval [CI], 1.0 to 6.9; p=0.04). Central AD, small AD, and middle lobe and lingular bronchiectasis were observed in 45 (34%), 31 (24%), and 17 (13%) patients, respectively. Each pair of these 3 subtypes were significantly associated with each other (p<0.001 in all comparisons). By multivariate logistic regression analyses without considering the overlaps with multiple subtypes of AD in the same patients, age and RF were identified as risk factors for central AD: the OR for age was 1.04 (95% CI, 1.00 to 1.08; p=0.04); the OR for RF was 3.0 (95% CI, 1.1 to 8.5; p=0.034). In contrast, DAS28-ESR values were identified as a risk factor for small AD: the OR for DAS28-ESR values was 1.5 (95% CI, 1.0 to 2.4; p=0.0498). Lastly, no significant risk factor was identified for middle lobe and lingular bronchiectasis by the multivariate logistic regression analysis, although disease duration tended to be longer in the patients with middle lobe and lingular bronchiectasis than in those without (p=0.12). In contrast, smoking histories was not significantly associated with whole AD or any subtypes of AD.

Conclusions: Radiologically defined AD was frequent comorbidity in RA patients, and multiple subtypes of AD were observed and coexisted. Furthermore, AD may be related to the pathology of RA, and different AD subtypes may have distinct risk factors. Prospective studies with early RA patients were warranted to further clarify these findings and clinical impact of AD.

Disclosure of Interest: None declared

AB0382 RAPAMYCIN SELECTIVELY INCREASES CIRCULATING TREG CELLS AND MAINTAIN REMISSION OF PATIENTS WITH RHEUMATOID ARTHRITIS

N. Yao1, H. Yao1, F. Hu1, J. Liang1, H. Niu1, X. Li1, C. Gao1, C. Wang1. 1Institute of Rheumatology, Tokyo Women’s Medical University Yachiyo Medical Center, Chiba, Japan; 2Division of Rheumatology, Saitama International Medical Center, Saitama Medical University, Saitama, Japan

Background: It is thought that Rheumatoid arthritis (RA) arises from a break-down in immunological self-tolerance. We have given some direct evidence for this concept that absolute number of peripheral CD4+ Regulatory T-cells (Tregs) decreased in RA patients[1]. Furthermore, rapamycin can significantly induce immune tolerance through up-regulate Tregs and down-regulate Th17 cells[2].

Objectives: To investigate the effect of rapamycin on the absolute numbers of Th17 and Treg cells and on maintenance of disease remission in RA patients instead of DMARDs.

Methods: Thirty-two patients, who achieved remission (DAS28 ≤2.6) by the treatment with two kinds of DMARDs for more than half a year, received rapamycin at a dose of 0.5 mg every other day for 12 weeks. Before and after treatment with rapamycin, the disease activity and immunological assessments of them were performed in this study. BD Trucount tubes with the lyophilized pellet of a known number of internal counting beads were used for determining absolute counts of total CD4+ T cells in peripheral blood and then calculating the absolute number of Th17 cells and CD4+ Tregs.

Results: At week 12, 65.6% of the patients maintained remission (DAS28 ≤2.6). The DAS28 was increased from a median of 2.03 (at week 0) to 2.15 (at week 12) (p<0.05). The absolute number of Treg cells was increased significantly from a median of 22.16 (at week 0) to 32.19 (at week 12) (P=0.039). The absolute number of Th17 cells was decreased from a median of 0.58 (at week 0) to 0.56 (at week 12) (p=0.05). The ratio of Th17/Treg cells was also decreased from a median of 0.245 (at week 0) to 0.19 (at week 12) (p<0.05). At the same time, the mean dosage of prednisone decreased from 6.29 mg/d to 5.35 mg/d and thatot DMARDs were also reduced from 93.75% to 56.25%.

Conclusions: Rapamycin was effective in the maintenance of remission (DAS28 ≤2.6) by increase of Treg cells and correcting the imbalance of Th17/Treg cells. Meantime, the mean dosage of conventional drugs such as glucocorticoid and DMARDs gradually decreased. In the future, rapamycin may replace current immunosuppressant for treatment of RA.

Disclosure of Interest: None declared

AB0383 CHANGES OF METABOLIC BIOMARKER LEVELS UPON ANTI-TNF THERAPY IN RHEUMATOID ARTHRITIS PATIENTS

N. Bodnar1, A. Puszta1, E. Végh1, Á. Horváth1, S. Szántó1, G. Szűcs1, A. Hamar1, A. Domján1, K. Hodosi1, I. Seres1, G. Kenéz1, Z. Szekanecz1. 1Department of Rheumatology; 2Department of Internal Medicine, Medical University of Debrecen, Debrecen, Hungary

Background: Rheumatoid arthritis (RA) has been associated with cardiovascular disease and metabolic syndrome. Numerous pro-inflammatory cytokines (e.g. TNF-α, IL-1, IL-6) are released, which cytokines cause increased reactive oxygen species (ROS) production and thereby contribute to the increased lipid peroxidation and reduction of many antioxidants. These processes not only lead to the deterioration of joints and other tissues but may also contribute to comorbidities, such as atherosclerosis.

Objectives: The aim of this study was to assess the effects of anti-TNF therapy on different metabolic markers, such as PON1 (paraoxonase 1), 1,25(OH)2 vitamin D3, and adiponectin. We also investigated whether these biomarkers correlated with various demographic, clinical and laboratory markers.
Methods: We treated 37 RA patients with either etanercept (ETN) or certolizumab pegol (CZP) in a 12 month follow-up study. Assessments were performed at baseline, and 3, 6 and 12 months after treatment initiation. Serum chemerin and adiponectin concentrations were measured by commercially available ELISA kits (R and D System, MN and USA). PON1 and aroylsteerase activities were measured by spectrophotometry. In addition, age, disease duration, disease activity (DAS28), CRP, anti-CCP, IgM rheumatoid factor and plasma lipid levels were also assessed. Arterial flow-mediated vasodilation (FMD), carotid intima-media thickness (cIMT) and arterial pulse-wave velocity (PWV) were assessed by ultrasound.

Results: Anti-TNF treatment resulted in a significant decrease in the levels of chemerin (p<0.001) and adiponectin (p=0.007) after 12 months. There were no significant changes in the levels of other metabolic biomarkers. We found the following correlations between the baseline values: the PON1 levels correlated with the disease activity (R=0.385, p=0.030), HDLC (R=0.417, p=0.012) and the triglyceride levels (R=0.481, p=0.003). The total cholesterol correlated with the PWV (R=0.449, p=0.021) and the levels of the LDL-C (R=0.911, p<0.001). The baseline triglyceride levels correlated with the IgM rheumatoid factor (R=0.343, p=0.023). The total cholesterol correlated with the LDL-C correlated with the disease activity (R=0.385, p=0.030). 

Conclusions: Metabolic factors, such as certain adipokines, PON1 and aroylsteerase may play a role in oxidative stress and atherosclerosis associated with RA. Anti-TNF treatment may affect adipokine levels.

### AB0385

**RHEUMATOID ARTHRITIS PATIENTS WITH VERY HIGH CARDIOVASCULAR RISK: POOR RESULTS IN CHANGES IN LIFESTYLE DURING FOLLOW-UP**

N. Vegas-Revejo1, V. Portilla1, I.C. Dominguez-Casas1, J.L. Martin-Villar1, B. Atienza-Mateo1, M. Agudo1, J. Rueda-Gotor1, J.L. Hernández2, R. Blanco1, M. A. González-Gay3, A. Corrales1, 1Rheumatology, 2Internal Medicine, Hospital Universitario Marqués de Valdecilla, Santander, Spain

**Background:** Rheumatoid arthritis (RA) is associated with accelerated atherosclerosis, which results in high cardiovascular morbidity and mortality. The European Atherosclerosis Society recommends a strict control of cardiovascular (CV) risk factors, focusing in a healthy lifestyle, for the prevention of future CV events.

**Objectives:** Our aim was to assess the characteristics of healthy lifestyle in patients with RA and very high risk of CV events.

**Methods:** Prospective study that included a group of 113 patients, of whom 65 presented carotid plaques on carotid ultrasound study and, due to this, were categorized as having very high CV risk at the baseline visit. At this time, patients were informed about the risks associated to their disease and the high risk of having CV events. They were even warned of the need of healthy lifestyle habits. Data on lifestyle, smoking, obesity and diabetes mellitus were collected at base-line and last visit (with an interval of more than 5 years).

**Abstract AB0385 – Table 1.** Clinic characteristics of 65 patients with RA and very high CV risk.

**COMPARATIVE ASSESSMENT OF BMD IN PRE-, POSTMENOPAUSAL WOMEN AND MAN WITH RHEUMATOID ARTHRITIS (RA)**

O. Garmish, A. Romanovskiy, T. Orfk. Institute of Cardiology, Kyiv, Ukraine

**Background:** RA doubles the risk of hip and vertebral fractures, regardless of the use of GCs, and disease activity is consistently associated with low BMD. But now, it is not clearly identified predictors of the individual risk of bone loss depends on sex and menopausal status patients with RA.

**Objectives:** To compare BMD in man, pre- and postmenopausal women with RA.

**Methods:** The study was performed on 145 patients: 117 women (mean age 45.4 ±13.0 years, mean disease duration 9.7±7.7 years, 41% (n=48) postmenopausal) and 28 man (mean age 46±16.9 years, mean disease duration 4.2±1.1 years) with RA. 91.6% have moderate/high disease activity by DAS28 68.4% women and 64.3% men received prednisone <10 mg/day more than 3 months; 87% of patients received MTX. BMD was measured in 3 part of the skeleton: hip, lumbar spine, distal part of forearm. Female patients were divided in two groups by menopause: premenopausal (Prem) in mean age 36.9±3 years and postmenopausal (PM) in the mean age 57.6±5.9 years.

**Results:** BMD was decreased in 44.5% of women and 42.9% of man. BMD of hip, lumbar spine, distal part of forearm were respectively decreased in 26.1%, 26.1%, 18.8% Prem women and 66.7%, 70.8%, 79.2% PM women. 39.3% of man had decrease BMD in the hip and 42.8% – in the lumbar spine. In women the age was strongly associated with BMD decrease, in man no association with age was found. In Prem women was not found association between BMD, disease duration, DAS28 and X-ray changes in hands and feet, only cortical index was correlated with BMD in all part of the skeleton. In PM women the disease duration was negatively correlated with BMD in total hip and forearm, in man – with BMD in lumbar spine and hip neck (p<0.01). It was found association between BMD and X-ray stage by Steinbrocker in PM women and man. DAS28 was strongly associated with low hip and forearm BMD in PM women and low spine BMD in men. According to dispersion analysis PM women with III-IV X-ray stages has significantly lower BMD in the hip (total: Z=2.16, p=0.04; neck: Z=2.81, p=0.01) and medium part of forearm (Z=2.92, p=0.001). Man had significantly lower BMD in all part of the skeleton since II X-ray stage (p<0.001) and negative correlation between BMD and presence of erosion.

**Conclusions:** A sexual differences in BMD loss was observed in different parts of the skeleton. In man the most affected part of the skeleton was spine and BMD changes were more likely to Prem women, had high association with disease activity by DAS28 and presence of erosions, and no association with age. In Prem women only cortical index had high predictive value for decrease BMD in all parts of the skeleton. Age, disease deration, duration of menopause, DAS28 and x-ray changes in hand and feet was strongly associated with decreased BMD in the hip and forearm in PM women.

RELATIONSHIP BETWEEN EXTRA-ARTICULAR MANIFESTATIONS AND JOINT SURGERY IN RHEUMATOID ARTHRITIS
O. Saidane, M. Sellami, R. Barhoumi, A. Ben Tekaya, H. Aljani, R. Tekaya, I. Mahmoud, L. Abdelmoula. Rheumatology, Charles Nicolle Hospital, Tunis, Tunisia

Background: Extra-articular organ involvement is a serious condition in rheumatoid arthritis (RA) associated with increased mortality. These manifestations may affect the course of the disease, but could they accelerate the joint destruction and shorten the pre–joint surgical period?

Objectives: Our objective was to study the impact of extra-articular manifestations (EAM) on joint surgery during RA management.

Methods: It is a retrospective comparative study involving 500 RA patients (according to 1987 ACR or 2010 ACR/EULAR criteria) in rheumatology department between 2000 and 2014. The assessment of EAM was systematically done in RA diagnosis and during management. We compared 2 groups of RA patients according to the presence or not of EAM.

Results: We enrolled 422 women and 78 men with mean age of 53.3 years (21–83) and mean disease duration of 12 years [2–40]. RA was Rheumatoid Factor positive and erosive in 71.4% and 90% cases respectively. A surgical procedure was considered necessary in 59 cases (11.8%). An EAM was diagnosed in more than a half of patients (62.4%) with a predominance of ocular and bone manifestation, mainly xerophthalmia (173 cases, 34.6%) and osteoporosis (120 cases, 24%). Secondary Sjögren’s syndrome was confirmed in 70 cases. Pulmonary manifestations related to RA were noted in 70 patients (14%), especially diffuse interstitial pulmonary in 48 cases (9.6%). Renal involvement was present in 45 patients, of which interstitial renal disease was the most common manifestation (29 patients, 64.4%), Rheumatoid nodules (4.6%) and small vessel vasculitis (0.6%) were the most frequent skin manifestations. A significantly higher incidence of joint surgery was noted in osteoporotic RA patients (OR=1.91; p=0.029). There was no significant correlation between joint surgery resort and other EAM.

Conclusions: Our study concluded to a higher incidence of EAM during RA management. Osteoporosis was the only EAM associated to greater frequency of joint surgery.

SLEEP DISTURBANCES IN INFLAMMATORY RHEUMATIC DISEASES
O. Addimanda1,2, M. Burattini1,3, L. Baldelli1,3, G. Chiaro1,3, E. Pignotti1,3, F. Provini1,3, R. Meloni1,2, 1Department of Biomedical and Neuromotor Sciences, University of Bologna; 2Medicine and Rheumatology Unit, Rizzoli Orthopaedic Institute, IRCCS; 3Neurology Unit, Institute of Neurological Sciences, Belfaria Hospital, Bologna, Italy

Background: Inflammatory rheumatic diseases such as Ankylosing Spondylitis (AS) and Rheumatoid Arthritis (RA) have recently been found to be associated with sleep disturbances especially obstructive sleep apnoea.

Objectives: The aim of our study was to evaluate the occurrence of sleep disturbances, especially REM Sleep Behaviour Disorder (RBD), in inflammatory rheumatic diseases, (rheumatoid arthritis -RA and Spondyloarthritides –SpA).

Methods: We enrolled 103 consecutive patients affected by inflammatory rheumatic diseases (RA 64, 62.1% or SpA (39, 37.9%). Patients underwent a neurologic and psychopathological assessment, including identification of sleep disorders by means of the Pittsburgh Sleep Quality Index (PSQI), the Berlin and the REM sleep behaviour disorder (RBD) questionnaires, a structured interview on sleep terrors and sleep paralysis, Beck Depression Inventory (BDI-II) and the Spielberg State-Trait Anxiety Inventory (STAI). Statistical analysis was performed utilising SPSS software.

Results: No significant differences were found between RA and SpA patients in age at diagnosis, disease duration, smoke habit, alcohol consumption, anamnesis, comorbidities (especially metabolic diseases, anxiety or depression), disease activity/remission and biologic Disease Modifying Antirheumatic Drugs use. No differences demonstrated in BDI-II, STAI, PSQI and RBD questionnaires; only the Berlin Questionnaire showed significant differences (17.2% in RA vs 35.9% in SpA, p<0.036). No differences in sleep paralysis (10.9% in RA vs 7.7% in SpA, p=0.74) and sleep terrors (37.5% in RA vs 20.5% in SpA, p=0.0826) which were found to be increased if compared with general population (2.6%).

Conclusions: Our data show an increased prevalence of sleep terrors in rheumatic patients when compared to the general population although no differences were highlighted between RA and SpA; also increased risk of sleep apnoea (Berlin Questionnaire) has been demonstrated in patients with SpA compared with RA.

IS RHEUMATOID ARTHRITIS A RISK FACTOR FOR DEMENTIA?
O. Saidane, M. Sellami, I. Mahmoud, A. Ben Tekaya, H. Aljani, R. Tekaya, L. Abdelmoula. Rheumatology, Charles Nicolle Hospital, Tunis, Tunisia

Background: A direct link between chronic inflammation and dementia was well established by different epidemiological studies. Nevertheless, data on impaired cognitive function during rheumatoid arthritis (RA) are still controversial and doubtful.

Objectives: To assess the association of RA and impaired cognitive function.

Methods: This is a case-control study involving patients with RA according to ACR/EULAR criteria 2010 and randomly-chosen controls by matching on age and gender during 4 months. The Mini Mental State Examination (MMSE) was used to evaluate cognitive functions. Cognitive impairment was defined by a MMSE score lower than 24 (or 26 in patients with primary education). The activity of RA was evaluated using Disease activity score (DAS28).

Results: A total of 20 RA patients (12 women and 8 men) with a mean age of 52.6 years [31–72] and 20 healthy controls (15 women and 5 men) with a mean age of 55.8 years [50–77] were included. No significant differences for age or gender between RA patients and controls were observed. Rheumatoid factor was positive in 95% of cases. Mean disease duration was 3.2 years [2–6]. Thirteen RA patients had active disease with mean DAS28 of 4.73. Three-quarters of RA patients had been treated with methotrexate and only 8 patients received biototherapy: 5 anti TNF alpha and 3 Rituximab. Forty percent of RA group were illiterate versus 49% in control group. Eleven RA patients (55%) had a normal cognitive function versus 15% (75%) in control group. A moderate cognitive impairment (mean MMSE of 18.62) was found in 8 RA patients (40%) and 2 controls (10%) primarily affecting constructional apraxia. No severe cognitive impairment was found in the 2 groups. Significant positive association was found between cognitive impairment and RA (p=0.001). Patients with RA using methotrexate had higher risk for cognitive impairment comparing to patients using biototherapy (p<0.02).

Conclusions: Our study highlighted a serious psychological expression of RA which was early onset of cognitive impairment and dementia. This is a possible effect of inflammation and vascular disease caused by RA.

HIPERTRIGLYCERIDEMIC-WAIST PHENOTYPE: A MARKER OF CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS PATIENTS

I.P. Guzmán Guzmán1, O. Zaragoza-García1, J.E. Navarro-Zarzaa2, J. Maldonado-Anicacio3, N. Castro-Alarcón4, I. Parra-Rojas5, 1 Facultad de Ciencias Químico Biológicas, Universidad Autónoma de Guerrero, Chilpancingo; 2Hospital General, Chilpancingo, Guerrero; 3Universidad Autónoma de Guerrero, Chilpancingo, Mexico

Background: The risk of cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA); about 50% of associated deaths in rheumatoid arthritis (RA) are attributed to CVD.1 Both traditional cardiovascular risk (CVR) factors and inflammation contribute to this risk. The hyperuricemia (HUC) and metabolic syndrome (MetS) are considered parameters of CVR, both closely related,2 and recently the hypertriglyceridemic-waist (HTGW) phenotype has been defined as well a marker to identify HUC in the general population.3

Objectives: To determine the prevalence of HTGW phenotype and to evaluate its association with CVR parameters among RA patients.

Methods: HTGW phenotype was defined as waist girth ≥102 cm in male and ≥88 cm in female and TG >150 mg/dl in 250 patients diagnosed with RA according to the ACR/EULAR 2010 criteria. The levels of uric acid >5.5 mg/dl defined HUC. The MetS and its individual components (NCEP-ATP III) were evaluated as parameters of CV risk.

Results: We identified 51 AR patients (20.4%) with HTGW phenotype. Adjusting for covariates in a logistic regression model, it was observed that the HTGW phenotype is associated with the presence of HUC (OR=6.14, p<0.001), and MetS (OR=5.7, 95% CI 2.7–12.2, p<0.001).

Conclusions: HTGW is prevalent in RA patients from southern Mexico. The HTGW phenotype can be considered at low cost marker, used as a tool screening to predict high metabolic risk during the clinical course of the rheumatic disease.

RELATIONSHIP BETWEEN BODY MASS INDEX AND PERSONALITY IN AN EARLY ARTHRITIS COHORT OF PATIENTS

Background: According to previously reported data from our early arthritis registry (PEARL, Princess Early Arthritis Register Longitudinal), patients with a higher BMI have higher scores in pain and disability scales. We also described some years ago that, in the same population, the structure of personality explored with the PANAS questionnaire (Positive and Negative Affect Scale) affects some outcomes in arthritis measures. Specifically, higher scores on the negative affect subscale associate higher scores in pain and disability scales.

Objectives: To analyse the relationship between BMI and the structure of the affect in the PEARL cohort.

Methods: PEARL registry includes patients with early arthritis (less than one year of duration), in whom, sociodemographic, disease related and treatment data are recorded in five protocolised visits. We analysed data from those patients in which the PANAS questionnaire data were available and whose classification, after 2 years of follow-up, were rheumatoid arthritis -according to the 1987 ACR classification criteria -- or undifferentiated arthritis. The structure of the effect was evaluated with the PANAS questionnaire administered in one single occasion. This questionnaire is used to evaluate the components of positive (PA) and negative affect (NA). It consists of 20 questions and the score obtained from its administration ranges between 10 and 50 points for each affect. The WHQ definition was used for low weight, normal weight, overweight and obesity (BMI <18.5, 18.5–25, 25–30 or >30 kg/m2 respectively). The statistical analysis were performed with ANOVA and Pearson’s correlation tests, as well as multivariate linear regression (including as independent variables sex, age and study level) using the Stata 12.1 software.

Results: We analysed the data of the 71 patients for whom PA values were available and of the 65 patients with NA values available. There was not a statistically significant relationship observed between PA and NA and BMI when analysed as a continuous variable (R=0.12, p=0.25 and R=0.1, p=0.36, respectively) or as a categorical variable. However, there was a non-significant trend to lower scores for both PA and NA in patients with a higher BMI (figure 1). The multivariate analyses, adjusted for sex, age and study level, also showed no statistically significant relationship between the BMI (analysed as continuous or categorical variable) and the PA and NA; but there was also a non-significant trend that sets a relationship between lower scores of both PA and NA and higher BMI values.

CONCLUSIONS: In our early arthritis registry there is no relationship between the BMI and the structure of the affect evaluated through the PANAS questionnaire. However, it is necessary to evaluate this relationship in a greater number of patients and in different populations before discarding this relationship definition.

CLINICAL, SEROLOGICAL AND TREATMENT ANALYSIS OF RHUPUS SYNDROME: A RETROSPECTIVE MONOCENTRIC STUDY

P. Rottenberg1, F. Jouen2, I. Marie3, T. Lequeux1,4, O. Vittecoq1,4, 1Rheumatology; 2Clinical Immunology Laboratory; 3Internal Medicine, Rouen University Hospital; 4U1234, INSERM, Rouen, France

Background: Rhupus syndrome is a rare condition in which rheumatoid arthritis (RA) features overlap with systemic lupus erythematosus (SLE) manifestations. Disease characterisation tends to improve, but some uncertainties remain, and therapeutic management has still to be defined.

Objectives: We aimed to perform a study of the patients followed at the Rouen University Hospital with rhupus diagnosis using both recent criteria and expert diagnosis, in order to perform an analysis of the clinical, radiological and biological characteristics, and to report the therapeutic procedures carried out.

Methods: We performed a retrospective research work covering a period of 10 years, using diagnosis code extraction for both RA and SLE from database of the medical information department, as well as biological data extraction concerning ACPA testing, anti-dsDNA and anti-RNP antibodies. Patients satisfying both ACR/EULAR 2010 and SLICC 2012 classification criteria for RA and SLE respectively, or with an expert diagnosis of rhupus were included. A screening of medical records was performed to collect clinical, biological and treatment data for each patient.

Results: Sixteen patients were identified and 12 fulfilled both classification criteria. RA most often preceded rhupus, and clinical analysis found a predominant articular pattern at initial and established disease, with erosive arthropathy (n=11). Skin involvement was the most frequent associated manifestation (n=12). Among other associated manifestations, serious events were reported, including active glomerulonephritis (n=2), ischaemic stroke (n=1) and myocardial infarction (n=1). Immunological profiles showed positivity for (n=14), anti-dsDNA (n=9) and ACPA (n=8). Ten patients required biological DMARD, in addition to conventional treatment. All types of RA approved bDMARD were used. Rituximab was the most prescribed (n=9) and the most effective, with sustained response in 5 patients.

Conclusions: Rhupus is a rare condition, with predominant articular pattern, but serious SLE-related manifestations can occur. In rhupus refractory to conventional treatment, biologics, and particularly rituximab, are a promising therapeutic approach.

RHEUMATOID ARTHRITIS AND RISK OF INCIDENT CHRONIC KIDNEY DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF COHORT STUDIES

P. Ungprasert1, S. Rakasasuk2. Research and development; Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Patients with rheumatoid arthritis (RA) may have a higher risk of developing chronic kidney disease (CKD) compared with general population. However, the data on this risk are limited and not well-characterised.

Objectives: This systematic review and meta-analysis aimed to comprehensively investigate the risk of incident CKD among patients with RA by reviewing all available studies.

Methods: A systematic review was performed using MEDLINE and EMBASE database from inception to December 2017 to identify all cohort studies (either retrospective or prospective) that compared the risk of incident CKD in patients with RA versus individuals without RA. Adjusted point estimates were extracted from individual studies and the pooled risk ratio and 95% confidence interval (CI) were calculated using random-effect, generic inverse-variance method of DerSimonian and Laird. Visualisation of funnel plot was used for evaluation for publication bias.

Results: A total of 4 retrospective cohort studies with 1,627,981 participants were included. The risk of incident CKD was significantly increased among patients with RA versus individuals without RA. The pooled risk ratio was 1.52 (95% CI, 1.28–1.80). The statistical heterogeneity of this study was high with an I² of 82%. The forest plot of this systematic review and meta-analysis is shown as figure 1. The funnel plot was relatively symmetric and, thus, did not suggest the presence of publication bias in favour of positive studies.

Conclusions: In this study, the use of antimalarial drugs was associated with an increased risk to present disturbances of the cardiac rhythm/conduction in patients with established RA.

AB0393

ELECTROCARDIOGRAPHIC DISTURBANCES IN PATIENTS WITH RHEUMATOID ARTHRITIS USING ANTIMALARIAL DRUGS

P. Rodriguez Henriquez1, F. J. Reyes-Muchiño2, L. M. Amezcua-Guerra3. 1Rheumatology; 2Internal Medicine, Hospital General Dr. Manuel Gea González, Mexico, Mexico; 3Immunology, Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico

Background: Cardiac involvement is present in 7% to 35% of patients with rheumatoid arthritis (RA). Anecdotal case series have associated the use of antimalarial drugs with the presence of electrocardiographic disturbances in patients with RA.

Objectives: To assess whether the use of antimalarial drugs is associated with the presence of electrocardiographic abnormalities in RA patients. The main clinical associations were also evaluated.

Methods: A single-centre, case-control (1:1 proportion) medical chart review study was performed. A total of 144 patients with RA (ACR/EULAR 2010 criteria) were studied, and grouped as follows: 72 with a history of antimalarial drug use (case) and 72 who never used antimalarial drugs (control). We excluded individuals with a history of ischaemic heart disease or an already diagnosed disturbance of the cardiac rhythm/conduction.

Results: A total of 37 cases of electrocardiographic disturbances were found in patients receiving antimalarials (51%), but only 18 cases (25%) in the control group (p=0.001), giving an odds ratio (OR) of 3.17 (95% CI, 1.57–6.42). P. Rodriguez Henriquez et al. Rheumatology 2005;45:iv39–42.

The average dose of hydroxychloroquine was 3.02±0.41 mg/kg, while the dose of chloroquine was 2.23±0.13 mg/kg. A history of prednisone consumption also was associated with an increased risk to present an electrical cardiac disturbance (p=0.005; OR 9.73, from 2.00 to 47.32).

Conclusions: In this study, the use of antimalarial drugs was associated with an increased risk to present disturbances of the cardiac rhythm/conduction in patients with established RA.

OBSERVATIONAL STUDY OF THE INCIDENCE OF CARDIOVASCULAR EVENTS AND ASSOCIATED COMORBIDITIES IN A COHORT OF PATIENTS WITH RECENT ONSET RHEUMATOID ARTHRITIS

R. Ortega Castro1, R. Jimenez-Gasco2, A. M. Cabezas-Lucena2, J. Calvo Gutierrez2, M. C. Castro-Vilegas3, M. Romero-Gomez1, A. Escudero-Contreras1, E. Collantes-Estélvez1, P. Font-Ugida1. 1Rheumatology, Reina Sofia University Hospital/IMIBIC/University of Cordoba; 2Rheumatology, University of Cordoba, Córdoba, Spain

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease whose main characteristic is persistent joint inflammation that results in joint damage and loss of function, and can involve other tissues and organs (extra-articular manifestations). RA is associated with a high risk of morbidity and premature death secondary to the earlier development of cardiovascular, lung diseases and malignancy, being cardiovascular disease secondary to accelerated atherosclerosis the main cause of mortality and mortality in these patients.

Objectives: Main objective: To calculate the incidence of comorbidities and CV events in patients with recent onset RA. Secondary objectives: To determine the clinical disease features according to baseline RA profile. To analyse the relationship between CV event and the different variables. To describe classic CV risk factors evolution throughout the follow-up.

Methods: We conducted a retrospective longitudinal observational study of 70 patients with recent onset RA according to ACR/EULAR 2010 criteria, at 5 years of follow-up. A descriptive study of the variables was carried out. For the bivariate analysis, the Chi-square test was used for the qualitative variables and the Mann Whitney U test for the independent quantitative ones. For the paired data, the McNemar test was used for the qualitative variables and T Student for the quantitative ones. A logistic regression model was used to associate the main variable with the rest of the variables. Finally, the analysis of survival and regression of COX was carried out. All the contrasts were bilateral and were considered significant when p<0.05. The statistical analysis was performed using SPSSV17.

Results: The incidence of CV event was 18.57% (31% acute myocardial infarction). During follow-up, an improvement in inflammatory and quality of life...
parameters (DAS28, ESR, CRP and HAQ) was observed (p<0.05). Likewise, the % of hypertensive and dyslipidemic patients increased during follow up (p<0.05), while the levels of cholesterol, triglycerides, glucose and diabetic patients remained similar. The presence of CV event was related to high levels of ESR, male sex and hypertension, (p<0.05).

Conclusions:
- The incidence of cardiovascular event in our recent onset RA cohort resembles that previously described in the literature, with the majority occurring during the first 5 years of follow-up.
- The development of hypertension and dyslipidemia occurs mainly during the first 5 years of follow-up.
- The presence of a cardiovascular event was related to male sex, high blood pressure and high ESR levels.

AB0395
CORRELATION BETWEEN CARDIOVASCULAR RISK CALCULATORS IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS
R. Castellanos-Moreira, S.C. Rodríguez-Garcia, S. Mandelikova, V. Ruiz-Esquide, B. Frade-Sosa, A.B. Azuaga-Piñango, C. Gonzalez-Delaurens, C. Camacho, J. Ramirez, M.V. Hernández, A. Cuervo, J. A. Gómez-Puerta, J.D. Carrete, R. Sanmartí. Rheumatology, Hospital Clinic de Barcelona, Barcelona, Spain

Background: EULAR recommends for patients with rheumatoid arthritis (RA) a cardiovascular (CV) risk assessment at least once every five years. Several risk calculators are available but most of them are based on data from general population, so they may underestimate the risk of RA patients. To obtain a more accurate estimation they should be adapted for RA by a 1.5 multiplication factor, unless the instrument includes RA as a variable. To date, there are no studies analysing the concordance and correlation between different CV risk calculators in spanish population.

Objectives: To analyse concordance and correlation of CV risk calculated using different tools and to determine the proportion of CV risk factors in a cohort of patients with RA.

Methods: We performed a cross-sectional study including patients with RA according to ACR/EULAR 2010 criteria, treated in a tertiary hospital. Individuals with previous CV events, diabetes and chronic kidney disease were excluded. Ten-year CV risk was obtained with the following calculators: Framingham-body mass index (FRS-BMI), Framingham-lipids (FRS-L), SCORE CV risk calculator (SCORE) and the Expanded CV Risk Prediction Score for RA (ERS-RA). A 1.5 multiplying factor was used to adapt the results for RA patients in those which didn’t include it in their models. CV risk was categorised as low or high using 10% as a cut-off for FRS-BMI and FRS-L and 5% for SCORE y ERS-RA. Correlation was evaluated using Spearman correlation coefficient (Rho) and concordance with weighted kappa.

Results: We included 88 patients (18 male), 87.5% Caucasian, mean age 56.9 ±10.6 years, mean disease duration 5.8±5.3 years. 67% and 76% had positive RF and ACPA respectively and 15% presented extra-articular manifestations (rheumatoid nodules, interstitial lung disease, pleuropericarditis). Regarding CV risk factors: 14.8% were active smokers, 60.2% were overweight or obese, 25% had hypertension, 47.8% had dyslipidemia. The median CV risk predicted at 10 years was 15% (1.5–50.0) for FRS-IMC, 11.8% (1.2–154.0) for FRS-L, 1.5% (1.1–16.5) for SCORE and 6% (0.6–27.8) for ERS-RA. 64 patients were categorised as low risk and 22 as high risk for ERS-RA. No significant differences were observed in the means of risk obtained by the different tools and in the risk categories according to ERS-RA when stratified by disease duration (more or less than 5 years).
For the correlation between ERS-RA and FRS-BMI, FRS-L and SCORE, Spearman’s Rho coefficients were 0.84, 0.79 and 0.80, (p<0.005).

For the concordance between ERS-RA vs FRS-BMI a weighted k=0.29 (Cochran’s Q=15.0–42.4) was obtained. For ERS-AR vs FRS-L, k=0.34 (Cochran’s Q=19.0–50.0) and for ERS-AR vs SCORE, k=0.70 (Cochran’s Q=52.0–87.0).

Conclusions: A strong correlation was observed between the CV risk calculators evaluated and good agreement only between ERS-AR and SCORE. Additionally, overweight, obesity and dyslipidemia were the most prevalent comorbidities.

AB0396
RELATIONSHIP BETWEEN PATIENT GLOBAL ASSESSMENT AND PAIN ASSESSMENT IN THE DISEASE ACTIVITY INDEXES IN RHEUMATOID ARTHRITIS, AND ITS CORRESPONDENCE WITH SONOGRAPHIC ALTERATIONS
R. Menor Almagro, R.M. Martinez, E.M. Rubio, M.M. Fernández. Rheumatology, Hospital Universitario Virgen del Rocio, Seville, Spain

Background: Disease activity indexes in rheumatoid arthritis (RA) provide information of different parameters in a single value. It is very useful in the evaluation of the disease activity and its progression. The subjective component of these indexes can modify the index final value.

Objectives: The aim of our study was to describe the relationship between the patient global assessment (PGA) and pain assessment (PA) with the sonographic alterations in AR.

Methods: Transversal study describing the ultrasonographic changes and disease activity indexes in AR. We included patients with RA according to ACR/EULAR classification criteria. They were sent by their usual clinician, in random selection. They were reviewed in the same day by a rheumatologist and blind sonographer. PGA, PA, HAC, tender and swollen joint count, CDAI, SDAI and DAS28 were evaluated. The ultrasound were realyzed by gray scale and doppler in 12 joints (wrist, second to fifth MCP and fifth bilateral MTF).

Results: A total of 48 patients had PGA <50 and 37 PGA ≥50. The mean age was 53.2±11.7 for group 1 and 56.5±10.2 for group 2, women 64.6% and 83.8% respectively. The positive rheumatoid factor resulted in 72.9% vs 73%. The evolution of the disease in months presented a median of 96 (47.2–132.7) vs 108 (48–138), p=0.564. The Body Mass Index in the groups was 26.6 (23.5–29.7) and 26.0 (22.8–30.0), p=0.647, and the tobacco consumption of 11 patients group 1 and 12 in group 2 (p=0.397). No significant difference was found in the treatment at the time of the evaluation with methotrexate, median of 10 (0–15) vs 7.5 (0–15), p=0.350, or corticosteroids 1.4 (0–2) vs 2.5 (0–4.5), p=0.05. 23 patients in the group 1 and 19 in the group 2 were in biological therapy. The results referring to the patient’s assessment of their disease, acute-phase reactants, clinical examination, ultrasound and disease activity indexes are presented in table 1.

Conclusions: Disease activity indexes in AR have been established as a very useful measure, both in the homogenization of the results obtained in the research and in the daily clinical practice. In our study, we observed the modification in the values of disease activity indexes due to PGA and PA, even those in which its contribution is less decisive than other parameters, as it happens in the DAS 28. Those variables no relatedation in their value with the patient assessment of his disease status did not show statistical significance between the groups. The patients’ valuation about activity of their AR and the modification of the indexes in which it participates in our study were not concordant with the echographic alterations found in grey scale and doppler echo.

AB0397  PREVALENCE AND FACTORS ASSOCIATED WITH DEPRESSION AMONG PATIENTS AFFECTED BY CHRONIC INFLAMMATORY ARTHRITIS: PRELIMINARY RESULTS OF A SINGLE-CENTRE EXPERIENCE IN ITALY

S. Pezzati1, S. Tomassi2, F. Fracassi1, A. Gioio1, C. Cairini1, F. Martinis1, M. G. Gnatta2, D. Cristofalo2, C. Boneto3, M.L. Marognoli2, S. Tosato2, A. Carletto1.

1Rheumatology, Reumatologia – AOUM Verona; 2Section of Psychiatry, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy

Background: Depression and anxiety disorders are more common in chronic inflammatory arthritides (CIA) than in the general population.1 In rheumatoid arthritis (RA), depressive and anxiety symptoms have been associated with disease activity and pain perception,2 physical disability,3 health care costs,4 and mortality.4 To our knowledge, data on the prevalence of depression in Italian patients with RA are scarce.

Objectives: To estimate the prevalence and factors associated with depression among patients affected by RA.

Methods: During an one year period, patients affected by RA have been consecutively enrolled. For each patient demographics and disease characteristics were recorded; the Hospital Anxiety and Depression Scale (HADS) was administered. HADS is a validate questionnaire to assess depressive and anxiety symptoms in patients affected by somatic disorders admitted to general hospital. An HADS >11 was considered diagnostic for depression.

Results: The table summarises the main results. We recruited 231 patients affected by RA, finding a prevalence of depression of 19.9% (95% CI 14.4–21.3%). Overall, patients with depression, when compared with patients without were older, more frequently females, with a lower education, higher physician global assessment and patient global assessment, more comorbidities. In particular, they had any cardiovascular, neurologic or musculoskeletal issue (p<0.018, p=0.032, p=0.014, respectively) and more often used glucocorticoids or NSAIDs. Conversely, no association was found between depressive symptoms and the use of biologic therapies or the presence of inflammatory markers. Interestingly, a positive history of depression was present only in few patients with an HADS >11.

Conclusions: These preliminary results suggest that more than one every seven patients with RA could suffer from depression, thus depression might be undiagnosed in a significant number of patients. Comorbidities, anti-inflammatory medications and both physician- and patient- driven evaluation of disease burden were the most striking factors associated with depression in this cohort of patients with RA.

AB0398  INVESTIGATION OF PREOPERATIVE INTRANASAL COLONISATION IN ORTHOPAEDIC SURGERY FOR PATIENT WITH RHEUMATOID ARTHRITIS

S. Tsuji1, J. Hashimoto1, T. Naguchi2, S. Akiti2, K. Yachi2, M. Saito1, S. Ohshima1, Y. Sakei1, 1Department of Rheumatology and Allergology; 2Department of Orthopaedic Surgery; 3Department of Clinical Research, National Hospital Organization, Osaka Minami Medical Center, Kawachinagano City, Osaka, Japan

Objectives: Coagulase-negative staphylococci (CoNS) is listed as the major SSI causative organism in the field of orthopaedic surgery, but detailed report on the presence or absence of methicillin-resistant CoNS of intranasal colonisation is not found.

Methods: In 13 months from July 2016 to the end of July 2017, 1000 cases of consecutive cases in which nasal cavity culture was performed within one month prior to hospitalisation for patients scheduled for our orthopaedic surgery. 223 men, 777 women, average age 64.6 years old, 197 cases of RA patients, 803 cases except RA patients. The method of intranasal culture is as follows. After culturing for 18 hours at 35 °C using blood agar medium (daily water) and CHROMagar MRSA selective medium (Kanto Kagaku), identification of bacterial species of the genus Staphylococcus grown and cultivation of drug susceptibility tests It was carried out by BD Phoenix according to the method of the Association (CLSI).

Results: The results of intranasal culture showed that S. aureus, S. epidermidis, CoNS (excluding S. Epidermidis) and culture negative were 18.2%, 27.8%, 7.8%, and 23.9%, respectively. MRSA, MRSE and MRCoNS (excluding MRSE) with methicillin resistance were 3.2%, 22.1% and 1.7%, respectively, and 27.0% of methicillin resistant bacteria were found to exist.

Conclusions: These preliminary results suggest that more than one every seven patients with RA, the methicillin-resistant bacterial colonisation rate was significantly higher (p<0.05) than 38.6% compared with 24.2% other than RA patients.

AB0399  AUDIT OF INFLUENZA AND PNEUMOCOCCAL VACCINATIONS IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGICS

S. Selvan, Rheumatology, Basildon and Thurrock NHS Foundation Trust, Essex, UK

Background: Rheumatoid arthritis (RA) patients are at increased risk of pneumococcal and influenza disease secondary to a deficient immune system and immunosuppressive medications.1 Despite the possible reduction in vaccine efficacy in RA, prophylactic vaccination for preventing pneumococcal pneumonia and influenza in RA patients should be routinely advised and practised.2 EULAR guideline lines recommend that influenza and pneumococcal vaccinations should be strongly considered for all patients with RA.2

Objectives: To study pneumococcal and influenza vaccination rates in a cohort of RA patients on biologic medications.

Methods: We undertook a prospective audit of RA patients on biologics attending routine rheumatology clinics in a DGH over a 6 week period. A proforma was given to patients, and data was collected on medications, comorbidities, Disease Activity Score (DAS) and vaccination status for influenza and pneumococcus.

Results: Of the 25 patients audited, 17 (68%) were female and 8 (32%) were male. The average age of patients included was 59 years (range 37–75). 18 (72%) patients were seropositive, and 7 (28%) were seronegative. The patients included had the following comorbidities; 14 (56%) none, 6 (24%) thyroid disease, 1 (4%) osteoporosis, 1 (4%) hypertension, 1 (4%) type 2 diabetes, 1 (4%) interstitial lung disease.

On reviewing their medications, 7 (28%) patients were on an Etanercept biosimilar (Benepali), 2 (8%) on Tocilizumab, 2 (8%) on Rituximab, 9 (36%) on Adalimumab, 2 (8%) on an Infliximab biosimilar (Remsima), 2 (8%) on Etanercept, and 1 (4%) on Certolizumab. In addition to their biologic agent, all 25 patients were on Methotrexate. 2 patients (8%) were also on Sulphasalazine, and 2 (8%) were on Hydroxychloroquine additionally. The average DAS CRP score was 2.7. 8 (32%) patients had received both influenza and pneumococcal vaccinations, and 9 (36%) patients had neither. On analysing the vaccination rates individually, 16 (64%) patients were up to date with influenza and 7 (28%) were up to date with pneumococcal. Of the 9 patients that had neither vaccination, 5 (20%) patients were unaware of their requirement, and 3 (12%) felt they were too unwell to receive them. 1 (4%) patient was unsure whether they could have the vaccinations as they had been recruited into a research trial.

Disclosure of Interest: None declared

1365

None declared
Conclusions: Only 32% patients had received both influenza and pneumococcal vaccinations. The uptake rate for influenza vaccination was reasonable at 64%, however the rate for pneumococcal vaccination was only 28%. Vaccination assessment should be performed routinely for all RA patients in clinic and in particular those on biologic medications to reduce the risk of developing these infections in this high risk cohort.

AB0400 HIGH PREVALENCE OF COMORBIDITIES IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SOUTH AFRICA
S. Botha-Scheepers, A.G.A. Mohammed, A. Gcule, B. Hadkisson, Medicine/ Rheumatology, Groote Schuur Hospital/University of Cape Town, Cape Town, South Africa

Background: Patients with rheumatoid arthritis (RA) are at increased risk to develop comorbidities. Data on the prevalence of comorbidities in RA patients in South Africa is lacking. Poorly controlled joint inflammation, common use of glucocorticosteroids and nonsteroidal anti-inflammatory drugs, a high prevalence of smoking and obesity, together with a high burden of infectious diseases may be important risk factors for comorbidities in this population.

Objectives: To assess the prevalence of comorbidities in RA patients in Cape Town, South-Africa and the association with disease activity and DMARD use using the METEOR (Measurement of Efficacy of Treatment in the Era of Outcome in Rheumatology) database.

Methods: This is an ongoing cross-sectional study. Data from 109 RA patients from regular clinic visits at Groote Schuur Hospital in Cape Town, South Africa have been entered in the Meteor database (from December 2016). The Meteor database is a free online tool that was developed to improve the management of RA patients by helping rheumatologists to register, monitor and tightly control disease activity. The tool is currently widely used in other countries, but has it has not yet been described in any African countries. Information on the following parameters were reported: demographics, disease duration, disease activity (CDAI), current DMARDs and comorbidities.

Results: The mean age (SD) was 57.6 (14.7) years, disease duration (SD) 14.1 (14.6) years, female gender 86.7%, RF positive 85.1% and ACPA positive 80.4%. The average (SD) CDAI was 13.1 (9.8) and 49.3% were smokers. Current DMARDs used was Methotrexate (72%), Sulphasalazine (29%), Chloroquine (67%), Low dose corticosteroids (47%), Lefunomide (11%), Etanacet (1%), but no other biological agents (0%). At least one comorbidity was present in 89% of the patients, two in 40%, three in 26%, four in 13% and five in 2% of the patients. The most frequently observed comorbid diseases were hypertension (45.5%), tuberculosis (TB) (11.1%), Diabetes Mellitus Type 2 (10.9%) and osteoarthritis (10.9%). Other diseases included hypercholesterolemia (7.1%), gastro-esophageal reflux disease/peptic ulcer (6.1%), COPD/emphysema (6.1%), HIV (4.0%), hypothyroidism (4.0%), ischaemic heart disease (3.0%), liver disease (3.0%), DVT/pulmonary embolism (3.0%), malignancies (3.0%), asthma (2.0%), discolitis erythematous (2.0%), interstitial lung disease (1.0%), anaemia (1.0%), rheumatic heart disease (1.0%), cerebrovascular accident (1.0%) and depression (1.0%).

Conclusions: This study shows a high prevalence of comorbidities among indigent patients with RA in South Africa. In particular, hypertension, TB and osteoarthritis were very common. More patients will be included in this study in the next few months. Furthermore, we will assess the association between comorbidities, disease activity and DMARD use. The METEOR tool offers the unique opportunity to study daily practice care as well as research questions in real life setting in a South African clinic. This study will provide information that is necessary to address the burden of comorbidities in patients with RA in South Africa.

REFERENCE:

AB0402 RECENT ONSET RHEUMATOID ARTHRITIS HAVE AND INCREASED LEFT ANTERIOR DESCENDING CORONARY ARTERY WALL THICKNESS: EVIDENCE OF SUBCLINICAL CORONARY ARTERY DISEASE
S. Hannawi1, I. Al Salmi2, H. Hannawi2, 1Rheumatology, Ministry of Health and Prevention of UAE; 2Cardiology, Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease of the joints with several extra-articular features. Cardiovascular disease (CVD) mortality accounts for 40–50% of all deaths in RA. Apart from atherosclerotic heart disease other cardiac abnormalities had been found to be prevalent in RA; including, pericarditis, heart failure, coronary vasculitis and valve disease.

Objectives: Due to scarcity of data regarding cardiac disease in the Middle East population, we studied echocardiographic features in RA patients compared to their age, sex, and traditional CVD risk factors matched controls.

Methods: In a cross-sectional study, we recruited 39 RA patients meeting the 1987 revised criteria of RA and 37 age, sex and traditional CVD risk factors matched controls. Standard trans-thoracic echocardiography examination was carried out by a specialties cardio-sonographer who was blinded to the status of the participants. Left ventricular dimensions, wall geometry, ejection fraction, diastolic parameters, right ventricular size and function, valve structure and function, pericardium, pulmonary pressures and aortic root dimensions were assessed by echocardiography. t-test and chi-2 test were used to compare the echocardiographic findings between the two groups. P value of<0.05 was considered significant.

Results: Thirty-nine RA patients (34 F, 4 M) and 37 controls (32 F, 5 M) were studied. Among RA, 27 (69%) were RF positive. The two groups were similar in terms of age (p=0.86), gender (p=0.71), and traditional cardiovascular risk factors. No significant difference was found between RA and the controls in term of left ventricular ejection fraction, wall geometry, diastolic parameters, right ventricular size and function, valve disease, pulmonary pressures, pericardium and aortic root dimensions. However, left ventricular end-diastolic diameter (43.1±1.14 vs. 39.3±0.6 mm respectively, p=0.01), end-systolic diameter (24.3±0.7 vs. 26.9±0.96 mm, respectively, p=0.03) and Left ventricular mass index (79.8±3.11 vs. 63.6±3.15, respectively, p=0.01) were significantly higher in RA patients than in the controls.

Conclusions: Patients with rheumatoid arthritis have higher left ventricular end-diastolic and end-systolic dimensions, and greater left ventricular mass index compared to their age, sex and traditional CVD risk factors-matched controls. As the increase in the left ventricular mass index is a predictor of cardiac sudden death, echocardiography might be a simple non-invasive tool for cardiac risk screening in RA.

AB0401 ECHO-CARDIOGRAPHIC ABNORMALITIES IN RHEUMATOID ARTHRITIS PATIENTS COMPARED TO AGE AND SEX-MATCHED CONTROLS
S. Hannawi1, K. Naeem2, 1Rheumatology, Ministry of Health and Prevention of UAE; 2Cardiology, Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease of the joints with several extra-articular features. Cardiovascular disease (CVD) mortality accounts for 40–50% of all deaths in RA. Apart from atherosclerotic heart disease other cardiac abnormalities had been found to be prevalent in RA; including, pericarditis, heart failure, coronary vasculitis and valve disease.

Objectives: Due to scarcity of data regarding cardiac disease in the Middle East population, we studied echocardiographic features in RA patients compared to their age, sex, and traditional CVD risk factors matched controls.

Methods: In a cross-sectional study, we recruited 39 RA patients meeting the 1987 revised criteria of RA and 37 age, sex and traditional CVD risk factors matched controls. Standard trans-thoracic echocardiography examination was carried out by a specialties cardio-sonographer who was blinded to the status of the participants. Left ventricular dimensions, wall geometry, ejection fraction, diastolic parameters, right ventricular size and function, valve structure and function, pericardium, pulmonary pressures and aortic root dimensions were assessed by echocardiography. t-test and chi-2 test were used to compare the echocardiographic findings between the two groups. Results: Thirty-nine RA patients (34 F, 4 M) and 37 controls (32 F, 5 M) were studied. Among RA, 27 (69%) were RF positive. The two groups were similar in terms of age (p=0.86), gender (p=0.71), and traditional cardiovascular risk factors. No significant difference was found between RA and the controls in term of left ventricular ejection fraction, wall geometry, diastolic parameters, right ventricular size and function, valve disease, pulmonary pressures, pericardium and aortic root dimensions. However, left ventricular end-diastolic diameter (43.1±1.14 vs. 39.3±0.6 mm respectively, p=0.01), end-systolic diameter (24.3±0.7 vs. 26.9±0.96 mm, respectively, p=0.03) and Left ventricular mass index (79.8±3.11 vs. 63.6±3.15, respectively, p=0.01) were significantly higher in RA patients than in the controls.

Conclusions: Patients with rheumatoid arthritis have higher left ventricular end-diastolic and end-systolic dimensions, and greater left ventricular mass index compared to their age, sex and traditional CVD risk factors-matched controls. As the increase in the left ventricular mass index is a predictor of cardiac sudden death, echocardiography might be a simple non-invasive tool for cardiac risk screening in RA.

Factors contribute to the level uric acid in rheumatoid arthritis

S. Hannawi1, A. al Salmi2, H. Hannawi2, Rheumatology, Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates; 2The Royal Hospital, Muscat, Oman; 3Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates

Background: Uric acid (UA) is a strong correlate of renal dysfunction in rheumatoid arthritis (RA), even in the absence of crystal deposition, by causing endothelial dysfunction, intrarenal vascular disease and renal impairment. In hyper or normo-uricemia RA, UA was the strongest independent predictor of GFR, even after adjustments for most of the potential confounding factors. Additionally, in RA patients UA had been found to be an independent predictor of hypertension and cardiovascular disease (CVD).

Objectives: This study aimed to investigate what could be the determinants of the UA level in RA patients.

Methods: RA patients with no clinically evident gout, CVD, thyroid disease, liver or renal disease were studied. Serum UA was obtained for all the patients. Renal function parameters, RA disease characteristics, inflammatory markers, and traditional CVD risk factors relation to uric acid level was examined using simple linear regression analysis. To test for the independence association between uric acid and variables of interest, multiple model was built for the same dependent and independent variables. Statistical significance was accepted at p-value<0.05.

Results: The study recruited 86 consecutive patients attending routine outpatient clinics at the Department of Rheumatology. Basic demographics and clinical characteristics of the group were obtained. Of the total 86 patients, 10% were men and 77% (89%) were women. The mean age of the participants was 47±14 years, with mean RA duration of 68±87 months. 64 out of 86 participants (74%) had RA disease characteristic variables. The mean UA value was 255±86 μmol/l, (NR: 180–340). The mean GFR, calculated using modified MDRD (Modification of Diet in Renal Disease) formula was 133±52 ml/min/1.73m².

Using univariate analysis revealed a positive linear relationship between uric acid level and each of the age of the participants (p=0.016, CI: 0.31, 2.92), age at RA symptoms onset (p=0.04, CI: 0.025, 0.039), age at RA diagnosis (p<0.03, CI: 0.101, 2.565), systolic blood pressure (p=0.04, CI: 0.054, 2.167), diastolic blood pressure (DBP) (p=0.02, CI: 0.332, 3.777), monocytes absolute count (p=0.014, CI: 2.510, 4.801), monocytes percentage (p<0.005, CI: 34.599, 193.595), cholesterol level (p=0.008, CI: -39.934, 6.286), Triglyceride level (p=0.04, CI: 0.064, 56.546), urea level (p=0.001, CI: 9.356, 28.743), creatinine (p=0.001, CI: 2.345, 3.960), urinary microalbumin (p=0.024, CI: 0.0296, 0.399), urinary microalbumin/creatinine ratio (p=0.006, CI: 0.791, 4.616), and ferritin level (p=0.025, CI: 0.044, 0.633).

As well, univariate analysis revealed a negative linear relationship between UA level and GFR (p<0.001, CI: 1.127, 0.486).

Building a multiple model, including the entire variable with significant association with the UA in the univariate analysis showed that the UA level in RA is determined by GFR, microalbumin creatinine ratio, cholesterol level, monocytes count, and DAS score. The adjusted R2 of the model was 54%.

Conclusions: Whether serum uric acid is merely a marker that reflects the integration of co-morbidities and subclinical renal impairment or a true risk-causative factor for CVD outcome remains as an important question, therefore it is important to know the determinant of UA level and control it.

APelin concentrations are associated with a reduced left atrial volume index and improved systolic function in patients with rheumatoid arthritis

S. Gunter, C. Robinson, L. Tsang, P.H. Dessein, A.M. Millen, 1Cardiovascular Pathophysiology and Genomics Research Unit, University of Wilhamsradd, Johannesburg, South Africa; 2Free University Brussels, Brussels, Belgium

Background: We recently reported that apelin concentrations are associated with reduced atherosclerosis and plaque vulnerability as well as improved aortic function in rheumatoid arthritis (RA)1,2. These relations were influenced by RA characteristics1,2. Besides protecting against atherosclerosis, apelin is also a vasodilatory peptide that improves cardiac contractility. In this regard, patients with RA experience a 2-fold increased risk of developing heart failure3. RA patients often demonstrate diastolic dysfunction and heart failure with a preserved ejection fraction (HFpEF). Traditional cardiovascular risk factors do not fully explain the increased heart failure incidence in this population. Metabolic risk factor driven inflammation is highly implicated in HFpEF.

Objectives: This study aimed to determine whether apelin can impact left ventricular function in RA and whether disease characteristics can modify this potential effect.

Methods: Relationships of apelin concentrations with echocardiographically determined markers of systolic and diastolic function including stroke volume, endocardial fractional shortening, midwall fractional shortening, ejection fraction, relative wall thickness, left ventricular mass, mitral inflow (E/A), filling pressure (E/e') and left atrial volume index (LAVI) were determined in multivariable regression models among 169 patients without established cardiovascular disease.

Results: In demographic characteristic adjusted analysis, rheumatoid factor (RF) positivity, joint deformity counts, and CRP were associated with increased apelin concentrations (p=0.01, 0.02 and 0.05, respectively). Apelin was associated with a reduced LAVI ([l(SE)=−4.6 (2.2); p=0.04]) but not with E/A, lateral e'/e' or e/A (p>0.05 for all). RA characteristics including disease duration, CRP, erythrocyte sedimentation rate (ESR), RF positivity, and joint deformity counts did not impact apelin concentration-diastolic function marker relationships (interaction p values>0.05).

Apelin levels were associated with increased endocardial fractional shortening ([l(SE)=5.99 (2.97); p=0.04]) and midwall fractional shortening ([l(SE)=−6.92 (3.0); p=0.03]). The ESR and anti-citrullinated peptide antibody (ACPA) status impacted the apelin level-endocardial fractional shortening relationships (interaction p=0.05 and 0.01, respectively). In stratified analysis, apelin concentrations were associated with improved endocardial fractional shortening in those with ([l(SE)=−14.1 (3.9); p=0.001] but not without an ESR >12 mm/hr (median value), and in those with ([l(SE)=−8.2 (3.7); p=0.03] but not without ACPA positivity.

Conclusions: In RA, apelin concentrations are associated with a reduced LAVI irrespective of RA activity and severity characteristics. Apelin concentrations are also associated with improved endocardial fractional shortening in patients with RA, particularly in those with high-grade inflammation and ACPA positivity. Whether apelin can improve left ventricular systolic and diastolic function in RA merits further exploration in longitudinal studies.

The aim of our study is to reveal recent clinical features and problems of elderly onset rheumatoid arthritis in ultra-ageing society—single centre retrospective cohort study

T. Kurusawa, Y. Okada, A. Shibata, S. Saito, K. Chino, A. Okuyama, H. Takei, T. Kondo, K. Amano, Department of rheumatology and clinical Immunology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan

Background: Japan is the ultra-ageing society ahead of any other country in the world, which ageing rate (the ratio of the population aged 65 and older to the total population) was reported to be 27.3% on October 1, 2016. The rate of aged patients, who followed up at the division of rheumatology in Saitama medical centre, had exceeded 40%.

Objectives: The aim of our study is to reveal recent clinical features and problems of elderly onset rheumatoid arthritis (EORA) patients for better management.

Methods: Patients had a diagnosis by 1987 classification criteria or 2010 ACR/ EULAR criteria. We firstly listed up RA patients who followed up our hospital from April 1 to September 30, and above aged 65 years old as of September 30. Then we retrospectively collected clinical information of EORA patients who onset
above 60 years old, diagnosed and made starts of treatment in our hospital, and observed more than 6 months, from medical records.

**Results:** One hundred eighty eight EORA patients were enrolled in this study. Female were 116 (62.0%). Mean observation period from first visit until September 30, was 68 months. Rheumatoid factor positive rate was 67.0%. Anti-CCP antibody-positive was 68.2% (107/157), and most of them (65.5%, 70/107) had high antibody titer over 100 U/mL. At the time of diagnosis, average CRP was 3.1 mg/dL. Respiratory complications were seen in 26.1% (49 cases), including 28 interstitial lung disease, 10 COPD/emphysema, 7 non-tuberculous mycobacteriosis/obstructive tuberculosis, and 8 bronchectasis. Other complications were diabetes 16.5% (past 25 cases, new 6), hypertension 38.3% (past 66, new 6), and hyperlipidemia 23.9% (past 33, new 12). Histories of cerebrovascular or cardiovascular events were seen in 10.6% (20 cases), and history of malignancy was seen in 6.9% (13 cases). During observation period, newly developed malignancy was seen in 14 cases (14/1000 person-years) including 4 MTX related lymphoproliferative disorders (MTX-LPD), 3 gastrointestinal cancer, 3 gynaecological cancer, 2 lung cancer, and so on. Infectious adverse event were occurred in 35 patients (35.3/1000 person-years). From the point of treatment, corticosteroids were prescribed in 32%, csDMARDs 88%, and biological DMARDs (BIO) 47%. Of 89 EORA patient treated with BIO, average DAS28-ESR was 5.77, and HAQ-DI 1.48 at the baseline. Twenty-nine cases were started to treat with BIO as monotherapy, 13 cases as switching to BIO from csDMARDs, and 47 as addition BIO to csDMARDs. During observation period, reasons of cessation of the first BIO were remission in 21, adverse events in 19 (7 infections, 6 injection-site/infusion reaction, 3 malignancies, and so on), insufficient response in 16, and patient’s hope in 2.

**Conclusions:** RF/anti-CCP antibody positive rate was lower than general RA population, but slightly higher than previous reports on EORA.1,3 BIO could be discontinued in 24% of 89 patients who received BIO because of remission. On the other hand, the frequency of infection and malignancy was still higher in EORA patients. So it is necessary to adjust anti-rheumatic therapy for poor prognostic cases, and we should be careful to follow up EORA patients.

ANALYSIS OF THE CORRELATION OF COMPOSITE INDICATORS OF ACTIVITY OF THE DISEASE AND THE CONCORDANCE BETWEEN THE DIFFERENT STATES OF ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Fontana, B. Ferreira Althot, C. Janson Ferreira, Y. Alfarro, G. Ricardo Werner De Castro, I. Alves Pereira, Rodovia Antonio Luís De Moura Gonzaga, Unisul Pedra Branca, Florianópolis, Brazil

Background: Rheumatoid arthritis (RA) is an inflammatory joint disease of systemic involvement and varied evolution, which uses different disease evaluation scores. It is essential that these instruments be evaluated according to the disease, so that the treatment algorithms can be applied independently.

Objectives: To analyse a correlation of disease activity indexes (ICADs) and a concordance between different states of activity in patients with Rheumatoid Arthritis.

Methods: Cross-sectional study based on 100 patients of outpatient care from a multicenter prospective cohort study. Approved by CEP UNISUL. Statistical analysis by the SPSS 18.0 program, using the Pearson Correlation Coefficient and McNemar-Bowker Concordance, considering significance level p<0.05.

Results: Majority female patients (86%), with an average age of 54 years, who were active in their jobs (53%) and had a positive rheumatoid factor in 65%. The average values of the ICADs were DAS-28 (3.6), DAS-28 PCR (3.0), SDAI (13.4), CDAI (12.5) and RADAI (3.5), respectively. Many were classified with moderate disease activity of the disease. The degree of correlation was very strong (>0.8) and strong (between 0.8 and 0.6) in most ICADs and a concordance of remission DAS-28PCR ranged from 41.3% to 54.3% with the other ICADs.

Conclusions: The ICADs presented a strong correlation with each other, as well a level of similarities in the classification of the different degrees of activity. These results confirm that in different patients with RA, the ICADs serve to define active disease and to aid in the treatment strategy, so it is not imperative to use only a single evaluation score.

DIAGNOSIS OF LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS, A PROSPECTIVE MONOCENTRIC STUDY

V. Huber Sommer1, S. Hirsch2, M. Chana3, R. Reiften1, E. Chatelus1, R-M. Javier, C. Sordet1, L. Arnaud1, J. Sibilia1, J-E. Gottenberg1, H. Petit2.1 Rheumatology, 2Pulmonology, 3Radiology, Strasbourg University Hospital, Strasbourg, France

Background: Respiratory involvement in rheumatoid arthritis (RA) is the most common extra-articular localisation, affecting 50% of patients, even though only 5% become symptomatic. Lung pathology as RA related interstitial lung disease is associated with significant morbidity and mortality. Involvement of the respiratory system seems frequent but remains underestimated because of the absence of guidelines about its detection in patients with RA.

Objectives: This study aimed at determining the prevalence of respiratory involvement among symptomatic and asymptomatic patients with rheumatoid arthritis managed in a university hospital.

Methods: We conducted a prospective observational study from May 2017 to January 2018 at the Strasbourg University Hospital. The patients included were over 18 years of age, had rheumatoid arthritis according to the ACR/EULAR 2010 criteria and signed informed consent. They responded to a self-administered questionnaire about their medical history, cardiopulmonary symptoms and lifestyle. Epidemiological, clinical and radiological data were assessed. All of the patients had a chest computed tomography (CT) and respiratory function tests (RFT). A collection of salivary flow and a test of Shimer were carried out, to investigate the presence of a sicca syndrome. Chest CTs were interpreted by a radiologist specialised in lung area.

Results: We included 102 successive patients, 73 women and 29 men. The average disease duration was 34 years. 60 patients were seropositive for rheumatoid factor and 68 for anti-CCP. 59 patients had bone erosions. The average disease activity score (DAS28-PCR) at inclusion was 3.5, 49 patients had associated Sjogren’s syndrome. 22 were active smoker. 43 patients were taking long-term corticosteroid therapy. 96 patients were treated with conventional DMARD treatment, 28 with anti-TNF alpha therapy, 16 with Tocilizumab, 12 with Abatacept, 2 with JAK selective inhibitor, and 18 patients were under Rituximab therapy. Of the 87 RFT performed, 39 were abnormal: 14 reported an obstructive syndrome, 8 a restrictive syndrome, 32 peripheral expiratory braking, suggestive sign of bronchiolitis, and 24 a decrease in the DLCO. Of the 91 chest CTs, 42 revealed lung nodules (42%), 15 of which were more than 6 mm; 29 interstitial syndrome (29%), among which 5 were non-specific interstitial pneumonitis (PINS), 3 common interstitial pneumonitis (Pic), and the other were non specific interstitial syndrome. 2 chest CT showed pleural effusion and 1 peri-carditis. 44 patients had coronary calcifications, among whom 32 had no lipid-lowering therapy.

Conclusions: Pulmonary systemic assessment of RA patients show high prevalence of respiratory involvement: 42% of patients had lung nodules and 29% had an interstitial syndrome. Detection of interstitial lung disease may raise questions about RA treatment such as anti-TNF alpha therapy. Rheumatologist should be more aware of respiratory involvement in RA patients and RFT, a non-invasive test, might be useful at diagnosis and follow-up.

AB0411

RISK OF REACTIVATION OF HEPATITIS B VIRUS IN RHEUMATOID ARTHRITIS PATIENTS WHO RECEIVED LONG-TERM LOW DOSE CORTICOSTEROID THERAPY

W. Jeong1, J. Kim2, E.J. Park3, B.-C. Song4. 1Rheumatology, Jeju National University Hospital, Jeju-Si; 2Rheumatology, National medical center, seoul; 3Hepatology, Jeju National University Hospital, Jeju-Si, Korea, Republic of Ireland

Background: It is well known that the use of corticosteroids results in increased viral replication and elevated ALT in patients with hepatitis B virus. The use of high dose corticosteroids for more than 4 weeks usually results in hepatitis worsening after cessation of steroids. However, few studies have investigated the effect of low dose corticosteroids on hepatitis B virus (HBV) reactivation.

Objectives: The aim of this study is to investigate the reactivity of HBV in rheumatoid arthritis (RA) patients treated with long term low dose corticosteroids and its risk factor.

Methods: Patients with HBsAg positive who were diagnosed with RA and who received prednisone of less than 10 mg/day over four weeks and immunosuppressive agent were selected at four university hospitals in South Korea between June 1996 and March 2017. Medical records and laboratory data were retrospectively analysed and multivariate analysis was performed.

Results: One hundred forty five patients were included in the study and 26 (17.9%) patients were reactivated with HBV. Mean age at diagnosis of RA was 50.7 years and 41 (28.3%) patients were male. Baseline characteristics including sex, age and laboratory findings at diagnosis of rheumatoid arthritis were not significantly different in patients with HBV reactivation compared to those without HBV reactivation. The average daily dose of prednisolone was 0.05±0.0 mg and the mean duration of prednisolone was 5.1±±0.05 years and the average cumulative dose of prednisolone was 5821±701.3 mg. Eleven (42.3%) of 26 HBV reactivated patients were reactivated within one year after prednisolone administration and the period from the start of prednisolone administration to the reactivation was 4.7±±0.77 years on average. The duration of prednisolone administration, mean daily dose of prednisolone, and cumulative prednisolone dose and administration of methotrexate, tacrolimus, tumour necrosis factor inhibitor and hydroxychloroquine did not significantly affect HBV reactivation in both univariate and multivariate analyses. However, the administration of leflunomide showed a significant difference in the reactivation of HBV (adjusted odd ratio 3.76; p=0.04).

Conclusions: The hepatitis B virus can be exacerbated by spontaneous viral reactivation, so it is difficult to conclude that hepatitis is caused by the administration of steroids. In this study, the administration of low-dose steroids did not affect the reactivation of HBV. However, leflunomide increased the risk of HBV reactivation when the effects of other disease modifying antirheumatic drug (DMARD) were corrected. Therefore, a prospective study is needed to evaluate the effect of DMARDs on HBV reactivation in the long–term administration of low–dose corticosteroids in RA patients.

DYNAMICS OF QUANTITATIVE BODY COMPOSITION INDICES BY THE METHOD OF DUAL-ENERGY X-RAY ABSORPTIOMETRY (DRA) IN PATIENTS WITH EARLY RA DEPENDING ON THE ACHIEVED ACTIVITY OF THE DISEASE

T. Popkova, L. Kondratyeva, A. Smirnov, E. Nasonov. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

Background: Adipose tissue an active endocrine organ. In pts with RA the redistribution of body fat mass. Using BMI and WC do not allow to distinguish between fat and lean (muscle) mass. Performing dual-energy X-ray absorptiometry allows to specify the quantitative composition of the body (mass of adipose tissue and muscle) in pts with early RA.

Objectives: to compare the indicators of the quantitative composition of the body in groups of RAPts with different disease activity before and after the appointment of therapy.

Methods: included 37pts with early RA(ACR/EULAR2010), 57 [46.5, 62] yrs, duration of disease 6 [5.5, 15.5]mths, IgMRF seropositive anticCP, with high RA activity(DAS285.5 [5.1, 6], SDAI 32.4 [22, 4, 2], CDAI 29 [17.9, 39.5]). After inclusion in the study, all pts started receiving MTX 10 [10–15 mg/week], after 12 weeks, with ineffective MTX, ADA 40 mg2 weeks was prescribed. The quantitative composition of the body was determined initially and after 6mths by means of DXA using the apparatus Hologic, analysing the following parameters: the total, of fat and lean mass.

Results: By the 24th week of therapy, 13 (35%)pts with early RA received combined therapy(ADA, MTX), 24 (65%) pts with RA monotherapy MTX. Depending on the activity of RA[1](a)by the 24th week of therapy, pts are divided into 2groups: I(n=18) pts with remission/low activity, II(n=19) with moderate/high RA activity (table 1). Initially, the groups differed in fat mass: this index was higher in the group of pts with moderate/high activity persisting, compared with the group of pts with remission/low activity of RA: 30.2 kg versus 19.4 kg. In the I group of pts before the treatment and after 6mths of therapy, a statistically significant decrease in muscle mass was observed: from 45.2 kg to 41.6 kg. A decrease in the mass of adipose tissue after 24 weeks of therapy was noted in the l igroup of pts with RA: from 30.2 kg to 28.2 kg. The difference in the indices between the groups by the 6 month of therapy was noted for the mass of adipose tissue. This composition of the body score was also higher in pts with moderate and high RA activity, compared to the group of pts with remission/low RA activity: 28.2 kg versus 19.9 kg (p<0.05 in all cases).

*p<0.05, **p=0.05 differences in factors before and after treatment and after 6mths(Willcox).

Conclusions: pts with RA who achieved l group after 6 mths of therapy initially had a smaller volume of adipose tissue, compared with pts with moderate and high RA activity. Despite the achievement of remission after 6mths of therapy, a loss of lean mass (probably the development of rheumatoid cachexia) continued in some pts, but these data need confirmation in studies with a large number of pts and a longer period of follow-up.

NODULAR POLYARTERITIS AS AN UNFORESEEABLE ADVERSE REACTION IN RA PATIENT TREATED WITH TOFACITINIB

Y. Muraviev1, S. Radenska-Lopovok2, V. Lebedeva1, S. Alamankina1. 1Federal State Budgetary Institution «Research Institute of Rheumatology» under the Russian Academy of Medical Sciences; 2I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Tofacitinib basic prescribing information and guidelines for medical use do not provide any description of such adverse drug reaction (ADR) as vascu- litis, in particular polyarteritis nodosa. We present a clinical case of vasculitis emerging during tofacitinib therapy.

Objectives: demonstration of an unexpected reaction to tofacitinib

Methods: A 59 y.o. RA female patient was hospitalised in December 2016 due to eruption of indurated nodules on her hips and legs producing sharp pain, ulceration of nodules on the legs, painful hip and ankle joints, and morning stiffness lasting for about one hour.

Results: Seropositive RA was diagnosed in this patient in April 2004 with subsequent DMARD with methotrexate (MT) at 7.5 mg/week. The remission achieved

Disclosure of Interest: None declared

Oxytocin (OXT), also referred to as a happy hormone, has been shown to influence the development of vasculitis (polyarteritis nodosa) in RA patient can

Conclusions:

The serum OXT levels were correlated with the disease duration (r=0.443, p=0.000). Weak correlations of MTX dose (r=0.208, p=0.030), swollen joint count (SJC) (r=-0.306, p=0.001), ESR (r=-0.245, p=0.010), CRP (r=-0.283, p=0.003) and the mental component summary (MCS) score (r=-0.196, p=0.041) of SF-36. The binomial logistic analyses findings were as follows: younger age (p=0.0209, odd ratio: 0.96, 95% CI: 0.94-0.99) and longer disease duration (p=0.0053, odd ratio: 1.08, 95% CI: 1.02–1.13). Other items did not correlate to the serum OXT levels included with the HAM-D score.

Conclusions: The serum oxytocin levels were correlated with longer disease duration and younger age.

Rheumatoid arthritis – biological DMARDs

DISEASE FLARES AMONG EARLY RHEUMATOID ARTHRITIS PATIENTS TREATED WITH CONTINUED METHOTREXATE EITHER ALONE OR IN COMBINATION WITH ADALIMUMAB

A. Kavankaev1, R. van Vollenhoven2, P. Sunkureddi3, Y. Zhang4, J. Subotnick4, J. Smolen1. 1Division of Rheumatology, Allergy, and Immunology, University of California San Diego, La Jolla, USA; 2Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands; 3University of Texas Medical Branch, Galveston; 4AbbVie Inc., North Chicago, USA; 5Division of Rheumatology, Department of Medicine, Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background: Some rheumatoid arthritis (RA) patients (pts) may experience flares in their disease even after reaching stable low disease activity (sLDA), but the consequences of even temporary elevations in disease activity are poorly understood.

Objectives: The purpose of this analysis was to explore the rates of flares after reaching sLDA in pts treated to target with either methotrexate (MTX) monotherapy or adalimumab combination therapy (ADA+MTX).

Methods: This post hoc analysis included pts from the randomised, double-blind, double-period OPTIMA trial achieving sLDA [DAS28(CRP) <3.2] for at least 28 wks (wk 22 and 26) at the end of period 1 (P1). In P1, pts were randomised to receive ADA +MTX or placebo (PBO) +MTX for 26 wks. Pts on ADA +MTX achieving sLDA were randomised to receive PBO +MTX (ADA Withdrawal) or continue on ADA +MTX (ADA Continuation) for an additional 52 wks in period 2 (P2). Pts who achieved sLDA on PBO +MTX in P1 continued their treatment in P2 (MTX Continuation). Pts achieving sLDA in each treatment group were categorised based on whether they experienced a flare (change in DAS28(CRP) >0.6 at consecutive visits and DAS28(CRP) >3.2); the proportion of pts experiencing flares and time to flare were assessed. For each group, mean change from wk 26 to wk 78 as disease activity [DAS28(CRP)], functional (HAQ-DI) and structural (mTSS) measures were analysed.

Results: In pts achieving sLDA at the end of P1, flare rates in P2 differed based on initial treatment assignment (ADA Continuation: 11.7% [11/94]; MTX Continuation: 22.4% [22/98]). Interestingly, flare rates in pts randomised to withdraw ADA in P2 (ADA Withdrawal: 25% [22/88]) were numerically similar to the MTX Continuation group. The mean time to flare was 193, 191, and 177 days in the ADA Withdrawal, ADA Continuation, and MTX Continuation groups, respectively. During P2, the mean DAS28(CRP) scores were predictably higher in pts who flared compared with those who did not across treatment groups. In pts experiencing flares in P2, disease activity and functional measures worsened from wk 26 to wk 78 as compared with pts without flares (table 1). Of the individual DAS28(CRP) components, pt global assessment of disease activity (PtGA) showed the greatest worsening. There were small differences in radiographic progression between pts experiencing flares compared with pts without flares.

∗Flare was defined as change in DAS28(CRP) >0.6 at consecutive visits and DAS28(CRP) >3.2.
LDA—low disease activity; DAS28(CRP)=28 joint disease activity score based on C-reactive protein; ADA=adalimumab; MTX=metotrexate; HAQ-DI=health assessment questionnaire disability index; mTSS=modified total Sharp score.

Background: In early RA pts achieving sLDA, flares were generally infrequent; however, they were more prevalent in pts receiving PBO+MTX compared with ADA+MTX. Flares were numerically associated with higher disease activity, functional deterioration, and higher PGA, underlining its impact on health-related quality of life and the importance of preventing flares as a therapeutic outcome.

AB0416 

ESTIMATING THE SHORT-TERM COSTS ASSOCIATED WITH NON-MEDICAL SWITCHING IN RHEUMATIC DISEASES

A. Gibofsky†, V. Garg‡, M. Yang§, C.Z. Qi*, M. Skup‡. 1Hospital for Special Surgery-Well Cornell Medicine, New York; 2AbbVie, Chicago; 3Analysis Group, Inc., Boston, USA

Background: As biosimilars are approved and commercialised for rheumatic diseases, patients may be switched from originator biologic treatment to biosimilars due to perceived cost savings between the two biologic products. However, in the short term, non-medical switching (NMS) may require additional patient education, office visits, lab/imaging tests, and administrative support which could lead to substantial costs.

Objectives: To estimate the short-term costs associated with NMS from originator biologics to biosimilars among stable patients with rheumatic conditions (e.g., rheumatoid arthritis, RA; ankylosing spondylitis, AS; psoriatic arthritis – PsA) from the perspective of a rheumatology medical centre in the United Kingdom.

Methods: An economic model was constructed including two components: the administrative burden for NMS program set-up and support, and the provider burden for initiating and managing NMS. Administrative burden was modelled at the center-level and considered staff time for program set-up, patient education, scheduling, documentation, and departmental meetings from pre-NMS planning to post NMS implementation (<1 year). The provider burden was modelled at the patient-level and considered the expected additional provider time needed and extra laboratory/imaging tests when managing NMS from the time of switching until 3 month post NMS implementation. Model inputs for the administrative burden came from the literature and for provider burden from survey of physicians. Literature was used to inform both the total number of rheumatology patients that underwent NMS, and the unit cost associated with provider/staff time and laboratory/imaging tests.

Results: From a rheumatology centre perspective, setting up an NMS program and the subsequent administrative support was estimated to cost £19 617 per centre, attributed to general overhead (40%), pharmacist time (26%), consultant time (21%), and nurse time (13%). After the set-up, provider burden for initiating and managing NMS was estimated to be £113 per switched patient. Assuming 5000 patients with relevant rheumatoid conditions in a centre, 572 stable patients with RA, PsA or AS were estimated to switch to biosimilars. The overall short-term cost associated with NMS was estimated to be £84 174 for the entire centre, with 23% attributed to the NMS program set-up and support, and 77% attributed to extra provider time and monitoring (on average £147 cost per switched patient).

Conclusions: Switching stable patients with a rheumatic condition from originator biologics to biosimilars could have considerable short-term costs for a centre. Additional real world studies are needed to better weigh the potential saving vs. cost associated with NMS.

AB0417 

BIODRUGS IN THE TREATMENT OF RHEUMATOID ARTHRITIS: REAL LIFE DATA IN A BRAZILIAN MULTICENTRIC STUDY

Background: Rheumatoid arthritis (RA) is a chronic disease, characterised by inflammatory involvement of the synovial joints. The “treat to target” concept is well established in the rheumatologic community, however, in many patients, especially in developing countries, its implementation is not feasible. Considering the high costs of treatment com of RA and the limited national epidemiological data available on this disease, we sought to describe the profile of use of biologi- cal drugs in Brazilian patients with RA to help the decision-making process by public health managers.

Objectives: To describe the frequency and time of use of biological drugs in Bra- zilian patients with rheumatoid arthritis.

Methods: The REAL – RA in real life in Brazil – is a multicenter prospective cohort study, with twelve-month follow-up period. To be included in this study, consecu- tive patients from 11 tertiary rheumatology centres had to meet the 1987 ACR or the 2010 ACR/European League Against Rheumatism (EULAR) criteria. Data were collected during routine clinical care and previous medical records were used as secondary sources. The present study present data taken from the particip- ants’ initial assessment. This research was approved by the Ethics Committees of each centre.

Results: A total of 1125 patients were analysed. 89% were women with a mean age of 56.6 years. The main clinic data were: DAS 28 (median)=3.52, HAQ (median)=0.87 and CDAI (median)=9. 1022 (90.84%) used synthetic DMARDs
and 406 (36.09%) biologic therapy. The frequency of use of the biologic therapy was: abatacept (73 patients/6.49%), etanercept (66/5.87%), tocilizumab (60/5.33%), adalimumab (54/4.8%), infliximab (50/4.44%), rituximab (49/3.66%), golimumab (37/3.29%), certolizumab (17, 1.51%). The time of use of the biological drugs is presented in table 1.

### Conclusions

The therapeutic profile of this cohort of Brazilian RA patients shows some interesting results. The relatively high number of patients on biologics, compared to other studies, may be related to the fact that the centres involved were reference centres, probably dealing with more difficult cases.

### AB0418

THE EFFECT OF CONCOMITANT METHOTREXATE ON SERUM TNF INHIBITORS LEVELS AND CLINICAL RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS IS DOSE DEPENDENT AND GREATER THAN OTHER DMARDs

A. Martinez-Feito, C. Plascencia, V. Aravotto-Compan, B. Hernández-Breijo, M. A. González, I. Monojo, L. Nuño, P. Nozal, D. Pascual-Salcedo, A. Balsa. Immuno-Rheumatology Research Group, University Hospital LA PAZ, Madrid, Spain

### Background

Several factors influence the pharmacokinetics (PK) of TNF inhibitors (TNFi). One of the most relevant influencing factors is the development of drug antibodies (ADA), which is associated with low circulating drug levels and loss of clinical efficacy. Previous studies, mostly about Adalimumab (Ada), have demonstrated a beneficial effect of concomitant use of methotrexate (MTX) in patients (pts) under TNFi therapy by reduction of immunogenicity. There are other csDMARDs (OD) as lefunomide, hydroxychloroquine or sulfasalazine which may have also an effect on PK.

### Objectives

To investigate the effect of csDMARDs on the presence of serum TNFi levels and on the clinical response during the first year of Ada or Infliximab (IFX) treatment in RA pts. Secondly, to evaluate if MTX has a dose-dependent effect on these outcomes.

### Methods

This is an inception cohort including pts with RA starting IFX or ADA in a tertiary hospital since 1999. At baseline, 6 and 12 months clinical (DAS28, EULAR response and dDAS28) and serological (drug and ADA levels) parameters were measured. Patients were clustered according to the use of concomitant csDMARDs at baseline in three groups: [i] TNFi monotherapy; [ii] TNFi + MTX (≤ 15 mg/week); [iii] TNFi + OD. Pts within the TNFi + MTX group were also classified according to the MTX dose: MTX <15 mg/week (TNFi + MTX <15) and MTX >15 mg/week (TNFi + MTX >15).

### Results

- A total of 92 RA pts [Ada(n=25) or IFX(n=67)] under TNFi were included. The number and percentage of pts in each group were as follows: TNFi monotherapy, 12 pts (13%); TNFi + MTX, 99 pts (84%); TNFi + OD 21 pts (22%). According to MTX dose, the distribution was: TNFi + MTX ≤ 15,18 pts (20%); TNFi + MTX >15, 41 pts (45%). Considering the overall of pts receiving any dose of MTX, the percent-age of them with drug levels after 12 months (71%) was numerically higher than in the other groups (20% in TNFi + OD and 9% in TNFi monotherapy, p<0.1). However, after stratifying pts by MTX dose, we observed that circulating drug levels at 12 months were more frequent in higher dose of MTX (54% of the pts with TNFi + MTX >15) compared to patients with TNFi + MTX <15 (17%), with TNFi + OD (20%) and with TNFi monotherapy (9%); p<0.002). According to EULAR response, pts treated with TNFi + MTX (81%) achieved more frequently a good response compared with the other groups (11% on TNFi + OD and 8% on TNFi monotherapy, p=0.6). Moreover, differences on clinical response were observed depending on MTX dose. While 58% with TNFi + MTX > 15 were good EULAR responders, 23% with TNFi + MTX <15 achieved this. Overall, the best effect on clinical response was observed in the group of MTX: p<0.4. Finally, the TNFi median survival time (months) was significantly higher in pts with TNFi + MTX than in pts with TNFi + OD or on TNFi monotherapy (5 years vs 2 years vs 2.15 years, respectively; p=0.03). Analysing by MTX dose, drug survival was superior for high (>15) and low MTX doses (<15) (58% and 3.3, respectivelly) compared to OD and TNFi monotherapy although the differences was not statistically significant (p=0.09).

### Conclusions

In RA pts under Ifx or ADA treatment, the presence of TNFi in serum, the clinical response and the TNFi survival are influenced by MTX but not by OD. Moreover, a MTX dose-dependent effect is closely associated with these outcomes.

### AB0419

FREQUENCY OF DISEASE FLARE AND STUDY OF THE OUTCOMES

A. Lo Monaco1, C.A. Scirel1, F. Casciano2, V. Tisato2, P. Secchierno2, M. Govoni1

1Department of Medical Sciences-Section of Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria Sant’Anna di Ferrara; 2Department of Morphology, Surgery and Experimental Medicine and LTTA Centre, University of Ferrara, Ferrara, Italy

### Background

Rheumatoid arthritis (RA) patients in a prolonged remission status represent a population whose future management has yet to be established. Treg cell function in patients with active RA is assumed to be impaired, a trend that seems to be reversed by TNFalpha antagonist therapy (aTNF). Theoretically a deeper remission may be represented by an immunological resetting of immune system, a condition which could enable to consider the possibility of a drug-free remission.

### Objectives

To evaluate the incidence of disease flare after cessation of aTNF in pts in remission together with reconstitution of the CD4+CD25highCD127low– Tcell subset respect to those patients in the same remission status with persistent low CD4+CD25highCD127low–Tcell population, assuming the Treg populations as a markers of deep remission allowing a better selection of those patients at low-risk of flare after aTNF withdrawal.

### Methods

Inclusion criteria: patients with RA (>18 years) fulfilling the 1987 ACR classification criteria treated with aTNF and synthetic DMARDs for at least 12 months, in remission (DAS28 <2.6/DAS44 <1.6)+6 months, without glucocorticosteroid. Exclusion criteria: <18 years, glucocorticosteroids within the three months before; another inflammatory disease other than RA; ongoing infections. Intervention: aTNF drug withdrawal with continuation of DMARDs previously associated (MTX or LFN); a 24 months of follow up was performed. Serial clinical and instrumental evaluation, blood sampling and radiographs have been performed according to the scheduled protocol. Treg population and several cytokines/chemokines/growth factors were analysed (Human Cytokine/Chemokine Panel I, Millipore).

### Results

- 23 patients were included, mean 53 years (SD 12.3), 68% RF+, 52% ACPA+, DAS28 medium 1.41 (SD 0.48); average duration of illness 9.62 years (SD ±5.73). During the 24 month post-suspension follow-up, for a total of 267 person-months, 11 patients presented a flare, for a flare rate of 3.74/100 person-months (CI95% 1.79–6.88). The average observed exacerbation time from aTNF withdrawal was 14.6 months (SD ±3.32). None statistical predictive value of Treg levels regarding disease outcome after aTNF withdrawal was observed (95% CI) 1.38 (0.82–2.30). None significant correlation among cytokines concentrations and disease status/Treg levels was observed. A correlation was observed between the presence of a synovitis with PD1* at the baseline and the loss of remission [HR 7.062 (1.64–30.41, p=0.009); higher values were exclusion criteria]. All 3 patients with positive US (PD1) who had flare-up were asymptomatic at baseline.

### Conclusions

47.8% of pts maintained aTNF-induced remission at 24 months continuing only csDMARDs therapy (MTX). Only in 1 case reintroduction of Adalimumab did not allow to regain clinical remission, which was obtained using another therapeutic target (anti-CTLA4). The presence of a residual synovitis, although mild (PD1), was correlated with the risk of exacerbation. Further results will be discussed.
DRUG SURVIVAL ON CERTOLIZUMAB AND PREDICTORS THEREOF IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, AND AXIAL-SPONDYLOARTHRITIS FROM THE APUOLIAN BIOPURE REGISTRY

A. Semeraro1, G. Carlini2, R. Bucci3, F. D’Onofrio4, P.C. Falappe6, S. Lopriore6, A. Marsico7, N. Marutti7, D. Mazzotta7, M. Muratore6, L. Quarta7, L. Santo6, C. Zuccaro7, F. Iannoni6, 7Rheumatology Unit; ASL Taranto; 8Rheumatology Service, ASL LE Casarano; 2Rheumatology Hospital Unit, Foggia; 3UCO Reumatologia Universitaria, University of Foggia; 4Rheumatology Outpatients, “A. Pennino” Hospital, Bifidi; 5DETO – Rheumatology Unit, University of Bari; 6UCO Reumatologia Universitaria, University of Foggia; 7O.U. of Rheumatology, “V. Fazzi” Hospital, Lecce; O.U. of Rheumatology, ASL Barletta, Italy

Background: In BIO.PU.RE. Registry are collected data from patients being treated with Biologics from rheumatologic centres in Apulia (Southern Italy).

Methods: We analysed longitudinal data of consecutive patients, affected with RA, PsA or axial-SPA starting a treatment with certolizumab (CTZ) in the time frame from 1st January 2011 to 30th June 2017. Demographic and disease related characteristics were collected at baseline and at last observation visit. Primary endpoint was the persistence on CTZ, and secondary endpoint was the search of baseline predictors of drug survival and clinical outcomes. Drug survival was evaluated by Kaplan-Meier life table analysis. Estimates hazard ratios (HRs, 95% confidence intervals (CI)) of drug discontinuation or achievement of low-disease/ remission in RA, and minimal disease activity (MDA) in PsA at last visit, adjusted for patient’s demographics, disease characteristics and prior biologic treatments were computed by Cox-regression stepwise backward models.

Results: 345 patients were included in this analysis (table 1). Global median survival time (95% CI) was 30 [23–36] months. Drug survival rate was significantly higher in PsA (63.9%, P=0.009) than in RA (54.0%) or PsA (54.5%). Within each disease, naïve-CTZ patients showed higher survival rates than biologic-experienced patients in RA (63.4% vs 45.7%, P=0.001), but not in PsA (59.1% vs 52.3%, P=0.60), or PsA (62.5% vs 64.4%, P=0.94). In the whole cohort, the only negative predictor of drug discontinuation was the CTZ-naïve status (HR 0.62, 95 CI 0.40–0.96, P=0.03). This association was even stronger for RA (HR 0.45, 95 CI 0.26–0.77, P=0.004). In PsA, patient’s age at baseline was weakly correlated to CTZ stopping (HR 0.96, 95 CI 0.93–0.99, P=0.02), but no predictor of CTZ discontinuation was detected in PsA. No factor did correlate to the achievement of low disease/remission in RA, while co-medication with MTX was significantly associated to CTZ stopping (HR 0.96, 95 CI 0.93–1.00, P=0.01) in PsA. Globally, the causes of discontinuation were: ineffectiveness (nr 94, 27.2%), adverse event (nr 40, 11.6%), pregnancy (nr 1, 0.3%), remission (nr 3, 0.9%), and other reasons (nr 12, 3.5%).

Conclusions: In our real-life experience CTZ seems to have better drug survival in PsA rather than in RA and SpA; in all these polyarthritides was observed CTZ-naïve status as negative predictor of drug discontinuation.

LOW RATES OF RETENTION OF BIOLOGIC DMARD MONOTHERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REAL LIFE SETTINGS

A. Lazanina1, K. Thomas2, E. Kalsonoudis3, A. Drosos4, P. Tsatsani5, S. Gazi5, L. Pantazi6, K.A. Bok7, P. Katsimbi8, D. Boumpas9, K. Fragiadaki9, M. Tektonidou9, P.P. Simakis10, K. Karagianni10, L. Saka10, E. Gerel10, V. Vlachoyiannopoulos11, G. Evangelatos11, A. liopoulos11, T. Dimitrualos11, A. Garyfallo11, K. Melissaropoulos10, P. Georgiou10, M. Are6, C. Georgan11, P. Vountotyipaidis11, G. Kitas11, D. Vassiliopoulou11, on behalf of Greek Rheumatology Society RA Study Group. Joint Rheumatology Program; National and Kapodistrian University of Athens School of Medicine, Athens; 2Rheumatology Clinic, University of Ioannina, Ioannina; 3Rheumatology Unit, KAT Hospital; 4Rheumatology Unit, Sismanoglio Hospital, Athens; 5Department of Rheumatology, University of Thessaly, Larissa; 6Rheumatology Unit, NIMTS Hospital, Athens; 74th Department of Medicine, Aristotle University, Thessaloniki; 8Rheumatology Unit, Agios Andreas Hospital, Patras; 9Private Practice, Livadeia; 10Private Practice, Athens; 11Private Practice, Thessaloniki, Greece

Background: A number of cross-sectional studies have shown that approximately one quarter of rheumatoid arthritis (RA) patients are being treated with biologic disease modifying anti-rheumatic drugs (bDMARDs) as monotherapy. Data regarding the retention of bDMARD monotherapy in real-life settings are limited.

Objectives: To study the survival rate of bDMARD monotherapy in RA patients in daily clinical practice.

Methods: Multicenter (11 hospital, 3 private office practices), prospective, RA epidemiological study in Greece. At baseline and after one year of follow-up, demographics, disease characteristics, treatments, co-morbidities and serious events (serious infections, cardiovascular events, neoplasms, osteoporetic fractures) were collected via a web-based platform.

Results: 1,323 RA patients with paired evaluations one year apart (mean interval: 33.2±3.7 months) were included. Among 611 bDMARD treated patients, 155 patients (25%) were on bDMARD monotherapy (women: 87%, mean age: 60.4 years), mean disease duration: 15 years, RF and/or anti-CCP positive: 66%; TNFi therapy: 57%). The majority had been previously on and had discontinued their csDMARDs (90%). During follow-up, 15% (n=24) discontinued their bDMARD; most of them stayed off any type of therapy (83%) while the rest continued with synthetic DMARD (csDMARD) monotherapy (17%). From the remaining 131 patients, 96 (73%) remained on bDMARD monotherapy (85%, n=82 on the same bDMARD), while in 27% (n=35) a csDMARD was added. Serious events occurred in 7.7% of patients (n=12). Overall, at the end of 1st year, approximately half of patients (53%, n=82) remained on their initial bDMARD monotherapy. Factors associated with continuation of the same bDMARD by multivariate analysis were a low HAQ score (OR=0.48, 95% CI=0.23–0.99, p=0.047) and corticosteroid use (OR=2.2, 95% CI=1.02–5.1, p=0.044) at baseline as well as the absence of a serious event during the 1st year of follow-up (OR=0.14, 95% CI=0.016–1.3, p=0.034).

Conclusions: In real life settings, only half of patients who are on bDMARD monotherapy continue the same agent one year later. Low HAQ score, corticosteroid use and absence of a serious event during therapy predicted bDMARD monotherapy survival.

AB0422
COST EFFECTIVENESS ANALYSIS OF MODIFIED DOSES REGIMEN OF BIOLOGICAL THERAPY IN CHRONIC INFLAMMATORY DISORDER: AN OBSERVATIONAL STUDY

B.D. Pandey5, M. Goyal2, M.M. Thabah3, A.K. Vishwakarma4, 1Rheumatology, Fortis Hospital, NOIDA, Uttar Pradesh; 2Rheumatology, Goyal Hospital, Udaipur, Rajasthan; 3Medicine, JIPMER, Puducherry; 4Pharmacy, Shri Jagdishprasad Jhabvala Tibrewala University, Junagadh, Rajasthan, India

Background: Cost of biologics in rheumatology is a prime concern in India. Due to lack of reimbursement system, a majority of the patients need to pay from their pocket for the therapy.
Objectives: Our objective was to estimate the cost-effectiveness in patients with the chronic inflammatory disorder on biological therapy with modified dosing regimens in patients of a tertiary care clinic.

Methods: In this retrospective observational study, data were captured from patients’ record in a tertiary care centre located in North India who received biological therapy in rheumatology care practice between 1 January 2013 and 31 December 2017. Modification in the dosing pattern was carried out in the patients and cost of therapy were estimated. These patients, who carried out the therapy, were monitored for any safety outcomes for up to 72 weeks.

Results: During the study period, 342 patients received modified dosing of biologicals indicated for rheumatoid arthritis and spondyloarthropathy. The cost comparison of biologicals is shown in table 1. Among all, 44 (12.86%) patients got reimbursement/claims from central and state government agencies. There were 73 (21.34%) patients who were followed up to 72 weeks (minimum possible) of the period for safety assessment. These patients achieved remission or low disease activity and urinary tract infection (5.26%) patient with infliximab) were reported. One patient (0.55% patient with rituximab) diagnosed with tuberculosis and diabetes after 37 months of initiation of rituximab and one case of hospitalisation was seen due to community-acquired pneumonia in the patient receiving infliximab. Two cases of mortality were reported in patients receiving etanercept after 18 months (due to clinical parkinsonism with aspiration pneumonia) and adalimumab after one month (reason unknown). After modified dosing, the patients tend to remain longer on therapy with no new safety signal.

AB0423 SEVERE INFECTIONS IN RHEUMATOID ARTHRITIS (RA) ARE RELATED TO THE USE OF BIOLOGIC DMARDs, ASSESSMENT OF REAL-LIFE PATIENTS

C.A. Arce-Salinas1, A. Trigo-Aguilar1, J.L. Amaya-Estrada1, F. Rodriguez-García2, F. Espinosa-Ortega3. 1Division of Internal Medicine; 2Service of Rheumatology, Hospital Central Sur de Pemex, Mexico, Mexico; 3Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden

Background: Current strategies for treatment of RA promotes early use of synthetic (s-)DMARDs, their combination, or biologic (b-)DMARDs to achieve remission or low-disease activity. However, such strategies are related to a wide variety of adverse effects, from mild to life threatening. Infections could be detected more frequently among patients with b-DMARDs, although comorbidities, steroid use, chronic accumulated damage, or disease activity could bias such conclusions. Objectives: To investigate the frequency and severity of infections comparing RA patients users of s-DMARDs or b-DMARDs in a long-term period.

Methods: Patients were selected from our RA Clinic. Those with at least 5 years using b-DMARD were compared with patients on s-DMARD, each one matched by disease duration, age, and comorbidities in a 1:1 ratio. Demographic features, disease characteristics, number and nature of infections during the follow-up, as well as disease activity, and treatment were recorded. Infections were considered as severe when it required hospitalisation or intravenous antibiotics. Comparison between groups was made with X2 or t-test as required.

Results: A total of 200 patients were prospectively assessed, 100 per group, mean age was 63±5:12:03 year-old, 91% were female, 78% were RF or ACPA positive, 20% had diabetes mellitus, and 3% other relevant comorbidities. When patients starting the use of b-DMARD, they had more active disease than those in the s-DMARD group (DAS28=4.99±1.5 vs. 3.91±1.2; p=0.01). Throughout 5 years of follow-up, there were 18 episodes of severe infections in the b-DMARDs group, and 2 episodes in the s-DMARD group (p=0.01); number of non-severe infections was 569 vs. 577 in such period, respectively (p=NS). No association was observed between severe infections and presence of diabetes mellitus, cumulative annual dose of prednisone, or DAS28, which did not differ in any other measure between groups. Sixteen patients in b-DMARD had severe infections: 6 acute pyelonephritis, 4 pneumonia, 4 acute bronchitis, 1 infectious diarrhoea, 1 emphysematous cystitis, 1 septic arthritis, and 1 haemorrhagic dengue compared with two severe infections in the s-DMARDs group: 1 pneumonia and 1 infectious diarrhoea. Median of hospitalisation days was 4.5, and no deaths were recorded. Infectious agents isolated were E. coli, C. albicans, Salmonella sp., and P. aeruginosa. The most frequent non-severe infections were upper respiratory disease, urinary tract infection, herpes zoster, acute diarrhoea, and bacterial vaginosus. Notoriously, 11 episodes of severe infection occurred in the first 2 years of b-DMARD use (7 in first, and 4 in second year), the other 7 in remaining 3 years. b-DMARDs more frequently used were etanercept, rituximab, adalimumab, certolizumab pegol, and tocilizumab, without association between severe infections and any biologic agent.

Abstract AB0423 – Figure 1

Conclusions: b-DMARDs use in our setting, combined with low dose methotrexate, reach higher frequency of severe infections than s-DMARDs, irrespective of comorbidities, steroid use or disease characteristics including disease activity.

Disclosure of Interest: None declared

AB0424 IL-6 RECEPTOR BLOCKADE INDUCED A DIFFERENT IMMUNE RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT IMMUNODEFICIENCY

C. Diaz-Torre1, P. Estrada1, M.A. Ortiz2, M. Moya1, C. Moragues1, B. Diaz-Torne1, P. Estrada1, M.A. Ortiz2, M. Moya1, C. Moragues1, 1Service of Rheumatology, 2Immunologia., Institut de Recerca Sant Pau, Barcelona, Spain

Background: Tocilizumab (TCZ) is a humanised antibody that blocks IL-6 receptor. Despite its effectiveness in rheumatoid arthritis (RA), there are patients that do not respond to the IL-6R blockade. The immune characteristics that would explain this lack of response are not known.

Objectives: Our aim was to determine the tocilizumab-induced changes in CD4+ T cells of patients that achieve, or not, remission at 12 m.

Methods: Prospective, multicenter study in 47 RA patients treated with TCZ during one year following standard clinical practice. Demographic, and treatment characteristics were collected at each visit. Ultrasound (US) grey scale and power doppler were assessed for joints and tendons using a semiquantitative scale from 0–3 points. Phenotyping of T lymphocytes was determined by flow cytometry and the plasma cytokine concentration was quantified by ELISA.

Results: Forty seven patients were treated with a mean age of 54±11 y and 85% were women. Years of disease were 13±6. We segregated patients according to the safety outcomes for 72 weeks. 34 patients achieved remission at month 12. We observed an absolute counts of neutrophils and CD4+ T lymphocytes decreased significantly in the remission group but not in the other one. Both memory and naïve CD4+ T
cells decreased in the remission group. The analysis of T cells classified according to chemokine receptors showed that memory (29.1±4.0 vs 22.7±2.7 x 10^4 cells/mm^3; p=0.06) and naïve (22.6±4.1 vs 17.2±2.8 x 10^4 cells/mm^3; p=0.01) CD4+ CXCR3+ and with CCR4+ were the subsets that decreased significantly in the remission group but not in the non-remission group. Since the expression of chemokine receptors defines the different Th subpopulations, we analysed them in the two groups of patients. Th1 tended to decreased in the remission group (3.5 ±0.7 vs 2.5±0.4; p=0.06) and Th9 decreased significantly in both groups (R: 5.0 ±0.8 vs 2.5±0.3; p=0.006 and Non R: 5.1±0.8 vs 3.1±0.4; p=0.001). In regard to the cytokines produced by CD4+ T lymphocytes, IL-17 (2.4±1.1 vs 1.2±0.5 ng/ml; p=0.04) and VEGF (0.5±0.2 vs 0.3±0.1 ng/ml; p=0.05) but not IL-6 and IL-22 changed significantly in the remission group. Interestingly, IL-17 and VEGF correlated with US findings before the initiation of the treatment (grey scale R=0.378, p=0.01 and R=0.322, p=0.03; power Doppler R=0.415, p=0.004 and R=0.320, p=0.03 respectively).

Conclusions: Tocilizumab induced changes in specific subsets of CD4+ T cells and their inflammatory associated cytokines in the remission group.

Disclosure of Interest: None declared

AB0426

EFFICACY OF MONOTHERAPY OF THE BIOLOGIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS: REAL-WORLD DATA FROM THE HONG KONG BIOLOGICS REGISTRY

C.C. Mok, R. Wan, B. Fong, on behalf of The Hong Kong Society of Rheumatology. Medicine, Tuen Mun Hospital, HK, Hong Kong

Objectives: To report the prevalence and efficacy of biologic DMARD (bDMARD) monotherapy in real life treatment of rheumatoid arthritis (RA).

Methods: RA patients registered in the Hong Kong Biologics Registry who were receiving bDMARD monotherapy (without concomitant conventional synthetic DMARDs [csDMARDs] except low dose prednisolone) were identified. The efficacy (clinical response and drug retention rate) of bDMARD monotherapy was compared with bDMARD combination therapy (with csDMARDs) using statistical tests.

Results: From December 2007 to April 2017, 2123 courses of bDMARDs/tsDMARDs were used in 1250 RA patients (83% women, mean age at therapy 53.8±12.7 years). Among 1881 courses of therapies with complete data, 164 (8.7%) was monotherapy at baseline. Low dose prednisolone (<10 mg/day) was used in 56% of these courses. In the combination group, the commonest csDMARDs used in combination with bDMARDs were methotrexate (79%), sulphasalazine (27%), hydroxychloroquine (25%) and leflunomide (21%). The bDMARDs/tsDMARDs most frequently used as monotherapy were tocilizumab (14.3%), tocilizumab (11.6%) and abatacept (11.2%). Overall, the non-TNF was more commonly used as monotherapy (11.2%) than the anti-TNF bDMARDs (7.4%). At 6 months of bDMARD/tsDMARD therapy, the DAS remission rate was non-significantly higher in the monotherapy group (11% vs 5%; p=0.42). The change in DAS28 score was also non-significantly greater in the combination group (Δ−1.95±1.26 vs −1.68±1.56; p=0.30). The difference in 6 month efficacy between the combination and monotherapy groups was greater in anti-TNF users. The overall cumulative withdrawal rate of the bDMARDs/tsDMARDs due to either inefficacy or serious adverse events (SAEs) was 0.55 at 3 years and 0.47 at 5 years. The anti-TNF biologics had a significantly higher withdrawal rate than the non-TNF biologics (hazard ratio [HR] 1.83 [1.56–3.14]; p<0.001). In Cox regression models, monotherapy of the bDMARDs was not significantly associated with drug withdrawal due to inefficacy (HR 0.95 [0.53–1.71]; p=0.87) or SAES (HR 1.27 [0.51–3.19]; p=0.61) after adjustment for age, sex, anti-TNF (vs non-TNF) biologic use, previous use of bDMARDs (vs first time use) and DAS28 at baseline. Separate analyses of the anti-TNF and non-TNF biologics again did not reveal a significant relationship between monotherapy of the biologics with the drug withdrawal due to inefficacy or SAES after adjustment for age, sex, previous use of bDMARDs and disease activity at baseline (HR 1.002 [0.56–1.80]; p=0.99 for anti-TNF and HR 1.20 [0.47–3.08]; p=0.70 for non-TNF biologics, respectively).

Conclusions: Monotherapy of bDMARD/tsDMARD was used in 8.7% of our RA patients in real life practice, probably due to intolerance, inefficacy or non-compliance to the csDMARDs. Short-term efficacy tended to be better with bDMARDs/csDMARDs combination, especially in the anti-TNF biologics, but the long-term drug retention rate was similar between bDMARD monotherapy and combination therapy with the csDMARDs.

COMPARATIVE SAFETY OF ABATACEPT VS TOFACITINIB IN ADULTS WITH MODERATE-TO-SEVERE RA: A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

D. Paul1, R. Diekemper1, M. Fazeli1, F. Husain2, A. Marshall3, Y. Kuang1, T. Curtice1.

1Bristol-Myers Squibb, Princeton, USA; 2Doctor Evidence, Santa Monica, USA; 3Doctor Evidence, Santa Monica, CA

Background: While targeted (biologic or synthetic) DMARDs are overall highly effective in improving symptoms and function in RA patients (pts), their comparative safety relative to each other remains inconclusive.

Objectives: Compare the safety of abatacept (ABA) and tofacitinib (TOF) through a systematic literature review (SLR) and network meta-analyses (NMA).

Methods: A comprehensive search of randomised and non-randomised clinical trials was conducted across MEDLINE, Embase and Cochrane CENTRAL databases from inception to June 2017. The PICO framework (population=moderate to severe RA; intervention=ABA and TOF; comparison=placebo and other RA therapies; outcome=AEs, treatment-related AEs [TrAEs], serious infections and treatment-related deaths) was used to design searches and define the eligibility of studies for inclusion. Additional searches were performed on relevant conference proceedings and the US clinical trials registry from the past 2 years (figure 1).

Data configuration was performed by expert methodologists using DOC Data 2.0 software.

Results: From 30 papers, 25 trials were included in the systematic review (14 for ABA and 11 for TOF) and 17 NMA were conducted. The patients characteristics are reported in Table 1. The all-cause AEs (P: 0.006; OR: 1.50 [1.20–1.87]) and serious AEs (P: 0.01; OR: 1.68±1.56; p=0.30). The difference in 6 month efficacy between the combination and monotherapy groups was greater in anti-TNF users. The overall cumulative withdrawal rate of the bDMARDs/tsDMARDs due to either inefficacy or serious adverse events (SAEs) was 0.55 at 3 years and 0.47 at 5 years. The anti-TNF biologics had a significantly higher withdrawal rate than the non-TNF biologics (hazard ratio [HR] 1.83 [1.56–3.14]; p<0.001). In Cox regression models, monotherapy of the bDMARDs was not significantly associated with drug withdrawal due to inefficacy (HR 0.95 [0.53–1.71]; p=0.87) or SAES (HR 1.27 [0.51–3.19]; p=0.61) after adjustment for age, sex, anti-TNF (vs non-TNF) biologic use, previous use of bDMARDs (vs first time use) and DAS28 at baseline. Separate analyses of the anti-TNF and non-TNF biologics again did not reveal a significant relationship between monotherapy of the biologics with the drug withdrawal due to inefficacy or SAES after adjustment for age, sex, previous use of bDMARDs and disease activity at baseline (HR 1.002 [0.56–1.80]; p=0.99 for anti-TNF and HR 1.20 [0.47–3.08]; p=0.70 for non-TNF biologics, respectively).

Conclusions: Monotherapy of bDMARD/tsDMARD was used in 8.7% of our RA patients in real life practice, probably due to intolerance, inefficacy or non-compliance to the csDMARDs. Short-term efficacy tended to be better with bDMARDs/csDMARDs combination, especially in the anti-TNF biologics, but the long-term drug retention rate was similar between bDMARD monotherapy and combination therapy with the csDMARDs.

Scientific Abstracts
initiative and based on the BIOBADADER Phase 3 platform. Phase 3 in México started gathering patient data in 2016, and to date has information on 216 patients. The database collects information such as gender, age, diagnosis, disease duration, biologic treatment, DMARD treatment, concomitant therapy, motives for discontinuation of biologics, comorbidities, adverse event (AE) severity, infection site and germ involved. Descriptive statistics were applied on the data collected from April 2016 to January 2018.

Results: We analysed data on the use of 267 biologic treatments in 216 patients. Most of them received biologic therapy through socialised medical insurance programs which may have led to bias. 89.1% of patients were female, mean age 49 ±15.2 (4–85) years, 42.5% belonging to the <50 group. 69.9% of patients in the registry have RA, 12.5% AS and 5.5% PsA. Mean disease duration is 11.6±9.8 (0–58) years. The most commonly used biologic overall is Abatacept (15.3%), followed by Adalimumab (15.8%), Tolctizumab (11.2%), Certolizumab (10.1%), Golimumab (8.6%), Rituximab (8.2%), Etanercept biosimilar (7.4%), Etanercept (6.3%), Infliximab (4.1%) and Benlysta (1.1%). All others, including JAK inhibitors, are used in <1% of patients. The preference for first biologic drug was Etanercept (32.4%), followed by Adalimumab (12%), Infliximab (8.3%), Tolctizumab (5.5% each) and Abatacept (2.7%). Most treatments were stopped due to lack of efficacy (60.4%), disease remission (7.4%), other causes (20.1%), AE (4.4%), with the rest of the causes each affecting 2–3% of patients. The most commonly used DMARD were Methotrexate (49.8%), steroids (33.3%) and Lefunomide (23.2%). Comorbidities were present in 87 patients (40%), the most common being Hypertension (13.4%), Diabetes (7.8%) and Dyslipidemia (6.9%). Non-lymphoma neoplasms were reported in 1.3%. 25% of AE were considered serious but most (70%) were mild. Only 6 patients reported infections with the most common sites being the skin (33.3%), urinary tract (16.6%) and middle-ear (16.6%). The causal germ was often undetermined (60%).

Conclusions: When using biologic drugs, TNF inhibitors are the most commonly used initial mechanism of action for the treatment of rheumatic diseases in the BIOBADAMEX registry. Upon treatment failure, patients undergo a switch to another mechanism of action, mainly using Abatacept. Adverse events and infections related to the use of biologics are infrequent, but 40% of patients present chronic comorbidities.

PREFERENCES IN THE USE OF BIOLOGIC DRUGS AND ADVERSE EVENTS IN PATIENTS WITH RHEUMATIC DISEASE FROM A NATIONAL BIOLOGICS REGISTRY IN MEXICO

D. Xibillé1, S. Carillo2, S. Sicis3, F. Irazoque4, A. Ramos5, S. Durán5, M. Saavedra6,1, L. Barile1, G. Olvera7, 1SSM, Cuernavaca; 2Hospital 1 Oct, ISSSTE, México; 3UMAE 71 IMSS, Torreón; 4CMN 20 Nov, ISSSTE, México; 5CMN NE 25 IMSS, Monterrey; 6CIRO SC, Guadalajara; 7HE CMN La Raza, IMSS, Colegio Mexicano de Reumatología, México, México.

Background: National registries of biologic drugs have proven to be valuable tools in following patients with rheumatic disease and some outcomes in real-life situations. Objectives: The objective of this study was to describe Mexican Rheumatologists’ preferences when treating patients with biologic drugs and to analyse factors associated to the use of this therapy.

Methods: Data from patients undergoing biologic treatment in México is gathered into the BIOBADADER Mexico online database, which is part of the BIOBADADER MÉXICO.

Results: Thirty-one randomised controlled trials (n=13,978) were included for ABA+MTX: risk ratio [RR] 1.1, 95% CI: 0.77, 1.5; TOF 5 mg vs ABA: RR 1.1, 95% CI: 0.78, 1.6. These findings remained consistent for the risk of total AEs and serious infections.

NO DIFFERENCE IN EFFECTIVENESS WITH EITHER ETANERCEPT OR BIOSIMILAR AS FIRST LINE BIOLOGIC TREATMENT FOR RHEUMATOID ARTHRITIS

D. De Cock1, R. Davies1, L. Kearsley-Fleet1, K. Watson1, K. Hyrich1,2, on behalf of the BSRBR-RA contributor group. Arthritis Research UK Centre for Epidemiology, Manchester University; Manchester Academic Health Science Centre, Central Manchester NHS Foundation Trust, Manchester, UK

Background: Biosimilars and their reference agents have been shown to be equivalent in clinical trials. In the United Kingdom, etanercept biosimilars (ETA-B) are, since 2016, a first-line treatment option for the management of severe rheumatoid arthritis (RA) defined as no response to 2 or more csDMARDs. However, real world data, including how it compares to the etanercept originator (ETA-O) are lacking.

Objectives: This study aims to compare the short-term effectiveness of etanercept originator with its biosimilar in patients with RA when used as a first biologic following csDMARDs.

Methods: This study included patients with RA registered with the British Society for Rheumatology Biologics Registers for RA (BSRBR-RA) at the point of starting either ETA-O or ETA-B since 2011 as their first biologic. Baseline information following csDMARDs.

Results: Between January 2010 and 11 December 2017, 1217 and 412 patients, starting ETA-O or ETA-B respectively were recruited and had ≥1 FU available. Complete DAS28 data at baseline and 1st FU were available for 740 ETA-O patients and 177 ETA-B patients. Patient characteristics were similar between the 2 cohorts (Table). After adjusting for baseline differences, no difference between groups was seen in DAS28 (p=0.1) or remission status (p=0.1) at 1st FU.
Nine (5%) and 48 (6%) of ETA-B and ETA-O patients had stopped their respective treatments by the 1st FU. The adjusted hazard ratio for stopping ETA-O versus ETA-B over this time period was similar (HR=0.8 (0.4-1.6); p=0.5). Risk of SAEs over the first 6 months was also similar between groups (HR [ETA-B versus ETA-O]=0.6 (0.3-1.1); p=0.1), with 10 (6%) and 73 (10%) SAEs reported in ETA-B and ETA-O patients respectively until 1st FU.

Conclusions: In the UK, etanercept biosimilars are now frequently used as first-line biologics in RA patients. These short-term follow-up data demonstrate in routine clinical care that ETA-B appears to be equivalent to ETA-O in terms of short-term effectiveness, drug survival and safety.

SUBJECTIVE ASSESSMENTS OF PATIENTS WITH RHEUMATOID ARTHRITIS REPORTED THAT BIO-HOLIDAY THERAPY BROUGHT THEM FINANCIAL AND PSYCHOLOGICAL IMPROVEMENTS

E. Torikai1, D. Suzuki1, M. Suzuki2, Y. Matsuyama2. 1Department of Rheumatology, Iwata city hospital, Iwata; 2Department of Orthopaedic surgery, Hamamtsu university school of medicine, Hamamatsu, Japan

Background: At EULAR 2016 and 2017 we reported that it is possible to maintain disease activity, radiographic progression, physical function, and bone metabolism status in rheumatoid arthritis (RA) patients with clinical disease activity index (CDAI) remission using the biologic agents (Bio)-holiday therapy. Currently, in RA therapy, patients’ assessments of their own health are also objective assessment of doctors is becoming more important. How does the patient think about Bio-holiday therapy?

Objectives: To evaluate the benefit of Bio-holiday therapy in RA patients with CDAI remission.

Methods: In the first and second survey, we conducted questionnaire survey in RA patients with CDAI remission; those treated with Bio-holiday therapy or Bio-continue therapy to evaluate the benefit of their therapies and to clarify the number of patients concerned about flare-up.

Results: In the first survey (figure 1), pain improvement and inexpensive treatment were the most and the second expected treatment effect, respectively. In the second survey (figure 2), for questions regarding expectation from RA treatment effect, the patients reported that the most beneficial points was pain improvement and flare-up.

Conclusions: Patients in both groups were equally satisfied with the improvement of their disease activity and progression of ADL. Reduction of the anxiety regarding treatment costs and flare-up in Bio-holiday therapy also helped to improve psychological aspects. Therefore, we recommended Bio-holiday therapy for RA patients with CDAI remission.

EARLIER AGE AT THERAPY INITIATION IS ASSOCIATED WITH BETTER RESPONSE TO TOCILIZUMAB THERAPY IN PATIENTS WITH JUVENILE IDIOPATHIC POLYARTHRITIS

E. Alexeeva1,2, T. Dvoryakovskaya1,2, M. Soloshenko1, R. Denisova1, K. Isaeva1, A. Mamutova1, V. Gladikh1,4, A. Moskalev1,4, 1National Medical Research Center for Children’s Health; 2Sechenov First Moscow State Medical University (Sechenov University, Moscow); 3EOL Labs ltd, Department of Biostatistics; 4Institute of Computational Mathematics and Mathematical Geophysics SB RAS, Novosibirsk, Russian Federation

Background: The use of therapy with anti-cytokine biologicals in routine practice has significantly increased the percentage of children showing good response to therapy and reduced the time to achieve pharmacological remission. Nevertheless, the problem related to selecting the optimal drug for a certain patient still remains to be solved.

Objectives: This study was aimed at identifying clinical and laboratory parameters associated with response to tocilizumab (TOC) treatment in patients with RF-negative polyarticular JIA.

Methods: The prospective study to assess TOC efficacy involved 55 patients with RF-negative polyarticular JIA aged 9.42 years (IQR 5.96–13.42), with females (85.5%) predominating was conducted at the National Medical Research Centre of Children’s Health (Moscow). Treatment efficacy was evaluated using the ACRPedi criteria; Wallace’s criteria were used to assess whether a patient had reached inactive disease or remission. The potential baseline characteristics associated with treatment response were identified using univariate and multivariate logistic regression analyses. Baseline factors included the clinical, laboratory, and anamnestic data.

Conclusions: Patients in both groups were equally satisfied with the improvement of their disease activity and progression of ADL. Reduction of the anxiety regarding treatment costs and flare-up in Bio-holiday therapy also helped to improve psychological aspects. Therefore, we recommended Bio-holiday therapy for RA patients with CDAI remission.

REFERENCE:

Disclosure of Interest: None declared

**Results:** TOC therapy showed high efficacy in children with RF-negative polyarticular JIA: 81.8±67.3/47.3/23.6% of patients reached the ACR30/50/70/90 criteria for the end of follow-up, respectively. The median time of achieving at least 30% improvement from baseline (ACR30) was 1 months (IQR 1:3).

Univariate analysis showed that earlier age at initiation of Tocilizumab therapy, higher physician’s global assessment score using the 100-point Visual Analogue Scale, and longer morning stiffness were the factors associated with reaching ACR90. Younger age at therapy initiation, greater number of swollen joints and joints with limited range of motion, and history of using fewer biologicals are the factors associated with reaching inactive disease and remission. However, multivariable analysis showed that only earlier age at initiation of TOC therapy was a statistically significant factor associated with achieving the best response to therapy in all the models.

**Conclusions:** Earlier initiation of TOC therapy is associated with higher chances for reaching ACR90 and pharmacological remission in patients with RF-negative polyarticular JIA. Further studies in larger cohorts are needed to identify the optimal age at therapy initiation.

**AB0432 BIOLOGIC DMARDS TREATMENT RETENTION IN PATIENTS WITH RHEUMATOID ARTHRITIS ACCORDING TO THE MOSCOW ARTHRITIS REGISTRY (MERA)**

E. Koltsova1, E. Zhilyaev2, G. Lukina3, E. Schmidt4. 1Research Institute of the Organization of health and healthcare management; 2CJSC «European Medical Center»; 3Moscow Clinical Scientific Center; 4City Clinical Hospital 1 named after N.I. Pirogov, Moscow, Russian Federation

**Background:** Retention on treatment is a good index of efficacy and safety of treatment used in the real clinical practice. These data may be useful to planning the treatment among some years. 1,2

**Objectives:** To compare the drug survival of biological therapies.

**Methods:** We followed rheumatoid arthritis patients treated with biologics DMARD and registered in MERA 2012–January 2018. All patients had more than one visit in the registry.

**Results:** We analysed 799 patients (mean age 57.3±13, mean diseases duration 15.6±10.3 years). The average time until a change of treatment for infliximab was 15,6±10,3 years). The average time until a change of treatment for infliximab was 399 days – the shortest treatment duration. Abatacept (median survival – 2922 days) demonstrated significant superiority over adalimumab (1339 days) (p<0.001), infliximab (399 days) (p<0.001), rituximab (2557 days) (p=0.004) and etanercept (1492 days) (p=0.035) when they was used as the first biologic drug. Among second-line therapy, the longest treatment survival has etanercept (3435 days), the shortest – infliximab (212 days).

**Abstract AB0432 – Figure 1**

**Conclusions:** The results of the trial show the differences in treatment survival of some biologics. It can be reasonable to take these significant differences into consideration by the long-term planning of the biologic treatment of rheumatoid arthritis patients.

**AB0433 TNF-INHIBITORS AND ANTI-B-CELL TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS, REAL-WORLD DATA FROM THE RUSSIAN NORTH-WESTERN BIOLOGICAL TREATMENT COHORT**

E. Vasilenko, R.R. Samigullina, V.I. Mazurov, E.A. Trofimov, I.Z. Gaydukova. North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation

**Background:** Biologics are drugs that improved the status of rheumatoid arthritis (RA). At the same time real-world data (RWD) from large cohorts can give some additional information about efficacy and safety of the biological agents.

**Objectives:** The aim of the study was to analyse the efficacy and safety of biological treatment in large prospective cohort during 102 weeks of treatment.

**Methods:** The data from 1 400 patients on biological treatment from North-Western State Medical University Biological Treatment Cohort Study (St. Petersburg, Russia) were analysed. In final analysis data from 758 patients with RA/EULAR 2010 criteria), were included. Following drugs were used: adalimumab (n=22), certoluzumab pegol (n=62), etanercept (n=64), golimumab (n=21) and infliximab (n=69), rituximab (n=520). The disease activity index (DAS28) and high-sensitive C-reactive protein (C-HP) were evaluated as markers of RA activity. Side effects were registered during the study.

**Results:** RA activity, demographic characteristics, and concomitant treatment (including methotrexate, glucocorticoids, NSAIDs, analgesics) at baseline were similar in all the treatment groups (p>0.05 for all the parameters). The faster response was found in golimumab and certoluzumab pegol patients (p and TT 0.01 for difference of DAS28 in golimumab, certoluzumab pegol treatment and other treatment groups at week 6), figure 1. After week 12 the similar efficacy of all the TNFa-blockers (figure 1).

**Abstract AB0433 – Figure 1**

RA activity, demographic characteristics, and concomitant treatment (including methotrexate, glucocorticoids, NSAIDs, analgesics) at baseline were similar in all the treatment groups (p>0.05 for all the parameters). The faster response was found in golimumab and certoluzumab pegol patients (p=0.01 for difference of DAS28 in golimumab, certoluzumab pegol treatment and other treatment groups at week 6), figure 1. After week 12 the similar efficacy of all the TNFa-blockers (figure 1). C-HP levels were similar in all the treatment groups in all time-points (p>0.05) DAS28 (mean ±SD) in RA patients, treated with rituximab, at baseline, and at weeks 24, 54, and 102 was 6.6±2.4, 3.7±1.7, 3.6±2.1 and 3.2±2.05, respectively; p>0.05 for the differences with all another treatment groups at the same time-points.

The most frequent side-effects were opportunistic infections, OR=1.8 [95% CI 1.4–2.1]. Risk of infections was higher in patients, receiving monoclonal antibodies to TNFα, as compared to other TNFα inhibitors (p<0.01 for differences between infliximab/adalimumab/golimumab and etanercept, and p>0.05 for differences between infliximab/adalimumab/golimumab and certoluzumab pegol).

The risk of cancer in RA patients on biological treatment and in total Russian population (including lymphomas and skin cancer) was comparable: for all the tumours OR=0.98 [95% CI 0.76–1.26], for lymphomas OR=1.23 [95% CI 0.92–1.41], for skin cancer OR=1.11 [0.88–0.36].

**Conclusions:** According to the RWD from the North-Western Biological Treatment Cohort, the efficacy of all the TNFα-inhibitors and rituximab in RA treatment
The Influence of Body Mass Index on the Efficacy of Tumor Necrosis Factor Blocking Therapy and Disease Activity in Patients with Rheumatoid Arthritis

E.N. Mole1, K. Zoupidou1, A. Alexoudis1, E. Koutsantonis2, C. Sfontouris1, G. Gaz1.
1. Department of Rheumatology, General Hospital of Attica "KAT"; Kifisia, Athens, Greece
2. Department of Rheumatology, General Hospital of Athens "Evaggelismos", Athens, Greece

Background: The impact of Body Mass Index (BMI) on efficacy of TNF blocking therapy in Rheumatoid Arthritis (RA) patients and therefore on control of the disease is an important question.

Objectives: The aim of this study is to determine the influence of BMI on the efficacy of TNF blocking therapy in terms of disease activity in patients with RA.

Methods: A retrospective, observational study of 168 consecutive RA patients who received subcutaneously (SC) TNF blocking treatment (adalimumab, etanercept, golimumab and certolizumab pegol). Their follow-up data, for at least 26 weeks, and their baseline BMIs were available. The WHO definition for normal weight, overweight and obesity was applied, whereas clinical response was compared by BMI subgroups.

Results: The average BMI was 26.83±3.44 kg/m² and the baseline Disease Activity Score in 28 joints (DAS28 [ESR]) was high at 5.72±0.84. Mean age was 53.4±7.12 years and 135 (80.36%) were female. The median disease duration was 13.01±8.57 years. Overall, patients with normal weight responded better to treatment regimen, followed by overweight and obese subgroups. After a follow-up period of 26 weeks, the obese group had significantly higher DAS28 (ESR) and Health Assessment Questionnaire (HAQ) than either normal or overweight subgroups (3.62±0.84 vs 2.72±0.78 vs 2.81±0.92, p<0.001, 0.42±0.02 vs 0.57±0.01 vs 0.17±0.01, p<0.001 respectively). Furthermore, obesity was significantly associated with a decreased tendency of achieving week 26 remission, based on DAS28 (<2.6) p=0.002 and normal HAQ (<0.5) p=0.003.

Consolidated Long-term Safety of Infliximab in Inflammatory Arthritis from a Prospective, Observational Registry

D. Choquette1, P. Rahmarn2, A. Chow1, W. Faraawi4, W. Olszynski3, E. Rampaakis2, O. Asin-Milan1, B. Osborne1, A.J. Lehman-Ngant3, T., 1. Institut de Rhumatologie de Montreal, Montreal, QC; 2. Memory Unit, St-John’s; 3. Croft Valley Rheumatology, Mississauga; 4. McMaster University, Hamilton; 5. Polimed Research Inc., Saskatoon; 6. JSS Medical Research, Montreal, Canada; 7. Janssen INC, Toronto, Canada

Background: Tocilizumab (TCZ) is a humanised monoclonal antibody targeting interleukin-6 receptor. Since TCZ Label for RA has been issued in many countries, administration patterns and dose modifications for managing adverse events (AEs) seems differ depending on clinical opinion. Few data are available from real world practice in China.

Objectives: To observe in routine clinical practice the treatment patterns of TCZ in RA patients with regard to persistence on drug and adherence to the licensed label recommendations.

Methods: This a 6 month non-interventional, multi-centre study enrolled patients with moderate to severe RA diagnosed per revised 1987 ACR criteria (age >18 years) and being treated with TCZ. Data was recorded during routine visit. The primary variable was the proportion of patients on TCZ treatment after 6 months.

Results: Of 407 patients from 23 centres in China, 396 were eligible, including 330 (83.3%) women. The mean age was 49±13.44 years. The mean diagnostic score was 5.4±6.24 years. Among 396 patients, 250 (63.1%) were RF positive, 253 (39.5%) were anti-CCP positive and 123 (31.1%) had anaemia (Hb <90 g/L). Of eligible patients, 293 (74.0%) completed the study. The primary reason of premature termination was treatment costs (n=49, 12.4%). There were 37 (9.3%) patients received anti-TNF biologics previously and 330 (83.3%) received concomitant DMARDs, of which 84 (21.2%), 149 (37.7%) and 97 (24.5%) received received 1, 2 or 3 types of DMARDs, respectively. Methotrexate (n=255, 64.4%) and Leflunomide (n=184, 46.5%) were the most commonly used DMARDs. A total of 126 and 197 patients received corticosteroids or nonsteroidal anti-inflammatory drugs (NSAIDs), respectively. During 6 months observation, 21.0% and 87.7% had TCZ dose modification or discontinuation, respectively. At month 3 and month 6, 161 (40.7%) and 102 (25.8%) kept TCZ treatment, respectively. The mean frequency of TCZ usage was 3.7±1.62. Effectiveness of TCZ was analysed in patients who were still using TCZ at month 6. The mean score of total TJC (28-joint count) at baseline and at month 6 was 11.2±8.03 (n=63) and 2.3±4.12 (n=77), respectively; mean change from baseline was –9.5±8.02 (n=53). The mean score of total SJC (28-joint count) at baseline and at month 6 was 8.0±6.81 (n=43) and 1.7±2.35 (n=77), respectively; mean change from baseline was –6.5±7.2 (n=53). The mean score of DAS28 at baseline and at month 6 was 6.13±1.33 (n=56) and 2.79±1.39 (n=66); mean change from baseline was –3.45±1.48 (n=46). Patients in low disease activity (DAS28 <3.2) or remission (DAS28 <2.6) were in those who still using TCZ at month 6 was 63.8% and 51.5%. The mean change from baseline in SDAI and CDAI was –28.03±16.75 (n=41) and –24.25±16.94 (n=51), respectively. Of 396 patients, 90 (22.7%) and 8 (2.0%) experienced at least one treatment-emergent AE and SAE, respectively. One patient died of severe pneumonia.

Conclusions: This was the first real-world study in RA patients treated with TCZ in China. The results show that Chinese RA patients have long disease history, TCZ was frequently used in combination with DMARDs, especially with ≥2 types of DMARDs. Compared with the dose recommendations, shorter treatment duration and longer dose interval of TCZ were found in China. TCZ demonstrated effectiveness in treatment of Chinese RA patients in real-life clinical practice with manageable safety profile.

Disclosure of Interest: None declared

Methods: Treatment was prescribed by the physician per actual clinical practice or standard of care for rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA); there was no randomised assignments to treatment. There were no restrictions on the use of concomitant medications. At enrolment (baseline) and approximately every 6 months thereafter, information was collected to assess safety, clinical outcomes, quality of life, comorbidities, pharmacoeconomics and treatment regimens.

Results: A total of 1390 patients were enrolled and used for this analysis. The proportion of patients by indication was 59.2% for RA (n=890), 29.5% for AS (n=389) and 7.4% for PsA (n=111). The mean (SD) exposure was 3.10 (3.26) years for a sum of 4290.25 patient-years. Treatment with IFX was generally safe, with AEs and SAEs being reported for 64.3% and 19.5% of patients, respectively. The incidence rate of AEs and SAEs was 116.0 and 11.2 events per 100 pt-years, respectively. More specifically, 338 SAEs were reported by 189 (21.2%) RA patients [SAEs/100 pt-yrs: 11.7], 150 SAEs were reported by 69 (15.4%) AS patients [SAEs/100 pt-yrs: 10.5] and 28 SAEs were reported by 22 (19.8%) PsA patients [SAEs/100 pt-yrs: 8.82]. The most commonly reported AE identified was arthralgia, viral upper respiratory tract infection, upper respiratory tract infection and nausea. For SAEs, the most commonly reported SOC (≥3% of patients) was “Infections and infestations” [5.3% (n=73); 2.16 SAEs/100 pt-yrs] and “Neoplasms benign, malignant and unspecified” [5.5% (n=49); 1.24 SAEs/100 pt-yrs] which occurred at similar rates to the general RA patient population1 and included two lymphomas [0.1%; 0.05/100 pt-yrs]. Across 3 closely monitored categories of AEs, a total of 302 closely monitored AEs were reported by 293 (21.1%) patients, including cancer (3.7%), lack of efficacy (17.1%) and tuberculosis (0.2%). A total of 21 deaths were reported during the study in 18 RA, 1 AS and 2 PsA patients. Cause of death included MACE (x5), lung cancer (x2), pulmonary fibrosis (x2), pneumonia (x2), respiratory failure, bronchitis, intestinal cancer, thyroid cancer, intestinal gangrene, disseminated TB, septic shock, procedural complication and drowning. The cause of death was not known for one patient.

Conclusions: The results of this longitudinal observational study showed that treatment with IFX was well tolerated in people living with AS, PsA and RA over a 15 year period in a real-world setting.

AB0438

SAFETY OF TNF BLOCKERS IN CASE OF NON-ALCOHOLIC FATTY LIVER DISEASE AND CIRRHOSIS. SYSTEMATIC REVIEW

F. Verheugen1,2, D. Weil-Verheoven2,3, T. Thevenot1, G. Pratil2, V. Di Martino1,2, D. Wending1,2,1, Rhumatologie, CHRU de Besançon, 2EA 4266 EPILAB, Université de Bourgogne Franche Comté, 3Hepatology, CHRU de Besançon, 4EA 4266 EPILAB, Université de Bourgogne Franche Comté, Besançon, France

Background: The management of inflammatory rheumatisms and psoriasis has largely evolved over the last 15 years with the emergence of biotherapies whose main adverse effect is the increased infection risk. The prevalence of metabolic syndrome is increasing and has been estimated at 30% in patients with rheumatoid arthritis with an excess of 45% compared to healthy subjects. One of the major complications of the metabolic syndrome is the Non Alcoholic Fatty Liver Disease (NAFLD), which prevalence is 25% in the global population, and 30% in a cohort of patients with rheumatoid arthritis. The main complication of NAFLD is

Conclusions: The AGIL study is one of the largest observational cohorts to provide long-term data on ADA therapy. Both objective and subjective measures support the effectiveness and safety of ADA in patients with RA during 5 years of therapy. Approximately 43% of patients experienced a therapeutic response to treatment at 6 months as assessed by statistical methods (DAS28-dc24), and this level of response increased to 60% at 5 years in patients remaining on therapy. About one-third of patients recovered full functional ability (HAQ-DI remission) at the 6 month and subsequent visits. Our data indicate that ADA is an effective and safe long-term therapy in RA patients who continue on treatment.

Acknowledgements: This study was sponsored by AbbVie Deutschland GmbH and Co KG, AbbVie contributed to the study design, data analysis, and in the writing, revision, and approval of the abstract. Cross, Ph.D. provided medical writing services on behalf of CIRI, Frankfurt am Main, Germany, under contract with AbbVie for medical writing services and Holger Gnann, GKM Gesellschaft für Therapieforschung, Munich, Germany, provided statistical analyses as a paid consultant.

the development of cirrhosis, known to increase infectious risk. Surprisingly, there are no data on the safety of TNF antagonists in patients with chronic inflammatory disease treated with NAFLD or cirrhosis.

Objectives: To assess infectious and liver safety of the main TNF blockers used in chronic inflammatory diseases in patients with cirrhosis or NAFLD.

Methods: A systematic review of the literature, following the Prisma recommendations, was conducted on the PubMed and Embase databases with the following keywords: “adalimumab”, “infliximab”, “etanercept”, “certolizumab”, “golimumab” “TNF blockers”, “liver cirrhosis”, “non alcoholic fatty liver disease”. We selected only studies including patients treated with TNF blockers and with cirrhosis or ultrasurally characterised NAFLD. We excluded animal models and non-English articles.

Results: We identified 39 articles and only 11 fulfilled the inclusion criteria. 9 Case Reports have reported the tolerance of TNF-blockers in patients with cirrhosis and one controlled study (44 patients) assessed the safety of etanercept in case of NAFLD. One study (7 patients) investigated the impact of infliximab in refractory autoimmune hepatitis. The cause of cirrhosis was primary biliary cholangitis (5 cases), alpha-1 antitrypsin deficiency (4 cases) and post hepatitis B cirrhosis (2 cases). All cirrhosis were compensated. Inflammatory diseases requiring the introduction of TNF-blocker were rheumatoid arthritis (n=5), psoriatic arthritis (n=4), ulcerative colitis (n=2) and psoriasis (n=4). The TNF-blockers prescribed were adalimumab in 2 patients, infliximab in 11 patients and etanercept in 49 patients. The duration of treatment ranged from 6 to 24 months. For the 9 cirrhotic patients with an inflammatory disorder, no infection was reported and two of them (2 cases of primary biliary cholangitis) even had an improvement in liver function secondary to the introduction of biologics. For the 7 arthritis patients receiving infliximab to treat auto-immune hepatitis, 5 patients presented recurrent infections. For patients with NAFLD, no infectious event was reported and an improvement of the hepatic biological parameters was observed, suggesting an improvement in liver function.

Conclusions: The results of this review suggest that in case of compensated cirrhosis, TNF-blockers were not deleterious for the liver and did not increase the infectious risk. In case of auto-immune cirrhosis, TNF-blockers increased the infectious risk. In case of NAFLD, TNF-blockers might improve liver function and prevent fibrosis.

ETHNIC MINORITIES EXPERIENCE INFREQUENT BIOLOGIC SWITCH DESPITE ACTIVE RHEUMATOID ARTHRITIS DISEASE

G. Kerr1 on behalf of EMRAC, C. Swearengen2, S. Hochberg1, J. Uede1, Y. Yazici2, on behalf of Ethnic Minority Rheumatoid Arthritis Consortium. 1VAMC HUIH, Washington, 2New York University, New York, USA

Background: The expanded therapeutic modalities in rheumatoid arthritis (RA) provide options to achieve low disease activity or remission. Yet, in routine care, the frequency and choice of switching of biologic DMARD (bDMARD) amongst ethnic subsets when there is ineffectivity, is unknown.

Objectives: To evaluate frequency and choice of biologic switch in ethnic RA subsets

Methods: Patients enrolled in the Ethnic Minority RA Consortium (EMRAC), with at least 12 months followup visit were analysed. Data included clinical outcomes assessed by RAPID3 tender/swollen joint counts; medication use (prednisone, methotrexate, other DMARD), and bDMARD (Tumour Necrosis factor inhibitors (TNFi) and non-TNF). Minimally clinical improvement (MCI) in RAPID3 was defined as a decrease of >3.2 points during followup. Differences between medication usage, biologic switch, and RAPID3 improvement between race and ethnicity groups while on biologics, was investigated.

Abstract AB0440 – Table 1. Demographic and clinical features of EMRAC cohort by race group

TNF: adalimumab, certolizumab, etanercept, golimumab, infliximab
Non-TNF: abatacept, anakinra, tocilizumab, tofacitinib, rituximab
Results: 1040 subjects with 3719 follow-up visits spanning an average of 63.2 weeks were analysed. African Americans and Hispanics comprised 24% and 16% of participants. Compared to Whites, African Americans had significantly less education (p<0.001 for both), significantly less biologic use (p<0.001 for both) and significantly less TNF use (p<0.001 for both). African Americans had significantly higher RAPID3 scores at enrollment than Whites as well (p=0.018).

Switching between TNFi and non-TNFi was recorded in only 9 subjects, with 7 subjects switching from TNFi to non-TNFi. There was no statistically different difference in race/ethnic groups in frequency of bDMARD switching, nor within bDMARD class (TNFi class, p=cc; non-TNFi class, p=bb). bDMARD treatment led to MCI in RAPID3 in 101 (38%) subjects and in more African Americans (29 [48%]) and Hispanics (12 [41%]) than in Whites (49 [37%]) (but not statistically significant).

Conclusions: In our cohort, disparity was seen in bDMARD use between race and ethnic groups but had similar and infrequent biologic switch. Based upon these data, efforts to eliminate biologic use disparity remains paramount and supersedes concerns regarding disparity in biologic switching.

LONG-TERM SAFETY AND EFFICACY OF BIOSIMILAR INFliximab (CT-P13) AFTER SWITCHING FROM ORIGINATOR INFliximab: RESULTS FROM THE 26-WEEK OPEN LABEL EXTENSION OF A NORWEGIAN RANDOMIZED TRIAL

G.L. Goll1, K.K. Jorgensen2, J. Sexton1, J.C. Olsen1, N. Bolstad1, M. Lorentzen2, E. A. Haavardsholm1, C. Merf1, J. Janssen1, T.K. Background: The NOR-SWITCH study was funded by the Norwegian government to investigate if switching from originator infliximab (INX) to biosimilar CT-P13 is safe in rheumatoid arthritis (RA), spondyloarthritis (SpA), psoriatic arthritis (PsA), Crohn’s disease (CD), ulcerative colitis (UC), and chronic plaque psoriasis (PsA).

Objectives: Assessing efficacy, safety, immunogenicity at week 78 in patients on CT-P13 for 78 weeks (maintenance group) vs CT-P13 for 26 weeks (switch group).

Methods: 481 adult patients on stable originator infliximab were randomised 1:1 to continued INX or switch to CT-P13 treatment in the main study. All extension participants received CT-P13. The primary endpoint was disease worsening, analysed with logistic regression, adjusted for diagnosis and treatment duration.

ASDAS, Ankylosing Spondylitis Disease Activity Score; DAS28, Disease Activity Score in 28 joints.

Results: 380 patients entered the extension trial. Demographic and baseline (52 w) characteristics of the extension study population are shown (table 1). Disease worsening in the study arms (Per Protocol Set, PPS) and in each diagnosis (explorative analyses) are shown (table 1). Generic disease variables, disease specific composite measures, trough drug levels, anti-drug antibodies and reported adverse events were comparable between groups (data not shown).

Conclusions: We found no difference between patients switched from INX to CT-P13 vs those on maintained CT-P13.

AB0443 THE EFFECTS OF DENOSUMAB FOR RHEUMATOID ARTHRITIS PATIENT

I. Yoshi, Rheumatology and Musculoskeletal Medicine, YOSHII HOSPITAL, Shimanto City, Japan

Background: Denosumab (dMAB), an anti-receptor activator of nuclear factor kappa-B ligand (RANKL) monoclonal antibody, is now popular anti bone absorption suppressant for osteoporosis. Recently, this drug has indicated for rheumatoid arthritis (RA) treatment, for expectance for suppressant in joint destruction. However, except of the effect on joint deformation, anti inflammation effect is not evident in randomised control trial (RCT), although rich case series for OP in RA patient is already collected in clinical practice.

Objectives: Aim of this study is to investigate effects of dMAB on RA, and evaluate other effects but joint destruction suppression.

Methods: In 352 patients who have been treated with dMAB, RA patients who have been treated with dMAB consecutively for more than 1 year, were picked up for this study. Patient who have had experience of biologic disease modifying anti rheumatic drug (bDMARD) or targeted synthetic DMARD, had been eliminated. In whom bone mineral density (BMD) in lumbar spine (LS), femoral neck (FN), and greater trochanter (GT), and tartrate-resistant acid phosphatase 5b (TRACP5b), 28-joints disease activity score with C-reactive protein (DAS28-CRP), Health Assessment Questionnaire Disability Index (HAQ-DI), visual analogue scale; HAQ-DI, Health Assessment Questionnaire Disability Index; SHS, Sharp/van der Heijde score (dSHS), joint space narrowing score (dJSN) and bone erosion score (dBES), and pain score with visual analogue scale (PS-VAS) were measured, and their mean values were compared between 6 months before start (BEF) and 6 months after start (AFT) statistically with paired T-test. Statistically significant level was set less than 1%.

Results: One hundred and three patients, in whom 100 were female and three were male, were donated in this study. All of them had been supplemented with Denotas Chewable Combination Tablets (Daichi Sankyo Co., Ltd. Tokyo, Japan), which is medical compound with calcium and natural vitamin D₃. Average age at start was 71.17 years old, and disease duration of RA at start was 7.42 years. Glucocorticoid was administered in 45 patients (44.7%), and methotrexate was administered in 72 patients (69.9%). BMD demonstrated from 74.03 (%YAM) to 77.32 in LS, whereas from 69.79 to 69.63 in FN, and from 71.98 to 74.27 in GT, from BEF to AFT, respectively. BMD of LS and GT at AFT demonstrated significant increase, while FN demonstrated no significant difference. TRACP5b demonstrated 2.12 to 1.86, 1.32 to 0.89, 2.13 to 2.01, 1.27 to 0.68, 0.80 to 0.70, 0.537 to 0.590, 81.76 to 80.98, 36.16 to 37.08, 46.96 to 44.27, respectively. DAS28-CRP, and all of its components, and EGA demonstrated significant decrease, although PS-VAS showed decrease yet demonstrated no significance, while HAQ-DI showed increase with no statistical significance. DSHS and dBES demonstrated significant less value than at BEF, while no significance for dJSN yet slightly increased in the AFT, even no significant difference demonstrated for absolute values (table 1).

Conclusions: The effect of dMAB on RA is suggested suppression of dBES, BMD increase in LS and GT, improvement of DAS28-CRP, and may have decrease of PS-VAS.

AB0444 DESCRIPTION IN REAL-WORLD OF THE EFFICACY AFTER SWITCHING FROM INTRAVENOUS TO SUBCUTANEOUS ADMINISTRATION OF TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS. THE ROSSWITCH STUDY

1 Rheumatology, University Hospital, Lille; 2 Rheumatology, General Hospital, Armentières; 3 Rheumatology, University Hospital, Reims; 4 Rheumatology, University Hospital, Amiens; 5 Rheumatology, General Hospital Victor Provo, Roubaix; 6 Rheumatology, Institut Francois Calot, Berck-sur-Mer; 7 Rheumatology, University Hospital Maison Blanche, Reims; 8 Clinical Operations, Roche SAS, Boulogne Billancourt; 9 Medical, Chugai Pharma France, Paris La Defense; 10 Rheumatology, Private Practice, Valenciennes; 11 Rheumatology, University Hospital Roger Salengro, Lille, France

Background: It has been proven, in a pivotal RCT, that SC tocilizumab (TCZ) was non-inferior to IV TCZ. However the switch from IV to SC TCZ has not been evaluated to date in a large real-world study.

Objectives: The main objective was to assess the maintenance of efficacy of SC TCZ 6 months (M6) after switching from IV to SC formulation in patients (pts) with rheumatoid arthritis (RA) in real-world. Secondary objectives were: characteristics of pts and RA, efficacy of TCZ at M12, TCZ retention rates at M6 and M12 for SC/IV, predictive factors of switching.

Methods: We analysed all RA pts of the shared medical file “RIC Nord de France” with >1 DAS 3 months before inclusion, treated with TCZ, switching or not from IV to SC TCZ, between April 30 2015 and January 15 2016. The primary efficacy endpoint was the% of pts remaining in their DAS28-ESR category remission/LDA and/or moving to an inferior DAS category at M6. Various sensitivity analyses were realised on the primary criterion of which a propensity score (IPTW).

Results: From the 314 included pts, 30% switched from IV to SC TCZ. At baseline, 77.7% were females, mean BMI was 27.5±6.4, mean RA duration was 14.9 ±9.2 years. Mean IV TCZ duration before inclusion was 35.0±23.1 months in Switch and 26.8±22.1 months in No-Switch pts. Mean DAS28 were 2.1±1.1 in Switch and 2.9±1.6 in No-Switch pts. 81.9% and 59.5% of the pts were in DAS28 remission/LDA, 18.1% and 28.6% in MDA, 0% and 11.8% in HAD in Switch and
No significant difference in therapeutic maintenance was found at 12 months according to the date of initiation and according to the number of previous bDMARDs.

Abstract AB0445 – Figure 1. Therapeutic maintenance of Abatacept at 12 months

Conclusions: Therapeutic maintenance at 12 months was 68%, this rate is similar to Pan-European Registry. The rate of CRP at initiation seems to have an impact on the maintenance of ABA at 12 months.

PHYSICIAN-REPORTED BEHAVIOURS AND TREATMENT TRENDS OF TUMOUR NECROSIS FACTOR INHIBITOR USE: CYCLING VERSUS SWITCHING IN FIVE EUROPEAN COUNTRIES: FRANCE, GERMANY, ITALY, SPAIN AND THE UK

J.R. Curtis1, E. Sullivan1, J. Kershaw2, S. Blackburn2, P. Mahajan3, S. Boklage4
1University of Alabama at Birmingham, Birmingham, USA; 2Adelphi Real World, Manchester, UK; 3Sanofi, Bridgewater; 4Regeneron Pharmaceuticals, Inc., Tarrytown, USA

Background: Previously, most biologics prescribed for treating rheumatoid arthritis (RA) were tumour necrosis factor inhibitors (TNFi) and it was common practice to prescribe a second TNFi after failure of the first. Biologics with different mechanisms of action (MOA) have become available and 2016 European League Against Rheumatism guidelines recommend cycling to another TNFi or switching to a biologic with a new MOA following failure of the first TNFi.

Objectives: Describe the proportion of patients in 5 EU countries who, after failure of a first TNFi, cycle to a second TNFi (‘TNFi cycling’) vs switch to a treatment with a different MOA (‘Switch’), and identify patient characteristics and physician attitudes associated with TNFi cycling vs switching.

Methods: Data were from the Adelphi Disease Specific Programme (DSP), a cross-sectional survey conducted in 2017 in France, Germany, Italy, Spain and the UK. Rheumatologists prospectively completed records about the next 10 patients with RA who consulted them during the study period; records captured treatment history and clinical details. Patients were included in the analysis if they had been prescribed at least 2 different biologics, their first was a TNFi and their second was known. Patients were assigned to 2 cohorts: ‘TNFi cycling’ patients received a TNFi at first- and a different TNFi at second-line; ‘Switch’ patients received a TNFi at first-line and a non-TNFi at second-line. Bi-variate comparisons of groups were conducted using nonparametric tests as appropriate.

Results: All physicians in the DSP sample (n=301) were questioned on their beliefs around TNFIs; 86.4% believed that there is a class effect with TNFIs regarding efficacy and/or safety (table 1). Data from 359 patients were included in the analysis (75.8% female; mean [SD] age 56.5 [12.7]), of whom 167 (46.5%) were TNFi cycling, and 192 (53.5%) were Switch patients (female: 70.7% vs 80.2%, respectively; p<0.04; age: 55.8 [13.1] vs 57.1 [12.4], respectively; p=0.42). The most common reasons for discontinuing first-line therapy among the TNFi cycling and Switch cohorts were worsening condition (36.3% vs 45.3%,
Conclusions: Despite evidence from literature suggesting that RA patients have a better treatment response switching to a non-TNFi after initial TNFi inadequate response and despite the majority of physicians in our study believing that there is a class effect with TNFis, regarding efficacy and safety, 46.5% of patients still cycled to a second TNFi rather than switched to a non-TNFi as second-line therapy.

AB0447 AUDIT OF THE CLINICAL EFFICACY AND SAFETY OF ETANERCEPT BIOSIMILAR TO ITS REFERENCE PRODUCT IN PATIENTS WITH INFLAMMATORY ARTHRITIS: EXPERIENCE FROM A DISTRICT GENERAL HOSPITAL IN THE UNITED KINGDOM
J. Mg, S. Peford, L. Jones, K. Douglas, H. John. Rheumatology, Russells Hall Hospital, Dudley, UK

Background: Etanercept has been widely used in rheumatology practice since NICE approval in 2000. Biologics have been pivotal treatments for inflammatory arthritis but are associated with a considerable economic burden. The expiry of patent protection has led to the introduction of biosimilar drugs at competitive prices.

Methods: The first 50 patients switched were sampled and followed up for 6 months. Data was collected from hospital databases and patient records (demographic; disease activity scores 6 months pre and post switch; adverse events (AE), Inclusion criteria: all patients established on reference etanercept for more than 12 months. Exclusion criteria: patients attempting to conceive, pregnant or breastfeeding women, patients on 25mg of reference etanercept or with JIA. Results: Of the 194 patients on reference etanercept in the Dudley area, 160 (83%) were successfully switched at the time of audit. Of the first 50 patients who switched, 32 (64%) patients had rheumatoid arthritis (RA), 15 (30%) anklylosing spondylitis (AS), and 3 (6%) psoriatic arthritis (PsA). The mean age was 60 years (range 29-83 years) with equal gender distribution. Mean years on reference etanercept was 6 years (range 1-13 years). In the RA cohort: 23(72%) patients were female with mean change of DAS28: +0.1(SD:0.87). In the AS cohort,14(93%) patients were male with mean change of BASDAI: -0.6 (SD:1.34). PsA: 2 patients symptoms were unchanged, 1 patient’s tender and swollen joint count decreased. At 6 months post switch, 84% patients continued etanercept biosimilar SB4.

Disclosure of Interest: None declared

AB0448 PATIENT-REPORTED OUTCOMES FOLLOWING DISCONTINUATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB: RESULTS FROM A RANDOMISED CONTROLLED TRIAL
1) Albany Medical College and The Center for Rheumatology, Albany; 2) Geisel School of Medicine, Dartmouth College, Lebanon; 3) Case Western Reserve University and the MetroHealth System, Cleveland; 4) Genentech, Inc., South San Francisco, USA

Background: Patients with rheumatoid arthritis (RA) often receive methotrexate (MTX) in combination with biologics; however, MTX may be discontinued due to intolerance or to reduce the medication burden once disease control is achieved. Whereas previous studies have established the efficacy of tocilizumab (TCZ) initiated as monotherapy (MONO) for the treatment of RA, patient-reported outcomes (PROs) after MTX withdrawal in patients achieving good clinical response to TCZ +MTX have not been evaluated. PROs are important measures when determining response to therapy in patients with RA with respect to health-related quality of life (HRQOL) and fatigue.

Methods: This study evaluated PROs between patients with RA who achieved low disease activity with TCZ +MTX and then continued or discontinued MTX in the COMP-ACT trial (NCT01855789). Patients who achieved DAS28-ESR≤3.2 at Week 24 were randomised 1:1 to receive TCZ-MONO or continue TCZ+MTX until week 52 (double-blind). Changes in PRO scores were measured between Week 24 and Weeks 40 and 52, and included patient global assessment of disease activity (PtGA; visual analogue score [VAS], 0–100 mm), pain (VAS), Health Assessment Questionnaire Disability Index (HAQ-DI, 0–3) and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue.

Results: Of the 296 randomised patients (TCZ +MTX, n=148; TCZ-MONO, n=148), 74.8% were women, mean age was 55.5 years, mean RA duration was 6.8 years and mean DAS28-ESR was 6.3 at baseline. At Week 24 (randomisation), PRO scores were similar between the randomised treatment groups. The mean changes in PGA, pain, HAQ-DI and FACIT-fatigue scores from Week 24 to Weeks 40 were similar between the TCZ +MTX and TCZ-MONO groups (table 1). The proportion of patients with HAQ-DI <0.5 was similar between the groups at Week 24 (randomization), and remained similar at Weeks 40 and 52.

Disclosure of Interest: None declared
Abstract AB0448 – Table 1. Changes in Patient-Reported Outcomes from Week 24 (Randomization) to Week 40 and Week 52

FACIT, Functional Assessment of Chronic Illness Therapy; HAQ-DI, Health Assessment Questionnaire Disability Index; MONO, monotherapy; MTX, methotrexate; PIAg, patient global assessment; SEM, standard error of the mean; TCZ, tocilizumab.

1 A negative change in score represents an improvement in the respective PRO except for Fatigue.

1 Estimated means from ANCOVA model includes Week 24 value as a covariate, treatment and the randomization stratification factors: DAS28 remission status at Week 24 ([≤2.6; >2.6 to <3.2], baseline weight-by-dosing group (<80 kg every 2 weeks [q2w]; ≥80 kg weekly [qw], 80 to <100 kg qw, 80 to <100 kg q2w; 100 kg qw), patient anti-TNF exposure (Yes or No).

Conclusions: Patients receiving TCZ who discontinue MTX appear to have similar PROs across multiple measures compared with patients continuing TCZ + MTX. Differences observed in clinical parameters between TCZ, MONO and TCZ + MTX did not appear to achieve a threshold that would be considered clinically meaningful. Similarities in PROs on both treatments were consistent with the clinical efficacy measures previously reported from COMP-ACT.

AB0449 SDAI REDUCTION AT WEEK 2 PREDICT 2 THE SDAI REMISSION AT WEEK 24 WHEN CERTOLIZUMAB PEGOL (CZP) WAS ADMINISTERED TO PATIENTS WITH RHEUMATOID ARTHRITIS

K. Ono1, S.-i. Mizuki, Matsuyama Red Cross Hospital, Japan, Matsuyama-Shi, Japan

Background: Certolizumab pegol (CZP) is approved for treatment of rheumatoid arthritis.

Objectives: To explore the predictor of efficacy of certolizumab pegol (CZP) for MTX-IR patients with rheumatoid arthritis in our retrospective study.

Methods: 50 patients who received CZP for rheumatoid arthritis of MTX-IR after 2013 were examined by logistic regression analysis using Age, sex, duration of disease, HAQ, TJC, SJC, gVAS, eVAS, CRP, SDAI, DAS 28-CRP, previous use of biologics, prednisolone use, ACA, RF, the reduction rate of SDAI at week 2 to assess the predicting factor for SDAI remission at week 24.

Results: As a factor capable of achieving SDAI remission at 24 weeks after CZP administration, SDAI reduction rate of 50% or more (n=28, p<0.001), females (p=0.01), the number of swollen joints (p=0.02) were extracted as significant factors. The odds ratio at which SDAI remission can be obtained at 24 weeks point is -15.4 (95% CI: 3.1–109.6) when the SDAI reduction rate at 2 weeks after the start of administration is 50% or more. SDAI remission rate at week 24 were 67% in SDAI reduction ≥50% at week 2 and 22% in another. The continuation rate at week 24 in SDAI reduction ≥50% at week 2 is 93%.

Conclusions: When SDAI decreased by 50% or more at 2 weeks after initiation of CZP administration SDAI remission was easy to obtain after 24 weeks, and continuation rate was also good.

AB0450 IMPACT OF THERAPEUTIC PATIENT EDUCATION ON SAFETY SKILLS AND INFECTIOUS EVENTS OF PATIENTS TREATED BY BIOLOGICAL DMARDS IN RHEUMATOLOGY: A BI-CENTRIC STUDY

L. Franzen1, M. Ardizzone1, L. Spanel1, D. Orfei1, N. Atti1, L. Ansaufi1, J. E. Gottenberg1, J. Sibilia1, C. Sortet1, 2Service de Rhumatologie, GHR Mulhouse Sud Alsace, Mulhouse, 2Service de Rhumatologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

Background: Patients treated with biologic DMARDs have to be aware of the specific adverse events and have to be able to manage their treatments in case of infectious disease. Therapeutic Patient Education aims to enable patient to acquire these safety skills.

Objectives: To assess the impact of Therapeutic Patient Education on safety skills and management of infectious events in patients treated with biologic DMARDs in rheumatology.

Methods: Bi-centric analytical study comparing safety skills and infectious events between two cohorts of patients (TPE and TPE-naïve). Safety skills were assessed by an auto-assessment called “Biosecure”, rated on a scale from 0 to 100. This assessment explores several dimensions of treatment management and was validated for assessment of safety skills in patients treated with biologic DMARDs in rheumatology in a preliminary study. Infectious events and their management were self-reported by patients. A cluster analysis aimed to separate patients into working group based on their shortcomings (on the basis of their answers to the Biosecure Assessment).

Results: 414 patients answered the assessment. The median Biosecure Score was 70.98/100 (O1Q3: 60.97–84.63). 47% attended Therapeutic Patient Education. The median Biosecure Score was significantly higher in the TPE group than in the TPE-naïve group (74.88 versus 67.20 [p<0.05]). Regarding the observance to treatment, activity scores, vaccination rates or incidence of infectious events, there were no significant difference between the groups TPE and TPE-naïve. Nevertheless, there were more treatment interruption for infectious events in the TPE group, suggesting that TPE could lead to better management of treatment during infectious events. Cluster analysis based on Biosecure assessment separated patients into 3 level groups but failed to identify specific patient profiles.

Conclusions: Therapeutic Patient Education could provide better safety skills and better treatment management in patients treated with biologic DMARDs in rheumatology. Prospective studies may confirm the impact of TPE on treatment management during infectious events. Further studies may assess the impact of TPE on incidence of serious infectious events.

AB0451 INCIDENCE OF OPPORTUNISTIC INFECTIONS DURING RITUXIMAB, ABATAcept OR TocilizumAB TREATMENTS FOR RHEUMATOID ARTHRITIS IN CLINICAL PRACTICE

L. Leon1,2, M. Perhuelas3, F.J. Candell4, D. Freitas4, L. Rodrigue4, J.A. Jover6, L. Abasolo1, 2Rheumatology and DISSC, Hospital Clinico San Carlos; 3Health Sciences, Camilo Jose Cela University; 4Microbiology; 5Rheumatology, Hospital Clinico San Carlos, Madrid, Spain

Background: With the expanding use of biologic disease-modifying anti-rheumatic drugs (bDMARDS), opportunistic infections (OI) are a major concern in Rheumatology.

Disclosure of Interest: None declared

Objectives: Our purposes were to describe and compare the incidence of OI in RA treated by non-TNF-targeted biologics.

Methods: We performed a retrospective longitudinal observational study from 2007 to 2017. We included subjects followed in our outpatient clinic, diagnosed with RA according to ACR criteria, whom started treatment with a bDMARD (rituximab (RTX), abatacept (ABA), or tocilizumab (TCZ)).

Results: A total of 164 patients with 219 different courses of bDMARDs treatment. Of these, 76% were women with a mean age at first bDMARD of 61.4±15.1 years. Rheumatoid factor was positive in 73.6%. Main comorbidities were: Hypercholesterolemia (53.3%), Hypertension (53.2%), Depression (25%), Diabetes (15%), and Ischaemic Heart Disease (9.8%).

Conclusions: The incidence of OI in non-TNF-targeted biologics in real life conditions is described. Incidence found was near 31 cases per 1000 patients-year. 86.4% of OI were fungus infections, 16.4% were virus infections, and 4.1% were mycobacterial infections. Risk factors associated with OI were ACR diagnosis (p=3.1×10⁻²), age at treatment (p=7.1×10⁻³), previous bDMARD therapy (p=3.3×10⁻¹), and previous BT (p=3.3×10⁻¹). Tocilizumab was significantly associated with a higher incidence of OI (IRR=2.02 [95% CI, 1.2–2.98] p=0.017 x 10⁻¹). Tocilizumab was significantly associated with a higher incidence of OI (IRR=2.02 [95% CI, 1.2–2.98] p=0.017 x 10⁻¹). Tocilizumab was significantly associated with a lower rate of global AE (IRR=0.6 [95% CI, 0.4–0.8] p=1.6 x 10⁻⁴).
AB0454  BIOLOGICAL THERAPIES SURVIVAL IN ADULTS AND JUVENILE ONSET ARTHRITIS. DATA FROM BIOBADAGUAY REGISTRY

M. G. Avila-Pedretti1, Z.Morel1, N. Cabrera2, S. Cabrera-Villalba1, I. Acosta Colman1, P. Babak1, P. Melgar1, G. Elizaur1, M. Franco1, P. Delgado1, D. Cordovilla Montero3, J. Losanto4, L. Roman1, E. Paredez1, J. Mazzoleni1, P. de Abreu8, on behalf of BIOBADAGUAY.

Background: Survival of biological therapies (BT) may be considered as an indicator of efficacy and safety of the drug. BT survival have been studied mainly in pediatric patients with a chronic inflammatory arthritis enrolled in the Para-BADAGUAY registry. Our objective is to compare BT survival in children and adults with chronic inflammatory arthritis.

Methods: Patients with a chronic inflammatory arthritis enrolled in the Para-BADAGUAY registry between 2015 and 2017 were included. For this study, patients were divided in two groups: 1. Adults with any chronic inflammatory arthritis and 2. Patients with juvenile idiopathic arthritis (JIA). To compare the groups according to BT, only the first biotherapy was considered.

Survival analysis was performed using Kaplan-Meier estimators and proportional hazard regression model. First we analysed global BT survival in both groups; and secondly we compare BT survival between groups.

Results: From 778 BTs (etanercept n=184, adalimumab n=440, rituximab n=44, infliximab n=27, tocilizumab n=75, and others n=8), 556 where identify as first line BTs. Of these, only adalimumab and etanercept were included in the study due to sufficient number prescibutions in both groups for the analysis.

We found a mean survival times for adults of 289 (±20.7 SD) weeks for etanercept and 287 (±6.6 SD) weeks for adalimumab. In JIA patients the mean survival were 243 (±26.0 SD) and 216 (±24.0 SD) weeks for etanercept and adalimumab respectively.

When comparing survival between groups, we found that JIA presented more discontinuation of BT when compare with adult patients (p=4.4 × 10–4, HR=0.51 [95% CI, 0.36–0.73]). Similar results were observed when analysing only etanercept (p=3.92 × 10–2; HR=0.50 [95% CI, 0.26–0.97]) or adalimumab (p=1.20 × 10–3; HR=0.48 [95% CI, 0.30–0.75]).

Conclusion: Our results show that different sets of clinical and demographical variables are significantly associated to biological therapy survival depending on the discontinuation cause.

Disclosure of Interest: None declared

AB0455  IMPACT OF ONE-YEAR TREATMENT WITH BIOTECNOLOGIC DRUGS ON WORK DISABILITY AND ACTIVITY IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Manara3, R. Caporal3, R. Gorla1, E. Fusaro2, R. Pellierito1, P.A. Rocchetta1, P. Sarzi Puttini4, S. Capi4, L. Sinigaglia1, G. Gaetano Pini Institute, Milan; 1University of Pavia, IRCCS Poliambulante San Matteo Foundation, Pavia; 2Spedali Civili, Brescia; 3Città della Salute e della Scienza, Ospedale Mauriziano, Torino; 4ASO SS. Antonio e Biagio e C. Amigo, Alessandria; 5L. Sacco Hospital, Milan; 6School of Economics and Management, LIUC University, Castellanza, Italy

Background: Disease activity significantly impacts on work ability of patients with Rheumatoid Arthritis (RA). Biologic agents can control disease activity, but their effects on productivity outcomes were not adequately investigated in Italian population.

Objectives: Aim of the study was to evaluate the impact of biologic therapy on work productivity outcomes in a cohort of biologic-naïve patients with active RA from northern Italy.

Methods: This is a multicentre prospective study on patients with active RA in working age (18–65 years), scheduled to undergo their first biologic treatment. Demographics and clinical data were collected at baseline and at 6 and 12 months, together with productivity outcomes assessed with the RA-specific work productivity survey (WPS-RA) and the Health and Labour Questionnaire (HLQ).

Primary outcome was the productivity loss or gain after 1 year of treatment.

Results: We included 100 patients from 7 rheumatology centres in northern Italy with active RA [mean DAS28: 5.1 (SD 0.9), median SDAI: 25.2 (IOR 18.7–33.2)]. Most of them were females (85%), with a mean age of 49.1 (SD: 10.3) years and a median disease duration of 7 (IQR: 3–14) years. Patients were treated with TNF-inhibitors (68%), Abatacept (24%) or Tocilizumab (8%). At baseline 39 patients were unemployed. After 1 year of treatment, 85 patients were still on follow-up, with an improvement in all indexes of disease activity [mean DAS28: 2.8 (SD 1.3), median SDAI: 5.1 (IQR 1.9–12.9)]. A significant reduction in number of days of work missed (absenteeism) and of reduced productivity (presenteism) was observed in employed subjects, as well as a significant decrease in number of days missed of household work and social activities in all the study population (table 1).

Abstract AB0455 – Table 1

AB0456  EFFICACY AND SAFETY OF SWITCHING FROM ETANERCEPT REFERENCE PRODUCT TO LBEC0101 (ETANERCEPT BIOSIMILAR) COMPARED WITH CONTINUING LBEC0101 IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y.W. Song1, H. Matsuuo2,3, M. C. Park4, M. Tomomitsu4, S. Shin5, J. Lee6, on behalf of LBEC0101 Research Group. 1Seoul National University Hospital, Seoul, Korea, Republic of Ireland; 2Tokyo Medical University, Tokyo; 3Matsuno Clinic for Rheumatic Diseases, Toyama, Japan; 4Division of Rheumatology, Yonsei University College of Medicine, Seoul, Korea, Republic of Ireland; 5Mochida Pharmaceutical Co., Ltd, Tokyo, Japan; 6LG CHEM, Seoul, Korea, Republic of Ireland

Background: LBEC0101 is a newly developed biosimilar of etanercept (ETN). As rheumatoid arthritis (RA) treatment is a long-standing process in the clinical practice, the long-term safety and efficacy of anti-TNF inhibitors have been studied and reported. Clinical studies have been conducted to evaluate the efficacy and safety of biosimilar after switching from their originator drug.

Objectives: To evaluate the long-term efficacy, safety, and immunogenicity of switching from the ETN reference product (RP) to LBEC0101 or continuing LBEC0101 in patients with RA.

Methods: This multicenter, single-arm, open-label extension study enrolled patients with RA who had completed the 52 week treatment period of the
Clinical equivalence in efficacy between ABP 501 and adalimumab in patients with moderate to severe rheumatoid arthritis: A tipping point sensitivity analysis

N. Zhang, H. Wang, E. Krishnan.

Background: ABP 501 is the first approved biosimilar to adalimumab. Patient withdrawals from clinical trials can result in missing data, which may lead to loss of statistical power and bias of the treatment difference estimate. Therefore, it is critical to examine the potential effects of missing data and analyse the sensitivity of statistical power and bias of the treatment difference estimate. Therefore, it is critical to examine the potential effects of missing data and analyse the sensitivity of statistical power and bias of the treatment difference estimate.

Objectives: To examine and confirm the robustness of the clinical similarity concept to examine the potential effects of missing data and analyse the sensitivity of statistical power and bias of the treatment difference estimate. Therefore, it is critical to examine the potential effects of missing data, which may lead to loss of statistical power and bias of the treatment difference estimate. Therefore, it is critical to examine the potential effects of missing data, which may lead to loss of statistical power and bias of the treatment difference estimate.

Patients who were deemed requiring continuous treatment for RA upon the investigator’s discretion and agreed to participate in this study were allowed for participation. All patients received ABP 501 50 mg/ml once a week for 48 weeks with the stable dose of methotrexate regardless of the randomization group in the Phase III study. Efficacy, safety and immunogenicity were assessed up to Week 100. Data were analysed for patients who continued to receive ABP 501 for 100 weeks (maintenance group) and for those who had received ETN-RP for 52 weeks and then switched to LBE0101 for 48 weeks (switch group).

Results: A total of 148 patients were enrolled in this study; 70 patients continued to receive LBE0101 and 78 patients switched to receive LBE0101 from ETN-RP. DAS28-ESR score in the full analysis set were maintained in both groups from week 52 through week 100 (from 3.068 to 3.103 in maintenance group from week 52 to week 100 respectively). Response rates at week 100 for maintenance and switch groups, respectively, were 79.7% vs. 83.3% for ACR20, 65.2% vs. 66.7% for ACR50 and 44.9% vs. 42.3% for ACR70. The incidents of adverse events were comparable between the groups (70.0% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 70.5% for switch group, respectively).

Conclusions: The efficacy and safety of LBE0101 were comparable in both maintenance and switch groups. The efficacy of LBE0101 was well sustained over 100 weeks.

Efficacy and B-cell depletion with very low dose rituximab (biosimilar) in sero-positive DMARD resistant rheumatoid arthritis: A 24 week study

N. Jain1, S. Pandya2, D. Shukla2, P. Srivastava3. 1. Department of Rheumatology; 2. Department of Rheumatology, VS Hospital Ahmedabad, Ahmedabad, India, India

Background: Very low dose rituximab (RTX) (100 mg) has been variously used in autoimmune diseases like ITP and rheumatoid arthritis (RA). As cost of treatment is an important issue in resource poor setups, we decided to study efficacy of very low dose RTX in patients with RA.

Objectives: 1) To study clinical efficacy of very low dose RTX in DMARD refractory RA, 2) To study B cell depletion with very low dose RTX

Conclusions: The tipping point sensitivity analyses support the findings of the key efficacy analyses in the phase 3 RA study and confirm that the effects of missing data would not change the conclusion of clinical similarity between ABP 501 and the RP.

Clinical equivalence in efficacy between ABP 501 and adalimumab in patients with moderate to severe rheumatoid arthritis: A tipping point sensitivity analysis

Background: ABP 501 is the first approved biosimilar to adalimumab. Patient withdrawals from clinical trials can result in missing data, which may lead to loss of statistical power and bias of the treatment difference estimate. Therefore, it is critical to examine the potential effects of missing data and analyse the sensitivity of the results under various assumptions on the mechanism of missing data.

Objectives: To examine and confirm the robustness of the clinical similarity conclusion between ABP 501 and adalimumab reference product (RP) through tipping point sensitivity analyses on ACR20 at week 24, the primary endpoint of the phase 3 study in patients with rheumatic arthritis.

Methods: The primary analysis for this trial has been previously published. The proportions of patients achieving ACR20/50/70 responses with last observation carried forward imputation at weeks 2, 4, 8, 12, 18 and 24, were similar between ABP 501 and the RP over time. Tipping point sensitivity analyses were used to estimate the difference between ABP 501 and the RP with varying assumptions on the outcomes in patients who withdrew from the study early and those who completed the study.

Results: The table 1 displays the results of tipping point analyses on the primary endpoint of ACR20 at week 24. There were no scenarios in which the 90% confidence interval (CI) failed to rule out a 12% loss/increase in the ACR20 response.

Abstract AB0457 – Table 1. Tipping point analysis results for RD (90% CI) of ACR20 at week 24

Methods: Prospective open labelled study. Biologic naive, conventional DMARD refractory, sero-positive RA patients ACR 2010 criteria) with high disease activity (DAS 28 ESR) were included after informed consent.

Arm 1: Total 4, weekly 100 mg doses(total dose 400 mg) of a RTX biosimilar were infused.

Arm 2: Single 100 mg RTX infusion.
Efficacy was assessed using standard outcome measures for RA (including RAPID3) at week 24. B cell depletion (CD19 levels in peripheral blood by flow cytometry) was studied at baseline, week 1 and week 12.

Results: Total number of patients in Arm 1=14 and in Arm 2=13.

In Arm 1: 28% (4/14) achieved EULAR remission while 78% (11/14) had EULAR good response. In Arm 2: 70% (9/13) had EULAR good response. All patients achieved complete B cell depletion (defined as <0.01%) at week 1 after just single dose of 100 mg RTX remained so at 6 weeks only to start rising again at week 12. There were no adverse events noted. Steroid doses were reduced in most patients at follow up visits with delta change in steroid dose-2.2 mg/day. Results comparable with other studies using both low dose and conventional dose of RTX. Limitations of the study includes small sample size and short follow-up.

Conclusions: Very low dose RTX is efficacious in conventional DMARD refractory RA patients. Single dose (100 mg) is as good as 400 mg up to week 24. Complete B cell depletion can be achieved even with 100 mg RTX as early as week 1.

REMISSION RATE OF TOCILIZUMAB IN CONTROLLED TRIALS AND OBSERVATIONAL STUDIES: SYSTEMATIC REVIEW OF RHEUMATOID ARTHRITIS

1Rheumatology, YILDIZIM BEAYAZIT UNIVERSITY; 2Rheumatology, Hacettepe University; 3Rheumatology, Numune Education and Research Hospital, Ankara; 4Rheumatology, Medical Science University Bakirköy Sad Konuk Hospital, İstanbul, 5Rheumatology, Aksioneer University, Antalya; 6Rheumatology, Kocaeli University, Kocaeli; 7Rheumatology, İzmir Katip Çelebi University, İzmir; 8Rheumatology, Eskişehir Osmangazi University, Eskişehir, Turkey

Background: In concept, the state of remission constitutes a clinical condition in which no active disease is present. Target of rheumatoid arthritis (RA) is achievement to remission. Tocilizumab (TOC) is a humanised monoclonal antibody that binds to the interleukin-6 receptor

Objectives: The aim of this study was to assess the remission rate of TOC for the treatment of RA patients in randomised controlled trials (RCTs) and longitudinal observational studies (LOS).

Methods: In January 2017, a systematic Review (SR) was performed in PUBMED MEDLINE. Publications were identified using the MeSH terms: (“rheumatoid arthritis and tocilizumab”) with a limitation to “humans”, “all adults: 19 +years”, “English” and “clinical trials”. All available studies describing the retention rate of TOC were recruited to SR. Retention rate of TOC were calculated according to route (SC or IV), dosage (4 mg/kg vs 8 mg/kg), monotherapy or combination with methotrexate. Of the 662 publications identified by the literature search, 42 were recruited in the analysis. Retention rates of TOC at 12–16 weeks, 24–32 weeks, 48–52 weeks, 2, 3, Years and 5 years were analysed.

Open label extension period of RCTs included to LOS. The causes of withdrawal of TOC were recorded as inefficacy, adverse event, and others.

Results: Of the 34 studies, 13 (38%) were RCTs and 21 (62%) were LOSs. Totally 12 043 patients (9834 (81%) female) were pooled to analysis that 6190 patients (51%) were from RCTs. The mean age was 53 years and mean disease duration was 9 years. Seropositivity was 73.6% for rheumatoid factor and 72.2% for ACPA. Overall, 5493 (54.6%) of patients were biologic-naive. TOC was used as monotherapy (2469/6077, 35.4%), or concomitant with methotrexate (8037/11429, 70.3%). Available baseline DAS-28 score, CDAI, SDAI, and HAQ-DI score were 6.2, 32.1, 33.3, and 1.49 respectively. Remission rate of TOC according to study type were shown in table 1.

Abstract AB0459 – Figure 1

Conclusions: These systematic literature results show that treatment with TOC has a high likelihood of inducing a clinically important benefit in terms of different remission criteria. Remission achieved both RCTs and real life results. Moreover, remission rate of TOC in LOSs was comparable with other biologic DMARDs, as well.

AB0460

LONG-TERM DRUG SURVIVAL OF ETANERCEPT VS OTHER TNF INHIBITOR THERAPIES IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Emery1, B. Vlahos2, P. Szczypa3, M. Thakur4, H. Jones2, J. Woolcock5, P. V Santos Estrella6, A. Gibbons7, C. Rolland7, G. Citrea8, L. Marshall9,10. Leeds Musculoskeletal Biomedical Research Centre LTH, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, UK; 2Pfizer, Collegeville, USA; 3Pfizer Ltd, Walton Oaks; 4Pfizer, Sandwich, UK; 5Weill Medical College, New York, USA; 6Envision Pharma Group, Horsham, UK; 7Consultontie Reumatologicos, Buenos Aires, Argentina

Background: TNFα inhibitors have profoundly altered outcomes for patients with rheumatoid arthritis (RA) since they were introduced >15 years ago, by reducing disease activity and radiographic progression and improving quality of life. As a chronic disease, RA often requires life-long treatment, understanding drug survival in real-world settings can be beneficial in optimising disease management.

Objectives: To compare the long-term drug survival of adalimumab (ADA), certolizumab pegol (CZP), etanercept (ETN), golimumab (GLM), and infliximab (IFX) in patients with RA based on systematic literature review (SLR).

Methods: In this SLR, the goal was to identify full-text articles containing registry data or systematic reviews on TNFα inhibitors, following Cochrane dual-reviewer methodology. Searches were conducted in November 2017 with no date restriction, using Embase*, MEDLINE*, the Cochrane Central Trials Register and Database of Systematic Reviews, other Cochrane Library databases, and PubMed. Outcomes extracted included drug survival data that were analysed and reported using Kaplan-Meyer or Cox regression methods.

Results: Of 3888 non-duplicated publications initially identified, 3299 were excluded based on titles or abstracts and 344 based on full-text screening, leaving 26 publications published between 2005 and 2017 included in the analysis. The number of studies (range of sample size) for each drug were ADA: 15 (25–2349), ETN: 17 (20–3892), IFX: 21 (26–2898), GLM: 4 (2–88) and CZP: 1 (NA). Among the analysed studies, the mean disease duration in years (range) was ADA: 10.7 (8.2–15.1); ETN: 15.9 (5.0–18.5); IFX: 14.2 (8.5–19.3); CZP: 10.3 (NA); GLM: 8.9 (8.1–11.5) and mean baseline DAS28 (range) was ADA: 5.0 (4.2–5.9); ETN: 5.2 (4.3–6.3); IFX: 5.3 (4.1–6.4); CZP: 4.7 (NA) and GLM: 4.7 (4.1–5.1). Trends for survival rates of first-line ETN were slightly higher than ADA at time points >36 months; ADA and ETN had higher survival rates than IFX at >48 months (figure 1).

Abstract AB0460 – Figure 1
Conclusions: Long-term survival rates for ADA, ETN, and IFX were similar and relatively high for treatment periods up to 36 months. After 36 months, there was a noticeable decline in drug survival for all three TNFi inhibitors. Heterogeneity in study size and design may contribute to the range of survival data for biologic agents.

RESULTS:

Abatacept Retention (Time to Discontinuation of SC Abatacept) Over 6 Months by Treatment Line

Conclusions: In this first observation of SC abatacept in a real-world setting, overall retention of SC abatacept at 6M was high and similar to that observed with IV abatacept. 1 Better retention and response rates were achieved with abatacept as an earlier bDMARD treatment line. Good/moderate EULAR response rates at 6M were consistently >70%, irrespective of treatment line and higher BL radiographic erosion in biologic-failure pts.

Abstract AB0462 – Figure 1. Treatment Retention Rate Over Time (Mths) in Study Population Evaluable for Effectiveness.

Conclusions: These real-world data demonstrate an acceptable safety profile for abatacept in Belgian pts with a stable retention rate of up to 5 years in a difficult-to-treat population. A temporary discontinuation also seems feasible.

A REVIEW OF THE OUTCOMES OF WOMEN WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH BIOLOGIC AGENTS ATTENDING THE SHEFFIELD COMBINED OBSTETRICS AND RHEUMATOLOGY CLINIC 2002 TO 2013

R. Smith1, R. Kilding1, K.-P. Kue1, F. Fairlie2, R. Jokhi1, T. Bonnett1, M. Smith1, M. Aki1, 1Rheumatology Department, 2Obstetrics and Gynaecology, Royal Hallamshire Hospital, Sheffield, UK

Background: Women with RA have increased risk of complications including preeclampsia, low birth weight babies and Caesarean sections compared with unaffected women.1 Higher levels of disease activity have a negative influence on birth weight.2 More women are being treated with biologic agents, and there is growing evidence for their safe use in pregnancy.3

Objectives: To assess disease activity during pregnancy, and to review foetal and maternal outcomes.

Methods: Retrospective review of case notes.

Results: Between 2002 and 2013, 17 women with RA treated with biologic agents attended the combined clinic. 13 were treated with Etanercept, 2 Adalimumab, 1 Tocilizumab and 1 Rituximab. 13 were in combination with disease modifying anti-rheumatic agents (DMARDs). There were 17 pregnancies, 2 women stopped their biologic prior to conception; 14 stopped on confirmation of pregnancy. 12 women had active disease during pregnancy. All had some form of steroid treatment, 3 had a DMARD introduced, and 1 restarted Etanercept at 20 weeks.

There were 14 live births and 2 first trimester miscarriages. There was 1 elective Caesarean section, 7 spontaneous deliveries, and 5 inductions, 3 of which proceeded to Caesarean. Data is missing for 2 women. 10 babies were born at term, 3 were pre-term and data is missing for 2. 2 babies weighed less than 2500 g and 2 more than 4500 g. Data is missing for 3 babies. The low birth weight babies were also pre-term, had cardiac abnormalities and required admission to the neonatal unit. Both mothers had stopped Etanercept at confirmation of pregnancy. Both flared during pregnancy.

6 women developed complications: hypertension, diabetes, proteinuria, cervical incompetence, and hypothyroidism. 4 of these had active disease during their pregnancies. 2 babies had intrauterine growth restriction, 2 cardiac abnormalities and 1 macrosomia. All had mothers who flared during pregnancy.

Conclusions: Our group of patients is small, but the outcomes are comparable to those of women with RA. There is no discernible increase in adverse events due to biologic use. In 2014 product recommendations were to stop biologics prior to conception.4 Since 2016 the British Society for Rheumatology has advised that Etanercept and Adalimumab are compatible with use in the first and second trimesters. Tocilizumab and Rituximab should still be stopped prior to conception.3 Local practice has changed to reflect this guidance, and the next step in this project is to review the data from more recent pregnancies to determine whether more prolonged use of biologics improves disease control and in turn foetal and maternal outcomes.

REFERENCES:
SAFETY OF RITUXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Batool1, M. Perry1, D. Russell2. 1Rheumatology; 2Pharmacist, NHS, Glasgow, UK

Background: The treatment of rheumatic diseases has been revolutionised in the biologic era. Remission and low disease activity are realistic targets. Several trials have suggested that dose reduction is achievable without loss of clinical effect. However, ‘real life’ response data is still lacking.

Objectives:
- To increase interval dose of biologic drugs in a standard rheumatology clinic setting
- To assess the clinical response and determine potential cost savings

Methods: Patients were identified by database interrogation and hospital prescription record, from a regional population of 4 000 000 over a 2 year period. All rheumatic conditions treated with anti-TNF and IL-6 blockers were potentially accepted for tapering. Those with low disease activity scores (RA and PsA DAS <2.1, AS BASDAI <4.1) for >1 year were screened and invited to consider dose reduction following discussion in a clinic.

Results: 154 biologic patients were screened and 97 contacted to consider dose tapering. Of these, 40 patients agreed to participate in biologic dose reduction. Demographics: Mean age 51 years, 18 male patients and 22 females, concomitant MTX use in 49%. Diagnosis: RA-24, PsA-9, AS-7. Drugs tapered included Adalimumab (28), Etanercept (5), Golimumab (5) and Tocilizumab (2). 8 patients flared during the program and response was recaptured in 2 patients after increasing dose. 32 patients were successfully maintained on reduced dose with no requirement to date to increase dosing frequency. Biologic drug was completely withdrawn in 1 patient and 2 patients were commenced on reduced dose of DMARD. Prior to dose reduction mean DAS was 1.91 and mean BASDAI was 2.45. Low disease activity scores were recorded (mean DAS 2.1, mean BASDAI 0.74). Duration of the treatment was similar in both groups. Suspension of biologic treatment was 5.8±7.1 years.

Conclusions: Successful tapering of biologic drugs can be achieved and sustained in non-trial settings for patients with low disease activity. Significant cost savings have been confirmed with likelihood of recurrent savings over future years.

REFERENCES:
[1] Edwards C, Fautrel B, Schulze-Koops H, Huizinga T, Kruger K. Dosing savings have been confirmed with likelihood of recurrent savings over future.
Methods: A retrospective observational study was conducted including patients with RA treated in a tertiary hospital between June 2006 and May 2017 who had received at least one RTX cycle. At RTX initiation we analysed: age, sex, comorbidities and Charlson score, disease duration, presence of rheumatoid factor (RF)/anti-citrullinated protein antibodies (ACPA), disease activity (DAS28), acute phase reactants (CRP, ESR), previous biological treatments; concomitant treatment (csDMARD/glucocorticoids (GC)). Serum Ig levels before every RTX cycle, the number of RTX cycles and adverse events (AE), including serious and opportunistic infections were also analysed.

Results: We included 53 patients (86.8% women, mean age 55.5±13.5 years), 58% with a Charlson score ≥3. Mean disease duration was 16±9.1 years; 84.9% and 92.5% were RF and ACPA positive, respectively. Before starting RTX, 81% of patients had received other biologic drugs (58.5% ≥ 2); 88% received concomitant csDMARD, (52% methotrexate and 32% leflunomide) and 81% were treated with GC (median dose 10 mg, P25-P75: 5–10 mg). The median number of RTX cycles received per patient was 5 (P25-P75: 2–6). 80 AE were reported: 12 infusion reactions, 8 cases of neutropenia, 51 infections (18 respiratory, 8 urinary, 4 skin and soft tissues, 8 gastrointestinal, 4 cases of non-disseminated herpes zoster, 1 bacteremia, 2 septic shock and 6 other) of which 19 were serious and 5 malignancies (2 melanomas, 2 cervix, and 1 bladder) were also notified. No opportunistic infections were reported. Ig levels were obtained for 41 subjects: 7, 5 and 1 patients had low levels of IgG, IgM and IgA, respectively. Patients who developed infections received a greater number of RTX cycles (p<0.0002) and had more frequently low levels of serum IgG during follow-up (p<0.044) than those who did not have infections.

Conclusions: Long-term exposure to RTX showed a good safety profile with a low incidence of serious infectious and no opportunistic infections. Factors associated with the development of infections were the number of cycles received and low serum levels of IgG at any point during follow-up.

AB0467 SUSTAINED CLINICAL RESPONSE IN REFRACTORY RHEUMATOID ARTHRITIS PATIENTS WITH A LOW-DOSE RITUXIMAB RETREATMENT REGIMEN

S.D.L.C. Rodríguez García, R. Castellanos-Moreira, M.V. Hernandez-Miguel, A. Cuervo, V. Ruiz-ESquipe, J. Ramirez, O. Camacho, J.D. Cañete, J. Gómez Puerta, R. Sanmartí. Rheumatology, Hospital Clinic de Barcelona, Barcelona, Spain

Background: The standard dose of rituximab (RTX) in rheumatoid arthritis (RA) is two intravenous (iv) 1 g infusions, separated by two weeks. Recently, the efficacy of a low-dose of RTX for retreatment in RA patients has been reported.

Objectives: Our aim was to assess the long-term sustained effectiveness of a low-dose of RTX in daily clinical practice.

Methods: Observational retrospective study including all RA patients treated on a tertiary hospital who had received at least one cycle of RTX, at the standard dose, between June 2006 and May 2017. We selected those patients who achieved a good or moderate EULAR response and thereafter were down-titrated to a low-dose regimen (1 g). Variables analysed: age, sex, disease duration, presence of ACPA (anti-CCP2) and rheumatoid factor (RF), glucocorticoid (GC) and conventional synthetic DMARD (csDMARD) use and dosage before and after RTX treatment, number of biologic DMARD (bDMARD) used prior to initiating RTX. Disease activity was measured using DAS28 index (prior to first RTX infusion, at low-dose regimen initiation and at last follow-up visit).

Results: 53 patients received; at least, one cycle of 2 g RTX, 70% achieved a good or moderate EULAR response and were step-downed to a low dose retreatment regimen. Baseline characteristics of patients receiving low-dose RTX were: mean age 56.4±10.9 years; 13.5% male, mean disease duration 12.7±9.8 years, 91.9% RF and 97.3% ACPA +; mean DAS28 prior to RTX initiation was 5.79 ±1.17.

73% of patients had received other bDMARD before RTX, 48% 2 or more. 92% were on cs-DMARDs, 51.4% methotrexate (MTX) and 37.8% leflunomide (LEF) and 86.5% were receiving concomitant GC (median dose 10 mg, P25-P75: 5–10 mg). 73% of subjects received only one standard cycle before RTX dose reduction.

Mean DAS28 decreased significantly between the first visit on 1 g RTX vs the last follow-up visit (4.08 vs 3.04; p<0.001). Additionally, 11 patients (8 MTX, 3 LEF) were able to reduce csDMARD dosage. 56.3% of patients receiving GC at the initiation of low-dose retreatment were able to reduce the dose (median 10 mg vs 5 mg; p<0.0001), and 28% discontinued GC therapy.

After a mean follow-up of 3±1.8 years, RTX was withdrawn in 10 patients: 8 due to adverse events (recurrent infections in 4) and 2 cases due to loss of efficacy.

Conclusions: A sustained clinical response was observed with the 1 gr retreatment of RTX after a long-term follow-up period.

AB0468 CLINICAL AND ULTRASONOGRAPHIC EFFECTIVENESS IN TWO COHORTS OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT: A REAL LIFE STUDY

S. Parisi, M.C. Ditto, M. Scarati, M. Priora, C.L. Peroni, E. Fusaro. Rheumatology Unit, AOUM Città della Salute e della Scienza di Torino, Turin, Italy

Background: Synovitis in Rheumatoid Arthritis (RA) is a phenomenon related to the development of erosions and progressive structural damage; early synovitis improvements are successfully associated with long-term clinical and structural outcomes.

Objectives: The aim of this study was to evaluate the efficacy of abatacept in two cohort of patients treated with Abatacept as the first and second or third line of treatment.

Methods: We evaluated patients affected by RA (according to ACR 2010 criteria) and were divided into two groups:

Group A: patients with moderate or severe active RA, non-responders to Metothrexa (MTX), bDMARDs naïve, treated with Abatacept 125 mg/wk;

Group B: patients with moderate or severe active RA, non-MTX and anti-TNF responders, treated with Abatacept 125 mg/wk;

The concomitant treatment with MTX was maintained unchanged in those patients who were taking it at stable doses before the start of the study (10–15 mg/week for ≥28 days); concomitant therapies such as low-dose systemic CS (prednisone ≤7.5 mg/day) and NSAIDs have been maintained for at least 4 weeks if stable. The activity of RA was calculated with the DAS28-CRP according to the clinical practice protocol (week 0,4,12,24). The Ultrasound (US) evaluation of the synovitis was done according to the Omeract criteria (Grey Scale and PDUS score: 0 to 3).

Results: We recruited consecutively 34 patients with RA, 16 pts (male n=4, 25.0%) took Abatacept as the first line (Group A), and 18 pts (males n=5; 27.7%) took Abatacept as followed by another anti-TNF drugs (Group B). The mean age was 57±10.7 years (median 60, range 45–72); mean of DAS28 at baseline was 4.8±0.9 (median 4.7; range 3.9–5.6); mean duration of the disease was 15.3±5.7 years (median 10; range 3–22). Tab.1

A constant improvement of the DAS28 score is shown in both groups examined until the end of the follow up, resulting respectively: -3.2 for Group A (p<0.05) and -Δ2.1 (p<0.05) for Group B. The total PDUS score decreased in both groups from week 4, with a mean change (85% CI) compared to baseline of –0.8 (range –1.4–0.2) and progressive mean significant improvement until follow-up (Gr.A p<0.05; Gr.B p<0.05). No serious adverse events or infections were observed. Patients with ACPA positive showed a greater improvement trend compared to other patients in both groups (p: 0.068), Figure 1.

AB0468 - Efficacy and Safety of Interleukin 6 Inhibitors in Rheumatoid Arthritis: A Systematic Literature Review

REFERENCES:

Disclosure of Interest: None declared

AB0469 - Efficacy and Safety of Interleukin 6 Inhibitors in Rheumatoid Arthritis

Background: Interleukin 6 (IL-6) inhibitors constitute a therapeutic option for patients with rheumatoid arthritis (RA). Currently, apart from Tocilizumab (TCZ), we have data from other drugs targeting the IL-6 pathway.

Objectives: To review published evidence on safety and efficacy of IL-6 inhibitors in RA.

Methods: We performed sensitive systematic literature searches in Medline and Cochrane (up to October 2017), screened EULAR and American College of Rheumatology meeting abstracts. An expert librarian designed the strategies that included Mesh and text word terms. The search was limited to human RA, adults and the English and Spanish language. The inclusion criteria were as follow: 1) RA patients on IL-6 Inhibitors including TCZ, sarilumab (SAR), olokizumab, sirukumab and clazakizumab; 2) Placebo and an active comparator were accepted as comparators; 3) Articles including typical efficacy and safety variables such as EULAR, radiographic progression or the infections rate; 4) Only meta-analyses, systematic reviews and clinical trials were selected. Two reviewers screened the titles and abstracts of the retrieved articles independently. They also collected the data from the studies included by using ad hoc standard forms. All collection was double by article and independent. Subsequently, a secondary manual search of the bibliography of the articles that were finally included was performed. Evidence tables were produced. The quality was evaluated with the Oxford 2009 scale.

Results: We included 64 articles of moderate-high quality, variable duration, between 12 and 108 weeks. These articles analysed more than 8000 patients with RA, most of them with established RA (although there are data on early RA), with high disease activity and severity criteria. More than a half of the studies are of TCZ. IL-6 inhibitors were effective both in the short and long term in terms of clinical remission, RA activity, radiographic progression, function, fatigue, bone metabolism, morning stiffness, pain, quality of life, or anaemia. They also decreased and even normalised CRP values in a rapid and sustained manner. The efficacy of blocking IL-6 has been seen in RA refractory to DMARD or anti-TNFα and in MTX-naïve patients, as well as in the intravenous and subcutaneous formulations (TCZ). TCZ and SAR are more effective than adalimumab in monotherapy. In general, no statistically significant differences were found between combined therapy and monotherapy. In terms of safety, the rate of adverse events increased over time and with the concomitant use of DMARDs. Infections and hypersensitivity reactions were the most frequent adverse events and infections the most frequent serious adverse events. IL-6 inhibitors were associated with a rapid and subsequently sustainable increase in serum lipid parameters, although this was not associated with a higher prevalence of cardiovascular events and related mortality, nor was it associated with neoplasms. Transtamiasine elevations were generally mild and without serious disorders. The incidence of gastrointestinal perforations was very low, and it was associated with a previous history of diverticulitis.

Conclusions: IL-6 inhibitors are effective to control RA activity and symptoms and to prevent radiographic damage in different disease profiles, with an acceptable safety profile.

AB0470 - Influence of Using Adalimumab in Complex Treatment on the Frequency of Eyes Involvement in Patients with JIA

T. Marushko, O. German, J. Golubovska. National Academy of postgraduate education named after P.L. Shupik, Kyiv, Ukraine

Background: Extra-articular organs involvement in JIA is frequent and mostly includes rheumatoid uveitis in ANA-positive oligoarthritis. In Ukraine almost 10% of children with JIA during systematic ophthalmologic examination have signs of ocular involvement. Early treatment with biological agents can influence inflammation progression in eyes of the JIA patients.

Objectives: The objective of the study was to investigate the frequency of recurrences of uveitis in patients with JIA and eyes involvement on methotrexate alone and methotrexate with adalimumab.

Methods: There were 23 patients with JIA and rheumatoid uveitis involved into the study. Mean age was 9,6 (4–16) years. Among them there were 14 (61%) girls and 9 (39%) boys. Serological characteristic included 17 (74%) patients with positive ANA, and 3 (13%) children with positive HLA-B27. All patients received 15 mg/m2/week of SC methotrexate. During onset and recurrence of uveitis all children received glucocorticoids with slowly tapering dosage (from 1 mg/kg/day to 0–0.1 mg/kg/day) until uveitis remission. Of 23 patients 11 (47,8%) received adalimumab in standard doses. Study were hold for 5 years during which every child were investigated by ophthalmologist every 3 months irrespective of clinical status.

Results: During 5 year follow up in “methotrexate” group (n=12) there were 15 episodes of uveitis recurrence (0,25 episodes per patient/year), of them 10 (66,6%) were revealed only by ophthalmological assessment and had no obvious clinical signs (subclinical uveitis). Same time only 2 episodes of uveitis recurrence were registered in “methotrexate +adalimumab” group (0,04 episodes per patient/year) (p<0.05).

Conclusions: Adding adalimumab to methotrexate in complex treatment of patients with JIA and eyes involvement allows decreasing frequency of both clinical evident and subclinical recurrences of rheumatoid uveitis.

Disclosure of Interest: None declared

AB0471 - Biosimilar Medicine is Acceptable to Patients if Recommended by a Rheumatologist in an Australian Tertiary RA Cohort

T. Kovaliwanchikarn4,5, D. Wang1,3, S. Raghunath2,3, L. Ky1, N. Walpole2, S. Pignataro2, S. Morton1, E. Morand2,3, M. Leech2,3.

Background: Advancement in biological disease-modifying antirheumatic drugs (bDMARDs) has greatly improved the prognosis of patients with rheumatoid arthritis. Their high costs, however, pose a significant health-economic challenge. Biosimilars are being adopted in Australia and worldwide to improve affordability and access to treatment. While the predominant focus of current literature has been on physicians’ awareness and confidence of biosimilars, an effective introduction of biosimilars requires an understanding of patient acceptance of these products.

Objectives: To investigate patient awareness and attitudes to biosimilar medicine in a tertiary hospital RA clinic.

Methods: A cross-sectional study of 127 patients with rheumatoid arthritis was performed in Melbourne, Australia. A brief education on biosimilars was provided. Patients rated concerns regarding biosimilar efficacy, side-effect profile, operation
The pharmacodynamic and safety of single-dose sarilumab SC or tocilizumab IV or SC in patients with rheumatoid arthritis (RA)

T. Ishii, Y. Satoh, Y. Munakata, M. Kajiwara, Y. Takahashi, F. Anwar, A. Pac্ল, P. Kovalenko, J. Parrino, A. Boyapati, C. Xu. 1 Tohoku University Hospital, Tohoku, Japan; 2 Sendai Medical Imaging Clinic, Sendai, Japan; 3 Munakata Yasuyuki Clinic, Sendai, Japan; 4 Sanofi K.K., Tokyo, Japan; 5 Sanofi Genzyme, Bridgewater, NJ, USA; 6 Regeneron Pharmaceuticals, Inc, Tarrytown, NY, USA

Background: Two studies (PDY14191 [NCT02404558]: randomised, open-label, Japanese patients; 6R88-RA-1309 [NCT02097524]: randomised, open-label, non-Japanese patients) assessed the pharmacodynamic profiles of two monoclonal antibody blockers of IL-6R, sarilumab and tocilizumab.

Objectives: To evaluate the pharmacodynamics of absolute neutrophil count (ANC), C-reactive protein (CRP), IL-6, soluble IL-6R (sIL-6R), and safety after a single dose of subcutaneous (SC) sarilumab, or intravenous (IV) or SC tocilizumab in patients with RA.

Methods: 30 Japanese patients (PDY14191) were randomised 1:1 and received a single injection with SC sarilumab 150 mg or SC tocilizumab 162 mg without background medication. 101 non-Japanese patients (6R88-RA-1309) were randomised 1:1:1:1 and received a single dose of SC sarilumab (150 or 200 mg) + methotrexate (MTX), or IV tocilizumab (4 or 8 mg/kg)+MTX. Pharmacodynamic and safety outcomes were assessed through Week 6.

Results: Baseline demographics were comparable between studies except for higher mean body weight in non-Japanese patients (mean 83 vs 57 kg). Although there were numeric differences in baseline pharmacodynamic parameters, the two studies, onset of effects on ANC, CRP, IL-6, and sIL-6R during the first week after a single drug dose were similar regardless of drug, dose, or route of administration in both studies. Within both studies, maximal effects on ANC and CRP nadir and on IL-6 and total sIL-6-R peaks were comparable for sarilumab and tocilizumab (table 1). The pharmacodynamic response was more prolonged with IV tocilizumab. Time for pharmacodynamic effects to return to baseline was consistent with the dosing intervals for SC sarilumab (q2w), and IV (q4w) and SC (q2w) tocilizumab. The safety profiles of sarilumab and tocilizumab were generally similar and both drugs were associated with laboratory effects consistent with their mechanism of action (ie, decrease in neutrophil count). There was a dose-dependent effect on ANC<1.0 Giga/L in study 6R88-RA-1309 and numeric differences in ANC<0.5 Giga/L between sarilumab and tocilizumab in PDY14191. The decrease in ANC was not associated with increased risk of infections.

Abstract AB0472 – Table 1. Baseline and change in pharmacodynamic parameters, and safety in studies 6R88-RA-1309 and PDY14191

Conclusions: The pharmacodynamic and safety profiles observed after a single-dose of sarilumab SC or IV/SC tocilizumab are consistent with results anticipated in patients with RA administered an IL-6R inhibitor.

References:

Disclosure of Interest: None declared

Background: Several biosimilars have been approved for the treatment of rheumatic diseases by the European Medicines Agency (EMA) or the US Food and Drug Administration (FDA).

Objectives: To summarise immunogenicity data from regulatory documents or confirmatory trials of biosimilars approved by the EMA or FDA for the treatment of rheumatic diseases.

Methods: EMA Public Assessment Reports (EPARs), FDA Clinical Summaries, PubMed records, and EULAR and ACR abstracts were searched for immunogenicity data from confirmatory trials of approved TNFα or CD20 inhibitor biosimilars in patients with rheumatic diseases. Data collected included the proportion (%) of patients positive for anti-drug antibodies (ADAbs) among all patients and the proportion (%) of patients with neutralising antibodies (nAbs) among ADAb-positive patients.

Results: We identified 10 biosimilars approved by the EMA or FDA: three each for adalimumab (Bi 695501, SBS, and ABP 501) and infliximab (SB2, CT-P13, and infliximab-dbqtx) and two each for etanercept (GP2015 and SB4) and rituximab (CT-P10 and GP2013). The duration of treatment periods in the 16 identified trials (which varied in design and methodology of ADAb/nAb detection) ranged from 12 weeks to 102 weeks. Across treatment groups in all trials, 0% to 62% of patients were ADAb-positive, of whom 0% to 100% were also nAb-positive. The lowest proportions of ADAb-positive (0%–13%) and nAb-positive patients (0%–3%) were observed in the trials of etanercept and its biosimilars, and the highest in the trials of infliximab and its biosimilars (ADAbs: 20%–62%; nAbs: 88%–100%). Consistent with the biosimilar designation, the proportions of ADAb- and nAb-positive patients in individual trials were similar between the originator and biosimilar products. Of note, in a 52 week trial of etanercept and its biosimilar SB4, the incidence of ADAs by Week 52 was significantly lower with SB4 than with etanercept (1% [3/299] vs 13% [30/296], p<0.001). However, as noted in the SB4 EPAR, this difference, which was not reflected in the incidence of nAbs and efficacy or safety of etanercept, may have been due to an ADAb assay bias in samples collected at Weeks 4 and 8, when 37/39 ADAbs in the etanercept group and 2/3 in the SB4 group were detected.

Conclusions: Immunogenicity of the approved biosimilars is generally similar to that of originator products. For ETN, which has been associated with relatively low ADAb levels, there was a discrepancy in ADAb incidence compared with its biosimilar SB4, but those differences were transient and did not affect clinical activity or safety.

**Abstract AB0474**

**The Clinical Effectiveness and Cost Savings of Tapering Biologic DMARDs in Patients with Inflammatory Arthritis at a UK District General Hospital**

W.P. Lee, R. Manhas, V. Sebbage, S. Kyle. Rheumatology, North Devon District Hospital, Barnstaple, UK

Background: Biologic DMARDs (bDMARDs) have led to substantial improvement in clinical outcomes for treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial/peripheral spondyloarthropathy (SpA), making remission a realistic target. Current guidelines suggest clinicians should consider tapering biologics withdrawn and remains at target treatment level (RA: DAS-28 <2.6; PsA:<3 tender joints and <3 swollen joints; SpA: BASDAI <4).

Objectives: To evaluate the tapering strategies on 3 major rheumatological disease entities (RA, PsA, SpA), the number of patients successfully tapered and the total cost saving from successful tapering.

Methods: The study was conducted at North Devon District Hospital in Barnstaple, UK and includes all bDMARDs users up until 31st December 2017. The tapering strategy was identified from hospital notes. Patients who are deceased, lost to follow-up or discontinued bDMARDs due to contraindication or adverse effects were excluded. Successful tapering is defined as patient on tapered dose or had their biologics withdrawn and remains at target treatment level (RA: DAS-28 <2.6; PsA:<3 tender joints and <3 swollen joints; SpA: BASDAI <4).

Results: There are a total of 298 patients: 174 RA; 59 PsA; 57 SpA; 8 other diagnoses. 94 patients (31.5%) had attempted tapering: 52 RA, 18 PsA, 22 SpA, 60 (20.1%) successfully tapered their bDMARDs: 34 RA (56.7%); 13 PsA (21.7%); 13 SpA (21.7%). Out of 34 RA, 30 seropositive; 4 seronegative; 24 co-prescribed with synthetic DMARDs, 10 on monotherapy. Out of 13 PsA, 8 co-prescribed with synthetic DMARDs; 5 on monotherapy. 59 tapered by increasing interval of subcutaneous treatment. Only 1 RA patient tapered its IV dose of tocilizumab. This patient is excluded from the final analysis. Tapering of subsequent bDMARDs therapy by disease and price (table 1). Number rounded to 2 decimal points.

AB0475
THE INFLUENCE OF SWITCHING FROM ETANERCEPT ORIGINATOR TO ITS BIOSIMILAR ON EFFECTIVENESS AND THE IMPACT OF SHARED DECISION MAKING ON RETENTION AND WITHDRAWAL RATES

W.D. Müskens¹, S.A.A. Rongen-van Dartel¹,², E. Adang², P.L. van Riel¹,², J.O. Healthcare, Radboud UMC, Nijmegen;²Rheumatology, Bernhoven, Uden;¹Health Evidence, Radboud UMC, Nijmegen, Netherlands

Background: With biological patents expiring, biosimilars are becoming a realistic, less costly alternative to their originator. The data from numerous randomised clinical trials support that it is safe, effective and cost saving to switch to a biosimilar. However, real world data about efficacy, safety, and cost-effectiveness of such a switch are lacking.

Since shared decision making (SDM) is a key factor in the treatment of rheumatic diseases, a non-mandatory open label transitioning from Etanercept originator to its biosimilar was performed at the rheumatology department of Bernhoven.

Objectives: The first goal of this study was to investigate the effect of switching from Etanercept originator to its biosimilar on the effectiveness of treatment. The second aim was to analyse the effect of SDM on the 1 year retention rates and reasons for withdrawal in daily clinical practice.

Methods: All patients with rheumatoid arthritis (RA), axial spondyloarthritis (SpA) and psoriatic arthritis (PsA) that were using Etanercept originator between 01–06–2016 and 23–10–2017 were informed by letter of the possibility to switch to its biosimilar. During the next outpatient visit with their rheumatologist the possibility to switch was discussed. Patients had the opportunity to ask questions regarding biosimilar and the switch to a biosimilar. If patients agreed the switch was made, with the reservation that they could switch back to the originator if they encountered difficulties with the biosimilar.

Using the registry of the rheumatology department at Bernhoven data were collected on disease activity (DA), medication use and adverse events from the moment of switch till 23–10–2017. As measure for DA the DAS28 was used for RA and PsA, the ASDAS was used for SpA. Stop reasons for biosimilars were verified using the health record system of the hospital. Reasons for change in disease activity and discontinuation of biosimilar treatment were assessed.

Results: Between 01–06–2016 and 23–10–2017 80% (69 patients) of the Etanercept originator users switched to its biosimilar. These patients switched to biosimilar after a median time of 5.1 (IOR 2.6–8.3) years. By 23–10–2017, median follow-up of 307 (IOR 196–357) days, the mean DA did not significantly differ from the DA at baseline, 3.1 (95%-CI 2.5–3.7) vs. 2.8 (95%-CI 2.5–3.1). At end of follow-up 25% of the patients had discontinued there treatment and either switched back to originator (18%), switched to another biological (3%) or stopped treatment with biologicals (4%).

Reasons for switching back to originator were adverse events (58%), lack of effect (17%) and “adverse event and lack of effect” (25%). Only one serious adverse event was reported. This was a drug hypersensitivity reaction. After the patient was recovered, the originator was restarted without any difficulties.

Conclusions: An open label non-mandatory switch from Etanercept originator to its biosimilar showed that around 80% of the patients is willing to perform this switch. Switching did not affect effectiveness of treatment during one year follow-up. 75% of the patients were able to continue biosimilar therapy. In the 69 patients that switched only one serious adverse effect occurred.

AB0477
INHIBITION OF LARGE JOINT DESTRUCTION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOCILIZUMAB

Y. Hirag, K. Hattori, R. Yamada, Rheumatology, Toyohashi Municipal Hospital, Toyohashi, Japan

Background: Rheumatoid arthritis (RA) causes not only inflammation of small joints, such as hands and feet, but also inflammation of large joints. Destruction of large joints is correlated with impairments of physical activity in RA patients more than destruction of small joints is (1). We experience strong inhibitory effect of inflammation in synovial joints, not only small joints but also large joints, by treatment with tocilizumab (TCZ), an antibody to IL-6 receptor in RA patients in daily clinical practice. Although inhibitory effects of small joint destruction by TCZ is well known, inhibitory effects of large joint destruction is unknown.

Objectives: This retrospective study investigated inhibitory effect of large joint destruction by TCZ treatment in RA patients.

Methods: Toyohashi RA database (TRAD) was used. TCZ was initiated in 65 RA patients in our institute, 31 cases (23 female and 8 male) who continued TCZ over 2 years were utilised in this study. Baseline characteristics and time course of disease activity were investigated. Delta-modified Sharp score (ΔmTS5) per year was used to evaluate small joint destruction. ARASHI score (2) was used to evaluate large joints destruction. Shoulders, elbows, hips, knees and ankles were evaluated using ARASHI score.

Results: Treatment continuation rate of TCZ was 86.3% at one year and 77.7% at two years in whole 65 cases (Kaplan-Meier methods). Baseline characteristics of 31 cases was as follows. Average age: 56 years old. Average RA duration: 6.6 years. Concomitant rate of MTX: 74.2%. Concomitant rate of prednisone;
Rheumatoid arthritis – non biologic treatment and small molecules

**AB0478** MILD AND MODERATE HEPATIC IMPAIRMENT HAVE NO CLINICALLY RELEVANT IMPACT ON UPADACITINIB PHARMACOKINETICS: RESULTS FROM A DEDICATED PHASE 1 STUDY

M.-E.F. Mohamed, S. Coppola, T. Feng, A.P. Lacerda, A.A. Othman, AbbVie, North Chicago, USA

**Background:** Upadacitinib is a selective inhibitor of Janus kinase 1 (JAK1) which is currently being evaluated for the treatment of several autoimmune disorders, including rheumatoid arthritis (RA). Although renal elimination plays a minor role in upadacitinib clearance (<20% of upadacitinib dose is eliminated unchanged in urine), a considerable number of RA patients have renal dysfunction. As such, characterisation of the effect of different degrees of renal impairment on upadacitinib plasma exposures is important for this patient population.

**Objectives:** The objective of this study was to assess the pharmacokinetics of upadacitinib in subjects with mild, moderate, and severe renal impairment compared to subjects with normal renal function.

**Methods:** This Phase 1 study was conducted in 24 adult subjects, who were assigned to one of four groups (six subjects per group) according to the estimated glomerular filtration rate (eGFR) as calculated by the Modification of Diet in Renal Disease (MDRD) equation: normal renal function (eGFR of >90 mL/min/1.73 m²), mild renal impairment (60–89 mL/min/1.73 m²), moderate renal impairment (30–59 mL/min/1.73 m²), and severe renal impairment (15–29 mL/min/1.73 m²). Subjects received a single 15 mg dose of upadacitinib extended-release formulation under fasting conditions. Blood samples for pharmacokinetic assessments were collected for 120 hours after dosing. The effect of renal impairment on upadacitinib plasma exposures was assessed through regression analysis as well as analysis of covariance across the renal impairment categories.

**Results:** The point estimates for upadacitinib plasma exposure ratios [90% confidence interval] in subjects with mild, moderate, and severe renal impairment were 1.18 [1.06–1.32], 1.33 [1.11–1.59], and 1.44 [1.14–1.82] for AUC and 1.08 [0.92–1.23], 1.11 [0.88–1.40], and 1.14 [0.84–1.56] for Cmax, respectively, relative to subjects with normal renal function. In this analysis, one subject with moderate renal function showed exposures significantly lower than subjects with normal renal function.

**Conclusions:** Mild and moderate renal impairment result in very limited effect on upadacitinib plasma exposures (<30% increase in upadacitinib AUC). Therefore, in clinical trials, dose adjustments in subjects with mild or moderate renal impairment are not warranted.

**Acknowledgements:** The studies presented were funded by AbbVie. AbbVie contributed to the study design, research, and interpretation of data, reviewing, and approving the publication. All authors are employees and shareholders of AbbVie.
renal function. This subject was excluded to ensure a conservative estimate of the impact of renal impairment on upadacitinib exposure. Results from the categorical analysis were consistent with the results from the primary regression analysis.

Conclusions: Renal impairment has only a limited effect on upadacitinib pharmacokinetics. Upadacitinib mean plasma exposures (AUC) in subjects with severe renal impairment are within 44% of mean exposures in subjects with normal renal function. This is in agreement with the known limited role of urinary excretion in upadacitinib elimination.

Acknowledgements: The studies presented were funded by AbbVie. AbbVie contributed to the study design, research, and interpretation of data, reviewing, and approving the publication. All authors are employees and shareholders of AbbVie.

DOI: 10.1136/annrheumdis-2018-eular.3538

FOLIC ACID SUPPLEMENTATION DELAYS CLINICAL IMPROVEMENT IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH METHOTREXATE

A. Sulli, C. Pizzorni, S. Paolino, V. Tomatis, M. Ghio, B. Riuaro, M. Cutolo. Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy

Background: Methotrexate (MTX) is the disease-modifying anti-rheumatic drug (DMARD) most commonly used in the treatment of rheumatoid arthritis (RA), and folic acid (FA) supplementation is usually employed to prevent MTX-related adverse effects. However, the need of FA supplementation remains controversial, as it might influence the efficacy of MTX therapy. Objectives: The aim of the present study was to evaluate the effects of FA supplementation on both efficacy and safety of low-dose MTX in the treatment of RA patients.

Methods: 120 RA patients (median disease duration 11±30 months, mean age 61 ±13 SD years), according to ACR criteria, who started low-dose MTX treatment were retrospectively evaluated. Patients were not complaining of serious diseases other than RA. Two groups of patients were selected: patients supplemented with FA (58%) and patients not-supplemented with FA (42%). MTX dose, prednisone dose, disease activity (DAS28), and adverse event (AE) were recorded at 3, 6, 9, 12, 24, 36, and 48 months. At baseline, MTX mean dose was 8.3±1.9 mg/weekly, prednisone mean dose was 7.4±3.1 and 5.3 ±3.2 mg/daily, and mean DAS28 was 5.1±1.2 and 4.8±1.1, respectively for both groups. The patients were followed-up until MTX discontinuation, new DMARD/BiologicDMARD addition, need for FA supplementation, or after 48 months of therapy (mean follow-up 40±20 months). The maximum MTX dose administered during the follow-up was 15 mg/weekly. Statistical analysis was performed by non-parametric tests.

Results: DAS28 decreased in both groups during the study. However, DAS28 was found significantly lower (p<0.04) in patients without FA supplementation, when compared with patients taking FA supplementation, at months 3, 6, 9, and 12. Patients without FA supplementation required significantly lower (p<0.01) doses of both prednisone and MTX during the follow-up. AEs were observed in 26% of patients with FA supplementation, as well as in 43% of patients without FA supplementation. The difference was statistically significant (p=0.049). No difference in AE type was observed between the groups (mainly, transaminase or mean red blood cell volume elevation, oral mucositis, urinary tract infections). AEs have been successfully managed in the majority of cases by either discontinuing MTX for two weeks or adding FA if required.

Conclusions: In RA patients taking low-dose MTX, FA supplementation decreases the efficacy of the treatment, delaying the clinical responsiveness. The lack of administration of FA increases the risk of AEs; however, by considering the benign type of AEs usually observed in this subset of patients, the treatment with low doses of MTX might be started without FA supplementation, and the FA administration deferred until AE appearance.

TRANSCUTANEOUS VAGUS NERVE STIMULATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Mohr Drewes1, C. Brock2, S.E. Rasmussen1, M. Pfeiffer Jensen1. 1Department of Rheumatology, Aarhus University Hospital, Aarhus, 2Mech-Sense, Department of Medical Gastroenterology, Aalborg University Hospital, Aalborg, Denmark

Background: Rheumatoid Arthritis is a prevalent, autoimmune disease causing joint destruction and severe physical disability. In various studies the vagal nerve has been postulated to play a role in modulation of systemic inflammation. Objectives: Our aim was to investigate the effect of transtcutaneous stimulation of the vagal nerve (t-VNS) in patients with rheumatoid arthritis. We hypothesised that stimulation of the vagal nerve and thereby enhanced parasympathetic tone would increase the activity of the vagal nerve and improve experienced clinical pain.

Methods: Sixteen patients with rheumatoid arthritis and flares (DAS28-CRP>3.2) and twenty without flare were recruited. Three bilateral electrical stimulations of the vagal nerve were done with a handheld device for 4 days. Cardiac vagal tone (CVT) was assessed with linear vagal scale (LVS) and DAS28-CRP were collected on the 1st, 2nd and 5th day.

Results: Cardiac vagal tone was significantly lower in patients with flare in comparison to patients without flare (3.2 vs. 4.9 LVS, p<0.03), t-VNS did not alter CVT in patients with flare, however decreased CVT in patients without flare (baseline: 4.9, 2nd day: 3.8 LVS, p<0.03). A decrease in DAS28-CRP in patients with flare was seen in response to t-VNS (baseline: 4.2, 5th day: 3.9, p<0.03), due to decrease in CRP (baseline: 8.2, 5th day: 6.0 mg/L, p<0.02) and number of swollen joints (baseline: 5.4, 5th day: 4.4, p<0.01) and tender joints (baseline: 3.7, 5th day: 2.8, p<0.02) in RA patients with flare. A negative association between baseline CVT and baseline DAS28-CRP was found in all RA patients, showing that lower CVT was associated to higher disease activity.

Conclusions: Baseline CVT was lower in RA patients with flare, possibly due to higher level of inflammation, and the observed decrease in DAS28-CRP was not associated to CVT modulation.

SIMILAR EFFICACY OF TOFACITINIB ON DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT PREVIOUS BIOLOGICS; RESULTS FROM THE TURKBIO REGISTRY

B. Zengin1, N. Inanç2, S. Akar3, G. Can1, E. Daikić1, A. Tufan2, S. Senel2, S. Serdar Koca1, S. Capar4, H. Yarkan Tugal1, M. Birlik5, N. Akkoç2, F. Onen1. 1Rheumatology, Dokuz Eylül University, İzmir, 2Rheumatology, Marmara Eylül University, İstanbul, 3Katip Celebi University, İzmir, 4Rheumatology, Uludag University, Bursa, 5Rheumatology, Gazi University, Ankara, 6Rheumatology, Erciyes University, Kayseri, 7Rheumatology, Firat University, Elazığ, 8Department of statistics, Dokuz Eylül University, İzmir, Turkey

Background: The aim of this study was to investigate the drug survival, its efficacy and safety in patients with RA based on the database from the Turkish TURKBIO registry.

Methods: A total of 180 patients were treated with TOFA for RA. Drug survival was assessed. In 118 patients with available data, treatment response was evaluated using the number of swollen and tender joints, VAS values, DAS28, HAQ score and treatment weeks 12,24,48 and 72.

Results: At baseline, RA patients had a median(Q1-Q3)disease duration of 14 years.75 patients had used ≥1 biologics previously. The other demographic and clinical features of the patients were shown in table 1. Median(Q1-Q3)followup period was 137 weeks. After 48 and 137 weeks,75% and 48% of the patients respectively, maintained TOFA (Figure 1). The most common reason for drug discontinuation was ineffectiveness of treatment(23%), followed by adverse events(23%). After 12 weeks, all disease activity parameters were reduced significantly compared to the baseline and most of them continued to be reduced until week60. No difference was observed in disease activity parameters between the groups.
with and without previous ≥1 biologics at weeks 0, 12 and 24 (table 2) Remission rate was (43%) at week 0, observed data (table 2) A total of 9 adverse events (3 infection, 3 allergic rx, 2 rash) were observed during the followup period. *p for week 0 vs 12; **p for week 0 vs 48, ***p for week 0 vs 60 #p das28 <3.1

Conclusions: Treatment with TOFA may provide good response rates in RA (3infection, 3allergic rx, 2 rash) were observed during the followup period.

Conclusions: The findings showed that patients with RA, who used MTX frequently, had insufficient information regarding MTX. Notably, patients are lack of information about the side effects of MTX, drug interactions and the need for contraception. Hence, we recommend that patients' knowledge should be increased regarding MTX. Physicians should be provided with training to raise awareness proper use of MTX.

MONOTHERAPY WITH FILGOTINIB, A JAK1-SELECTIVE INHIBITOR, REDUCES DISEASE SEVERITY AND ALTERS IMMUNE CELL SUBSETS IN THE NZB/W F1 MURINE MODEL OF LUPUS

**Background:** Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease characterised by immune system hyperactivity leading to the production of autoantibodies and immune attack on multiple organs including the skin and kidneys. High levels of type I interferons (IFNa/b) after the activation state of immune cell populations and have been identified as a risk factor for SLE. Anti-body blockade of the interferon alpha receptor (IFNAR) has demonstrated clinical efficacy in a Phase 2b study in SLE, and validates targeting this pathway in SLE. Janus kinase 1 (JAK1) is critical for mediating downstream signalling of type I IFNs. Inhibition of JAK1, therefore, is anticipated to reduce IFN signalling, activation of immune cell subsets, and SLE disease activity. The JAK1 selective inhibitor filgotinib (FL) is currently being evaluated in three proof-of-concept Phase 2 studies in SLE-like diseases.

**Objectives:** To characterise the efficacy and mechanism-of-action of FL in the NZB/W F1 spontaneous mouse model of lupus in a therapeutic setting.

**Methods:** FL was tested in the NZB/W F1 model of lupus at two concentrations (0.05% and 0.1%) formulated in chow and administered *ad libitum* from weeks 28–40. Cyclophosphamide (CP) was used as a positive control at 5 mg/kg, once daily, i.p. Efficacy was determined by changes in proteinuria, renal histopathology, and survival. Splenic cell populations were analysed by flow cytometry at study termination at week 40 to measure changes in immune cell subsets in diseased versus non-diseased mice and following FL treatment. An *in vitro* murine whole blood pSTAT1 assay and PK exposure data were used to assess target coverage in the model.

**Results:** In the NZB/W model, FL showed a dose-dependent decrease in proteinuria with a concomitant reduction in BUN levels, renal inflammation, improved glomerular morphology, and increased survival (table 1). Diseased mouse spleens had decreased frequencies of naive T cells, increased frequencies of CD11c+ dendritic cells (DCs), and an increased ratio of memory/ naive T cells versus non-diseased mice. FL treatment showed a dose-responsive reversal of these populations toward non-diseased levels. FL inhibited in vitro IFNA-stimulated pSTAT1 signalling in T cells. Calculated JAK target coverage of pSTAT1 inhibition was similar to that observed in human studies at clinical doses.

**Conclusions:** Filgotinib demonstrated efficacy in comparison to TNF inhibitors and was slightly better than abatacept in clinical practice in RA patients who did not respond to SC methotrexate.

**AB0485**

COMPARATIVE EFFICACY OF TOFACITINIB AND BIOLOGIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH INSUFFICIENT RESPONSE TO SUBCUTANEOUS METHOTREXATE IN CLINICAL PRACTICE

E.L. Luchikina, D. Karateev, G. Lokuina, M. Borisova, N. Demidova, E. Nasonov, R. Jones, F1 1st Department of internal medicine, Moscow Regional Research and Clinical Institute (MONIKI); Department of rheumatology, Moscow Clinical scientific center; V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Tofacitinib (TOFA) – the first registered member of the group of Janus-kinase inhibitors – actively entered into practice. Some clinical trials show efficacy similar to biological DMARDS, but we still do not have enough data from the practice of post-marketing use.

**Objectives:** To evaluate the comparative effectiveness of TOFA and biological DMARDs in clinical practice.

**Methods:** Patients with RA (according to the ACR/EULAR 2010 criteria) having active disease despite treatment by subcutaneous (SC) methotrexate (MTX) were included in post-marketing observational study (REMARCA trial). The patients received a combination of MTX and biologics or TOFA. The follow-up period was 12 months. Patients received biologics in clinical practice according to national standards of care. We used SDAI as a main parameter of disease activity.

**Results:** In total 163 patients were included (81.6% females, 80.4% anti-CCP positive, 79.8 RF-positive, 74.9% with erosive disease, mean age 50,65±12.54, disease duration 30,45±4,19, BMI 27,1±5,78). All patients received SC MTX in the mean dose 22,17±3,62 mg per week, but the most of them had high activity at baseline (SDAI=32,45±14,59). After switching to a combination treatment regimen 88 patients received TNF inhibitors (70 patients – adalimumab, 18 patients – certolizumab pegol), 34 patients – abatacept (ABA), 41 patients – TOFA. Patients in the groups were comparable according to age and the main characteristics of disease severity. We found significant decrease of disease activity in every group (see table 1). In the group receiving TOFA results at 12 months were comparable with patients on anti-TNFs and significantly better than in patients on ABA. Remission (SDAI <3,3) has been achieved in 35,7% of patients on TOFA, in 28,4% with patients on anti-TNFs and significantly better than in patients on ABA.

**Abstract AB0485 – Table 1. Changes in disease activity in RA patients during follow-up period.**

SUBCUTANEOUS METHOTREXATE DISCONTINUATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Gridnev1, Y. Muraviev2. Federal State Budgetary Institution «Research Institute of Rheumatology» under the Russian Academy of Medical Sciences, Moscow, Russian Federation

Background: Safety of methotrexate (MT) therapy remains the most important issue of early rheumatoid arthritis (RA) therapy.

Objectives: A prospective evaluation of most common causes of MT discontinuation in RA patients with disease duration <3 years.

Methods: An open 1 year study included 106 patients with active RA meeting ACR/EULAR 2010 or ACR 1987 (DAS28 >3.2) criteria, naïve to subcutaneous (SC) MT. All pts were administered SC MT, starting with 10–15 mg/week dose, and following 5 mg up-titration each 1–2 weeks (to max 30 mg/week) until achieving the target (remission or minimum disease activity) or emergence of adverse reactions (AR). Pts’ monthly monitoring procedures included physical examination, blood analysis and biochemistry panel. T. Woodworth et al. inventory was used to assess the severity of ARs, and Naranjo scale was used to assess usual relationship of MT with an AR.

Results: Totally 12 (11%) MT discontinuations for the period of >3 weeks were analysed. Permanent discontinuation occurred in 9 pts (8%), and temporary (from 4 weeks to 4 months) – in 3 (3%). 83% of all cases of withdrawal took place during the first 3 months. In 3 patients MT was discontinued because of an AR and inefficiency. Combination of drug failure with AR was the reason for permanent SC MT discontinuation in 3 pts.

The causes led to SC MT discontinuation were: skin reactions in 3 pts(25%), "after-dose reactions" – in 2 (17%), allergic rash – in 2 (17%), diarrhea – in 2 (17%), elevated liver enzymes – in 3 (25%), leucopenia – in 1 (8%), breast abscess – in 1 (8%). Some patients manifested multiple ARs. Two ARs (17%) were serious (grade 4 severity). Grade 3 ARs were documented in 4 cases (30%), Grade 2 ARs – in 4, and Grade 1 (mild) ARs – in 2 (17%) pts.

Skin lesions became the underlying cause for SC MT discontinuation, such as active dermatitis (n=1) and lichenoid skin reaction (n=1).

Totally 11 (11%) MT discontinuations for the period of >3 weeks were analysed. Permanent discontinuation occurred in 9 pts (8%), and temporary (from 4 weeks to 4 months) – in 3 (3%). 83% of all cases of withdrawal took place during the first 3 months. In 3 patients MT was discontinued because of an AR and inefficiency. Combination of drug failure with AR was the reason for permanent SC MT discontinuation in 3 pts.

The causes led to SC MT discontinuation were: skin reactions in 3 pts(25%), "after-dose reactions" – in 2 (17%), allergic rash – in 2 (17%), diarrhea – in 2 (17%), elevated liver enzymes – in 3 (25%), leucopenia – in 1 (8%), breast abscess – in 1 (8%). Some patients manifested multiple ARs. Two ARs (17%) were serious (grade 4 severity). Grade 3 ARs were documented in 4 cases (30%), Grade 2 ARs – in 4, and Grade 1 (mild) ARs – in 2 (17%) pts. Skin lesions became the underlying cause for SC MT discontinuation, such as active dermatitis (n=1) and lichenoid skin reaction (n=1).

Conclusions: Skin reactions were the most common cause for SC MT discontinuation. Therapeutic failure as the leading cause for drug discontinuation was not documented in a single patient.

DISEASE ACTIVITY AT ONE YEAR AFTER ADDITION OF IGRUTAMID OR SULFASALAZINE TO METHOTREXATE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: PROPENSITY SCORE ANALYSIS

K. Tokunaga1, A. Shiraishi2, H. Oshikawa3, N. Hagino4, S. Tohma5, 1Department of Rheumatology, JAPANESE RED CROSS KUMAMOTO HOSPITAL, Kumamoto-City Higashi-ku; 2Emergency Department, Kameda Medical Center, 3Department of Rheumatology, Teikyo University Chiba Medical Center, Chiba; 4Department of Rheumatology, Tokyo National Hospital, National Health Organization, Tokyo, Japan

Background: Igrutamid (IGU) is a small-molecule disease-modifying anti-rheumatic drug (DMARD) that has been shown to suppress inflammation via the inhibition of nuclear factor-kappa B activation in vitro. The efficacy of combination therapy with IGU and methotrexate (MTX) has been demonstrated in comparison with that of placebo in rheumatoid arthritis (RA). However, its efficacy in comparison with other DMARDs such as sulfsalazine (SSZ) has not been elucidated.

Objectives: To assess the disease activity at one year after addition of IGU in comparison with SSZ to MTX in typical clinical practice.

Methods: We analysed data from 16,988 RA patients registered in a large database (NiNja: National Database of Rheumatic Diseases by iR-net in Japan) from April 2012 to March 2017. In this study, we compared the two groups who received IGU or SSZ in addition to methotrexate in the early year. We excluded patients who started receiving biologic DMARDs, and IGU or SSZ the year prior to the study period, and those whose regimens were changed to other DMARDs such as tacrolimus and bicuculline.

Baseline characteristics were compared using the t test, Wilcoxon test, or chi-square test. Fisher analysis was conducted for both outcomes. The predicted probability of IGU treatment was calculated by fitting a logistic regression model using all clinically relevant variables as presented in table 1. Moreover, to reduce the effect of treatment-selection bias and potential confounding in this observational study, we performed rigorous adjustment for significant differences in the baseline characteristics of patients with propensity-score matching using the following algorithm: 1:1 optimal match with ±0.2 caliper and no replacement. We used the standardised difference to measure covariate balance, whereby a standardised mean difference of >0.1 represents meaningful imbalance. The outcome was remission rate with disease activity score 28 CRP (DAS28-28CRP) in the year after initiation of IGU or SSZ therapy.

Results: The group that received IGU in addition to MTX included 113 patients; the other group that received SSZ in addition to MTX included 244 patients. Table 1 shows the results of the pre- and post-propensity score matching of patients’ characteristics. One hundred and nine patients were compared in each group after score matching. The remission rates of DAS28-28CRP in the following year was 45.0% (49/109 patients) and 54.1% (59/109 patients; p=0.22), and drug retention rate was 79.8% (87/109 patients) and 78.9% (86/109 patients; p=1.00), in the IGU and SSZ groups, respectively.

MULTICENTER 24-WEEK STUDY TO ASSESS THE EFFICACY AND SAFETY OF TACROLIMUS IN ACTIVE RHEUMATOID ARTHRITIS PATIENTS

J. Hur1, S. Hong2, S. Kim2, G. Kim3, S. Choi4. 1Internal medicine, Eulji university college of medicine; 2Internal medicine, Kyunghee university school of medicine, Seoul; 3Internal medicine, Ulsan university college of medicine, Ulsan; 4Internal medicine, Kusan university college of medicine, Busan; 5Internal medicine, Korea university college of medicine, Ansan, Korea, Republic of Ireland

Background: Rheumatoid arthritis (RA) is characterised by persistent synovitis and structural joint damage with T cell-driven inflammation. Tacrolimus suppresses activation of T cells through the inhibition of calcineurin.

Objectives: We evaluated the efficacy and safety of tacrolimus in Korean active RA patient who had inadequate response to disease-modifying anti-rheumatic drugs (DMARDs) including Methotrexate (MTX).

Methods: During the study period from Aug. 2012 to Jan. 2016 in this open labelled, multicenter study, 115 patients were enrolled with DAS28 >3.2. Patients received tacrolimus during 24 weeks. The initial dose was 1 mg once daily and was increased to 3 mg by every 4 weeks. The disease activity and safety was assessed.

Results: Data from 97 patients were evaluated in full set analysis. At week-24, EULAR response rate were 83.5% (81 of 97) with improvements from week-16 in 74.2% (72 of 97). Mean DAS28-ESR was continuously decreased of 5.64 at baseline, 4.14 (±1.22, p<0.001) at week-16 and 3.66 (±1.39, p<0.001) at week-24. Efficacy rates according to SDAI were 89.7% (87 of 97) and KHAQ-20 score decreased –2.42 (±3.07, p<0.001) from baseline 7.27 (±4.59) at week-24. Mean ESR was decreased –10.97 (±2.16, p<0.001) at week-16, –14.77 (±24.57, p<0.001) at week-24 from baseline 46.05 (±23.22). Mean CRP was decreased from 2.86 (±7.85, p<0.0578) at baseline to 1.34 (±3.02, p=0.0367) at week-24. In serious adverse events (6 of 108, 5.56%), two cases (pneumonia, high glucose level) were related with tacrolimus and recovered with treatment.

Conclusions: This study demonstrated the efficacy of add on tacrolimus therapy to MTX in patients with active RA patients.

**EVALUATION OF INHIBITORY FACTOR OF RADIOGRAPHIC PROGRESSION BY IGURATIMOD ADD-ON THERAPY IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSES TO DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS**

K. Katayama1, Y. Kori2, T. Okubo3, R. Futaki4, Y. Nakano5, H. Itô6, 1Orthopedic Surgery, Katayama Orthopedic Rheumatology Clinic, Asahikawa; 2Rheumatology, Sapporo Rheumatology and Immunology Clinic, Sapporo; 3Radiology, Katayama Orthopedic Rheumatology Clinic, 4Pharmacology, Seien Pharmacy, 5Medicine, Asahikawa Medical University; 6Orthopedic Surgery, Asahikawa Medical University, Asahikawa, Japan

**Background:** Igramotimod (IGU) is one of csDMARDs (Conventional synthetic Disease modified anti-rheumatoid arthritis drug) for RA patients in Japan. It was reported to suppress the production of inflammatory cytokines by inhibiting NFkappa B pass-way. IGU add-on therapy was efficient in patients with RA who were previously designated MTX-monotherapy inadequate responders (MTX-IR). The efficacy of IGU add-on therapy in bDMARDs (Biological DMARD)-IR patients was also reported. In this study, we showed disease activity and safety, and showed also radiographic evaluation for the first time by adding IGU.

**Objectives:** To obtain DAS28-ESR and adverse event data about adding IGU on RA patients with poor response to csDMARDs and/or bDMARDs in single-centre, open label and retrospective study. Furthermore, to show the radiographic evaluation after one year.

**Methods:** Clinical and radiographic efficacy was assessed by disease activity score of 28 joints (DAS28) (ESR (n=68) and the modified total Sharp score (mTSS) (n=44), respectively. We evaluated which factors are important in determining a prognosis of clinical response and mTSS. For safety, adverse events (AE) were investigated on all patients (n=89).

**Results:** 89 RA patients were recruited, and male was 28% (n=25). Mean age was 61.5 years old and mean of disease duration was 87 months. Main csDMARDs were MTX (72%). The mean dose of MTX was 7 mg/week (The average dose in Japan). Observational period was 13 months (range, 1 to 30). DAS28-ESR changed from 4.3±1.1 to 3.6±1.2 after adding IGU for 6 months (p=0.0001). The relation with the predictive factors before treatment and the response by Igramotimod. CRP, ESR, swelling joint, DAS28-ESR, CDAI and
OBJECTIVES: To investigate the effects of natural milk antibodies (Ab) on intestinal bacteria composition, and consequent therapeutic effect on disease activity of RA by monocentric randomised double blind clinical trial (UMIN CTR: 00009492).

Methods: Eighty-seven patients with RA with disease activity score of 28 joints (DAS28-ESR) values above 3.2 were divided into 3 groups (29 patients each), and treated with 600 mg of Ab, 300 mg of Ab plus 10 g of skim milk (prebiotics), and 20 g of skim milk alone, respectively, for 12 weeks. The therapeutic effects of milk antibody treatment were determined by DAS28-ESR, swollen joint count (SJC), tender joint count (TJC), and visual analogue score (VAS). The biological effects of milk antibodies were examined by serum and faecal LPS concentration, and faecal bacterial composition changes before and after the treatment. Bacteria composition changes was determined by quantitative PCR of bacterial 16S rRNA.

Results: A significant reduction in DAS28-ESR values from 4.6 to 4.1 was observed at 4th week in Ab 300 mg plus skim milk group (figure 1). Importantly, this effect was lasted through until 12th week (p<0.01), but DAS28-ESR values gradually returned to original levels after discontinuation of the treatment. On the other hand, neither high dose of milk antibody (600 mg) nor 20 g of skim milk had little effect on DAS28-ESR. Characteristic effect of milk antibody treatment observed in the Ab 300 mg plus skim milk group was the improvement of SJC, TJC, and Pain VAS. No severe adverse events have been observed. Enteric microbe analysis before the treatment indicated lower Bacteroides fragilis (less than 1/100 compared to healthy adults) and higher Staphylococcus aureus population (1000x higher) in patients with RA, indicating a dysbiosis in RA. The author thanks my colleagues, Drs. H. Shionoya, K. Kitamura, S. Suzuki, R. Fukai, T. Okubo, K. Kamiya, T. Sato, T. Abe, S. Uda, K. Nishimura, H. Takemori, H. Baba, T. Waritani, K. Terato, and H. Ito for conducting this study.

Conclusions: Natural milk antibody treatment modulates the intestinal bacterial composition, and consequently may contribute to improving disease activity of RA.

Results: To detect the most effective JAKi in blocking the inflammatory response induced by IL-1β, RA-FLS were first pretreated with different JAKi for 2 hour with concentrations of 1 μM and 10 μM and then additionally stimulated with IL-1β (20 ng/ml) for 18 hour. Even at the highest concentration of 10 μM Tofacitinib and Baricitinib did not change the IL-6 levels, whereas Peficitinib and Filgotinib reduced the IL-6 release at 10 μM. Tofacitinib and Baricitinib reduced the cytokine release if the RA-FLS were stimulated with OSM, a factor directly inducing the JAK-dependent IL-6-pathway (n=3).

To obtain a dose-response curve for the clinically relevant range of concentrations between 0.01 μM and 5 μM, RA-FLS were pretreated with Filgotinib and Peficitinib for 2 hour and then stimulated with IL-1β (10 ng/ml) for 17 hour. In contrast to Filgotinib, Peficitinib at 5 μM caused a reduction of IL-6 levels of 66% compared to control with IL-1β (p<0.01, n=5). The MMP-3 release was decreased by both substances at 5 μM. In comparison to the control with IL-1β, Peficitinib caused a reduction of 92% (p<0.0001, n=5) whereas Filgotinib only reduced the levels by 43% (p<0.05, n=3). Furthermore, Peficitinib at 1 μM decreased the MMP-3 release by 46% (p<0.01).

The treatment with Peficitinib did not affect the viability, cytotoxicity or apoptosis of RA-FLS (n=3). Therefore, the effects of Peficitinib on the inflammatory response were not caused by cell death.

Conclusions: Peficitinib reduced the release of proinflammatory cytokines and of matrix metalloproteinases after activation of RA-FLS with IL-1β and appeared to be superior to Tofacitinib and Baricitinib in targeting the pro-inflammatory and matrix destructive properties of RA-FLS.

AB0493  EFFECTIVENESS OF SUBCUTANEOUS PRESENTATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Villarreal1, M. Rivero2, D. Buitrago-García2, M. Cabrera1, P. Santos-Moreno4, 1Health Services; 2Pharmaceutical Chemist; 3Epidemiology; 4Rheumatology, Biomab, Center For Rheumatoid Arthritis, Bogota, Bogota, Colombia

Background: Methotrexate (MTX) is one of the most used drugs for the treatment of rheumatoid arthritis (RA) and has become the gold standard of therapy. It can be given via oral, intramuscular or subcutaneous (SC). MTX is a highly effective therapy for patients with RA; however, oral MTX has been associated with gastrointestinal intolerance diminishing the adherence of patients to treatment and increasing the switching to biological therapy. Thus, the use of SC methotrexate can improve its efficacy compared to oral MTX.

Objectives: The aim was to determine the effectiveness and safety of SC MTX in patients with rheumatoid arthritis.

Methods: We performed a retrospective descriptive analysis; our main goal was to provide real-life data regarding effectiveness of SC MTX in patients with RA. We excluded patients who were in remission. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3–5 weeks (DAS28 >-3.1), every 7–9 weeks (DAS28 >3.1 and ≤5.1), and every 11–13 weeks (DAS28 ≤3.1). Tender joint count (TJC), swollen joint count (SJC) and DAS28 were measured on each visit. Therapy had to be adjusted with DAS28 >3.2 unless patient’s conditions don’t permit it; regarding the effectiveness of SC MTX we calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We performed a bivariate analysis using Pearson’s chi² test.

Abstract AB0493 – Table 1. DAS28 and CDAI in patients with RA receiving SC MTX

Results: A total of 132 patients meet our inclusion criteria, 88% were female and 12% male. Mean age was 61 years.9. Mean DAS28 at baseline was 3.8±0.83, while at 12 months mean DAS28 was 3.2±0.112. Clinical disease activity CDAI at baseline had a mean of 9.6±7.2 and at 12 months 7.8±7.5. We achieved remission in 33% of patients according to DAS28% and 29% according to CDAI, also it was a significant decrease in patients with moderate disease activity see table 1. Finally, there was a statistical significance between disease activity at baseline compared to disease activity at 12 months (p<0.005). It was not observed major complaints with SC MTX, only 5% of the patients reported some mild and transient discomfort at the local application site.

Conclusions: Subcutaneous MTX is an effective and safe alternative for the treatment in patients with RA and intolerance to oral MTX, and could be a good option to prevent a premature switching to biological therapy.

AB0494  USABILITY OF A PRE-FILLED PEN FOR SELF-ADMINISTRATION OF SUBCUTANEOUS METHOTREXATE

M. Hattesohl1, M. Tribanek, K. Gescher. MEDAC GmbH, Wedel, Germany

Background: Methotrexate (MTX) is the first-line DMARD for the treatment of rheumatoid arthritis (RA).1 It is also of high significance in the treatment of psoriasis arthritis (PsA) and psoriasis vulgaris (PsV).2,3 Studies in RA patients found that there are advantages in terms of bioavailability and efficacy when MTX is administered subcutaneously (SC) as compared to orally.4,5 Since the introduction of MTX pre-filled syringes, patients are principally enabled to self-administer methotrexate subcutaneously, however not all patients are able to use syringes easily. Auto-injection using a pre-filled pen can facilitate administration by the patient. Results of a comparative crossover study showed that SC self-injection with a pre-filled pen is mainly preferred to a pre-filled syringe with regard to use, acceptability, and satisfaction6. Usability of the pre-filled pen was found in an actual-use study7, however no comprehensive data from routine clinical use are available so far.

Objectives: The aim of this practice documentation was the evaluation of the usability of a MTX pre-filled pen under everyday clinical conditions.

Methods: This multicentric non-interventional practice documentation, which took place from 2013 to 2015 in Germany, was open to naïve patients and to those who had already been treated with the pre-filled pen in accordance with the approved indications. Usability was evaluated by the patient and the physician through assessment of the individual steps of two self-injections in an interval of approximately 12 weeks (V1, V2) and through a final overall assessment using ordinal scales. Data analysis was carried out descriptively by means of standard statistical methods. Calculation of a total usability score allowed for comparison of V1 and V2.

Results: The 478 participating patients had a mean age of 56.2±13.7 years, 57.1% were female; 39.3% suffered from RA, 34.7% from PsV, 23.4% had PsA, and 12.6% were diagnosed with other conditions. 87.7% received treatment with the pre-filled pen for the first time, and 61.5% had previously received MTX. The individual steps of self-injection, removing of a protective cap, placing the device onto the skin, pressing the injection button, removing the pen, and ergonomics of the pen, were rated as "very good" and "good" by more than 90% of patients as well as of physicians in both visits. Comparing V1 and V2, usability was assessed to be even better at the second visit (p<0.0001 in the total score). Injections were carried out accurately by more than 93% of the patients.

Conclusions: Autoinjection with a pre-filled pen enables patients to self-administer subcutaneous MTX easily and comfortably in routine clinical practice.

REFERENCES:

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Efficacy and safety of tofacitinib have been shown in patients (pts) with RA in global Phase (P)2, P3 and a long-term extension (LTE) study and in 2 P2 and 1 LTE study in Japanese pts.

Objectives: To evaluate safety of tofacitinib following drug approval in Japanese pts with RA using all-case post-marketing surveillance (PMS) data.

Methods: An interim analysis (IA) of safety data from an ongoing 3 years PMS study was conducted (5 Nov 2017 data-cut). All Japanese RA pts receiving tofacitinib were prospectively registered in the PMS study. All adverse events (AEs) were collected during tofacitinib treatment. Follow-up surveillance after discontinuation was conducted for serious infection events (SIEs; 1 year), malignancy and death (3 years). For all AEs and serious AEs, 6 month IA data was used. For AEs of special interest, all-period data (up to 36 months) was used to calculate cumulative incidence rates (IRs; pts with events/100 pt-years [pyrs]) over time for herpes zoster (HZ) and SIEs during treatment >28 days and for malignancies during the full observation period.

Results: Overall, 3929 tofacitinib-treated pts with 1704.1 pt-yrs of exposure were included in the 6 month IA of safety: 80.5% were female, mean age was 62.7 years, with 32.6% of pts aged 70 years. Of these, 892 pts (22.7%) discontinued treatment, mainly due to AEs (351 pts; 8.9%) or lack of effectiveness (335 pts; 8.5%). At least one AE was observed in 1313 pts (33.4%); infections were observed in 493 pts (12.5%). The most frequent AEs were HZ (145 pts; 3.7%) and abnormal hepatic function (72 pts; 1.8%). SAEs occurred in 287 pts (7.3%); the most frequent SAEs were HZ (24 pts; 0.6%) and pneumonia/bacterial pneumonia (33 pts; 0.8%). SAEs occurred in 130 pts (3.3%). Malignancy (all causality) was reported in 25 pts (0.6%); lymphoma/lymphoproliferative disorder occurred in 5 pts (0.1%) and breast cancer in 3 pts (0.08%). There were 21 deaths (0.5%) during the 6 month period. The most common causes of death (including pts with multiple causes listed) were infection (6 cases) and malignancy (5 cases). For AEs of special interest from all-period data the IR of HZ (serious and non-serious) was 5.81 (294 pts; 3876 pt-yrs), the IR of SIEs was 5.38 (212 pts; 3941 pt-yrs) and the IR of malignancy was 1.25 (61 pts; 4874 pt-yrs).

Conclusions: This IA of tofacitinib PMS in Japan did not reveal any new or unexpected safety signals vs the tofacitinib RA clinical trials. IRs for HZ and malignancy were similar to IRs in clinical trials of tofacitinib in Japanese RA pts and the SIE IR was within the range reported in PMSs of biologic treatments. Continuous monitoring of SAEs is required until the final PMS results.

Acknowledgments: Study sponsored by Pfizer Inc. Medical writing support was provided by A MacLachlan of CMC and funded by Pfizer Inc.

AB0497 EFFECTIVENESS, TOLERABILITY, AND SAFETY OF TOFACITINIB IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE ANALYSIS OF REAL-WORLD DATA FROM THE ST. GALLEN AND AARAU COHORT

R. Mueller1, F. Popo1, F. Mattow1, M. Dumis2, A. Souza1, H. Schutze-Koops1, P. Hasler2, J. von Kempis1. 1Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen; 2Division of Rheumatology, Kantonsspital Aarau, Aarau; 3iterar AG, Grönichen, Switzerland; 4Rheumaheilkunde, University of Munich, München, Germany

Background: Tofacitinib is an oral JAK inhibitor indicated for the treatment of RA. Efficacy and safety of tofacitinib have been shown in several randomised clinical studies.

Objectives: The present study aimed to assess the clinical tolerability and effectiveness of tofacitinib among patients with RA in real life.

Methods: Consecutive patients between June 2013 and April 2017 with RA who fulfilled the American College of Rheumatology/EULAR 2010 criteria were analysed in a prospectively designed analysis of retrospective data. Patients were initiated on tofacitinib 5 mg bid. The primary objective was to analyse safety of tofacitinib in a real-life cohort. Safety was assessed by the reasons to stop tofacitinib follow-up and adverse events. The secondary outcome was to analyse frequency of and time to achieve low disease activity (LDA) and remission as defined by DAS28.

Results: Overall, 144 patients were treated with tofacitinib. 84.9% of the patients were pre-exposed to at least one biological agent. The average DAS 28 at initiation of tofacitinib was 4.43. 50.0% were rheumatoid factor and 49.0% ACPA positive. The mean follow up was 1.22 years (range 10d – 3.7a) after initiation of tofacitinib treatment. 94.64% patients remained on tofacitinib during follow up. The average time to stop tofacitinib was 190.0 days.

Conclusions: Tofacitinib is safe and effective treatment option for patients with RA. Tofacitinib follow up and adverse events of RA patients with active disease, even after use of one or more biologics, though the rate is significantly higher in patients naïve to biologic agents as compared to patients pre-exposed to biologics (LDA naïve: 100% after median 100d, pre-exposed 57.0% after 359d; remission: naïve 86.7% after 132d, pre-exposed 44.1% after 720).

AB0498 OPTIMISATION OF METHOTREXATE DOSE INDUCED SUCCESSFUL REDUCTION OF GLUCOCORTICOIDS IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Hirata1, T. Kondo1, K. Yukawa1, T. Tokunaga1, K. Oi1, Y. Yoshida1, M. Funaki1,2, K. Oda1,3, T. Nojima1,4, E. Sugiyama1. 1Department of Clinical Immunology and Rheumatology, Hiroshima University Hospital; 2Department of Rheumatology, JR Hiroshima Hospital; 3Hiroshima Clinic; 4Nojima AG, Gränichen, Switzerland

Background: Use of short-term glucocorticoids (GCs) along with methotrexate (MTX) have been recommended for newly onset patients with rheumatoid arthritis (RA) in EULAR recommendation 2016. However, it is not always easy to reduce or withdraw GCs due to patients’ fear of relapsed pain or fatigue. As well, some patients are negative to increase MTX dose for fear of adverse events.

Objectives: To clarify whether GCs could be reduced without impaired disease control by optimising MTX dose in RA patients with stable medication in real-world clinical practice setting.

Methods: 70 patients with RA who regularly visit our outpatient clinic for ≥1 year were enrolled. Clinical characters, disease activity, and medications at present and 1 year before were retrospectively collected. Therapeutic strategy was to increase MTX with reducing prednisolone (PSL) based on patient’s consent. Initiating bDMARDs was allowed in case of uncontrollable disease. Wilcoxon test and chi-square test were used for statistics.

Results: Clinical characters (median [IQR]) were: age 62±11.66 yrs; female 69%; disease duration 6.8 [3.4, 13.7] yrs. Rate of MTX was elevated from 57% to 62%, and dose (mean ±SD) was increased from 9.8±3.2 to 11.6±3.7 mg/w (p<0.0001) for uses only, whereas PSL was suppressed from 56% to 26%, and decreased from 2.3±1.1 to 0.8±1.8 mg/w (p<0.0004) for all patients. bDMARDs were used for 16 patients, and newly initiated for 2 patients. Although not significant, median CDAI, SDAI, and DAS28 were suppressed from 5.7 to 3.8, 6.2 to 3.9, and 2.92 to 2.77, and remission rate were increased from 24% to 39%, 27% to 41%, and 36% to 41%, respectively.

AB0499 EVALUATION OF THE EFFECTIVENESS OF METOTRAZOXINE IN THE HEPATIC TOXICITY DUE TO METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Parisi, M.C. Ditto, M. Scarati, M. Priora, F. Enrico. Rheumatology Unit, AOUMC della Salute e della Scienze di Torino, Turin, Italy

Background: Methotrexaet metabolizes the metabolism of purines resulting in the accumulation of adenosine; it also inhibits the activation of T cells and suppresses the expression of intercellular adhesion molecules for T cells. Side effects may show up during the treatment and among them there is hepatic toxicity, characterised by an increase of AST and ALT; such increase is usually asymptomatic but it may lead to a suspension of the treatment. Metadoxine (MTDX) is a drug which is used in order to treat both acute and chronic alcohol intoxication; it also prevents the inactivation of ATP from acetaldehyde and pyrogulatic acid. MTDX also showed to improve hepatic function markers and to decrease oxidative stress leading to a protective effect against radicals.

Objectives: The aim of this preliminary study was to evaluate the possible effect of MTDX on hepatic function in patients affected by RA in therapy with MTX.

Methods: The study involved the recruitment of patients affected by RA in treatment with MTX; a following random selection of a subgroup of patients who took MTDX (500 mg twice a day for 28 days, from the 5th to the 8th week of therapy with MTX) was performed. All the patients underwent a 12-week-follow up in which these parameters were evaluated: demographics, blood tests required for MTX in accordance with datasheets (especially AST and ALT), CRP, ESR, ACPA, numbers of swollen and tender joints, concomitant medications (NSAIDs and steroids) and the degree of disability (HAQ, table 1).

Results: 24 patients affected by RA (20 women), with an mean age of 51.3 years ±14.1 and mean MTX dose of 12.3±2.6, were recruited. 70.3% took GC with a medium dosage (3.7±2.71). Among these 24, 13 patients were underwent MTX 500 mg twice a day from the 5th to the 8th week. Patients treated with MTDX-MTX showed a significant decrease of hepatic markers (AST Δ–18.38 p=0.004 – ALT Δ–19.23 p=0.004) compared with patients with MTX only (AST Δ–4.27 p=0.110 – ALT Δ–6.09 p=0.045) after a 12-week-monitoring, with no statistically significant difference concerning disease activity (table 2).

Conclusions: This study showed the possible effect of MTDX in increasing the tolerance to the MTX without affecting its effectiveness. Its role may indeed have useful implications in patients who start the therapy with MTX or in those who develop hepatic toxicity during the treatment.

Efficacy and Safety of Tofacitinib (TOF) in Patients with Rheumatoid Arthritis at 52 Weeks in Clinical Practice

T. Aramaki1, K. Kojima, S. Kurushima, Y. Tsujii, N. Nakachi, N. Iwamoto, K. Ichinose, K. Terada, K. Eguchi, Y. Ueki, A. Kawakami, 1Rheumatic Disease Center, Sasebo Chuo Hospital, Sasebo, Japan

Objectives: To determine and compare the incidence of adverse events during treatment of RA patients with different therapeutic regimens, focusing on mono and combination therapy.

Methods: The SSDM includes interfaces of both physicians and patients with Rheumatoid Arthritis (RA) reported by patients applying smart system of disease management (SSDM) mobile tools: A cohort study of RA patients in China.

Results: From Aug 2014 to Jan 2018, a total of 7048 RA patients from 480 rheumatologists contributed data to the database the five most common treatment regimens is LEF monotherapy (3801 cases), MTX monotherapy (1000 cases), LEF+HCC monotherapy (1000 cases), LEF+MTX monotherapy (900 cases) and LEF+MTX+HCC monotherapy (800 cases). The incidence rate of hepatic events was lower for LEF monotherapy (3080/1000 PY) than MTX (1231 PY), LEF +MTX (1086 PY), HCC monotherapy (715 PY), LEF +HCC (576 PY). The incidence rate of hepatic events was lower for LMTF monotherapy (5 events/1000 PY) than MTX (52 events/1000 PY) and LEF +MTX combination therapy (115 events/1000 PY) (p<0.01). The incidence rate of leukopenia was lower for LEF monotherapy (42 events/1000 PY) and MTX monotherapy (39 events/1000 PY) than LEF +MTX combination therapy (84 events/1000 PY) (p<0.01).

Conclusions: The findings show that mono or combination of csDMARDs are the most commonly used drugs in Chinese RA patients. And AEs may be well described in this patient report database because of the large sample sizes and empowering patient themselves. RA patients can get better safety in the long-term treatment via SSDM.

AB0502

**DRUG SURVIVAL ANALYSIS OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Y. Karakol1, I. Erçen2. 1Rheumatology Clinic, Biyozf Meditk Centre; 2Biostatistics, Uludag University Medical Faculty, Bursa, Turkey

**Background:** The drug survival rate of tofacitinib in patients with Rheumatoid Arthritis (RA) has not been reported so far.

**Objectives:** To determine the tofacitinib drug survival rate and the factors that may affect it in patients with RA from a single rheumatology clinic.

**Methods:** We have retrospectively analysed the track records of RA patients to whom tofacitinib was prescribed between June 2014 to December 2017. Descriptive analysis includes sex, duration of disease, autoantibody association, smoking, major trauma exposure, initiation in DMARD/Anti-TNF resistant patients, monotherapy/use in combination with DMARD. According to the duration of the disease, the patients were grouped as early (0–4 year), established (5–10 year), and late RA (>10 year).

Drug survival was estimated using Kaplan-Meier survival analysis, and the independent variables that may affect the discontinuation were investigated by log-rank test and modelled by Backward Stepwise Cox regression analysis. Tofacitinib was prescribed to patients who were resistant to at least three different types of csDMARDs. Low-dose Steroid (below 10 mg) and NSAID drugs were used as needed.

**Results:** During the study period, 192 (163 F, 85%) patients were prescribed tofacitinib in our clinic. Median age was 56.6–61 years, the median age at onset was 45.7–72 years, and median disease duration was 10.6–44.8 years in this study. The ratio of RF and anti-CCP positivity were 63% and 60%, respectively, 33% of patients were seronegative. The patients with a smoking history were 26%, and exposure to major trauma was 16%. 15% of patients were early, 31% established, and 54% late RA. Tofacitinib was prescribed in 92 (48%) bio-naïve and 100 (52%) bio-experienced patients. It was used as monotherapy in 112 (58%) and in combination with csDMARDs 80 (42%).

The drug survival rates in Kaplan Meier analysis were 77% at 3rd, 69% at 6th, 62% at 12th, 54% at 18th and 49% at 24th, 49% at 30th months. Tofacitinib was discontinued in 51 (27%) patients due to no response and in 22 (11%) patients due to side effects. None of the independent variables in regression analysis showed a relationship to tofacitinib discontinuation (p>0.05). During the follow-up period, one patient had breast cancer, and one had recurrent pneumonia. There were no tuberculosis or shingles cases reported. Two patients died from pulmonary thromboembolism.

**Conclusions:** We found that drug survival rates of tofacitinib in RA patients were 77% at 3rd month, 69% at 6th month, 62% at 12th month, 54% at 18th month and 49% at 24th month, 49% at 30th months. The main cause of discontinuation of the drug was inefficiency and the loss of efficiency. We could not find any link between the predetermined independent variables and the drug discontinuation. This result raises questions about why the drug loses its efficacy in some patients in time, and how this could be preventable.

**Acknowledgements:** One of the theories of autoimmunity is that Damage-Associated Molecular Patterns (DAMPs) may give rise to autoimmune inflammation. We were curious about how many of patients suffered from major trauma, which was defined as accidents terminated with fractures and dislocations or falls from a height of at least three metres.

**EFFICACY OF PROLONGED MAINTENANCE MONOTHERAPY WITH RITUXIMAB IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: THREE-YEAR FOLLOW-UP**

A. Tomashina1, E. Rodionova1, T. Satonova2, V. Vasiliev1. 1Nasonova Research Institute of Rheumatology, 2Research Institute of Ophthalmic Diseases, Moscow, Russian Federation

**Background:** There are currently no effective systemic therapies of primary Sjögren’s syndrome (pSS), however, open label series have suggested that rituximab may be beneficial for systemic and glandular manifestations.

**Objectives:** To estimate clinical efficacy and safety of prolonged maintenance B-cell targeted monotherapy for pSS.

**Methods:** 25 with pSS ACR-EULAR criteria, 2016 were included in this research. Indications for treatment were significant immunological activity (high titres of rheumatoid factor (RF) and/or anti-nuclear antibodies) and/or hypogammaglobulinaemia in 20 patients, parotid enlargement (lymphoma was excluded) – 5, arthritis – 3, lymphadenopathy – 3, severe keratoconjunctivitis sicca in 7, of them corneal survival – 1, onychodystrophy – 1, peripheral neuropathy – 2. The choice of rituximab was based on the presence of two or more major criteria (RF > 40IU/ml and/or anti-DNA antibodies > 100IU/ml), the presence of one major and two minor criteria or three major criteria. The indication for rituximab was corroborated by the clinical activity of the disease.

**Results:** Indications for treatment were fulfilled in 25 patients with pSS ACR-EULAR criteria, 2016. Because of the presence of two or more major criteria (RF > 40IU/ml and/or anti-DNA antibodies > 100IU/ml), the presence of one major and two minor criteria or three major criteria. The indication for rituximab was corroborated by the clinical activity of the disease.

**Conclusions:** In our study, the therapeutic immunosuppressive approach was mostly used in attributed, C/F and P manifestations. In patients treated with immunosuppressants, the favourable outcome was lower in C/D phenotype.

**Disclosure of Interest:** None declared

**DOi:** 10.1136/annrheumdis-2018-eular.6854
Results: All patients were women with a mean age at diagnosis of 49 years [29–70] and median duration of disease was 6 years (1–20). The average cumulative dose of rituximab was 10000 mg (7000–12000 mg). The median European Sjögren’s Syndrome disease activity index (ESSDAI) decreased from 2.5 (2–3) to 0 (0–1) by the end of the study. The increase in salivation and lacrimation according to Schirmer test and tear film break-up time was insufficient, however, in median size of the saliva glands normalised and the keratoconjunctivitis sicca improved. Furthermore, 7 patients with severe keratoconjunctivitis sicca improved the course of the disease. The healing of corneal ulceration in all patients was observed one year after the initiation of therapy. A significant decrease in the RF level (from 198 IU/ml [51–442] to 71 IU/ml, p<0.002) and gammaglobulins (from 28%±5% to 19.3%±3.5%, p<0.001) was observed one year after this study beginning. Unreliable decrease of gammaglobulins was noticed in 23% of patients by the end of the follow-up, that did not increase the risk of secondary infections. We observed good tolerability of therapy, only 4 patients had mild infusion reactions.

Conclusions: Rituximab therapy is highly effective, well tolerated and helps to avoid long-term use of glucocorticoids/cytotoxic agents in pSS.

EARLY AND SUSTAINED REMISSION IN SLE CAN BE ACHIEVED BY USING PULSE METHYL-PREDNISOLONE, HYDROXYCHLOROQUINE AND LOW-MEDIUM DOSE-PREDNISONE

B.R. Ruiz Estévez1, G.R. Instarozza1, E. Lázaro2, I.Ruiz Anzuza1, P. Duffau4, P. Blanco1, on behalf of Systemic Autoimmune Diseases Unit of Cruces Hospital. Bordeaux Hospital, Bordeaux; 3Autoimmunity Diseases Unit, Cruces Hospital, Bilbao; Internal Medicine, Bordeaux Hospital, Bordeaux; 4Autoimmunity Diseases Unit, Cruces Hospital, Bilbao, Spain; 5Internal Medicine, Bordeaux Hospital, Bordeaux, France.

Objectives: To compare the different therapeutic schemes used in two longitudinal cohorts of patients with Systemic Lupus Erythematosus (SLE): the Systemic Autoimmune Diseases Unit of Cruces University Hospital, Barakaldo, Spain (cohort B), using a low-medium dose prednisone scheme; and the Internal Medicine Department of Bordeaux, France (cohort B) which follows the standard treatment guideline.

Methods: We included patients from both cohorts diagnosed with (SLE from year 2000), with a follow-up from the time of diagnosis (inception cohorts) and for at least 5 years. We analysed the different use of glucocorticoids (prednisone and pulse methylprednisolone), hydroxychloroquine (HCQ) and immunosuppressive drugs in both cohorts. To compare the efficacy of both therapeutic schemes, we analysed the rate of clinical remission and clinical remission on treatment, according to the DORIS definitions, during the 5 years of follow-up.

Results: 173 patients were studied: Bordeaux (B): 81 and Cruces (C): 92. Base-line clinical variables were similar between both groups, including demographics, autoimmunity and organ involvement. The baseline SLEDAI was: 8 (B) vs. 7 (C), p=0.06. The proportion of patients in treatment with prednisone was similar from year 1: 79% (B) vs. 72% (C), p=0.269, to year 5: 63% (B) vs. 55% (C), p=0.315. However, patients in cohort B received higher doses of prednisone: mean maximum dose at year 1: 38 mg/d (B) vs. 14 mg/d (C), p<0.05; at year 5: 8 mg/d (B) vs. 3 mg/d (C), p<0.05; average dose of prednisone at year 1: 15.8 mg/d (B) vs. 4.4 mg/d (C), p<0.05; at year 5: 6.6 mg/d (B) vs. 3.2 mg/d (C), p<0.05. Methyl-prednisolone pulses were ever used in 26% (B) vs. 42% (C), p<0.05; the mean total pulses per patient was 3 (B) vs. 7 (C), p<0.05; however, the mean total dose of methyl-prednisolone per patient was similar 1725 mg (B) vs. 1635 mg (C), p=0.835, revealing a lower dose per pulse in patients from cohort C. The proportion of patients in treatment with HCQ was lower in cohort B at year 1: 80% (B) vs. 97% (C), p<0.05 and at year 5: 73% (B) vs. 99% (C), p<0.05. Methotrexate was used more frequently in cohort C (p<0.05) with no differences in cyclophosphamide, azathioprine and mycophenolate use.

Clinical remission in both cohorts was as follows: year 1: 25% (B) vs. 40% (C), p<0.05; year 2: 29% (B) vs. 42% (C), p=0.07; year 3: 37% (B) vs. 42% (C), p=0.54; year 4: 37% (B) vs. 48% (C), p=0.15; year 5: 36% (B) vs. 49% (C), p=0.08.

Clinical remission on treatment: year 1: 43% (B) vs. 84% (C), p<0.05; year 2: 70% (B) vs. 87% (C), p<0.05; year 3: 73% (B) vs. 88% (C), p<0.05; year 4: 73% (B) vs. 93% (C), p<0.05; year 5: 73% (B) vs. 93% (C), p<0.05.

Conclusions: • The more frequent use of hydroxychloroquine, pulse methylprednisolone and methotrexate in the Cruces cohort resulted in reduced doses of oral prednisone. • Patients from the Cruces cohort achieved clinical remission earlier and in a more sustained way during the follow-up.

HYDROXYCHLOROQUINE HAS NO PROTECTIVE EFFECT ON THE DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS IN 7004 PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: A NATIONWIDE POPULATION-BASED STUDY

B.-C. Hsu, K.-T. Tang. Department of Allergy, Immunology, and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China

Background: Hydroxychloroquine (HCQ) has been proposed to be associated with later onset of systemic lupus erythematosus (SLE) and is widely used in patients with primary Sjögren’s syndrome (pSS) which may evolve to SLE. We want to explore the potentially protective role of HCQ in the development of SLE among patients with pSS.

Objectives: This study was conducted to assess whether exposure to HCQ in pSS patients is associated with a reduction in the development of SLE.

Methods: This retrospective cohort used claims data from the National Health Insurance Registry Database (NHIRD) in Taiwan. Patients with incident Sjögren’s syndrome (SS) from 2000 to 2010 in the Registry of Catastrophic Illness Database (RCIPD) of the NHIRD, which was certified by two rheumatologists, were identified. The date when SS was diagnosed in the RCIPD was defined as the index date. Those who were diagnosed as having SLE, rheumatoid arthritis, polymyositis, dermatomyositis, or systemic sclerosis in the RCIPD before the index date were excluded. Other exclusion criteria included patients who were diagnosed as having SLE in the RCIPD within one year after the index date, patients who withdrew from the NHIRD within one year after the index date, and patients who used oral, intramuscular, or intravenous corticosteroids, methotrexate, azathioprine, leflunomide, sulfasalazine, cyclosporine, tacrolimus, mycophenolate, mercaptopurine, or cyclophosphamide for more than or equal to 90 days within one year before or after the index date. The included SS patients who used HCQ for more than or equal to 90 days within one year after the index date were eligible to HGC group. The study endpoint was defined as newly-diagnosed SLE in RCIPD or withdraw from NHIRD during the 14 year follow-up period (January 1, 2000 to December 31st, 2013).

Results: A total of 7004 pSS patients were identified. The mean follow-up time was 6.9 years in the HGC group (n=4282) and 7.0 years in the non-HGC group (n=2722). There were 22 newly-diagnosed SLE (0.5%) in the HGC group and 16 (0.6%) in the non-HGC group. The overall event rate of SLE was 8.78/10,000 person-years in the HGC group and 9.83/10,000 person-years in the non-HGC group (adjusted hazard ratio 0.97, 95% confidence interval 0.50–1.88, in a Cox proportional hazard model).

Conclusions: There is no protective effect of HCQ on the development of SLE in patients with pSS.

AB0510 IMPROVING KNOWLEDGE OF SLE DISEASE FLARES AND TREATMENT OPTIONS AMONG RHEUMATOLOGISTS AND PRIMARY CARE PROVIDERS: EFFECT OF AN ONLINE EDUCATIONAL INTERVENTION

E. Jackson, D. Blathenwick, K. Badal. Medscape Education, New York, USA

Background: With a significantly higher mortality in patients affected by systemic lupus erythematosus (SLE) developing chronic damage, prevention is a major goal in management.1 Flares are a common feature throughout the course of SLE and can result in organ damage.2 As a result, clinician knowledge on how to prevent, recognise, and treat flares is crucial.

Objectives: Determine whether an online educational intervention could effectively address a knowledge gap and an underlying educational need in the areas of SLE disease management among rheumatologists and primary care providers (PCPs).

Methods: An online educational intervention focusing on SLE disease management was made available online, intended for rheumatologists and PCPs who treat patients with SLE. The intervention consisted of a 30 min video presentation by a recognised expert in the treatment of SLE. Synchronised slides supported the presentation. The educational impact was assessed by comparing participants’ responses to 3 repeated-pair, multiple-choice pre- and post-intervention questions. The impact on self-reported confidence was also assessed through a separate, 5-point Likert-scale question. Data were collected from 9/28/2017 through 11/29/2017. Statistical analysis included a paired t-test comparing mean pre-intervention and post-intervention scores, McNemar’s y² statistic for measuring changes in responses to individual questions, and Cramer’s V to determine the overall impact of the intervention.

Results: Analysis of pre- versus post-intervention responses demonstrated a significant (p<0.05) improvement in overall knowledge in both rheumatologists (79% to 87%, n=118) and PCPs (61% to 73%, n=253). The overall impact of the intervention was similar in both groups (V=0.106 for rheumatologists and V=0.123 for PCPs). This intervention resulted in increased knowledge surrounding several specific areas of SLE, such as pathophysiology, relationship between disease activity and organ damage, and selection of SLE therapies (see table 1).

Abstract AB0510 – Table 1

<table>
<thead>
<tr>
<th>Topic area</th>

<td>23% (40% to 63%, p&lt;0.05)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Relationship between disease activity and organ damage</td>
<td>8% (84% to 92%, p=0.05)</td>
<td>5% (70% to 75%, p=0.197)</td>
</tr>
<tr>
<td>Treatment selection</td>
<td>7% (79% to 86%, p=0.173)</td>
<td>6% (74% to 80%, p=0.093)</td>
</tr>
</tbody>
</table>

The intervention resulted in a 4% shift in self-reported confidence in addressing flare symptoms among rheumatologists, and a 26% shift among PCPs.

Conclusions: Participation in an online video educational intervention with synchronised slides was associated with significant overall improvement in knowledge levels of rheumatologists and PCPs in several important aspects of SLE management. Based on assessment of residual gaps, future directions for education should be tailored to specific learner groups including case-based reinforcement of knowledge and competence among rheumatologists, and additional foundational education for PCPs in the areas of pathophysiology and disease progression.

AB0511 THE EFFECT OF MILNACIPRAN ON FATIGUE IN A CLINICALLY STABLE LUPUS COHORT

E.P. Katsaros1, F. Dong2, I. Moldovan3. 1Internal Medicine; 2Graduate College of Biomedical Sciences, Western University of Health Sciences, Pomona; 3Internal Medicine, Loma Linda University, Loma Linda, USA

Background: Systemic lupus erythematosus (SLE) is a chronic multi-system autoimmune disease impacting the physical wellbeing and health related quality of life (HRQOL) of patients1. Fatigue occurs in up to 90% of SLE patients and affects their HRQOL2. The purpose of this pilot study is to determine the effect of milnacipran, a norepinephrine and serotonin reuptake inhibitor used to treat fibromyalgia, on fatigue in clinically stable SLE patients with widespread pain (WSP). To date, no clinical trials have demonstrated efficacy for the primary treatment of fatigue and WSP in adult SLE patients.

Objectives: The objective is to determine the effect of milnacipran on fatigue in a clinically stable lupus cohort.

Methods: SLE patients, 18 years and older, with fatigue, WSP and on more than 4 weeks of stable therapy were recruited for a 15 week prospective, double-blind placebo-controlled study. Patients were randomised at a 1:1 ratio to receive 14 weeks of milnacipran 50–100 mg twice a day or placebo. Disease activity was measured by the Systemic Lupus Erythematosus Disease Activity Index (SLE-DAI). Measurements of fatigue, pain and a patient’s general impression of change from baseline were assessed at baseline and week 14 using the Fatigue Severity Scale (FSS), the Short-Form McGill Pain Questionnaire (SF-MPQ), and the Patient’s Global Impression of Change (PGIC) respectively.

Results: A total of 14 patients were included in the final analysis with seven patients in each group. Upon entry and throughout this study, both groups had low disease activity (mean SLEDAI <3.5 at week 0 and week 14). Fatigue as measured by FSS in the intervention group improved from 5.70 at week 0 to 5.14 at week 14 and improved in the placebo group from 5.90 to 5.59 respectively (Delta=0.56, 0.31 for the intervention and placebo group, respectively, p=0.70). Pain as measured by the SF-MPO changed in the treatment group from 20.80 at week 0 to 18.80 at week 14, and in the placebo group from 15.40 to 13.2 respectively (Delta=2.00, 2.20 for the intervention and placebo group, respectively, p=0.97). The patient’s Global impression of change was greater in the intervention group than the placebo group (0.67, 0.49, p=0.21).

Conclusions: Although results were not significantly different in this pilot study, improvement in fatigue and the patient’s impression of global change appeared to be greater in the intervention group than the placebo group even though lupus activity remained low in both groups and the difference in pain between the two groups were nearly identical. Therefore, milnacipran may improve fatigue independently of disease activity and pain in lupus patients. Future randomised controlled trials of the drugs effect with larger cohorts are needed to confirm these findings.

AB0512 OCCURRENCE AND CONSEQUENCES OF ANTI-DRUG ANTIBODIES TO RITUXIMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS

F. Faustini1, I. Parodi1, N. Dunn2, M. Ryner3, A. Fogdell-Hahn1, I. Gunnarsson1.
1Medicine, Unit of Rheumatology; 2Clinical Neuroscience, Center for Molecular Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

Background: Anti-drug antibodies (ADA) to rituximab (RTX) have been reported to a limited extent in rheumatoid arthritis (RA, 4%–11%) and in multiple sclerosis (MS, 26%–37%), in the latter being associated with incomplete B-cell depletion.1 In SLE, data on the clinical significance of ADA are lacking.

Objectives: To define the frequency and consequences of ADA to RTX in a SLE population by setting a disease specific threshold using a sensitive ADA method.

Disclosure of Interest: None declared
Methods: SLE patients fulfilling the 1982 ACR classification criteria who received RTX treatment at the Karolinska University Hospital during the years 2001–2015 were included. Store serum samples obtained prior to and after six months from initiation of treatment were analysed for the detection of ADA using a GSK-developed and validated electrochemiluminescence assay. Disease specific screening and confirmation cut-point for SLE samples (1.44 AU/mL and 29% respectively) were used. Clinical and laboratory data were retrieved from electronic medical charts. SLE activity was measured using SLE disease activity index 2000 (SLEDAI-2K).

We defined treatment response according to the SLE responder index (SRI), defined as SLE disease activity index 2000 score decrease ≥3 and ≤3 points with ≤moderate (≤10%) improvement of Laboratory Parameters (LPS).

The statistical analysis was performed using the chi-square and Wilcoxon signed-rank test. SLEDAI-2K was used to determine disease activity at baseline. The proportion of percentages of ADA positive patients or earlier repopulation were evaluated. A p-value <0.05 was considered statistically significant.

Results: Thirty-eight patients (89.5% females, median age 35.0 years; IQR: 27.7–55.0) were included in this retrospective analysis. The median disease duration was 6.2 years (IQR: 2.1–11.6) and the baseline median SLEDAI-2K was 6.9 (IQR: 7.0–16.5). The indications for RTX were active lupus nephritis (65.8%), CNS involvement (10.5%), arthritis (13.2%), haematological manifestations (7.9%), or mucocutaneous involvement (2.6%). Twenty-six patients (68.4%) received RTX according to the lymphoma regimen (375 mg/m2 at day 1, 7, 14, 28) while 12 (31.6%) according to the arthritis regimen (2 infusions at a dose of 1 g, 14 days apart). Intrafollicular corticosteroids and cyclophosphamide were given in 65.8% and 63.2% of the patients, respectively.

ADA were detected in 18 patient samples (47.4%) at follow-up and stratified into reactive samples (confirmed positive with a lower <2 AU/mL ≤n=3), low positive (2–10 AU/mL; n=6), medium positive (11–50 AU/mL; n=4), and high positive (>51 AU/mL; n=5).

We found no association between the occurrence of ADA and either SRI response (p=0.25, Fisher exact test) nor the concomitant use of high dose IV 6-methylprednisolone (p=0.56, c2-test) or IV cyclophosphamide (p=0.11, c2-test). At follow-up, patients positive for ADA had higher levels of CD19 +B-cells (median: 0.03 × 10⁹ cells/L; IQR: 0.01–0.13) compared to negative patients (median: 0.01 × 10⁹ cells/L; IQR: 0.005–0.01; p=0.007, Mann-Whitney test).

Conclusions: ADA to RTX in SLE are more frequent than in RA and MS and occur irrespective of treatment response and cotreatments, but are associated with higher counts of CD19 +B-cells at follow-up. Such finding could reflect either incomplete B-cell depletion in ADA positive patients, or earlier repopulation. Further studies should address the relation between ADA titers and clinical outcomes as well as immunological consequences.

AB0514 THE EFFECT OF HYDROXYCHLOROQUINE ON REDUCING PROTEINURIA IN STABLE SLE PATIENTS

H. Takahashi, Y. Nasa, E. Takamasu, S. Sugii, N. Yokogawa, Rheumatology, Tokyo Metropolitan Tama Medical Hospital, Fucy Tokyo, Japan

Background: It is thought that hydroxychloroquine (HCQ) reduces proteinuria by preventing endothelial dysfunction in mouse models, but the effects in systemic lupus erythematosus (SLE) patients are not known.

Objectives: To investigate the effects of HCQ on proteinuria in stable SLE patients.

Methods: This was a single-centre, prospective cohort study. We included stable SLE patients who met the updated or revised American College of Rheumatology 1997 criteria for SLE or the 2012 Systemic Lupus International Collaborating Clinics criteria, and had no active organ dysfunction that needed an increase in immunosuppressive therapy. The subjects (HCQ group) were SLE patients with proteinuria >0.2 g/gCr who started HCQ between 11/1/2015 and 8/1/2017. The controls (non-HCQ group) were SLE patients with proteinuria >0.2 g/gCr seen between 11/1/2016 and 10/31/2017. The proportion of proteinuria over 6 months in the HCQ and non-HCQ groups was compared. The following patients were excluded from the analysis: those who had proteinuria of other aetologies (diabetic nephropathy, etc.), those who increased the prednisolone (PSL) dose or started immunosuppressive agents, angiotensin converting enzyme inhibitors, or angiotensin II receptor blockers beginning 1 month before the observation period started until its end. Improvement was defined as a reduction in proteinuria >0.1 g/gCr. The statistical analysis was performed with the t-test and chi-square test.

Results: There were no significant differences in disease duration, sex, Systemic Lupus Erythematosus Disease Activity Index, or the use of immunosuppressants at baseline between the HCQ (n=16) and non-HCQ (n=14) groups. The mean proteinuria at baseline was 5.9±2.8 and 3.3±3.8 g in the HCQ and non-HCQ groups (p=0.042). Patients in the HCQ group were younger (mean 47±12 vs. 63±14 years, p=0.005). The kidney pathology of the HCQ group was 6.25, 6.25, 6.25, and 6.25% class I to V, respectively, compared with 7.14% class IV, 14.2% class V, and 14.2% class IV-V in the non-HCQ group. The other patients were diagnosed with lupus nephritis clinically.

Proteinuria was significantly lower in the HCQ group than in the non-HCQ group (p=0.017 vs 0.343 g/gCr vs. p=0.038). The mean proteinuria at baseline and 6 months later was 0.501±0.276 and 0.331±0.274 g/gCr, respectively, in the HCQ group, and 0.587±0.409 and 0.717±0.720 g/gCr in the non-HCQ group. The proportion of patients who improved in the HCQ and non-HCQ groups was 68.7% (11/16) and 28.5% (4/14), respectively (p=0.028).

Conclusions: HCQ may reduce proteinuria in SLE patients. This suggests that HCQ administration protects the kidneys of SLE patients.

**AB0515** SPANISH SOCIETY OF RHEUMATOLOGY (SER) RECOMMENDATIONS ON PRIMARY ANTIPHOSPHOLIPID SYNDROME (APS), IN A PATIENT WITH OBSTETRIC APS, WHICH TREATMENTS ARE MORE EFFECTIVE? SYSTEMATIC REVIEW

H. Sánchez Pérez1, M. Nishishiyama Aquino2, C. Pereda3, P. Díaz del Campo Fortecha1, M. Martínez Zamora5. 1Rheumatology, Hospital Universitario de Canarias, La Laguna; 2Programa de doctorado en Ciencias de la Educación y el Deporte de la Facultad de Psicología, Ciencias de l’Educació i de l’Esport Blanquerna, Institut Troughtumatològic Quiríni, Barcelona; 3Rheumatology, Hospital Mediterráneo, Almería, 4Unidad de Investigación, Sociedad Española de Reumatología, Madrid; 5Servicio de Obstetricia y Ginecología, Hospital Clinic, Barcelona, Spain

**Background:** Pregnancy complications and poor obstetric prognosis are part of the manifestations of APS. The obstetric APS (O-APS) includes 3 or more early miscarriages, 1 or more intrauterine foetal deaths, prematurity secondary to pre eclampsia or placental insufficiency, intrauterine growth retardation and HELLP syndrome among others. There is disagreement among different published studies regarding the need of preconceptional or primary thromboprophylaxis (treating with anticoagulant/antiaggregant drugs in the presence of specific autoantibodies but without previous clinical events) and the most effective and safest drug to use, as well as which treatment should be chosen in the case of secondary thromboprophylaxis (treating in the presence of autoantibodies and recurrent miscarriages or previous obstetric complications).

**Objectives:** To evaluate the available scientific evidence on which treatments are the most effective and safest in O-APS.

**Methods:** A systematic review (SR) was performed to evaluate the efficacy and safety of different interventions (Aspirin (ASA), Heparin, Antimalarials, Immunoglobulin IV (IVIG), others) in pregnant women with O-APS. We included SR, randomised clinical trials (RCTs) and comparative cohort studies. Result measures on morbidity (prematurity, low birth weight, need for intensive care, impaired cognitive development, preeclampsia, eclampsia, HELLP, abruptio placenta) and mortality included both the newborn and the pregnant woman. A peer review selection and analysis of the studies was carried out (SP,H; NA, MB).

**Results:** 788 citations were identified (Medline, EMBASE, CENTRAL. May 2017). We included 17 studies: 5 SR, 5 RCTs and 7 cohort studies. Results are shown on the table 1 below:

<table>

**Conclusions:** In women with O-APS:

- Secondary thromboprophylaxis: The combination of ASA +Heparin is more effective than ASA monotherapy.

With regards to the use of IVIG, corticosteroids and statins: NO representative conclusions can be drawn from published studies

- Pre-conceptional thromboprophylaxis, primary thromboprophylaxis: NO representative conclusions can be drawn from published studies.

**Acknowledgements:** This review is part of the preparation of SER Recommendations on Primary APS treatment.

**AB0516** THERAPEUTIC STRATEGIES AND PROGNOSIS IN CHINESE PATIENTS WITH SEROLOGICALLY ACTIVE CLINICALLY QUIESCENT SYSTEMIC LUPUS ERYTHEMATOSUS

H. Huang1,2, L. Mou1, Y. Hao1, Z. Zhang1, W. Zhou1. 1Rheumatology and Clinical Immunology Department, Peking University First Hospital; 2Rheumatology and Clinical Immunology Department, First Hospital of Tsinghua University, Beijing, China

**Background:** SACQ patients with SLE appears to account for 6%-12% of all patients with SLE, but there is disagreement about whether such patients are indeed clinically stable, especially in Chinese patients. And there is no conclusion as to what kind of treatment should be taken for such patients.

**Objectives:** To identify the frequency and outcome of SACQ patients with SLE. And we tried to find out potential predictors of flare.

**Methods:** 682 patients with systemic lupus erythematosus were followed up for more than 6 months at Peking University First Hospital from January 2007 to December 2015 were summarised. SACQ was defined as an at least a 6 month period with persistent serologic activity and without clinical activity and could be taking a daily dose of prednisone or equivalent less than 7.5 mg. Serologically quiescent clinically quiescent (SQCQ) patients and serologically active clinically active (SACA) patients served as control groups. Data including demographics, initial symptoms, duration to SACQ, treatments before and after SACQ, and characteristics of the flare group were analysed.

**Results:** Of the 682 patients, 170 were SACQ patients (24.9%), 187 were SQCQ patients, and 325 were SACA patients (47.7%). SACQ patients (38.61±15.08 years old) were older at study start than did SACQ patients (38.61±15.08 years old, p=0.000), but there was no significant difference between that of SACQ and SACA patients. 56 of the 170 SACQ patients (32.9%) experienced flare. Corticosteroids (OR 1.323, 95% CI 1.135 to 1.542, p=0.000) was an independent risk factor for flare, while antimalarials (OR 0.040, 95% CI 0.004 to 0.418; p=0.007) and immunosuppressants (OR 0.321, 95% CI 0.153 to 0.673; p=0.003) were protective factors.

**Conclusions:** SLE patients with SACQ remained relatively stable, with 32.9% of patients relapsed. The group of flare patients took greater use of corticosteroids than non-flare ones, whereas antimalarials and immunosuppressants agents were protective factors.

**AB0517** INVASIVE ASPERGILLOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY FOCUS ON CLINICAL CHARACTERISTICS AND RISK FACTORS OF IN-HOSPITAL MORTALITY

H. Ning1, C.-Y. Tsa2. 1Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital; 2Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital, Taipei, Taiwan, Province of China

**Objectives:** To analyse the clinical features and outcomes of patients with invasive aspergillosis (IA), the mortality risk factors and all-cause mortality in patients with systemic lupus erythematosus (SLE) in single centre of Taiwan.

**Methods:** A retrospective study was performed to identify the mortality risk factors associated with IA in patients with systemic lupuserythematosus (SLE). We reviewed the medical records of patients with SLE who were diagnosed with invasive aspergillosis between Jan. 2006 and Jun. 2017 from Taipei Veterans General Hospital in Taiwan. Clinical and laboratory parameters as well as treatment outcomes were analysed.

**Results:** Twenty-one patients diagnosed with proven (n=4; 19.04%) and probable (n=17; 80.95%) invasive aspergillosis according to revised definition by European organisation for Research and Treatment of Cancer/Invasive Fungal Infections Cooperative Group and the National Institute of Allergy and Infectious Diseases Mycoses Study Group (EORTC/MSG) Consensus Group were enrolled in the study and separated into survivors(n=7; 33.33%) and non-survivors (n=14;
Efficacy of Belimumab for Primary Sjögren Syndrome: Results of a Systematic Review of the Literature

Background: Belimumab is a human monoclonal antibody that inhibits B-cell activating factor shown to be efficacious in systemic lupus erythematosus. In other B cell mediated autoimmune disease such as primary Sjögren’s syndrome (pSS) the efficacy is unclear.

Objectives: To evaluate the efficacy of belimumab in patients with pSS.

Methods: A systematic literature review was performed (EMBASE, MEDLINE and Cochrane) as part of the Spanish Rheumatology Society’s Recommendations for the Use of Biological Therapies in Primary Sjögren’s Syndrome. Inclusion criteria was defined as: Population: patients with pSS according to American-European Consensus Criteria 2002 Intervention: belimumab; Control: synthetic or biologic DMARDs, corticosteroids, ursodesoxicolic acid or placebo; Outcome: efficacy in systemic activity, parotid enlargement, dryness, lymphadenopathies, articular manifestations, fatigue and B cell biomarkers.

Results: 3 articles were included out of 13. All of them published results from the same study2 at different timepoints. The study design was experimental but with a small sample size and no control group or randomization.

Discussion: The study of De Vita et al 20152 compared results at week 52 (W52) and W28 in 19 patients, of whom 15 had previously responded to treatment. Of these 15 patients 13 maintained response and 3 out of the 4 patients that did not respond achieved primary outcome. The improvement at W52 continued for ESSDAI, glandular inflammation, lymphadenopathy and joints. B cell biomarkers remained stable. Overall items contributing to ESSDAI decreased but only physician’s VAS for disease systemic activity was statistically significant (3.2 W28 vs 2.5 W52; p=0.04).

Disclosure of Interest: None declared
AB0519 IMPACT OF HIGHER BODY MASS INDEX (BMI) IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I. Săulescu, D. Opris Belinski, A. Borangiu, L. Groseauan, S. Daia-Ilieiscu, D. Mazilu, M. Negru, V. Stoian, V. Bojina, A. Balanescu, C. Constantinescu, R. Ionescu. Internal Medicine and Rheumatology, UMF Carol Davila, SF. Maria Hospital, Bucharest, Bucharest, Romania

Background: Systemic lupus erythematosus (SLE) patients may have nutritional changes triggered by disease itself or by treatment with possible implication for patients prognosis.

Objectives: The main focus of the study was to evaluate nutritional status and its impact in a SLE cohort with disease duration of at least 1 year.

Methods: 105 SLE patients admitted in St. Maria Clinical Hospital in 2017 were enrolled. Inclusion criteria were represented by disease evolution of at least 1 year. All patients agreed to participate in this observational study. Data about demographic, clinical or serological characteristics, but also activity (SLEDAI), damage accrual (SLICC damage index SDI) and treatment or complications (osteoporosis, cataract, glaucoma, etc) were collected. Nutritional status was evaluated by calculating Body Mass Index (BMI) for each patient. A descriptive and analytical statistics was performed with SPSS.

Results: 99 females and 6 males were enrolled. Mean age at SLE diagnosis was 34.39, SD 11.34. BMI was calculated as ratio of body weight to squared height (kg/m2). According to BMI, 5% of patients were underweight (BMI <18.5), 56% had normal weight (BMI 18.5–25), 25% were overweight (BMI 25–30) and 14% were obese (BMI >30). Increased BMI was correlated with longer disease duration (p 0.0001, r 0.30) and older age (p 0.0001, r 0.35), but these correlation loose the significance for patients older than 40 years (p 0.04, r 0.15), suggesting a more pronounced weight gain at the beginning of the disease. Quality of sleep was significant altered in patients with abnormal BMI (p 0.005, r 0.35). As expected, overweight and obese patients had a sedentary lifestyle (p<0.01). Higher BMI was correlated also with higher SDI score (p 0.026, r 0.35) and higher number of complications related to chorticotherapy per patient (p 0.0001, r 0.45).

Conclusions: SLE patients have an increased risk for higher BMI, especially patients younger than 40 years, in the first years after diagnosis. Optimising weight in our SLE patients should be in our focus in order to limit number of complications, damage accrual and lifestyle patterns that negatively impact their life.

AB0521 SAFETY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF SINGLE DOSES OF A BISPESIFIC ICOSL AND BAFF INHIBITOR, AMG 570, IN HEALTHY SUBJECTS

Background: Autoimmune diseases, including systemic lupus erythematosus (SLE), are associated with dysregulation in both T cell and B cell responses. Targeting the activity of both cell types simultaneously holds promise as a treatment for autoimmune disease. AMG 570 is a bispecific molecule targeting both T cell and B cell activity through neutralisation of the inducible costimulator ligand (ICOSL), and the B cell activating factor (BAFF).

Objectives: To investigate the safety, tolerability, pharmacokinetics, and pharmacodynamics of AMG 570 in healthy subjects after single subcutaneous doses.

Methods: This ongoing, double-blind, randomised, placebo-controlled trial has enrolled healthy subjects (age ≥18 years) into escalating single-dose cohorts. Eight participants were enrolled into each cohort and were randomised 3:1 to receive either AMG 570 or placebo across six cohorts of increased dose level. The primary endpoint of the study was treatment-emergent adverse events (AEs). Secondary endpoints included pharmacokinetics and pharmacodynamics (eg, receptor occupancy of ICOSL, changes in B cell subpopulations, and serum immunoglobulin levels).

Results: As of an ad hoc interim analysis on October 5, 2017, 48 participants were enrolled and received one dose of investigational product (either AMG 570 or placebo). 73 AEs were reported; all were mild (n=56) to moderate (n=14) in severity (3 injury AEs had no grade reported). Upper respiratory tract infection and injection site erythema were the most commonly reported AEs. No drug-related serious adverse events were reported. No severe, life-threatening, or fatal AEs were reported. AMG 570 demonstrated nonlinear pharmacokinetics consistent with cell surface target (ICOSL) interaction. In the highest dose tested, AMG 570 achieved greater than 90% mean ICOSL receptor occupancy on circulating B cells 8 days after dosing, and high levels (>85% mean ICOSL receptor occupancy) were observed 29 days after dosing. AMG 570 led to a reduction in circulating naive B cells and an increase in circulating memory B cells. No apparent changes were observed in serum IgM or IgG.

Conclusions: Overall, AMG 570 was safe and well tolerated by healthy subjects. AMG 570 demonstrated pharmacodynamic activity consistent with ICOSL and BAFF neutralisation.

AB0520 ASSESSMENT OF ANTI-MÜLLERIAN HORMONE LEVELS IN SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH IMMUNOSUPPRESSOR

J. Yu. Rheumatology, Distinct Healthcare, Shenzhen, China

Background: Systemic lupus erythematosus (SLE) is a chronic immune-mediated inflammatory disease that affects predominantly females during childbearing age. Fertility in SLE patients is considered to be normal but several factors, such as disease activity, renal involvement and treatment with immunosuppressor may negatively influence fertility.

Objectives: To investigate the ovarian reserve of patients with SLE by measuring anti-müllerian hormone (AMH) levels, and compare the AMH levels before and after treatment with immunosuppressor.

Methods: This was a self-control study performed on newly diagnosed premenopausal female SLE patients fulfilled the 1997 American College of Rheumatology (ACR) criteria. Serum concentrations of AMH in peripheral venous blood were measured using a human AMH ELISA kit (MSK BIO, Wuhan, China) before and after treatment with 6 month immunosuppressor.

Results: 45 patients were recruited. AMH serum levels reduced after treatment in the cyclophosphamide (CTX) group (n=6) and leflunomide (LEF) group (n=7), P<0.05. AMH serum levels did not differ before and after treatment in the myco- phenolate (MMF) group (n=11), tacrolimus group (n=8) and methotrexate (MTX) combined with cyclosporin A (CsA) group (n=13), P>0.05.

Conclusions: In this self-control study, the AMH serum levels reduced after 6 month treatment of CTX or LEF, indicating CTX and LEF might negatively influence ovarian reserve function. AMH serum levels did not differ after 6 month treatment of MMF, tacrolimus or combined use of MTX and CsA, indicating these immunosuppressor might be relatively safe for ovarian reserve function.

TACROLIMUS IN REFRACTORY LUPUS NEPHRITIS: A PROSPECTIVE MULTICENTRIC STUDY CARRIED OUT IN CLINICAL PRACTICE SETTING

Rheumatology Unit, Department of Medicine-DIMED, University of Padova, Padova; Rheumatology and Clinical Immunology Unit, Ospedale Civile, Brescia, Brescia; Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome; Clinic of Rheumatology, Department of Medical and Biological Sciences, University Hospital "Santa Maria della Misericordia", Udine, Italy.

Background: The efficacy of tacrolimus (TAC) in lupus nephritis (LN) has been recently demonstrated in several randomised controlled trials in asian cohorts. Nevertheless, data on real-life experience and long-term safety of TAC are still lacking.

Objectives: To assess efficacy and safety of TAC in SLE patients with refractory LN in a multi-centric prospective cohort.

Methods: Adult SLE patients with refractory LN from 4 Italian centres were prospectively followed for at least 12 months. Clinical and serological variables and previous/concomitant medications were collected at baseline, 3, 6, 12 months after starting TAC. Renal response was assessed by using EULAR/ERA-EDTA definitions. Adverse events (AEs) included non-infectious and infectious AEs; they were defined severe (SAE) when hospitalisation and/or death and/or life-threatening manifestations occurred. Data were analysed using SPSS (v.24.0).

Results: Thirteen SLE patients (8 females, 5 males, mean age 33.7±10.2, mean disease duration 11.9±5.9) were enrolled (table 1). Concomitant medications included: prednisone (100%), mycophenolate mofetil (92.3%), hydroxychloroquine (53.8%), azathioprine (7.7%), belimumab (7.7%) and cyclosporine (7.7%). The average number of previous immunosuppressants taken by each patient was 3.15±1.90. Six-months renal response was achieved by 5/13 patients (38.5%): complete renal response (CRR) in 2/13 (50.0%) and partial renal response (PRR) in 2/13 (50.0%). One patient achieved complete renal response (CRR) in 6 (60.0%) and partial renal response (PRR) in 12 months (50.0%). Twelve-months renal response occurred in 4/13 patients (30.8%): CRR in 2/13 (50.0%) and PRR in 2/13 (50.0%). One patient achieved non-infectious SAE, and 1 non-response.

Conclusion: Our preliminary data from clinical practice setting suggest that TAC could be a therapeutic rescue strategy for refractory LN. Further studies are needed to prove TAC efficacy in the long term.

METFORMIN COMBINED WITH CONVENTIONAL THERAPY INCREASES ABSOLUTE NUMBER OF REGULATORY T CELLS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Hao, Z. Liang, X. Jing, X.O. Liu, C. gao, X. liu, J. chen
The Second Hospital of Shanxi Medical University, Taiyuan, China; Brigham and Women’s Hospital, Harvard Medical School, Boston, USA.

Background: Systemic lupus erythematosus (SLE) is multisystem and multorgan autoimmune diseases and the main treatment is hormone combined with immunosuppressant and biological agents. Since the conventional treatment regimen has not achieved expected effects, it is of great practical value to search for good efficacy, lower side-effects, and low-cost drugs. Recently, we have found that the absolute number of CD4+CD25+FOXP3+ regulatory T (CD4+ Treg) cells reduced in SLE. Metformin, a basic hypoglycemic drug, has been shown to increase the number of Treg cells and decrease the number of Th17 cells.[1,2,3]

Objectives: To observe the clinical efficacy of metformin on the treatment of SLE and levels of CD4+Treg and Th17 cells.

Methods: Twenty-three patients with SLE were enrolled in this study. They fulfilled the ACR1982 standard, their average age was 32.22±8.18 years, and duration was 51.41±15.52 months. These patients were administered metformin (250 mg Bid) combined with conventional therapy for 6 weeks. At week 0 and week 6, the absolute numbers of Th17 cells and Treg, the symptoms, and laboratory indicators were collected.

Results: After metformin treatment combined with conventional therapy, absolute number of Treg cells in 23 patients increased significantly from20.2 (20.28) (week 0) to 25.76 (25.1) (week 6) (P=0.073) while that of Th17 cells increased slightly from5.29 (6.43) (week 0) to 5.57 (6.05) (week 6) (P=0.956), which led to reduce average ratio of Th17/Treg from 0.25 (0.31) (0 week) to 0.19 (0.23) (6 weeks) (P=0.147). The treatment attenuated the symptoms of the patients and meantime, the dose of prednisone was decreased. At week 6, metformin combined with interleukin-2, the dosage of prednisone in SLE patients were decreased from 23.70±19.41 mg/dl (0 week) to 20.44±17.03 mg/dl (6 weeks) (P=0.548).

Conclusions: Our findings suggest metformin can effectively up-regulate Treg cells as well as increase Th17 to a certain extent, which restores the balance of Th17/Treg cells in SLE, metformin combined with conventional therapy can reduce the dosage of glucocorticoid, but the long-term effect needs further investigation.

HOW DO WE TREAT DRYNESS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME? A PATIENTS' THEORY ON how the disease affects them

1Rheumatology, Hospital Infanta Sofia, Madrid; 2Research Unit of the Spanish Society of Rheumatology; 3Rheumatology, Hospital Puerta de Hierro Majadahonda, Madrid; 4Rheumatology, Hospital Marques de Valdecilla, Santander; 5Rheumatology, Hospital Germans Trias i Pujol, Barcelona; 6Rheumatology, Hospital Marina Baixa, Alacant, Spain

Background: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease whose main characteristic is the involvement of the exocrine glandular system. Thus, its most common clinical manifestation is eye and mouth dryness. No therapy has been demonstrated to significantly modify disease course and, currently, evidence-based therapy for pSS is mainly limited to symptomatic drugs for dryness.

Objectives: To describe the dryness treatment in a cohort of primary Sjögren Syndrome patients.

Methods: SJÖGRENSE registry is a multicentre descriptive cross-sectional study of pSS patients, fulfilling European-American criteria, from 33 Spanish rheumatology departments. Data were collected by reviewing clinical records and interviewing the patients. Informed consent was obtained and local ethics committees approved the study. Variables were analysed by descriptive statistics using means, medians and ranges. Chi square test was used to compare categorical variables. A p<0.05 was considered significant.

Results: Four hundred and thirty seven patients were included (female 95%; median age 58 years). Ninety four per cent of the patients complained of daily, persistent, troublesome dry eyes for more than 3 months; 92% had sensation of sand in the eyes, 16% developed corneal ulcer. Ninety four per cent of the patients complained of dry mouth for more than 3 months and 27% had dental loss. The most frequent oral dryness treatments were tear substitutes (96%), followed by lubricating ophthalmological ointments (46%), autologous sera solutions (14%), topical corticosteroids (13%), topical cyclosporine (6%). Comparing patients with and without oral dryness, only pilocarpine and lubricating eye ointment were used significantly with more frequency in symptomatic patients (p<0.05); tear substitutes were used significantly with more frequency in symptomatic patients only in the subgroup of patients that used tear substitutes more than 3 times a day. The most frequent oral dryness treatments were chewing gums or candies without sugar (65%), followed by pilocarpine (56%), special toothpaste (22%), mucolytic agents (20%), saliva substitutes (19%), lubricating oral gel (13%) xylitol (11%) and fluoride (11%). Comparing patients with and without oral dryness, chewing gums or candies without sugar, xylitol and fluoride were not used significantly more frequently in symptomatic patients. In contrast, saliva substitutes, lubricating oral gel, pilocarpine, mucolytic agents and specific toothpaste were used significantly more frequently in symptomatic patients (p<0.05). The median in ESSPRI (Eular Sjögren’s Syndrome Patient Reported Index) in SJÖGRENSE cohort was 5.3 (25–75, 3.67–7). Only topical corticosteroids and pilocarpina were used significantly more frequently in patients with a dryness VAS<5 in ESSPRI index.

Conclusions: Despite the high number of symptomatic patients, the use of dryness treatments is limited in patients. Chewing gums or candies without sugar, xylitol and fluoride were not used significantly more frequently in symptomatic patients. In contrast, variables such as lubricating eye ointment or pilocarpine were used significantly more frequently in symptomatic patients (p<0.05). The median in ESSPRI (Eular Sjögren’s Syndrome Patient Reported Index) in SJÖGRENSE cohort was 5.3 (25–75, 3.67–7). Only topical corticosteroids and pilocarpina were used significantly more frequently in patients with a dryness VAS<5 in ESSPRI index.

IDENTIFICATION OF EFFECTIVE PARAMETERS INFORMING THE SELECTION OF INTRAVENOUS CYCLOPHOSPHAMIDE VERSUS MYCOPHENOLATE MOFETIL FOR INDUCTION THERAPY FOR LUPUS NEPHRITIS

N. Ming1, H. Yamashita, K. Motomura, M. Nakahara, K. Sugah, A. Yashima, Y. Takahashi, H. Kaneko. Rheumatology, National Center for Global Health and Medicine, Tokyo, Japan

Background: The 2012 EULAR recommendations gave equal weight to intravenous cyclophosphamide (IVCY) and mycophenolate (MMF) as the induction therapy for class III/IV lupus nephritis (LN). However, there are no effective parameters that could inform the choice the induction therapy (IVCY or MMF) in individual cases.

Objectives: This study examined the patient characteristics that determine the most appropriate treatment for LN: IVCY or MMF.

Methods: We retrospectively examined 29 patients with LN who received induction therapy with IVCY (n=16) or MMF (n=13) between January 1994 and December 2015. Their baseline characteristics and the complete response (CR) rate at week 24 were analysed. CR was defined as a urine protein:creatinine ratio <0.5 g/gCr with normal urine sediment.

Results: At baseline, the time since diagnosis of systemic lupus erythematosus (SLE) was longer in the IVCY group than the MMF group (4.8±6.4 vs. 1.3±2.5 years, p=0.06) and the IVCY group had more frequent flares (1.9±2.4 vs. 0.7±1.1 times, p=0.08); however, the differences were not significant. Moreover, there was no difference in age, sex, complement levels, anti-dsDNA antibody titers, anti-Sm/RNP antibody positivity rates, proteinuria, or rate of abnormality in urine sediment at baseline between the two groups. CR was achieved at week 24 in 11/16 patients (69%) in the IVCY group and 9/13 patients (69%) in the MMF group. Considering the 20 patients who achieved CR at week 24, univariate analyses revealed that in addition to a longer time since diagnosis of SLE (4.5±6.6 vs. 1.0±1.7 years, p=0.12) and more frequent flares (1.9±2.8 vs. 0.6±1.0 times, p=0.16), the anti-RNP antibody positivity rate was higher (OR 8.5; p=0.07) in the IVCY group. Furthermore, the positivity rate of anti-RNP antibody differed significantly (OR 12.9; p=0.03) in the multivariate model.

Abstract AB0526 – Table 1. Univariate analyses of patients with CR at week 24

IMBALANCE IN ELASTIN-ELASTASE SYTEM LEADING TO CLINICAL MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS

O. Emelianova1, O. Rusanova1, I. Gontar2, L. Maslakova3, N. Emelianov2
1Federal State Budgetary Institution «Research Institute of Clinical Ind Experimental Rheumatology named after A.B. Zborovsky»; 2Federal State Medical Budgetary Institution of Higher Education “Volgograd State Medical University” of the Ministry of Healthcare of the Russian Federation, Volgograd, Russian Federation

Background: It is believed that in systemic lupus erythematosus antibodies induce a disturbance in the elastin- elastase metabolism, which yields altered soluble isoforms followed by triggering of autoimmunity mechanisms, which damage the elastin-containing tissues.

Objectives: Studying antibody formation in the elastin-elastase system in patients with systemic lupus erythematosus (SLE) using magnetoccontrollable adsorbents with an immobilised form of corresponding antigen.

Methods: Sera from 30 donors and 65 SLE patients were studied. Antibodies to ribonucleoprotein antibody; OR, odds ratio; CI, confidence interval. (*p<0.05)

Disclosure of Interest: None declared

The greatest elastin antibody titer was noted in patients with SLE grade III (57.1%, 4 people), with grade II in 42.5% (17 people), and with grade I – in 33.3% (6 people). The elastin antibody titer in SLE patients being admitted to hospital was reliably higher than in donors (p<0.001).

An analysis of the findings showed that patients with vascular lesions demonstrated a significant elevation of elastin antibodies (p<0.05). Besides studying elastin antibodies, we analysed elastase antibodies. Elevated elastase antibodies were revealed in 72.2% of SLE patients with grade I of the condition; in 80.0% with grade II, and in 85.7% of patients with grade III. The titer of elastase antibodies in SLE patients admitted to hospital was reliably higher than in the control group (p<0.01). The highest elastase antibody titer was noted when the skin and joints are affected, and vasculopathy is present.

Conclusions: The regularities revealed by pathogenetic method can be accounted for by considerable B-clonal expansion in SLE patients as the condition progresses. From the point of view of immunology, hyperproduction of elastin and elastase autoantibodies is noted, which results in autoimmune lesion of the ligamentous apparatus, joints, skin and vessels where this protein is naturally present.

AB0527

S100 PROTEINS ARE NOVEL BIOMARKERS FOR THE EFFICACY OF HCQ TREATMENT TO SKIN LESION IN SYSTEMIC LUPUS ERYTHEMATOSUS

Department of internal medicine, Division of hematology, rheumatology and respiratory medicine, Kagawa University, Kagawa, Japan

Background: Systemic lupus erythematosus (SLE) is deeply associated with not only acquired immunity but also innate immunity throughout toll-like receptors (TLRs) signalling. Among many TLRs, TLR7 and TLR9 were reported to be closely associated with IFN-α production which contributed the pathogenesis of SLE. On the other hand, several reports demonstrated that S100A8 and S100A9 proteins which was known as one of damage-associated molecular patterns (DAMPs), were associated with disease activity of lupus nephritis. These proteins were also shown to reflect the treatment response by immunosuppressive therapy for SLE.1,2 However, there is no report about the effect of hydroxychloroquine (HCQ) on S100A8 and S100A9 proteins expression.

Objectives: To find a new biomarker of treatment with HCQ, we focused on expression of S100A8 and S100A9 proteins in SLE.

Methods: We enrolled all SLE patients treated with HCQ in the absence of additional immunosuppressive therapy more than 3 months in our institute from Jan 2016 to Dec 2017. Serum levels of S100A8 and S100A9 proteins were measured by ELISA(CircuLex ELISA Kit, MBL) at the screening, 3 months and 6 months after HCQ administration. Disease activity of SLE was measured using the SLENA-SLEDAI 2011. Pathogenesis of disease activity was evaluated by Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI). Immunological activity was examined by the levels of complement (C3, C4, CH50), anti-dsDNA, anti-ELAST antibodies and counting blood cell.

Results: 61 patients were enrolled in this study. HCQ was administered 48 cases with usual dose based on ideal weight, 15 cases with low dose than usual dose (table 1).

CONCOMITANT MEDICATION IN SYSTEMIC LUPUS ERYTHEMATOUS (SLE) PATIENTS TREATED WITH BELIMUMAB IN CLINICAL PRACTICE SETTINGS: RESULTS FROM THE OBSERVE STUDY IN SWITZERLAND

J. von Kempis1, S. Dütsch2, N. Reuschling3,2, D. Schaer4, F. Vallelian4, R. Villiger5, P.M. Villiger6, R.B. Muder6, 1Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen; 2GlaxoSmithKline AG, Münchenbuchsee; 3Division of Rheumatology, Hirslanden, Basel; 4Universität Hospital Zürich, Zürich; 5Department of Rheumatology, Inselspital Bern, Bern, Switzerland

Background: Systemic lupus erythematosus (SLE) is a complex and potentially severe autoimmune disease. Belimumab is the latest drug, and the first biologic compound, that was registered for treatment of SLE. There is limited information on safety and effectiveness of belimumab and its effects on the use of concomitant medication outside of randomised controlled trials.

Objectives: To describe the overall patterns of SLE care, outcomes and concomitant medication among belimumab users in Switzerland.

Methods: OBSERVE Switzerland (GSK 201232) was a retrospective, multi-centre observational cohort study collecting data on the use of belimumab therapy in routine care of SLE Patients in Switzerland. SLE patients were included who had started therapy with 10 mg/kg belimumab/4 weeks at least six months before documentation. All patients were included regardless of treatment discontinuation during the study period. All statistical analyses were descriptive for both categorical and quantitative data.

Results: 53 SLE patients with belimumab as part of their routine treatment were analysed for this study. 81% of the patients were female, the mean age was 46.7 years and the mean BMI was 25.4 kg/m². The reasons to initiate belimumab were ineffective previous treatment (66.0%), worsening of patient condition (28.3%), and/or the intent to decrease glucocorticosteroid (GC) dose (47.2%).

Abstract AB0528 – Figure 1. S100A8 and S100A9 proteins associated with CLASI score. Compared with SLE patients of 50% and less rate of change of CLASI activity, those of more than 50% rate of change of CLASI activity significantly decreased serum levels of S100A8 and S100A9 proteins after administration of HCQ. There were no SLE patients whose skin lesion got worse during HCQ treatment in this study.

Conclusions: HCQ reduced the expression of serum S100A8 and S100A9 proteins, which reflected SLE disease activity especially in skin lesion. The measurement of S100A8 and S100A9 proteins is novel predictive biomarker for the efficacy of HCQ treatment on skin lesion in SLE patients.

Disclosure of Interest: None declared
During treatment, 58% of patients (n=53) showed an improvement of $\geq 20\%$ and 23% of $\geq 50\%$, based on physicians' evaluation of disease activity. This was consistent with an improvement of SELENA-SLEDAI (mean) from 8.0 at therapy start to 3.6 after six months on the basis of all available data (n=27).

Similar outcomes were observed for arthritis, fatigue, rash, dsDNA antibody and complement levels. Among the 42 patients treated with GC at time of belimumab initiation, GC dose was reduced by 5.7 mg/day (mean) during treatment with belimumab (11.6$\pm$5.9 mg/day at six months). During the six months before initiation of belimumab, GC dose was stable or had to be increased in the majority of patients; however, during the six months therapy with belimumab, GC dose could be reduced in the majority of patients and GCs was discontinued in two patients. The percentages of patients receiving SLE co-medication other than GC were stable over the first six months of belimumab therapy. Within the first six months of treatment, no included patient had discontinued treatment with belimumab.

Conclusions: Treatment with belimumab over six months after initiation led to clinical improvement in a significant number of patients in real life settings and had an overall steroid-sparing effect. Belimumab was well-tolerated; no included patient discontinued the treatment within the first six months.

AB0529 AN AUDIT FOR SCREENING OF OSTEOPOROSIS AND ITS MANAGEMENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S.A. Syed, K. Sumbayye, S. Shaflu. Rheumatology, University Hospitals of Leicester, NHS Trust, Leicester, UK

Background: Systemic lupus erythematosus (SLE) is an autoimmune, multi-system, chronic inflammatory condition. It is managed with long-term immunosuppressive therapy which includes steroid use. SLE is therefore considered an independent risk factor for osteoporosis.

Objectives: This clinical audit was undertaken to evaluate the screening of osteoporosis in patients diagnosed with SLE and assess adherence to national guidelines for the management of patients with low bone mineral density (BMD) on prolonged steroid therapy.

Methods: We studied 64 SLE patients seen at the Leicester Royal Infirmary. Demographic and clinical data was collected from the clinic letters. Steroid use for a cumulative period of over 4 weeks per year was considered significant and use of bisphosphonates or calcium and vitamin D supplements alone were taken into account for bone protection. BMD measurements by dual X-ray absorptiometry were performed. Osteoporosis was defined as a T score less than $-2.5$ SD in at least 1 region of measurement.

Results: Of the 64 patients studied, 54 (84.4%) were female and 10 (15.6%) male with an age range of 23 to 86 years and mean age of 47.45 years. Steroids were used in 46 (71.9%) patients while 18 (28.1%) patients did not receive any steroids. Twenty-one (32.8%) patients had DEXA scans and whilst 43 (67.2%) patients had not. Of those who had received steroids, 20 (43.4%) patients underwent DEXA scans and whilst 43 (67.2%) patients had not. Osteoporosis was diagnosed in 3 (14.3%) patients out of the 21 scanned. The therapies used are summarised in figure 1.

Conclusions: Studies have shown that SLE is an independent risk factor for low BMD and use of corticosteroids is already a well-recognised risk for osteoporosis. Our study has shown that a large section of patients (43.8%) did not receive any form of bone protection although, a significant proportion (71.9%) were on oral steroids. Although a small section of those scanned demonstrated osteoporosis (14.3%), many patients were already initiated on bisphosphonates without a DEXA. There was also no exclusion criteria set for young patients (age $<$45 years) or those who were newly diagnosed. Despite this, our study demonstrates the need for robust guidelines for the screening and management of bone health in patients with SLE in order to improve morbidity and mortality rates in this patient cohort.

AB0530 TREATMENT OUTCOME IN LUPUS NEPHRITIS PATIENTS TREATED WITH MYCOPHENOLATE MOFETIL: FROM REAL-WORLD CLINICAL PRACTICE

S.M. Jung1, D. Kim1, H.W. Kim1, S.-W. Lee1, J.J. Song1, Y.-B. Park1. 1Internal Medicine, Yonsei University College of Medicine; 2Internal Medicine, Seoul National University Bundang Hospital, Seoul, Korea, Republic of Ireland

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease often characterised by the development of glomerulonephritis. There is a growing interest in the use of mycophenolate mofetil (MMF) as induction therapy and maintenance therapy for lupus nephritis.

Objectives: This study aimed to evaluate the therapeutic outcome of MMF in lupus nephritis from real-world clinical practice, and identify the predictors for failure of remission after MMF treatment.

Methods: Korean patients with pathologically proven lupus nephritis class III, IV, and V were recruited from nephrology clinic in Severance Hospital, Yonsei University College of Medicine between Nov 2011 and Aug 2017 Patients who treated with MMF for at least 3 months were included in the analysis. The probability of remission after MMF therapy, and the difference between patients who achieved remission or failed to achieve remission were analysed using Kaplan-Meier analysis and Cox proportional hazards model.

Results: Of 153 patients with lupus nephritis, 116 patients were included in this study. Seventy two patients continued MMF until the last follow-up. The mean age of patients was 34.2 years, and the median duration of SLE was 5.7 months. Anti-dsDNA antibody was positive in 82.8% of patients, and 9.5% of patients showed a histological class with pure V pathology. Mean protein/creatinine ratio in spot urine was 4.6, and active urinary sediment was found in 82.8% of patients. During median follow-up period of 5 years, 80% of patients achieved clinical remission of lupus nephritis. Median time to remission was 4.2 months (IQR 0.9–9.1). Risk factors for failure of remission were nephritic-range proteinuria and seronegativity of anti-dsDNA antibodies.

Conclusions: This study shows the real-world data on MMF treatment in patients with lupus nephritis. Patients with risk factors for failure to remission may require more intensive treatment and management.

REFERENCES:
AE0531 DECISION TO INITIATE IMMUNOSUPPRESSION IN PATIENTS WITH PRIMARY SJOGREN’S SYNDROME

Background: There is limited data available (case series, small clinical trials and expert opinion) regarding the need to initiate immunosuppressive therapy in patients with primary Sjogren syndrome (pSS).

Objectives: The aim of this study is to determine the factors that correlate with physician’s decision to start immunosuppressive therapy in pSS patients.

Methods: Subjects with pSS diagnosed according to the classification criteria in use at the time of their first presentation, were included in a monocentric cohort. A retrospective analysis was performed. The EULAR Sjogren’s Syndrome Disease Activity Index (ESSDAI) at onset and Sjogren Syndrome Damage Index (SSDI) at the last evaluation were calculated. Treatment was given according to the physician’s decision. Laboratory tests and Ultrasonography (US) of major salivary glands were performed in all cases. The data was analysed using Windows Excel

Results: Corticotherapy was prescribed in 26/30 cases (86.6%), mean duration 50.65 months. Immunosuppressive treatment with hydroxychloroquine was given in 26/30 cases (86.6%). Immunosuppressive treatment was required in 10/30 patients (33.3%)-azathioprine 7 (23.3%), cases, methotrexate 3 (10%) cases. The mean ESSDAI score was 6.53±3.1. In 19 (63.3%) cases disease activity was moderate or high (ESSDAI ≥5). The mean damage score value (SSDI) was 3.1±SD1.2. There was a moderate correlation between the activity score ESSDAI and the damage score SSDI (r=0.41, p<0.05). The physician’s decision to start immunosuppression correlated significantly with the presence of hypergammaglobulinemia (n=4, p<0.05). The duration of immunosuppressive treatment correlated moderately with specific Sjogren’s US pattern of salivary glands (n=4.0, p<0.05). In contrast, immunosuppressive treatment duration did not correlate with the activity and damage scores (ESSDAI and SSDI).

Conclusions: An important number of patients received corticotherapy, immunomodulatory agents and immunosuppressive therapy. The decision to initiate and maintain immunosuppressive therapy correlated with hypergammaglobulinemia and specific Sjogren’s US changes. The damage score (SSDI) does not correlate with immunosuppressive therapy duration.

AB0533 PATTERN OF DRUG USE IN SYSTEMIC LUPUS ERYTHEMATOSUS IN REAL WORLD CLINICAL PRACTICE

T. Costa1, M. Eusóbio2, S. Falcao3, F. Araújo4, P. Nero5, L. Inês6, M. Rodrigues7, D. Jesus8, S. Barreira9, C. Maceira10, M. Cabral11, G. Sequeira12, J. Branco13, M. Santos14, 1Hospital Egas Moniz; 2Sociedade Portuguesa Reumatologia; 3Hospital Sant’Ana; 4Hospital CUF Descobertas, Lisboa; 5Centro Hospitalar Universitário, Coimbra; 6Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Centro Académico de Medicina, Lisboa; 7Hospital Fernando Fonseca, Amadora; 8Centro Hospitalar Universitário do Algave, Faro; 9Hospital Garcia de Orta, Almada, Portugal

Background: Pharmacological treatment for systemic lupus erythematosus (SLE) is aimed at reducing disease activity, preventing flares and minimizing the damage. The use of medication varies widely and therapeutic strategies are well defined only for certain organ manifestations. Hydroxychloroquine is the standard treatment for most SLE patients during the entire disease course, while immunosuppressants are recommended for those with severe organ involvement. Belimumab is the only biological currently licensed for SLE, although others are used off-label in clinical practice.

Objectives: To describe the real-world patterns of drug use in SLE patients, and their relationship with disease phenotype.

Methods: Observational study of adult SLE patients registered in the Rheumatic Diseases Portuguese Registry, who have clinical diagnosis of SLE, followed for at least 1 year and with available data on medication, which was retrieved. Sociodemographic and clinical characteristics were compared among treatment groups defined as: group 1 antimalarials and/or glucocorticoids; group 2 immunosuppressants (azathioprine (AZA)/mycophenolate mofetil (MM)/methotrexate (MTX)) and/or antimalarials and/or glucocorticoids; group 3 biologics/immunosuppressants and/or antimalarials and/or glucocorticoids. To assess possible differences
between the groups, univariate regression analyses were made. In all analyses significance level was set at 0.05.

Abstract AB0533 – Table 1. Sociodemographic and clinical characteristics according to treatment groups

Results: A total of 824 SLE patients were included, mean age of 47.3±14.4 years, 92.3% female. The mean age at first symptoms was 31.6±14.1 and at SLE diagnosis of 34.1±14.3 years. On their last assessment, 678 (82.3%) were being treated with antimalarials, 463 (56.2%) glucocorticoids, 343 (41.6%) immunosuppressants (149 AZA, 99 MM, 67 MTX, 14 cyclosporine, 11 cyclophosphamide, 3 leflunomide), 53 (6.4%) biologics (32 rituximab, 21 belimumab) and 26 (3.2%) were off medication. The sociodemographic and clinical characteristics according to treatment groups are shown in table 1. Gender distribution was similar across groups. A high prevalence of women, Caucasians, non-smokers, acute cutaneous lupus and arthritis was found in all groups. Patients in group 1 had lower disease activity measured by SLEDAI, less organ damage measured by SLICC and lower physician’s global assessment. In group 2 patients were younger and had higher prevalence of renal involvement. Patients in group 3 had higher SLEDAI score and damage, higher prevalence of mucocutaneous, articular, neurologic and hematologic involvement and more use of glucocorticoids.

Conclusions: Almost all SLE patient with established disease were chronically medicated, most with antimalarials and/or glucocorticoids. As expected, group 1 had less severe disease. Patients under immunosuppressants had a higher frequency of renal involvement, which denotes a targeted therapeutic strategy. In routine clinical settings biologics are rarely used, being restricted to patients with very active SLE and multiple clinical manifestations.

PROPORTION OF SJÖGREN’S SYNDROME PATIENTS REFERRED TO ORAL SPECIALISTS AT A RHEUMATOLOGY TERTIARY CENTRE AND FACTORS ASSOCIATED WITH THEIR REFERRAL

G. Levinson1, U. Ahmed1, C. Curtin1,2, 1UCL, 2Department of Rheumatology, UCLH, London, UK

Background: Ideally all patients with Sjögren’s Syndrome (SS) and symptoms of mouth dryness should be assessed by an oral specialist (OS) team at 3–6 monthly intervals for optimisation of their treatment for xerostomia and minimisation of the risk of dental loss1. However, in reality specialist input is not always offered.

Objectives: To determine the proportion of SS patients at a rheumatology tertiary centre who were referred to OS and evaluate if any factors were associated with referral.

Methods: We retrospectively collected data about 105 patients with primary or secondary SS who attended outpatient clinics in October – November 2016, including duration of symptoms and years since diagnosis, presence of SS associated symptoms, medications trialled to date, and serological, imaging and histological patient features. We have also assessed proportion of patients referred to OS, as well as the medication recommended by the OS. p<0.05 was considered significant.

Results: In our cohort, 58.1% of SS patients were referred to an OS. We compared patient demographics and various disease features (table 1) in SS patients who were referred to OS and those who were not.

Disclosure of Interest: None declared

BACKGROUND: Primary Sjögren’s syndrome (pSS) is one of the more common rheumatological diseases. Despite continued advances, the use of conventional drugs or biologic agents in patients with pSS does not provide expected efficacy and a targeted treatment of pSS is not available at present. We have shown that absolute number of peripheral CD4+CD25+FOP3+ regulatory T cells (Tregs) decreased in pSS patients. And rapamycin is an inhibitor of mTOR that can decrease Th17 cells but increase regulatory T cells (Tregs).

OBJECTIVES: To observe the effect of rapamycin on Th17/Treg cell balance in patients with refractory pSS.

METHODS: Twenty-eight refractory SS patients (26 women and 2 men) and 93 health controls were enrolled, with a mean duration of 76.64±49.66 months and mean age of 52.39±10.62 years. They fulfilled the 2002 pSS international classification criteria and were treated with glucocorticoid and immunosuppressant for more than one year, but had not yet reached the disease relief. After the eligible patients are given rapamycin in combination with conventional therapy at 0, 12, 24 weeks, we respectively collect the clinical symptoms, blood routine, urine routine, ESR, the absolute number of Th17 and Treg cells, the ratio of Th17/Treg, and the dosage of corticosteroids and immunosuppressant. Alleviation criteria: no clinical symptoms, inflammation normal range, no organ damage.

RESULTS: The absolute number of Th17 cells decreased significantly in peripheral blood of pSS patients compared with that of healthy controls. By rapamycin combined with conventional therapy, flow cytometry showed the absolute number of T cells in refractory SS patients was increased from 25.51 cells/μl (at week 0) to 27.88 cells/μl (at 12 weeks) and 29.6 cells/μl (at 24 weeks) (P<0.05) respectively. The ratio of Th17/Treg decreased from 0.38 (at week 0) to 0.21 (at 12 weeks) and 0.22 (at 24 weeks) (P<0.05). There was no significant difference in the usage of prednisone, whereas 5 patients gradually stopped using CTX at 24 weeks. Also, the dose of hydroxychloroquine and leflunomide were markedly diminished.

CONCLUSIONS: Our results suggest that rapamycin combined with the conventional treatment greatly alleviated symptoms of patients with pSS, and gradually reduced the use of DMARDs. The absolute number of peripheral Th17 cells decreased in pSS patients and restored by this combined therapy. It still needs to be further confirmed by large sample studies.

SLE, Sjögren’s and APS – clinical aspects (other than treatment)
1426

Scientific Abstracts

deviations were reported for continuous variables. Number and percentages were
shown for categorical variables and chi-square test was utilised for comparison.
T- test was used to compare patients between the groups.
Results: Total of 1362 patients with SLE fulfilling revised ACR criteria were
included; 60.9% were Caucasian and 32.8% African American. 596 had biopsyproven LN however 524 patients were excluded because they had proteinuria
before or at cohort entry. Only first available BMI were analysed: 32.7% were
obese (BMI >30 kg/m2), 27.2% overweight (BMI: 25–29.9 kg/m2), 37.5% normal
(BMI: 18.5–24.9 kg/m2) and 2.6% underweight (BMI <18.5 kg/m2). 39.4% (537)
patients were on steroids at first BMI measurement. Results are described in table
1. BMI measured as continuous (p=0.51) and categorical variables (overweight
p=0.64, obese p=0.67) were not associated with LN after adjusting for age, sex
and ethnicity. SLE patients with obesity were found to have lower disease activity
(SLEDAI), proteinuria, dsDNA titers and higher complement levels.

CORRELATION BETWEEN MORPHOLOGICAL AND
FUNCTIONAL MICROVASCULAR DAMAGE IN SYSTEMIC
LUPUS ERYTHEMATOSUSPATIENTS

A. Sulli1, B. Ruaro1, C. Pizzorni1, V. Smith2, S. Paolino1, M. Pendolino1, L. Verni1,
M. Cutolo1. 1Research Laboratory and Academic Division of Clinical
Rheumatology, Department of Internal Medicine, University of Genova, San
Martino Polyclinic Hospital, Genoa, Italy; 2Department of Rheumatology, Ghent
University Hospital, Department of Internal Medicine, Ghent University, Ghent,
Belgium
Background: Numerous articles have investigated peripheral microcirculation in
primary Raynaud’s phenomenon (PRP).1–3 However, reports that analyse peripheral microcirculation in systemic lupus erythematosus (SLE) are scanty.4 5
Objectives: The aim of this study was to investigate possible correlations
between morphological and functional aspects of microcirculation in different skin
areas of the hands and face in SLE patients and to compare the results with PRP
patients and healthy subjects (HS).
Methods: A total of 14 SLE patients without RP (ACR criteria)6 (mean age 53
±14 SD years, mean disease duration 7±4 years), 14 PRP patients (LeRoy and
ACR/EULAR 2013 criteria)7 8 (mean age 53±17 years, mean RP duration 6±5
years) and 14 HS (mean age 50±17 years) were enrolled during the winter period.
Nailfold videocapillaroscopy (NVC) and laser speckle contrast analysis (LASCA)
were performed in the three groups of patients. The absolute nailfold capillary
number (CN) per linear millimetre at first distal row was assessed by NVC. Blood
perfusion (BP) was detected by LASCA at the level of fingertips, periungual areas,
dorsum and palm of both hands and face. The average BP was calculated as perfusion units (PU).2 Patients were not taking vasodilator drugs since at least one
month. Statistical analysis was performed by non parametric tests.

Results: SLE patients showed a positive correlation between BP and nailfold CN
in all areas of hands (p<0.0001), but no statistically significant correlation was
observed between BP and nailfold CN at the level of face (p=0.10). In both PRP
and HS no statistically significant correlation was observed between BP and nailfold CN in all examined areas (p=0.70 and p=0.20, respectively). SLE patients
showed a statistically significant lower nailfold CN than both PRP and HS (median
9.1 vs 10.3 vs 11.0, respectively, p<0.0005). Conversely, no statistically significant difference of nailfold CN was observed between PRP and HS. PRP patients
showed a statistically significant lower BP than both SLE and HS at the level of fingertip (median 90, 114, 187 PU, respectively; p<0.0001), periungual (median 74,
100, 141 PU, respectively, p<0.0001), dorsal (median 61, 72, 128 PU, respectively, p<0.0001), and palm areas (median 76, 96, 124 PU, respectively,
p<0.0001). Conversely, PRP, SLE and HS patients showed similar BP values at
the level of face (median 141, 139, 137 PU, respectively, p=0.30).
Conclusions: This study demonstrates a correlation between morphological and
functional microvascular features in SLE patients. SLE patients without RP have a
subclinical microangiopathy, showing lower nailfold CN and BP than HS. Conversely, PRP patients show only a functional dysfunction, having a lower peripheral skin BP than both SLE patients and HS. The clinical value of this new finding
is undergoing further analysis.

2
Cardiology; 3Immunology, Hospital Universitari Germans Trias i Pujol, Badalona,
Spain, Badalona, Spain
Background: Cardiac block in neonatal lupus is associated with placental transfer of anti-Ro antibodies. The effect of these antibodies on cardiac conduction disorders in adult patients is controversial. The association between anti-Ro
antibodies and heart rhythm disorders have been described in isolated cases.
However, there are just a few studies that analyse the relationship between autoimmune diseases and electrocardiographic disturbances.
Objectives: To determine if there are differences in cardiac conduction of SLE
patients in presence of anti-Ro antibodies.
Methods: All patients included fulfilled the SLE criteria, SLICC 2012 and they
were followed up in a single centre. The inclusion was consecutive and voluntary.
Patients who took drugs that altered the conduction (except antimalarial drugs),
and those who had heart or thyroid disease were discarded. All patients were
assessed blindly by a cardiologist who performed an interrogation and physical
examination, an electrocardiogram, an echocardiogram and a 24 hour Holter
study. Besides, a rheumatologist performed a clinical and analytical assessment
including a qualitative analysis by immunoblotting of anti-Ro Ab and a quantification by chemiluminescence of the anti-Ro52 and Ro60 Ab. The presence of other
SLE specific Ab (ANA, DNA, antiphospholipids), was also analysed. Clinical, analytical and, activity and damage indexes, were collected (SLEDAI and SLICC).
The data were compared by Student’s t test, Fisher’s test and Chi square using 21
SPSS version. The level of significance was established at 5%.
Results: 145 patients were included: 91.7% women, average age 45±12, average disease duration 11 years. The patients were undergoing the following treatments: antimalarial 91%, mycophenolate 20%, azathioprine 12%, biological
treatment 5% and glucocorticoids 70%. The clinical characteristics are summarised in table 1.
There were no significant differences between the group of positive and negative
anti-Ro Ab in terms of gender, age, clinical characteristics or cardiovascular risk
factors. None of the patients was affected by an atrio-ventricular block and the
rest of the electrocardiographic alterations had no clinical significance and did not
predominate in the positive Ro Ab group. Additionally, no differences in heart rate,
ventricular extrasystoles or PR, QT or QRS intervals were detected between both
groups. The echocardiogram’s findings were not relevant and there were no differences between groups.


Since the majority of patients with SLE are double positive, differences between the two subtypes of Ro (52 and 60) could not be analysed. On the other hand, no differences were found in cardiac conduction according to the treatments received, the activity or damage indexes, or the analytical or clinical characteristics of the patients.

Conclusions: The study results show that there are no differences in cardiac conduction according to the presence of anti-Ro antibodies in SLE patients. Thus, the cardiac screening in SLE patients with anti-Ro positive antibodies seems not helpful in clinical practice.

HEPCIDIN AND INTERFERON-A IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

D. Archimandriti1, A.T. Tzallas2, T.-E. Meme1, P. Spyrou1, A.A. Drosos1, P. V. Voulgar1, 1Rheumatology Clinic, Department Of Internal Medicine, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA; 2Department of Computer Engineering, School of Applied Technology, Technological Educational Institute (TEI) of Epirus, Kostaki, 47100, Arta, Greece, Ioannina, Greece

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease where interferon (IFN)-α is considered to play a central role in its pathogenesis. Anaemia of chronic disease (ACD) in SLE is common. Hepcidin may contribute to anaemia by limiting iron availability for erythropoiesis.

Objectives: The aim of the study was to evaluate INF-α and hepcidin levels in sera of anaemic and non-anaemic SLE patients.

Methods: This was a pilot study of SLE patients with established disease. Patients were divided as anaemic and non-anaemic according to the haemoglobin (Hb) levels: Hb value <13.5 gm% for men and <11.5 gm% for females. ACD was defined according to the levels of iron and ferritin. Serum hepcidin (the active 25 amino acid form) was measured using ELISA (Peninsula Laboratories International). IFN alpha was also measured using ELISA (eBioscience, affymetrix). The inter-assay coefficient of variation was <20% for both assays. All analyses were performed with IBM SPSS Statistics for Windows (version 21).

Results: Forty SLE patients (36 women and 4 men) were studied. Demographic parameters were as follows: age 46.78±16.04 years, disease duration 10.55±6.58 years. Levels of Hb were 12.49±1.28 g/dl. Levels of INF-α were 0.16±0.47 pg/ml while hepcidin levels were 2.54±2.63 ng/ml. When the patients were divided into anaemic (20 patients) and non-anaemic (20 patients) groups (Hb: 11.41±0.56 vs. 13.57±0.77 g/dl, p<0.001), patients with anaemia had lower disease duration (9.75±6.16 vs. 11.55±7.03 years, p=0.45), lower levels of INF-α (0.13±0.035 vs. 0.19±0.036 pg/ml, p<0.001) and higher hepcidin levels (2.92±2.9 vs. 2.17±2.35 ng/ml, p=0.37) than the patients without anaemia. No correlation was observed between levels of hepcidin with all variables. There was also no correlation between hepcidin and INF-α levels.

Conclusions: INF-α does not seem to contribute in ACD pathogenesis in SLE patients and does not correlate with hepcidin levels in SLE patients. Further studies will clarify the role of INF-α in anaemia in SLE.

MULTIPLE SCLEROSIS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

E. Kaltsonoudis1, E. Pelechas1, S. Konitsiotis2, P.V. Voulgar1, A.A. Drosos1. 1Rheumatology Clinic, Department Of Internal Medicine, 2Neurology Clinic, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA, Ioannina, Greece

Background: Imaging and histopathological studies in patients with primary Sjögren’s Syndrome (pSS) have demonstrated white matter lesions which are indistinguishable from those observed in multiple sclerosis (MS).

Objectives: The purpose of this study was to evaluate the frequency of MS in a cohort of patients with pSS.

Methods: One hundred and twenty-one patients with pSS had been evaluated and followed up in the outpatient Rheumatology Clinic at predefined times since 1994. All patients were classified according to the 2016 ACR-EULAR criteria for SS. During follow-up the clinical, laboratory and imaging findings were all recorded. In addition, Magnetic Resonance Imaging and electrophysiological studies as well as spinal fluid analysis were performed when indicated. The diagnosis of MS was based on the 2010 revised McDonald criteria.

Results: Seven patients were diagnosed as having MS. All patients with MS were female. Mean age at the time of MS diagnosis was 65.5±3.6 years, while pSS had been diagnosed at the mean age of 54.4±3.2 years. Mean time of MS development was approximately 10 years after the pSS diagnosis. pSS patients who developed MS had severe sicca symptoms without other extraglandular manifestations and had positive Ro (SSA) antibodies and a positive minor salivary gland biopsy. pSS patients with MS development were treated appropriately in the Neurology department with biological medications with some improvement of the sicca symptoms.

Conclusions: We found that 5.8% of pSS patients as having MS. This percentage of patients clearly indicates the possibility for the coexistence of a second autoimmune disease with similar if not common pathogenetic mechanisms. Thus patients with pSS should be evaluated carefully and screened appropriately for MS when indicated.

CORRELATION BETWEEN SYSTEMIC LUPUS ERYTHEMATOSUS DISEASE ACTIVITY AND OCULAR SIGNS IN OPHTHALMOLOGICALLY ASYMPTOMATIC PATIENTS

S.A. Fouad1, S.M. Esmat Mahmoud Ali2, A.R.L. Rozk Alnagar1, S. Mahfouz1, M. Essam2, H. El-Gendy1. 1Internal Medicine Department, 2Ophthalmology, Kasr Al Einy hospital, Cairo University, Giza, Egypt

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease involving different organs and systems. Ocular manifestations of lupus may manifest as a presenting feature of the disease or as a complication that can be sight threatening. Almost any part of the eye and visual pathway can be affected by inflammatory or thrombotic processes yet ophthalmological assessment in those patients may be delayed.

Objectives: Detection of various ocular pathologies in ophthalmologically asymptomatic SLE patients using Optical Coherence Tomography (OCT), Fundus Fluorescein angiography (FFA), and fundus examination, in addition to studying the

</tbody>
</table>

Conclusions: FFA is can detect early retinopathy changes in patients of SLE which cannot be detected by fundus examination. FFA changes are correlating with disease activity. On the other hand, there was no correlation between OCT changes and disease activity. OCT is more sensitive to detect changes from hydroxychloroquine and steroids intake.

IS LUPUS MORE PREVALENT IN WORLD’S MOST STRESSED COUNTRIES?

A. Almakhour, D. Pyne, A. Pakozdi, R. Rajkaria, A. Cove-smith, M. Lewis, on behalf of Barts Lupus Center. BARTS NHS TRUST, London, UK

Background: A number of studies have implicated psychological stress as a trigger for autoimmune diseases. In a questionnaire study involving 120 lupus patients emotional stress was selected in over 75% cases as a trigger for their disease. The role of stress as a trigger in lupus however is controversial. Here we study whether there is an association between the prevalence of lupus in various countries and their reported stress measures.

Methods: We undertook a literature review of the reported prevalence of lupus in various countries across the world. We then recorded the reported stress index in those countries from Bloomberg’s study, which utilised seven equally weighted variables: homicide rates, GDP per capita income inequality, corruption perception, unemployment, urban air pollution and life expectancy to rank 74 countries according to stress levels. Pearson's correlation was used to measure association between national stress indices and lupus prevalence.

Results: Results are presented in graph 1. Prevalence data was only available in the literature for limited countries. Of the countries studied no correlation was found between national stress indices and lupus prevalence (r = 0.028 (p-value 0.449).

Abstract AB0545 – Figure 1

Conclusions: We found no association between a country’s prevalence of lupus and the measured stressfulness of its living environment.

CRYOGLOBULINEMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL AND IMMUNOLOGICAL FEATURES

A. Barrera-Vargas1, F.J. Antiga-López2, J. Rangel-Pathio2, R. Rosado-Canto4. 1Immunology and Rheumatology; 2Internal Medicine; 3Hematology; 4Nephrology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background: Systemic lupus erythematosus (SLE), as the prototype of systemic autoimmune diseases, has a wide array of clinical manifestations. An association between cryoglobulinemia and certain clinical and immunological features of SLE has been proposed, and there are various physiopathologic pathways that could be involved in this relationship. Although the presence of cryoglobulinemia in SLE patients may be related to specific disease features and could even have prognostic value, this association has not been addressed thoroughly.

Objectives: To describe clinical and immunological characteristics in SLE patients with cryoglobulinemia.

Methods: We performed a retrospective, case-control study, in which we included all patients with a cryoglobulin determination between January 2005 and December 2016 in a third level referral centre in Mexico City. Patients with SLE and a positive cryoglobulin test (cryocrit >1%) were included in the case group, whereas SLE patients with a negative cryoglobulin determination were considered controls. We studied demographic, clinical and immunological characteristics at the time of the positive cryoglobulin result, as well as three months earlier, and 6 and 12 months later.

Results: Thirty-six SLE patients had a cryoglobulin determination throughout the study period. Ten patients had cryoglobulin levels >1% and were included in the case group, whereas 26 patients with a negative determination were included as controls. Mean age was 37.7±18.3 in cases and 41.7±19.3 in controls. 70% of cases and 88.5% of controls were women.

Among subjects with cryoglobulinemia, the cryocrit was 1% in 9 patients, and 3% in one. Regarding clinical and immunological characteristics, a positive lupus anticoagulant and a history of vasculitis were more frequent in patients with serum cryoglobulins (p=0.004 and 0.04, respectively).

At the time of the cryoglobulin measurement, patients in the case group had lower levels of C3 and C4 (p=0.026 and p=0.003, respectively), and serum albumin (p=0.028). They also had a higher prevalence of serositis (p=0.021) and peripheral oedema (p=0.034), as well as a higher SLICC Damage Index score (p=0.014) than controls.

Regarding follow-up, patients in the case group had a higher SLEDAI score after six and twelve months (p=0.009 and 0.034, respectively). Also, after 12 months they had a higher prevalence of renal activity (p=0.004) and lower C4 levels (p=0.001). Among patients with renal activity, 20% of cases and 35% of controls had achieved complete remission after 12 months.

Conclusions: Serum cryoglobulins in SLE patients were associated with positive lupus anticoagulant and hyocompletemenia. Cryoglobulinemia was also associated with specific disease manifestations, such as serositis and vasculitis, and with damage accrual. At follow-up, patients with cryoglobulinemia had a higher prevalence of renal activity, as well as an increased disease activity overall. Whether cryoglobulins could be used as a biomarker for renal activity or worse renal prognosis remains to be determined, and larger prospective studies will be needed to address this possibility.

LYMPHADENOPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL RELEVANCE AND HISTOLOGICAL SUBTYPES

A. Berbel1, M. Estevez2, M. Freire3, E. González4, L. González-Vázquez5, I. Carballejo6, B. Sopena7, on behalf of CEAG (Círculo de Estudios en Enfermedades Autoinmunes de Galicia). 1Medical Student. Faculty of Medicine., University of Santiago de Compostela, Santiago de Compostela (A Coruña); 2Systemic Diseases Unit; 3Systemic Diseases Unit, CHUVI, Vigo; 4Systemic Diseases Unit, CHOU, Ourense; 5Department of Medicine, POVIISA, Vigo; 6Systemic Diseases Unit; 7Hospital Clínico Universitario de Santiago de Compostela (CHUS), Santiago de Compostela (A Coruña), Spain

Background: Some patients with Systemic Lupus Erythematosus (SLE) have lymphadenopathy (LAP) at diagnosis or if follow-up. The prevalence of LAP in SLE varies from 20% to 40%, being the highest in the 1993 EURO-LUPUS series. However, in the last two decades its prevalence was not mentioned. However, the presence of LAP and their histological type may have clinical relevance.

Objectives: To study the prevalence and histologic characteristics of LAP in a cohort of patients with definite SLE and evaluate its relationship with clinical manifestations.

Methods: All patients diagnosed with SLE according to the 1997-ACR criteria at the Autoimmunity Units of three different hospitals since 2005 were followed looking for lymph node enlargement at every consult. The moment when LAP was detected, the concomitant clinical symptoms, LAP manifestations and laboratory variables were recorded. The group of patients with and without LAP were compared. A tissue sample was obtained when indicated. All patients agree to participate in the study.

Results: 103 patients with definite SLE were included in the study. Valuable LAP (>10 mm) was found in 28 patients (27%). The gender and age of SLE patients with and without LAP was similar (80% vs 78% females, and 34±15 vs 40±28 years respectively). LAP was detected at the time of SLE diagnosis in 54% of patients. Fever was significantly more frequent in patients with LAP (60% vs 5%, p<0.01) like dermopathy (86% vs. 60%; p<0.05) and serositis (45% vs 16%; p<0.01). High titters of anti-dsDNA antibodies (71% vs. 42%; p<0.05) and hypocompletemenia (89% vs. 60%; p<0.05) were also more frequent in patients with LAP. A total of 28 tissue samples were obtained in 17 patients (FNA 6, Ultrasound-guided biopsy 6 and surgical excision in 17). The histopathological study showed: Reactive lymphadenitis 20, histiocytic necrotizing lymphadenitis in 6 and Non-Hodgkin Lymphoma in 2 (B-cell lymphoma on methotrexate treatment, and a Burkitt lymphoma). All 6 patients with SLE and histiocytic necrotizing lymphadenitis have cutaneous involvement but none of them developed lupus nephritis.

Conclusions: Patients con SLE and lymphadenopathy had significantly more fever, cutaneous lesions and serositis. High levels of anti-dsDNA antibodies and hypocompletemenia were more frequent in these patients. In some occasions malignancy could be the cause of lymphadenopathy.
AB0548 CAN THE OVERALL THROMBOTIC RISK IN SYSTEMIC LUPUS ERYTHEMATOSUS BE DETERMINED? THE COMBINED ROLE OF CLASSIC CARDIOVASCULAR FACTORS AND ANTIPHOSPHOLIPID ANTIBODIES

Background: Systemic Lupus Erythematous (SLE) is a chronic inflammatory disorder. Antiphospholipid syndrome (APS) is a thrombotic disorder associated with the presence of antiphospholipid antibodies (APA) and increased cardiovascular (CVR) risk. Framingham (FRM) and SCORE (Systematic Coronary Risk Evaluation) scales are available CVR assessment systems. aGAPSS (adjusted Global Antiphospholipid Syndrome Score) combine positive APA and CVR factors, which was suggested to determine the thrombotic risk in persistently positive APA (PPAPA) patients.

Objectives: To determine the role of the thrombotic factors in SLE patients, considering CVR factors and APA. To access the application of different thrombotic risk scales.

Methods: A retrospective cohort study of 84 patients with SLE followed in an outpatient setting of a Portuguese central hospital was performed. The study evaluated patient gender, current age, age at diagnosis, duration of illness, presence of another autoimmune disease (AID), CVR factors [obesity (OB), diabetes (DB), arterial hypertension (AH), dyslipidaemia (DL), smoking (SM)], presence of APA, treatment, dose and duration of steroids. The FRM, SCORE and aGAPSS scores were calculated. The data was analysed using SPSS and considered significant if p<0.05.

Results: Table 1 characterises the study population. Male patients had a higher prevalence of AH (p=0.022), DL (p=0.047), and SM (p=0.001), with a risk of 11%–20% in the FRM scale and a risk of 5%–14% in the SCORE (p=0.000). Female patients had a higher prevalence of another AID (p=0.014) and treatment with disease-modifying antirheumatic drugs (p=0.014). FRM scale reveals a risk of 11%–20% in the presence of AH and >20% in SM (p=0.001). The SCORE scale reveals a risk of 5%–9% in the presence of AH (p=0.003) and 10%–14% in DL (p=0.024). When the risk is 6%–20% in the FRM scale, the risk is lower in SCORE (p=0.000). APA does not correlate with an increased CVR. All APA are associated with another AID, APS and PPAPA. The aGAPSS associates a score of 7–12 if another AID is present (p=0.000); 4–9 with APS;>7 with PPAPA (p=0.000); 4–6 with DB (p=0.039), DL (p=0.002) and AH (p=0.000)>7 with lupus anticoagulant (LA);>7 with anticardiolipin antibodies (aCL) and >12 with anti-b2-glycoprotein-I antibody (anti-b2GPI) (p=0.000).

Conclusions: This study highlights the existence of thrombotic factors in SLE. Their risk is even more elevated when another AID is present. The FRM and SCORE scales reflect the CVR. In SLE patients both the CVR factors and the presence of APA must be evaluated. Therefore, not only should the FRM scale be calculated, but also the global thrombotic risk, using the aGAPSS, must be assessed.

AB0550  CLINICAL-EPIDEMIOLOGICAL FEATURES OF PATIENTS WITH A LATE-ONSET LUPUS IN A TERTIARY CARE HOSPITAL

A. Crespo Colmar, C. Moriano, M. Garijo, C. Higuero, I. González, A. López, E. Díez, C. Álvarez, M. Martín, E. Vallejo, T. Pérez. Rheumatology Department, University Health Care Complex of León, León, Spain

Background: Different frequency of clinical and serological manifestations has been detected according to the age of onset of the patients with Systemic lupus erythematosus (SLE). According to the literature, senile SLE manifests between 6% and 18% of the patients with lupus.

Objectives: 1. To identify and analyse the clinical-serological and epidemiological features of senile SLE in our environment. 2. To determine the average survival time and mortality in these patients, identifying its main cause.

Methods: Observational retrospective study of 319 patients diagnosed with SLE (according to ACR 1992 and SLICC 2012 criteria) at the Hospital of León between 1997-2017 and with an age of onset ≥65 years, obtaining a total of 88 patients with senile SLE.

Results: The mean age at diagnosis was 75.4±12.1 years, with a female/male ratio of 2.4. The most frequent manifestations were as joint (63.2%) and haematological manifestations in the form of leuco-lymphopenia (55.9%). The hemolytic anaemia only appeared in 2.9% of the cases and the thrombocytopenia in 25%, 36.8% of patients showed photosensitivity and 29% had other cutaneous manifestations, being the malar erythema the most prevalent type (60%), followed by the discoid lupus erythematosus (20%) and the subacute lupus (15%). Alopecia was only observed in 4.4%. Lupus nephritis was detected in the form of proteinuria in 4.4% of the patients, and only one patient had microscopic haematuria. Lung involvement was uncommon (8.8%), taking precedence the UIP (33.3%) over the rest of the pulmonary manifestations. Only 11.1% of the patients with senile SLE had serositis, being in the form of pleuritis in 75% of the cases, pericarditis in the 37.5% and ascites in the 12.5%. Regarding the neurological involvement, 5 patients showed polyneuropathy and 1 had chorea. Likewise, the frequency of Sjögren, Raynaud and secondary antiphospholipid syndrome was of 16.7%, respectively.

The most important serological findings were: 97.3% ANA; 44.1% DNA and 20.6% hypercomplementemia, with 54.4% of the patients having serological activity. Only 5.9% had anti-Sm. Antiphospholipid antibodies were positive in 41.2% of the cases, with 4.4% of them showing triple positivity. The average survival time was of 13.7 years (SD: 10.9–16.5). Out of the total patients, 14 died (20.5%), mostly due to infectious etiology (35.7%) and 14.28% due to disease activity. Other less common causes were neoplasia or ischaemic heart disease (7.14% respectively).

Conclusions: 1. The late–onset SLE prevails in our environment, one of every 5 patients diagnosed with SLE in our consulting room is older than 65 years. 2. It is found most often in women and it is confirmed a lower male/female ratio than expected. 3. Joint and haematology manifestations and cutaneous involvement in the form of malar erythema define the clinical profile of our patients with senile SLE, with the renal involvement or the presence of serositis being uncommon. 4. Half of the patients had serological activity at the onset, having hypercomplementemia only in 1 out of 5 cases. 5. Infections were the first cause of mortality in our sample with an average survival time of around 13 years.

AB0551  OBSTETRICAL MORBIDITY RELATED TO ANTI-SSA ANTIBODIES: DATA FROM A FRENCH MONOCENTRIC RETROSPECTIVE STUDY

L. Plaçais1, F. Carrot2, L. Carballon3, P. Nicaise4, A. Benbara5, O. Fain1, A. Meckinian1. 1Internal Medicine; 2Epidemiology and Public health, Saint Antoine hospital; 3Obstetrics and Gynecology, Jean Verdier hospital; 4Auto-immunity and hypersensibility, Bichat hospital; 5Obstetrics and Gynaecology, Jean Verdier hospital, Paris, France

Background: Obstetrical morbidity is an issue among autoimmune diseases patients. Anti-SSA positivity is well known for its effect on fetus and risk of congenital heart block but no evidence has been yet found for its effect on obstetrical morbidity.

Objectives: To investigate anti-SSA positivity effect among a large monocentric cohort of obstetrical morbidity patients and to evaluate the efficacy of different treatment regimens.

Methods: All women who were seen from January 2010 to January 2015 in Jean-Verdier University Hospital for obstetrical morbidities were retrospectively included. All patients had been tested for anti-nuclear antibodies and anti-SSA/Ro and anti-SSB/La antibodies.

Results: We included 244 women (median age 34 years [interquartile range 21–53]) with 869 pregnancies overall. In 27 (11%) patients with anti-SSA antibodies, the median age at the time of pregnancy was 29.5 (17–40) years, with mean number of 3.66 pregnancies per woman. For these 27 patients, 83/99 pregnancies (84%) had an adverse obstetrical outcome: fetal loss (n=65; at a median of 20 (4–88) weeks of gestation), preterm delivery (n=58), premature rupture of membranes (n=18), congenital heart block (n=2). In comparing women with obstetrical antiphospholipid syndrome and unexplained adverse complications, there was no major difference in frequency of recurrent miscarriages, preterm deliveries, preeclampsia or fetal loss. Among factors associated with obstetrical outcome and fetal loss, aspirin and hydroxychloroquine treatments were significantly associated with a favourable obstetrical outcome: odds ratio 0.05 [95% confidence interval 0.01; 0.37; p=0.003] and 0.15 [0.02; 0.98] (p=0.04).

Conclusions: Women with unexplained recurrent obstetrical complications should be screened for anti-SSA antibodies. The benefit of aspirin and hydroxychloroquine treatment to improve the obstetrical outcome should be confirmed in prospective studies.

Disclosure of Interest: None declared

AB0552  THE CLINICAL AND LABORATORY FEATURES OF ANTIPHOSPHOLIPID ANTIBODY POSITIVE PATIENTS WITH OR WITHOUT SYSTEMIC LUPUS ERYTHEMATOSUS

A. Yazici1, A. Omma2, S. Yilmaz2, S. Yavuz2, K. Ayar2, E. Kasapoglu3, B. Kısakci2, A. Cetle1, D. Erkani1, 1Rheumatology, Kocaeli University School of Medicine, Kocaeli, Turkey; 2Rheumatology, Nurunte Health Hospital, Istanbul, Turkey; 3Rheumatology, Suite Training and Research Hospital, Ankara, Turkey; 4Rheumatology, Bilkent University School of Medicine, Istanbul, Turkey; 5Rheumatology, University of Health Sciences Yüksek İhtisas Training and Research Hospital, Bursa, Turkey; 6Rheumatology, Göztepe Training and Research Hospital, Istanbul, Turkey; 7Rheumatology, Medicalpark Hospital, Gaziantep, Turkey; 8Barbara Volcker Center for Women and Rheumatic Diseases, Hospital for Special Surgery, Weill Cornell Medicine, New York, USA

Background: A multicenter antiphospholipid antibody (aPL) clinical database was created in 2016 with the participation of six rheumatology centres around the country. The purpose has been to better define aPL-related clinical manifestations and management strategies; and also to establish a resource for future clinical studies.

Objectives: In this first analysis, we compared the clinical and laboratory features of aPL-positive patients with and without systemic lupus erythematosus (SLE).

Methods: The demographic, clinical, laboratory, treatment characteristics of the aPL-positive patients with/without other systemic autoimmune diseases (SAID) are recorded at enrollment according to a predefined protocol. The inclusion criteria are positive aPL (lupus anticoagulant test [LA], anticardiolipin antibody [aCL], and/or anti b2-glycoprotein-I antibody [a[lg]GPI]) based on the Updated Sapporo Antiphospholipid Syndrome (APS) Classification Criteria at least twice within one year prior to enrolment. For the purpose of this analysis, we only included aPL-positive patients without other autoimmune hemolytic anaemia, aCL IgG, and hydroxychloroquine use in SLE aPL/APS patients (table 1).

Results: As of January 2018, 105 aPL-positive patients were recruited (mean age: 42.6±10.1 [min-max: 19–79]; 83 [79%] female; and 67 [84%] with another SAID). Ten patients were excluded from the analysis due to their SAID history other than SLE. Of the remaining 95 patients, 38 (40%) had primary aPL/APS, 57 (60%) fulfilled the ACR SLE Classification Criteria; 42 (44%) had thrombotic APS (TAPS) (8 arterial, 24 venous, and 8 both); 21 (22%) had obstetric APS (OAPS); 22 (23%) had both TAPS and OAPS (7 arterial, 14 venous, and 1 both); and 10 (11%) had no TAPS/OAPS. Fifty percent of the patients had history of at least one non-criteria aPL-manifestation. Demographics, clinical and laboratory manifestations, and medications were similar between primary aPL/APS and SLE aPL/APS patients except increased frequency of autoimmune hemolytic anaemia, aCL IgG, and hydroxychloroquine use in SLE aPL/APS patients (table 1).

Disclosure of Interest: None declared

Conclusions: The analysis of our multicenter aPL database demonstrates that the frequencies of thrombosis and pregnancy morbidity are similar between aPL-positive patients with or without SLE. Half of the patients in both groups had history of at least one “non-criteria” aPL-manifestation; only autoimmune hemolytic anaemia was more frequent in aPL-positive patients with SLE.

REFERENCES:

Disclosure of Interest: None declared
Conclusions: Fatigue, depression and anxiety have a greater influence on QoL in SLE than disease activity and damage. Of these, fatigue appears to be the most important variable which influences QoL.

**IS HIGHER FITNESS ASSOCIATED WITH BETTER HEALTH-RELATED QUALITY OF LIFE IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS?**

Department of Physical Education and Sport; Department of Personality, Evaluation and Psychological Treatment, University of Granada, Spain

Background: Patients with systemic lupus erythematosus (SLE) present reduced health-related quality of life (HRQoL). As an adjunct to traditional medical therapy, higher levels of physical fitness seem to be associated with better symptomatology and HRQoL. However, a comprehensive characterisation of the association of different components of physical fitness with the different dimensions of HRQoL in this population is lacking and would provide valuable information for the design of prospective studies.

Objectives: The aim of this study was to investigate the association of different physical fitness components (flexibility, muscle strength and cardiorespiratory fitness) with all dimensions of the SF-36.

Methods: A total of 49 women with systemic lupus erythematosus (SLE) and 36 healthy women (controls) were included. Physical fitness was measured using the Senior Fitness Test battery (n=49) (from the Senior Fitness Test battery) as well as the handgrip strength test (n=49) (from the Senior Fitness Test battery) as well as the handgrip strength test. The median value of each fitness test [flexibility (n=49), muscle strength (n=49), cardiorespiratory fitness (n=49)] was used for the analysis. Differences in HRQoL between groups of low and high CRF (p<0.05). Patients with a high level of flexibility only presented better physical function than those with a low level (p=0.03). Upper and lower muscle strength were correlated with physical function, physical role, bodily pain and physical component (rpartial between 0.28 and 0.50; all, p<0.05) with differences between groups of low and high muscle strength (upper and lower body) in all those dimensions (p=0.06). CRF was correlated with physical function, bodily pain and physical component (rpartial between 0.39 and 0.65; all, p<0.01) with differences in physical function and physical component between groups of low and high CRF (p<0.05).

Conclusions: The main findings of the present study suggest that flexibility, muscular strength and cardiorespiratory fitness are associated with different dimensions of HRQoL, particularly with those related to self-reported physical health, in women with systemic lupus erythematosus. Future prospective research should assess the predictive role of fitness regarding disease activity and function.

**THE DIAGNOSTIC AND PREDICTIVE SIGNIFICANCE OF NAILFOLD VIDEO CAPILLAROSCOPY IN CTD PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION**

B. Jiang, X. Xu, K. Zhou, C. Wang, L. Geng. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: Pulmonary arterial hypertension (PAH) is a serious complication of connective tissue diseases (CTD), defined as an elevation in mean pulmonary artery pressure 25 mmHg at rest. The 1 year, 3 year survival rates of CTD-PAH are only 69% and 30%, respectively. Therefore, to early prediction and diagnosis of PAH is very critical for prolonging survival of CTD patients. Nailfold video capillaroscopy (NVC), is an imaging technique for the study of microcirculation. Until now, capillary abnormalities in systemic sclerosis (SSc) are well documented, but rare study focus on the association between the abnormality of capillary with PAH in CTD patients.

Objectives: Through estimating the correlation of the abnormality of nailfold capillary with pulmonary arterial hypertension (PAH) and other organs injury to find out its importance on early diagnosis and prediction for PAH in the patients with connective tissue disease (CTD).

Methods: Nailfold video capillaroscopy (NVC) was performed using a videocapillaroscope to test the fingers capillaries of 123 hospitalised CTD patients with and without PAH. The parameters of NVC were estimated including: the inter, outer and top loop diameter, loop number, misshaped or giant capillaries, flowing speed, haemorrhage, erythrocyte aggregation, et al. The organ involvement like interstitial lung disease (ILD) and cardiovascular complications were also considered. Mann-Whitney test was used to estimate the difference.

Results: 1) The number of capillary loops in patients with SSc was much lower, but morphologic score, liquid score, and total score were all higher than other CTD patients (Tab). 2) The loop number was significantly decreased but abnormal scores of morphology, liquid, diameter, misshaped loop number, flowing speed, erythrocyte aggregation were increased in CTD-PAH patients especially in SLE-PAH compared with non-PAH patients (Fig). 3) ILD relates the abnormality of peripheral circulation such like capillary malformation, decreased loop number, diameter and blood flow, increased haemorrhage, but the influence of PAP may be larger than ILD. 4) Down-regulated loop number, increased morphology, liquid and total score, and abnormal diameter, malformation, erythrocyte aggregation were found in CTD patients with cardiovascular complications, especially in CTD-PAH patients and SLE patients. 5) Age doesn’t directly influence the capillaries of CTD patients, but in young and middle age patients, the difference between PAH and non-PAH groups were more evident.

**Abstract AB0556 – Figure 1. Loop number and other indexes of nail fold capillaries in patients with various CTD and CTD-PAH with non-PAH CTD**
Conclusions: In all CTD, the capillaries in SSC patients are most severely damaged. The disease of capillaries in CTD patients correlates with PAH, ILD and cardiovascular complications. So, NVC could be a predictive detection method for PAH and cardiopulmonary disease in CTD patients.

HAEMATOLOGICAL INVOLVEMENT (CYTOPENIA) AT THE TIME OF THE DIAGNOSIS IS ASSOCIATED WITH LESS SEVERE OCULAR INVOLVEMENT IN PATIENTS WITH PRIMARY SJÖGREN SYNDROME

C. G. Burzaci1, S. Daia-Iliecu2, I. Saulescu1, D. Zaharia1, C. Purice1, T. Gudu1, A. Borangiu1, L. Groseau1, V. Bojinca1, F. Bergea1, A. Balanseu1, D. Predetea1, R. Ionescu1, D. Oprea-Beliniski2. Internal Medicine and Rheumatology, "SFANTA MARIA" Clinical Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background: In patients with primary Sjögren Syndrome (pSS), haematological involvement – autoimmune cytopenia, might be present at the time of the diagnosis or can develop in time after the characteristic glandular involvement. (1,2)

Objectives: The objective of the study is to evaluate the correlation between glandular involvement (ocular) and presence of cytopenia in patients diagnosed with pSS.

Methods: A retrospective analysis was performed on a cohort of patients diagnosed with primary Sjögren Syndrome under surveillance in one Rheumatology Centre between 2009 and 2016. The documented cases have been diagnosed according to the 2002 American-European Consensus group classification criteria, the 2012 ACR criteria or 2016 ACR/EULAR Classification Criteria for pSS. The EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) was calculated for all patients. Ocular assessment and follow-up were performed in collaboration with the same ophthalmologist. The data was analysed using Windows Excel/SPSS2.0.

Results: 30 female patients diagnosed with pSS were included in the study. The mean age at the time of diagnosis was 52.1±9.1 years. The ESSDAI was calculated for all patients at baseline: 5 (17%) patients presented high disease activity (ESSDAI >14), 14 (46%) patients moderate disease activity (ESSDAI 8–14) and 11 (37%) patients low disease activity (ESSDAI <5). The domain weight for glandular involvement when calculating ESSDAI is fairly low (2), so in the studied group there wasn’t obtained a statistically significant correlation between ocular involvement and disease activity as evaluated by ESSDAI.

In the clinical case series, Spearman’s rank correlation coefficient between haematological (autoimmune cytopenia), and biological markers (hypocomplementemia) and ocular involvement were calculated. A strong negative correlation was found between autoimmune cytopenia and glandular manifestations (ocular involvement-xerophthalmia) (r=0.60; p<0.05). Another strong negative correlation was obtained between hypocomplementemia and severe ocular involvement (corneal ulceration) (r=0.59, p<0.05), respectively.

Conclusions: Patients diagnosed with primary Sjögren Syndrome that presented at disease’s onset cytopenia and hypocomplementemia had a less severe ocular involvement.

THE PREVALENCE OF NON-CRITERIA ANTI-PHOSPHOLIPID ANTIBODIES IN ANTI-PHOSPHOLIPID SYNDROME

C. Li1, L. Zhu1, Z. Wang1, Y. Sun2, R. Mu1, Z. Li1, 1Peking University People’s Hospital, Beijing; 266 Hospital of Chinese People’s Liberation Army, Chengde, China

Background: Antiphospholipid syndrome (APS) is an autoimmune disease characterised mainly by arterial and/or venous thrombosis, recurrent pregnancy morbidity, with the presence of a variety of heterogeneous circulating antiphospholipid antibodies. However, there are a group of APS patients with persistently negative antiphospholipid antibodies. It is necessary to validate new specific antibodies to better recognition of these APS patients.

Objectives: To explore the clinical significance of non-criteria anti-phospholipid antibodies in a large cohort of Chinese patients with anti-phospholipid syndrome (APS).

Methods: Serum samples were obtained from 214 APS patients, 122 disease control including systemic lupus erythematosus, sjogren syndrome, ankylosing spondylitis, rheumatoid arthritis, osteoarthritis and 50 healthy control. Anti-phosphatidylserine(anti-PS)/IgG(anti-PS)/IgM(anti-PS) (aPS), anti-phosphatidylethanolamine (anti-PE), anti-prothrombin-antibodies (aFGaGF/FGM) (aPT), anti- annexin V-antibodies (aLP/PL) were measured with enzyme-linked immunosorbent assay (ELISA) and/or western blot method. The prevalence of aPS, aPE, aFGaGF/FGM, aLP, aPL was recorded in terms of organ and system involvement, hemogram results, disease activity. SLEDAI >6 were considered active disease. Concurrent peripheral blood Th17 and T-reg levels were studied. 15 healthy control subjects were included in the study.

Results: 19 of the patients were women, the mean age was 37.3±12.9 years and mean duration of the disease was 7.9±1.29 years. Hematologic involvement was present in 15 (71.4%) of the patients, renal involvement in 17 (81%) and joint involvement in 7 (42.9%). Both Treg cells and CD4 +IL17+ cell levels were significantly higher in SLE group than HC group in terms of CD4 +CD25+, CD4 +FOXP3+T reg cell levels (p<0.01, p=0.001, p=0.001 and p=0.040, respectively). There was no significant difference between active (n=12) and inactive (n=9) SLE patients in terms of Th17 and T-reg levels. However, in the inactive period, the levels of CD4 +FOXP3+T reg and CD4 +CD25+FOXP3+Treg cells tended to increase compared to the active period.

Conclusions: This study showed the tendency of increasing in Treg cells in the inactive period. This may be related to the modification of immunosuppressive drugs. It may be more appropriate to perform similar studies before and after treatment.

ARE REGULATORY T CELL LEVELS DIFFERENT IN ACTIVE AND INACTIVE SLE PATIENTS?

H. Üsküdar Teke1, D. Üsküdar Cansu1, C. Bal1, G. Korkmaz2. 1Internal Medicine, Hematology; 2Internal Medicine, Rheumatology; “Biostatistics, Eskişehir Osmangazi University, Eskişehir, Turkey

Background: The subgroups of T helper cells and regulatory T cells (T-reg) are involved in the pathogenesis of systemic lupus erythematosus (SLE). T-reg cells suppress immune response to autoantigens and prevent autoimmune diseases (AID). Although there are studies suggesting that Treg cells are reduced during the active period of SLE, there are also studies claiming reversal.

Objectives: To determine whether there is a difference between T-reg and Th-17 cell levels in active and inactive SLE patients and to demonstrate the effects of these cells on disease course.

Methods: 21 SLE patients without active infection were included. Erythrocyte sedimentation rate, CRP, C3, C4, anti-ds-DNA levels, SLEDAI values were recorded in terms of organ and system involvement, hemogram results, disease activation. SLEDAI >6 were considered active disease. Concurrent peripheral blood Th17 and T-reg levels were studied. 15 healthy control subjects were included in the study.

Results: 19 of the patients were women, the mean age was 37.3±12.9 years and mean duration of the disease was 7.9±1.29 years. Hematologic involvement was present in 15 (71.4%) of the patients, renal involvement in 17 (81%) and joint involvement in 7 (42.9%). Both Treg cells and CD4 +IL17+ cell levels were significantly higher in SLE group than HC group in terms of CD4 +CD25+, CD4 +FOXP3+T reg cell levels (p<0.01, p=0.001, p=0.001 and p=0.040, respectively). There was no significant difference between active (n=12) and inactive (n=9) SLE patients in terms of Th17 and T-reg levels. However, in the inactive period, the levels of CD4 +FOXP3+T reg and CD4 +CD25+FOXP3+Treg cells tended to increase compared to the active period.

AB0560 PATIENTS WITH RHEUMATOID ARTHRITIS AND LUPUS HAVE SIMILAR PREVALENCE OF PERIODONTITIS – A CROSS-SECTIONAL SURVEY

C. Curiñ3, M. Orlandi2, J. Bakshi1, J. Guinto1, B. Bernstein1, F. D’Auito1.
1Rheumatology, University College London; 2Oral Health, Eastman Dental Hospital, London, UK

Background: Periodontitis (PD) is a chronic inflammatory disease of the gingival tissues triggered by a dysbiotic microflora and causing the loss of soft and hard tissues surrounding the dentition. Over the last two decades, PD has been linked to a systemic inflammatory response and an increased risk of other comorbidities including cardiovascular diseases and diabetes. Numerous observational studies have confirmed an association between PD and rheumatic diseases. Some evidence suggests an association with rheumatoid arthritis (RA) and a beneficial effect of periodontal treatment on RA outcomes. Scarce evidence instead exists on the association between PD and Systemic Lupus Erythematosus (SLE). The main aim of this study was to evaluate the prevalence of PD in RA and SLE.

Methods: We conducted a cross-sectional survey of consecutive eligible outpatients with RA and SLE attending the Rheumatology Department at UCLH. PD diagnosis was estimated administering a validated self-reported questionnaire. Medical histories, cardiometabolic risk factors and assessment of standard biomarkers of inflammation and RA activity were collected as part of the outpatients’ visit.

Results: 86 patients affected by RA and 122 by SLE and 5 presenting both diseases were recruited and agreed to complete the questionnaire. PD was detected in 100 patients of the overall survey (47%). 38 (44%) patients with RA and 50 (48%) patients with SLE had prevalent PD. There was no statistically significant difference in the prevalence of PD between the two patients’ groups (p=0.575). PD was associated with diagnosis of diabetes (p=0.023), hypertension (p=0.004) and hypercholesterolemia (p=0.001). Diagnosis of PD was associated with increased levels of C-reactive protein (CRP) (2.8±3.3 vs 4.0±4.4, p=0.03) in the whole population. In RA patients PD was associated with increased CRP (3.2±3.2 vs 5.2±4.4, p=0.014) and ESR (9.8±10.0 vs 18.3±16.6, p=0.008).

Conclusions: Prevalence of PD is similar in both RA and SLE (approximately 45%) and to the UK national estimates (Adult Dental Survey 2009). PD could contribute to an increased inflammatory profile in patients with RA and SLE. Our data highlight the need of assessing oral health needs of patients with rheumatic diseases.

AB0561 INFECTIONS IN NEWLY DIAGNOSED SPANISH PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: DATA FROM THE RELES COHORT

C. Gonzalez-Echavarri1, M. Garcia2, G. Espinosa3, G. Ruiz-Irastorza4, on behalf of the Autoimmune Diseases Group GEAS, 1Internal Medicine Department, Cruces University Hospital; 2Autimmune Diseases Unit, Internal Medicine Department, Cruces University Hospital; 3Department of Autoimmune Diseases, Hospital Clinic, Barcelona, Spain

Background: Infections continue to be an important source of morbidity and mortality in systemic lupus erythematosus (SLE).1 Susceptibility to infections is thought to be due to a combination of disease related factors and immunosuppression; however differential contributions during disease course has not been yet studied.

Objectives: Using data of patients from the longitudinal inception cohort Registro Español de Lupus Eritematoso Sistémico (RELES), we aimed to analyse how predictors of infection change during the course of the disease.2

Methods: Two hundred and eighty-two patients from the RELES cohort were included. Markers of lupus activity, average prednisone doses and use of immunosuppressive drugs were compared between patients with and without infections within the first and second year of disease. For the analysis, drugs given during the first month of follow-up were considered for infections during the first year and medications given during the first year were considered for infections during the second year.

Results: Nineteen patients (6.4%) had a documented episode of infection during the first year of follow-up and 16 patients (5.67%) during the second. The following variables were associated with infections during the first year: hypocomplementemia at diagnosis (p<0.01), nephritis at diagnosis (p<0.03), SLEDAI score (p<0.01), average dose of prednisone higher than 30 mg/day (p<0.01), methylprednisolone pulses (p<0.05), and mycophenolate use (p<0.02). The independent variables in the final model were hypocomplementemia (OR 4.1, 95% CI 0.96–20.2) and average dose of prednisone higher than 30 mg/day (OR 6.60, 95% CI 1.3–32.4). The following variables were predictors of infections during the second year in the univariate analysis: average dose of prednisone higher than 7.5 mg/ day (p<0.05), methylprednisolone pulses (p<0.07), duration of therapy with anti-malarials (p<0.04), mycophenolate use (p<0.01) and cyclophosphamide use (p<0.05). The independent variables in the final model were average dose of prednisone higher than 7.5 mg/day (OR 4.5, 95% CI 0.99–21) and duration of therapy with antimalarials as a protective factor (OR 0.99, 95% CI 0.99–1.00).

Conclusions: Patients with high baseline activity are at a higher risk of infection during the first months but intensive lupus therapy, specifically with medium-high doses of prednisone, is the strongest predictor of infectious events. Continued use of antimalarials protects from infections.

AB0562 EXTRAGLANDULAR MANIFESTATIONS IN PATIENTS WITH PRIMARY SJÖGREN SYNDROME IN A TERTIARY HOSPITAL IN MADRID

C.M. Piñao Moratala, C. Sobrino-Grande, C. De la Puente-Bujodis. Rheumatology, Hospital Ramón y Cajal, Madrid, Madrid, Spain

Background: Primary Sjögren syndrome (pSS) is a chronic autoimmune disorder characterised by generalised dryness. In a variable percentage of cases (up to 50%) patients can present extraglandular disease, which frequently determines the prognosis.

Objectives: To determine the frequency of both glandular and extraglandular disease in patients with SSp seen in a tertiary hospital in Madrid and to compare them with the frequency observed in the large cohorts (SER and EULAR).

Methods: A descriptive, observational cross-sectional study was conducted. We included patients with diagnosis of pSS according to the ACR/EULAR Classification criteria (2016) attended in our Rheumatology Unit from 2012 to 2017. A database was created, including clinical and epidemiological data and a descriptive analysis was carried out comparing the results with those obtained in the Sjögren-SER project and EULAR group.

Results: 106 patients with pSS were included. 92.5% were female (98), with a mean age at diagnosis of 45 years (range: 32–58). Frequency of exocrine gland disease is shown in table 1. Dry eye was the most frequent symptom (91%), with nearly half of them presenting ocular complications. 69.8% complained of dry mouth and 18.9% associated complications such as dysphagia and oral candidiasis. 16 patients (15%) suffered from recurrent parotiditis and 13 (12.3%) from salivary gland enlargement. Glandular disease also included xerostomia (25%), dyspareunia (11.3%), upper respiratory tract dryness (12.3%) and atrophic chronic gastritis (14%). Frequency of extraglandular disease is shown in table 2. Chronic fatigue was the most frequent symptom, similar to the observed in both cohorts (50.9%), followed by arthralgia which was less frequent than in the Spanish cohort (40.6% vs 34.5%). 35 patients suffered from inflammatory arthropathies and 3 cases associated fibromyalgia, less than the expected (2.8% vs 14.6% and 22%–33%). Sixteen patients suffered from interstitial lung disease, this being higher than the observed in both cohorts (15.1% vs 6.64% and 5%). Fewer patients suffered from depression compared with the EULAR group (24.5% vs 40%). Both peripheral neuropathy and renal disease were diagnosed in a percentage of patients similar to the expected (11.3% vs 8.92% vs 1.83% respectively). 7 patients had autoimmune thyroid disease. Finally, 5 patients (4.7%) developed lymphoma, 3 of them being MALT lymphoma of the parotid gland.
METABOLIC SYNDROME PREDICTS NEW DAMAGE IN DRY SYNDROME IN RA PATIENTS. COMPARISON WITH BOTH A PUBLIC HEALTH AND A CLINICAL PROBLEM. The MetS has also been reported to factors for the occurrence of cardiovascular disease and diabetes, and it is now the metabolic syndrome (MetS) is a complex of interrelated risk Background:

1University of Alabama, Alabama, USA
2Universidad Científica del Sur, Lima, Peru
3Rheumatology, Hospital Guillermo Almenara Trigoyen; 2Universidad Científica del Sur, Lima, Peru; 4School of Medicine, University of Alabama, Alabama, USA

Conclusions: Extraglandular disease in SS, although less frequent than sicca symptoms, have a special relevance when it comes to patient management. In our study the frequency of both glandular and extraglandular disease was similar to the observed in Sjögren-SER and EULAR groups although there were some differences. Fibromyalgia was less frequent in our group, whereas interstitial lung disease and peripheral neuropathy were more prevalent.

Disclosure of Interest: None declared

Background: The metabolic syndrome (MetS) is a complex of interrelated risk factors for the occurrence of cardiovascular disease and diabetes, and it is now both a public health and a clinical problem.1 The MetS has also been reported to be associated with new organ damage, vascular events and mortality in Systemic Lupus Erythematosus (SLE) patients.2

Objectives: To determine whether the MetS predicts damage accrual in SLE patients.

Methods: This prospective study was conducted in a cohort of consecutive SLE patients seen since 2012 at one single institution. Patients had a baseline visit and follow-up visits every 6 months. Patients with ≥2 visits were included. Evaluations included interview, medical records review, physical examination and laboratory tests. Damage accrual was ascertained with the SLICC/ACR damage index (SDI), and disease activity with the SLEDAI. The MetS was defined if the patient fulfilled 3 of 5 criteria according to Alberti et al.1 Survival univariable and multivariable Cox-regression models were carried out to determine the risk of developing new damage. The multivariable model was adjusted for age at diagnosis, disease duration, socioeconomic status, SLEDAI, baseline SDI, the Charlson Comorbidity Index, baseline use of prednisone (PDN), antimalarials and immunosuppressive drugs.

Results: Two hundred and forty-nine patients were evaluated; 232 were females and 17 males. Their mean (SD) age at diagnosis was 35.8 (13.1) years; nearly all patients were mestizo. Disease duration was 7.4 (6.6) years. The SLEDAI was 5.2 (4.3) and the SDI 0.9 (1.3). The average daily dose of PDN was 7.3 (6.4) mg/d and the time of exposure to PDN was 8.9 (6.2) years. One hundred and eight patients (43.4%) had MetS at baseline. During follow-up, 116 (46.6%) patients accrued at least one new point in the SDI damage index. In multivariable analyses, the presence of MetS was a predictor of development of new damage; with a Hazard Ratio (HR) 1.54 (1.05–2.26); p<0.029.

Conclusions: The presence of MetS predicts the development of new damage in SLE patients, despite of other well-known risk factors for such occurrence.

AB0564 DRY SYNDROME IN RA PATIENTS. COMPARISON WITH SJÖGREN’S SYNDROME PATIENTS

D. Peñalo[1], G. Bonilla[1], R. Montenegro[2], A. Boto[1], A. Del Hierro[2], I. Monojo[3], C. Plasencia[1], A. Balsa[1]. Rheumatology, 0Rhopthalmology, Hospital Universitario la Paz, Madrid, Spain

Objectives: The aim of the study is to analyse the clinical characteristics of Rheumatoid Arthritis (RA) patients and dry syndrome, and to compare with primary Sjögren’s syndrome (PSS) patients.

Methods: Patients with RA and dry syndrome derived from Rheumatology Clinic to Comea Unit were evaluated. According to symptoms and ophthalmological examination, patients were classified as high or low probability of Sjögren Syndrome (SS). Clinical and laboratory assessments included sex, age and smoking habit, DAS28, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), rheumatoid factor (RF), anti-citrullinated peptide antibodies (ACPA), antinuclear antibodies (ANA), anti Ro, anti La and presence of other extraarticular manifestations. In addition, the ophthalmological examination data (Ocular Staining Score [OSS] and Schirmer test), salivary gland scintigraphy (SGS) and salivary gland biopsy (biopsy) were analysed. The percentage of patients who would be classified according to the criteria of the Revised American-European Consensus Group (AECG) 2002, NIH-funded Sjögren’s International Collaborative Clinical Alliance (SICCA) 2012 criteria and ACR/EULAR 2016 criteria is evaluated. RA patients with high probability of SS are compared with SSP patients. Statistics analysis was made by mean ±SD, and comparison was made by t-Student test (quantitative parameters) and non parametric test (qualitative) (p<0.05).

Results: 24 RA with dry syndrome were included. 71% were women and the mean age was 64±14 years. The disease duration was 17±12 years. All patients had ocular manifestations, 23 oral manifestations, and 17 other extra-articular manifestations. According to DAS28, 33% of the patients were in clinical remis- 33% in high activity, and the others in low-moderate activity. 17 patients (71%), 19 (86%) and 5 (21%) were positive (+) for RF, ACPA and ANA, respectively. One patient had Anti Ro + and another anti La +. The mean OSS was 4.2 (±3.1) and the average of Schirmer was 10 (±11). In relation to other tests: 7 patients had a biopsy performed (2 positive [29%], 5 patients had GGS (2 positive [40%]). 17 of the 24 RA patients (71%) were considered “high probability Sjögren’s Syndrome” (SS and AR). These patients were compared with the PSS group (see table 1), showing differences in immunological parameters, sex, age and in the% that fulfilled the classification criteria. No significant differences were found in the ophthalmological examinations or the acute phase reactants.
Conclusions: Most of this RA patients cohort with dry syndrome were considered as "high probability SS", however only a small percent (12%–23%) fulfilled the classification criteria. This can be explained by the low rate of specific antibodies (6%), and by the poor performance of some tests included in the criteria.

AB0565 CHANGES IN HEALTH RELATED QUALITY OF LIFE IN RENAISSANCE COHORT OF RUSSIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

E. Aseeva1, L. Vorobyova1, S. Soloviev1, G. Koliubabaeva3, S. Glukhova3. 1Intensive care department, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2rheumatology department, National Center of Cardiology and Internal Medicine named after Academician M. Mirrakhimov, Bishkek, Kyrgyzstan

Background: The Lupus Quality of Life (LupusQol) is recommended to assess health related quality of life (HRQOL) in systemic lupus erythematosus (SLE).

Objectives: The aim of the current study was to assess HRQOL in the first year observation in cohort of patients with systemic lupus erythematosus in Russian Federation (RENAISSANCE).

Methods: The LupusQol-Russian was administered to a cohort of 128 Russian patients affected with SLE at baseline and follow up visit (in 12 months). Disease activity was evaluated by the SLE disease activity index-2000 (SLEDAI-2K), and chronic damage by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI) at baseline and follow up visit.

Results: 128 patients (118 (92%) women; aged 33.02±11.04 years, mean disease duration 100.8±84.3 months) were included. At baseline mean SLEDAI 2K was 11.2±8.5; mean SDI = 3.2±1.6, mean daily prednisolone 16.8±10.9 mg/day). For 12 months all patients received standard therapy according SLEDAI 2K and their clinical manifestations (prednisolone 100%, Hydroxychloroquine 72.4%, Mycophenolate mofetil 25%, Cyclophosphamide 17%, Azathioprine 12.5%, Rituximab 27.3%, bismuthum 12.5% pts). At follow up visit SLEDAI 2K score significantly improved up to 6.9±6.93 (p<0.000029), SDI significantly worse up to 1.7±1.9 (p<0.04), mean daily prednisolone significantly reduced up to 12.2±10.7 mg (p<0.04). All 8 subscales LupusQol showed improvement in the 12 months versus baseline (Table 1). Spearman’s correlation with SLEDAI 2K was obtained for Physical health (r=-0.13), Pain (r=-0.16), Planning (r=-0.21), Intimate relationship (r=-0.17). Burden to others (r=-0.16), emotional health (r=-0.13), Body image (r=-0.21).

AB0566 ANTI-PHOSPHOLIPID ANTIBODIES SERO-NEGATIVIZATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TREATED WITH BELIMUMAB

E. Rubini, M. Radin, I. Cecchi, D. Roccatali, S. Sciaccia. Università Degli Studi di Torino, Turin, Italy

Background: Belimumab is a monoclonal antibody that blocks the B lymphocyte stimulator, preventing it to bind its receptor on B-lymphocyte’s surface, thus avoiding B cell activation. Despite some benefits showed in murine models of anti phospholipid syndrome (APS), the use of belimumab in this condition needs further investigation.

Objectives: To investigate changes in the antiphospholipid antibodies (aPL) profile in Systemic Lupus Erythematosus (SLE) patients treated with belimumab.

Methods: We retrospectively collected data from patients who attended the S. Giovanni Bosco Hospital, Turin, Italy. Inclusion criteria comprised: a) fulfilled ACR criteria for SLE. b) persistent aPL positivity (confirmed ≥3 occasions over a time >24 months before belimumab treatment), c) previous or ongoing belimumab therapy.

Results: This retrospective study included 3 patients with diagnosis of SLE [median age 39(range 33–51), male:female 2:1]. Table 1 resumes the characteristics of patients. All 3 patients received belimumab because of SLE flares. Before the treatment, Patient#1, classified as SAPS, presented a persistent triple positivity for lupus anticoagulant (LA), high-titer aCL IgG isotype (>200 GPL) and anti-β2Glprotein1 antibodies (>50 GPL) (anti-β2GPI) IgG isotype. Patient#2 was persistently positive for IgG aCL and IgM anti-β2GPI (both 20–30 GPL and MPL, respectively; cut-off >7U), and had a history of pregnancy morbidity. Patient#3, classified as SAPS, presented positivity of LA and IgG aCL (10–20 GPL).

After 12 months since belimumab was started, a marked reduction of aPL was noticed, as follows: Patient#1 became negative for antiβ2GPI, while his aCL titre significantly decreased. Antiβ2GPI and aCL both turned negative in Patient#2. After being on belimumab for one year, she planned a pregnancy and she stopped the treatment; after 8 months since suspension, IgG antiβ2GPI antibodies were detectable (cut-off >3.5 U). Patient#3 was persistently negative for aCL while being on belimumab. When he discontinued the therapy, IgG aCL antibodies returned positive. Figure 1 illustrates aPL titres of the 3 patients in relationship with belimumab therapy.

Conclusions: Despite its limitations, this pilot study is the first report of aPL negativization after starting therapy with belimumab. The clinical relevance of these findings should be investigated in prospective multicenter studies.

CLINICAL SIGNIFICANCE OF THE DETECTION OF HLA-DRB1 ALLELES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
E. Belolipetskaia1, I. Beliaeva2, V. Guseva2, O. Inamova2, G. Kostrova2, N. North-Western State Medical University named after I. I. Mechnikov, 2. St. Petersburg State Medical University named after I. P. Pavlov, 3. Clinical Rheumatological Hospital № 25, Saint-Petersburg, Russian Federation

Background: Associations between clinical manifestations of systemic lupus erythematosus (SLE), presence of antiphospholipid antibodies (aPL) and the HLA-DRB1 alleles have been established, these associations however need clarification.

Objectives: Clarify the associations between clinical features of APS in patients with SLE and the presence of aPL and the HLA-DRB1 alleles.

Methods: 79 SLE patients were enrolled in the study (MF: 7/72; mean age 11.0 years, range (18,078,0). The main group consisted of 41 aPL carriers (28 of them with antiphospholipid syndrome (APS), a comparison group consisted of 38 aPL-negative SLE patients. The groups were comparable in age, duration and SLE activity.

ELISA was used to test for aPL. Lupus anticoagulant (LA) was evaluated using the DRVV test method. The HLA-DRB1 alleles were identified using HLA-typing.

Results: While comparing both groups, HLA-DRB1*08 allele was found significantly less frequently in aPL-carriers group (p<0.04). In aPL group HLA-DRB1*08 allele was present significantly more often (p=0.002), both HLA-DRB1*03 and *15 alleles were found significantly less often (p=0.008) in comparison with the aPL-negative group. SLE patients with HLA-DRB1*16 allele were more likely to develop an early pregnancy loss (OR=19, p=0.04), patient with HLA-DRB1*11 allele – more likely to develop a fetal loss (OR=4.9, p=0.04) in comparison with other alleles; in patients with HLA-DRB1*01 allele both early pregnancy loss and fetal loss occurred less often (OR=0.18, p=0.04; OR=0.29, p=0.04) compared with other alleles. The highest level of anti-double-stranded DNA was found in patients with HLA-DRB1*13 allele (Me=54, [17.0, 290.0 IU/ml], p=0.005), and lowest level – in patients with HLA-DRB1*04 (Me=0.15, [0.0; 14.2 IU/ml], p=0.005).

In the group of aPL carriers significant correlations between the HLA-DRB1*08 allele and elevated level of anticardiolipin antibodies (aCL) IgM (r=−0.42, p=0.005) and anti-annexin V antibodies IgG (r=0.3, p=0.01), between HLA-DRB1*04 allele and elevated level of aCL IgG (r=0.31, p=0.008), between the HLA-DRB1*12 allele and an elevated level of anti-annexin V antibodies IgM (r=0.31, p=0.01) were found. Correlations between HLA-DRB1*16 allele and early pregnancy loss (r=0.37, p<0.001), between HLA-DRB1*11 allele and fetal loss (r=0.30, p<0.001) were observed.

Conclusions: 1. HLA-DRB1*08 allele is a risk factor for the development of APS in SLE patients.
2. HLA-DRB1*03 and *15 alleles were more often detected in aPL-negative SLE patients.
3. The presence of HLA-DRB1*16 and *11 alleles in SLE patients is a risk factor for the development of obstetric complications.
4. In the group of aPL carriers significant correlations between HLA-DRB1 alleles and elevated levels of aPL were found.
5. SLE patients with HLA-DRB1*01 were less likely to develop any obstetric complications.

AB0569

RELATIONSHIP BETWEEN THE LEVELS OF VITAMIN D AND THE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS IN DOMINICAN REPUBLIC

Background: Systemic Lupus erythematosus (SLE) is a multi-system autoimmune disease with an increased mortality and morbidity rate compared to the controlled population. One of the commonest causes of mortality and morbidity in SLE is infection. This is a result of not only the immunosuppressive effect of the disease process itself but also treatment involving disease modifying anti-rheumatic drugs (DMARDs). In fact, corticosteroids and immunosuppressants increase the risk of opportunistic infection, in addition to the more common pathogens. Vaccines provide long lasting protective immunity against microbial pathogens and prevent clinically relevant infections. Recommended vaccinations in SLE patients include H. Influenza, Pneumococcal, Hepatitis A and B, and Human Papilloma Virus (HPV). Influenza vaccines are given annually and a Pneumococcal booster dose is given at 5 years following the initial vaccine.

Objectives: To assess whether, in routine clinical practise, patients with SLE are immunised against preventable disease according to EULAR recommendations and to assess the level of patient awareness.

Methods: A questionnaire was designed to assess the degree of compliance with current recommendations adapted from the EULAR-recommended vaccinations in patients with autoimmune inflammatory rheumatic diseases on DMARD therapy. The questionnaire enquired into the awareness and uptake of the influenza B, pneumococcal and hepatitis B vaccines. They were sent out by postal mail, with an enclosed stamped address envelope, to all SLE patients within the university hospitals of Leicester (UHL) NHS trust identified via the rheumatology patient database. Questions included awareness of the need to have vaccinations whilst on DMARDs. The audit was conducted over a three month period and the results were compiled in Microsoft excel.

Results: Of the 396 SLE patients within UHL, 86 responded. Among the patients studied 38% were on DMARD therapy, an equal proportion claimed they were not and 23% were unclear if they were on DMARD therapy. Approximately 65% were unaware of the need for vaccinations and only 27.9% acknowledged awareness for the need of the 3 vaccines mentioned above. Fifty-six (60%) patients had the influenza vaccine yet only 26 (28%) and 15 (21.8%) had the Pneumococcal and Hepatitis vaccines respectively.

Conclusions: The increased infection rate in SLE can be reduced through vaccination. This highlights the importance of increasing both physician and patient awareness. Although the sample size was small, the above audit has revealed that current local practice, with regards to ensuring that all SLE patients are appropriately vaccinated, requires improvement. This can be achieved through patient and healthcare worker education, and also creating a checklist that can be added to the clinic notes. Working together with our primary care colleagues will also help bridge the divide between compliance and non-compliance. Such measures will aim to improve mortality and morbidity in SLE patients.

KNOW YOUR VACCINES – A CLINICAL AUDIT ON THE UPTAKE OF VACCINATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS
E.E. Varughese, M. McCartney, K. Sunnboyne, S. Shaffu. Rheumatology, University of Leicester-Leicester Royal Infirmary, Leicester, UK

Background: Systemic Lupus erythematosus (SLE) is a multi-system autoimmune disease with an increased mortality and morbidity rate compared to the controlled population. One of the commonest causes of mortality and morbidity in SLE is infection. This is a result of not only the immunosuppressive effect of the disease process itself but also treatment involving disease modifying anti-rheumatic drugs (DMARDs). In fact, corticosteroids and immunosuppressants increase the risk of opportunistic infection, in addition to the more common pathogens.

Vaccines provide long lasting protective immunity against microbial pathogens and prevent clinically relevant infections. Recommended vaccinations in SLE patients include H. Influenza, Pneumococcal, Hepatitis A and B, and Human Papilloma Virus (HPV). Influenza vaccines are given annually and a Pneumococcal booster dose is given at 5 years following the initial vaccine.

Objectives: To assess whether, in routine clinical practise, patients with SLE are immunised against preventable disease according to EULAR recommendations and to assess the level of patient awareness.

Methods: A questionnaire was designed to assess the degree of compliance with current recommendations adapted from the EULAR-recommended vaccinations in patients with autoimmune inflammatory rheumatic diseases on DMARD therapy. The questionnaire enquired into the awareness and uptake of the influenza B, pneumococcal and hepatitis B vaccines. They were sent out by postal mail, with an enclosed stamped address envelope, to all SLE patients within the university hospitals of Leicester (UHL) NHS trust identified via the rheumatology patient database. Questions included awareness of the need to have vaccinations whilst on DMARDs. The audit was conducted over a three month period and the results were compiled in Microsoft excel.

Results: Of the 396 SLE patients within UHL, 86 responded. Among the patients studied 38% were on DMARD therapy, an equal proportion claimed they were not and 23% were unclear if they were on DMARD therapy. Approximately 65% were unaware of the need for vaccinations and only 27.9% acknowledged awareness for the need of the 3 vaccines mentioned above. Fifty-six (60%) patients had the influenza vaccine yet only 26 (28%) and 15 (21.8%) had the Pneumococcal and Hepatitis vaccines respectively.

Conclusions: The increased infection rate in SLE can be reduced through vaccination. This highlights the importance of increasing both physician and patient awareness. Although the sample size was small, the above audit has revealed that current local practice, with regards to ensuring that all SLE patients are appropriately vaccinated, requires improvement. This can be achieved through patient and healthcare worker education, and also creating a checklist that can be added to the clinic notes. Working together with our primary care colleagues will also help bridge the divide between compliance and non-compliance. Such measures will aim to improve mortality and morbidity in SLE patients.

high activity. Of the patients who reported disease activity, only 13.3% had insufficient vitamin D. There is no significant difference between patients who have vitamin D values greater than or less than 20 ng/ml. In both groups, the majority had SELENA-SLEDAI in low activity.

Conclusions: The vitamin D levels were not associated with an increase in disease activity in our study patients. Although our country is an island, the use of sunscreen and avoid sunbathing is something common, it causes to find low levels of vitamin D, not only in patients with SLE, where avoiding sunbathing is a recommendation, but also in other pathologies in some comorbidities that come to our service. We believe that vitamin D levels should be measured in the general population, to have a reference range and study their influence on health.

AB0570 ASSOCIATION BETWEEN SLEDAI-2K DOMAINS AND ORGAN DAMAGE ACCRUAL
K. Zhang1, S. Boyd2, F. Petjeiann2, A. Hoi3, R. Koelmeyer3, E. Morando2, H. Nim2, 1Monash University, Melbourne, Australia. 2Information Technology, Faculty of Medicine Nursing and Health Sciences, Monash University, Melbourne, Australia
Background: Prevention of permanent organ damage is a key goal of SLE management. Overall disease activity measured by SLE Disease Activity Index (SLEDAI-2k) is a risk factor for damage but, the contribution of organ-specific activity to damage risk has not been enumerated.
Objectives: We sought to determine the degree to which organ domains of SLEDAI-2k are associated with organ damage accrual.
Methods: A dataset of SLE patients (2007–2017) at the Australian Lupus Registry was studied. Variables collected at each visit included all domains of SLEDAI-2k, Physician Global Assessment, and medications. Systemic Lupus International Collaborating Clinics/ACR Damage Index (SDI) was recorded annually and each visit was labelled “damage transition” or “non-damage transition” based on whether SDI increased at the subsequent annual measure. The association of risk of SDI increase with SLEDAI-2k domains was assessed using multivariable logistic regression analysis adjusted for confounding by medication use.
Results: 5538 visits from 268 patients (86.5% female, 47.4% Caucasian, 66% dsDNA positive) were analysed; at enrolment median (range) SLEDAI-2k was 4 (0–26) and SDI was 0 (0–4). Upon multivariable regression analysis, domains found to be significant were: low complement, proteinuria, haematuria, leukopenia, pyuria, pericarditis, alopecia, rash and arthritis. Upon further adjustment for prednisolone exposure, the effects of some domains were attenuated, but pericarditis (odd ratio (OR)=4.06, 95%CI:1.69–8.93), pyuria (OR=1.94, 1.47–2.56), arthritis (OR=1.71, 1.35–2.16), and rash (OR=1.43, 1.20–1.60), alopecia (OR=1.43, 1.10–1.86) and leukopenia (OR=1.36, 1.03–1.78) remained significant. No other SLEDAI-2k domains showed a significant association, in part due to infrequent occurrence. SLEDAI-2k domains weightings were not congruent with the respective risk of damage accrual.
Conclusions: In study, only some SLEDAI-2k domains were significantly associated with organ damage accrual. Re-appraisal of weightings in SLE disease activity scores based on their association with outcome is potentially warranted.

AB0571 FACTORS RELATED TO ALEXITHYMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS
F. Rasta, D.P.E. Margiotta, G. Dolcini, V. Batani, A. Vemucio, M. Vadacca, A. Afeltra. Università Campus Bio-medico di Roma, Rome, Italy
Background: Alexithymia describes the difficulties of people in identifying, differentiating and articulating emotions of others and themselves and in discriminating those from bodily sensations, with a limited fantasy and a concrete, externally oriented cognitive style. A high prevalence of alexithymia has been found in patients with a variety of health conditions, including SLE. Previous authors identified mood states and quality of life as the main factors related to alexithymia in Systemic Lupus Erythematosus (SLE).
Objectives: Aim of our study was to assess the impact of clinical, immunological, psycho-social factors on the presence of alexithymia in Systemic Lupus Erythematosus (SLE).
Methods: We consecutively enrolled 104 patients in a cross-sectional study. Alexithymia was assessed using the Toronto Alexithymia scale (TAS-20). We also evaluated symptoms of mood disorders using BDI and HAM-H, quality of life using MOS-SF-36, sleep disorders with PSQI and physical activity using IPAQ.
Results: The mean (standard deviation) TAS-20 score was 49.5 (15.6). The prevalence of alexithymia (TAS-20 >61) was 28%. Alexithymic patients (TAS-20 >61) were significantly older (p<0.0005), presented more severe depressive and anxiety symptoms (p<0.0001), a higher level of sleep disorder (p<0.0001), a reduced Fadt-Fatigue score (p<0.0007), reduced SF-36 mental and physical component summary scores (p<0.0001 and 0.004) and increased daily sedentary time (p<0.002). In the multiple logistic regression analysis the variables associated to the presence of alexithymia were age (OR 1.07, p<0.02) and the score of depressive symptoms (OR 1.15, p<0.02).
Conclusions: About a third of SLE patients presented a dysfunctional processing of emotion. It is necessary to carefully consider the symptoms of mood disorders to optimise SLE patient management.

AB0572 CORRELATION OF 24 HOURS URINARY PROTEINQUANTIFICATION WITH RANDOM SPOT URINE PROTEIN/CREATININE RATIO IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS
F. Elbadawi, M. Khamashia, J. Aslaheh. Rheumatology Department, Dubai Hospital, Dubai, United Arab Emirates
Background: Proteinuria is an important signal of Lupus nephritis. The standard method of proteinuria quantification is 24 hours urine collection. The ongoing practice of using spot urine sample to determine the ratio between protein and creatinine excretion as a convenient, alternative method of proteinuria estimation is not without limitation and criticism questioning its accuracy. Objectives: Given the cumbersome expressed by some patients on collecting 24 hours urine for protein quantification, our aim was to determine the correlation between spot urine protein-to-creatinine ratio (PCR) and 24 hour urinary protein (UP) in patients with active Lupus nephritis.
Methods: The active patients included in the analysis was 53 attending Dubai Hospital shared Rheumatology/Nephrology clinic during the period of June 2016 till Dec 2017. All diagnosed to have systemic lupus erythematosus who either had flare with proteinuria or newly diagnosed as Lupus nephritis.,. Suspicion of active Lupus nephritis was evidenced by active urine sediment and 24 hours UP quantification of more than 0.5 gm or more than 1.0 gm regardless to urine sediment. Paired baseline urine samples were obtained and results included in the final analysis. Most of the patients undergone ultrasound guided kidney biopsy to classify the nephritis according to ISN/RPS 2003 classification, unless contra-indicated or patient refused to give consent. We used Minitab 18.1 software to determine the Spearman’s correlation coefficient (r), and it is significance. P-Value <0.05 was considered statistically significant.
INFLUENCE OF SMOKING AND OBESITY ON THE RISK OF DEVELOPING PRIMARY SJÖGREN’S SYNDROME: A POPULATION-BASED COHORT STUDY

G. Maciel1, L. Servolí1, C. Nannini2, C. Crowson3, E. Matteson3, D. Connec4, A. Berti5, Maciel Hospital, Montevideo, Uruguay; 2Department of Rheumatology, Hospital of Prato, Prato, Italy; 3Mayo Clinic, Rochester MN, USA; 4Rheumatology Department, Brest Teaching Hospital, Brest, France; 5Immunology, Rheumatology, Allergy and Rare Diseases Department, San Raffaele Scientific Institute, Milan, and Rheumatology Department, Santa Chiara Hospital, Trento, Italy

Objectives: Cigarette smoking and obesity have been identified as risk factors for developing several autoimmune diseases, and may be protective for others. This study explored the role of these risk factors in primary Sjögren’s syndrome (pSS).

Methods: A cohort of Olmsted County, Minnesota residents diagnosed with pSS between January 1, 2000 and December 31, 2015 was identified based on individual medical record review. Each of the cases was matched to 3 age- and sex-matched comparators without pSS randomly selected from Olmsted County residents, indexed to the date of pSS diagnosis. Smoking status was divided into three categories of current smoker, ex-smoker and never smoker. The body weight and height closest to date of diagnosis/index date (±1 year) were used. Obesity was defined as a body mass index (BMI) >30 kg/m².

Results: 106 incident cases of pSS and 318 controls were identified. The odds ratio (OR) of pSS comparing current smokers with never smokers was 0.34 (95% confidence interval (CI): 0.14, 0.85; p<0.05), while the OR for former smokers compared to never smokers was 1.27 (95% CI, 0.80, 2.03). Smoking status was not associated with an anti-nuclear antibody, anti-SSA, anti-SSB or rheumatoid factor positivity (p>0.05). The OR of pSS comparing obese subjects with non-obese subjects was 0.79 (95% CI, 0.48, 1.30), while the OR of pSS for BMI analysed as a continuous variable was 0.97 (95% CI, 0.94, 1.01).

Conclusions: In this population-based study, current smokers have a lower risk of developing pSS while BMI does not affect this risk.

RENAL ACTIVITY PATTERNS AND THERAPEUTICS IN LUPUS NEPHRITIS OBSERVATIONS IN 5 MEXICAN RHEUMATOLOGY CENTRES

G. Pickens1, D.A. Herrera-van Oostdam1, F. Izaguirre-Palazuelos2, S. Cerpa-Cruz3, M.A. Saaavedra-Salinas4, C. Mendoza-Pinto5, C. Abud-Mendoza5.
1Rheumatology, Hospital Central Dr. Ignacio Morones Prieto, San Luis Potosí; 2Rheumatology, Centro Médico Nacional ‘20 de Noviembre’, Ciudad de México; 3Rheumatology, Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara; 4Rheumatology, Hospital de Especialidades Centro Médico Nacional “La Raza”, Ciudad de México; 5Rheumatology, Hospital General Regional Numero 36 “San Alejandro”, Puebla, Mexico

Background: Lupus nephritis (LN) develops in 40%–60% of Systemic Erythematous Lupus (SLE) patients; 45% don’t achieve complete response or eventually relapse and 10%–20% progress to end stage renal disease.

Objectives: Describe renal activity patterns and therapeutic schemes employed in 5 Mexican Rheumatology Centres.

Methods: Retrospective analysis of renal activity in 193 patients with LN with ≥6 months follow-up. If follow-up was ≤1 year, response was classified as complete (CR), partial (PR) or no response (NR). If follow up was >1 year, response was classified as one of the following patterns: persistent inactive (PI), relapsing-remitting (RR), chronic active (CA) and mixed.

Results: Biopsy was available in 166 subjects (86.01%): class IV (42.77%), III (23.49%), V (10.24%), II (9.03%). The most prevalent schemes were CYC+MMF 46.6%, only CYC 18.13%, only MMF 12.4%, CYC+MMF+ TAC 9.84%. Thirty-eight patients had follow-up ≤1 year with the following response: CR 16 (42.1%), PR 13 (34.21%) y PR 9 (25.7%). One hundred and fifty five patients had >1 year follow-up with the following activity patterns: PI 55 (35.48%), RR 38 (24.51%), CA 31 (20%), mixed 31 (20%).

We then compared patients whose therapeutic schemes were classified as the National Institutes of Health regime (n=109) (as considered by the treating physician) to those with different therapeutic schemes. We observed a higher final GFR (100±39.2 SD VS 87.1±37.9 SD, p=0.029) and more frequent CYC use (106 ±100 SD VS 87±49.3 SD, p<0.001) in the NIH group. There weren’t statistically significant concerning renal response or activity patterns. Although treating physicians stated they had used the NIH regime in 57.9%, 64.3% actually received CYC+MMF 46.6%, and 14.4% CYC+MMF+ TAC 9.84%. We then compared the group that received CYC monotherapy to the groups that received CYC+MMF and CYC+MMF+ TAC and did not observe any statistically significant differences.

Conclusions: The most prevalent renal activity patterns were those that translated intermittently of continuous activity (64.51%). Strict adherence to the original NIH regime is questionable, most subjects actually received CYC+MMF at some point. We did not observe any statistically significant superiority of renal outcomes of combination therapy over CYC monotherapy. Limitations: preliminary initial analysis, heterogeneous information and missing data.

Features of Neurological Manifestations of Systemic Lupus Erythematosus in the Kyrgyz Cohort of Patients

G. Koliubayeva1, E. Aseeva2, S. Soloviev2, T. Reshetnyak3.

Background: The development of a variety of neuropsychiatric symptoms in SLE patients can significantly worsen the patient’s condition and complicate the prognosis.

Objectives: To study the features of neurological manifestations of SLE in the Kyrgyz cohort of patients.

Methods: The basis of the study were the results of an initial examination of 460 patients with prospective observation, with a reliable diagnosis of SLE. Out of them, 112 patients were neurological, at the age of 30 (median) [26, 41], predominantly of Kyrgyz nationality (87), with duration of the disease from 6 months to 7 years (median – 2.0) treated in the National Cardiology and Therapy Centre named after M. Mirrakhimov (NCTC) from January 2012 to December 2017.

Neurologic manifestations of SLE were diagnosed by clinical examination by a neurologist using some instrumental methods of investigation.

To assess the neuropsychiatric state of patients, the classification criteria by the American College of Rheumatology (1999) were used. Neuropsychiatric disorders were diagnosed through a clinical examination by the psychotherapist using the classification of mental disorders and behavioural disorders according to ICD (International Classification of Diseases) – 10.

Results: The damage of the nervous system was observed in 112 (24.30%) Kyrgyz patients from 460, mainly of the central nervous system – in 77 (68.75%), to a lesser extent – the peripheral nervous system (PNS) – in 35 (31.25%) out of 112. In half of the observed patients with CNS lesions, various neuropsychiatric disorders were registered – in 39 (50.65%) out of 77, with psychosis prevalence with visual and auditory hallucinatory syndrome – in 34 (87.18%) out of 39 patients. There were 14 patients with cerebrovascular infection (18.18%) out of 77, mainly with ischaemic stroke in the SMA basin. There was one patient with aseptic meningocellitis with manifestations of mild hemiparesis and with the disruption of the function of the pelvic organs in the form of mandatory urges. Symptoms of myelopathy with mal-function of the pelvic organs were registered in 9 (11.69%) patients out of 77.

Five patients had symptoms of combined CNS and PNS lesions. In one of them cases the patient had encephalomyeloneuradiculoathy of the Guillian-Barre type with the phenomena of coarse tetraparesis and with disruption of the function of pelvic organs in the form of delay, with a single epiphrism.

Conclusions: Neurological manifestations of SLE in the majority of Kyrgyz patients were mainly caused by CNS lesions (68.75%), mostly in the form of neuropsychiatric disorders (50.65%), with a predominance of psychosis with visual and auditory hallucinatory syndrome (87.18%).

Characteristics of Valvular Heart Disease in a Monocentric Malaysian Lupus Cohort

H.J. Ding, S.G. Ong, S.S. Md Sani. Medicine, Kuala Lumpur Hospital, Kuala Lumpur, Malaysia

Background: Valvular heart disease (VHD) is one of the commonest cardiovascular manifestations of autoimmune disease, including systemic lupus erythematosus. Its prevalence ranges from 18% to 74%, with predominantly regurgitant lesions and valvular thickening. The cause of such abnormalities is yet unclear. There have been very few such studies performed in Asian patients, and only one in Malaysian patients to date.

Objectives: We sought to evaluate the valvular abnormalities of a multicentric cohort of lupus patients and also examine the association of these abnormalities with potentially related factors.

Methods: The medical records of all patients with SLE who had attended the Rheumatology Clinic of Kuala Lumpur Hospital between January 2008 and December 2016 were reviewed. All patients fulfilled the 1997 updated ACR criteria for SLE. Transthoracic echocardiographic examinations as part of their standard of care were performed by trained technicians using a standardised protocol. Multivariable logistic regressions were conducted to determine factors associated with valvular abnormalities in these patients.

Results: There were 207 patients in this study. VHD was found in 67.1% of patients: they were asymptomatic and did not have murmurs. The main abnormalities were tricuspid regurgitation (TR) (45.4%), mitral regurgitation (MR) (40.6%) and valvular thickening (19.2%). The majority of cases comprised mild TR (37.2%), mild MR (25.1%) and mitral valve thickening (10.6%). There were more patients with moderate to severe MR compared to TR (15.5% vs 8.2%). Median pulmonary artery systolic pressure was 23.0 mmHg (IQR 13.2). Risk of VHD was higher in patients with lower C3 levels (<0.83 g/L) (OR 3.36, 95% CI 1.74–6.66). MR (83.3%) and mitral valve (MV) thickening (58.3%) were the commonest abnormalities in patients with APS. Having APS greatly increased the risk of MR (OR 8.10, 95% CI 1.65–77.95) and mitral valve thickening (OR 16.30, 95% CI 3.93–73.84). Risk of mitral valve thickening was increased by presence of lupus anticoagulant (OR 20.82, 95% CI 1.12–402.08), anticoagulant (OR 5.24, 95% CI 1.42–17.76), antiphospholipid antibodies (OR 6.35, 95% CI 1.18–37.14) and diabetes (OR 7.85, 95% CI 1.43–40.24). Risk for MR was increased by presence of lupus anticoagulant (OR 3.55, 95% CI 1.10–12.43). Hypertension was associated with an increased risk for developing aortic regurgitation (OR 4.70, 95% CI 1.67–13.44). Anti-histone antibody positivity appeared to protect against development of VHD (OR 0.46, 95% CI 0.21–0.99) which was not statistically significant.

Conclusions: More than half of our patients had VHD, with regurgitant lesions and valvular thickening being the commonest abnormalities. Our finding of the association of MR and mitral valve thickening with APS and individual anti-phospholipid autoantibodies concurs with earlier studies. However, what were unusual about our cohort were that TR was the prevalent abnormality and the association of VHD with low C3. We suggest that all patients with SLE have at least one echocardiogram, especially the patients with APS or antiphospholipid antibodies.

Analysis of Clinical Features and Risk Factors of In-Hospital Mortality in Cytomegalovirus (CMV) Diseases with Systemic Lupus Erythematosus

H. Ming1, C.-Y. Tsai2. 1Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital; 2Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital, Taipei, Taiwan, Province of China

Background: Cytomegalovirus (CMV) is known as a major cause for life-threatening complications in immunocompromised hosts, including status post allogeneic bone marrow transplantation, solid organ transplantsations, and acquired
IMMUNOLOGICAL RESULTS OF SALIVARY GLAND BIOPSY AND THEIR RELATIONSHIP WITH CLINICAL AND SEROLOGICAL PARAMETERS IN PRIMARY SJÖGREN’S SYNDROME

H.S. Pask1, L. Martinez Martinez2, B. Magallares1, M. Fernandez Castro1, M. A. Martin1, F. Sanchez Alonso1, I. Castelvi1, A. Laz1, C. Diaz-Tome1, M. Millan Arciniegas1, P. Moja Alvardo2, I. Lopez Vilario2, M.C. Hernandez Lafuente2, E. Molto Lacosta2, C. Juarez Rubio2, H. Coromina1, 1Rheumatology, H.U. Sant Pau, Barcelona; 2Pathology, H.U. Sant Pau, Barcelona; Spain

Background: Positive minor salivary gland biopsy(MSBG) is a major criteria for the diagnosis of primary Sjögren’s Syndrome (PSS). In our centre the MSBG analysis is carried out by Immunology and Pathology Department in parallel. The immunological analysis identifies the lymphocytic composition of the inflammatory infiltrate. Their results show: the number of T and B cells, the ratio between CD4 and CD8 T lymphocytes and other non infiltrating lymphocytes.

Objectives: The goal of our study was to evaluate whether there is an association between the lymphocytic composition of the MSBG with the clinical and serological findings of PSS patients.

Methods: Patients diagnosed of PSS according American-European criteria (2002) underwent MSGB between February and November of 2017

Results: Fifty-six patients diagnosed with CMV diseases were enrolled in the study and separated into survivors(n=24) and non-survivors (n=32) groups. All patients in CMV disease demonstrated significantly higher incidence of CMV pneumonitis (71.43%). The higher SLEDAI-2000 score (p<0.009, HR 1.154, 95% CI 1.037–1.285), percentage of recent pulse therapy (p=0.013, HR 4.569, 95% CI 1.313–15.902), and plasmapheresis during hospital course (p=0.005, HR 6.905, 95% CI 1.637–29.122) was more common characteristics in non-survivor group than in survivor group. Non-survivors had significantly higher percentage of pancytopenia (p=0.001, HR 96.67, 95% CI 2.307–40.511), CMV-positive PCR of blood and bronchoalveolar (BAL) lavage fluid (Blood: p<0.001, HR 15.000, 95% CI 3.932–57.223, BAL fluid: p=0.021, HR 6.176, 95% CI 1.151–33.151), and presence of concurrent infections (bacteremia: p=0.026, HR 4.833, 95% CI 1.122–20.824, other fungal infections: p<0.001, HR 11.424, 95% CI 2.722–47.952) than survivors. Septic shock (n=10, 41.2% of non-survivor group) is the most common cause of in-hospital mortality in CMV diseases.

Conclusions: The recent pulse therapy, pancytopenia, and concurrent infections are risk factors of in-hospital mortality in CMV diseases of patients with Systemic Lupus Erythematosus. The serological data of non-survivor groups showed negative findings of CMV immunoglobulin M (IgM) with detection of CMV DNA by polymerase chain reaction (PCR) was observed in CMV diseases. The pulmonary haemorrhage and acute respiratory distress syndromes (ARDS) were the factors of in-hospital mortality in CMV pneumonitis.

IMMUNOLOGICAL RESULTS OF SALIVARY GLAND BIOPSY AND THEIR RELATIONSHIP WITH CLINICAL AND SEROLOGICAL PARAMETERS IN PRIMARY SJÖGREN´S SYNDROME

H.S. Pask1, L. Martinez Martinez2, B. Magallares1, M. Fernandez Castro1, M. A. Martin1, F. Sanchez Alonso1, I. Castelvi1, A. Laz1, C. Diaz-Tome1, M. Millan Arciniegas1, P. Moja Alvardo2, I. Lopez Vilario2, M.C. Hernandez Lafuente2, E. Molto Lacosta2, C. Juarez Rubio2, H. Coromina1, 1Rheumatology, H.U. Sant Pau, Barcelona; 2Pathology, H.U. Sant Pau, Barcelona; Spain

Background: Positive minor salivary gland biopsy(MSBG) is a major criteria for the diagnosis of primary Sjögren’s Syndrome (PSS). In our centre the MSBG analysis is carried out by Immunology and Pathology Department in parallel. The immunological analysis identifies the lymphocytic composition of the inflammatory infiltrate. Their results show: the number of T and B cells, the ratio between CD4 and CD8 T lymphocytes and other non infiltrating lymphocytes.

Objectives: The goal of our study was to evaluate whether there is an association between the lymphocytic composition of the MSBG with the clinical and serological findings of PSS patients.

Methods: Patients diagnosed of PSS according American-European criteria (2002) underwent MSGB between February and November of 2017

Demographic (sex and age), clinical (disease duration, xerostomia, queratoconjunctivitis sicca, Schirmer test, systemic disease) data were collected. Present or previous treatment with steroids and/or immunosuppressive therapy, serological studies such as ANA, RF, anti Ro and anti La were also included. MSGB data with the number of infiltrates, quantitative composition of T and B lymphocytes, CD4/CD8 ratio and presence of other non infiltrating lymphocytes were registered. Pathology data concerning Chisholm-Mason scale, presence of fibrosis, atrophy and size of infiltrate (small, moderate and severe) were also registered. A multiple logistic regression for each item of the immunological analysis adjusted for sex and age was made. We also measured the odds ratio and performed correlation test for all variables included.

Results: Table 1 and 2 summarise our cohort characteristics. The presence of T lymphocyte was associated with B lymphocyte, OR 99.21 (95% 5.12–19.21, p=0.002) and with higher CD4/CD8 ratio, OR 17.34 (95% 1.45–206.15, p=0.024). CD4/CD8 ratio was also associated with the presence of T lymphocytes OR 10.54 (95% 2.16–51.50, p=0.004) and B lymphocytes were associated with the presence of T lymphocytes as well OR 5.38 (95% 1.63–17.72, p=0.006). Other non infiltrating lymphocytes were composed of CD8 T cells and were associated with a positive Schirmer test OR 17.47(95% 0.16–188.13, p=0.018) but inversely associated with Chisholm-Mason grade ≥ 3 OR 0.09(95% 0.014–0.58, p=0.011). There was no other association observed with clinical or analytical parameters. Colinearity test between pathological and immunological analysis was negative.

Conclusions: MSGB in our PSS patients demonstrated an association between T lymphocytes, B lymphocytes and CD4/CD8 ratio. The infiltrate is mostly based on CD4 more than CD8 T cells. Other significant findings were the association between CD8 T lymphocytes and Chisholm-Mason scale grade ≥ 3, regardless of the number of infiltrates. No correlation or colinearity was observed with the number of infiltrates by immunological analysis and the Chisholm-Mason grade reported by the pathology analysis.

CONGENITAL HEART BLOCK AND MATERNAL PREGNANCY OUTCOMES IN WOMEN WITH POSITIVE ANTI-RO AND ANTI-LA AUTOANTIBODIES: A SINGLE CENTRE-STUDY

I. Alfon Olate, M.Á. Ferrer González, I. Notario Ferreira, L. Pérez Albaladejo, M. Ramírez de la Torre, S. Quirosa Flores, A. García Sánchez, M.C. Ramírez Barberena, J.M. Andreu Ubeo, R. Cáiz Cáiz1. Rheumatology, Hospital Universitario Virgen de las Nieves de Granada, Granada, Spain

Abstract AB0580 – Figure 1. Immunosuppressive therapy received during the 46 pregnancies (%) 

Conclusions: Our results demonstrate that both treatment with hydroxychloroquine and close control in a multidisciplinary unit are effective in the prevention of congenital heart block development, in the decrease in the number of abortions and in a reduction of maternal and fetal morbidity and mortality. The multidisciplinary evaluation is essential in women diagnosed with rheumatic diseases with high obstetric risk.

Disclosure of Interest: None declared

PREGNANCY OUTCOMES IN WOMEN WITH ANTIPHOSPHOLIPID SYNDROME AND THROMBOPHILIA TREATED IN A MULTIDISCIPLINARY UNIT

I. Alfon Olate, M.Á. Ferrer González, L. Pérez Albaladejo, I. Notario Ferreira, M. Ramírez de la Torre, S. Quirosa Flores, A. García Sánchez, M.C. Ramírez Barberena, J.M. Andreu Ubeo, R. Cáiz Cáiz1. Rheumatology, Hospital Universitario Virgen de las Nieves de Granada, Granada, Spain

Abstract AB0581 – Figure 1

Background: The Antiphospholipid Syndrome (APS) and Thrombophilia predominantly affect women of fertile age, so their pregnancies should be considered high obstetric risk. These pregnant women need close monitoring in a multidisciplinary unit.

Objectives: To evaluate the efficacy of the treatment on the pregnancy outcomes of women with APS and thrombophilia from a Spanish cohort.

Methods: Descriptive, prospective, longitudinal and open study of 88 pregnant women with positive autoantibodies anti-Ro/La. They were attended in a specialised multidisciplinary unit of Rheumatic Diseases and pregnancy (integrated by Gynaecologists, Haematologists and Rheumatologists). The following variables were collected: age, maternal pathology, presence of antiphospholipid antibodies, thrombotic episodes and prior abortions, number of childbirths, treatment during pregnancy, obstetric outcomes births-abortion, pregnancy length and maternal/fetal complications.

Results: 88 pregnant women were included in the study. 64.3% were diagnosed with Systemic Lupus Erythematosus, 21.4% with Sjögren’s syndrome, 10.7% with undifferentiated connective tissue and 3.6% with rheumatoid arthritis. Our patients were an average of 32.24±5.34 years old and the 35% were elder than 35 years. 46 pregnancies were developed during the monitoring with an average of 1.61±0.74 pregnancies per patient. Before the inclusion in our unit, 52% patients had 1 or 2 abortions, 25% had 3 abortions and 23% had 4 or more abortions. 10% patients had presented a previous thrombosis. Our patients were an average of 33.6±5.5 years old and the 44.3% were elder than 35 years. Among the 44 patients with APS: 50% presented positivity to Lupus Anticoagulant (LA), 25% had triple positive antiphospholipid antibodies (LA, anticardiolipin antibodies and anti-ß2-glycoprotein) and 27% had double positive autoantibodies. As for the treatment received during the 140 pregnancies: 50% pregnant women received treatment with prophylactic doses of low-molecular-weight heparin (LMWH) together with acetylsalicylic acid (ASA), 26% were treated in monotherapy with LMWH and 9% in monotherapy with ASA. 10 patients received treatment with LMWH, 24% had triple positive antiphospholipid antibodies (LA, anticardiolipin antibodies and anti-ß2-glycoprotein) and 27% had double positive autoantibodies. For the treatment received during the 140 pregnancies: 50% pregnant women received treatment with prophylactic doses of low-molecular-weight heparin (LMWH) together with acetylsalicylic acid (ASA), 26% were treated in monotherapy with LMWH and 9% in monotherapy with ASA. 10 patients diagnosed with thrombophilia, with an average of 5.3±1.5 abortions per patients, received treatment with LMWH, ASA and intravenous gammaglobulin. All patients who received LMWH during pregnancy also received LMWH after birth for 6 weeks. The mean gestational age was 38 weeks with an average birth weight of 3058.5±595.6 grams. 13% babies were preterm and 32% births were caesarean. 87% of our patients did not have complications in the puerperum.

Conclusions: Our results demonstrate that both treatment with hydroxychloroquine and close control in a multidisciplinary unit are effective in the prevention of congenital heart block development, in the decrease in the number of abortions and in a reduction of maternal and fetal morbidity and mortality. The multidisciplinary evaluation is essential in women diagnosed with rheumatic diseases with high obstetric risk.

Disclosure of Interest: None declared
Conclusions: The treatment is effective in the prevention of abortions. Our results demonstrate a decrease in the number of abortions and a larger number of term pregnancies since the inclusion of patients with high-risk pregnancies in our unit. The multidisciplinary evaluation is essential to prevent complications in women diagnosed with APS and thrombophilia in order to reduce adverse pregnancy outcomes and exacerbations of the mother’s pathology.

SOLUBLE TRIGGERING RECEPTOR EXPRESSED ON MYELOID CELLS-1 (STREM-1) AND ADRENOGENULIN ARE ELEVATED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
1Institute of Rheumatology, Belgrade, 2Institute of Biochemistry, Belgrade; 2Clinical Centre of Serbia, Belgrade, Serbia

Background: Adrenomedulmin is a peptide firstly isolated from human pheochromocytoma with vasodilatory effects. Secretion of adrenomedulmin is modified by inflammatory cytokines and it may be important as a suppressor of lupus nephritis activity. Triggering receptor expressed on myeloid cells-1 (TREM) is a member of immunoglobulin superfamily clearly elevated in inflammatory conditions. Some subgroups of patients with systemic lupus erythematosus-SLE may have especially elevated levels of s-TREM.

Objectives: The aim of this study was to examine adrenomedulmin and s-TREM levels in patients with SLE and healthy controls and to assess their relation with SLE disease activity index-SLEDAI

Methods: Serum samples from 50 SEL patients and 40 healthy blood donors were analysed. Serum levels of adrenomedulmin, s-TREM, complement components C3 and C3, and anti-dsDNA antibodies were measured

Results: Patients with SLE had higher adrenomedulmin (9.8±4.5 vs. 15.3±7.2 pg/mL, p<0.05) and s-TREM (11.7±4.1 vs. 20.3±13.1 pg/mL, p<0.05) levels. s-TREM showed correlation with anti-dsDNA antibodies (r=0.405, p<0.05) and SLEDAI score (r=0.386, p<0.01). In multivariate analysis s-TREM did not appear as an independent predictor of SLEDAI score, while only anti-dsDNA antibodies were significant in multivariate analysis.

Conclusions: Increased adrenomedulmin and s-TREM are found in lupus sera. Despite of correlation with SLEDAI score, s-TREM is not better then anti-dsDNA antibodies as a predictor of SLE disease activity.

NEOPLASIA PREVALENCE IN PRIMARY SJÖGREN’S SYNDROME IN HISPANIC PATIENTS
1Servicio de Reumatología e Inmunología Clínica, Departamento de Medicina Interna, Hospital Universitario “José E. González”, Monterrey; 2Departamento de Reumatología e Inmunología, Instituto Nacional de Ciencias Médicas y Nutrición “Salvador Zubirán”; 3Servicio de Reumatología, Jüarez de México/Centro Médico ABC, Mexico, Mexico

Background: A rheumatic disease may be a casual factor in the pathogenesis of a neoplastic disease, as in other cases, cancer may lead to the development of paraneoplastic rheumatic manifestations that may be the only initial symptoms. Lazarus et al. demonstrated in their cohort study with 112 patients that of the 22% of patients who developed some neoplasm during the study, the most prevalent was lymphoma with 44%. According to the same study, patients with pSS present a risk of generating lymphoma, with 37.5 times more than that of the general population. of generating lymphoma, with 44%. according to the same study, patients with pSS present a risk of generating lymphoma, with 37.5 times more than that of the general population. Among the most prevalent neoplasms in non-Caucasian pSS patients. We observed the presence of non-hematological malignancy 60.86% of our patients, whether it risk is increased in pSS patients is still not well established.

Objectives: Determine the prevalence of cancer in patients with ss in the mexican population.

Methods: Cross-sectional, observational study was conducted in which 393 patients were included, of which 221 (52%) came from the international institute of medical sciences and nutrition “salvador zubirán”, 92 (23.4%) from the university hospital “José E González” and 80 (20.6%) of the juarez mexico hospital/ABC medical centre whom fulfilled the diagnosis of ss according to the 2002/2012 criteria of the american college of rheumatology/european league against rheumatism. Bivariate analysis was performed, normality was demonstrated using the K.S test, the student’s T test was used for the numerical variables and the chi2 test for the categorical ones, and no difference was found between the characteristics of patients with or without cancer.

Results: We include 393 patients, the majority were women (n=377, 95.9%) with an average age of 56.4 (±13.60), of these 23 (5.85%) had some type of neoplasm regardless of their malignancy. the most prevalent was lymphoma with 9 cases (34.6%), followed by breast cancer with 5 (19.2%), 3 (11.5%) of basal cell cancer and 2 (7.7%) cases of cervical uterine cancer.

Abstract AB0583 – Figure 1. Neoplasia prevalence in primary sjögren syndrome in Mexican-Mexico patients
PAEDIATRIC VS ADULT ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: THE SIMILARITIES AND DIFFERENCES: A STUDY FROM A TERTIARY CARE CENTRE FROM NORTHERN INDIA

J. Patel1, M. Agarwal2, A. Shipuri3, G.S. Bhardani1, N. Jain4, S. Sawhney2, L. Duggal2. 1Rheumatology, 2Pediatric Rheumatology, 3Sir Gangaram Hospital, New Delhi, India

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with myriad of systemic features. While the disease manifestations and therapy remain same for both paediatric onset (cSLE) and adult onset SLE (aSLE), disease manifestation and burden of disease differs in the two populations.

Objectives: To study disease profile within 6 months of disease onset and burden of disease by SLEDAI of aSLE and cSLE to understand the similarities and differences and to compare with those from around the world

Methods: Retrospective review done of 100 aSLE and cSLE patients, from June 2015 to June 2016, fulfilling SLICC criteria. Demographic data, clinical profile and ds burden at onset (highest of ≥10) of 6 months of ds onset) by SLEDAI patents were recorded on a predesigned proforma

Results: The incidence of skin involvement (acute and chronic cutaneous lupus, alopecia) serositis more in aSLE. Oral mucositis, nephropsychiatric SLE(NPSLE) and lupus nephritis(LN) more common in cSLE. LN was also higher in cSLE from other centres around the world as compared to aSLE. Of statistical significance and lupus nephritis(LN) more common in cSLE. LN was also higher in cSLE from New Delhi, India.

Conclusions: This study showed significant difference in initial systemic involvement and onset of presentation in aSLE and cSLE. cSLE present with more subtle features and seldom have a classic presentation with malar rash, oral mucositis and alopecia which oft herald aSLE. cSLE and aSLE though being the same disease often have a varied spectrum of presentation and the generalist and the treating teams need to be aware of these for prompt recognition of the disease and optimum therapy

CURRENT IMPACT OF ETHNICITY ON RENAL
L. Duggal2.

at onset was higher in cSLE than aSLE. The higher incidence of LN in cSLE than aSLE was also similarly higher in cSLE. The Spanish Society registry also reported similar findings.2

Abstract AB0584 – Table 1

Conclusions: This study showed significant difference in initial systemic involvement and onset of presentation in aSLE and cSLE. cSLE present with more subtle features and seldom have a classic presentation with malar rash, oral mucositis and alopecia which oft herald aSLE. cSLE and aSLE though being the same disease often have a varied spectrum of presentation and the generalist and the treating teams need to be aware of these for prompt recognition of the disease and optimum therapy

A LUPUS LOW DISEASE ACTIVITY STATE IS ASSOCIATED WITH REDUCED FLARE, LOWER ORGAN DAMAGE ACCRUAL, AND BETTER QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J.-H. Kang, K.-E. Lee, D.-J. Park, S.-S. Lee. Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of Ireland

Objectives: To identify the potential predictors of a lupus low disease activity state (LLDAS), and the relationship between LLDAS and disease flare, organ damage, and quality of life in Korean patients with systemic lupus erythematosus (SLE).

Methods: The study followed 181 SLE patients from a single centre for three years. LLDAS was defined as follows:1) SLE Disease Activity Index (SLEDAI) – 2K≤4, with no activity in major organ systems;2) no new lupus disease activity compared with the previous assessment;2) SLEDAI Physician Global Assessments;1,5 a current prednisolone (or equivalent) dose ≤5 mg daily; and 3) well-tolerated standard maintenance doses of immunosuppressive drugs. We assessed data annually and divided 4 groups according to the number of LLDAS: LLDAS=0, 1, 2, and 3. Univariate and multivariate analyses were performed to identify predictors of LLDAS.

Results: Of the 181 patients, 16.0% attained LLDAS on three consecutive years. Each group shows as follows: no LLDAS (n=30); LLDAS=1 (n=60); LLDAS=2 (n=62); and LLDAS=3 (n=29). The patients who had higher number of LLDAS had shorter duration of symptoms, lower anti-histone antibody positivity, lower cumulative prescribed dose of prednisolone at baseline, lower mean PGA, lower mean SLEDAI, lower mean Mental Component Summary in SF-36, lower change in SLICC/ACR damage index, and a lower frequency of flare. In the multivariate analysis, LLDAS was significantly associated with lower mean PGA (OR=0.671, 95% CI: 0.412–0.989; p=0.019) and a reduced risk of flare after adjusting for confounders (OR=0.612, 95% CI: 0.001–0.448, p=0.017).

Conclusions: Attaining LLDAS was associated with an improved outcome, as represented by a decreased rate of disease flare, lower organ damage accrual, and better quality of life in Korean patients with SLE.

CURRENT IMPACT OF ETHNICITY ON RENAL HISTOLOGY AND OUTCOME OF LUPUS NEPHRITIS

J. Nossen1,2, W. Raymond2, A. Kang3, D. Wong2, M. Ognević4, A. Chakera5,6
1Rheumatology, Sir Charles Gairdner Hospital, Nedlands, 2Rheumatology, School of Medicine, University of Western Australia, Crawley, 3Pathology, PathWest Laboratory Medicine, Nedlands, 4School of Medicine, University of Western Australia, Crawley, 5Nephrology, Sir Charles Gairdner Hospital, Nedlands, Australia

Background: Lupus Nephritis (LN) remains a serious complication of Systemic Lupus Erythematosus (SLE) and continuous worldwide demographic changes as well as new mechanistic insights and treatment options necessitate regular updating of our knowledge of LN.

Objectives: To investigate the current relevance of demographic, clinical and histological characteristics as outcome predictors in patients with Lupus Nephritis.

Methods: A retrospective single centre cohort study of all SLE patients undergoing a first renal biopsy for LN evaluation between 1997–2017 in a metropolitan hospital in Western Australia with a 750,000 catchment area. Demographic, laboratory and treatment data were collected at baseline and at last follow-up using a predefined form and histological findings (ISN class) were re-evaluated. Kaplan Meier survival estimates for patient and renal survival were tested by log-rank test.

Results: The final study cohort included 90 SLE patients (age 31.5 years, 88% female, time since SLE diagnosis ≥3 years.) of Caucasian (n=42), Aboriginal (n=11) and other ethnicity (n=7, mainly SubSaharan Africans). The annual LN incidence estimate was 0.6/100,000. There were no significant differences across subgroups regarding renal (overall median 14) and nonrenal SLEDAI (median 4) scores, proteinuria (median PCR 300 mg/mmol), presentation with raised serum creatinine (31% overall), anti-dsDNA Ab (83%) or hypocomplementaemia (88%) or presence of proliferative (Class III/IV: 66%) or membranous (Class V:19%) LN. Corticosteroid (86%), immunosuppressive (97% overall) and
antihypertensive drug (69%) use were similar across ethnic subgroups (all p>0.2). After a mean follow-up of 95 months, eight patients (9%) had died, six (7%) received renal replacement therapy and five (6%) had developed CKD. Five and ten years patient survival was similar for Asian and Caucasian patients (95%) and poorest in Aborigines (81% and 70%) (p=0.016) with no impact of gender, ISN class, full house IF findings or PCR >300. Renal 5 and 10 year survival (endpoint RRT) was 100% for Asian, 100% and 96% for Caucasian vs 86% and 64% for Aborigines(p=0.02). PCR >350 predicted worse renal survival (p=0.03), which was not influenced by gender, increased baseline creatinine, ISN class, A/A/C subclass and presence of full house IF deposits.

Conclusions: Asian patients have similar clinical and histological LN findings and experience equally good renal and patient outcomes as Caucasian patients in Western Australia, where the incidence rate of LN is comparable with Europe. Whether the grim outlook for Aboriginal patients relates to intrinsic differences in LN pathophysiology and/or socioeconomic circumstances deserves further study.

HAEMATOLOGICAL ALTERATIONS IN COLOMBIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. Sanchez-Bautista1, Y. Santamaria-Alzua2, A. Coy-Quiroga2, M. Alarcon-Gomez2, J. Fajardo-Rivero3, C. Figueroa-Pineda4, on behalf of Internal medicine department, Industrial University of Santander, Colombia. 1Johns Hopkins University, Baltimore, USA; 2Internal medicine, Universidad Industrial de Santander, Bucaramanga, Colombia

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease, with multiple organs and system involvement. The most usual haematological findings are anaemia, leukaemia, and thrombocytopenia. The prevalence of SLE in Colombia was 8.77 per 10 000 persons between 2012 and 2016.1

Objectives: To evaluate the haematological alterations in a cohort of patients with SLE in Bucaramanga, Colombia.

Methods: A retrospective cohort study of 149 patients diagnosed with SLE according to the Systemic Lupus International Collaborating Clinics (SLICC) criteria. Descriptive analysis with frequencies, measures of central tendency and dispersion was done using Stata 12.0 software. The primary outcome was the presence of cytopenia, the secondary outcomes were anaemia, leukaemia, and thrombocytopenia. In the group comparison analysis, a chi-square test was used for qualitative variables and Wilcoxon or T student test for quantitative variables according to their distribution. Bivariate analysis using logistic regression with OR measurement, p-value, and confidence intervals was performed.

Results: 82.5% were women, average age was 36.8 years. The primary outcome was found in the 78.6%, anaemia in the 76.5%, thrombocytopenia in the 22.1% and leukaemia in the 18.7%. In group comparison analysis (cytopenia vs no cytopenia) a statistical difference was found in the variables sex (p=0.023), skin involvement (p=0.003), acute nephropathy (p=0.050), activity of the disease measured by the ECLAM scale (p=0.037) and anti-DNA antibody titers (p=0.032). In the bivariate analysis, there was an increased risk of cytopenias with statistical significance in patients with ECLAM scale greater than 5 (OR: 4.76) and strongly positive anti-DNA antibodies (OR: 3.97). Regarding leukaemia, there was a association with antiphospholipid syndrome (OR: 2.75), ECLAM greater than 5 (OR: 2.51), SLEDAI MEX greater than 10 (OR: 2.35) and strongly positive anti-DNA antibodies (OR: 2.36). Likewise, an increased risk of mortality was found in patients with leukaemia (OR: 3.92). In the case of thrombocytopenia, an association was found with a pericardial alteration (OR: 2.46), ECLAM greater than 5 points (OR: 3.65), SLEDAI MEX greater than 10 points (OR 2.42). An association with mortality was also observed (OR: 2.97). The risk of presenting cytopenia, such as the increase in the activity of the disease, which is susceptible to intervention. It is noteworthy that both leukaemia and thrombocytopenia are markers of mortality in patients with SLE.

IDENTIFICATION OF RISK FACTORS FOR HERPES VIRUS INFECTIONS WITH IMMUNOPHENOTYPING DURING INDUCTION THERAPY IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS

J. Kikuchi1, M. Ushikubo2, S. Saito3, H. Yasusaka1, K. Yamazaki1, K. Tsujimoto2, K. Sugahara3, T. Takeuchi4, 1Division Of Rheumatology, Department Of Internal Medicine, Keio University School of Medicine; 2Department of Connective tissue disease, National Hospital Organization Tokyo Medical Center, Tokyo; 3Research UnitImmunoology and Inflammation, Mitsubishi Tanabe Pharma Corporation, Kanagawa, Japan

Background: Herpes virus infections (HVs) including cytomegalovirus infections (CMVs) and herpes zoster (HZ) remains as major complications during treatments with immunosuppressant (IS) in patients with autoimmune diseases. 1-3 Previous reports have suggested the associations between virus infections and characteristics of T cells. 4-6

Objectives: To elucidate the characteristics of peripheral immune cells associated with risk factors of HVs during induction therapies in patients with active lupus nephritis (LN).

Methods: Standardised peripheral immunophenotyping was performed using flow cytometry in active LN and ANCA-associated vasculitis (AAV) patients starting induction therapy and also with inactive LN patients with maintenance therapy between April 2015 to April 2017. The definition of HVs was the infection necessary to administer anti-viral agents.

Results: Sixty-two LN patients and 11 AAV patients were enrolled. Among 30 active LN patients, 27 were analysed except for 3 patients (2 died and 1 withdrawn consens). Mean age was 41.7 years, 9 patients (33%) had newly-onset, and mean SLE disease activity index (SLEDAI) was 19.3. All active LN patients were treated with prednisolone (PSL) (mean 51.7 mg/day) and 25 were treated with an additional IS (cyclophosphamide [CYC];13, mycophenolate mofetil;8, tacrolimus;3, rituximab [RTX];1). Six (22.2%) patients developed HVs (5 CMVs and 1 HZ) within 3 months following induction therapy. None of the 32 LN patients in maintenance phase (mean age, 54.8; SLEDAI, 2.5; PSL, 2.5 mg/day) developed HVs during the mean 2.8 years-observational period. Two (18.2%) AAV patients developed HVs within 3 months following induction therapy. All 32 AAV patients (mean age, 64.3) were treated with PSL (mean 41.8 mg/day) and 10 with IS (CYC,5;RTX,3; azathioprine,1; methotrexate,1).

Among active LN patients, univariate analysis revealed that older age, lower proportion of naïve CD8+ T cells, higher proportions of effector CD8+ T cells and HLA-DR+regulatory T cells (Tregs) at baseline and lower naïve CD8+ T cells at month 3 associated with HVs (p<0.011, p<0.001, p=0.009, p<0.024, p<0.001 respectively). Unexpectedly, lymphocyte count, IgG titer, usage of CYC at baseline, renal response and change in SLEDAI at month 3 did not associate with HVs. Multivariate analysis revealed that low proportions of naïve CD8+ T cells and high proportions of HLA-DR+ Tregs at baseline were the only detectable independent risk factor for HVs (p=0.014).

Among AAV patients, univariate analysis showed that older age, lower proportions of naïve CD8+ T cells, higher proportions of effector CD8+ T cells and HLA-DR+regulatory T cells (Tregs) at baseline and lower naïve CD8+ T cells at month 3 associated with HVs (p=0.011, p<0.001, p=0.009, p<0.024, p<0.001 respectively). Unexpectedly, lymphocyte count, IgG titer, usage of CYC at baseline, renal response and change in SLEDAI at month 3 did not associate with HVs. Multivariate analysis revealed that low proportions of naïve CD8+ T cells and high proportions of HLA-DR+ Tregs at baseline were the only detectable independent risk factor for HVs among them.

Conclusions: Our results suggest that active LN patients with low proportion of naïve CD8+ T cells and high HLA-DR+ Tregs at the time of induction therapy should be closely monitored for HVIs. The different results between LN and AAV implied the different risks of HVIs by immunophenotyping. Larger prospective study is desired to confirm our results.

AB0589  RELEVANCE OF B AND T CELL SUBSETS TO LUPUS FLARE IN KOREAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J.H. Koh1, N. Lee2, W.-U. Kim3. 1Division of Rheumatology, Department of Internal Medicine, Pusan National University Hospital; Pusan; 2Center for Integrative Rheumatoid Transcriptomics and Dynamics, The Catholic University of Korea; 3Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary’s hospital, the Catholic university of Korea, Seoul, Korea, Republic of Ireland

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease with heterogeneous clinical manifestations and is characterised with auto-reactive T cells and autoantibody overproduction by activated B cells.

Objectives: The aims of this study were to characterised T-cell and B-cell subpopulation in lupus patients with pregnancy complications. There is a lack of validated pregnancy questionnaires to assess previous pregnancy morbidity reliably in aPL positive patients. We therefore designed the pregnancy morbidity questionnaire (PMQ).

Methods: To validate the pregnancy morbidity questionnaire (PMQ) in the prospective Vienna Lupus Anticoagulant and Thrombosis Study (LATS) cohort.

Objectives: To validate the pregnancy morbidity questionnaire (PMQ) in the prospective Vienna Lupus Anticoagulant and Thrombosis Study (LATS) cohort.

Methods: The Vienna Lupus Anticoagulant and Thrombosis Study (LATS) is an ongoing, single-centre, biobank-based, prospective observational cohort study enrolling patients (age >18 years) who are persistently positive for lupus anticoagulant (LA) (two positive tests at least 12 weeks apart) with or without a history of thrombosis or pregnancy complications1. The cohort currently consists of 150 patients (mean age: 41.3 years, female gender: n = 122 (81.3%), history of thrombosis or pregnancy complications: n = 111 (74.0%)). Of these 150 women, 15 were approached at their follow up visit and invited to fill out the PMQ. The PMQ consists eight questions outlined in table 2.

Results: Twelve women agreed to participate, of whom nine had a previous history of pregnancy and/or pregnancy complications. Patient characteristics are shown in table 2. PMQ results are outlined in table 2.

REFERENCES:

Conclusions: The number of B cells and CD8+ T cells were not different between SLE patients and healthy subjects; however, non-switched memory (NSwM) B cells was decreased in SLE patients. Double negative (DN) T cells, CD4+ T cells and its subset [naïve, central memory (CM), effector memory (EM) and terminally differ-entiated effector memory (TEMRA) cells] were decreased in SLE patients compared to healthy controls. Patients with lupus flare-up showed significantly decreased CD4+ and DN T cells, whereas CD4+ EM T cells were increased in patients with lupus flare up, compared to stable SLE. SLEDAI was correlated with the number of DN T cells, CD4+ CM T cells at baseline when they were stable.

**AB0591** SLE RES PONDER INDEX (SRI) UNDERESTIMATES CLINICAL RESPONSE IN MUSCULOSKELETAL SYSTEMIC LUPUS ERYTHEMATOSUS

K. Mahmoud1,2, A. Zayat1,2, M.Y. Md Yusof1,2, E. Hersol1,2, P.G. Conaghan1,2, P. Emery1,2, E. Vital1,2. Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, University of Leeds; 2NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, LEEDS, UK

**Background:** Musculoskeletal (MSK) SLE manifestations are common in SLE. Many recent clinical trials were negative or had small benefits vs. placebo. SRI is a common primary endpoint but has not been independently validated. Ultrasound is an objective measure of synovitis validated in inflammatory arthritis.

**Objectives:** To compare the responsiveness of clinical outcome measures with ultrasound in MSK-SLE.

**Methods:** 20 SLE patients meeting SLICC 2012 criteria with inflammatory MSK symptoms were studied with clinical assessment (BILAG2004, SLEDAI-2K over 30 days, patient and physician VAS, symptomatic, tender and swollen joint counts in 28 joints) and MSK ultrasound (grey scale and power Doppler scores, number of abnormal joints) at 0, 2, and 4 weeks after 120 mg IM depomedrone. Change in each variable was measured using Wilcoxon matched pairs and effect sizes (r=Z/ sqrt(2N)) compared using Cohen (1988) criteria. Changes were compared for SRI-4 responders and non-responders.

**Results:** All patients were ANA positive, CCP negative and female. At baseline, 15/20 had clinical synovitis. The others had either ultrasound synovitis (GS in 18/20, PD in 17/20) or ≥60 min EMS, 19/20 patients scored 4 points on SLEDAl for musculoskeletal involvement, BILAG scores were A in 7/20, B in 8/20, and C in 5/20. MSK-SLEDAl score improved in 9/20 at 4 weeks, MSK-BILAG improved in 16/20. For changes, see table 1.

**Conclusions:** Ultrasound was the variable most consistently sensitive to change. All commonly used clinical variables significantly improved on week 4 but there was variation in responsiveness between them. BILAG-2004 and physician VAS had similar responsiveness to ultrasound. SRI-4 underestimated response, with substantial objective improvements in synovitis in SRI-4 non-responders. Developing organ-specific outcome measures may improve the ability to measure treatment effects in SLE clinical trials.

**AB0592** IMPAIRMENT IN HAND STRENGTH, DEXTERTY AND ACTIVITIES OF DAILY LIVING PERFORMANCE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF A CROSS-SECTIONAL STUDY

K. Keramiotou1, C. Anagnostou2, A. Galanos3, P. Sliskakis1, M.G. Tektouidou1.
1First Department of Propaedeutic and Internal Medicine, Medical School, National and Kapodistrian University of Athens; 2General Hospital of Efetis; Thriasio; 3Medical School, National and Kapodistrian University of Athens, Athens, Greece

**Background:** Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease affecting multiple systems. To date a small number of studies have assessed the hand function and performance of daily activities in SLE.

**Objectives:** To examine the grip and pinch hand strength, the dexterity, and the performance of Activities of Daily Living (ADL) in SLE patients compared with healthy controls.

**Methods:** 197 SLE patients (48.03±12.76, 88.3% female) and 100 healthy controls (47.87±12.77, 86% female), matched by age and gender, were enrolled in the study. Both groups were assessed by hand grip and pinch grip strength, dexterity and ADL performance tests. Hand grip strength was measured by Jamar dynamometer, and pinch grip strength by pinch gauge, in both hands. Dexterity was measured by purdue pegboard test. Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire and Health Assessment Questionnaire (HAQ) were used in order to determine the difficulties in ADLs.

**Results:** Hand grip strength, both lateral and jaws pinch grip strength, and dexterity, were significantly impaired (p<0.001) in both hands of SLE patients compared to healthy subjects (table 1). DASH questionnaire (19.78±20.93 vs 2.43±2.9, p<0.001) and Health Assessment Questionnaire score (HAQ) (0.41±0.52 vs 0.03 ±0.52, p<0.001) were also significantly different between SLE patients and healthy controls.

**Disclosures:** These findings demonstrate that SLE patients have lower grip, pinch strength and dexterity and more difficulties in ADL performance. These findings underlie the need to develop specific hand therapy programs for SLE patients.

PREDICTORS OF FATIGUE AND SEVERE FATIGUE IN A LARGE MULTICENTER INTERNATIONAL COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUS: THE FATILUP STUDY

L. Arnaud1, P.-E. Gavand2, Z. Amoura3, G. Blaison4, R. Voli5, A. Schwartzzin5, N. Magy Bertrand’, F. Maurier1, J.-L. Pennaforte6, V. Poidron7, P. Kieffer8, B. Bonnotet9, H. Lorenzet10, C. Fiehnt11, J. Sibilia1, T. Martin2, on behalf of LBBR working groups. 1Rheumatology, University of Heidelberg, Strasbourg; 2Clinical Immunology, APHP, Paris; 3Internal medicine, CH Colmar, France; 4Rheumatology, uniklinik, Freiburg; 5Internal medicine, Acura, Rheumatology Center Rhineland Palatinate, Bad Kreuznach, Germany; 6Internal medicine, CHU Besançon, Besançon; 7Internal Medicine, CH Metz, Metz; 8Internal Medicine, CHU Reims, Reims; 9Internal Medicine, CH Mulhouse, Mulhouse; 10Internal Medicine, CHU Dijon, Dijon; France; 11University of Heidelberg, Heidelberg; 12Unit for Rheumatology and Clinical Immunology, Medical Center Baden-Baden, Baden Baden, Germany

Background: Fatigue is an important issue in systemic lupus and has a major impact on quality of life of the patients. Data are controversial about the factors associated with this complex symptom.1

Objectives: To identify the factors associated with fatigue and severe fatigue in patients with systemic lupus erythematosus (SLE) in a large cohort using a multivariate model to precise the importance of each parameter in this multidimensional system.

Methods: We used the LBBR data base, a German French data base of SLE patients. All patients fulfilled the 1997 ACR criteria for SLE. The Fatigue Scale for Motor and Cognitive Functions (FSMC) was used to assess fatigue and severe fatigue. The depression and anxiety were measured with Hospital Anxiety and Depression Scale (HADS). Tests were performed at sampling.

Results: A total of 570 patients were included (89.1% female). The median age was 42 years (QR25: 35–52). The median value of the SELENA-SLEDAI was 75: 52). The median value of the SELENA-SLEDAI was 2 (QR25–75: 0–4) and 138 patients had a SELENA-SLEDAI score >6. Fatigue was reported by 386 patients (67.7%) including severe fatigue by 209 (36.7%). In univariate analysis among the individual components of the SLEDAI arthritis (p=0.003) and oral ulcers (p=0.002) were associated with fatigue. In multivariate analysis fatigue was strongly associated with anxiety (OR: 4.49 [95% CI: 2.60–7.77], p=0.0001) and depression (OR: 4.72 [95% CI: 1.39–16.05, p=0.01). It was also associated with age at sampling (OR: 1.01 [95% CI: 1.00–1.03, p=0.03] per 1 year increase), SLEDAI (OR: 1.05 [95% CI: 1.00–1.12, p=0.043] per 1 SLEDAI point increase) and glucocorticoids treatment (OR: 1.54 [95% CI: 1.00–2.38, p=0.04]). It was not associated with physical activity.

Severe fatigue was strongly associated with depression (OR:6.87 [95% CI: 3.12–15.11, p<0.0001) and anxiety (OR: 3.80 [95% CI: 2.46–5.87, p<0.0001) but not with SLEDAI or physical activity.

Conclusions: Fatigue is a common symptom in SLE patients and is strongly associated with anxiety and depression. While remission remains an important therapeutic target, these manifestations should also be taken care of with psychological counselling and pharmacological intervention, when needed.

PREVALENCE OF FRACTURE IN WOMEN WITH SLE, THEIR CONNEXION WITH THE COURSE OF THE DISEASE AND THE NATURE OF PHARMACOTHERAPY

S. Shevchuk, L. Derynychyk, E. Shevchuk. National Pirogov Memorial Medical University, Vinnytsya, Ukraine

Background: Patients with rheumatic diseases are known to have the risk of osteoporosis and fragility fractures, which is significantly higher than in the healthy population. Recent studies demonstrate that age, sex, postmenopausal status, inactivity, glucocorticoid use, nutrition etc. play an important role in the reduction of bone mineral density (BMD) in systemic lupus erythematosus (SLE) patients. The role of the disease severity and the activity of the inflammatory process in the reduction BMD and the incidence of fractures in SLE patients is discursive.

Objectives: The aim of the study was to determine the frequency of osteoporosis and fragility fractures in the Ukrainian SLE patients and to establish their connexion with the course of the disease.

Methods: The main study group involved 91 women with a diagnosis of SLE according to the American College of Rheumatology criteria. The disease activity was determined using the SLE Disease Activity Index (SLEDAI), and organ damage was measured using the Systemic Lupus International Collaborating Clinics American College of Rheumatology (SLICC/ACR) Damage Index. In all patients the cumulative dose of glucocorticoids was calculated. Serum CRP and IL-6 levels were determined by immunoassay. BMD at the lumbar spine (L1–L4) and femoral neck were measured using dual-energy X-ray absorptiometry. For pre-menopausal SLE patients BMD by Z-score <-2.0 SD was defined as «below expected range for age». For post-menopausal women osteoporosis was defined by T-scores: –2.5 SD, and osteopenia – between –1.0 and –2.5 SD. To determine fractures female SLE patients were examined with x-ray.

Results: In pre-menopausal SLE patients the abnormal BMD of the lumbar spine was found in 9.8%, at the level of the femoral neck it was in 11.1%, in postmenopausal SLE patients – 18.4 and 13.6%, respectively. In the control group there was any premenopausal woman with low bone mass at both sites, whereas among postmenopausal individuals, these were 12.5 and 6.2%, respectively. Osteoporotic fractures were detected in 13 (14.2%) SLE patients, of which 30.7% had hip fractures and 69.3% had vertebral fractures. The reduction of bone strength and fractures were associated with a high damage index. In particular, in persons with fractures it equalled to 4.85±0.65 points, and in persons without fractures – 3.09±0.22 points. A similar tendency was detected by the disease activity SLEDAI. Glucocorticoid use also had a negative effect on the bone strength in patients with SLE. Thus, in women with fractures, the cumulative dose of glucocorticoids defined 60.9±6.3 g, and was by 37.1% higher than in patients without fractures.

Conclusions: In patients with SLE the prevalence of low BMD and fragility fractures is high. Progressive loss of the BMD and the occurrence of osteoporotic fractures are closely associated with the severity of organ damage and glucocorticoid use.

Disclosure of Interest: None declared

ANTIPHOSPHOLIPID SYNDROME (HUGHES SYNDROME) IS A DISEASE WITH PROTEAN FACES: MULTIDISCIPLINARY APPROACHES ON SERBIAN COHORT OF APS PATIENTS

L. Stojanovich, A. Djikovic, N. Stanisavljevic, G. Bogdanovic, M. Zdravkovic. Internal medicine department, University Hospital Center Beaznjaka Kosa, Belgrade, Serbia

Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterised by thrombophatic state and circulating antiphospholipid antibodies (aPLs) including anti beta2GPI-IgG.

Objectives: Since it became one of the most systemic conditions. In the last three and half decades, a variety of clinical manifestations involving almost all organs and tissues (cardiac, pulmonary, neurological, renal, cutaneous, hematologic, gastrointestinal, ocular, skeletal and endocrinologic), have been described associated with antiphospholipid antibodies (aPL).

Methods: Our study comprises a total of 608 patients: 420 primary APS (PAPS) patients and 188 SLE patients with secondary APS (SAPS). aPL analysis included detection of aCL, a2GPI, and LA.

Results: Thrombosis was diagnosed in 46.5% patients, with higher prevalence in PAPS compared to SAPS patients: 51.2% and 38.3%, respectively, p=0.045. Pseudoinfective endocarditis was observed in 12.8% secondary APS patients and 3.1% in primary APS patients (p=0.004). 30% of the patients with high levels of aCL IgG antibodies had valve thickening and dysfunction, as compared to 4.1% without valve abnormalities (p=0.002). Presence of IgG IgG was significantly related to stroke, and overall IgG (IgG and IgM) positivity was significantly related to TIA in SAPS patients. Valvular manifestations were significantly related to TIA in both groups of patients and were independent risk factors for TIA in SAPS (OR 3.790 CI 1.597–8.998 p=0.003: table 2). In PAPS, epilepsy correlated with IgG IgG and LA. Livedo reticularis was more prominent in PAPS with high levels of IgG IgG. Skin ulcerations were more prevalent in aCL-IgM positive SAPS patients and epilepsy more frequently had high levels of anti IgG IgG in SAPS.

Conclusions: In this cross-section analysis of a large cohort of APS patients we analysed that APS patients can be presented with a wide variety of thrombotic manifestations involving most of the main organ systems.
and non-thrombotic manifestations. The key to the success is multidisciplinary approach in all time of patient’s life. Antiphospholipid syndrome is really a disease with protein faces.

THE IMMUNE COMPLEXES OF IGG/IGM BOUND TO B-2 GLYCOPROTEIN I ARE ASSOCIATED WITH LIVEDO RETICULARIS, THROMBOCYTOPENIA AND SICCA IN APS PATIENTS

D. Pérez1, L. Stojanović2, L. Naranjo3, N. Stanisavljević2, G. Bogdanović2, M. Serrano1, A. Serrano1. 1Immunology, Hospital Universitario 12 de Octubre, Madrid, Spain, 2Institut de Medicina, Belgrade, Serbia

Background: Several manifestations strongly associated with APS have been excluded as classification criteria.

Objectives: The aim of this study was to investigate correlation between circulating immune-complexes of IgG or IgM antibodies bound to B2GPI (B2G-CIC and B2M-CIC) and clinical manifestations in Serbian cohort of APS patients.

Methods: A total of 57 patients with APS were evaluated: 35 with PAPS and 22 patients with SAPS. Mean age was 47.6±1.6 years; 36 (63.2%) were women. All patients have met the 2006 revised Sydney criteria for APSQuantification of B2G-CIC and B2M-CIC levels was performed as previously, for detecting B2G-CIC was used anti-human IgG HRP-conjugate and for B2M-CIC human IgM HRP-conjugate, both from INOVA (INOVA Diagnostics Inc., San Diego, CA, USA).

Results: In our cohort Serbian APS patients the prevalence of CIC was 19.29% (11/57); 8 patients with B2M-CIC and the remain 3 patients with B2G-CIC. Livedo reticularis was diagnosed with higher prevalence in patients with CIC compared with patients without CIC; 63.6% and 23.9%, respectively (OR: 5.57, p=0.01). In patients with CIC, thrombocytopenia and leukopenia were more prominent: 54.4% vs 17.4% (OR: 5.70, p=0.01) and 45.5% vs 13.0% (OR: 5.56, p=0.01), respectively. Ophthalmic sicca was more prevalent in patients with CIC; 54.4% vs 8.7% (OR: 12.6, p<0.001). Although complement consumption was more frequent in patients with CIC (figure 1).

Figure 1. Mean levels of C3 (A) and C4 (B) complement in groups. Mean levels of C3 (115.6±9.2 mg/dl and 140.9±4.3 mg/dl, group-1 and group-2 respectively) and mean levels of C4 (140.9±4.3 mg/dl and 30.8±1.6 mg/dl, group-1 and group-2, respectively).

Conclusions: B2G-CIC and B2M-CIC are strongly associated with clinical manifestations related to APS. Widening the APS spectrum is indispensable to better understand this syndrome.

SIGNIFICANCE OF NON CRITERIA ANTI-PHOSPHOLIPID ANTIBODIES IN THE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ASSOCIATED WITH ANTIPHOSPHOLIPID SYNDROME

M. Druljevski1, A. Majdan2, M. Majdan1. 1Department of Rheumatology and Connective Tissue Diseases; 2Chair of Oncology, Medical University, Lublin, Poland

Background: Systemic Lupus Erythematous (SLE) is a chronic inflammatory autoimmune disease in which the uncontrolled activation of the immune system leads to overproduction of autoantibodies (Ab) with different mechanisms of action. Coexistence of anti-phospholipid antibodies (aPL) significantly increases the risk of thromboembolic complications and worsens the clinical course and prognosis of SLE.

Objectives: The aim of study was to determine the relationship between the presence of non-criteria aPLs in SLE patients with criteria and non-criteria clinical symptoms of APS.

REFERENCES:

Disclosure of Interest: None declared

Methods: The study involved 70 (52-female and 18-male) patients treated in the Department of Rheumatology and Connective Tissue Diseases. All patients ful-
filled the SLICC classification criteria of SLE: 46/70 pts fulfilled clinical and labora-
tory criteria of Antiphospholipid Syndrome (I group SLE/APS-46pts) and 24/70 pts (II group SLE/aPL (+) – 24) - they had criteria antibodies but did not display clinical criteria symptoms of APS. In the whole study group the mean age was: 38.5±12.9 years (range 18–71), the duration of the disease was 8.3±6.5 years (range 0–37). The presence of Ab was detected in patients’ sera using the commercially avail-
able tests: aPL-immunodot assay Anti-Phospholipid 10 Dot, for the qualitative detection of IgG or IgM antibodies. Statistical data analysis was performed using

StataInc v13.0

Results: In the study group of 70 patients we detected the presence of the following aPs: a- cardiolipin IgM –33,7%, IgG –50%; a-phosphatidic acid IgM –17,5%, IgG –11,2%; a-phosphatidylcholine IgM and IgG –0; a-phosphatidylethanolamine IgM and IgG –0; a-phosphatidylglycerol IgM –4,4%, IgG –10%; a-
phosphatidylinositol IgM-11,2%, IgG-10%; a-phosphatidylserine IgM-31,2%, IgG-
48,7%; a-annexin V IgM –20%, IgG –10%; a-b2- GPI IgM-33,7%, IgG-30%; a-
prothrombin IgM –51,4%, IgG-30%

The following non-criteria clinical symptoms of APS were present: nephropathy in 27,1%, hypertension-41,1%, livoed reticulains 11,4%, convulsions/chores 5,7%, thrombocytopenia -20% of the study group.

No statistically significant differences in the frequency of occurrence of individual non-criteria aPs, as well as non-criteria clinical symptoms of APS have been found in the examined subgroups of SLE/SAPS and SLE/aPL (+) patients.

Conclusions: The prevalence of non-criteria aPs in SLE and APS pts is similar to pts with SLE with criteria-aPL. Non-criteria clinical symptoms of APS occurred with the same frequency in pts with SLE and APS and in SLE with criteria aPL.

RELATION BETWEEN THE DEFICIT/DEFICIENCY OF VITAMIN D AND THE DEPRESSION/ANXIETY IN PATIENTS WITH LUPUS IN THE DEPARTMENT OF RHEUMATOLOGY OF THE HOSPITAL OF CLINICS

M .A. Vazquez1, N. Ortz1, V. Martinez1, L. Roman1, K. Bauman1, M. Melo1, E. Acosta1, M. Duarte1, I. Acosta Colman1, Central, Hospital de Clinicas San Lorenzo, Central, Instituto de Investigacion en Ciencias de la Salud San Lorenzo, Asuncion, Paraguay

Background: It has been postulated that low concentrations of 25-hidroxivitamin D serum [25 (OH) D] is associated with a greater prevalence of depression. People with deficient levels of vitamin D are more likely to experience mood disorders such as depression and anxiety. The vitamin D plays a role in the release of neurotransmitters such as serotonin and dopamine which is why is interesting the study of this in patients with systemic lupus erythematosus, who are discouraged from sun exposure.

Objectives: To evaluate the IOP values and the presence of increased excavation in patients with SLE, reinforcing the importance of ophthalmoscopy in this population.

Methods: Descriptive study. Analysis of IOP measurement and papillary excavation of 50 SLE patients.

Results: All patients had IOP values within the normal range (8–21 mmHg). In a total of 100 eyes evaluated, four (4%) had increased papillary excavation.

Conclusions: Type I collagen is essential for the maintenance of biomechanical parameters and resistance of the cornea. At the corneal level, the activation of the complement system results in the lysis of type I collagen fibres, reducing corneal thickness and resistance. Therefore, IOP values for tonometry will be reduced and underestimated. Comparing the IOP values of SLE patients and healthy volunteers, there are lower results (p<0.001) in lupus patients. In the present study, no patient had IOP changes. However, 4% of the eyes revealed increased excavation. These findings reflect the results of Yazici at al, and reinforce the importance of ophthalmoscopy in the screening of glaucoma in SLE patients.

ENTHESES ULTRASONOGRAPHY IN TUNISIAN PRIMARY SJÖGREN’S SYNDROME PATIENTS

K. Ben Abdelghani, M. Chammakht, A. Fazaa, K. Ouenniche, S. Kassab, S. Chekili, A. Lataar. Rheumatology, Mongi Slim Hospital, La Marsa, Tunisia

Background: Primary Sjögren’s Syndrome is an auto-immune disease characterised by dryness of the eyes and the oral cavity. Musculoskeletal manifestations are common. However, the underlying mechanism remains often unknown.

Objective: The aim of the current study was to describe subclinical entheseal involvement in patients with Primary Sjögren’s Syndrome via ultrasound, to calculate a modified Madrid sonography enthesis index and to compare it with a group of healthy controls.

Methods: The study was conducted in the rheumatology department of Mongi Slim hospital in Tunisia, between June 2015 and December 2017, including 29 patients with Primary Sjögren’s Syndrome and 25 healthy sex- and age-matched controls. Cases were defined according to the American-European Consensus Criteria for Sjögren’s Syndrome. All the included subjects underwent an enthesis ultrasound exploration (EsaoteMyLab 60 machine and a 13–18 MHz linear array transducer) by a rheumatologist experimented in ultrasound. Five enthesis locations bilaterally (distal Achilles tendon, distal and proximal patellar ligaments, distal quadriceps, and brachial triceps tendons) in each patient were explored. The following elemental lesions of enthesis were evaluated: thickening, presence of calcifications, erosions, enthesophyte, loss of fibrillar pattern and power Doppler signal. The calculated index was compared by Mann-Whitney U test between cases and controls. The significance level was set at 5%.

Results: In our study population, the median age was 53.2±11.3 years and the median body mass index was 29.4±4.4 kg/m². All included subjects were female. The ultrasound abnormalities in the Primary Sjögren’s Syndrome were as follows: erosions in 19.2% of cases, enthesophytes in 16.4% of cases, calcifications in 6% of cases, hypoechogeneity in 2.8% of cases, thickening in 2.4% of cases, power Doppler signal in 1.6% of cases and loss of fibrillar pattern in 1.2% of cases. The total enthesis index was 4.96±2.91 among cases and 5.72±2.92 among healthy control subjects with no statistically significant difference. Considering each affected enthesis, cases had no significantly higher scores than controls.

Conclusions: Our study did not find a significant entheseal involvement among patients with Primary Sjögren’s Syndrome that could explain the chronic indefinable pain. The diagnosis of an associated fibromyalgia should be kept in mind.

ANTIPHOSPHOLIPID SYNDROME COMPONENTS IN PATIENTS WITH CORONARY HEART DISEASE

M. Nazarova1, M. Stanislavchuk2, L. Burdeina3. 1PhD-student of the internal medicine clinic chair #1; 2Professor, the head of the internal medicine chair #1; 3PhD of the internal medicine clinic chair #1, National Pirogov Memorial Medical University, Vinnytsia, Ukraine

Background: Antiphospholipid antibodies (aPL), such as anticardiolipin antibodies (aCL), are the immunological markers of the antiphospholipid syndrome (APS). The aPL are found in association with venous and/or arterial thrombosis. Myocardial infarction (MI) is usually related to atherosclerosis and thrombosis of coronary arteries. The clinical significance of aPL in MI, however, has not yet been well established.

Objective: To evaluate the presence and levels of aPL in patients with history of MI.

Methods: 50 patients (100% male) with average age 49.5±6.09 (M±SD) years with history of MI were examined. Serum IgG aPL (anti-cardiolipin, -phosphatidylserine, phosphatidylinositol, -phosphatidylacetate) were determined by enzyme-linked immunosorbent assay (ELSSA).

Results: IgG isotype aPL were detected in 26 (52%) patients with the history of MI and 24 patients were negative. The average age (M±SD) of aPL positive patients was 44.1±5.00 years and of aPL negative patients was 47.7±4.83 years (p=0.01). The difference comprises more than 3.5 years.

Patients with recurrent MI (two and more) had higher level of IgG aPL, then patients with one MI (18,02±7.53 vs. 11,5±4.21 GPL-U/ml). The difference is significant (p<0.05).

Conclusions: Determined younger age of the first MI in aPL positive patients and higher level of IgG aPL in patients with recurrent MI indicate the possible involvement of the autoimmune factor in the pathogenesis of MI. This proves the necessity for further research in this direction.

FRAGMENTED QRS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RELATION TO THE DISEASE ACTIVITY: A CROSS-SECTIONAL STUDY

M. Hosonuma, N. Yajima. Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan

Background: Cardiovascular disease is an important contributor to mortality in Systemic Lupus Erythematosus (SLE). Fragmented QRS (fQRS) is an easily evaluated non-invasive electrocardiographic parameter defined as additional spikes within the QRS complex. fQRS can represent conduction disturbance and a predictor of cardiac events. Even in a patient with SLE, it has reported that the prevalence of fQRS appears to be higher than in controls. However, no clinical studies have investigated the prevalence at the time of diagnosis. In addition, there is no report that examined the association of disease activity of SLE and fQRS.

Objective: This study aimed to assess the relationship between disease activity of SLE and fQRS in Japanese SLE patients at the time of diagnosis. We hypothesised that the frequency of fQRS on ECGs would be greater in SLE patients with high disease activity.

Methods: The study design was a cross-sectional study. The participants were SLE patients who diagnosed at Showa University Hospital and Showa University Koto Toyosu Hospital from January 2010 to December 2017. The participants who satisfied American College of Rheumatology (ACR) criteria were included. The patients with already treatment at the time of ECG measurement, cardiovascular disease, history of arrhythmia, cardiomyopathy, rheumatoid arthritis, systemic sclerosis were excluded. The exposure was the appearance of fQRS. The intermediate outcome was Systemic Lupus Erythematosus Disease Activity Index (SLEDAI-2K). The secondary outcomes were the complement level, the ds-DNA antibody level and the organ involvement. In the main analysis, a multiple regression analysis was conducted to assess the association between fQRS and SLE activity adjusted for age, sex and period from the estimated date of onset to the date of diagnosis. In the secondary analysis, a multiple regression analysis was conducted to assess the association between fQRS and the serological activity of SLE (the complement level, the ds-DNA antibody level) and the organ involvement. In the main analysis, no significant associations were found between fQRS and the blood test or the organ involvement.

Disclosure of Interest: None declared

References
Conclusions: Our results demonstrated that the frequency of QRS on ECGs would be greater in SLE patients with high disease activity.

INITIAL CLINICAL AND IMMUNOLOGICAL FACTORS ASSOCIATED WITH MANIFESTATIONS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: A SINGLE CENTRE RETROSPECTIVE STUDY

M. Tsukamoto1,2, K. Suzuki1, T. Takeuchi1. 1Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; 2Department of Rheumatology, National Tokyo Medical Center, Tokyo, Japan

Primary Sjögren’s syndrome (pSS) is a prototypical systemic autoimmune disease that manifests various signs and symptoms. Although a few studies have focused on these manifestations over the long term,1,2 the association of immune disease that manifests various signs and symptoms. Although a few studies have focused on these manifestations over the long term,1,2 the association of initial clinical and immunological factors with subsequent longer-term manifestations has not been fully elucidated.

Objectives: To identify initial clinical and immunological factors associated with manifestations in patients with pSS.

Methods: A retrospective review was performed on pSS patients followed over a 10 year period at our department. Clinical and immunological data, including levels of serum immunoglobulin (Ig) and autoantibodies, were collected and statistically analysed.

Results: A total of 224 patients diagnosed with pSS who had met the classification criteria were enrolled. Among them, 201 patients were diagnosed with pSS at our hospital. Of these, we followed the 91 patients who continued to visit our hospital over 10 years. Of the other 110 patients, 69 suddenly interrupted treatment, 20 visited different hospitals, and 13 interrupted treatment at our department and visited dentistry or ophthalmology departments. During observation, 7 patients were newly diagnosed with rheumatoid arthritis in addition to SS and one patient died. We then analysed the 91 patients who continued to visit. Of these, 88 were female and 3 were males. Average age was 52 years, 72 and 33 patients had anti-SS-A antibody and rheumatoid factor (RF), 82, 68 and 7 patients had neutropenia, anaemia and thrombocytopenia, respectively. 15% of patients used corticosteroids and/or immunosuppressant treatment. 10% of patients took traditional Chinese medicine. On follow-up for 10 years, titer of IgG, A and M were significantly decreased, whereas complement levels were elevated. The proportion of patients with extraglandular involvement decreased from 90% to 73%, whereas 14% of patients had new extraglandular organ involvement. The frequency of extraglandular involvement at 10 years was high in patients with hyper IgG at the initial test (39% vs 85%, p<0.01). The frequency of extraglandular organ involvement at 10 years was high in patients who were RF-positive at diagnosis (3% vs 15%, p<0.05). 9% of patients developed malignancies. 29% of patients without RF at the initial test had RF during the 10 years observation. The presence of dry eyes or mouth findings did not change during follow-up in pSS patients.

We then created a multivariate model of predictors for malignancies, extraglandular involvement and extraglandular organ involvement with possible variables at diagnosis. Age, anti-centremore antibody, hyper IgG and anaemia were identified to be significant variables associated with malignancies. Extraglandular involvement was associated with the presence of hyper IgG (p<0.01), and extraglandular organ involvement was associated with RF positivity (p<0.05).

Conclusions: Our study newly identified initial clinical and immunological factors associated with manifestations in patients with pSS over a long period. pSS patients with RF and hyper IgG at diagnosis were candidates for the development of extraglandular involvement in the future.

PROCALCITONIN MIGHT BE USED FOR DISCRIMINATING INFECTIONS FROM INCREASED DISEASE ACTIVITY IN PRIMARY SJÖGREN SYNDROME

B. Arican Tarim1, M.E. Tezcan2, A. Orcun2, O. Keskin1. 1Internal Medicine; 2Rheumatology; 3Biochemistry, University of Health Sciences, Kartal Training and Research Hospital, Istanbul, Turkey

Background: Procalcitonin is a polypeptide which is secreted as a response to bacterial stimulus and accepted as an early and sensitive marker of infection. In healthy subjects procalcitonin should be <0.1 ng/mL. In case of infection it may rise over 0.5 ng/mL.1 Its level in inflammatory diseases usually does not reach to such high levels as in infections. Differentiating infection and disease activation may be confusing in autoimmune diseases. For this purpose, there were several studies that evaluated the role of procalcitonin for excluding infection on suspicion of increased autoimmune disease activity.2

Objectives: As far as we know, there is no study in literature that evaluated procalcitonin levels in patients with primary Sjögren’s syndrome (pSS). Our aim is to evaluate procalcitonin levels in pSS and determine whether we can use it as a marker to differentiate infection from disease activation.

Methods: The following two groups of patients were included in the study: Forty-eight patients with pSS, who met ACC 2012 Classification Criteria for Sjögren’s Syndrome; and fifty-three subjects as control group who have no chronic diseases. Patients with possible infection were excluded according to their clinical evaluation and laboratory data. Then, serum procalcitonin levels were compared between the groups. Finally, we evaluated the correlation between disease activity, measured by Sjögren’s syndrome disease activity index (SSDAI) and procalcitonin levels.

Results: Procalcitonin levels in pSS group were found statistically higher than control group, whereas it was still in normal ranges (p<0.01). Furthermore, no correlation was found between disease activation and the procalcitonin levels (p=0.63).

</tbody>
</table>

Statistically significant $P$ values were shown bold. Numerical variables were summarised by median [interquartile range]

Conclusions: Procalcitonin levels were found higher in pSS patients. But, none of the patients had clinically significant increase in procalcitonin. We thought that with careful clinical evaluation, procalcitonin would be an indicator for differentiating infection from disease activation in pSS patients.

NEUROPSYCHIATRIC LUPUS IN A SAMPLE OF EGYPTIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: PREVALENCE AND CLINICAL CHARACTERISTICS

M. Essa, B.M. Medhat, A. Moghazy. Department of rheumatology and rehabilitation, Cairo University, Cairo, Egypt

Background: Neuropsychiatric (NP) lupus is common among patient with systemic lupus erythematosus (SLE). It occurs in about 30%–56% of all SLE patients. However, the diagnosis of neuropsychiatric SLE (NPSLE) remains difficult. Neuropsychiatric lupus (NPL) can present with a wide variety of clinical manifestations.

Objectives: The aim is to determine prevalence of NPSLE among a sample of Egyptian SLE patients from a single centre and to describe its features and characteristics.

Methods: The study included 301 adult SLE patients from Cairo University Hospital. The patients were classified according to the Systemic Lupus International Collaborative Clinics (SLICC) criteria for SLE. Neuropsychiatric manifestations were recorded using the ACR NPSLE nomenclature and case definitions (1999) Global disease activity was quantified by the SLE Disease Activity Index 2000 (SLEDAI-2K) at first and at last visit of the patient. Systemic Lupus International Collaborative Clinics/ACR Damage Index (SLICC/ACR-DI) was used to measure damage. The period of data collection took 4 months. The collected data included demographic, clinical, serologic data and medications.

Results: 301 SLE patients (87.4%) females and (12.6%) males with mean age 30.7±9.2 years and disease duration 72 months (2–288) were included. 101 (33.5%) were diagnosed as having NPSLE. The highest NP manifestation in frequency is headache (55.4%) followed by psychosis (33.7%) then seizures (21.8%). NP manifestation is the onset of the disease in 42.6% of all NPSLE patients. Compared to non-NPSLE group, NPSLE group is significantly older at onset of disease and have longer disease duration (p<0.05). They are significantly more active at the onset of the disease than non-NPSLE and have significantly more disease damage (p<0.05). Regarding clinical manifestations of lupus, NPSLE are significantly higher in frequency of discoid rash, cutaneous vasculitis, serositis, secondary anti-phospholipid syndrome (APS), associated avascular necrosis of the joints and osteoporosis (p<0.05). Anti-cardiolipin IgM ant bodies are significantly more frequent in NPSLE group (p<0.05). Notably, frequency of psychosis, superior sagittal thrombosis and cerebrovascular disease were significantly higher in NPSL with positive APS than those with negative APS (p<0.05).

Conclusions: NPL is different from non-NPL and more active at the onset of the disease than non-NPSLE and have significantly more disease damage (p<0.05). Regarding clinical manifestations of lupus, NPSLE are significantly higher in frequency of discoid rash, cutaneous vasculitis, serositis, secondary anti-phospholipid syndrome (APS), associated avascular necrosis of the joints and osteoporosis were significantly higher in NPSL with positive APS than those with negative APS.

CLINICAL PROFILE OF FILIPINO PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A.-T.M. Santiago1, M. Tee2, C. Tee2. 1IM-Rheumatology; 2Pediatric Rheumatology, University of the Philippines Philippine General Hospital, Manila, Philippines

Objectives: To determine the clinical profile of Filipino SLE patients as determined using the 2012 Systemic Lupus Collaborating Clinics (SLICC) criteria.

Methods: We checked which among the SLICC criteria were fulfilled by Filipino SLE patient when we examined them and their case records, as part of a nationwide genetic study on SLE conducted from October 2015 to March 2017.

Results: Two hundred twenty-five patients who were diagnosed to have SLE after 18 years of age were evaluated. The mean age of the population at the time of evaluation was 37.76 years. Females comprised 98% of our population. Mean age of onset was 30.68-year-old, while the mean age at diagnosis was 31.52-year-old. Acute cutaneous rash was found in 82%; arthritis 80%; non-scarring alopecia 65%; oral ulcers 52%; renal disorder 41%; chronic cutaneous rash in 28%; leukopenia 23%; hemolytic anemia 17%; thrombocytopenia 16%; serositis 13%; and neurologic disorder 6%. Anti-nuclear antibody was present in 88%; low complement 33%; antinsDNA in 29%; direct Coombs’ 4%; antiphospholipid antibody 2%; and anti-Smith antibody in 2%. Kidney biopsy was performed in only 6% (15/225) of patients, 33% of whom had Class IV histopathologic results.

Conclusions: Filipino SLE patients typically present with acute cutaneous rash, arthritis, non-scarring alopecia and oral sores. Renal disorder, hematologic and neurologic manifestations are found to be less common among them. Finally, it was noted that renal biopsy is not commonly performed among these patients.

CLINICAL PROFILE OF FILIPINO PAEDIATRIC PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A.-T.M. Santiago1, M. Tee2, C. Tee2. 1IM-Rheumatology; 2Pediatric Rheumatology, University of the Philippines Philippine General Hospital, Manila, Philippines

Background: The clinical profile of paediatric SLE patients may present differently from that of adults.

Objectives: To determine the clinical profile of Filipino paediatric SLE patients as determined using the 2012 Systemic Lupus Collaborating Clinics (SLICC) criteria.

Methods: We checked which among the SLICC criteria were fulfilled by Filipino paediatric SLE patient when we examined them and their case records, as part of a nationwide genetic study on SLE conducted from October 2015 to March 2017.

Results: Ninety-eight who were diagnosed to have SLE before 18 years of age were evaluated.

The mean age of the population at the time of evaluation was 19.77 years. Females comprised 94% of our population. Mean age of onset was 14.42-year-old, while the mean age of diagnosis was at 14.58-year-old. Acute cutaneous rash was found in 87%; oral ulcers 65%; renal disorder 65%; non-scarring alopecia 61%; arthritis 58%; chronic cutaneous rash in 37%; leukopenia 36%; hemolytic anemia 34%; serositis 24%; thrombocytopenia 22% and neurologic disorder 8%.

Anti-nuclear antibody was present in 88%; low complement 33%; anti-dsDNA in 28%; direct Coombs’ 16%; antiphospholipid antibody 3%; and anti-Smith antibody in 1%. Kidney biopsy was performed in only 14% (15/104) of patients, of whom 27% had class III histopathologic characteristic.

Conclusions: Filipino paediatric SLE patients typically present with cutaneous, mucocutaneous renal and musculoskeletal involvement. Hematologic and neurologic manifestations are found to be less common among them. Finally, it was noted that renal biopsy is not commonly performed among these patients.

CORRELATION BETWEEN PLASMA LIPOPROTEIN PHOSPHOLIPASE A2 (LP-PLA2) AND ANTI PHOSPHOLIPID ANTIBODY(APL-AB) IN PATIENTS WITH CONNECTIVE TISSUE DISEASES

M. Yang, Z. Lin, X. Zhang, Q. Lv, Y. Zhang, Y. Jiang, Z. Liao, J. Gu. Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Plasma LP-PLA2 has both anti-inflammatory and pro-inflammatory activity in vascular-related pathologies and is an independent risk predictor for coronary heart disease and stroke because of its important role in atherosclerosis and thrombosis. However, vasculitis is a common pathological feature of connective tissue disease.

Objectives: Therefore, the aim of this study was to investigate the association of plasma LP-PLA2 level with antinuclear antibody (ANA) titer, karyotype, anti-cardiolipid antibody (ACA) and anti-β2GP1 antibody and lupus anticoagulant (LA, including PT-IGG and PT-IFG).

Methods: Outpatient and inpatient with connective tissue diseases from Department of Rheumatology of the Third Affiliated Hospital of Sun Yat-sen University from 2015 to 2016 were randomly selected. Venous blood was collected, plasma LP-PLA2 level was measured by Elisa method. ANA titer and karyotype were detected by indirect immunofluorescence assay. ACA, anti-β2GP1 antibody, PT-IGG and PT-IFG were detected by Elisa method. SPSS23.0 statistical software was used for statistical analysis.

Results: A total of 176 patients with connective tissue disease including 38 males (21.59%) and 138 females (78.41%) were enrolled in this study, and the average age was 42.22±17.31 years. The mean plasma level of LP-PLA2 was (363.96 ±203.19 ng/ml). There was no significant difference in LP-PLA2 level between different genders (p=0.072), and LP-PLA2 level have no correlation with age (p=0.098). The ANA titer were classified as negative (35.80%), weakly positive 1:100 (11.93%), positive 1:200 (12.50%), positive 1:1000 and positive 1:3200 (9.66%). There was no significant difference in plasma LP-PLA2 level between different titers of ANA (p=0.088). ANA karyotypes
Correlation between traditional cardiovascular risk indexes and arterial stiffness in patients with generalised lupus erythematosus

M. Vázquez-Del Mercado1,2, A. Llamas García1, A. Coldzar-Gabriel2, E. Gómez-Bañuelos1, D.A. Victoria-Rios1, J.J. López-Blaquero1, K.J. Arrona-Rios1, F.D.J. Perez-Vazquez2, G. Díaz-Rubio2, F. Grover-Páez2. Servicio de Reumatología, Hospital Civil de Guadalajara Dr. Juan I. Menchaca, Mexico

Background: Cardiovascular disease (CVD) is the leading cause of late death in patients with systemic lupus erythematosus (SLE). SLE is related with up to 50% of cardiovascular mortality. It has been shown that CVD is more common in SLE patients mainly due to arterial stiffness. Traditional scores (Framingham, SCORE, ASCVD) underestimate cardiovascular risk in patients with SLE compared to the SLEDAI-2K disease activity index (SLEDAI).

Methods: Patients with SLE of 18 years old and older, diagnosed according to SLICC 2012 criteria, were included in this study. Thirty-two patients (66.67%) disease progression, six (12.5%) had the same disease activity over time. Traditional scores (Framingham, SCORE, ASCVD) underestimate cardiovascular risk in patients with SLE. The most important finding is that qIMT was able to correlate more than age, to BMI and cLDL in SLE patients.

Results: Total of SLE patient were 44 (100%), with a mean age of 34±12 years. Mean SLEDAI-2K was 19,25 (range 0–42) in adulthood and 7125 (range 0–30) in adulthood. In adulthood, thirty-two patients (66.67%) showed improvement, three (6.25%) disease progression, six (12.5%) had the same disease activity over time. Traditional scores (Framingham, SCORE, ASCVD) underestimate cardiovascular risk in patients with SLE compared to the SLEDAI-2K disease activity index (SLEDAI). The most important finding is that qIMT was able to correlate more than age, to BMI and cLDL in SLE patients.

Disease activity and organ damage in patient with childhood-onset systemic lupus erythematosus, from childhood to adulthood: a retrospective study over the last 25 years

E. Hosticka1, M. Novoselec1, M. Sestan1, N. Cekada1, M. Frkovic1, I. Paden2, M. Sentic3, B. Anic2, M. Jelusic1. 1Department of Paediatrics, 2Department of Internal Medicine, University Hospital Centre Zagreb, University of Zagreb School of Medicine, Zagreb, Croatia

Background: Although clinical symptoms and immunological findings are common in both children and adults with systemic lupus erythematosus (SLE), children generally have a more severe clinical presentation at the time of diagnosis with a larger number of affected organs, a much more aggressive clinical course and greater chance of developing organ damage over time.

Objectives: To compare the SLEDAI-2K disease activity index in patients with SLE at the time of diagnosis with SLEDAI-2K in the same patients in adulthood and to compare of the SLICC/ACR damage index (SDI) in patients with cSLE at the last follow up in childhood with SLICC/ACR of the same patients in adulthood.

Methods: This retrospective study included children who were diagnosed with cSLE according to the ACR 1997 and SLICC 2012 criteria, in the period from 1991–2016 at the Referral Centre for Paediatric and Adolescent Rheumatology Republic of Croatia, Department of Paediatrics, University Hospital Centre Zagreb and who by the end of March 2017 reached the age of majority at 18 and continued their treatment at the Department of Internal Medicine, University Hospital Centre Zagreb.

Results: Out of 95 children with cSLE, 48 patients (42 females and 6 males) who attained the age of majority, were included in the study. Mean age at the time of diagnosis was 13.5 years (range 6–18), and the mean disease duration was 11 years. Mean SLEDAI-2K was 19.25 (range 0–42) in childhood and 7125 (range 0–30) in adulthood. In adulthood, thirty-two patients (66.67%) showed improvement, three (6.25%) disease progression, six (12.5%) had the same disease activity over time. Thirty-two of 48 patients (66.67%) had organ damage at the last follow up with mean SDI 0.43 (0–6) and 20 patients in adulthood (41.67%) had organ damage with SDI 0.75 (0–6). Cataract, erosive arthritis and avascular necrosis were the most common organ damage in both groups. The most common presenting symptoms in childhood were musculoskeletal (predominantly arthritis) occurring in 34 children (70.83%), mucocutaneous (rash) noted in 31 (64.58%) and fever in 21 patients (43.75%). Of different laboratory tests the most common were positive antinuclear antibodies (ANA) screen (95.83%) and hypocomplementaemia (75%). Proteinuria was noticed in 26 children (54.17%). Similarly, in adulthood the most common symptoms were arthritis in 10 (20.83%) and rash in 8 patients (16.67%). Alopecia, headaches and visual disturbances were represented with 12.5% each. ANA screen was positive in 27 patients (56.25%) and hypocomplementaemia present in 22 patients (45.83%).

Conclusions: At the time of diagnosis in childhood, disease activity is very high while in adulthood there is a significant decrease in disease activity. Higher disease activity in childhood is related to the development of the organ damage in adulthood.

AB0612 INFRINGEMENT OF THE BLOOD LIPID SPECTRUM IN CHILDREN AND ADOLESCENTS WITH SLE AND THEIR PREDICTIVE VALUE FOR THE FURTHER COURSE OF THE DISEASE
N.S. Shevchenko1,2, L.F. Bogmat2, I.M. Bessonova2, V.V. Nikonorova2.
1department of pediatrics No2, V. N. Karazin Kharkiv National University; 2department of cardiorheumatology, Institute of Children and Adolescents Health Care; 3department of pediatrics, V. N. Karazin Kharkiv National University, Kharkiv, Ukraine

Background: Infringements of the lipid blood spectrum, or so-called dyslipidemia, are common in adults suffering from SLE and ranges from 36% to 60%.

Methods: A total of 35 people aged 7–18 years with SLE who were ill for more than one year and received complex therapy with glucocorticoids and immunosuppressive drugs were examined. The average age of the patients was 173.56 ±4.17 months; the total duration of the disease was 48.45±3.18 months. General clinical trials included the complex included autoantibodies, disease activity, drugs. Total cholesterol (TCh), triglycerides (TG), high density lipoprotein cholesterol, low-density lipoprotein cholesterol, apolipoprotein B, APOa-I and lipoprotein-α were evaluated. The state of the blood coagulation system was also studied: fibrinogen of the blood, prothrombin index, thrombin time, active partial thrombin time, d-dimer, international normalised ratio.

Conclusions: Therefore, violations in the lipid spectrum of blood are often formed in adolescents with SLE and signs of dyslipidemia were within the norm except for lipoprotein-α and prothrombin index.

AB0614 THE LUPUS STUDIES: THE EUROPEAN AND SPANISH POINT OF VIEW
N. Bahamontes-Ross1, A. Muñoz Jiménez2, F.J. Hidalgo3, M.V. Pardo1, J.I. Diago Cabezo1,2; GSK, Madrid; “Hospital Virgen del Rocío, Sevilla, Spain

Background: Improving systemic lupus erythematosus patient care comes from advances performed first in basic science that improved our understanding of the mechanism underlying the pathogenesis and finding effective and safe medications that led to treatment improvement. Furthermore, clinical trials play a key role in advancing both our medical knowledge of the disease and novel treatments.

Objectives: This work aims to offer an overview of the type and characteristics of lupus studies and to analyse the contribution that Europe and Spain have made in supporting those investigations.

Methods: A systematic review of the public registry database of publicly and privately supported clinical studies (CS), ClinicalTrials.gov, was done considering “lupus” as a search criteria (database generated with all CS registered on the 19th September 2017). Data collected included: CT code, title, sponsor, countries participating, study phase, condition and intervention.

Results: Study distribution. By 19th September 2017 there were a total of 256127 CS registered in the world, from which 611 (0.24%) are associated with lupus studies. From those, 27.2% are carried out in Europe. Spain is the third country in Europe in number of lupus CS after France and Germany.

Type and distribution of the clinical trials. In the generated clinicaltrials.gov data base, the studies are associated to a type of study. The distribution varies depending on the geographical area. In general, the main type of lupus studies conducted in the world are related to the discovery and development of new treatments (n=406) but there are also behavioural, devices investigation, diagnostic test, dietary supplementation, genetic and radiation studies. In Spain, 94.6% of the studies registered are related to new treatment development.

The distribution of the lupus studies are as follows:
Financial support. 58.6% of all studies are funded by sources other than industry and 34.8% are supported by it. In a detailed analysis, 12.5% of the studies are under the economic support of the National Institutes of Health (NIH) or the partnership of NIH-other partners. The scenario is different in Europe where industry supported 54.8% of the studies and in Spain where industry supported 87.3% of the studies.

Moreover, the funding profile in Spain showed that 92.3% of the studies associated with new treatments are supported by industry and 7.7% of them are supported by other sources. On the other hand, 100% of the studies not related with
new treatments development are supported by funding source other than industry.

* The percentages have been rounding

Conclusions: Europe participate in more than a quarter of Lupus clinical studies and Spain is the third European country participating in those clinical studies. New treatment development studies are the main CT performed worldwide and the percentage is even higher in Spain. Regarding the study phase, the distribution of CT in Europe and Spain are similar although phase I studies in Spain are less frequent.

From all studies registered, the majority are non-industry sponsored studies. In Europe and in Spain the situation is the opposite, as 87.3% of the studies are pharma-sponsored studies.

Abstract AB0615 – Changes in Somatosensory Evoked Potentials in Patients with Primary Sjögren’s Syndrome

E. Dziadkowiak, A. Sebastian, M. Wieczorek, A. Kus, E. Dziadkowiak, M. Waliszewska-Prosol, P. Willard, M. Ejma, 1 Department of Neurology, 2 Department of Rheumatology and Internal Medicine, Wroclaw Medical University, Wroclaw, Poland

Background: Primary Sjögren’s syndrome (pSS) is an autoimmune disease, which, in addition to impaired function of exocrine glands, can affect other organs including nervous system.

Objectives: The aim of the study was to establish whether in patients with pSS without central nervous system (CNS) involvement, the function of the central portion of the sensory pathway can be challenged.

Methods: In 33 patients diagnosed with pSS without clinical features of CNS damage and normal head CT scan, somatosensory evoked potentials (SEP) were studied. The results were compared to other clinical parameters of the disease, particularly to immunological status. The control group consisted of 20 healthy volunteers selected with respect to age and sex.

Results: Mean latency of all components of SEP were considerably prolonged in patients compared to the control group. Mean interpeak latency N20-N13 (duration of central conduction TT) did not differ significantly between the groups. However, in the study group, mean amplitude of N20P22 and N13P16 was significantly higher compared to healthy individuals. In patients with pSS, significant differences in SEP parameters depending on duration of the disease, duration of arthralgia and presence of SSA and SSB antibodies were noted. No significant differences in mean SEP parameters were observed with respect to skin lesions, xerophthalmia, current joint pain and swelling, focus score, levels of C3 and C4 complement components, ESR, CRP and presence of Ro52 antibodies.

Conclusions: The authors confirmed central nervous system involvement often observed in patients with pSS. They also showed dysfunction of the central sensory neuron as a difference in amplitude of cortical response, which indicates subclinical damage to the CNS.

Abstract AB0616 – The Correlation Between Focus Score and Ultrasonography of Major Salivary Glands in Primary Sjögren Syndrome

A. Sebastian, J. Sliski, A. Halor, P. Willard, 1 Department of Rheumatology and Internal Medicine, 2 Department of General and Paediatric Radiology, 3 Division of Pathomorphology and Clinical Cytology, Department of Pathomorphology, Wroclaw Medical University, Wroclaw, Poland

Background: Currently, the role of salivary gland ultrasonography (SGUS) in the diagnosis of primary Sjögren’s syndrome (pSS) is being determined. So far, in none of the proposed classification criteria for pSS SGUS is taken into consideration. The most recent analyses of patients show that SGUS can prove to be useful in the identification of even early forms of pSS.

Objectives: We analyzed the SGUS changes in patients with pSS and its correlations with focus score (FS) of minor salivary glands and immunological and laboratory profile.

Methods: We included 68 patients with pSS in the mean age of 51, based on the classification criteria from 2002.

Results: In 33 (48%) patients were abnormal findings in major salivary glands detected (table 1). Scattered hypoechoic changes of different size were the most common observed changes in SGUS, mainly in parotid glands.

Table 1 – Abnormal images in salivary and mandibular glands in patients with pSS.

<table>
<thead>
<tr>
<th>Number of patients</th>
<th>33</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes in SGUS</td>
<td>- Parotid glands 23 patients (70% of changes) - Submandibular glands 10 patients (30% of changes)</td>
</tr>
<tr>
<td>SGUS changes:</td>
<td>- gland enlargement 48% of changes - scattered hypoechoic changes of different size 85% of changes - fibrosis 6% of changes - lymph glands 15% of changes - gland atrophy 12% of changes - ducts enlargement 3% of changes</td>
</tr>
<tr>
<td>Parotid glands 23 patients</td>
<td></td>
</tr>
<tr>
<td>Submandibular glands 10 patients</td>
<td></td>
</tr>
</tbody>
</table>

The FS was significantly higher in patients with changes in SGUS compare to the patients with normal images of major salivary glands (2.6 SD 1.3 vs 1.8 SD 1.2; p=0.02).

In 33 patients with SGUS abnormalities the hypergammaglobulinemia was most often observed (1.7 g/dl vs 1.2 g/dl; p=0.02). There was not the correlation between changes in major salivary glands and age (p=0.5), CRP value (p=0.1), ESR value (p=0.1), with blood cell count (p=0.1), rheumatoid factor (p=0.1), dry eye (p=0.1), oral dryness (p=0.2), anty-SSA antibodies (p=0.5), anty-SSB antibodies (p=0.2), anty-Ro52 antibodies (p=0.4).

Conclusions: SGUS is a useful tool in patients with pSS. The abnormal images in SGUS of major salivary glands correlated with focus score of minor salivary glands and hypergammaglobulinemia but not with specific antibodies.

Abstract AB0617 – Across-Sectional Study of Nailfold Capillary Microvascular Changes in Indian Patients with RNP+ Lupus and MCTD Using Nailfold Videocapillaroscopy

P.P. Chebbi, R. Goel, R. Aithal, G. Mahamastamp, D. Danda, 1 Clinical Immunology and Rheumatology, 2 Biostatistics, Christian Medical college, Vellore, India

Background: Nailfold Capillary (NFC) changes represent degree of microvascular involvement in autoimmune connective tissue diseases. Anti U1-RNP is associated with specific internal organ involvement in SLE. Nailfold capillaroscopy may objectively predict the systemic microvascular abnormalities in SLE patients with positive Anti U1-RNP antibody.

Objectives: To study nailfold microvascular changes (NFVC) in SLE patients with RNP+ and compare them with NFVC changes observed in patients with RNP negative SLE and Mixed connective tissue disease (MCTD).

Methods: Nailfold videocapillaroscopic (NFVC) examination (Optilimedoscope, 200X) was performed in consecutive patients satisfying classification criteria of
SLE with or without Anti-U1 RNP positivity. Patients satisfying criteria for MCTD were recruited as disease controls. Individual NFC parameters were analysed by a blinded assessor. Changes in three groups were compared using non-parametric tests. Ordinal logistic or linear regression were used wherever applicable to assess any independent association of NFC changes with disease groups.

**Results:** Total of 81 patients were studied, of which 28 had SLE with RNP+ (age 30.0±10.37; 26 females), 26 had SLE without RNP negativity (age 29.4±9.20; 25 females) and 26 had MCTD (age 37.0±9.86; 25 females). Capillary density was significantly reduced in MCTD as compared to RNP+SLE patients (5.1±1.69/mm vs 7.25±1.38/mm, p=0.0001), as well as in RNP+SLE as compared to RNP negative SLE patients (7.25±1.38/mm vs 8.92±1.13/mm, p=0.0001). Conversely, patients with RNP+SLE had more frequent giant capillaries, enlarged capillaries and ramified/branched capillaries as compared to RNP negative SLE patients (p=0.047, 0.001 and 0.029 respectively). However, there was no statistical difference in number of haemorrhages among these groups. These changes were more severe in patients with MCTD as compared to RNP+SLE. Ordinal logistic regression showed more severe reduction in capillary density in patients with RNP+SLE as compared to RNP negative SLE (OR=9.5, p=0.007) independent of the presence of Raynaud’s, ILD and disease duration.

**Conclusions:** Presence of anti-U1 RNP antibody is associated with micro-vascular abnormalities in SLE as detected by NFVC. Patients with MCTD have more profound abnormalities as compared to RNP+SLE patients.

**Disclosure of Interest:** None declared

**AB0619**  
**MANY PERIPHERAL FRACTURES DESPITE NORMAL BONE MINERAL DENSITY CAUCASIAN SLE PATIENTS**

R. Biesen, E. Wiebe, D. Freier, K. Zeiner, U. Schneider, T. Alexander, F. Hiepe, F. Buttgeir, Rheumatology, Chantel, Berlin, Germany

**Background:** Clinical outcome has improved in systemic lupus erythematosus (SLE) and thus, early management of comorbidities like cardiovascular disease and osteoporosis has become highly important. In this disease, osteoporotic risk factors such as female gender, early onset of disease leading to long disease duration, high degree of systemic inflammation, high frequencies of glucocorticoid usage often at higher doses, and chronic fatigue or pain compromising physical activity are often present in combination.1 Rh-G1OP (NCT02719314) is an ongoing prospective study monitoring glucocorticoid (GC)-induced osteoporosis of rheumatic patients, established in 2015 at the Charité University Hospital. To date, the database comprises clinical data and bone mineral density data measured by dual x-ray absorptiometry (DXA) of 592 patients with inflammatory rheumatic diseases.

**Objectives:** To quantify bone mineral density and fractures in SLE patients.

**Methods:** Bone mineral density (BMD) data of SLE patients as measured by dual x-ray absorptiometry (DXA) were analysed with regard to their relation to detailed clinical data.

**Results:** 43 female and 6 male SLE patients aged between 20 and 77 years (mean: 46.31 years) were assessed by DXA (all of Caucasian ethnicity, mean disease duration: 15.49 years; 61% denied any physical activity). SLE medication included glucocorticoids (93.9%); mean cumulative dose: 25.5 g, antimalarials (67.3%), azathioprine (30.6%), mycophenolate-mofetil acid (22.4%), belimumab (16.3%), cyclophosphamide (10.2%) and methotrexe (8.1%). In 26 (60.5%) of all studied SLE patients, 36 (92.3%) peripheral and 3 (7.7%) vertebral fractures were recorded. Notably, 6 of these patients with fractures were younger than 30 and only 4 older than 60 years. 10 of all 39 fractures (25.6%) were low-trauma fractures. Of note, 11/26 patients (42.3%) with fractures had a normal BMD, 9/26 (34.6%) osteopenia and 6/26 (23.7%) osteoporosis, while only 4 (15.4%) of them initially received anti-osteoporotic medication.

**Conclusions:** There is a high occurrence of peripheral fractures in SLE. Moreover, 4 out of 10 SLE patients developed fractures despite a normal BMD, stressing that this parameter is of limited value for correctly identifying the fracture risk in SLE. The analysis of a larger number of patients and in-depth analyses are necessary to improve management of osteoporosis and to better prevent fractures in SLE patients.

HIGH RISK OF MISTAKEN CLASSIFICATION OF PRIMARY ANTIPHOSPHOLIPID SYNDROME AS SYSTEMIC LUPUS ERYTHEMATOSUS ACCORDING TO THE SLICC CRITERIA: ANALYSIS OF A COHORT OF 214 ANTIPHOSPHOLIPID PATIENTS

Background: The diagnosis of systemic lupus erythematosus (SLE) is based on the association of clinical and biological manifestations and on clinical experience. In 2012, a major revision by the Systemic Lupus International Collaborating Clinics (SLICC) group sought to improve their sensitivity and specificity. In replication, the SLICC classification produced fewer errors than the previous version; its higher sensitivity but lower specificity meant that some patients could be classified with SLE although they had another disease. In fact, the distinction between PAPS, APS associated with SLE, and isolated SLE may be difficult in some cases because the two diseases share some clinical and biological manifestations.

Objectives: To assess the limitations of the SLICC (Systemic Lupus International Collaborating Clinics) classification criteria for systemic lupus erythematosus (SLE), in patients with primary antiphospholipid syndrome (PAPS).

Methods: Retrospective study of a cohort of APS patients (Sydney criteria), we successively excluded patients with at least one “SLE-specific” manifestation (biopsy-proven SLE nephropathy, arthritis, cutaneous, or neurologic SLE manifestations, pericarditis, autoimmune haemolytic anaemia, oral and nasal ulcers, non-scarring alopecia, anti-dsDNA, and anti-Sm antibodies), any other autoimmune connective tissue disease, and/or an antinuclear antibodies >1/320. Careful file review confirmed PAPS among the remaining patients. We then assessed the number of SLICC criteria each patient met.

Results: Among these 214 APS patients, we excluded 85 with at least one SLE-specific manifestation (biopsy-proven SLE nephropathy, arthritis, cutaneous, or neurologic SLE manifestations, pericarditis, autoimmune haemolytic anaemia, oral and nasal ulcers, non-scarring alopecia, anti-dsDNA, and anti-Sm antibodies), any other autoimmune connective tissue disease, and/or an antinuclear antibodies >1/320. Careful file review confirmed PAPS among the remaining patients. We then assessed the number of SLICC criteria each patient met.

Conclusions: Because 28% of our patients with longstanding and strictly defined PAPS could be mistakenly classified as SLE, they were at risk of deleterious therapeutic management. We therefore suggest that any future classification for SLE should specifically require at least one SLE-specific criterion for patients with aPL.

Conclusions: Pregnancy should be planned when the disease is in remission. Lupus nephritis, is an important risk factor for preeclampsia. Also, the presence of lupus anticoagulant is a risk factor for preeclampsia, and hematologic determinations during pregnancy. The risk factors for pregnancy complications were: secondary antiphospholipid syndrome, presence of lupus nephropathy, thrombocytopenia, our study shows that the exacerbations depend on the disease activity in the moment of conception.

AB0625 SYSTEMIC LUPUS ERYTHEMATOSUS IN EGYPTIAN COHORT OF PATIENTS: A MULTICENTER STUDY

S.A. Elbakry1, N. Afifi1, S.A. Hussein1, N. Mohanna2, I.H. Bassouyi3, N.F. Abou elezez4. 1Department of internal Medicine-Rheumatology Division, Ain Shams University-Cairo-Egypt, Cairo; 2Department of internal Medicine-Rheumatology Division, Alexandria University Hospitals-Alexandria, Alexandria; 3Rheumatology and Rehabilitation Department, Faculty of Medicine, Cairo University; 4Community and Public Health Department Faculty of Medicine, Ain Shams University-Cairo-Egypt, Cairo, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease that mainly affects females in the reproductive age. The disease presents with a diverse spectrum of clinical and immunological manifestations which has been studied in many countries and ethnic groups. Data from North Africa especially Egypt are minimal.

Objectives: To study the clinical and immunological characteristics of an Egyptian cohort with SLE and compare it with data from MENA region and international data.

Methods: In this retrospective study, data of 569 SLE patients who fulfilled the modified American College of Rheumatology (ACR) criteria for the diagnosis of SLE were collected from three tertiary care centres in Cairo and Alexandria from the period of January 2014 to December 2017. Disease activity was assessed by using the SLE disease activity index (SLEDAI).

Results: Of 569 patients 92.6%were females and 4.7% males with mean age at presentation 26.3±8.8 years and mean disease duration four years (min 0.08- max 30 years). The main presenting symptom was musculoskeletal (arthritis/arthralgia) in 44.1% followed by fever in 39.4% and nephritis in 14.2%. Renal affection was present in 374 patients (65.7%) and renal biopsy was done in 268 patients with the most common is class III and IV lupus nephritis (18.3% and 14.1% respectively) (table 1). Antinuclear antibodies (ANA) was positive in all patients and immunofluorescence pattern was done in 256 patients; homogenous
Conclusions: These data are similar to that reported from MENA region; however, with little difference from international data as regard presenting symptom and immunological pattern. Differences observed among ethnic groups probably reflect the genetic component of ethnicity.

walking, moderate, and vigorous intensity, according to SLEDAI-2K and SDI were not found. In addition to high PCS of SF-36 (p=0.006) and SLEDAI-2K (p=0.038), less vigorous physical activity were related with lupus nephritis (p=0.033). However, the risk of CVD was not associated with physical activity of SLE.

Conclusions: This study showed that patients with lupus nephritis had less vigorous physical activity. It implicates that SLE-related organ damage might be associated with levels of physical activity.

AB0629 INFECTIONS IN HOSPITALISED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A PROSPECTIVE OBSERVATIONAL STUDY FROM A TERTIARY CARE CENTRE IN SOUTHERN INDI

S. Alur1, M.M. Thabah1, V.S. Negi2, S. Sistla3.

Background: Infections are one of the main causes of morbidity and mortality in SLE. The high prevalence of infection is attributed to use of immunosuppressive agents and disease activity. There is paucity of literature from India on infections, types of infections, predictors and outcome.

Objectives: To determine the frequency, types and determinants of major infections in hospitalised patients with SLE.

Methods: Patients with SLE (2012 SLICC-ACR criteria) aged ≥13 years, admitted to Clinical Immunology and Medicine wards were included. Clinical evaluation for major organ involvement of SLE, disease activity was assessed by SLEDAI-2K. Whenever there was a suspicion of infection appropriate work up to find the etiology of infections was done. Major infection was defined as presence of either one of the following a) sepsis b) pneumonia, or pyelonephritis, or endocarditis, or meningitis. c) skin or soft tissue infection requiring hospital admission for treatment d) Infection requiring IV antibiotic therapy. The diagnosis of infection was made by supportive clinical, microbiological and imaging criteria.

Results: From December 2016 till January 2018, 63 (55 women and 8 men) were included; Mean age was 28.8±9.8 years; mean SLEDAI-2K was 14.6±7.03. Median duration of hospital stay was 14 days; range 2–64 days. Disease manifestation (including present and ever present) were arthralgia/arthritis in 51 (81%), discsaters 56 (88.9%), myositis 10 (15.9%), lupus nephritis 35 (55.6%), CNS lupus 14 (22.2%), serositis 14 (22.2%), cardiac involvement 13 (20.6%), APS 3 (4.8%). At the time of enrollment thrombocytopenia was present in 13 (20.6%), and leukopenia 11 (17.5%). Twenty-three of 63 (36.5%) had infections (table 1), 14/23 (60.8) were microbiologically proven, remaining (39.2%) were confirmed by clinical features and imaging.

Seven of 63 (11.1%) died; 5 (21.7%) in the infection group versus 2 (5%) in no infection group, p=0.08 OR 5.58 [CI 0.98–33.2]. Almost 36% of SLE patients in hospital have infections. There was no association of infections with the dose of prednisolone or previous immunosuppression with cyclophosphamide.

Conclusions: Almost 36% of SLE patients in hospital have infections. There appeared to be an increase in number of deaths among patients with infections. There was no association of infections with the dose of prednisolone or previous immunosuppression with cyclophosphamide.

AB0630 EXPRESSION OF TNF-A AND IL-6 IN SYSTEMIC LUPUS ERYTHEMATOSUS: RELATIONSHIP WITH DISEASE ACTIVITY

T.A. Panafidina, T.V. Popkova, A.A. Novikov, E.L. Nasonova, V.A. Nasonova
Research Institute of Rheumatology, Moscow, Russian Federation

Background: Cytokines play an important role in the pathogenesis of SLE. TNF-α, IL-6 are the cytokines with suggested proinflammatory and immunoregulatory actions in the pathogenesis of SLE with differential effects on B or T cells, as well as on programmed cell death. Fas/APO-1 and Fas ligand (FasL) are involved in the apoptosis. Fas is a marker of apoptosis, it induces cell apoptosis when binds to Fas/APO-1. Both are expressed in membrane-associated and soluble forms (sFas/APO-1 and sFasL). sFas/APO-1 is known to inhibit the apoptosis via blocking the binding of Fas/APO-1 to FasL/sFasL.

Objectives: We evaluated the levels of IL-6 and TNF-α and their possible association with disease activity, apoptosis markers. Methods: The study included 52pts (89% female, age 30.0 [26.5–44.5 years] (median [interquartile range 25% >75%]) with SLE ACR, 1997 and 20 controls (100% female without any rheumatic and infectious diseases, age 30.0 [25.0–39.5 years]). SLE-related factors, including disease duration, clinical features, SLE Disease Activity Index (SLEDAI-2K) and Systemic Lupus International Collaborating Clinics (SLICC) damage index were evaluated in parallel with relevant laboratory findings, autoantibodies. Serum levels of IL-6 and TNF-α (pg/ml), sFas/
APO-1 (pg/ml) and sFasL (ng/ml) were measured by ELISA (Bender MedSystem GmbH, Austria).

Results: Median SLE duration was 5 [1-11] years. SLEDAI 2K-9.5 [4.0-16.0], SLICC-6 [0-1], current prednisone dose-5.0 [0-11.9] mg/day, 44% of pts received hydroxychloroquine, 17% cyclophosphamide, 10% azathioprine, 4% mycophenolate mofetil, 8% biologics. SLE pts had higher level of IL-6 vs controls (2.9 [1.5-9.7] vs 1.4 [0.7-2.1] pg/ml, p<0.01) and lower level of TNF-α [1.9 [0.5-3.2] vs 4.5 [3.5-6.4] pg/ml, p<0.0001), lower levels of sFas/APO-1 vs control (657.5 [483.2-791.4] vs 1456.9 [426.5-2060.8] pg/ml, p<0.05) and lower levels of sFasL vs control (0.01 [0.01-0.03] vs 0.07 [0.05-0.10] ng/ml, p<0.001). In SLE pts serum level IL-6 correlated with IgM (r=0.69, p<0.01), K+ (r=0.43, p<0.01), TNF-α (r=0.50, p<0.01), APRIL (r=0.39, p<0.01) and sFas/APO-1 levels (r=0.29, p<0.05), TNF-α level correlated with SLICC(r=0.32, p<0.05), APRIL (r=0.42, p<0.01). IL-6 (r=0.50, p<0.01), haemoglobin concentration (r=0.39,p<0.01), sFasL (r=0.44, p<0.01) and total cyclophosphamide dose (r=0.28,p<0.05). We divided SLE pts on two groups: the 1st pts(n=31) with high activity (SLEDAI 2K<8), the 2nd-pts (n=21) with low (SLEDAI 2K>8). The pts in the 1st group had lower level of TNF-α compared to 2nd (0.3-2.2) vs 2.8 [1.3-4.5] pg/ml, p<0.05, with no difference in IL-6 level.

Conclusions: SLE pts demonstrated higher IL-6 and lower TNF-α levels as compared to healthy controls. Pts with high activity of SLE had decreased level of TNF-α. There is no correlation between disease activity and IL-6 level, as well as between elevated IL-6 and acute phase indicators. We suggest an immunoregulatory not proinflammatory role of IL-6 in SLE and probable protective role of TNF-α in SLE pathogenesis (it’s deficiency can lead to the development and high activity of SLE). There was no correlation between IL-6, TNF-α levels and any SLE features. The correlation of IL-6 with sFas/APO-1 level (apoptosis inhibitor that blocks binding of sFas/APO-1 to sFasL) and TNF-α with sFasL concentration (a marker of apoptosis) suggests different roles in the mechanisms of apoptosis.

ESSEDAI DOMAIN EVALUATION OF PRIMARY SJOGRÊN’S SYNDROME (PSS) PATIENTS ENROLLED IN TWO INDEPENDENT POC STUDIES INDICATES DIFFERENTIAL UTILITY OF DOMAINS FOR TRIAL INCLUSION AND COMPOSITE ENDPOINTS IN PSS TRIALS

T. Dörrner1, B.A. Fisher1, X. Ren3, P. Faerber2, P. Gergely2, L. Mooney1, Y. Li3, S. J. Oliver1, W. Hueber1, A.M. Wright3. 1Charité Hospital, Berlin, Germany; 2Rheumatology Research Group, University of Birmingham, Birmingham, UK; 3Novartis Institutes for BioMedical Research; 4Novartis Pharma, Basle, Switzerland

Background: According to international consensus, disease activity in primary Sjögren’s syndrome (PSS) patients shall be scored across 12 different domains according to the European Sjögren’s Syndrome Disease Activity Index (ESSDAI). Two separate phase 2 proof-of-concept (PoC) studies using either BAFF receptor inhibitor (VAY736; inanulab) or CD40 inhibitor (CFZ533) have recently been completed in comparable pSS cohorts with ESSDAI as the primary endpoint.

Objectives: To evaluate contribution of individual domains to composite ESSDAI scores at baseline and after interventional treatment with either VAY736 or CFZ533, or placebo. Aggregate efficacy and safety results were presented at previous meetings.2 3

Methods: Key inclusion criteria for both studies were fulfilling revised European US consensus criteria for pSS,4 autoantibody positivity, exclusion of secondary SS and ESSDAI ≥6. Permitted background medications in both trials included stable doses of hydroxychloroquine, methotrextate and prednisol ≤10 mg/d and also azathioprine in the CFZ533 trial. The primary endpoint was change in ESSDAI at week 12. Descriptive and principal component analysis were done with the goal to identify distinct subgroups of patients based on ESSDAI involvement at baseline (BL), and the relative importance of single domain contribution to overall ESSDAI responses were explored.

Results: 27 patients received single i.v. dose VAY736 10 mg/kg (n=12) or 3 mg/kg (n=6) or placebo, and 44 patients received multiple doses of CFZ533 10 mg/kg i.v. (n=21) or 3 mg/kg s.c. (n=8) or placebo. ESSDAI breakdown at BL showed a predominance of the articular, glandular, biological, constitutional and lymphadenopathy domains in both trials. Activity in more than 3 domains was recorded for 12/27 (44%) and 12/44 (27%) of patients in the VAY736 and CFZ533 studies, respectively. Principal component analysis identified the articular domain as the key component describing the difference between patients in their ESSDAI domains at BL. Two other domains that explained the variability between patients were the biological and glandular domains. Treatment effects in domains with low BL scores were more difficult to assess using ESSDAI. The majority of ESSDAI domains were not amenable to quantitative analysis, due to absence or low incidence at baseline.

Conclusions: The most frequently observed ESSDAI domain was articular involvement. Our results provide insights into ESSDAI domain frequency and distribution in the randomised controlled trial setting that may have implication for future trial design in pSS.

MEASURING WHAT MATTERS TO LUPUS PATIENTS: TRANSLATING PATIENT VIEWS INTO NOVEL PATIENT-REPORTED OUTCOMES

S. Cleanthous1, A. Regnault2, M. Schneider2, C. Gordon3, S. Bartlett3, S. Cano3, T. Morel4, 5Modus Outcomes, Cambridge, UK; 2Modus Outcomes, Lyon, France; 3Policlinic and Hiller Research Unit of Rheumatology, UKD, Heinrich-Heine-University, Düsseldorf, Germany; 4University of Birmingham, Birmingham, UK; 5McGill University, Montreal, Canada; 6UCB Pharma, Brussels, Belgium

Background: The 2010 U.S. FDA guidance1 on systemic lupus erythematosus (SLE) acknowledged that "improvements in clinical outcome measures in patients with SLE may not always translate to improvements in how patients feel or function" and encourages the use of patient-reported outcome instruments (PROs) to assess changes in outcomes that matter most to patients. Fatigue, identified by patients as their chief complaint during the Lupus Patient-Focused Drug Development (PFDD) meeting,7 is not optimally measured by existing PROs.1 There is a need for new patient-centred outcome measures as they are pivotal to PFDD. To address this, UCB has been conducting a multi-faceted, patient-centric, mixed methods research programme including evidence generated from >2100 SLE patients.

Objectives: There were three main objectives of the programme: 1) identify what concepts are most important to measure for SLE patients when evaluating treatment benefit; 2) critically evaluate the extent to which these concepts are captured by existing PROs; and 3) explore the opportunity to develop and evaluate new conceptually-based SLE PROs in SLE.

Methods: There were three stages: 1) development of a preliminary treatment benefit conceptual model related to SLE including disease symptoms and impacts (generated from literature review, and patient and clinician input); 2) formal comparison of the conceptual model and the content validity (qualitative review) of existing SLE PROs and ii) psychometric properties (ie. SF-36, FACIT-F, and LupusQoL in the discontinued EMBODY Phase 3 studies for epratuzumab); 3) development of new conceptually-based PROs in SLE (figure 1).

Results: A preliminary treatment benefit conceptual model in SLE was developed. Among the many symptoms and disease impacts reported by SLE patients, physical fatigue, mental fatigue (‘brain fog’), sudden fatigability, joint/muscle stiffness and pain, skin symptoms and mobility difficulties featured as most troublesome. The content validity of 10 widely used PROs was found to be limited when compared to this conceptual model. Psychometric analysis (based on Rasch Measurement Theory) confirmed the limitations of the SLE PROs used in the EMBODY studies and suggested post-hoc reconceptualisation would improve the ability of the scales to detect clinical change. This led to the development of five new conceptually-based SLE PROs (ie. fatigue, pain, mobility, symptom severity, and emotional state), which are currently being explored in >500 SLE patients in a Phase 2b dapirolizumab pegol study (NCT02804763) and two cross-sectional, non-interventional, observational studies. Data on the new PROs are currently being assessed at seven sites in the USA, Latin America, UK and Germany and will be available in the coming months.

Conclusions: New, well-defined and reliable PROs to better capture the patient perceptions of the symptoms and impact of SLE are needed. UCB has developed five new PROs which offer the promise of improved patient-centred outcome measurements in SLE and other autoimmune diseases.

AB0634 CHARACTERISATION OF SLE PATIENTS WHO UNDERWENT CARDIOVASCULAR SURGERY

T. Kawamoto1, S. Matsushita2, H. Amano1, K. Minowa1, Y. Asai1, K. Yamaji1, A. Amaro1, N. Tamura1. 1Internal medicine and rheumatology; 2Cardiovascular Surgery, Juntendo University School of Medicine, Tokyo, Japan

Background: SLE is characterised by alternate occurrences of flares and remissions throughout its course. During these flares, immune complexes are excessively produced and deposited in affected tissues. Previous reports suggest that immune complexes deposited in the blood vessels, atrioventricular valves, and other associated components of the heart cause disorders in these tissues. Although, the characteristics of patients in whom tissue injuries progress and ultimately require surgery have not been clarified.1

Objectives: Heart diseases are categorised into valvular disease, ischaemic heart disease, and aortic aneurysm. This study was conducted to determine whether there was a correlation between the activity of SLE and the progression and aggravation of heart disease in each category.

Methods: Of the 2707 patients who were diagnosed with SLE at Juntendo University Hospital from 2012–2017, 35 underwent cardiac surgery. Six patients met the exclusion criteria, and thus, 29 patients were included. Patients with infectious endocarditis and those in whom SLE had not been diagnosed prior to surgery were excluded. Indices for SLE activity were anti-DNA Ab and CH50. Peak and bottom values of these indices before surgery were recorded, and the values obtained during the pre-surgery 180 day period were compared with those that had been determined prior to this period.

Results: The mean disease duration at the time of cardiac surgery was 24.2 years. The cardiac diseases were heart valve disease (V) in 10, ischaemic heart disease (I) in 7, and aortic aneurysm (A) in 12 patients. The integrated values obtained by the activity indices, anti-DNA Ab, and disease duration were 14 020 for V, 32 966 for I, and 29 444 for A. Thus, there was a tendency for values to be slightly lower in the heart valve disease category. The peak/bottom values for CH50 and anti-DNA Ab in the pre-surgery 180 day period were no different from those obtained prior to this period. Investigation of anti-phospholipid antibodies indicated that the rates of positive result for either CLβ3, GPI, anti-CL antibodies, or LA were 60% for V, 28% for I, and 33% for A, and thus, higher in the heart valve disease category. All patients were treated with steroids, and five patients (17.2%) of the 29 used immunosuppressants. This rate tended to be lower than the previous frequency of the combined use of immunosuppressive drugs at our hospital (onset:18.4%, first flare 33.3%).2

Conclusions: There is a possibility that the long-term duration of SLE may lead to cardiac disease requiring surgery. The integrated value for DNA Ab was lower in the heart valve disease category; therefore, the presence of anti-phospholipid antibodies may be a risk factor for valvular disease. The low frequency of combined use of immunosuppressants in SLE patients with cardiovascular manifestations requiring surgery, suggest the possibility that treatment with a single steroid may require heart surgery.

REFERENCES:

Disclosure of Interest: A. Amano2, N. Tamura1. 2Cardiovascular Surgery, Juntendo University School of Medicine, Tokyo, Japan

Background: Myocarditis in lupus is an uncommon clinical manifestation, with unknown pathogenesis. Suggested etiologies include immune-complexes, cell mediated damage and anti-phospholipid antibodies. The latter may affect the myocardial function microthrombi in cardiac vessels or direct cytotoxicity. Previ-ously, small studies have suggested an association between antiphospholipid tests as myocarditis. Objectives: To evaluate whether myocarditis in SLE is associated with antiphos-pholipid positivity. Methods: This was a cross-sectional study in which patients fulfilling SLICC crite-ria 2012 for SLE or ACR/Sapporo criteria for MCTD were included after consent. Patients were recruited as ‘Cases’ if they had myocarditis/cardiomyopathy defined by poor generalised contractility and/or dilation of all chambers and/or reduced ejection fraction on echocardiography without any obvious cause. Those with regional wall motion abnormalities or pulmonary artery hypertension (moderate or severe) were excluded. Controls were age (±2.5 years) and disease duration (±25%) matched patients of SLE without any abnormality on echocardiography. Serum titers of anticardiolipin antibodies and b2 GP1 (both IgG and IGM) were measured by commercial ELISA kit. Lupus anticoagulant was detected by Dilute Russell Viper Venom Test (dRVVT) with both screening (prolonged) and confirmation steps (shortening on higher phospholipid content, ratio >1.2) on doubly centrifuged, platelet poor plasma. Proportions were compared between groups. (p=0.3).

Results: A total of 51 patients were recruited in this study that included 21 cases and 30 controls. All had SLE, except 1 case was of MCTD (among cases). There was no difference in mean (±SD) age (33.3±14.7, 32.8±12.4 years, p=0.9) or median (interquartile range) disease duration (30.2–36.5, 25 (13.5–45) months, p=0.6) between groups. Mean ejection fraction of Cases was 31.7% (±3.3%) while that of Controls was 55.7% (±1.7%) (p<0.001). There were no significant differences between proportion of Cases (42.9%) and Controls (40%) with positive antiphospholipid tests (p=0.7). The majority had positive anticardiolipin antibodies, followed by b2 GP1, and lupus anticoagulant was positive in only two in each group (figure 1). Among 9 Cases positive at baseline, 6 patients could be re-tested (1 expired and 3 were lost), with 1 being persistently positive. There was no significant difference in persistent positivity between groups. (p=0.3).

Conclusions: This study did not find any significant association between anti-phospholipid antibodies (single time or persistent) with cases of lupus myocarditis.

REFERENCES:
Conclusions: The most common haematological disorders in pSS patients are leukopenia, and cytopenia in pSS patients might be related to disease activity.

AB0638 CLINICAL SIGNIFICANCE OF ESR IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Xu, X. Feng, L. Sun
Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: During the process of systemic lupus erythematosus (SLE), disease flare and infection are often accompanied by each other and always pose a major challenge to clinical treatments. Although erythrocyte sedimentation rate (ESR) has been tested in SLE patients for many years, there is still a lack of consensus on its value.

Objectives: To validate the value of ESR in Chinese SLE patients at the time of their first admission and to determine whether it is related to a poor outcome.

Methods: Clinical data of patients with ESR tested on their first admission were extracted from our SLE database; (Feng et al. PLoS ONE 2016;11(12): e0168619) and analysed for the relation with disease activity (SLEDAI), infection status, organ involvements and survival situation. To determine the risk of ESR for long-term mortality, cumulative survival was illustrated with the Kaplan-Meier plot and factors were compared using the Log-rank test.

Results: Totally 1225 patients were included in this study, of which 92.2% were female and the median age at admission was 34.3 years. The most often seen organ involvements were mucocutaneous (66.4%), musculoskeletal (55.0%), renal (51.7%) and hematologic (45.2%) respectively. ESR levels were correlated with SLEDAI scores (r=0.145, p<0.000), but not elevated in patients with infections. Patients with cardiopulmonary, renal or hematologic impairments had higher ESR levels (all p<0.05). Subgroup analysis showed that serositis, renal insufficiency and anaemia might be responsible for the respective organ involvement. The ten year survival rates for patients with elevated ESR was 80.57%, with higher ESR levels (all p<0.05). Subgroup analysis showed that serositis, renal insufficiency and anaemia might be responsible for the respective organ involvement. The ten year survival rates for patients with elevated ESR was 80.57%, higher ESR levels (all p<0.05). Subgroup analysis showed that serositis, renal insufficiency and anaemia might be responsible for the respective organ involvement. The ten year survival rates for patients with elevated ESR was 80.57%, higher ESR levels (all p<0.05). Subgroup analysis showed that serositis, renal insufficiency and anaemia might be responsible for the respective organ involvement. The ten year survival rates for patients with elevated ESR was 80.57%, higher ESR levels (all p<0.05). Subgroup analysis showed that serositis, renal insufficiency and anaemia might be responsible for the respective organ involvement. The ten year survival rates for patients with elevated ESR was 80.57%, higher ESR levels (all p<0.05). Subgroup analysis showed that serositis, renal insufficiency and anaemia might be responsible for the respective organ involvement.

Conclusions: High ESR levels in SLE patients are associated with active disease and specific organ involvements, and may predict a poor prognosis. It should be checked routinely for the monitoring of SLE patients.

AB0640 IMPLAUSIBLE ANTI-SMITH ANTIBODY IS NOT IMPLAUSIBLE TO AUTOIMMUNE DISEASE IN CHINESE POPULATION USING THE EUROIMMUNE LINE IMMUNOASSAYS

Y. Wu, Y. Meng
Department of Laboratory Medicine, West China Hospital, Sichuan University, Chengdu, China

Background: Anti-Sm antibody is important test for lupus. In China, many labs detected anti-Sm using Euroimmun line immunoads (LIA) kit, which mixture with purified Sm and RNP antigens as target antigens in Sm/RNP band and purified Sm antigens in Sm band. On the instruction, anti-Sm results should be determined according to the 2 bands. That is divided as true anti-Sm positive cases (having positive Sm and Sm/RNP bands) and implausible cases (having Sm band without Sm/RNP band), the value of implausible anti-Sm is not very clear now.

Objectives: We aimed at investigating the clinical value of the implausible anti-Sm in Chinese population.
Correlation Between Physicians and Patients in the Assessment of Disease Activity in Systemic Lupus Erythematosus

Y. Nass1,2, N. Yokokawa3, H. Takahashi4, E. Takamatsu5, S. Sugii6. 1First Department of Internal Medicine, Kansai Medical University, Osaka; 2Department of Rheumatic Diseases, Tokyo Tama Medical Metropolitan Hospital, Tokyo, Japan

Background: In the assessment of systemic lupus erythematosus (SLE), laboratory data and clinical findings have been more focused than patient-reported outcomes which reflect quality of life. Previous studies showed discrepancy between patients and physicians in assessments of disease activity in SLE.1 The Systemic Lupus Activity Questionnaire (SLAQ), a lupus disease activity index which consisted of only patient reported outcomes, and SLE Disease Activity Index 2000 (SLEDAI-2K) were poorly correlated.2

Objectives: We aimed to investigate the correlation between SLAQ and SLEDAI-2K scores in those who had discordance between patients’ VAS and physicians’ VAS or not.

Methods: Both SLEDAI-2K and SLAQ were routinely measured at every outpatient visit in all SLE patients. We analysed the data between 9/12/2017 and 12/31/2017. Patients were divided into concordance (patients’ VAS-physicians’ VAS) <25 or discordance (patients’ VAS-physicians’ VAS) ≥25.2 We measured correlation between SLAQ score vs SLEDAI-2K or SLEDAI-2K-nolab scores by Spearman’s correlation in the concordance group and the discordance group. Comparison between the concordance group and the discordance group were performed using chi-squared test for categorical variables and Student t-test, Welch’s t-test or Mann-Whitney U test for continuous variables.

Results: Total 130 patients were analysed; 91% of female, a mean age (SD) of 44.12 years, steroid use of 91%, immunosuppressant use of 54%, HCQ use of 70%, Median SLEAQ, SLEDAI-2K and SLEDAI-2K-nolab scores were 4 [IQR: 2–7], 4 [IQR: 2–4] and 0 [IQR: 0–2], respectively. Among them, 86 (66%) were classified in the concordance group. The SLAQ scores were weakly correlated with the SLEDAI-2K scores (r = 0.228, p = 0.009), and with SLEDAI-2K-nolab scores (r = 0.352, p < 0.001). In the concordance group, the SLAQ scores correlated with SLEDAI-2K scores (r = 0.327, p = 0.002) and SLEDAI-2K-nolab scores (r = 0.523, p < 0.001). The pain VAS and RAPID3 in the discordance group were significantly higher than those in the concordance group (30.77±26.54 vs. 10.71±14.31, p < 0.001, 8.11±5.87 vs. 2.97±3.23, p < 0.001, respectively). In the discordance group, the SLAQ scores were not correlated with SLEDAI-2K scores (r = 0.029, p = 0.849) and with SLEDAI-2K-nolab scores (r = 0.083, p = 0.957).

Conclusions: The correlation between SLAQ vs SLEDAI-2K or SLEDAI-2K-nolab scores was exhibited in the concordance group. Musculoskeletal pain may be associated with the discordance between patients’ and physicians’ assessment.

Glucocorticoid Intake, Hyperglycemia and Osteoporosis in Patients with Autoimmune Diseases

Y. Jiang, G. Du, X. Wu, Y. Xie, M. Zhao, Z. Liao, J. Gu. Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Autoimmune diseases (AID) are often treated with glucocorticoids. Glucocorticoids have a number of substantial side effects in human body, including hyperglycemia and osteoporosis.

Objectives: Our study was to investigate the use of glucocorticoid in patients with autoimmune diseases and its negative influence on blood glucose and osteoporosis in the patients who receiving glucocorticoid treatment.

Methods: Patients with autoimmune diseases were enrolled from July to December 2017 in rheumatology department of the Third Affiliated Hospital of Sun Yat-sen University. Demographic information, family history, past medical history, and clinical information were collected by two rheumatologists, including years of having glucocorticoids for treatment, largest dose of methylprednisolone, current dose of glucocorticoids. Blood glucose, glycosylated haemoglobin, and bone mineral density was required. The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis.

Results: Of all the 75 patients, 15 (20%) were male patients. 14.7% had primary education, while 26.6% received education in university. Numbers of the patients were stated as follows. Lupus, 29; rheumatoid arthritis, 4; Sjögren’s syndrome, 10; systemic sclerosis, 10; myositis, 4; mixed connective tissue disease, 1; autoimmune hepatitis, 1; vasculitis, 5; other diseases, 11. Mean age was 40.29±14.64 years. Mean disease duration was 4.74±6.62 years. 3 (4%) patients had family history of diabetes. 3 (4%) patients had past medical history of diabetes. 3 (4%) patients had past medical history of diabetes. Mean duration of taking glucocorticoids was 3.30±4.40 years. 13 (17.3%) of the patients underwent high dose of glucocorticoid intravenous pulse (120 mg to 1000 mg of methylprednisolone). Current dose of glucocorticoids was 5.30±3.96 tablets of methylprednisolone. Mean blood glucose was 4.61±0.92 mmol/L. Mean glycosylated haemoglobin was 5.6±0.84. 2 patients were found to have diabetes in this study. 5 other patients were found to have higher blood sugar than normal range (3.9–6.1 mmol/L, according to our laboratory). 14 (18.7%) of the patients had osteoporosis according to BMD scores. In 17 patients who had receiving glucocorticoids for more than five years, 3 (17.6%) patients were found to have higher
blood sugar than normal range and 5 (29.4%) patients were found to have osteoporosis.

Conclusions: Glucocorticoids have substantial side effects in hyperglycemia and osteoporosis in the patient receiving glucocorticoid treatment. More years of taking glucocorticoids could lead to more hyperglycemia and osteoporosis. We should evaluate side effects of glucocorticoids in the patients with AIDs.

PREGNANCY OUTCOMES OF PLANNED PREGNANCY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE MULTICENTER STUDY

Z. Zhan1, D. Chen1, M. Lao2, X. Cai2, J. Zhang4, 1Department of Rheumatology, 2Department of Rheumatology and Department of Geriatrics, The First Affiliated Hospital of Sun Yat-sen University, 3Department of Rheumatology, Guangzhou First People’s Hospital, The Second Affiliated Hospital of South China University of Technology, 4Department of Rheumatology, The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: Compared with the general population, patients with SLE are still at high risk of adverse pregnancy outcomes (APOs). A number of studies have shown that patients with SLE are more likely to develop fetal complications, including fetal loss, preterm birth and IUGR, compared to healthy women.

Objectives: To investigate the fetal and maternal outcomes, as well as predictors for APOs in women with SLE who conceived when disease was stable, the so-called “planned pregnancy”.

Methods: A retrospective multicenter study of 243 patients with SLE who underwent planned pregnancy was performed. APOs in fetus and mothers were recorded.

Results: The average age at conception was 28.9±3.9 years. Duration of SLE prior to pregnancy was 4.4±4.3 years. Fetal APOs occurred in 86 (86/243, 35.4%) patients. Preterm births, intrauterine growth retardation (IUGR), fetal distress, and fetal loss accounted for 22.2%, 14.8%, 11.1%, and 4.9%, respectively. Forty-two preterm infants (42/54, 77.8%) were delivered after the 34th week of gestation. All the preterm infants were viable. Fifty-two patients (52/243, 21.4%) had disease flares, among which 45 (45/52, 86.5%) cases were mild, 6 (6/52, 11.5%) were moderate and 1 (1/52, 1.9%) was severe. Fifty-two disease flares (21.4%) occurred, among which 8 disease flares occurred during the first-trimester, 15 during the second-trimester, and 29 during the third-trimester. Disease activity was mild in 45 (45/52, 86.5%) patients, moderate in 6 (6/52, 11.5%), and high in 1 (1/52, 1.9%). Disease flares were mainly presented as active lupus nephritis (41/52, 78.8%), thrombocytopenia (10/52, 19.2%), and skin/mucosa lesions (9/52, 17.3%). Pregnancy-induced hypertension (PIH) occurred in 29 patients, among which 3 were gestational hypertension and 26 were preeclampsia. Multiple analyses showed that disease flares (OR 8.1, 95% CI 3.8-17.2, p<0.001) and anti-cardiolipin antibodies positivity (OR 7.4, 95% CI 2.5-21.8, p<0.001) were associated with composite fetal APOs.

Conclusions: Planned pregnancy improved fetal and maternal outcomes, presenting as lower rate of fetal loss, more favourable outcomes for preterm infants as well as less severe disease flares during pregnancy. Our research reinforced the importance of planned pregnancy, which allowed women with SLE to conceive in a proper time monitored by multidisciplinary experts.

ANCA VASCULITIS: THE EXPERIENCE AND TRENDS IN PATIENT CARE FROM A SINGLE CENTRE

A. Bankole1, B. McCoy3, B. Year3, G. Verma, Gita2, Medicine, Virginia Tech Carilion School of Medicine, Roanoke; 2, Medicine, Centra Medical Group Bedford, 3, Bedford, USA

Background: ANCA-associated vasculitis (AAV) is a small-medium vessel vasculitis that presents in a multi-systemic fashion, and is associated with significant mortality. Outcomes have improved with the introduction of immunosuppressive medications (ISM), the evidence supporting the initial choice ISM in AAV is limited, and may be influenced by health disparities related to social factors.

Objectives: The objective of this study was to compare various factors known to influence management and outcomes in AAV. Factors including, patient demographics, socioeconomic, clinical presentations, and medication choices were reviewed in relation to outcomes within the cohort.

Methods: This was a retrospective, single centre, hospital-affiliated cohort study. A list of all patients seen by the Rheumatology service between 2011 and 2016 with a diagnosis of AAV was generated. A review of the 3000 charts confirmed 77 patients that met the 1990 American College of Rheumatology criteria for AAV. General demographic data including age, gender, zip code, and median household income as well as disease related data including serology, disease manifestation, and treatment were obtained through a chart review and recorded in the database. Supplemental socioeconomic information for each patient zip code was obtained from the United States Government Census website.

Results: In our cohort the anti-protease 3 [PR3] antibody was the most common positive antibody. There was a relationship between PR3 antibody positivity rate
and body mass index [table 1]. Given the low number of non-Caucasians we were unable to comment on the relationship between antibody and race.

Medication choice and mortality were independent of mean household income. Rituximab was the most commonly prescribed ISM [44%]. The median age of rituximab exposure patients was 65 years and 60 years for unexposed patients. There was no significant relationship between age and medication choice. Rituximab was prescribed 60% of the time in renal AAV [p=0.01] and 53% of the time in pulmonary AAV [p<0.01]. Other commonly prescribed medications in the cohort included Mycophenolate [20%], Methotrexate [24%] and Cyclophosphamide [28%].

The overall mortality rate was 17% [13/75] [figure 1]. There was no significant difference in the mortality rate of patients 65 years and older [23%, 9/39] compared to patients 64 and younger [11%, 4/36; p=0.17]. The mortality rate was also independent of median household income.

Abstract AB0645 – Table 1

</tbody>
</table>

Conclusions: There was no relationship between age, sex, income, immunosuppressive therapy, and mortality in our AAV cohort. The mortality rate was higher in more severe disease and rituximab was more commonly used in such cases as well as in older patients. The limitations of the study include this being a hospital-based cohort, where social demographics may have less of an impact. There was a lack of racial diversity, though the cohort did reflect the general demographics in southwest Virginia.

AB0646
IDENTIFICATION OF RISK FACTORS FOR RECURRENTITY IN POLYMYALGIA RHEUMATICA

A. Ueno, M. Hirata, Y. Yamamura, K. Fujita, N. Shibutou, M. Yamamura. Center for Rheumatology, Okayama Saiseikai General Hospital, Okayama, Japan

Background: Glucocorticoids (GCs) are effective for polymyalgia rheumatica (PMR); however, some patients relapse during GC tapering and develop adverse events of GCs.

Objectives: To identify risk factors for recurrence in patients with polymyalgia rheumatica (PMR)

Methods: Cox proportional hazards regression analyses was performed 78 patients with PMR who had been treated first with GCs. They were at the age of 71±15.8, including 34 males and 44 females. Duration of symptoms before therapy was 2.0±2.0 months and the PMR duration was 21.2±15.5 months. Twenty-seven patients had arthralgia/myalgia other than shoulders and hips. The maximum dose of prednisolone was 15.9±4.4 mg/day. US findings of shoulder were positive in 65 patients. Relapses occurred in 37 patients (47%), when the dose of prednisolone was reduced to 5.6±5.5 mg/day at 8.9±6.4 months. MTX (8.6±3.1 mg/ek) was added in 29 patients or the dose of prednisolone was increased in 8 patients, similarly to the 2015 EULAR/ACR recommendations for the management of PMR. Additional MTX was ineffective in 16 patients, followed by adding tocilizumab in 8 patients. Forty patients discontinued GCs at 17.6±10.6 months.

On univariate analysis, 4 variables were identified as significant risk factors affecting PMR recurrence: increased platelets (p=0.00192), low IgA (p=0.00149), arthralgia/myalgia limited to shoulders and hips (p=0.02), and the maximum dose of prednisolone used (p=0.0062). These 4 variables were introduced into the multivariate analysis, and the following 3 variables were retained as independent significant risk factors: the maximum dose of prednisolone (p<0.005), limitation of arthralgia/myalgia to shoulders and hips (p<0.05) and low IgA (p<0.005).

Conclusions: These results indicate that the maximum dose of prednisolone, the absence of peripheral joint pains and low IgA may be associated with the recurrence in PMR patients

Disclosure of Interest: None declared

TAKAYASU’S ARTERITIS IN ITALY: CLINICAL PRESENTATION, DIAGNOSTIC DELAY AND VASCULAR PATTERNS

A. Tomelleri, C. Campochiaro, S. Sartorelli, C. Sembenini, S. Franchini, F. Motta, D. Vanni, G. Cavalli, E. Baldissera, L. Dagna. Unit of Rheumatology, Immunology, Allergy and Rare Diseases (UnIRAR), San Raffaele Scientific Institute, Milan, Italy

Background: Takayasu arteritis (TA) is a large vessel vasculitis. At disease presentation TA patients may present with inflammatory symptoms, sometimes associated with vascular pain. As arterial lesions ensue, more characteristic features may be found, such as limb claudication, decreased or absent pulses, vascular bruits, discrepancies in blood pressure. Since initial symptoms are often non-specific, early detection of TA is challenging and patients at diagnosis frequently have established damage.

Objectives: To describe symptoms presentation and vascular involvement in a large cohort of Italian TA patients. To assess the diagnostic delay associated with symptoms and arteries involved at presentation

Methods: Data from 114 TA patients diagnosed according to ACR classification criteria at our tertiary centre were retrospectively collected. Signs and symptoms subsequently attributed to TA, age at first symptom onset, and age at diagnosis were analysed. The diagnostic delay was calculated. Arteries involved before the diagnosis were identified. Non-parametric statistic tests were used

Results: The cohort included mostly female patients (104; 91.2%). Mean age at first symptom subsequently attributed to TA was 30.5 years (±13.1). Age at presentation of the first TA-related symptom was 16–40 years in 88 (59.6) ±18 years in 20 (17.5%). Mean diagnostic delay was 65.6 months (±85.3). Diagnostic delay was <1 year in 75 patients (65.8%). The most frequent finding before diagnosis was raised inflammatory markers (82.4%), the least common pulmonary hypertension (2.8%). The features significantly associated with a diagnostic delay >1 year were arthralgias, hypertension, previous vascular surgery. The mean diagnostic delay (in months) was significantly higher in patients with raised inflammatory markers (8.4±9.9 vs 100.5±151.8; p=0.005), cardiomyopathy (5.4±15.7 vs 34.2±35.9; p=0.034) and in patients who had upper limb claudication (110.1±13.2 vs 65.4±77.01; p=0.002). Data about arteries involved before diagnosis were available for 86 patients (75.4%). They were: subclavian in 43 (50%), carotid in 38 (44.2%), renal in 19 (22.1%), abdominal aorta in 18 (20.9%), ascending aorta in 15 (17.4%), axillary in 12 (14%), vertebral in 11 (12.6%), superior mesenteric in 10 (11.6%), thoracic aorta in 11 (12.8%), aortic arch in 11 (10.5%), celiac trip in 9 (10.5%), brachiocephalic in 8 (9.3%), iliac in 8 (9.3%), coronary in 6 (7%), femoral in 6 (7%), pulmonary in 5 (6%), brachial in 3 (5.5%), popliteal in 2 (2.3%) patients. There was no significant difference in the arteries involved between patients diagnosed <1 year and >1 year from symptoms onset. Mean diagnostic delay was not significantly different according to the arteries involved

Conclusions: In Italy TA diagnosis is burdened with an important diagnostic delay. In our cohort it seems that the presence of both specific and non-specific symptoms is associated with delayed recognition of TA. Moreover, the need for vascular surgery in young women should rise the concern about TA

Conclusions: Since fatigue was not related to clinical characteristics, tiredness declared by the patient should not be interpreted as a symptom of active disease. There were no connections between fatigue and socio-demographic variables. The strong association between fatigue and depression and anxiety levels indicates the necessity to supplement the standard drug therapy and/or cognitive-behavioural therapy aimed at reducing anxiety and improving mood.

Conclusions: This is the first evaluation of primary vasculitis patients who used biological agents from TURKBIO registry. According our data, there was high switching rate with anti-TNF agents in TA patients. The limitation of this study was the low number of the patients with primary vasculitis who used biological agents.

THROMBOTIC MICROANGIOPATHY ASSOCIATED TO ANCA-POSITIVE VASCUITIS: A FRENCH RETROSPECTIVE CASE CONTROL STUDY AND LITERATURE REVIEW

A. Demail, on behalf of Francisca Barclay M.D, Jean Jacques, Boiff, Eric. Rondeau, Pierre Yves, Hatron, Christophe, Deligny, Stephane, Bally, Olivier. Fain, Paul, Corjage, Arakai, Mekinian, Saint-Antoine, Paris 2. Rheumatology - Montfermeil; HOPITAL MONTFERMEIL, MONTFERMEIL, France

Objectives: In this large nationwide French case-control study, we describe the features of TTP and ANCA-positive vasculitis; compare to vasculitis without associated TTP; describe the outcome and treatments.

Methods: We collected all cases with TTP and associated vasculitis. We conducted a literature review using PubMed, Web of Science, congress posters from January 2005 to August 2017 of PTT and ANCA-positive vasculitis.

A control group of MPA without TTP during all the disease follow-up was extracted from the Saint Antoine and Montfermeil Hospital patients with vasculitis. Firstly we compared our PTT cases and the literature review cases and secondary with a control group ANCA vasculitis without MAT.

Results: 8 patients with MAT secondary to ANCA associated vasculitides were included in our French series 75% of Women with a median age 45 years.17–19 positive ANCA in 50% and 37.5% is MPO, BVSA score at 1, FFS at 1. In 10 literature cases 90% Women, a median age 60 years [17–77], positive ANCA in 100% and 30% is MPO, BVSA score at 10, FFS at 1.

The clinical features at the diagnosis of vasculitis were fewer (n=5; 62%), ENT involvement (25%), kidney crescent glomerular involvement (n=1; 12.5%), in one case each Median C3:180 [150–200], C4:140 [100–160], haptoglobin at 0 [0–1], creatinine at 205 [80–757]. ANCA were present in 4 patients (50%), MPO in 3 cases (37.5%). The time between the diagnosis of vasculitis and TTP was 9 months [0–51].

TTP features were: Hb at 7.8 g/dl [4.8–10], LDH at 1658 [777–3110], platelets 33000 [3000–1 25000], haptoglobin at 0 [0–0.05], creatinine at 205 [80–757]. ADAMTS 13 levels were at 10 [1–13], positive ANCA in 50% and 37.5% is MPO, BVSA score at 1, FFS at 1. In 10 literature cases 90% Women, a median age 60 years [17–77], positive ANCA in 100% and 30% is MPO, BVSA score at 10, FFS at 1.

Conclusions: In our case series, the literature patients have similar organs involvement, but median creatinine levels and BVAS levels were higher in the literature cases. Considering TTP features, our cases have less frequent active vasculitis, less important creatinine levels and thus less recus to kidney dialysis.

In vasculitis associated with TTP, there was no significant differences in organ involvements, BVAS and FFS scales values, laboratory data and ANCA levels. Only creatinine as expected was higer in vasculitis associated with TTP (225 Mmol vs 150 Mmol, p=0.004).

FREQUENCY OF PULMONARY HYPERTENSION IN BEHÇET’S DISEASE

B. Armağan1, M. Oksu2, Y.Z. Sener2, A. Sarif2, A. Erden1, G.K. Yardımcı1, L. Kılıç1, U. Kalyoncu1, O. Karadağ1, S. Apras Bilgen1, S. Kiraz1, I. Ertenli1, A. Akdoğan1.
1Hacettepe University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology; 2Hacettepe University Faculty of Medicine, Department of Cardiology, Ankara, Turkey

Background: Behçet’s disease (BD) is a systemic vasculitis that involvement of pulmonary arteries can be seen.

Objectives: The aim of this study was to determine the frequency and the causes of pulmonary hypertension (PH) in patients with BD.

Methods: We studied consecutively 154 BD patients who were fulfilled the International Study Group criteria for diagnosis of BD. All patients were evaluated with transhastoric echocardiography (TTE) for the presence of PH. BD patients were categorised according to the involved organs in 5 groups: group 1 mucocutaneous and articular, group 2 ocular, group 3 vascular, group 4 gastrointestinal and group 5 neurologic involvements. The presence of PH was defined as estimated sPAB ≥40 mmHg. By TTE. Every subject evaluated by a detailed medical history and physical examination was performed. Additional laboratory results were obtained from hospital file records.

Results: The mean age (SD) and the median (min-max) disease duration of the patients were 41.8±12.6 years and 126 (6–540) months respectively. PH was detected in 17 (11%) BD patients. Only 9 (52%) patients were symptomatic (NYHA FC ≥2). Left sided heart disease (Group II: 9 (52%) patients) was the leading cause of PH. Four (23%) patients had group IV PH and 75% (3/4) were symptomatic. Diastolic dysfunction (DD) was found in 32 (20.8%) patients and only 1 patient had systolic dysfunction. The number of patients with BD was significantly higher in patients with PH as compare to patients without PH (8 (47.1%) vs 24 (17.6%), p=0.005). There were no difference in demographic and clinical features of patients with and without PH. Only acenilea lesion was more frequently in patients without PH as compare to patients with PH, p=0.047 (table 1). There were no differences in frequency of PH in BD groups (table 2).

PET/MR IN LARGE-VESSSEL VASCULITIS: CLINICAL VALUE FOR THE DIAGNOSIS AND ASSESSMENT OF DISEASE ACTIVITY

C. Laurent1, L. Ricard1, I. Buvat2, O. Fain1, A. Mekinian1, M. Soussan2, on behalf of French PET–Inflammation Network, 1Internal Medicine, Hôpital Saint-Antoine; 2Nuclear Medicine, Hôpital Avicenne, Paris, France

Background: The diagnosis and the activity determination could be challenging in large-veessel vasculitis (LVV).

Objectives: The aim of this study was to analyze the value of hybrid PET/MR in LVV.

Methods: All consecutive patients with LVV who underwent PET/MR were included. PET/MR patterns were defined as inflammatory in the case of positive PET (grade=3) and abnormal MR (stenosis and/or wall thickening) and fibrous in the case of negative PET (grade 1 or 2) and normal MR.

Results: Thirteen patients with median age at 67 years (23–87 years) and 10% (77%) females were included, and underwent 18 PET/MR scans. Eleven PET/MR performed at diagnosis (n=4) or relapse (n=7) and 7 in patients in remission. 8/18 (44%) had PET/MR inflammatory pattern and 3/18 (17%) had fibrous pattern. PET/MR were normal in 2/10 (20%) cases of TA versus 5/8 (62%) cases of GCA

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2018-eular.8672
The median SUVmax was 3.0 (1.8–8.6) without significant difference between GCA and TA. 3.4 (2.1–8.6) versus 2.6 (1.8–7.1) (p=0.4), respectively. Eleven PET (61%) were performed under treatment, which consisted of steroids with a median dose at 30 mg/day [3–240]. Among 11 patients with active disease, 8 had inflammatory patterns and 3 had normal PET/CT. i.e a sensibility of 73%, and the sensitivity increased to 100% in patients with active TA disease. Median SUVmax were 4.7 [2.1–8.6] in patients with active disease versus 2 [1.8–2.6] in patients with remission (p=0.003).

Conclusions: PET/CT is a new hybrid modality of imaging which is interesting for the diagnosis and the follow-up of large-vessel vasculitis.

PREDICTION OF RELAPSES IN AUTOIMMUNE LARGE-VESSEL VASCULITIS – TOWARDS PERSONALISED IMMUNOSUPPRESSIVE TREATMENT STEWARDSHIP

P.S. Fuchs1, M.B. Bigler2, C. Küng3, T. Manigold4, M. Aschwanden5, D. Staub6, D. Kyburz2, V. Greil7, T. Daikeler8, C.T. Bergner9. 1Clinical and Translational Immunology, 2Translational Immunology, 3Rheumatology, 4Angiology, University Hospital Basel, Basel, Switzerland, 5Computational and Systems Immunology, University of Oslo, Oslo, Norway

Background: Giant cell arteritis (GCA) is an autoimmune disease of the large arteries. Treatment consists in long-term immunosuppression with glucocorticoids (GC). About half of the patients have disease flares ‘relapses’ despite standard therapy. Tocilizumab (TCZ) – an anti-IL6 receptor antibody – is highly effective in reducing relapses, but has high costs.

Objectives: Here, we tested whether the initial clinical presentation and/or immunological findings might predict a GCA patient subset with poor response to GC. These might benefit from early TCZ therapy.

Methods: We performed a chart review on 113 patients from our prospective GCA cohort over the first two years after diagnosis. All had a follow-up of at least three months (median follow-up 24 months, IQR 12.6–24)). Clinical findings at diagnosis, routine labs (at 0, 1, 3, 6, and 12 months) and therapy information (drug and dose) were extracted from the electronic database. Relapses were defined as the presence of GCA-related symptoms (ischaemic pain, polymyalgia (PMR)) and/or elevated systemic inflammation parameters (CRP, ESR) that responded to an increase in GC-dose. GC receptor (GCR) expression levels in T cells were assessed using flow cytometry. Patients were genotyped for two polymorphisms in the Glucocorticoid receptor gene (NR3C1) that have been associated with steroid-responsiveness in other autoimmune disease (Systemic lupus, Pemphigus…).

Results: Over the first 12 months, 50.6% experienced at least one relapse. The majority of relapses occurred after three months of treatment (median time to relapse 102 days, range 19–312). This is when the GC dose is tapered below 20 mg/d. ‘Relapses’ had an average of 1.66 (range 1–4) relapses in the first year. Patients with fever at initial presentation had a 2.2-fold (CI 1.1–5.0) higher risk to experience relapses (p=0.02). Other clinical findings were not associated with subsequent relapses. Low lymphocytes after the first month of therapy was the only lab value associated with relapse free follow up (588/uL vs 1021/uL, p=0.02). This was independent of the cumulative GC dose that ‘non-relapsers’ and 'relapsers' received in this period (1747 mg vs. 1710 mg, p=0.4). Relapsers had lower GCR expression levels, as assessed by flow cytometry.

Conclusions: Fewer, lack of lymphocytopenia after one month of therapy and low GCR expression are risk factors for relapses in GCA. Low GCR expression combined with absence of lymphocytopenia during high dose GC therapy points at a constitutional steroid-resistance in relapers. Whether patient stratification based on these parameters allows to safely adapt (‘personalise’) the intensity and/or duration of GCA treatment needs to be tested in a prospective clinical trial.

CLINICAL PROFILE AND RISK FACTORS OF INFECTIONS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS (AAV) – 18-YEAR DATA FROM A SINGLE TERTIARY CENTRE

C.-H. Hg. Department of Medicine, Queen Elizabeth Hospital, Kowloon, Hong Kong

Background: Despite advances in the treatment of AAV, there are still considerable morbidities related to treatment-related complications. Infection is one of the most commonly encountered problems in patients on immunosuppressive therapy.

Objectives: This single centre, retrospective study reviewed the clinical features and investigated the risk factors for infections among patients with AAV.

Methods: 104 patients with AAV diagnosed between January 2000 and December 2017 in a tertiary hospital were included. Demographic data and clinical parameters were reviewed. Logistic regression was performed to identify factors predicting infections.

Results: Around two-thirds of the 104 patients included were female (63.5% n=66). Mean age at diagnosis was 64.4-year-old. The majority (65.4%, n=68) had microscopic polyangiitis (MPA), 19.2% (n=20) had granulomatosis with polyangiitis (GPA) and 15.4% (n=16) had eosinophilic granulomatosis with polyangiitis (EGPA).

More than half of the patients (58%, n=61) experienced at least one episode of infection and 22% (n=23) had recurrent sepsis during their disease course. Infection was the leading cause of mortality of the 56 deceased patients in this series. Infections were less frequent in EGPA patients compared to their counterparts with MPA and GPA (37.5% vs 61.8%–65%). Most infections were bacterial and multiple-drug resistant organisms were the causative agents in 8 patients. Two had neutropenic sepsis. Three had M. tuberculosis and five had herpes zoster. One had concomitant VZV and pneumocystis jiroveci pneumonitis.

Abstract AB0564 – Table 1.

<table>
<thead>
<tr>
<th>Factors predicting infection</th>
<th>Odds Ratio (p&lt;0.05)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age</td>
<td>1.034</td>
</tr>
<tr>
<td>Renal insufficiency (serum creatinine &gt;140 umol/L) at diagnosis</td>

<tr>
<td>Dialysis support</td>
<td>6.504</td>
</tr>
<tr>
<td>Use of cyclophosphamide as induction agent</td>
<td>2.956</td>
</tr>
</tbody>
</table>

Conclusions: Infections were common and often led to significant morbidities and mortalities among AAV patients. Risk factors included age, renal insufficiency (serum creatinine >140 umol/L) on presentation, disease-related organ failure, need for renal supportive therapy, and the use of cyclophosphamide as induction agent.

AGREEMENT BETWEEN 18-FDG PET/CT AND CLINOMETRIC TAKAYASU ACTIVITY SCORES

D. Hernandez-Lopez1, L.A. Martinez-Martinez1, D. Jimenez-Arenas2, B. Rivera-Bravo3, E. Hernandez-Lemus2, J.A. Barragan-Garlas4, V. Guanier-Lanz1, M. E. Soto-Lopez1, 1Instituto Nacional de Cardiología Ignacio Chavez, 2PET/CT Unit, School of Medicine at National Autonomous University of Mexico; 3Instituto Nacional de Medicina Genómica; 4Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico

Background: The 18-FDG PET/CT is an objective tool employed for the diagnosis of Takayasu arteritis and also is used for the assessment of disease activity of this vasculitis. 1 There are few clinimetric scores developed for Takayasu clinical activity assessment such as the Indian Takayasu Clinical Activity Score (ITAS2010/ITAS.A).2 The National Institutes of Health criteria (NIH score) from USA3 and the Mexican effort by Dabague-Reyes (DR score)4. The validity and
utility of 18-FDG PET/CT to measure the disease activity by studying wall enhancement compared to the clinimetric assessment has been slightly studied.

**Objectives:** To explore the agreement between 18-FDG PET/CT and the clinimetric tests for the estimation of Takayasu activity in one national reference centre.

**Methods:** The clinical records of patients that had performed an 18-FDG PET/CT were consecutively included. The required information to fulfill the ITAS2010, ITAS.A, NIH and DR were gathered from clinical charts. The cut-off points we used are the following: SUVmax ≥ 2.1 for 18-FDG PET/CT, for ITAS2010 ≥ 2 points, for ITAS.A: ≥ 4 points, for NIH: ≥ 2 points and for DR: ≥ 5 points. kappa index was calculated, comparing SUVmax with all the clinimetric measures. As an exploratory exercise, ROC curves were performed. A p value less than 0.05 was considered statistically significant.

**Results:** Thirty six clinical records were reviewed. There was enough information to score ITAS2010 in 31 patients, ITAS.A in 28 patients, NIH and DR in 35 patients each. In our patients, moderate agreement was observed between 18-FDG PET/CT and DR score (Kappa=0.542, p<0.001). A tendency of weak agreement was observed with the NIH score (Kappa=0.215, p=0.086) and ITAS.A (kappa=0.351, p=0.063). There was no agreement with ITAS2010 (Kappa=0.107, p=0.519). Significant AUC were observed with DR (AUC=0.817, p=0.005) and NIH (AUC=0.756, p=0.025); however, this results were not obtained with ITAS2010 (AUC=0.675, p=0.124) and ITAS.A (AUC=0.697, p=0.083).

**Conclusions:** There was no strong agreement between 18-FDG PET/CT and any of these activity indices. On the other hand, these data suggest that the best disease activity tool in Mexican patients were DR and the NIH scores. Comparative studies in other populations are warranted.

**CRYOLOBULIN EVALUATION: ANALYSIS OF INTRA-LABORATORY AND INTER-LABORATORY VARIABILITY**

D. Campioll1, P. Natal1, D. Debbia1, A. Spinelita2, G. Sandri2, C. Cerami2, L. Sicchiolone1, F. Fontana1, MT. Mascia1. 1Department of Laboratory Medicine; 2Chair and Rheumatology Unit, University of Modena and Reggio Emilia, Policlinico of Modena; 3Chair and Nephropathy Unit, University of Modena and Reggio Emilia, Policlinico of Modena, Modena, Italy

**Background:** Cryoglobulins (CRG) are immunoglobulins that precipitate in serum at temperatures below 37°C and resolubilize upon warming. The main reasons of interest of a clinical pathologist in the study of cryoglobulinemia are: 1) lack of standardisation in the preanalytical, analytical and postanalytical phases of the process (classification and reporting); 2) peculiarities of physiopathological mechanism 3) important clinical consequences. Vermeersch et al. studied these issues in 2008. To assess current practice in the detection, analysis, and reporting of cryoglobulins, a questionnaire was sent to 140 laboratories. They showed that only 38% of laboratories used standard procedures of analysis. Consequently, they concluded that standardisation was needed for cryoglobulin detection to avoid missed diagnoses and improve the comparability of results. Sargur et al. in 2010 reviewed the classification and clinical features of cryoglobulins and suggested "best practice" guidelines for laboratory detection and identification of cryoglobulins. They particularly highlighted the relevance of preanalytical and analytical phases: maintenance of the sample at a stable temperature of 37°C, especially throughout the initial steps (collection and transportation); centrifugation and separation methods; cryoprecipitate quantification; cryoprecipitate washing techniques; immunocharacterization of cryoprecipitates especially through immunofixation techniques (considered the "gold standard").

**Objectives:** To verify and assess the variability of laboratory processes of CRG.

**Methods:** We checked laboratory databases of Hospital and University (Lab A and B) of Modena with long tradition in the cryoglobulin analysis (more than 6000 tests from 2002 to 2017). Concerning CRG testing, 734 patient samples were studied in both laboratories. We compared our results according to Brouet classification into subgroups: type I, II and III. Therefore, we evaluated intra-laboratory variability, compared to previous or more frequent results. Finally, we studied inter-laboratory variability based on non-concordant laboratory reports.

**Results:** In the following table, we have represented the comparison between labs about the same patient cohort in 734 patient samples:

<table>
<thead>
<tr>
<th></th>
<th>I type (n)</th>
<th>II type (n)</th>
<th>III type (n)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lab A</td>
<td>21</td>
<td>242</td>
<td>108</td>
</tr>
<tr>
<td>Lab B</td>
<td>42</td>
<td>270</td>
<td>108</td>
</tr>
<tr>
<td>Chi-</td>
<td>p=0.0016</td>
<td>p=0.0004</td>
<td></td>
</tr>
</tbody>
</table>

Intra-laboratory variability: 14% Lab A, 16% Lab B (ns). Inter-laboratory variability: non-concordance in 35% of cases, considering 133 patients studied in both laboratories (Chi-square test).

**Conclusions:** No data about variability in CRG analysis are reported in literature. National and international guidelines are not explicative enough. Furthermore, many doubts about classifications are established. Our experience is unique but limited in two laboratories. Given the variability of testing conditions used in different laboratories and the lack of test standards and reference values, we confirm the need of further investigations into standardisation of CRG testing. New guidelines are fundamental, in order to optimise all phases of CRG research (pre and post analysis) and to ensure correct diagnosis and adequate treatments of the associated diseases.

**DIFFERENT ORBITAL MANIFESTATIONS OF GRANULOMATOSIS WITH POLYANGIITIS. COMPARATIVE STUDY**

D. Iremalova1, I. Abramova2, P. Novikov2. 1Institute of Eye Diseases of Russian Academy of Medical Sciences; 2Rheumatology, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

**Background:** Ophthalmic manifestations are typical for granulomatosis with polyangiitis (GPA), and occur in 28.8%–60% of patients. In 8% of cases they lead to permanent visual loss. According to different studies orbital lesion develops in 5%–30.6% of GPA patients and is considered to be the second most prevalent ophthalmic manifestation after conjunctivitis/episcleritis.

**Objectives:** To study clinical features of different orbital manifestations of GPA.

**Methods:** 74 GPA patients with orbital involvement were studied and compared.

3 types of orbital involvement were proposed: orbital mass (45 patients),...
PREVALENCE AND CLINICAL FEATURES OF CRANIAL AND EXTRACRANIAL GIANT CELL ARTERITIS

E. Fernández1, I. Monjo1, L. Coronel2, D. Benaventi1, A. Balsa1, E. De Miguel1.
1Rheumatology, Hospital Universitario La Paz, Madrid; 2Rheumatology, Hospital Universitario Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, Spain

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in adults. Although it typically affects the cranial branches derived from the aortic arch, there is increasing evidence of the damage occurring to large vessel extracranial arteries, which is usually misdiagnosed. This subset of large vessel extracranial GCA may have specific clinical features that could hinder the diagnosis, which highlights the need for a different treatment and follow-up.

Objectives: To analyse the frequency and clinical and analytical features in cranial and extra-cranial GCA.

Methods: An observational retrospective descriptive study analysing data from patients with GCA who was performed in our hospital. Colour duplex sonography (CDS) studies carried out in the last 29 months were revised. Standardised CDS images from the fronto and parietal branches of the temporal superficial artery (TA) and auxiliary artery (AXE) with GCA compatible image with intra- or extra-cranial involvement (hypoechoic, homogeneous and circumferential thickening of the artery wall >0.34 mm in TA, and >1 mm in AXE, respectively). SPSS version 23 were used to analyse a total of 29 variables.

Results: Out of the 119 patients that were tested in our fast track GCA clinic, with standardised CDS of TA and AXE, 22 had GCA. All GCA patients were hall sign in CDS. From them, 7 had large vessel involvement (31.8%), from whom 6 were mixed and 1 had exclusively extra-cranial involvement. Mean age at diagnosis was 76±9.7 SD in the extracranial GCA arteritis and 79±5.7 SD in the cranial GCA. The extracranial subset had a greater number of men than the cranial (28.6% and 26.6%, respectively) and suffered usually more fewer (28.5% vs 6.6%, respectively), constitutional syndrome (85.7% vs 40%), and polymyalgia rheumatica (42.8% vs 40%, respectively). However, they suffered with more frequency from headache (85.7% vs 93.3%) and jaw claudication (28.5% vs 33.3%). None of them suffered from visual impairment or central nervous system involvement; both did appear in the cranial GCA group in 13.3% and 6.6% in the blood test, mean ±standard deviation was: ESR 87.6±39 mm in cranial GCA and 89.5±19.5 SD mm in extracranial GCA, CRP 65±7.6 and 82.6±48.4 mg/L and Hb 11.4±1.3 and 12.1±1.3 g/dl, respectively. Patients with large vessel involvement met ACR criteria in 80% opposite 92.8% from these with solely cranial GCA. AT biopsy was performed in 7 patients in the cranial subset and 2 in the extra-cranial subset positive for GCA in 5 (71.4%) for the cranial group, and none in the extra-cranial one. CT-PET was performed in 2 patients with cranial GCA with negative results, and in 4 with large vessel involvement, testing positive in 50%. Despite the large differences, the statistical analysis didn’t reach statistical significance due to the small size sample.

Conclusions: One third of the patients in our study had large vessel involvement, making axillary vessel CDS an important tool for the clinical exam of this disease. These patients tend to be younger and start more often with fever or general syndrome and less with GCA typical symptoms like headache, jaw claudication or visual loss.

AB0680 THE ROLE OF ANTI-NEUTROPHIL CYTOPLASMIC AUTOANTIBODY SPECIFICITY FOR MPO OR PR3 IN PHENOTYPE OF ANCA ASSOCIATED VASCULITIS: KNOWING THE AUTOIMMUNITY IN LATIN AMERICA

E. Calle1, M. Calle1, H.B. Cabrera1, D. Jaramillo-Arroyave1,2,4, A.L. Vanegas-García1,4, G. Vásquez-Duque2, M. Restrepo-Escobar3, L.A. González-Naranjo1, H. Hernández-Zapata2, C.H. Muñoz-Vaholo1,5,1 Grupo de Reumatología Universidad de Antioquia, Medellín; 2Universidad CES, Medellín; 3Medicina Interna, Universidad de Antioquia; 4Universidad CES; 5IPS Universitaria Clínica León XIII, Medellín; 6Grupo de Reumatología Universidad de Antioquia, Medellín; 7Hospital Universitario San Vicente Fundación, Medellín, Colombia

Background: Antineutrophil cytoplasmic antibodies (ANCA) are present in up to 90% granulomatosis with polyangiitis, 80% microscopic polyangiitis and 70% eosinophilic granulomatosis with polyangiitis. MPO-ANCA has been associated with vasculitis limited to the kidney, chronic renal damage and less frequent gastrointestinale or respiratory tract involvement. PR3-ANCA are characterised by destructive lesions of the ears, nose and throat, alveolar haemorrhage,combination of upper and/or lower respiratory tract involvement with renal compromise and increased number of relapses. The frequency of pulmonary involvement is similar in both serotypes, and most ANCA associated vasculitis (AAV) patients are diagnosed between ages 50 and 70 years.

Objectives: To describe differences in clinical profiles of patients with AAV regarding ANCA specificity against MPO or PR3 in a Colombian based adult population

Methods: All medical records of patients with a diagnosis of AAV in two high complexity hospitals in Medellín, Colombia from January 1, 2014 to December 31, 2016 were reviewed. The clinical and demographic characteristics were abstracted and analysed with descriptive and inferential statistics in SPSS 22.

Results: Of 59 cases of AAV, 44 were positive for MPO or PR3-ANCA with male predominance (65.5% men vs 34.5% women) and similar age at diagnosis (47 years in MPO-ANCA vs 50 in PR3-ANCA). MPO-ANCA group had more fever and weight loss (34.8% vs 20%), arterial hypertension (34.5% vs 26.7%), hematuria (34.5% vs 26.7%), proteinuria (31% vs 26.7%), creatinin higher than 5.6 mg/dL (20.7 vs 13.3%), myalgias (13.8% vs 0%) pachymeningitis (7% vs 0%) and skin compromise. PR3-ANCA patients had more arthritis/arthralgias (40% vs 31%), escleritis (33% vs 13.8%), epiclesis (13.3% vs 0%) and uvetitis (10% vs 7%).

Conclusions: In this Latin American population ANCA specificity affected the phenotype of clinical disease. MPO-ANCA patients had more constitutional symptoms, renal and central nervous system compromise while PR3-ANCA patients showed more acicular and ocular involvement.

AB0661 ASSESSMENT OF DAMAGE AND PROGNOSIS IN PATIENTS WITH ADULT IGA VASCULITIS: RETROSPECTIVE MULTICENTERED COHORT STUDY

F. Albiz-Once1, A. Omma2, A. Saní1, Ó. Gazel1, Ó. Üsküdar Cansu1, A. Yazıcı2, A. Cefe3, C. Bex1, Ö. Karadağ1, H. Direksen1,1 Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey; 2Rheumatology, Ankara Numune Research and Training Hospital, Turkey; 3Rheumatology, Hacettepe University, School of Medicine, Ankara, Turkey; 4Rheumatology, Osmanagazi University, School of Medicine, Eskişehir, Turkey; 5Rheumatology, Kocate University, School of Medicine, Kocaeli, Turkey; 6Rheumatology, Bakırköy Sadi Konuk Research and Training Hospital, Istanbul, Turkey

Objectives: IgA Vasculitis is a leukocytoclastic vasculitis involving small vessels with depositions of immune complexes containing IgA. IgA Vasculitis is a predominantly paediatic vasculitis. There is limited data for the prognosis of adult IgA Vasculitis, with also no damage assessment. In this study, we aimed to evaluate

Disclosure of Interest: None declared

the clinical characteristics, treatment, outcome and damage of patients with adult
IgA Vasculitis.

Methods: We assembled a retrospective cohort of patients with adult IgA Vasculi-
tis from tertiary Rheumatology Centres in Turkey. The demographics, clinical
characteristics, treatment and outcomes of patients were abstracted from medical
records. Birmingham Vasculitis Activity Score (BVAS), prognostic Five Factor
Score (FFS) and vasculitis damage index (VDI) were calculated.

Results: The study included 103 (male/female: 67/36) patients with adult IgA Vasculitis. The mean age was 42.6±17 years. Infection history within 6 weeks
before presentation was present in 40 (38.8%) patients (32 upper respiratory tract, 3
urinary tract, 2 gastrointestinal, 3 others). Cutaneous manifestations and arthri-
tis/arthritis were the most common clinical manifestations (table 1). 92 (89.3%)
patients were treated with oral glucocorticoids (GC). Pulse GC treatment was also
given to 29 (28.1%) patients. As additional immunosuppressive agents, azathiop-
rine was given to 36 (34.9%) and pulse cyclophosphamide to 13 (12.6%) patients.
Fifty-nine patients (58.2%) had follow-up of mean 35.6 months. Eleven
(18.6%) patients relapsed during follow-up. While 5 relapses were major, six of
them were minor relapses. At the last visit, disease status was evaluated as active
or treatment failure by the treating physician in 7 (11.8%) patients. The rate of
chronic renal failure was 8.3%(n=5). Mortality was 1.6% (n=1) during follow-up,
due to pneumonia. The mean VDI score was 0.3 in the last visit. Twelve (20.3%)
patients had at least one damage item at the end of follow-up period.

Conclusions: Our results showed that approximately one fifth of patients with
adult IgA Vasculitis had relapses during follow-up and had at least one damage
item at the end of follow-up. Although, 31% of patients had FFS>1, the mortality
rate was observed to be very low in the present study.

SUBCLOTTIC STENOSIS IN GRANULOMATOSIS WITH POLYANGITIS

C.E. Pena1, F. Giordano2, L. Garcia1, C. Costi1, G. Pendon2, A. Vulcano1, D. Pereira3, M. Garcia1,2, Rheumatology, HIQA San Martin La Plata, Roma1,2, Rheumatology, Hospital Gutierrez La Plata, La Plata, Argentina

Background: The characteristic lesion of laryngotracheal involvement in granu-
lomatosis with polyangiitis (GPA) is subglottic stenosis (SGS), due to active dis-
ease or from chronic recurrent inflammation, 8% to 23% during the course of GPA
and as initial manifestation in 1% to 6% of cases.

Objectives: Describe clinical features and treatment of patients with SGS

Methods: We retrospectively reviewed the medical records of 46 patients with
SGS due to GPA diagnosed at a Rheumatology department (2000–2017). We
retrospectively reviewed the medical records of 46 patients with SGS due to

Results: 6/46 patients with GPA diagnosis presented SGS (13%). 83% women,
mean age of 37.8 years (DS ±14.8). Mean time between the presentation of the
GPA and the diagnosis of SGS: 18 months. Most frequent clinical manifestations of
SGS: dyspnea (83%), stridor (83%), dysphonia (50%), cough (33%), broncho-
spasm (16%). One patient presented SGS as initial manifestation of the disease.
Mean BVAS:14. Two patients presented such complication with evidence of sys-
temic manifestations. Re stenosis was observed in one patient.

Treatment: IV CYC 83%, oral CYC 16%, methylprednisolone (MP) 83%, oral ste-
roids, plasma exchange (16%) in each one. Endoscopic intervention and balloon
dilatation33%, and intralesional Mitomycin 16%.

Conclusions: 13% patients with GPA presented SGS, being in the majority of
cases associated with other manifestations of the disease. However, 67%had no
signs of systemic involvement (localised disease). Local treatment was necessary
in only 33% because there was a good response to IS in 67% of the cases.

18F-FDG-PET/CT DISEASE DISTRIBUTION IN A LARGE VESSEL VASCULITIS COHORT – SUPPORTS VASCULAR ULTRASOUND AS A SCREENING AND DIAGNOSTIC TOOL

E. Cothi1, F. Laskou1, S. Moghui2, A. Sidhu1, S. Banerjee1, T. Aung1, S. Jain2, J. Mo2, B. Dasgupta1, Rheumatology, 2Radiology, Southend University Hospital, Westcliff-On-Sea, UK

Background: Subsets of GCA have extensive vascular involvement, termed
Large Vessel GCA (LV-GCA), seen in 12%–37% depending on imaging used. These
patients have higher relapse rates and are more often refractory to gluco-
corticoids (GC), requiring steroid-sparing treatment to minimise GC toxicity and
vascular complications. Diagnosis is reliant upon imaging, given the relative inac-
cessibility of tissue for histological analysis beyond temporal artery biopsy (TAB).
If axillary and subclavian arteries are often affected, vascular ultrasound could be
an effective screening tool.

Objectives: To determine disease distribution in the Southend Large Vessel Vas-
culitis (LVV) cohort, particularly levels of axillary and subclavian involvement.

Methods: The cohort has sixty-five patients (2010–2017), from which sixty 
18F-FDG-PET/CT scans were performed. They were retrospectively examined by two
nuclear radiologists. Vascular involvement was determined by consensus opinion
at six territories (thoracic-aorta, abdominal-aorta, subclavian, axillary, carotid, ver-
tebral, and iliac and femoral). Six negative scans were excluded from analysis,
vascular complications. Diagnosis is reliant upon imaging, given the relative inac-
cessibility of tissue for histological analysis beyond temporal artery biopsy (TAB).
If axillary and subclavian arteries are often affected, vascular ultrasound could be
an effective screening tool.

Objectives: To determine disease distribution in the Southend Large Vessel Vas-
culitis (LVV) cohort, particularly levels of axillary and subclavian involvement.

Methods: The cohort has sixty-five patients (2010–2017), from which sixty
18F-FDG-PET/CT scans were performed. They were retrospectively examined by two
nuclear radiologists. Vascular involvement was determined by consensus opinion
at six territories (thoracic-aorta, abdominal-aorta, subclavian, axillary, carotid, ver-
tebral, and iliac and femoral). Six negative scans were excluded from analysis,
with LVV confirmed from other evidence (ultrasound, computed tomography). Of
these, four were on concurrent GC (7–12 mg prednisolone), raising the possibility
of “false negatives”. Nineteen scans were positive despite GC (1–60 mg prednisol-
one). Higher doses tended to be of short duration, being unable to postpone due
to clinical necessity, but exceeded the 3 day limit at which FDG signal starts to
attenuate.

Abstract AB0663 – Figure 1. Disease distribution via 18F-FDG-PET/CT

Results: 14.8% (n=8) had isolated supra-aortic disease, 14.8% (n=8) had iso-
lated aortic disease, and 29.6% (n=16) had involvement in both (Fig 1). 72.2% of
LIFE EXPECTANCY IN PATIENT WITH GIANT CELL INTERSTITIAL LUNG DISEASE AMONG PATIENTS WITH GCA

Background and purpose: Several epidemiologic studies reported increased mortality in patients with GCA, while others found that the overall survival was essentially identical to that of the general population. Those studies used different methods to calculate the mortality rates.

Objectives: In this retrospective study we evaluated longevity in a group of GCA patients using specific gender and age-matched life expectancy tables.

Methods: Medical records of patients diagnosed with GCA in one Medical Centre between 1980–1999 were reviewed for clinical parameters at the time of diagnosis and during the first year of treatment, and for time of death and cause of death. For each patient the observed survival was compared with the specific age and gender-matched life expectancy in the general population, based on life expectancy tables of the Israel Central Bureau of Statistics.

Results: 87 patients (51 females, 36 males) were included, their mean age at the time of GCA diagnosis was 73.9±8.4 and 75±8.1 years, respectively. The calculated mean life expectancy for this group of patients, from the time of diagnosis and during the first year of treatment, was significantly shorter, 7.5±6.2 years (p<0.001) in females, and 7.7±7.3 years (p=0.005) in males. Survival was significantly shorter, 7.5±6.2 years (p<0.001) in females, and 7.7±7.3 years (p=0.005) in males. Survival was not significantly affected by the intensity of inflammation at the time of diagnosis (based on the presence of fever, anaemia, sedimentation rate above 100 mm/h, thrombocytosis and leucocytosis), by the daily dose of prednisone at 1 year, or by the use of low-dose aspirin during the first year. However, vision loss at the time of presentation (n=13), was associated with further decrease in survival, 4.1±3.4 years compared to 8.3±6.8 years in GCA patients with no vision loss (p=0.035). Causes of death were defined in 54 further decrease in survival, 4.1±4.4 years compared to 8.3±6.8 years in GCA patients with no vision loss (p=0.035). Causes of death were defined in 54.

Conclusion: Infectious diseases were often the cause of mortality In this group of GCA patients, relative to the background population. Survival following GCA diagnosis was significantly shorter than expected, especially in patients presenting with vision loss.

AB0665 INTERSTITIAL LUNG DISEASE AMONG PATIENTS WITH GIANT CELL ARTERITIS

H. Tamaki1, T. Jinta1, M. Okada1. 1Immuno-Rheumatology Center, St Luke’s International Hospital, 2Pulmonary Medicine, St Luke’s International Hospital, Tokyo, Japan

Background: Lately interstitial lung disease (ILD) has been recognised more and more as a manifestation of primary systemic vasculitis, particularly among patients with microscopic polyangiitis (MPA), which is predominantly a disease of the elderly in Japan. Another primary systemic vasculitis that occurs frequently in
the elderly is Giant Cell Arteritis (GCA) and one of the unusual manifestations of GCA includes non-productive cough that can occur in about 10% of patients. It is speculated that vasculitis in the area of cough receptors results in this manifestation. There have been only anecdotes about the association of GCA with ILD and it is unknown whether ILD is truly prevalent in patients with GCA.

Objectives: Here we systematically reviewed chest images of patients with GCA and investigated the prevalence of CT scan abnormality consistent with ILD among patients with GCA.

Methods: Single centre retrospective chart review was conducted at St. Luke’s International Hospital in Tokyo. The charts of patients with the diagnosis of GCA who were seen from March 2004 till August 2017 were extracted. The clinical data were obtained. Pulmonary images were reviewed by one of the authors, who is a pulmonologist and characteristics of the pulmonary lesions based on computed tomography (CT) of the lung were recorded.

Results: Forty-six patients had a diagnosis of Giant Cell Arteritis. Thirty-nine of them had a chest CT scan. The mean age of the patients was 69±17 years and 27 patients (58%) were female. Ten patients (26%) had abnormality in the CT scan. The abnormality included linear infiltrates beneath the posterior aspect of the pleura in the lung bases (n=9), ground glass opacities (n=3), honeycombing (n=3), and reticulonacular infiltrates (n=2). Two patients received prednisolone for ILD, ILD of whom were stable. No patients died during the median follow up of 14.5 months.

Conclusions: Chest CT abnormality consistent with mild ILD was prevalent among patients with GCA. The prognosis of these patients appears to be favourable and these patients responded to prednisolone.

Disclosure of Interest: None declared

Diagnosis

- Biopsy proven: 2/22 9.09%
- PET positivity: 12/20 60.0%
- ESR: 30.9±9.0
- GC therapy: 21.3%
- Oral steroids (mg/day): 33±30.0
- Dose of oral prednisone (mg/day): 49.7±53.1
- First line immunosuppressive therapies: 62.3%
- Methotrexate (mg/week): 11±23.3
- Methotrexate (mg/week): 16.7±7.5
- Mycophenolate (mg/day): 6±18.1
- Methotrexate (mg/week): 2.3±5.6

Conclusions: This retrospective study confirms the efficacy of biological therapies in the management of GCA. Besides, in our experience TCZ allowed a significant reduction of GCs use, especially in the first month of therapy, when compared to standard GCs-based regimens.

Abstract AB0667 – PREGNANCY OUTCOMES IN A TERTIARY TAKAYASU ARTERITIS CARE CENTRE

L.E. Szabo1, M.M. Tamás1,2, L. Damian1, I. Filipescu1,2, I. Dobrota1, S. Rednic1,2.
1Department of Rheumatology, Emergency Clinical County Hospital; 2Department of Rheumatology, Iuliu Hatageanu University of Medicine and Pharmacy, Cluj-Napoca, Romania

Background: Fertility and pregnancy are concerning issues in women of childbearing age with Takayasu arteritis (TA). Available data on the management and expected events in TA during pregnancy are sparse and inconsistent among study populations.2,3 Conflicting reports exist on both favourable pregnancy outcomes as well as increased fetal or maternal complications.1,4

Objectives: To assess the obstetric and maternal outcomes in a tertiary center TA cohort.

Methods: 15 female patients fulfilling the American College of Rheumatology 1990 criteria for the classification of TA were included in this retrospective study. Data regarding number of pregnancies, disease characteristics and pregnancy related events were gathered from medical records. Disease extent was classified according to Numano classification criteria for TA: type I (4 patients, 26.66%), type III (4 patients, 26.66%), type V (3 patients, 20%), type IV (2 patients, 13.33%), type IIa (1 patient, 6.66%), type IIb (1 patient, 6.66%). The prevalence of obstetric and maternal complications was evaluated in women before or after TA diagnosis. 6 patients were further excluded due to the paucity of information concerning pregnancy outcomes.

Results: A total of 15 pregnancies were identified in 9 patients, with 9 (60%) occurring before TA diagnosis – group 1, and 6 (40%) occurring concomitant with or after TA diagnosis – group 2. In the first group the extent of arterial involvement was mostly consistent with type I TA (6 pregnancies, 66.66%). No fetal or maternal complications were observed in this group. Type III TA was most commonly encountered (4 pregnancies, 66.66%) in group 2. Only one patient from the second group had more than 1 pregnancy after TA diagnosis. Active disease (National Institutes of Health/NIH score >1) was reported in 2 (33.33%) pregnancies in the second group. Cardiovascular events occurred exclusively during 2 (33.33%) pregnancies exhibiting active disease. One patient suffered severe aortic regurgitation and gestational hypertension during pregnancy, while the second patient experienced worsening of preexisting hypertension. These required steroid dose increase and addition of antihypertensive drugs. There were no obstetric events in group 2.

Conclusions: Most TA pregnancies are uneventful, bearing favourable fetomaternal outcomes. However, pregnant TA patients with active disease, have higher risk of developing maternal complications, especially cardiovascular events. In this setting, close monitoring and disease remission should be maintained during pregnancy.

AB0668 TREATMENT OF THROMBOTIC EVENTS IN BEHÇET DISEASE: A SYSTEMATIC LITERATURE REVIEW

I. Janta, R.D. Gonzalez Benitez, B. Serrano Benavente, I. Monteagudo Saez. Rheumatology, Gregorio Marañón General Hospital, Madrid, Spain

Background: Behçet’s disease (BD) is a systemic disease which etiopathogenesis is largely unknown. It is characterised by a wide variety of clinical manifestations. Venous disorder is a serious manifestation being potentially life-threatening. There is little evidence on the management of the venous complications in BD.

Objectives: To perform a systematic literature review on the treatment used in venous thrombotic events in BD.

Methods: The objective was reformulated according to the PICO approach. Several synonyms for the main components (i.e. Behçet, thrombosis, treatment) were used. Search limits were applied for humans. The literature search was performed in Medline and Embase from databases inception to 1st November 2017. Only articles in English and Latin languages were retained. We excluded abstracts, reviews and letters. From the selected studies, data about the venous involvement and treatments were retreived using a predefined data collection form.

</table>

Results: The literature search resulted in 1552 articles, of which 632 were captured in Medline and 920 in Embase. Figure 1 shows the study flow-chart for article selection. The main reasons for article exclusion after full-text review were the lack venous involvement and the lack of explanation of venous involvement treatment. 28 articles reporting 1904 patients were included in qualitative analysis. The mean (range; SD) duration time between the disease onset and the vascular onset was evaluated in 15 articles and was 4.9 (1.2–9.3; 2.7) years. Superficial thrombosis was evaluated in 6 (21.4%) articles, profound thrombosis in 19 (67.9%) articles, cerebral in 7 (25%), inferior or superior cava vein in 15 (53.6%) and Budd-Chiari syndrome in 8 (28.6%) articles. Table 1 shows the treatments described in the selected articles. Treatment response was evaluated in 6 (21.4%) articles; in 7 of these treatments response was evaluated in a subjective way. In total, 52 (2.7%) deaths were reported in relation to BD. In 319 (16.7%) patients, partial efficacy or recurrence of thrombosis was reported. Considering the heterogeneity of the reported data and the variability in the measures of treatment response, predictors of mortality risk cannot be analysed. However, in the reviewed articles, a higher mortality rate was observed in patients with hepatic involvement due to Budd-Chiari syndrome. We have also observed a higher risk for the development of venous thrombosis in patients with pathergia phenomenon and male sex. Two studies suggested that immunosuppressive treatment concomitant with anticoagulant treatment is associated with a lower risk of thrombosis relapse compared with anticoagulant treatment alone.

Conclusions: There is a great variability in the treatment of venous thrombosis related to Behçet’s disease. Budd-Chiari syndrome seems to be related to a worse prognosis of the disease.

Disclosure of Interest: None declared

AB0669 MAINTENANCE TREATMENT WITH ADALIMUMAB IN REFRACTORY UVEITIS DUE TO BEHÇET’S DISEASE: OPTIMISED VS NON-OPTIMISED GROUP

Background: Uveitis is the most common ocular manifestation in Behçet’s Disease (BD), which can cause irreversible blindness.1-2

Objectives: To assess efficacy, safety and cost-effectiveness of adalimumab (ADA) therapy optimisation in a series of patients with uveitis due to BD.

Methods: Multicenter study of 74 ADA-treated patients with BD uveitis refractory to conventional immunosuppressants. Following remission, optimisation was performed by increasing the ADA dosing interval. Comparison between optimised and non-optimised group was performed.

Results: Ocular remission was achieved in 65 (86.6%) patients after a median ADA duration of 6–12 months. ADA was optimised in 23 cases. In the remaining 42 ADA was maintained at 40 mg/sc/2 weeks. No baseline differences were found at ADA onset between the optimised and non-optimised groups. Ocular outcomes were similar after a mean ±S.D. follow-up of 34.7±13.3 and 26±21.3 months in the both groups (table 1). Adverse effects were seen in non-optimised group (lymphoma, pneumonia, local reaction and bacteremia). Mean ADA duration of 63 months in the both groups (table 1). Adverse effects were seen in non-optimised group (lymphoma, pneumonia, local reaction and bacteremia). Mean ADA duration of 63 months (49.4, 51.9–71.4) years. Superficial thrombosis was evaluated in 6 (21.4%) articles, profound thrombosis in 19 (67.9%) articles, cerebral in 7 (25%), inferior or superior cava vein in 15 (53.6%) and Budd-Chiari syndrome in 8 (28.6%) articles. Table 1 shows the treatments described in the selected articles. Treatment response was evaluated in 6 (21.4%) articles; in 7 of these treatments response was evaluated in a subjective way. In total, 52 (2.7%) deaths were reported in relation to BD. In 319 (16.7%) patients, partial efficacy or recurrence of thrombosis was reported. Considering the heterogeneity of the reported data and the variability in the measures of treatment response, predictors of mortality risk cannot be analysed. However, in the reviewed articles, a higher mortality rate was observed in patients with hepatic involvement due to Budd-Chiari syndrome. We have also observed a higher risk for the development of venous thrombosis in patients with pathergia phenomenon and male sex. Two studies suggested that immunosuppressive treatment concomitant with anticoagulant treatment is associated with a lower risk of thrombosis relapse compared with anticoagulant treatment alone.

Conclusions: There is a great variability in the treatment of venous thrombosis related to Behçet’s disease. Budd-Chiari syndrome seems to be related to a worse prognosis of the disease.

AB0670

SHORT AND LONG-TERM TREATMENT WITH INFliximAB IN Retinal Vasculitis of BehÇet’s Disease. MULTICENTER Study of 72 Patients

Background: Retinal vasculitis (RV) is a serious complication of uveitis due to Behçet’s disease (BD). 1–3

Objectives: We assess the short/long-term efficacy of Infliximab (IFX) in refractory RV of BD.

Methods: Multicenter study of patients with RV of BD refractory to corticosteroids and at least 1 conventional immunosuppressant (IS). We compared efficacy of IFX between baseline, 1st week, 6 months and 1–6 years in PMR patients.

Results: 72 patients/129 affected eyes (40/43) with mean age of 39.6±9.7 years. HLA-B51 was (+) in 63%. Before IFX onset, patients had received: oral/e.v. glucocorticoids (n=98), CyA (n=56), AZA (n=43), MTX (n=34) and other IS (n=22). IFX was used as monotherapy in 17 patients and combined with conventional IS in the remaining 55. IFX dose was as follows: 3 mg/kg/4–8 w (n=5), 4 mg/kg/4 w (n=1), 5–5.5 mg/kg/4–8 w (n=66). Following IFX onset, an improvement in RV was seen, as well as in the other ocular outcomes. This enhancement was maintained (table 1). After a mean follow-up of 26.5±2.1 months, IFX was discontinued in 44; remission (n=15), primary failure (n=16), preference of another route of administration (n=8), pregnancy (n=1) and adverse effects (n=4).

Abstract AB0670 – Table 1

Conclusions: IFX seems an effective short/long-term treatment in RV of BD.

FIRST DOCUMENTATION OF R53PE AFFECTING THE HANDS ON 18F-FDG WHOLE BODY PET/CT IN POLYMYALGIA RHHEUMATICA

C.E. Owen1,2, A.M. Poort3,2, L.P. Yap, J.L. Leung2,3, D.F. Lieuw2,3, S.T. Lee2,3,5, A. M. Scott-Scott2,3,5, R.R. Buchanan1,2, R. Rheumatology, Austin Health, Heidelberg VIC; *University of Melbourne, Parkville VIC; †Molecular Imaging and Therapy; ‡Radiology, Austin Health; †Olivia Newton-John Cancer Research Institute, Heidelberg VIC, Australia

Background: Remitting seronegative symmetrical synovitis with pitting oedema (RS3PE) syndrome describes a clinical entity characterised by distal synovitis with pitting oedema, the absence of rheumatoid factor (RF) and an excellent response to glucocorticoid therapy. 1 Most frequently associated with polymyalgia rheumatica (PMR), tenosynovial shear inflammation represents the magnetic resonance imaging (MRI) hallmark of this condition, with concomitant joint synovitis also present in some cases. 2 More recently, diffusely increased 18F-fluorodeoxyglucose (18F-FDG) uptake in the soft tissues surrounding the ankles and feet has been described as the correlate of RS3PE on whole body positron emission tomography/computed tomography (PET/CT). 3,4

Objectives: To document the clinical and radiologic appearance of RS3PE syndrome affecting the hands on MRIs between 1st week, 6 months and 1–6 years.

Methods: Patients with newly diagnosed PMR were prospectively recruited as part of the Melbourne Predictors of Relapse in PMR (MPR-PMR) study. A standard physical examination was carried out with specific focus upon the presence of peripheral synovitis and pitting oedema. In patients with findings suggestive of RS3PE, clinical photography was undertaken. All study participants underwent a whole body PET/CT scan including dedicated views of the hands using the Ethris 2 T/F machine prior to prednisolone commencement. To precisely identify anatomic correlates of abnormal 18F-FDG uptake in patients with RS3PE, MRI of the wrist and hand was performed using a 1.5 Tesla magnet.

Results: 3/35 patients (8.6%) were noted to have distal synovitis and pitting oedema of the hands at enrolment. Mean age was 70.9±10.1 years, two patients were male, and all were Caucasian. RF and anti-citrullinated peptide antibody (ACPA) bodies were negative in all cases. On whole body PET/CT, intense 18F-FDG uptake was visualised at the wrist joint and hand in a distinctive volar distribution. MRI of the wrist and hand in two participants (contraindicated in the third)
confirmed flexor tenosynovitis (white arrows) and intercarpal synovitis (yellow arrow) in keeping with RS3PE syndrome.

Abstract AB0671 – Figure 1

Conclusions: On whole body PET/CT, RS3PE syndrome is associated with a distinctive volar pattern of abnormal 18F-FDG uptake at the wrist and hand, which correlates with flexor tenosynovitis and intercarpal synovitis as previously described on MRI.

18F-FDG WHOLE BODY PET/CT AS A DIAGNOSTIC TEST FOR POLYMYALGIA RHEUMATICA IN PATIENTS WITH NORMAL INFLAMMATORY MARKERS

C.E. Owen1,2, E. Martin1, A.M. Poore2,3, J.L. Leung1,2, D.F. Liew1,2, S.T. Lee2,3,4, A.M. Scott2,3,4, R.R. Buchanan1,2. 1Rheumatology, Austin Health, Heidelberg VIC; 2Medicine, University of Melbourne, Parkville VIC; 3Molecular Imaging and Therapy, Austin Health; 4Olivia Newton-John Cancer Research Institute, Heidelberg VIC, Australia

Background: Despite abnormal C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) being required in the 2012 EULAR/ACR classification criteria, 7%–20% of polymyalgia rheumatica (PMR) patients possess normal inflammatory markers at diagnosis. A characteristic pattern of 18F-fluorodeoxyglucose (18F-FDG) uptake is seen on whole body positron emission tomography/computed tomography (PET/CT) in PMR, hence this imaging modality may be a useful diagnostic test in this clinical scenario.

Objectives: To report the utility of whole body PET/CT for diagnosing PMR in patients with normal inflammatory markers and compare the clinical and radiologic characteristics of this subgroup with patients from the Melbourne Predictors of Relapse in PMR (MPR-PMR) study.

Methods: Patients presenting with clinical features of PMR according to the 2012 EULAR/ACR classification criteria but normal CRP and ESR underwent 18F-FDG PET/CT as part of their diagnostic work-up. A whole body scan from skull vertex to feet (including dedicated hand views) was performed using the Phillips T9 machine prior to prednisolone commencement. Quantitative and semi-quantitative (standardised uptake value maximum [SUVmax]) scoring of abnormal 18F-FDG uptake was undertaken. Newly diagnosed and untreated PMR patients who underwent the same 18F-FDG PET/CT protocol as part of the MPR-PMR study were used as the comparator group. Statistical analysis was conducted using Stata 13.1 (StataCorp, College Station, TX, USA).

Results: Three patients with normal inflammatory markers (Median CRP 1 [0.9–2], median ESR 61–7) underwent 18F-FDG PET/CT. Mean age was 60.15±7.55 years, two patients (66.67%) were male and all were Caucasian. Shoulder and hip pain was present in all cases, but only one patient reported peripheral joint involvement. Median early morning stiffness (EMS) was 30 min. On whole body PET/CT, characteristic 18F-FDG uptake was visualised in each patient at the shoulder capsule, trochanteric bursae and adjacent to the ischial tuberosities, with hip capsule involvement similarly present in 2/3. When compared with 35 patients from the MPR-PMR study, there were no statistically significant differences in the clinical characteristics nor the distribution or intensity of abnormal 18F-FDG uptake between the two populations.

Conclusions: In patients with suggestive clinical features but normal inflammatory markers, whole body PET/CT may be utilised to confirm a diagnosis of PMR.

ANCA-ASSOCIATED VASCULITIS AND INFECTIONS: RETROSPECTIVE ANALYSIS IN A REFERRAL CENTRE

J. Álvarez Troncoso, Z. Iannaccone, E. Álvarez Valiente, C. Busca Arenzana, L. Ramos Ruperto, G. Daroca Bengoa, J. Vasquez Manau, F. Amarcha Fernández, J.J. Rios Blanco. Internal Medicine, Hospital Universitario La Paz, Madrid, Spain

Background: The antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are rare multisystem autoimmune diseases of unknown cause, characterised by inflammatory cell infiltration causing necrosis of blood vessels. The AAV comprise granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA). The AAV are autoimmune diseases with potentially severe systemic involvement that require prolonged immunosuppressive therapy. Infection is a frequent complication in AAV and is associated with increased morbidity and mortality.

Objectives: The aim of this study was to define epidemiology, ANCA patterns, treatments, infections and outcomes of a series of 39 patients with AAV.

Methods: We retrospectively analysed 39 patients diagnosed with AAV between 1995 and 2017 from the Internal Medicine Department of a Spanish referral centre.

Results: A total of 39 patients were reviewed. 23 female (58.9%). Mean age at diagnosis was 55.6 years. Median time delay to diagnosis was 7.6 weeks. Median follow-up was 91.3 months. Most frequent AAV was MPA with 16 patients (46.2%), followed by GPA with 1 (28.2%) and EGPA with 10 (25.6%). 6 patients (15.4%) had a concomitant autoimmune disease: Systemic sclerosis, Antiphospholipid syndrome, Lupus and Sjögren. Only 2 patients (5.1%) had previous infection with hepatitis C virus. Regarding the treatments, all patients received corticoids (bolus 24 patients, 61.5%), 29 (74.4%) cyclophosphamide, 10 (25.6%) rituximab, 19 (48.7%) azathioprine, 4 (10.3%) mycophenolate and 1 (2.6%) methotrexate. 16 patients presented post-treatment lymphopenia, 19 (48.7%) azathioprine and 1 (2.6%) methotrexate. 16 patients presented post-treatment lymphopenia, 5 (12.8%) presented any infection after the diagnosis. The most frequent were bacterial infections (15 patients), presenting 9 patients with sepsis criteria (7 due to gram-negative organisms). 9 opportunistic infections were described: 3 infections by cytomegalovirus, 5 by tuberculosis and 1 by Mycobacterium avium. There were no cases of Pneumocystis jiroveci despite the fact that only 16 patients (41%) performed primary prophylaxis. The factors associated with increased risk of infections were: lymphopenia, pancytopenia and increased BVAS (p=0.05). 6 patients had died at the time of the study (3 associated with infections, 2 with neoplasms and 1 directly with AAV). The Charlson index performed at the time of the study was the best predictor of mortality (p<0.01).

Conclusions: Infections were a frequent complication in patients with AAV and one of the main causes of mortality. Risk factors were lymphopenia, pancytopenia and increased BVAS. Bacterial infections were the most frequent but opportunistic infections must be taken into account.

RISK FACTORS OF ATHEROSCLEROSIS IN PATIENTS WITH TAKAYASU’S ARTERITIS

J. Du, Beijing Anzhen Hospital, Beijing, China

Background: The incidence of atherosclerosis (As) in Takayasu’s arteritis (TAK) was significantly higher than that of other people of the same age and gender. The incidence of carotid artery plaque in TAK patients was 27%, while only 2% of the age and sex matched controls were in the control group. Autopsy confirmed that atherosclerotic lesions were found in arterial wall in TAK. Inflammation of the vascular wall may promote As in TAK, which may be related to the disorder of lipid metabolism disorder, which accelerates the development of As. The ratio of low-density lipoprotein cholesterol (LDL-C)/high-density lipoprotein cholesterol (HDL-C) predicted As progression better that LDL-C or HDL-C alone. Higher triglyceride (TG)/HDL-C ratio was found to be associated with presence of endothelial dysfunction and As.

Objectives: The aim of this study is to investigate the clinical manifestations, serological and imaging features in TAK with As and non-As, to find the risk factors of As in those patients.

Methods: A retrospectively study of 105 patients in TAK were divided into 2 groups according to with or without As. We compared the difference of general information, traditional risk factors, disease activities and imaging features between 2 groups. Logistic model were used to determine the risk factors of As in TAK patients.

Results: In this study, 53 patients (50.48%) with TAK were had As. The duration of disease in TAK patients with As significantly longer than non-As group (p=0.011). LDL-C/HDL-C ratio in TAK with As significantly higher than non-As patients (p=0.025). Serum level of CRP in TAK with patients lower than non-As patients. In disease activities, there were no differences in Kerr score and ITAS between 2 groups. The traditional risk factors of As in two groups were compared, hypertension (p=0.001) and family history of As (p=0.012) were all higher in As group than non-As group. In As group, most common angiographic type was Numano type V, which was higher than in non-As patients (58.49% vs 38.46%, p=0.040). Logistic regression showed the age above 40 years old is 5.196 times higher in the patients who are under 40 (p=0.009; CI: 1.843–14.648) to develop to As. The incidence of As increased by 2.945 times every 5 years (p=0.002, CI: 1.431–6.062). History of hypertension has more risk to As (p=0.029, OR=4.088, p=0.002). More important, the LDL-C/HDL-C ratio was above the predicted cut-off value 3.038, the incidence of As increased by 8.515 times (p=0.023, CI: 1.343–53.976), the TG/HDL-C ratio was above predicted 0.909 cut-off value, the incidence of As increased by 3.725 times (p=0.024, CI: 1.185–11.711).

Conclusions: Our study showed the duration of disease and LDL-C/HDL-C more higher in TAK patients with As than without As. Age >40 years old, the duration of disease, hypertension, TG/HDL-C and HDL-C/HDL-C ratios were the risk factors of As in TAK patients.

RHEUMATOID FACTOR POSITIVITY IS RELATED TO CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

J. Inam, Y. Kaneko, Y. Ohta, T. Takeuchi. Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), which is characterised by vasculitis with allergic features such as asthma and eosinophilia. Although rheumatoid factor (RF) positivity is known to be as high as 37–50% in AAV patients the clinical significance of RF-positivity remains unknown.

Objectives: To investigate clinical features in patients with RF in EGPA.

Methods: Consecutive patients who were diagnosed with EGPA between January 2008 and January 2018 in Keio University Hospital were enrolled. Clinical information were collected from medical records retrospectively. We divided patients into 2 groups according to RF positivity, and compared clinical features.

Results: Seventeen patients were enrolled in the study. The mean age was 57.4 years old, and 82% were female. Among them, 11 patients were RF positive (RF positive group) and 6 patients were negative (RF negative group). The female ratio tended to be higher in the RF positive group than the negative group (82% vs 50%, p=0.087). While the Birmingham Vasculitis Activity Score was comparable between the two groups (21.5 vs 17.3, p=0.329), general symptoms (fever and weight loss) and gastrointestinal lesions were more frequent in the RF positive group (55% vs 17%, p=0.072; 45% vs 17%, p=0.137) and central nervous involvement was less frequent (18% vs 67%, p=0.024). No patient with negative RF presented with arthralgia/arthritis. The count of eosinophil and IgA levels at diagnosis were significantly higher in the RF positive group than the RF negative group (15704/mCL vs 4751/mCL, p=0.009; 238 mg/dL vs 162 mg/dL, p=0.048). Interestingly, ANCA positivity was negatively correlated with RF positivity. MPO-ANCA was positive in 27% of the RF positive group and in 66% of the RF negative group, and PR3-ANCA was positive in none of the RF positive group and 17% of the RF negative group. Double negative was more frequent in RF positive group (73% vs 33%, p=0.060).

Conclusions: RF positivity was associated with clinical and serological characteristics in patients with EGPA, suggesting different pathogenesis or immunological disturbances is related.

Efficacy of Rituximab Therapy Against Anti-Neutrophil Cytoplasmic Antibody-Related Hypertrophic Pachymeningitis: A Case Series

1. Third Department of Internal Medicine, University of Yamanashi, Chuo city, Yamanashi, Japan
2. Department of Rheumatology, National Hospital Organization, Shimoshizu Hospital, Department of Internal Medicine, Nartta Red Cross Hospital, Department of Allergy and Clinical Immunology, Chiba University Hospital, Chiba, Japan

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides presents with various symptoms. ANCA-associated hypertrophic pachymeningitis (HP) is a very rare pathology.

Objectives: This study aimed to investigate the efficacy of rituximab (RTX) against patients with ANCA-related HP.

Methods: Seven patients were identified by retrospective chart review from local registries at four Hospitals in Japan. All patients met Chapel Hill 2012 Consensus Conference definitions of ANCA–associated vasculitides and were complicated with HP. We assessed the dose of prednisolone, CRP, and MRI findings of HP before and after RTX administration.

Results: Three female and 4 male were evaluated. Median age was 66 years old. Four cases had HP at the onset of vasculitis. Relapse of HP before RTX administration was found in 2 cases. RTX was used as an initial treatment in one patient. Daily dose of prednisolone and CRP were significantly decreased from baseline levels 24 weeks after RTX treatment. Evaluation of HP by contrast MRI showed improvement in six of seven cases. No relapse after RTX treatment was observed during the follow-up period of 24 weeks. Severe adverse effects were not found in any patients.

Conclusions: Our case series highlight the efficacy of RTX against patients with difficult-to-treat ANCA-related HP. Future studies in this context in a prospective manner are definitely required to establish the B-cell depletion therapy by RTX as a treatment option for ANCA-related HP.

Bone Mineral Density and Glucocorticoid Treatment in Patients with Giant Cell Arteritis and/or Polymyalgia Rheumatica

K. Neiser1, D. Freier1, E. Wiebe2, B. Robert1, U. Schneider1, T. Alexander1, F. Bürggeret1. Rheumatology and Clinical Immunology, Charité University Hospital, Berlin, Germany

Background: Glucocorticoids (GC) are widely used in treating giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) because of their strong anti-inflammatory and immunomodulatory effects. However, considerable adverse effects like osteoporosis may occur, especially when GC are used as a long-term treatment and disease relapses are frequent. While additional treatment options with conventional immunosuppressive drugs such as MTX showed modest effects, the most recent and promising evidence points towards use of biologic agents like the IL-6-receptor antagonist Tocilizumab (TCZ) as an efficient novel treatment option in GCA.

Objectives: Rh-GIOP is an ongoing prospective study monitoring GC induced osteoporosis in patients with inflammatory rheumatic diseases, established in 2015 at the Charité University Hospital (ClinicalTrials.gov Identifier: NCT02719314). To date, our database comprises clinical data and bone mineral density (BMD) data measured by dual x-ray absorptiometry (DXA) collected from 592 patients with inflammatory rheumatic diseases. The objective of this cross-sectional analysis was to describe GCA and PMR patients in terms of their clinical characteristics, immunosuppressive therapies and BMD.

Methods: We evaluated data from the initial visit of 61 patients (37 female, 24 male), 43 (70.5%) with PMR, and 18 (29.5%) with GCA (with or without PMR symptoms). Statistical analyses were performed for the overall cohort (GCA+PMR) and separately for the subgroups GCA and PMR. For subgroup analyses non-parametric tests were used.

Results: The whole group showed a mean age of 70.4 years (±9.0), BMI of 27.7 kg/m² (±4.8), disease duration of 2.9 years (±4.0), daily GC dose of 12.5 mg (±19.6) and cumulative GC dose (CGCD) of 6.1 g (±5.6). While 40 (93%) PMR patients and all 18 GCA patients received GC on a daily base, GCA patients took significantly higher median doses (8.75 mg, interquartile range (IR) 5/27.5 mg) than PMR patients did (5 mg, IR 3.5/10 mg, p=0.03). However, no significant difference was seen in the CGCD. Overall, 34 (55.7%) patients demonstrated osteopenia and 5 (8.2%) patients osteoporosis. 27 (44.3%) patients suffered from at least one fracture, while 10 (16.4%) of these cases were confirmed fragility fractures. Methotrexate (MTX) was the most common concomitant immunosuppressive drug being used in 12 (27.9%) PMR and in 6 (33.3%) GCA patients. 2 (11.2%) GCA patients and 1 (1.6%) PMR patient were treated with TCZ.

Conclusions: No increased prevalence of osteoporosis or fractures was found in our patient cohort compared to a normal German population over 50 years. This might be due to therapeutic approaches, which include optimal disease control, the use of lowest possible GC doses and GC-saving co-medications, and a rigorous osteoporosis prevention and treatment strategy. Alternatively, the number of patients may be still too small to identify significant differences when comparing with a non-diseased population.

Peripheral Ulcerative Keratitis Associated to Autoimmune Systemic Diseases: Visual Proceedings and Occurrence While Systemic Disease in Remission

L. Pelegrín1, J. Hernández-Rodríguez2, J. Torras1, G. Espinosa1, A. Adán3, M. T. Sanz1. Uveitis Unit “Autoimmune diseases; Hospital Clinic, Barcelona, Spain

Background: Peripheral ulcerative keratitis (PUK) is a rare crescent-shaped inflammatory damage with without concomitant scleritis. PUK can occur isolated or as part of an underlying systemic disease (SD).

Objectives: Objective: To characterise a cohort of PUK patients with a long-term follow-up and to evaluate clinical (ocular and systemic) parameters as predictors of ocular prognosis, in terms of relapses and visual outcomes.

Methods: Methods: Retrospective review (1996–2017) of patients with PUK (from a multidisciplinary Uveitis Unit (Ophthalmology/Autoimmune Diseases). Data recorded included ophthalmological features, clinical assessment and laboratory markers at disease onset, and therapeutic interventions, ocular relapses and visual outcomes during follow-up.

Results: Results: Among 18 PUK patients evaluated, 3 were idiopathic, 3 infectious and 12 (67%) associated with systemic diseases (SD-PUK): 8 rheumatoid arthritis (RA), 2 ANCA-vasculitis, 1 SLE and 1 Takayasu’s arteritis. Among SD-PUK patients, sex ratio favoured women (rate 9:3) with a median age of 72 (range 33–85) years. Unilateral/bilateral involvement occurred in 7/5 patients and associated scleritis in 50% (11 eyes). All patients presented with eye pain/redness and visual impairment. Four (33%) patients (5 eyes) suffered ocular perforation and required surgery. All patients received topical glucocorticoids (GC), 75% systemic GC, 33% additional immunosuppressant, and 42% biologic therapy. Mean follow-up were 7.3 (range 0.5–12) years. The annual relapse rate was 0.3. Final visual acuity worsened in 42% (8 eyes). In 10 (83%) patients PUK onset occurred previous to SD diagnosis or with SD in remission, and only 3 (25%) were receiving
treatment for SD. No prognostic factors were found to correlate with PUK relapses and final visual acuity/ocular perforation.

Conclusions: Conclusions: RA and ANCA-vasculitis are the SD more frequently associated with PUK. Visual outcomes are poor in less than 50% of patients despite of topical and systemic GC/biologic therapy. SD-PUK may emerge previous to the SD diagnosis or with the associate SD in remission.

**LEVEL OF SERUM 25(OH)D WITH DISEASE ACTIVITY OF A COHORT STUDY**

L. Hua, Department of Rheumatology and Immunology, Beijing Anzhen Hospital, Capital Medical University., Beijing, China

Background: Takayasu’s arteritis (TAK) is a chronic large vessel vasculitis primarily involving the aorta and its major branches. TAK has been considered a rare disease that affected mostly young Asian women[1]. Its pathogenesis is still under investigation. However, some studies have demonstrated that immune disorder results in TAK. Especially cellular immunity plays a vital role in TAK. Recently, some studies showed that Vitamin D can regulate immune system in rheumatological diseases, such as SLE, RA and so on[2]. The relationship between Vitamin D and disease activity of TAK has not been reported yet. This study focuses on identifying the role of Vitamin D in pathogenesis of TAK through studying the correlation of serum 25(OH)D level and the disease activity of TAK.

Objectives: To evaluate the level of serum 25-hydroxyvitamin D in patients with Takayasu’s Arteritis (TAK)

Methods: Totally 57 untreated TA patients (TA group) and 51 healthy people (control group) were enrolled. The level of serum 25(OH)D were measured and compared between groups. The correlations of 25(OH)D level with related indicators were analysed.

Results: Lower concentrations of serum 25(OH)D were detected in TA patients compared with healthy subjects [11.91±5.26 ng/ml versus (17.64±8.85) ng/ml] (p<0.01). In all patients with TAK, serum 25(OH)D correlated negatively with erythrocyte sedimentation rate (ESR), interleukin (IL)–6 (r=−0.321, p=0.022; r=−0.322, p=0.031). There was no correlation between serum 25(OH)D level and NIH score, ITAS2010 score, ITAS.A score, anti-tumour necrosis factor (TNF)-a antibody. TAK patients with therapy showed a significantly higher serum level of 25(OH)D compared with that before therapy [(10.74±3.49) ng/ml versus (18.66±8.03) ng/ml] (p<0.01). After therapy, the changes of 25(OH)D level present a positive correlation with the changes of NIH score, ITAS2010 score AND ITAS.A score.

Conclusions: We observed a high prevalence of vitamin D deficiency in patients with TAK. The 25(OH)D levels in serum was negatively correlated with ESR and IL-6. Levels of 25(OH)D were improved after therapy. The changes of 25OHD level correlation to Disease Activity of Index.

**NON OPHTHALMOLOGICAL NEUROISCHAEMIC MANIFESTATIONS OF GIANT CELL ARTERITIS**

L. Coronel Tarancón1, I. Monjo1, E. Fernandez2, A. Balsa2, I. De Miguel2.

1Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife; 2Hospital Universitario La Paz, Madrid, Spain

Background: Giant cell arteritis (GCA) is a very infrequent cause of stroke. It is diagnosed in 0.15% of brain infarctions. On the other hand, in scientific literature there are very little patients with ischaemic brain infarctions that describes stroke as the clinical presentation of GCA. It might suggest that it is a underdiagnosed condition.

Objectives: To check the frequency of stroke as presentation symptom of GCA and other findings related with it.

Methods: Retrospective observational study of 123 consecutive patients diagnosed of GCA in our hospital. We reviewed the past medical history to obtain sings, symptoms and ultrasound parameters of the first medical evaluation. We searched for: age, sex, hypertension, diabetes, dyslipidemia, anterior ischaemic optic neuropathy (AION), headache, visual disturbances, Polymyalgia Rheumatica (PMR), jaw claudication, general symptoms, non ophthalmological brain ischaemic symptoms, disease outbreak and laboratory test: erythrocyte sedimentation rate (ESR), C reactive protein (CRP), Haemoglobin (Hb). For the analysis we divided the sample into two groups: a) Neurological symptoms b). Other presentations.

For statistical comparisons, we used SPSS version 17.0. Descriptive analysis and comparison was performed of the two groups. X2 was used for qualitative values and means comparisons for quantitative.

**BIOPSY RESULTS FROM PATIENTS WITH SUSPECTED GRANULOMATOSIS WITH POLYANGIITIS IN A DECADE (2005–2015). ALEATORISED SAMPLE ANALYSIS OF CLINICOPATHOLOGICAL CORRELATION**

1Department of Pathology, Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico; 2Department of Otorhinolaryngology, Head and Neck Surgery; 3Department of Pathology, Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico

Background: The diagnostic yield of airway biopsies in granulomatosis with polyangiitis (GPA) is usually less than 50%.

Objectives: To review the histologic diagnostic yield of airway biopsies sent with a suspected GPA diagnosis in a single-centre devoted to respiratory diseases by use of previously published criteria. Also, to know the interobserver variability among in-house pathologists, correlate signs and symptoms with GPA positive histologic findings, and with additional paraclinical data, apply the algorithm proposed by the European Medical Agencies (EMA) to know if a higher number of biopsies confidently supported a GPA diagnosis.

Methods: From 137 airways biopsies during a decade (2005–2015), fifty were randomly selected for the second review by an expert pathologist. Thereafter, with the incorporation of antineutrophil cytoplasm antibodies (ANCA) the EMA algorithm was applied. Demographic data were descriptively analysed, and
results expressed according to their distribution. Categorical data, expressed in percentages, were analysed with χ² test and variance analysis. The associations of independent variables were analysed with one-tail exact Fisher test. Simple logistic regression was used for variable associations. The interobserver correlation was tested with calculation of the kappa coefficient.

**Results:** A poor interobserver correlation was found among pathologists (kappa = 0.19), and no airway sign or symptom was predictive of a positive GPA biopsy. Several pitfalls were noticed: lack of adequate clinical information on files (including endoscopic); incomplete relevant information sent to pathologists and inadequate tissue sampling. Nevertheless, in patients with generalised disease, a 2.6 probability to obtain a diagnostic GPA airway biopsy was found. After expert pathologist’s review, and applying Devaney et al and Travis et al proposed criteria, from 16 initial GPA diagnoses, the number increased to 25. It further raised to 35/50 randomised biopsies when ANCA results were incorporated, and the EMA algorithm was applied.

**Conclusions:** Carefully retrieved clinical, endoscopic and serological data, coupled with systematic histopathologic sample review in patients with a GPA suspicion shall be incorporated in an orderly fashion in order to increase the diagnostic yield of this malady, especially in patients with the limited form of the disease.

**RISK FACTORS ASSOCIATED WITH RELAPSE OF ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS**

M. Nakashara, H. Yamashita, Y. Takahashi, K. Araki, N. Mino, K. Sugia, A. Yashima, H. Kaneko. Rheumatology, National Center for Global Health and Medicine, Tokyo, Japan

**Background:** Several factors increasing the risk of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides have been reported. These include pulmonary and cardiovascular lesions, PR3-ANCA positivity in patients with granulomatosis with polyangiitis, and persistent ANCA positivity or an increase in the titer of such antibodies.

**Objectives:** We aimed to identify potentially novel factors predicting relapse in patients with ANCA-associated vasculitides.

**Methods:** We reviewed data on 73 patients (61 with microscopic polyangiitis [MPA], 12 with granulomatosis with polyangiitis [GPA]; 46 females) treated in our centre from 1998 to 2017 for whom medical histories were available. All achieved at least one remission after induction therapy. Relapse was defined as novel organ involvement or a need for therapy intensification. Follow-up continued to the first relapse or for as long as possible if no relapse was noted.

**Results:** The median age at disease onset (interquartile range) was 74 years (range: 67–80 years). The relapse rate was 42.5% (MPA 41%, GPA 50%), thus not significantly different between the two groups (p=0.75). The median follow-up duration was 23 months (range: 11–65 months) and the median time to relapse was 18 months (range: 10.5–54 months). Although pulmonary and cardiac lesions reportedly increased the relapse rate, neither contributed significantly to the rate in this study. Furthermore, ANCA positive after remission and increases in ANCA levels prior to relapse did not significantly increase the relapse risk. In terms of medical histories recorded at the time of first onset of disease, the frequency of diabetes, dyslipidemia, coronary artery disease, and cerebral infarction did not differ significantly between patients who did and did not relapse. However, in MPA patients, a history of hypertension was significantly less in those who relapsed (p=0.01). In a multiple logistic regression analysis adjusted for sex and age, history of hypertension was a significant predictor of fewer relapse (odds ratio: 0.23, 95% confidence interval 0.07–0.69, p=0.009).

**TREATMENT WITH STATINS IN PATIENTS STUDIED BY FDG-PET/CT FOR POSSIBLE LARGE VESSEL VASCULITIS IS ASSOCIATED WITH A LOW VASCULAR SCORE**

M.A. Cimmino1, F. Iannello2, D. Camelli1, S. Morbelli1, C. Pizzorni1, M. Cutolo1, G. Sambuceti3. 1Department of Internal Medicine; 2Autoimmunology Laboratory; 3Division of Nuclear Medicine, University of Genova, Genova, Italy

**Background:** Polymyalgia rheumatica (PMR), giant cell arteritis (GCA), and fever of unknown origin (FUO) may show large vessel vasculitis (LVV) when studied with FDG-PET/CT. Statins, widely used to lower cholesterol concentrations, have shown anti-inflammatory activity in both the atherosclerotic plaque and in rheumatoid arthritis.

**Objectives:** To test the hypothesis that the concomitant treatment with statins induces a low uptake of the vessels in patients with PMR, FUO and GCA.

**Methods:** Consecutive patients with a diagnosis of PMR, GCA or FUO underwent a thorough clinical examination, including drug history, and a PET/CT scan. Arterial uptake of FDG was scored relative to liver uptake as 0=no uptake present, 1=lower than liver uptake, 2=similar to liver uptake, 3=higher than liver uptake. The values of each district were summed to obtain a total vascular score (TVS). A further semi-quantitative analysis of FDG uptake was carried out, drawing regions of interest (ROIs) on the theoretical arterial wall and within the left ventricular chamber (blood-pool, BP). Arterial FDG uptake was quantified by calculating the mean standardised uptake value (SUV) within each ROI and the results expressed as the ratio between mean SUV value of each ROI and BP ROI (SUV/BP).

**Results:** 129 patients were included, 87 women, with median age of 74 years (range 50–92). 95 patients were diagnosed with PMR, 13 with GCA, 16 with both PMR and GCA and 5 patients presented with FUO. 37/129 patients (28.7%) were assuming glucocorticoids (GC) at the time of examination. The mean interval between onset of symptoms and PET/CT was 85 days (range 4–1957 days), LVV was present in 75 patients (58.2%) when a cut-off ≥2 was used and 32 patients (24.8%) had a score of 3.

Twenty/129 patients (15.5%) were treated with statins for hypercholesterolemia. The median TVS was significantly lower in these patients when compared with those not treated with statins (8 [range 1–27] vs. 12 [range 0–42], p=0.02). This difference was present at the ascending aorta (p=0.017), the aortic arch (p=0.023), and the femoral arteries (p=0.025). The analysis of SUV was not
A REVIEW OF TEMPORAL ARTERY BIOPSIES AT A DISTRICT GENERAL HOSPITAL

M.A. Yusuf, M. Al-Zaza, T. Walton, Colchester Hospital University NHS Trust, Colchester, UK

Background: Giant cell arteritis is the most common vasculitis in the western world in the over 50 population. The morbidity associated with its natural progression and treatment is significant. No single investigation has been identified to accurately confirm or reject its diagnosis, though for some years biopsy of the superficial temporal artery has been carried out to support the diagnostic process. More recently, doppler ultrasound of the artery has gained prominence, though its widespread use is limited.

Temporal artery biopsy (TAB) is a significant use of resources, involving a surgeon and their team, as well as a histopathologist. It is an invasive procedure with the risks that this entails. It behoves the referring doctor to ensure that the probability of a positive result is as high as practicable.

Objectives: To determine the factors providing the highest likelihood of a positive TAB result.

Methods: The notes of all patients undergoing a TAB during a 3 year period 2013–2016 were reviewed from the Medical Records department at a district general hospital. The first 100 of these were reviewed by the authors. Each set of notes was examined for the following:
- Demographics (sex, age)
- The first department the patient was referred to (Rheumatology/Ophthalmology/Neurology/direct from the General Practitioner to Vascular Surgery)
- Period of time from symptom onset to biopsy
- Period of time on steroids to biopsy
- Initial dose of steroids prescribed
- Pre-treatment ESR
- Pre-treatment CRP
- Presence of symptoms (headache/jaw claudication/polymyalgia rheumatica)
- Other causes for a raised ESR
- The pre-test probability of a positive TAB result as assessed by the reviewer
- TAB result as reported by local histopathologist
- Evidence of the biopsy result impacting treatment

Results: Of the 100 TAB’s reviewed, 16 yielded positive results (16%). A breakdown of the notes review for these patients is included in the following table:

Legend: GCA giant cell arteritis; lv-GCA extracranial large vessel GCA; c-GCA cranial GCA; PMR polymyalgia rheumatica; TA temporal artery; TA* tendonerness or decreased pulse; TAB temporal artery biopsy; CDS colour Doppler sonography; ESR erythrocyte sedimentation rate; ACR American College of Rheumatology; * median (interquartile range).

Conclusions: GCA is the most common vasculitis in adults aged 50 years or above, with an annual incidence rate of 8.7 per 100,000. c-GCA is nearly 3 times more common than lv-GCA.
ARTERIAL ANEURYSMS IN BEHÇET’S DISEASE: A RETROSPECTIVE DESCRIPTIVE ANALYSIS AND LONG-TERM OUTCOME

N. H. A. El Ghozbasy, A. El-Garf, K. El-Garf. Rheumatology, Cairo University, Cairo, Egypt

Background: Behçet’s Disease (BD) was described in 1937 after Hulusi Behçet; as a triad of recurrent aphthous and genital ulcers together with iridocyclitis.1–3 Arterial disease is seen in 3%–5% of the patients.4–6 Thrombosis and/or aneurysmal formation are common sequelae mainly false aneurysms.7 In spite of the fact that BD is not uncommon in the clinical practice in Egypt; the paucity of data that looked specifically to the arterial aneurysms in the Egyptian patients with BD had prompted the present study.

Objectives: Arterial aneurysm in Behçet’s disease is a rare manifestation of Behçet’s disease. The presence of Arterial aneurysm in Behçet’s disease change the course of disease and it is management remains a challenge for rheumatologists.

Methods: A retrospective review of files of 160 patients admitted and followed up in the rheumatology department, Cairo University Hospitals between 2004–2017 was done. We looked specifically for the prevalence of arterial aneurysms.

Demographic characteristics of patients with aneurysms, clinical presentation, and associated clinical features.

Results: Twenty-seven (16.8%) patients had arterial aneurysms. All of them were males and the onset of development of the aneurysm is usually under the age of 40 years. 74% of the patients developed aneurysm; 3.2±3.0 years after their disease onset. Apart from the oro-genital ulcerations; deep venous thrombosis was the most common associated manifestation. Pulmonary artery was the most common artery involved in 12 (44.4%) of patients, followed by the abdominal aorta in 4 (14.8%). Surgical intervention was done for 11 (40.7%) patients; all of them received cyclophosphamide pulses before surgery except one. Four (14.8%) patients in this study died.

Conclusions: Arterial aneurysms are common in Egyptian patients with BD. The profile of Egyptian BD patient that is susceptible for development of arterial aneurysm is a male patient, under the age of 40 years, smoker with relatively short disease duration.

AB0688 PULMONARY AND THORACIC VASCULAR FINDINGS OF BEHÇET’S DISEASE AT COMPUTED TOMOGRAPHY

N. Isaksan Özbülut1,2, D. Üsküdar Cansu2, C. Korkmaz3, Radiation, Internal Medicine, Rheumatology, Eskişehir Osmangazi University, Eskişehir, Turkey

Background: Behçet disease is a multisystemic and chronic inflammatory disorder with unknown etiology. Pulmonary involvement is relatively infrequent.

Objectives: To investigate the pulmonary parenchymal changes and thoracic vascular abnormalities due to Behçet’s disease at computed tomography.

Methods: 21 patients diagnosed with a diagnosis of Behçet’s disease between 2004–2017 were evaluated. Clinical, laboratory, and thoracic computed tomography findings were retrospectively evaluated. Also, the immunosuppressive treatments of the patients were documented.

Results: 18 of the patients (85.7%) were male. The mean age of the patients was 44.2±11.7 years, onset of age at the disease was 32.4±6.4 years, length of follow-up was 8.12±3.3 years. 13 of the patients (61.9%) had hemoptysis at the time of initial diagnosis of Behçet’s disease. 14 of the patients (66.6%) showed vascular involvement except pulmonary system. Pulmonary artery aneurysm was observed in 9 patients (%42.8). Pulmonary artery thromboembolism was observed in 15 patients (71.4%). Thoracic computed tomography demonstrated that 5 patients (23.8%) with pulmonary infarct, 4 patients (19%) with pulmonary consolidation, 5 patients (23.8%) with ground-glass opacity in the lung representing pulmonary haemorrhage, 2 patients (9.5%) with pleural effusion, 7 patients (33.3%) with non-specific parenchymal changes, and one patient with focal atelectasis. Also, one of the patients had intracardiac thrombus. Five of the patients were smokers.

Conclusions: Aneurysm of the pulmonary artery with or without thrombosis is the most common manifestation of Behçet’s disease. Pulmonary vasculitis and thrombosis of pulmonary vessels result in infarction, hemorrhage, focal disease. The primary endpoint of this study was anti-GBM antibody positivity at the time of relapse. All charts were reviewed for baseline demographics, clinical manifestations, anti-GBM antibody and anti-neutrophil cytoplasmic antibody (ANCA) positivity at the time of initial presentation; these were compared between those with relapsing and non-relapsing disease. Results were analysed using a two tailed standard t-test. These same characteristics were also examined the relapsing cohort at the time of relapse.

Results: 40 patients were confirmed as having anti-GBM disease at our institution. Mean follow up from disease onset to the date of last follow up was 56±2 months. 8 patients had relapsing disease and 32 patients had non-relapsing disease. Baseline characteristics and clinical manifestations were similar between groups (table 1). Patients with relapsing disease had a statistically higher incidence of ANCA co-positivity as compared to non-relapsing patients (62.5% vs. 21.7% respectively p-value: 0.03).

In patients with relapsing disease, only 14.7% (1/7 tested patients) had positive anti-GBM antibodies at the time of their relapse.

Abstract AB0687 – Table 1. Clinical features and laboratory values at baseline and at the time of relapse of Anti-GBM disease

Values are expressed as mean (range) or percent

AB0688 DOES ANTI-GLOMERULAR BASEMENT MEMBRANE (ANTI-GBM) ANTIBODY POSITIVITY CORRELATE WITH RELAPSE IN PATIENTS WITH ANTI-GBM DISEASE? N. Duro1, A. Katz2, J. Sedor3, R. Haj-Ali2. 1Nephrology, Cleveland Clinic Foundation, Cleveland, USA

Background: Anti-GBM disease is characterised by rapidly progressive glomerular nephritis with or without pulmonary haemorrhage. It is usually monophasic in nature and disease severity correlates with antibody titre. The disease is mediated by pathogenic antibodies directed against the non-collagenous region of the c3 chain of type IV collagen.

Despite the known pathogenicity of anti-GBM antibodies, and the correlation of disease severity with their titres, there is conflicting reports on whether anti-GBM antibody positivity correlates with disease relapse on long term follow up.

Objectives: To assess for correlation of anti-GBM antibody positivity and disease relapse in patients with anti-GBM disease.

Methods: Patients seen in one single academic centre between 1997 and 2017 were initially screened for the presence of anti-GBM disease by ICD 9/10 code for anti-GBM disease or Goodpasture’s syndrome. 435 patients were identified. Patients were then included in the study if the diagnosis was confirmed by a board certified rheumatologist or nephrologist at our institution and had positive anti-GBM antibodies and/or biopsy results consistent with a diagnosis of anti-GBM disease.

Results: 21 patients diagnosed with a diagnosis of Behçet’s disease between 2004–2017 were evaluated. Clinical, laboratory, and thoracic computed tomography findings were retrospectively evaluated. Also, the immunosuppressive treatments of the patients were documented.

Results: 18 of the patients (85.7%) were male. The mean age of the patients was 44.2±11.7 years, onset of age at the disease was 32.4±6.4 years, length of follow-up was 8.12±3.3 years. 13 of the patients (61.9%) had hemoptysis at the time of initial diagnosis of Behçet’s disease. 14 of the patients (66.6%) showed vascular involvement except pulmonary system. Pulmonary artery aneurysm was observed in 9 patients (%42.8). Pulmonary artery thromboembolism was observed in 15 patients (71.4%). Thoracic computed tomography demonstrated that 5 patients (23.8%) with pulmonary infarct, 4 patients (19%) with pulmonary consolidation, 5 patients (23.8%) with ground-glass opacity in the lung representing pulmonary haemorrhage, 2 patients (9.5%) with pleural effusion, 7 patients (33.3%) with non-specific parenchymal changes, and one patient with focal atelectasis. Also, one of the patients had intracardiac thrombus. Five of the patients were smokers.

Conclusions: Aneurysm of the pulmonary artery with or without thrombosis is the most common manifestation of Behçet’s disease. Pulmonary vasculitis and thrombosis of pulmonary vessels result in infarction, hemorrhage, focal
atypical computed tomography can clearly demonstrate the pulmonary and vascular abnormalities of Behçet’s disease.

AB0689 EXTRAVASCULAR MANIFESTATIONS OF TAKAYASU ARTERITIS: HISTORICAL COHORT STUDY IN KOREA
O.C. Kwon1, S.-W. Lee2, Y.-B. Park3, W.J. Seo3, J.S. Oh4, S. Hong3, C.-K. Lee1, B. Yoo1, Y.-G. Kim3,1 Division of Rheumatology, Department of Medicine, University of Ulsan, College of Medicine, Asan Medical Center; 2Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine; 3Division of Rheumatology, Department of Medicine, Seoul Veterans Hospital; 4Clinical Research Center, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of Ireland

Background: Takayasu arteritis (TAK) is systemic disease characterised by large vessel involvement. Although the vascular characteristics of TAK are well characterised, there is no well-organised study demonstrating the extravascular manifestations of TAK.

Objectives: To evaluate the characteristics of extravascular manifestations of TAK, and to identify the association between vascular and extravascular manifestations of TAK.

Methods: TAK patients from two independent cohorts who fulfilled the 1990 ACR classification and encoded M314 according to ICD-10 code between January 2012 and October 2017 were included in the study. Characteristics of the patients were retrospectively collected from the electronic database. A radiologist reviewed CT scans of all included patients to evaluate the pattern of vascular involvement and presence of sarcoidosis. Clinical findings including uveitis, skin lesion, oral ulcer, arthritis, and inflammatory bowel disease (IBD) were reviewed. Logistic regression analysis was performed to evaluate the association between vascular and extravascular manifestation.

Results: A total of 268 TAK patients were included. Mean age at diagnosis was 41.2±14.2 years and 236 (88.1%) were female. The most commonly involved vessel was common carotid artery (176 [65.7%]), and the most common type of vascular involvement was type V (120 [44.8%]). Extravascular manifestation of TAK was observed in 51 (19.0%) patients (table 1). The most common extravascular manifestation was arthritis (axial arthritis [sacroiliitis] [7.1%), and/or peripheral arthritis [6.0%] (11.9%) followed by recurrent aphthous stomatitis (8.6%) and IBD (2.6%). In multivariable logistic regression analysis, the following factors were significantly associated with presence of arthritis (axial and/or peripheral arthritis): type IIB vascular involvement (adjusted OR 2.956, 95% CI 1.337-6.537, p=0.007) and erythrocyte sedimentation rate (ESR) (adjusted OR 1.014 95% CI 1.003-1.025, p=0.012).

Abstract AB0689 – Table 1. Extravascular manifestations of Takayasu arteritis

| Any extravascular manifestation | n=268 | 51 (19.0%) |
| Arthritis (axial arthritis [sacroiliitis] and/or peripheral arthritis) | 51 (19.0%) | 32 (11.9%) |
| Recurrent aphthous stomatitis | 23 (8.6%) |
| Inflammatory bowel disease | 7 (2.6%) |
| Erythema nodosum | 4 (1.5%) |
| Uveitis | 2 (0.7%) |

Conclusions: Extravascular manifestations of TAK are not rare and observed in up to one-fifth of patients. The most common extravascular manifestation was arthritis including sacroiliitis (11.9%). Type IIB vascular involvement pattern and high ESR were significantly associated with arthritis in TAK.

AB0691 INTESTINAL LUNG DISEASE AND MYSCROSCOPIC POLYANGIITIS IN CHILEAN PATIENTS

Background: Microscopic Polyangiitis (MPA) is an ANCA associated vasculitis (AAV), associated with p-ANCA (perinuclear) fluorescence pattern and anti-myeloperoxidase (MPO) specificity. Most frequently involved organs are kidney (80%–100%), peripheral nervous system and skin (30%). There is Pulmonary involvement in 25%–35% of patients, being alveolar haemorrhage frequently described. Intestinal lung disease (ILD) has also been recognised.

Objectives: The aim of our study is to report the characteristics of MPA Chilean patients with ILD and to compare it with other series.

Methods: Retrospective study. Patient diagnosed between 2007 and 2016 at the Hospital Clínico Universidad de Chile, with ILD, defined as interstitial lung disease on CT scan with Usual Intestinal Pneumonia (UIP) or Non Specific Interstitial Pneumonia (NSIP) pattern, and MPA were included. Demographic, clinical, laboratory and mortality data were plotted. Data from other series were compared with our results. Other causes that could explain the pulmonary involvement were excluded.

Results: From 94 patients with AAV, 36.1% were MPA, being 16 patients with ILD. All were Hispanic, mean age 65.3 years, 24–female 62.5% (table 1). Common manifestations were constitutional symptoms (100%), weight loss (88.7%) and fever (88.7%). All patients had anemia, high ESR (mean 84 mm/hr. range 33–120) and CRP (8–22 times above upper normal limit). All patients were ANCA-p MPO positive. In 10 cases ILD was diagnosed concomitantly with MPA and in 6 was 0.5 to 15 years before. 4 patients developed pulmonary haemorrhage. Images patterns were 10 UIP and 5 NSIP. All patients received corticosteroid as induction therapy, 15 also received cyclophosphamide. One patient plasmapheresis, and one received Rituximab after a relapsed. Azathioprine was used as

AB0690 DIAGNOSTIC VALUES OF ENDOTHELIN-1 IN PATIENTS WITH SYSTEMIC NECROTIZING VASCULITIS
L. Petelytska1, O. Iaremkenko1, K. Iaremkenko2, Bogomolts National Medical University; “Oleksandriyska City Clinical Hospital, Kyiv, Ukraine

Background: Systemic necrotizing vasculitis (SNV) is characterised by destructive and inflammatory changes in the vessels. Binding of autoantibodies and immune complexes on the surface of endothelial cells stimulates the synthesis of endothelin-1 (ET-1), which leads to activation of macrophages and adhesion of neutrophils, remodelling of the vascular wall and its damage.

Objectives: To evaluate the serum level of ET-1 in patients with SNV and the possibility of its using for the diagnosis of SNV and involvement of individual organs.

Methods: The study included 36 patients with SNV (polyarteritis nodosa – 8, ANCA-associated vasculitis – 28) and healthy controls (n=26). Clinical characteristics of patients were calculated according to the Birmingham Vasculitis Activity Score (BVAS). All patients had active disease (BVAS >11). The serum levels of ET-1 (pmol/L) were determined by immunoassay analysis using the kits of Biomedica. The outcomes of this study were the differences in marker levels between patients with active SNV and healthy controls, patients with different forms of vasculitis, with varying degrees of BVAS activity, with involvement different organs and systems estimated by analysis of the absolute changes in marker levels and the areas under receiver operating characteristic (ROC) curves (AUC).

Results: The level of ET-1 (Mx+ in the general group of patients with SNV was 0.31±0.24 and did not differ significantly from the control group (0.27±0.10; p>0.05). At the same time, in patients who did not receive at screening glucocorticoids and immunosuppressants (n=14), it was significantly elevated (0.62±0.58; p<0.03). However, ROC analysis indicated the moderate sensitivity (67%) and the low specificity (48%) of ET-1 for diagnosis of SNV. There were no significant differences in the levels of ET-1 between patients with different forms of vasculitis and with varying degrees of BVAS activity. In the analysis of the values of the ET-1 depending on the involvement of different organs and systems, it was found that only in patients with kidney involvement (n=15) its level (0.40±0.33) was significantly higher compared with patients without kidney involvement (0.28±0.22; p=0.04) and control group (p<0.01). ROC analysis showed that the AUC for ET-1 is 0.75±0.10 (p=0.004), which indicates acceptable capacity for ET-1 differentiate groups of patients with kidney involvement and patients without kidney involvement (specificity – 80.0%, specificity – 78.3%).

Conclusions: The serum level of ET-1 were elevated in patients with SNV with kidney involvement (48% compared to healthy controls and 43% compared with patients without kidney involvement), which can be used for diagnostic purposes.

ANCA, anti-neutrophil cytoplasm antibodies; BEL, belimumab; CYC, cyclophosphamide; GPA, granulomatosis with polyangiitis; IR, induction regimen; IV, intravenous; MPA, microscopic polyangiitis; MPO, myeloperoxidase; PBO, placebo; PR3, proteinase 3; RTX, rituximab

*n>=49 (BEL); n=50 (PBO)

Results: At BL, RTX patients had B cell counts<LLQ. CYC patients had notably low BL B cell counts; the lowest were in oral-CYC patients. Circulating memory B cells (CD20+/CD27+) increased rapidly with BEL, then gradually returned to BL (CYC); no major changes occurred with PBO. No trends in change in ANCA status over time occurred, regardless of IR. Individual patient data showed no apparent trends between ANCA titres and AAV activity.

Conclusions: Choice of IR for active AAV affects B cell dynamics. BEL pharmacodynamic effects occurred in patients with AAV receiving SoC. Given the small sample size and high variability, data must be interpreted with caution.

BELIMUMAB IN COMBINATION WITH AZATHIOPRINE FOR REMISSION MAINTENANCE IN GRANULOMATOSIS WITH POLYANGIITIS AND MICROSCOPIC POLYANGIITIS: EFFECT ON BIOMARKERS

D. Jayne1, D. Blockmans2, R. Luqmani3, B. Henderson4, Y. Green4, L. Hall5, D. Roth6, R. Henderson7, P. Macchioni1, C. Salvareni1

Background: GPA and MPA (related types of ANCA-associated vasculitides [AAVs]) are organ-/life-threatening systemic vasculitides. B cells and increased circulating BlyS (a B cell survival factor) are implicated in AAV pathogenesis, suggesting a role for BlyS in these vasculitides. BEL is an anti-BlyS human immunoglobulin (lg) G1 monomeric antibody.

Objectives: Examine the effects of BEL plus azathioprine (AZA), on biomarkers in patients with AAV for remission maintenance following standard induction (IND) with glucocorticoids (GC) and CYC or RTX.

Methods: This double-blind, placebo-controlled, multicentre study (BEL115466/NCT01663823) randomised (1:1) patients (18 years) with new-onset AAV following IND (oral or IV CYC or RTX), to AZA 2 mg/kg/day and oral GC, plus IV BEL 10 mg/kg or PBO (Days 0, 14, 28 and every 28 days until completion). Remission was defined as Birmingham Vasculitis Activity Score=0, plus GC £10 mg/day. The study was truncated after initiation (n=300 to 100) due to revised AAV standard of care (SoC) affecting recruitment. Biomarker endpoints (serum lgs, B cells and ANCA [anti-MPO/PR3]) were measured at baseline (BL) and thereafter. Summaries by IR were post hoc; no analyses were performed.

Disclosure of Interest: None declared

DEMOGRAPHIC, CLINICAL, LABORATORY AND IMAGING CHARACTERISTICS OF AN INCIDENCE COHORT OF 93 PATIENTS WITH LARGE VESSEL GCA

P. Macchioni1, L. Boiard1, G. Restuccia1, F. Muratore1, P. Mancuso2, M. Catanos2, C. Salvareni1, O. OSPEDALE SANTA MARIA NUOVA;

Background: Few study have evaluated the clinical and imaging data of patients with large vessel GCA (LVGCA).

Objectives: To evaluate clinical, demographic and imaging data of an inception cohort of 93 patients with LVGCA recruited in Reggio Emilia (Northern Italy)

Methods: All patients with incident large vessel GCA diagnosed between 1 January 2005 and 31 December 2016 in the Reggio Emilia area, were identified by capture and re-capture checking of computerised discharge diagnosis codes (ICD10) and using outpatient databases from rheumatology, internal medicine, surgery, pathology, imaging departments of Reggio Emilia Hospital as well as other regional centres.

Disclosure of Interest: None declared

AB0691 – Table 2. Characteristic of patient with ild and MPA worldwide

Conclusions: Among chilean patients there are more females, have a more NSIP pattern, and less mortality that other worldwide series.

REFERENCES:
as by examining the Reggio Emilia district database for rare diseases. To be included in the study, patients must satisfy the following 2 criteria: Age at disease onset > 50 years; evidence of large-vessel vasculitis by clinical criteria, angiography, MRA, CTA, PET/CT and/or ultrasonography. Demographic, clinical, laboratory and imaging data collected at first visit were retrieved from patients records.

**Results:** There were 93 incident cases of LV GCA (66 women, 71%) during the 12 year study period; Mean ±SD age at diagnosis was 72±19 years. The three most prevalent signs appearing were: systemic in 49 pts (52.7%), GCA cranial symptoms in 39 pts (41.9%) and PMR in 35 pts (37.6%). Peripheral ischaemic symptoms were observed only in 8 pts (8.6%). Forty four pts had temporal artery biopsy and 70.5% resulted positive. At US examination the three most common involved arteries were: common carotid artery (59.2%) pts, subclavian artery (61.8% pts) and abdominal aorta (58.8% pts). Celiac trunk and mesenteric artery were involved in 18.4% of pts and renal artery in 10.2% of pts.

**Conclusions:** In an inception cohort of LVGCA systemic manifestations had the highest prevalence among presenting symptoms. Imaging studies demonstrated an high prevalence of aortic and subclavian involvement.

GIANT CELL ARTERITIS EPIDEMIOLOGY IN LA REUNION: A RETROSPECTIVE CASES SERIES

O. Richier1, T. Deltombe1, A. Fouchez7, C. Roussin3, A. Randrianjohany4, A. Gerber1, P. Poubeau1, L. Raffray1, *Internal Medicine, CHU de La Réunion, Saint Denis; 2Internal Medicine, CHU de La Réunion, Saint Pierre; 3Internal Medicine, CH Gabriel Martin, Saint Paul; 4Internal Medicine, Groupe Hospitalier Est Réunion, Saint Benoit, France

**Background:** Giant Cell Arteritis (GCA) is the most common vasculitis in people over 50 years, with incidence varying according to geographic location. In Europe, the average incidence is 10–30 per 100 000 inhabitants over 50 years, whereas in Africa and Asia it is approximately 1.5 per 100 000.

**Objectives:** To define GCA epidemiology in La Réunion, a French overseas territory in South West Indian Ocean characterised by several ethnic groups and genetic admixture.

**Methods:** Retrospective study between January 2005 and August 2017 in the 4 main hospitals of La Réunion. Patients were identified through hospital informatics databases and practitioner records. A definite diagnosis of GCA was considered for patients fulfilling ACR criteria and/or by assessment by a trained rheumatologist. Incidence and prevalence calculation was based on French national census data.

**Results:** Sixty patients were included, of which 60% were women. Mean age at diagnosis was 73.7 years, with a mean delay to diagnosis of 6.8 months. Cases met an average of 3.7±5 ACR criteria, and 78% had ≥2 criteria. The mean annual incidence was 2.33 per 100 000 inhabitant of 138 patients (203,000), with 95% confidence interval (IC) of 1.74–2.92. The prevalence at the end of period study was 24 cases per 100,00 (IC: 18–30). There was no seasonal variation regarding disease onset. Clinically, patients complained of asthenia and headache in 75%, fever in 33% and ophthalmologic damage for 32% of the cases, of which 5 had anterior ischaemic optic neuropathy. Polymyalgia rheumatica was associated in 42% of all cases. Total blood cells counts were usually within normal values, whereas mean CRP was 111 mg/L. Anicteric cholestasis was a common finding: mean GGT=78 IU/L (n<42) and alkaline phosphatase=107 IU/L (n<104). Radiological examinations contributed to diagnosis in only 9/31 cases. Temporal artery biopsy was performed in 91% of patients and showed specific histological features of GCA in 55%. Corticosteroid regimen was introduced in 59 patients (1 died the day of the biopsy) and mean treatment duration was 26 months, for a total dose of 10.6 g. Antiplatelet therapy was given in 47% of patients. One patient in three experienced one or more relapses.

**Conclusions:** This is the first study to describe GCA in La Réunion, and more generally in Indian Ocean. It shows an incidence 4–12 times lower than in most European countries with white ancestry background. This discrepancy could be explained by the contribution of the various ethnic groups of La Réunion, especially those coming from parts of the world characterised by a lower GCA incidence (Africa, India, South East Asia). A shorter life expectancy may also account for this observation, assuming that GCA incidence increases with age. Sex ratio and age at diagnosis were similar to European studies, as well as clinico-biological features, response to treatment and side effects. Some limitations of our study should be taken in consideration: exclusions of hospitalised patients only, informatics record limits and retrospective design that did not afford for ethnic background determination.

PREDICTIVE FACTORS OF LONG-TERM CLINICAL OUTCOME IN BEHÇET’S SYNDROME PATIENTS WITH OCULAR INVOLVEMENT: DOES ACTUALLY THE DISEASE TEND TO GROW DIM OVER TIME?

R. Talajic1, M. Figus2, C. Posserelli3, A. D’Ascanio1, R. Neiri4, C. Tani1, C. Baldini1, M. Mosca1, 1Department of Clinical and Experimental Medicine, University of Pisa, Rheumatology Unit, 2Department of Surgical, Medical, Molecular Pathology and Emergency, University of Pisa, Pisa, Italy, 3Ophthalmology Unit, Pisa, Italy

**Background:** Behçet’s syndrome (BS) is a multisystemic, chronic relapsing inflammatory disease classified among the vasculitides. Eye involvement represent one of the most serious manifestation of BS and occurs in half of all patients. It seems more frequent and severe among young males and, unluckily, it still represents a significant cause of morbidity.

**Objectives:** The aims of the study were: to study the relapse rate of BS patients with ocular involvement and to identify factors able to predict long-term outcome in these cases. Among a cohort of 138 patients with a diagnosis of BS according the ISG criteria, 62 patients (37 males and 25 females; mean age at the onset 38±5 years) with ocular involvement were prospectively studied. The probability of clinical relapse after remission of the first ocular attack was calculated using the Kaplan-Meier method. Predictors of long-term outcome were identified by univariate analysis using the log-rank test and by multivariate analysis using Cox proportional hazards regression models.

**Results:** The mean time between the first initial symptoms of BS and the onset of eye lesions was 2±2 years. The number of ocular attacks were the following: 43 posterior uveits, 27 anterior uveitis, 26 retinal vasculitis, while panuveits developed in 18 subjects. The cumulative relapse rates at 1 year, 3 years, and 5 years after remission of the first ocular attack were 41%, 31%, and 28%, respectively. On multivariate analysis, a younger age (<30 years) at the onset of ocular involvement, male sex and medical treatments other than biological agents represent independent predictive factors for more early relapses in BS patients with ocular involvement.

**Conclusions:** The relapse rate seems to be more frequent in the first years of diseases, and probably it could be related to the fact the disease tend to grow dim over time. As literature data suggest, younger age and male sex still represent predictive factors of poor long-term clinical outcome.

CLINICAL CHARACTERISTICS AND OUTCOME OF PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS (GPA) ACCORDING TO ANCA POSITIVITY AND SPECIFICITY

R. Solans-Llague1, J. Rios2, M. Rodriguez-Caballero3, B. Frutos4, L. Saez2, F. Pasqual1, J. Oristrell2, E. Fonseca5, G. Fraile6, on behalf of REVAS-GEAS (SEMI), 1Autoimmune Diseases Unit. Internal Medicine Department, Vall-Hebron Hospital, Barcelona; 2Internal Medicine, H La-Paz, Madrid; 3Internal Medicine, H Mutua, Terrassa; 4Internal Medicine, H Fuenlabrada, Madrid; 5Internal Medicine, H Miguel-Servet, Zaragoza; 6Internal Medicine, H Marina-Baxa, Alicante; 7Internal Medicine, H Parc-Taulí, Sabadell; 8Internal Medicine, H Cabañeros, Asturias; 9Medicine, H Ramon-Cajal, Madrid, Spain

**Background:** GPA is a necrotizing granulomatous vasculitis associated with ANCA that usually involves ENT, lung and kidneys. ANCA are mostly directed against proteinase 3 (PR3), although in few cases are directed against myeloperoxidase (MPO) or negative.

**Objectives:** To analyse the phenotype, clinical course and outcome of patients with GPA according to ANCA positivity and specificity

**Methods:** multicenter retrospective-longitudinal study that included patients diagnosed with AAV between Jan 1995 and Jan 2016 in 21 Hospitals from Spain (REVAS-Study). We analysed the clinical characteristics, treatment and outcome, depending on the ANCA positivity and specificity. Statistical analysis was performed using SPSSvs.20

**Results:** 221 patients with GPA were included:162 with PR3-ANCA, 36 with MPO-ANCA, and 23 with negative-ANCA. The mean-age at disease onset was higher in patients with PR3-ANCA (58±16.5 years) than in patients with PR3-ANCA (50±16.5) and negative ANCA (48±14.5), P<0.006. Compared to
patients with PR3-ANCA, patients with MPO-ANCA presented a lower prevalence of toxic syndrome (42.9% vs. 55.6%, p=0.021), arthralgias (34.3% vs. 59.9%, p=0.001), arthritis (6.8% vs. 26.5%, p=0.026), pulmonary involvement (cavitating infiltrated nodules, p=0.007 and p=0.05), and anaemia (57.1% vs. 77.8%, p=0.05). Renal disease was less severe in patients with MPO-ANCA (20% vs. 6.8%, p=0.056 and 34.3% vs. 18%, p=0.03). The mean BVAS at baseline was lower in patients with MPO-ANCA (15.3±8.8) and negative ANCA (12.5±6.7) than in patients with PR3-ANCA (19.5±8.9), p=0.029. Patients with negative ANCA had less frequently toxic syndrome, fever, arthritis, subcutaneous nodule, kidney disease, and peripheral neuropathy, and more frequently orbital masses. Disease relapses were less frequent in patients with MPO-ANCA than in patients with PR3-ANCA, lower percentage of relapses and lower requirement of aggressive ther-apy. Patients with negative ANCA had the best prognosis. Our findings are similar to those recently published, although our patients with MPO-ANCA were older. Classification of GPA patients considering ANCA specificity can improve the treatment stratification and reduce adverse events.

CONCLUSIONS: A small percentage of patients with GPA present MPO-ANCA or negative ANCA. In our series, patients with MPO-ANCA were older at the disease onset, presented limited or less severe organic disease than patients with PR3-ANCA, lower percentage of relapses and lower requirement of aggressive thera-pies. Patients with negative ANCA had the best prognosis. Our findings are similar to those recently published, although our patients with MPO-ANCA were older. Classification of GPA patients considering ANCA specificity can improve the treatment stratification and reduce adverse events.

Giant Cell Arteritis with Normal Inflammatory Markers at Diagnosis

R. Solans-Largue1, E. Fonseca2, B. Escalante1, A. Martinez-Zapico3, G. Fraile4, M. Perez-Conesa5, M. Abdila7, M. Montagud8, on behalf of REVAS-Study

Background: GCA is an inflammatory vasculitis affecting medium and large-sized arteries, that can result in arteritic anterior ischemic optic neuropathy. C-reactive protein (CRP) level and erythrocyte sedimentation rate (ESR) are usually elevated at GCA diagnosis, but inflammatory-marker negative disease does occur.

Objectives: To analyse the clinical and histological findings of patients with biopsy-proven GCA and negative inflammatory-markers at diagnosis.

Methods: multicenter-longitudinal retrospective study that included patients with biopsy-proven GCA recruited at 10 Hospitals from Spain (REVAS Study). Statistical analysis was performed using SPSS vs. 21.

Results: 418 patients: 290 (69.4%) females (ratio F:M: 2.3:1) were included. The mean age at diagnosis was 75.5±7 (53–92). The most frequent symptoms at diag-nosis were recent onset headache (81%), toxic syndrome (47%) and rheumatic polyarthritis (44.5%). Jaw claudication, cranial hyperesthesia and amaurosis fugax were reported in 44.5%, 31.8% and 16.3% of patients, respectively. A total of 84 patients suffered permanent vision loss. Fourteen patients (3.3%) had normal ESR (<40 mm/h) and CRP (<5 mg/L) at diagnosis. No significant differences were found related to age at disease onset in these patients. Most patients (85%) reported headache; 42.9% jaw claudication, 28.6% cranial hyperesthesia and 42% rheumatic polyarthritis. Fever was less frequent in patients with negative inflammatory-markers (7.7% vs. 40.4%, p=0.022), as well as loss of vision (21.4% vs. 51.5%, p=0.031). In contrast, patients with negative inflammatory-markers had more frequently amaurosis fugax (35.7% vs. 16.8%, p=0.03) and optic ischaemic neuropathy (50% vs. 18.7%, p=0.009). Temporal arteries were abnormal (thickened and/or pulse less) in 78.6% of patients with negative inflammatory-markers vs. 37% of patients with elevated ESR and/or CRP. Amaurosis was less common in patients with negative inflammatory-markers (28.9% vs. 81.5%, p=0.001, mean haemoglobin 12.9±1 g/dL). No significant differences were found related to temporal artery biopsy findings, although patients with normal ESR and CRP showed giant cells in 74.3% of cases vs. 62%.

Conclusions: typically patients with GCA present with elevated inflammatory-markers (ESR and CRP) at disease onset. However, a few percentages of patients (4%–5%) have normal ESR and CRP at diagnosis. In our series, 3.3% of patients had negative inflammatory-markers at diagnosis. These patients had fewer constitutional symptoms and more visual symptoms (amaurosis fugax and permanent visual loss) than patients with elevated ESR and/or CRP. Our result are similar to those published in the literature. Abnormal temporal arteries on physical examination may help to diagnosis

AB0698

A Comparison of the Effectiveness of Mycophenolate Mofetil or Methotrexate in Combination with Prednisolone Versus Prednisolone Alone in the Treatment of Large Vessel Vasculitis

R. Smith1, R. Kilding1, K.-P. Kuet1, M. Ali2, J. Maxwell3. Rheumatology Department, Royal Hallamshire Hospital, Sheffield, UK

Background: The mainstay of treatment for large vessel vasculitis is glucocorticoids. Immuno-suppressants, including mycophenolate mofetil (MMF) and methotrexate (MTX) are used as steroid-sparing agents. A previous study at our centre showed MMF to have a steroid sparing effect in 97% of patients and to reduce C-reactive protein (CRP) in 80%.

Objectives: This study was undertaken to compare the efficacy of MMF or MTX combined with prednisolone or prednisolone alone in the treatment of large vessel vasculitis.

Methods: Patients with large vessel vasculitis (LVV) confirmed on positron emission tomography (PET) scan and those meeting ACR criteria for a diagnosis of giant cell arteritis (GCA), treated with prednisolone alone, prednisolone with MMF or prednisolone with MTX started within 3 months of prednisolone being com-menced and with a minimum follow up of 24 months were included in a retrospec-tive single centre study. CRP and prednisolone doses were recorded at baseline, after 3, 6, 9, 12, 18 and 24 months of treatment and area under the curve (AUC) calculated for CRP and prednisolone doses. Median AOC prednisolone dose for patients treated with MF or MTX was then compared with that of patients treated with prednisolone alone. A quantile regression model was also constructed to compare prednisolone dose between the 3 treatment groups, adjusted for CRP.

Results: 65 patients were included in the study, 41 with GCA and 24 LVV. 49 were female and 16 males. Mean age at diagnosis was 68; range 21 to 87. 37 patients were treated with prednisolone alone; 35 had GCA and 2 LVV. 20 were treated with MMF and prednisolone; 4 with GCA and 16 LVV. 8 were treated with MTX and prednisolone; 2 had GCA and 6 LVV. The AOC for prednisolone and CRP were not normally distributed across the cohort, and non-parametric meth-ods were therefore used for comparisons. Median AOC prednisolone dose for the prednisolone only group was 68.0, (interquartile range (IQR) 17.7, n=37), for the MMF treated group 70.8 (IQR 28.7, n=20) and for the MTX treated group 67.8 (IQR 20.4, n=8). Median AOC CRP was highest in the group treated with prednisolone alone (58.9, IQR 34.5) compared to MMF (43.8, IQR 26.5) and MTX (49.3 IQR 67.5) but there were no statistical differences between median AOC preni-solone dose or CRP in either the unadjusted or regression models.

Conclusions: No significant difference was shown between the groups. MMF is slightly more effective as a mono-therapy as compared to MTX, and was well tolerated by the patients. However, there are limitations to the study. The patient group was small. There was no randomisation to treatment group; treatment choice was based on clinician prefer-ence. There was potential bias in that patients perceived to be more difficult to treat may have been given MMF or MTX in addition to prednisolone, and there was a higher proportion of patients with LVV compared to GCA in the MMF and MTX treated groups.

BENZATHINE PENICILLIN IN TREATMENT OF ULCERS OF BEHCET’S DISEASE

S. Benamour, ALMS, Casablanca, Morocco

Background: Prednisone therapy, Thalidomide, azathioprine, anti-TNF-alpha inhibitors are presently used in resistant mucocutaneous lesions of Behçet’s Disease (BD). In this study, we used only ambulatory Benzathine Penicillin (BP), without being preceded by high doses of penicillin infusion. This Study confirm the value of BP in the treatment of refractory ulcers of BD and point out a probable role of Streptococcus on the pathogenesis of BD.

Objectives: This open study confirm the value of BP in refractory oral, genital and skin ulcers of BD. We propose to use BP when ulcers of BD are resistant to colchicine 1.5 mg/day and to add BP in the recommendations of EULAR for the treatment of resistant cases of mucocutaneous involvement.

Methods: 15 patients with BD (12 patients fulfilled all criteria for BD) had Giant (mean size of ulcer superior to 1 cm), or Multiple oral, genital, skin ulcers received BP at the dose of 2.4 million units in intramuscular injection; 3 intramuscular injections with an interval of 3 weeks between injection. Colchicine at the dose of 1 mg/ day was maintained. Serology of syphilis was negative. Patients had seen 15 days, 3 months and 1 year after the starting treatment.

Results: This study started in 2012, in a private office and comprised 15 patients: 9 males; 6 females. Arthritis was observed in 11 patients, uveitis in 6 cases. BP was used in 8 patients with oral ulcers (4 Giants and 4 multiples), Genital ulcers in 3 patients (2 multiple and 1 Giant), oral and genital ulcers (2 multiples) and cutaneous aphthosis in 2 patients 0.2 weeks after the first injection of BP, recovery from ulcers was achieved. BP was administrated a second time with success, in 9 patients who have developed resistant ulcers, after 1 to 3 years of recovery. One patient with panuvereitis treated with azathioprine in 2015 and interferon alpha in 2015 and 2017, developed refractory ulcers: Excellent efficacy of BP was observed in this patient.

Conclusions: In this study, we confirm the recovery from refractory oral, genital and cutaneous ulcers (Giant, Multiple) in these 15 patients with BP. We recommend using more frequently BP and we propose to add BP in the recommendations of EULAR for the treatment of resistant cases of mucocutaneous involvement because treatment with BP is rather easy in outpatients, it is efficient, it has a low cost and have few side-effects.

IS IT FEASIBLE TO WITHDRAW IMMUNOSUPPRESSIVE TREATMENT IN REAL-LIFE PATIENTS WITH ANCA-ASSOCIATED VASCULITIS?

S. Monti1,2, B. Vitolo1, S. Balduzzi1, M. Felicetti2, R. Padoan1, A. Bert1, M. Bond1, L. Quartuccio3, G. Paolozzi4, F. Schiavoni5, C. Montuccio1, R. Caporal1.

1Rheumatology, IRCCS Policlinico S. Matteo Foundation; 2University of Pavia, PhD in Experimental Medicine, Pavia; 3Rheumatology, University of Padova, Padova; 4Rheumatology, Santa Chiara Hospital, Trento; 5Rheumatology, University Hospital S. Maria della Misericordia, Udine, Italy

Background: The optimal duration of remission-maintenance treatment in ANCA-associated vasculitis (AAV) is still unknown, with international recommendations suggesting to maintain it for at least 24 months. Data supporting the correct balance between relapse risk, treatment-related adverse events and damage are highly needed.

Objectives: To analyse the frequency and predictors of withdrawal of remission-maintenance immunosuppressive drugs (IS) in a large real-life cohort of AAV patients.

Methods: Clinical records of patients with granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) were retrospectively analysed from a multicentric cohort. We divided the cohort into group A (withdrawal) and group B (ongoing).

Results: We included 185 patients. Forty-one patients (22%) had withdrawn IS at the end of follow-up (median 7.3 months, IQR 4–115). Concomitant glucocorticoids were stopped in 33%. There were no significant differences in AAV subtype, ANCA pattern, age at diagnosis, diagnostic delay or comorbidities rates between group A and group B (table 1). Disease onset with pulmonary involvement was significantly more frequent in patients in whom IS was maintained (69.7% vs 45%; p=0.004). Figure 1. Disease activity at onset, but not during follow-up, was significantly higher in patients from group B (ongoing): median BVAS 18 (12–24) vs 15 (8–20) p=0.02. The type of IS used for remission induction did not differ between the two groups. Maintenance treatment with Rituximab (RTX) was associated with higher probability of discontinuing IS by the end of follow-up (21% vs 7.6%; p=0.02). There was no difference in the number of major relapses between the two groups. Safety profile was equally good in both groups, except for a higher number of infections over the course of disease in patients who withdrew IS (5% vs 0). Vasculitis damage index (VDI) was comparable between the two groups.

Abstract AB0700 – Table 1. Clinical characteristics and outcome: comparison between IS withdrawal group (A) and ongoing group (B).

</tbody>
</table>

Conclusions: IS withdrawal was observed in a minority of real-life patients with AAV. Drug-free remission was negatively associated with pulmonary involvement and higher BVAS at disease onset. Remission maintenance with RTX was associated with a higher frequency of drug withdrawal at the end of follow-up.

COMPARISON OF THE NEW ACR/EULAR CLASSIFICATION CRITERIA OF ANCA-ASSOCIATED VASCULITIS WITH THE EMA ALGORITHM IN CLASSIFICATION OF VASCULITIS

S.Li1, Q. Zhang2, Department of Rheumatology and Immunology, Peking University International Hospital; 2Department of Rheumatology and Immunology, The First affiliated hospital of Chinese PLA general Hospital, Beijing, China

Objectives: A new set of classification criteria for ANCA-associated vasculitis (AAV) was presented in 2017’s ACR annual scientific meeting. In order to evaluate this new set of classification criteria, we conducted the current study to compare it with the EMA’s consensus algorithm for classification of systemic vasculitis proposed by Watt et al. in our centre.

Methods: One hundred and twenty-two Chinese patients with clinically diagnosed as AAV in our centre during the past 15 years were retrospectively studied. Applying the EMA’s consensus algorithm with surrogate parameters, in the same cohort of patients with primary systemic vasculitis.

Results: Applying the EMA’s consensus algorithm with surrogate parameters, the diagnoses were EGPA (n=3), GPA (n=55), microscopic polyangiitis (MPA) (n=47), drug related AAV (n=2), and unclassified (n=5). Using the new ACR/EULAR’s classification criteria for AAV, the diagnoses were EGPA (n=8), GPA (n=33), MPA (n=65), overlap with EGPA and GPA (n=2), overlap with GPA and MPA (n=8), and unclassified (n=7). (See the below picture).

Conclusions: The new 2017 ACR/EULAR classification criteria for AAV and Watts’ algorithm were all useful methods to classify patients with systemic vasculitis. The Watts’ algorithm can classify all patients into a single category, with more GPA patients, less unclassified patients and without overlapping diagnosis, in comparison, the new 2017 ACR/EULAR classification criteria classified more MPA patients, more unclassified and more overlapping patients.

AB0703

LONG TERM FOLLOW-UP OF BEHÇET’S SYNDROME PATIENTS TREATED WITH CYCLOPHOSPHAMIDE

1Istanbul University, Cerrahpasa Medical School; 2Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 3Cleveland Clinic, Department of Hematology and Oncology, Taussig Cancer Institute; 4Cleveland Clinic, Department of Internal Medicine, Cleveland, USA

Background: Cyclophosphamide (CYC) remains an important treatment option for Behçet’s syndrome (BS) patients with life-threatening conditions such as articular abnormalities. However, several adverse events may occur with CYC and this has led to increased use of biologic agents such as rituximab in other vasculitides.

Objectives: The aim of this study is to delineate the outcome and short and long-term adverse events with CYC use among BS patients.

Methods: We conducted a retrospective chart review of all BS patients treated with oral or intravenous CYC between 1976 and 2006. Patients were called and a standard form was used for collecting demographic characteristics, CYC indication, cumulative dose of CYC and short-term serious adverse events necessitating the cessation of therapy and/or requiring hospitalisation and long-term adverse events (malignancy and infertility), and outcome.

Results: We identified 198 (M/F: 184/14) BS patients who had received CYC. After a median follow up of 17 (IQR: 9–26) years after the initiation of CYC therapy, 52 (26%) patients had died within a median duration of 4–17 years, 33 (17%) were lost after a median follow-up of 9 (3.5–14) years, and 113 (57%) were contacted. CYC was prescribed for vascular involvement in 132 (67%) patients, eye involvement in 52 (26%), central nervous system involvement in 5, both vascular and eye involvement in 7 and both vascular and central nervous system involvement in 2 patients. The median duration of CYC use was 12 (IQR:4–24) months and median cumulative dose was 13.5 (IQR:6–49) gr. Among the 52 patients who died, reasons for death were vascular involvement in 26, malignancies in 7, infections in 5 (5 bacterial infections, 1 additional tuberculosis), neurologic involvement in 2, ischaemic stroke in 1, traffic accident in 1, and secondary amyloidosis in 1, esophageal variceal bleeding in 1, and unknown in 5 patients. Sixteen (8%) patients experienced serious adverse events associated with short-term CYC use and 1 of them died due to infection. Among these adverse events, haemorrhagic cystitis occurred in 7 patients, infections in 4 (1/4 died), leukopenia, acute myocardial

to comment on variables, which could have contributed to this but hey likely represented already administered aggressive glucocorticoid treatment at time of serum measurement or atypical presentation of GCA. Raised ALP sensitivity at the current cut off value was very low (14.8%) but with high specificity (90.5%), which was reinforced following ROC curve analysis. Pearson coefficient analysis suggested that there was a weakly associative relationship between raised ALP and degree of clinical suspicion (Correlation 0.346, Sig 0.01)

Conclusions: Patients with a higher level of clinical suspicion and TAB positivity were more likely to have a raised ALP. However, the association strength was weak. ALP is suggested to be highly specific for TAB positivity. The association of raised ALP to degree of clinical features and suspicion of GCA is weak and of low significance, likely a reflection of the limitations of this study. Further robust research may further evaluate this observed relationship.

ALKALINE PHOSPHATASE AS A PREDICTOR OF GIANT CELL ARTERITIS – A RETROSPECTIVE ANALYSIS OF CLINICAL FEATURES AND TEMPORAL ARTERY BIOPSY FINDINGS

S. Varier, C. Li, Rheumatology, Royal Surrey County Hospital, Surrey, UK

Background: Giant cell arteritis (GCA) is the most common large vessel vasculitis in the United Kingdom and Northern Europe. Inadequate treatment and delay in diagnosis can lead to serious complications.

Objectives: This study looks at whether the presence of a raised alkaline phosphatase (ALP) may aid the diagnosis of GCA, improve the sensitivity of TAB, including in the presence of other proven serum markers and whether it has any correlation with severity of clinical presentation.

Methods: Retrospective multicenter cohort study.

Information was retrospectively gathered on patients who underwent TABs following a clinical working diagnosis of GCA. Only patients who fulfilled the American College of Rheumatology (ACR) classification criteria and had ALP measured within 4 weeks of undergoing TAB were included in the study. Once patients were identified, further information was extrapolated including the values of other serum markers taken, and presenting clinical features.

Results: Our sample population who fulfilled the inclusion criteria reflected typical GCA patients: 147 (65.9%) were female and mean age was 73.1 years (SD 10.5). TAB was positive in 54 patients (24.2%). Two patients (3.7%) who had a positive TAB had completely normal serum markers. We were unable
Infection, anaphylactic reaction, azosperma, liver toxicity, and severe nausea in 1 patient each. Overall, 16 malignancies were observed in 14 (7%) patients after a median follow-up of 25 (IQR: 15–26) years. The malignancies were bladder carcinoma (n=4), lung adenocarcinoma (n=3), prostate adenocarcinoma (n=2), carcinoma of unknown primary origin, pancreas adenocarcinoma, T-MDS-AML, lymphoma, colon adenocarcinoma, squamous cell carcinoma and thyroid papillary carcinoma. Among the 113 patients, we were able to question regarding infertility, 67 patients (59%) had children, 22 (19.5%) did not wish to have a child and 24 (21.5%) tried to have a child, but was not able to.

Conclusions: Short term serious adverse events occurred in 8% of the patients during CYC treatment. During long term follow-up malignancies occurred in 7% and infertility in 21.5% of the patients. These results underline the need for safer and effective alternatives to CYC for serious organ involvement in BS, similar to that in other vasculitides.

CLINICAL-ANALYTICAL CHARACTERISATION OF 52 DIAGNOSED PATIENTS OF BEHÇET DISEASE WITH INCLUSION OF PEDIATRIC CASES IN A SPANISH TERTIARY HOSPITAL

S. Zegarra Mondragon, A. Alia-Jimenez, C. Bouroncle Alaluna, A. Boteanu. Rheumatology, Hospital Ramon y Cajal (Spain), Madrid, Spain

Background: Behçet’s disease (BD) is a chronic and recurrent inflammatory disease of unknown etiology, classified into polygenic autoimmune diseases or variable vessel vasculitis. It has a wide spectrum of symptoms with a very variable range of severity, from mucocutaneous involvement to neurological manifestations, systemic vasculitis and severe ocular manifestations. About 5.4%–7.6% of Behçet’s cases have a paediatric debut.

Objectives: To evaluate and compare the clinical and laboratory manifestations of a series of 52 patients, adults and children, diagnosed with BD according to the classification criteria of the International Study Group of BD (ISGBD-1990).

Methods: Retrospective cross-sectional observational study, which included 43 adult patients and 9 paediatric patients diagnosed with BD in the Rheumatology Department of a Madrid tertiary hospital. The clinical-analytical characteristics of both groups were evaluated, as well as the correlation of HLA-B51 with the described symptomatology.

Results: The mean age at diagnosis of BD was 36.9±11.8 years in adults and 11.4±5.1 years in children. 27.3% of adults and 11.1% of children with BD were male, with oral ulcers close to 90% in both groups. Contrary to what was reported in other series, genital ulcers were more frequent in children (77.8% versus 65.9% male, with oral ulcers close to 90% in both groups. Contrary to what was reported in other series, genital ulcers were more frequent in children (77.8% versus 65.9% male, with oral ulcers close to 90% in both groups). Contrary to what was reported in other series, genital ulcers were more frequent in children (77.8% versus 65.9% male, with oral ulcers close to 90% in both groups).

Conclusion: Those who had it had a mean age at diagnosis of 26.5 years compared to a mean of 11.4±5.1 years in children. 27.3% of adults and 11.1% of children with BD were male, with oral ulcers close to 90% in both groups. Contrary to what was reported in other series, genital ulcers were more frequent in children (77.8% versus 65.9% male, with oral ulcers close to 90% in both groups).

AB0706

OCULAR PRESENTATION IN GRANULOMATOSIS WITH POLYANGITIS (GPA) PATIENTS: RELATION TO AUTOANTIBODIES AND DISEASE ACTIVITY

T.A. Gheit1, E.M. Abd El-Latif2, 1Rheumatology and Clinical Immunology, Faculty of Medicine, Kasr Al-Ainy School of Medicine, Cairo University, Cairo; 2Ophthalmology, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Objectives: To study the disease characteristics, autoantibodies and activity in granulomatosis with polyangiitis (GPA) patients with ocular manifestations.

Methods: 46 GPA patients visiting the ophthalmology clinic were included. Ocular manifestations, clinical and slit lamp examination were performed. The Birmingham Vasculitis Activity Score (BVAS) was recorded. Laboratory investigations were recorded and the antineutrophil cytoplasmic antibody (ANCA) performed.

Results: The median age of the patients was 44.5 (32–63) years, 22 males:24 females and disease duration 6.5 (1–16) years. Ocular manifestations were present in all patients; 12 (26.1%) had posterior, 41 (87%) scleritis/episcleritis with perforation in 3 (6.5%), keratoconjunctivitis in 33 (71.7%) – acute infiltrative stromal keratitis in 11, peripheral ulcerative keratitis in 15 and sclerosing keratitis in 11 patients. Uveitis was present in 11 (23.9%) and retinal changes included vasculitis, exudates and haemorrhage was present in 7 (15.2%). 43 (93.5%) of the patients had blurring of vision and vision loss was present in 2 (4.3%). Glaucma was present in the total (8.7%). Involvement was bilateral in 32 (69.6%) patients. Rheumatoid factor was positive in 56.5% and significantly associated with uveitis (p=0.04) while ANA was positive in 45.7% and significantly associated with keratoconjunctivitis (p=0.04). BVAS tended to be higher in those with uveitis (p=0.05).

Conclusions: Ocular involvement must be considered in all GPA patients and referral to an experienced ophthalmologist is mandatory for proper management and improved outcome of such a rare systemic disease. ANA and RF positivity may raise suspicion for KC or uveitis respectively. There was a remarkable association between uveitis and disease activity.

AB0705

LONG-TERM OUTCOMES AND PROGNOSTIC FACTORS ASSOCIATED WITH AORTIC VALVE SURGERY IN PATIENTS WITH TAKAYASU ARTERITIS AND AORTIC VALVEREGURITATION

S.H. Nam1, O.C. Kwon1, W.J. Seo2, Y.-G. Kim1, C.-K. Lee1, B. Yoo1, S. Hong1, Internal medicine, Asan Medical Center, Internal medicine, Veterans Health Service Medical Center, Seoul, Korea, Republic of Ireland

Background: Some patients with Takayasu arteritis (TA) have aortic valve (AV) involvement, which can lead to aortic regurgitation (AR). However, data on the long-term outcomes, including survival of TA patients with AR, are lacking. Moreover, previous studies were limited to patients who underwent AV surgery.

Objectives: This study aimed to characterise the long-term outcomes and clinical characteristics of TA patients with AR regardless of whether they underwent surgical or percutaneous interventions.

Methods: Medical records of patients with TA between January 1995 and December 2015 were retrospectively reviewed. AR was diagnosed using transthoracic echocardiography. Poor outcomes were defined as all-cause death and major adverse cardiac and cerebrovascular events (MACCE). Multivariate analysis was performed to determine the factors affecting poor prognosis in the surgical group.

Results: Of the total 105 patients with TA and AR, 41 (39.0%) underwent AV surgery. Among patients who underwent AV surgery, inflammation values (Erythrocyte sedimentation rate, 62.0±73.1 mm/hr vs. 39.16±28.4 mm/hr; C-reactive protein, 3.66±4.1 mg/dL vs. 0.92±1.7 mg/dL, AR degree (3.56±0.7 grade vs. 2.08±1.0 grade), and sinus diameter (37.2±45.5 mm vs. 33.2±24.5 mm) were significantly higher than in those who did not undergo AV surgery. Long-term survival and freedom from MACCE were not significantly different between the groups (10 year survival, 84.3% vs. 79.4%; p=0.827, 10 year event-free survival 51.8% vs. 71.2%; p=0.29). Twelve of the 41 patients who underwent AV surgery had a poor outcome during follow-up (median, 92.5 months; IQR, 54.5–183.5), and eight of them had a recurrence of AR requiring reoperation. Multivariate Cox analysis revealed that coronary disease (hazard ratio (HR), 4.234; 95% confidence interval (CI), 1.381–12.979; p=0.012), LV dysfunction (HR, 3.387; 95% CI, 1.143–10.042; p=0.028), and impaired renal function (HR, 19.983; 95% CI, 3.480–114.731; p=0.001) were significant risk factors associated with poor outcomes at follow-up (table 1).

Variables HR 95% CI p-value
Coronary disease* 4.234 1.381–12.979 0.012
LV dysfunction** 3.387 1.143–10.042 0.028
Impaired renal function 19.983 3.480–114.731 0.001

*coronary disease: severity is more than moderate stenosis
LV dysfunction: EF <50%

Conclusion: In patients with TA with AV involvement, there were no significant differences between long-term survival rate and event-free survival (MACCE) among those who had or had not undergone AV surgery. In the surgical group, the prognosis was poor when coronary artery disease, LV dysfunction, and renal impairment were present at the time of surgery.

FOUR DISTINCT CLINICAL PHENOTYPES OF VASCULITIS AFFECTING MEDIUM-SIZED ARTERIES

T. Shira, H. Fuji, Y. Shirota, T. Ishii, H. Harigae. Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Polyarteritis nodosa (PAN) is a necrotizing arteritis of medium-sized arteries. PAN is divided into systemic and cutaneous PAN (cPAN). cPAN is further classified into mild cPAN or severe cPAN, which presents with ulcer, necrosis, or neuritis. However, it is sometimes difficult to distinguish between severe cPAN and systemic PAN, and their optimal managements are still unclear. The aim of this study is to evaluate clinical characteristics of patients with necrotizing arteritis of medium and small arteries.

Objectives: To evaluate the clinical characteristics of patients with necrotizing arteritis of medium-sized arteries in order to further clarify the subtypes of PAN.

Methods: Forty-nine patients diagnosed with necrotizing arteritis of medium-sized arteries between 2008 and 2017 at our institution were enrolled to this study. Patients with evidence of glomerulonephritis or vasculitis in arteries, capillaries, or venules, which are hallmarks of small-vessel vasculitis, were excluded. Clinical backgrounds, laboratory findings including inflammatory markers and antineutrophil cytoplasmic antibodies (ANCA), affected organs, treatments, and rates of relapse and death were evaluated.

Results: Among 49 patients, 11 patients (22%) presented with systemic vasculitis. Organ involvement was diverse and ranged from central nervous system to cutaneous manifestations. The remaining 38 patients were diagnosed as cPAN and further classified as mild cPAN (16 patients) or severe cPAN (22 patients: ulcer type, 9; neuritis type, 9; both, 4). There was one case of cPAN which resulted in renal damage. The clinical characteristics of mild cPAN included female preponderance (87.5%) and younger age (median, 32), and patients tend to have normal inflammatory markers and laboratory findings. Those of systemic PAN included older age (median, 69), higher levels of inflammatory markers, lower levels of serum proteins, and organ damage. Nonspecific elevation of autoantibodies is frequently observed. Particularly, 54.5% of systemic type possessed MPO-ANCA though the titers were significantly lower than those of microscopic polyangiitis, suggesting nonspecific elevation of MPO-ANCA in Japanese population.

Severe cPAN manifested with intermediate phenotypes, and inflammatory activities were significantly correlated with age (p<0.001). Although the mortality rates were indistinguishable, the relapse rates of cPAN (ulcer type) were significantly higher than those of other types (88.9%, Figure). The mean doses of prednisolone (PSL) used to treat mild cPAN, severe cPAN, and systemic type were 18.5, 38.6, and 39.1 mg/day, respectively. Immunosuppressants were used in 20% of mild cPAN, 80.9% of severe cPAN, and 72.7% of systemic PAN patients. Most patients with cPAN (ulcer type) were initially treated by corticosteroid monotherapy, and immunosuppressive agents were added when they relapsed. Considering its high relapse rate, it might be reasonable to select combination therapy with cyclophosphamide for severe cPAN (ulcer type) as is proposed in non systemic vasculitic neuropathy.

Conclusions: The clinical characteristics of mild cPAN, severe cPAN (ulcer type), severe cPAN (neuritis type), and systemic PAN were distinct from each other. Particularly, patients with severe cPAN (ulcer type) had higher relapse rates, thus indicating the importance of combination therapy in this patient cohort.

THE USE OF TEMPORAL ARTERY BIOPSIES (TAB) IN DIAGNOSIS AND MANAGEMENT OF PATIENTS WITH GIANT CELL ARTERITIS (GCA): A RE-AUDIT IN RHEUMATOLOGY IN THE BELFAST HEALTH AND SOCIAL CARE TRUST (BHSCT)

U.A. Laverty, E. Banks, M. McHenry, NHS, Belfast, Ireland

Background: Patients should meet at least 3/5 American College of Rheumatology (ACR) criteria for a diagnosis of GCA. British Society of Rheumatology (BSR) guidelines on the management of GCA from 2010 emphasise the importance of early referral for specialist management. TAB should be considered depending on local experience and availability of other imaging modalities. Biopsy should be at least 10 mm in length and ideally done within 14 days of presentation. TABs performed in BHSCT over a three-year period were audited in 2014.

Objectives: We re-audited the Rheumatology TAB referrals in the BHSCT from August 2016 to August 2017 to assess how biopsies influenced the management of patients with GCA in comparison to the previous audit.

Methods: Histopathology based LabCentre search detected 36 TABs within the given period. A retrospective audit was carried out with the use of Electronic Care Record and 16 of these patients were Rheumatology based TAB referrals. A proforma was used to aid data collection.

Results: Female:Male ratio was 2:2.1, age range was 61–91 with a mean age of 76. 94% of patients presented with headache. Of those patients referred for biopsy, 100% already fulfilled 2 of ACR criteria, compared with only 80% in previous audit. TAB was positive in 25%, In those with a positive biopsy, 75% had an ESR >50. All patients were on steroid treatment at the time of biopsy. In 42% of patients with a negative biopsy, steroids were rapidly reduced. 100% of patients with a positive biopsy continued on steroids. 68% of biopsies were greater than 10 mm compared with 38% in the previous audit. 68% of patients had a TAB within 14 days of commencing on steroids, with 31% having biopsy within 7 days of commencing steroids. 63% of patients developed steroid related complications. In 56% of patients the biopsy result changed patient management.

Conclusions: The percentage of appropriate referrals for biopsy (based on the ACR criteria) has improved compared with the previous audit. The length of biopsy improved. 32% of patients were waiting longer than 2 weeks for biopsy but some of these patients presented late to the rheumatology team. Biopsy results changed management in 56% of patients. Areas for consideration include improvement in time to biopsy and biopsy length.

SWITCHING FROM ORIGINATOR INFLIXIMAB TO BIOSIMILAR INFLIXIMAB: EFFICACY AND SAFETY IN A COHORT OF PATIENTS WITH ESTABLISHED BEHÇET’S DISEASE

V. Veneto1, G. Lopalco1, L. Cantarini1, C. Fabiani2, M. Nivon1, F. Cacciapaglia1, M. Galeazzi2, G. Lapadula1, F. Iannone1, 1Department of Emergency and Organ Transplantation, Rheumatology Unit, University of Bari “Aldo Moro”, Bari; 2Department of Medical Sciences, Surgery and Neurosciences, Rheumatology Unit, Poliomico “Le Scotte”, University of Siena, Siena; 3Department of Ophthalmology, Humanitas Clinical and Research Center, Rozzano, Italy

Background: Infliximab (IFX) has been proved to be effective in several organ involvement of Behçet’s Disease (BD). A recent report describing rapid loss of efficacy of biosimilar IFX after switching from originator IFX suggests the necessity to exercise caution regarding the automatic substitution of originator IFX with biosimilar IFX in patients achieving remission with originator IFX.

Objectives: The purpose of the present study was to describe our experience with biosimilar IFX CT-P13 in patients affected with BD, who were switched from originator IFX.

Disclosure of Interest: None declared

**Methods:** Retrieved data including demographic characteristics, clinical manifestations and previous treatments were collected. All patients met the ISG and/or ICBD classification criteria for Behcet’s Disease. In order to evaluate disease activity, the BD Current Activity Form (BDCF) has been evaluated before starting biosimilar, at three, six and nine months after switching to CT-P13. The occurrence of adverse events was also recorded. Wilcoxon matched-pairs signed-ranks test was carried out to evaluate differences between BDCF distributions pre-switch and either at three, at six and at nine months after switching.

**Results:** Thirteen Caucasian adult BD patients (mean age 39.77±7.46 years) with a mean disease duration of 12.54±4.21 years, underwent IFX treatment at licensed dosage for a period of 117.66±48.01 months. After 106.92±46.37 months of treatment with originator IFX, all of them were switched to CT-P13 biosimilar IFX. At 3 months after switching, none of them had discontinued CT-P13 biosimilar IFX treatment. No significant difference was noticed between BDCF mean score assessed at switch and 3 months after switching (p=0.15). At 6 months follow up, 2/13 patients (15.38%) discontinued CT-P13 biosimilar IFX treatment, both for recurrence of mucocutaneous involvement. One out of 2 patients who discontinued CT-P13 IFX had previously experienced a disease flare under originator IFX therapy, requiring a modification of ongoing therapy. BDCF mean score assessed before and 6 months after switching were not significantly different (p=0.81). Nine months after switching 2 out of the remaining 11 patients were lost follow up. Once more, no difference was shown between BDCF mean score assessed at switch and at 9 months follow up (p=0.85). No adverse events occurred during the observed period.

**Abstract AB0709 – Figure 1**

**Conclusions:** Despite the short follow up period, these data suggest that switching BD patients from originator IFX to CT-P13 seems to be effective and safe; only a small percentage of patients experienced relapse of symptoms, whereas a significant modification of BDCF pre-switch and post-switch was not noticed. Although encouraging, these results need to be confirmed over a longer follow up period and on larger cohorts of patients.

sants, was effective and well tolerated in severe/refractory vascular BD, with a
TCZ, in combination with corticosteroids and immunosuppress-
ber and dosage in 3 (42.9%) and 3 patients (42.9%), respectively. No serious
adverse event or TB reactivation was observed.
Conclusions: TCZ, in combination with corticosteroids and immunosuppres-
sants, was effective and well tolerated in severe/refractory vascular BD, with a favourable steroid- and immunosuppressant-sparing effect.

AB0712
ELIGIBILITY OF PATIENTS WITH GIANT CELL ARTERITIS FOR ENTRY INTO A PROSPECTIVE RANDOMISED CONTROLLED TRIAL: A SINGLE-CENTRE EXPERIENCE

W. A. Schmidt1, K. Hoheinz1, S. Burger1, V. S. Schäfer1,2, A. Juche1, Medical Center for Rheumatology Berlin-Buch, IMMANUEL KRANKENHAUS BERLIN, Berlin, Germany

Background: The interest in pharmaceutical trials in giant cell arteritis (GCA) is increasing. Trial recruitment may be more challenging in GCA than in other rheumatic diseases because of a higher proportion of elderly patients who are addi-
tionally faced with a new diagnosis when being considered for trial participation.

Objectives: To analyse the eligibility of newly diagnosed and flaring GCA patients for one centre in randomization for the SIRRESTA trial (ClinicalTrials.gov Identifier, NCT02531633; sirukumab versus placebo), to list reasons for non-ran-
donization, and to compare eligible with non-eligible patients.

Methods: All patients with newly diagnosed or relapsing GCA considered for trial participation between August 2016 until trial termination in October 2017 were included. The trial was prematurely terminated by the sponsor based on the deci-
sion to discontinue development of sirukumab in autoimmune diseases. Analysis of variance, two-sided Fisher’s exact and Pearson’s chi-squared tests were applied for calculating statistical significance.

Abstract AB0712 – Table 1. Comparison of eligible and non-eligible GCA patients for trial participation

Total Eligible for trial Not eligible for trial Significance
N 95 12 (13%) 83 (87%)
Age (SD) 71.1 (8.3) 65.3 (6.0) 71.8 (8.5) years 0.008*
Females 61% 75% 59% 0.356

Headache 59% 59% 63% 1.0
Jaw claudication 34% 33% 34% 1.0
PAM 62% 83% 59% 0.125
ESR (SD) 71 (30) mm/h 85 (31) mm/h 69 (34) mm/h 0.125
CRP (SD) 9 (8) mg/l 12 (83) mg/l 85 (45) mg/l 0.095
*p<0.05, significant; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; GCA, giant cell arteritis; PAM, polymyalgia rheumatica; SD, standard deviation

Results: Ninety-five patients were pre-screened. Fifteen of these patients were screened and only 12 of the 95 (13%) pre-screened GCA patients were eligible for randomization based on inclusion and exclusion criteria. The other 83 patients were not eligible for one or more of the following reasons: Concomitant diseases (42%) including second autoimmune diseases (11%), malignancy (6%), history of diverticulitis (5%), hepatitis (1%), failure to meet inclusion criteria (41%), including symptoms (12%), history/imaging (1%), exceedance of maximum glucocorticoid dose (7%), low ESR and CRP (10%), low treatment duration (11%), declined consent (29%), before (11%) and after receiving the consent form (18%); too long distance to study centre (5%).

Patients eligible for the trial were younger. They had no ischaemic complications (see table 1). A higher proportion of relapsing GCA patients were included. This subgroup of a larger trial represents only data from one centre. It may not be repre-
sentative for the findings in other centres or the whole study.

Conclusions: Many newly diagnosed or relapsing GCA patients were not eligible for a trial due to concomitant diseases, failing inclusion criteria or declined consent. Eligible patients were younger; and more had relapsing disease.

AB0713
INTERFERON-ALPHA FOR THE MANAGEMENT OF LOWER EXTREMITY DEEP VEIN THROMBOSIS IN BEHÇET’S SYNDROME: A CASE SERIES

Y. Ozguler, G. Hatemi, F. CETINKAYA, S. UGURUL, E. SEYahi, H. Yazici, M. Melikoglu. Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey

Background: Lower extremity deep vein thrombosis (LEDVT) is a disabling compi-
lcication of Behçet’s syndrome (BS). Relapses are frequent and cause permanent disability due to post-thrombotic syndrome.1 The management of LEDVT in Behcet’s syndrome (BS) constitutes mainly of azathioprine (AZA) and corticosteroids (CS) as first-line agents.2 Interferon-α (IFN) has been used with good results in the management of eye involvement of BS. However data regarding its efficacy for vascular involvement has been scarce.3

Objectives: We aimed to evaluate the efficacy and safety of IFN for LEDVT in BS.

Methods: All BS pts who had a first episode of acute LEDVT since March 2010 are being prospectively followed with a standard protocol in our dedicated BS centre. Acute LEDVT is confirmed by Doppler ultrasonography (DUS) at initial diagnosis and serial DUS assessment is performed and also repeated in case of clinical suspicion of relapse. Our standard treatment strategy consists of AZA and CSs as first-line treatment in pts with LEDVT. IFN has been used in pts who were refractory or intolerant to this regimen, or who had co-existing eye involvement. Our endpoints for assessing efficacy of IFN have been recanalisation of the index thrombus and prevention of relapses. Presence of recanalisation of thrombosed vein and extension of thrombosis have been assessed at each visit. Recanalisa-
tion has been assessed in the transverse plane and defined as the ratio of the vein area at maximum compressibility to the non-compressed vein area. Good recanalisation was defined as a ratio of at least 50%. Adverse events during IFN use were recorded.

Results: 33 pts with LEDVT (26 M/7 F) were prospectively followed for a mean of 40.7±13.4 mo. Among these IFN was started in 18/33. In 2 pts IFN was started at the first episode of LEDVT due to co-existing uveitis. Seven pts were treated with IFN due to LEDVT relapses under AZA. In the remaining 9 pts, the reasons for switching from AZA to IFN were adverse events with AZA (n=2), relapse of superfi-
cial thrombophlebitis (n=4), leg ulcers due to severe post-thrombotic syndrome (n=2) and eye involvement (n=1). Among 17 pts treated with IFN mainly for vascu-
lar involvement during a mean follow-up of 29±20 mo, 3 pts already had good recanalisation when starting IFN. In the remaining 14 pts, 13 (93%) had good recanalisation under IFN. Two pts (11%) experienced relapses. One of the 2 pts who had a relapse had poor recanalisation despite IFN. In contrast, among the 29 pts treated with AZA, only 13 (45%) had good recanalisation and 13 (45%) pts experienced relapses. Nine of the 13 pts who had relapses under AZA had poor recanalisation. Overall we observed 23 LEDVT relapses in 15 pts. Relapse rates were 29%, 37% and 45% at 6, 12 and 24 months respectively. The only adverse event with interferon-alpha causing drug withdrawal was thyroiditis in 1 patient.

Conclusions: Relapse rate for LEDVT in BS is high despite AZA treatment. IFN seems to be a promising agent for preventing LEDVT relapses and achieving good recanalisation, an important predictor of relapse. The small number of pts and the lack of a parallel control group are the limitations of this prospective study.

MONOCYTES TO LYMPHOCYTES RATIO IS CORRELATED WITH DISEASE ACTIVITY IN BEHÇET’S DISEASE

V. Huang, S. Zheng, T. Li, F. Feng, W. Deng, Q. Huang, Z. Huang, Z. Huang, X. Pan. Department of Rheumatology and Immunology, Guangdong Second Provincial General Hospital, Guangzhou, China

Background: Behçet’s disease (BD) is a complex, inflammatory multisystem disorder. Since the lack of universally recognised pathognomonic laboratory test, the diagnosis relies heavily on clinical findings. Currently, the Monocytes to lymphocytes ratio (MLR), Neutrophils to Lymphocytes ratio (NLR), Platelets to Lymphocytes ratio (PLR) and Red blood cell Distribution Width(RDW) have been demonstrated as a assessment of disease severity in many rheumatism diseases. Nevertheless, to our knowledge, only a few studies have investigated NLR, PLR, RDW in patients with BD.

Objectives: The aim of this study is to determine MLR, NLR, PLR and RDW in BD and to investigate their relationships with disease activity.

Methods: A total of 37 patients with BD fulfilling the criteria of the International Study Group for BD and 37 age and gender-matched healthy controls were enrolled in the study retrospectively. MLR, NLR, PLR, RDW, C-reactive protein (CRP) level and Erythrocyte Sedimentation Rate(ESR) level were evaluated. The correlation between the variables were tested with Pearson correlation. Area Under Curve(AUC) value, sensitivity, specificity, and the optimal cut-off values were determined using Receiver Operating characteristic Curves (ROC). According to the optimal cut off value, BD patients were divided into low-value group (>the optimal cut off value) and high value group (>the optimal cut off value). The patient’s clinical characteristics between the two group were compared.

Results: The MLR, NLR, PLR and RDW were (0.37±0.24), (2.91±1.95), (155.09±55.08) and (13.83±1.77) in BD group, while (0.18±0.04), (1.45±0.46), (115.66±28.01) and (13.07±1.19) in control group, the difference was significant (P all<0.05). MLR, NLR and PLR were all correlated positively with ESR(r=0.363, P<0.05; r=0.496, P<0.05) and CRP(r=0.713, P<0.05; r=0.785, P<0.05). RDW was not correlated with ESR and CRP. ROC curve results showed that the AUC of MLR, NLR, PLR and RDW for BD were 0.841(CI95%: 0.748–0.935), 0.815(CI95%: 0.712–0.918), 0.720(CI95%: 0.699–0.840), 0.635(CI95%: 0.505–0.765), MLR yielded a highest AUC. In addition, the optimal cut off value of MLR for BD was 0.23, with the specificity of 73.0% and sensitivity of 83.8%. In 37 BD patients, 14 belong to low MLR group, 23 belong to high MLR value group. The comparison results show that high MLR value group have higher CRP level and higher incidence of genital ulceration(P<0.05).

Abstract AB0714 – Figure 1

Conclusions: MLR was elevated in BD patients as compared to control group, having a close relationship with disease activity.

AB0716 AN AUTOPSY CASE OF SYSTEMIC SCLEROSIS WITH SEVERE INTESTINAL INVOLVEMENT AND LITERATURE REVIEW
A. Aoki1, H. Hirano2, H. Kobayashi3, T. Okubo1, Y. Umebayashi1, H. Oka1
1Dept. of Rheumatology; 2Dept. of Pathology; 3Dept. of Dermatology, Tokyo Medical University Hachioji Medical Center, Tokyo, Japan

Background: The gastrointestinal tract (GIT) is the second most common internal organ affected by systemic sclerosis (SSc). The rate of SSc patients who develop severe GIT symptoms is lower than 10%, although various degrees of chronic intestinal pseudo-obstruction (CIPO) may occur in as many as 40% of cases (1,2).

Objectives: To report an autopsy case of SSc with severe intestinal involvement and review the associated literature.

Methods: We will present the clinical features and autopsy findings of a SSc patient and literature concerning Japanese SSc autopsy cases associated with severe intestinal involvement, found Igaku-chuo and Pub-med on Internet.

Results: A 69-year-old Japanese woman was diagnosed with diffuse cutaneous SSc from skin sclerosis, Raynaud’s phenomenon, and mild intestinal pneumonia in January 2013. The antinuclear antibody was positive (1:160, speckled pattern), but the specific antibodies, including the anti-RNP, topoisomerase I, and centromere antibodies, were negative. In August 2015, at the age of 71, she was hospitalised for vomiting and abdominal pain. Plain abdominal radiograph showed dilation of the small bowel with air-fluid levels. Abdominal CT revealed large dilation of the small bowel in the absence of any mechanical obstruction. These findings were consistent with CIPO. Her symptoms soon improved by decompression with a long intestinal tube. But she experienced frequent relapse of CIPO. During this hospitalisation in May 2016, an abdominal CT showed pneumatoses, oesophageal dilatation (PCI) and free air in the peritoneal cavity. Medical management failed to control the CIPO. Her general conditions had gradually worsened with weight loss of 10 kg in 3 years. Home parental nutrition was initiated in January 2017. On May 2017, she developed severe pneumonia after vomiting, and her condition gradually deteriorated. She finally succumbed to her illness and an autopsy was performed. The whole alimentary tract except for the duodenum showed a thinning of the lamina propria and atrophy of the smooth muscular layers. Intimal proliferation and narrowing of arterioles were also noted. There was non-specific interstitial pneumonitis in the both lower lobes and diffuse alveolar damage in the both of upper lobes of the lungs. Vasculopathy was also seen in the lungs and heart. The cases in the literature are summarised in table 1. Vascular damage and/or smooth muscle atrophy were presented in all cases.

Abstract AB0716 – Table 1. Autopsy cases of systemic sclerosis associated with severe gastrointestinal symptoms in Japan

M: male; F: female; yr: years; mo: months; GIT: gastrointestinal tract; IP: interstitial pneumonia; CIPO: chronic intestinal pseudo-obstruction; PCI: pneumatoses intestinales; 1) Intimal proliferation and narrowing of the small arteries

Conclusions: Vasculopathy in SSc involves small vessels, and it precedes fibrosis.3 The triggering event of vasculopathy is unknown, but the narrowing of intestinal arterioles causing hypoxia might be responsible for dysmotility of GIT.

AB0717 RISK ASSOCIATION BETWEEN SCLERODERMA DISEASE CHARACTERISTICS, PERIODONTITIS AND TOOTH LOSS
G. Isola1, R. Williams2, A. Lo Guilo3, M. Materese4, L. Ramaglia5, G. Materese6
1Department of Biomedical Sciences and of Morphological and Functional Images; 2Residencia Gil Martino, Messina, Italy; 3Department of Periodontology, UNC School of Dentistry, Chapel Hill, USA; 4Clinical and Experimental Medicine; 5University of Messina, Messina; 6Department of Neurosciences, Reproductive and Odontostomatological Sciences, University of Naples “Federico II, Napoli; 7Department of Biomedical Sciences and of Morphological and Functional Images, University of Messina, Messina, Italy

Background: Systemic Sclerosis (SSc) is a multi-system disorder that can have significant adverse effects upon the health of the mouth.

Objectives: The aim of this study was to investigate the associations between the disease characteristics of SSc, periodontal disease (PD) and tooth loss.

Methods: Fifty-four patients affected by SSc and 55 non-diseased controls were matched for age and gender. SSc was characterised in subtypes and with the mean duration of disease and the Modifed Rodnan Skin Score [mRSS]. Patients were surveyed and examined through the evaluation of the periodontal parameters and the number of teeth.

Results: A logistic regression analysis showed that patients with SSc presented a higher number of missing teeth (p<0.001) and a significant median increased odds 2.95 (95% CI 1.26 to 6.84) of PD (defined as clinical attachment loss, CAL) compared to non-diseased controls (6.83, 95% CI 1.94 to 24.36). Moreover, the less values of PD was correlated with mRSS in the total SSc group and with the mean duration of disease in patients with limited SSc (p<0.007), even after adjusting this correlation with the presence of the major organs involvement.

Conclusions: This study showed that patients with SSc presented an increased odds of PD and tooth loss compared to non-diseased controls. In SSc patients, the magnitude of PD was strongly associated with the mRSS and with the mean duration of the disease. The clinicians should be aware of the potential systemic health problems related to PD.

Disclosure of Interest: None declared
(Raynaud’s phenomenon, pulmonary interstitial involvement, digital ulcers, digestive alterations, presence of sclerodermal renal crisis) and activity index variables (modified Rodnan skin score, HAQ-DI, mRSS). Results: Four patients were included (75% women). The median age at the time of the AHST was 36.5 years (range 27–51). In all cases, the initial diagnosis was diffuse cutaneous ES, refractory to corticosteroids and at least one DMARD. Prior to autologous hematopoietic stem-cells transplantation, the clinical manifestations presented were a) severe Raynaud’s phenomenon (100%) with significant joint and cutaneous involvement; b) digital ulcers (50%); c) interstitial lung disease (50%) and d) sclerodermal renal crisis (25%). In 3 of the 75% cases the antitpoisonase antibodies were positive. The conditioning treatment for the autologous hematopoietic stem-cells transplantation was cyclophosphamide at high doses (50 mg/kg x 4 days) and anti-thymocyte globulin. In 3 patients (75%) there were slight post-transplant complications (febrile neutropenia, diarrhoea) after a median follow-up of 6.5 years (range 1–15). The response to AHST is summarised in Table 1. All patients showed values <1 in the Health Assessment Questionnaire on the Disability Index (HAQ-DI), in 75% with a modified Rodnan skin score (mRSS) lower than 7.

**CLOSE TEMPORAL ASSOCIATION BETWEEN SILICONE COSMETIC SURGERY AND SYSTEMIC SCLEROSIS ONSET**

A. Sulli, S. Paolino, E. Alessandri, B. Ruaro, M. Pendolino, M. Cutolo, C. Pizzorni. Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genova, Italy

**Background:** The pathogenesis of systemic sclerosis (SSc) still remains unclear, however it is increasingly thought to result from interactions between environmental factors and epigenetic features leading to the onset and progression of SSc in genetically susceptible patients. Case reports of women with silicone breast implants who developed SSc have been published, but several case–control series and prospective studies in connective tissue diseases (including SSc) failed to find a significant increased risk associated with silicone cosmetic surgery. How- ever, several biases may be recognised in these studies, i.e. heterogeneous cohorts of enrolled patients not selective for SSc, non homogeneous either disease duration or disease stage at study entry. For these reason the possible effect of silicone implants as immune adjuvants is not clear.

**Objectives:** Retrospective study to find out patients who developed SSc after cosmetic surgery.

**Methods:** The clinical files of 110 female patients with systemic sclerosis were retrospectively evaluated. Among these, four patients showing a history of silicone cosmetic surgery (3.6%) were identified, and clinical data collected.

**Results:** The clinical data of the four patients are below reported. 1. LS 28 year old female who underwent cosmetic breast prosthesis: two years later she complained of Raynaud’s phenomenon (RP), and one year more later aggressive diffuse cutaneous SSc, along with anticientromere antibodies (ACA) positivity. 2. PJ 38 year old female who underwent cosmetic breast prosthesis: one year later she experienced RP and one more year later aggressive diffuse cutaneous SSc; anticentromere antibodies were positive with a speckled pattern, but specific SSc-related autoantibodies negative. 3. BS 33 year old female who underwent cosmetic breast prosthesis: two years later she complained of RP and one more year later limited cutaneous SSc with ACA positivity; SSc clinical condition partially improved and its progression stopped after breast prosthesis removal. 4. CM 58 year old female who underwent cosmetic lip silicone application: one year partially she complained simultaneous onset of RP and aggressive diffuse cutaneous SSc with anti-Topoisomerase positivity; she died during follow-up.

**Conclusions:** This study reports a prevalence of 3.6% of silicone cosmetic surgery before SSc onset. The close temporal association between silicone implant and disease development suggests a possible role of silicone in SSc pathogenesis. Specifically addressed clinical studies or big-data studies need to rule out this matter.

**SYSTEMIC SCLEROSIS AND CANCER DEVELOPMENT. A SINGLE-CENTRE EXPERIENCE**

E. Pelechais, E. Kaltsonoudis, P.V. Voulgari, A.A. Drosos. Rheumatology Clinic, Department Of Internal Medicine, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA, Ioannina, Greece

**Background:** Systemic Sclerosis (SSc) is an autoimmune connective tissue disease with multisystem involvement, and sometimes devastating results. In bibliography there are reports that scleroderma patients present a higher incidence of risk for cancer when compared with the general population. However, different estimates have been reported.

**Objectives:** The purpose of the present study was to evaluate the frequency of cancer development (CD) in a cohort of patients with SSc.

**Methods:** Patients that fulfilled the 2013 American College of Rheumatology/European League Against Rheumatism criteria for SSc and were followed up since 1999, were included. Date of disease onset, disease duration, autoantibodies, age, pulmonary hypertension, comorbidities and the type of CD have all been taken into account, during the period 1991–2016.

**Results:** Seventy-nine SSc patients have been included. 46 with limited (lcSSc) and 33 with diffuse cutaneous Systemic Sclerosis (dcSSc). Six of them, (7.6%), developed different types of cancer. Most of them were adenocarcinoma. More specifically, 2 developed pulmonary adenocarcinoma (1 with lcSSc and 1 with dcSSc), 1 follicular carcinoma of the thyroid gland (lcSSc), 1 colortal adenocarcinoma (lcSSc), 1 B-cell lymphoma (MALT lymphoma), and 1 prostate adenocarcinoma (lcSSc). Five out of six were female patients. Mean age at the time of cancer diagnosis was 66.8-years-old, while SSc has been diagnosed at the mean age of 49.4 years. Mean time of developing any type of cancer was 15.8 years after SSc diagnosis. The diagnosis of cancer was done in the last 20 months. All patients were non-smokers, had gastro-oesophageal reflux disease and pulmonary fibrosis, while 4/6 had also pulmonary hypertension and were under treatment with phosphodiesterase 5 inhibitors and bosentan. Scleroderma patients with CD have been referred to the corresponding oncology clinic for further treatment.

**Conclusions:** The present study on SSc and CD provides data showing a potential association between the two entities. We found a high frequency of cancer development in patients with SSc (7.6%). Thus, a careful monitoring and screening is required when physicians follow-up scleroderma patients.

**AB0721**

**TRANSFER OF SYSTEMIC SCLEROSIS AFTER ALLOGENIC BONE MARROW TRANSPLANTATION**

**Background:** It is accepted that donor-derived immunity is transferred with allogeneic bone marrow transplantation (BMT).

**Objectives:** To show evidence of the transfer of systemic sclerosis by allogeneic BMT.

**Methods:** In this report we describe a patient with T acute lymphoblastic leukaemia treated with allogeneic BMT from his mother in February of 2012.

First seen in November 2017 for digital ulcers that appeared one year before. He presented two necrotic ulcers: one on the second finger of the left hand and other on the third finger of the right hand (IMAGE 1). He was admitted to receive intravenous prostaglandins and complete the study.

**Conclusions:** This study reports a prevalence of 3.6% of silicone cosmetic surgery before SSc onset. The close temporal association between silicone implant and disease development suggests a possible role of silicone in SSc pathogenesis. Specifically addressed clinical studies or big-data studies need to rule out this matter.
The analysis showed ANA 1/640 centromere pattern, anticientromere antibodies, reumatoid factor (RF) (852 IU/mL) and C3 of 86.4 mg/dL. Previously to the BMT he had negative ANA, but we do not know the rest of the previous autoimmunity. On the videocapillaroscopy we observe an active scleroderma pattern (IMAGE 2–3).

He was diagnosed with systemic sclerosis based on Raynaud’s phenomenon, digital ulcers, anticientromere antibodies and abnormal nailfold capillaries.

He had not familiar background of connective tissue diseases, but his mother presented Raynaud’s phenomenon since she was thirty. So we studied her. She presented facial telangiectasia, puffy fingers and fingertip pitting scars and the same autoantibodies: ANA 1/320 centromere pattern, anticientromere antibodies, RF (159 IU/mL) and consumption of C3 (74.3 mg/dL) and C4 (7.6). We do not have previous autoimmune studies of her. On the videocapillaroscopy we observed a late scleroderma pattern (IMAGE 4–5).

She was also diagnosed with systemic sclerosis, based on Raynaud’s phenomenon, puffy fingers, fingertip pitting scars and facial telangiectasia, anticientromere antibodies and abnormal nailfold capillaries.

Conclusions: Experimental animal studies and human clinical reports have described the transfer of immune-mediated diseases from affected donors to unaffected recipients, because of that the importance of screening this diseases in the donor before a BMT. To our knowledge, this will be the first described case of transmission of systemic sclerosis by this mechanism. However, other explanations should also be taken into consideration. This include recipient’s own persistent intrathymic lymphocyte population that may produce autoantibodies and autoimmunity in the context of cGVHD. However, this last hypothesis is not supported since there is a familiar background and presence of anticientromere antibodies.

AB0722
CAPILLAROSCOPY AND PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW

A Vanhaecke1,2, V Smith1,2, K Meliens1,2, S Paolino3, Y Piette2, A Sulli1, A C Trombetta3, F De Keyster1,2, E Vandecasteele6, M Cutofo6, on behalf of the EULAR study group on microcirculation in Rheumatic diseases, 1Department of Internal Medicine, Ghent University, 2Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, 3Research Laboratory And Academic Division Of Clinical Rheumatology, Department Of Internal Medicine, Ircs San Martino Aou, University Of Genoa, Genoa, Italy, 4Department of Cardiology, Ghent University Hospital, Ghent, Belgium

Background: At this very moment, no systematic review evaluating the role of nailfold videocapillaroscopy (NVC), with standardised definitions, in pulmonary arterial hypertension (PAH) has been published.

Objectives: To systematically identify and review all available literature evaluating the role of capillaroscopy in PAH in SSC, according to the definitions of the EULAR study group on microcirculation in Rheumatic diseases.

Methods: A systematic literature search was performed in Pubmed, EMBASE and Web of Science. All retrieved articles were screened on title, abstract and full-text level. Reference lists and google scholar were additionally searched. Original research papers that documented an association between NVC and PAH (con- firmed on right heart catheterization [RHC]) in SSc were included. Subsequently, NVC parameters were subdivided in quantitative (density, dimension, morphology and haemorrhages), semi-quantitative (NVC score) and qualitative assessment (presence of scleroderma pattern, severity of scleroderma pattern and worsening of scleroderma pattern) according to the definitions of the EULAR study group on microcirculation in Rheumatic diseases.

Results: The systematic search identified 215 unique search results, of which 171 references were withheld after title screening. Abstract screening resulted in 51 references, only 19 were eligible for full-text review. Finally, 9 references were included in the final analysis after full-text screening (n=7) and bibliographic and google scholar search (n=2) (see table 1).

Regarding cross-sectional studies, density has been evaluated in 5 studies, with no unequivocal results for mean density: avascular score has been unequivocally associated with PAH. Dimension has been evaluated in 4 studies, with no unequivocal results. Morphology has been evaluated in 1 study and has been unequivocally associated with PAH. Haemorrhages and scleroderma pattern has been evaluated in 1 and 2 studies respectively, with no association. Severity of scleroderma pattern has been evaluated in 3 studies and has been unequivocally associated with PAH.

Regarding longitudinal studies, density (i.e. capillary loss) has been evaluated in 2 studies and has been unequivocally associated with incident PAH. Dimension and haemorrhages have been evaluated in 1 study both, with no association. Morphology has been evaluated in 2 studies, with no unequivocal results. Worsening of scleroderma pattern has been evaluated in 2 studies and has been unequivocally associated with incident PAH.

Conclusions: This systematic literature review, on behalf of the EULAR study group on microcirculation in Rheumatic diseases, is the first to investigate unequivocal associations between (incident) PAH and capillaroscopic alterations in a standardised way. Unequivocal associations were found in cross-sectional studies between avascular score, morphology, NVC score and severity of scleroderma pattern and PAH and in longitudinal studies between capillary loss and worsening of scleroderma pattern and incident PAH.

SEROPREVALENCE OF EPSTEIN-BARR VIRUS AND CYTOMEGALOVIRUS IN SYSTEMIC SCLEROSIS PATIENTS: PRELIMINARY RESULTS

A.C. Trombetta1, V Tomats1, E Alessandrini, S Paolino1, C Pizzorni1, M Ghi1, B. Ruaro1, M Patane1, E Gotelli1, F Goergen1, A Sulli1, V Smith1, M Cutofo1, 1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, IRCCS Polyclinic Hospital San Martino, University of Genoa, Genoa, Italy, 2Department of Rheumatology, University Hospital of Ghent, Ghent, Belgium

Background: Epstein-Barr Virus (EBV) and cytomegalovirus (CMV) are among the most diffused virus in humans, with prevalence of 90% and 80% respectively in adult immunocompetent population. Hypothesis for a role of EBV and CMV in systemic sclerosis pathogenesis was reported.

Methods: A total of 49 patients (44 females and 5 males, age 65.6±9 years, 34 with limited cutaneous involvement and 14 with diffused cutaneous involvement) diagnosed according to the 2013 ACR/EULAR criteria were randomly enrolled at their follow-up visit for a further more detailed analysis. After consent, all participants underwent serological testing for VCA- IgM, VCA-IgG and EBNA-IgG and CMV IgM and IgG, to determine prior or actual EBV and/or CMV infection. All SSC patients undergone also to clinical examination and instrumental evaluations according to SSC clinical standard follow up.

Results: The systematic search identified 215 unique search results, of which 171 references were withheld after title screening. Abstract screening resulted in 51 references, only 19 were eligible for full-text review. Finally, 9 references were included in the final analysis after full-text screening (n=7) and bibliographic and google scholar search (n=2) (see table 1).

Regarding cross-sectional studies, density has been evaluated in 5 studies, with no unequivocal results for mean density: avascular score has been unequivocally associated with PAH. Dimension has been evaluated in 4 studies, with no unequivocal results. Morphology has been evaluated in 1 study and has been unequivocally associated with PAH. Haemorrhages and scleroderma pattern has been evaluated in 1 and 2 studies respectively, with no association. Severity of scleroderma pattern has been evaluated in 3 studies and has been unequivocally associated with PAH.

Regarding longitudinal studies, density (i.e. capillary loss) has been evaluated in 2 studies and has been unequivocally associated with incident PAH. Dimension and haemorrhages have been evaluated in 1 study both, with no association. Morphology has been evaluated in 2 studies, with no unequivocal results. Worsening of scleroderma pattern has been evaluated in 2 studies and has been unequivocally associated with incident PAH.

Conclusions: This systematic literature review, on behalf of the EULAR study group on microcirculation in Rheumatic diseases, is the first to investigate unequivocal associations between (incident) PAH and capillaroscopic alterations in a standardised way. Unequivocal associations were found in cross-sectional studies between avascular score, morphology, NVC score and severity of scleroderma pattern and PAH and in longitudinal studies between capillary loss and worsening of scleroderma pattern and incident PAH.

CARDIO-PULMONARY DISEASE MANAGEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS: CARDIO-RHEUMATOLOGY CLINIC AND PATIENT CARE STANDARDISATION PROPOSAL

A. Spinella1, F. Lumetti1, A.V. Mattioli2, F. Coppì2, R. Rosario2, E. Cocchiarà1, M. Coletti2, G. Ferri1, C. Salvareno1, D. Giuggioli1, Sclerodermia Unit, Chair of Rheumatology, Department of Surgical, Medical and Dental Department of Morphological Sciences related to Transplant, Oncology and Regenerative Medicine, Chair of Cardiology, University of Modena and RE, Modena, Italy

Background: Systemic sclerosis (SSc) is a chronic connective tissue disease characterised by endothelial dysfunction, dysregulation of fibroblasts with excessive fibrosis of the skin and internal organs and autoimmune abnormalities. Cardio-pulmonary manifestations are common in SSc and their detection in the early stage of the disease as well as their careful follow-up are mandatory in order to counteract their impact on the overall disease outcome. Despite the need of establishing a proper methodology, literature provides few reports about this issue.

Objectives: To evaluate the activity of our Cardio-Rheumatology Clinic in order to optimise diagnostic management of cardio-pulmonary disease in SSc patients.

Methods: We retrospectively analysed data from 350 consecutive SSc patients referred to our University-based Rheumatology Centre and SSc Unit (F:M 308/42; ic/idSSc 45/305; mean age 50.8±14.7 years; mean disease duration 10.9±7.0 years). All patients underwent general and cardio-pulmonary assessment, in particular they were evaluated in the Cardio-Rheumatology Clinic. The following parameters were considered: physical examination; past and current drugs; blood tests, in particular Erythrocyte sedimentation rate-ESR, C-reactive protein-CRP, CPK enzymes, troponin, NT-pro-BNP, d-dimer, serum autoantibodies, 25-OH-vitamin D; capillaroscopy; pulmonary function tests; high resolution scan of the lungs (HRCT); standard electrocardiogram (ECC) and 24 hour Holter ECG monitoring. Doppler echocardiography; cardiac stress test; coronary angiography and right heart catheterization (RHC); cardiac MRI and CT; vascular ultrasound (intima-media-thickness, carotid-femoral and brachial-ankle pulse-wave-velocity). The clinicians decided to perform these examinations according to clinical picture and current methodologies.

Results: In the last 12 months we assessed 300 patients with 1st-level screening (cardio-rheumatologic evaluation, standard ECG, Doppler echocardiography, pulmonary function tests, thoracic imaging). Among 2nd-level, 30 procedures of 24 hour Holter ECG and 15 RHC tests were performed. Cardiac MRI, coronary CT angiography and vascular ultrasound were assessed, when requested, as 3rd-level examinations (30 procedures). After 1 year we observed a mean time of 10±5 days between request and clinical cardio-rheumatologic evaluation, 20±12 days to perform 1st-level screening, 25±15 days to execute the 2nd-level examinations. Figure-1 shows Cardio-Rheumatology algorithm for the management of SSc cardio-pulmonary disease.

Conclusions: The activity of our Cardio-Rheumatology Clinic optimises the cardio-pulmonary SSc assessment, determining an early detection of these harmful complications with reduced waiting times which are critical issues. Screening algorithms are useful to stratify the risk and to establish the most appropriate diagnostic-therapeutic protocols, improving outcome of scleroderma patients. The development of a cardio-pulmonary risk score and the standardisation of a patient care approach, according to international quality indexes, could represent further tools to optimise SSc management.

AB0725

SEVERE DYSPHAGIA “POOR PROGNOSTIC MARKER” IN IDIOPATHIC INFLAMMATORY MYOPATHIES

Background: In Idiopathic Inflammatory Myopathies (MII), 18%–20% of patients have dysphagia.

Objectives: To evaluate the frequency of dysphagia in patients with MII, association with other manifestations of the disease, treatment and evolution.

To evaluate clinical characteristics and evolution of severe dysphagia.

To compare clinical characteristics and evolution of mild-moderate versus severe dysphagia.

Methods: Retrospective, observational study. Patients with a diagnosis of MII were included according to modified classification criteria of Bohan and Peter. Demographic, clinical and complementary studies were recorded. Serious dysphagia was considered: contraindication of oral feeding. Descriptive statistics were performed. Chi2 test, Student’s test or Mann Whitney as appropriate.

Results: We included 91 of 106 patients evaluated from 1992 to 2017: 76% female, mean age at diagnosis 48±14 years. 53% presented dysphagia: mild/mild-moderate 62.5% (30/48 pts), severe 37.5% (18/48). Idiopathic dermatomyositis was the most frequent MII in these patients (71%). In patients with dysphagia, proximal muscle weakness was 90%, weakness of neck muscles 45%, weakness of respiratory muscles 27%.

A significant association was found between dysphagia and weakness of respiratory muscles, weak neck muscles, glucocorticoid pulses, gammaglobulin, grave infections and death. (Data not shown in the summary).

In patients with severe dysphagia, we observed a significant association with the requirement for mechanical ventilation, hospitalisation in an intensive care unit, serious infections and death (table 1).

When comparing mild-moderate dysphagia vs severe dysphagia, a statistically significant association was found with neck muscles weakness, respiratory muscle weakness, glucocorticoid pulses, gamma globulin use, requirement for mechanical ventilation, hospitalisation in an intensive care unit, severe infections and mortality (table 2).

Conclusions: This was the first multicentre Portuguese study about ILD in SSc.

In our cohort, ILD occurred in about 30% of the pts and was associated with a mortality rate of 3.4%.

Our results confirm that some variables are associated with pulmonary disease development, and thus its identification may help the clinician to detect pts with a higher risk of early ILD.

Abstract AB0727

ANTIBODY PROFILE AND SYSTEMIC SCLEROSIS: CLINICAL FEATURES – MYTH OR REALITY?

A.C. Duarte, A. Cordeiro, M.J. Santos, J. Canas da Silva. Rheumatology, Hospital Garcia de Orta, Almada, Portugal

Background: Antinuclear antibodies (ANA) occur in 80%–98% of systemic sclerosis (SSc) patients (pts), with different specificities. Anticentromere antibody (ACA), anti-topoisomerase I (anti-Scl70) and anti-RNA polymerase III are the commonest and are included in the new SSc ACR/EULAR classification criteria. According to literature, ANA specificities are associated with clinical features of the disease.

Objectives: Evaluate the relationship between antibody profile and clinical manifestations in a cohort of SSc pts.

Methods: We conducted a retrospective analysis of SSc pts followed in our department. Demographic data, disease duration, ANA specificities and clinical manifestations were collected. Mann-Whitney U test and Chi-square were used for comparisons between pts who tested positive or negative for different ANA specificities.

Results: In total, 117 pts were included, 91.5% female with mean age of 60.7 ±15.2 years and mean disease duration of 11.9±10.7 years. Seventy-five pts (64.1%) had limited cutaneous SSc (lcSSC), 26 (22.2%) diffuse cutaneous SSc (dcSSC), 8 (6.8%) very early diagnosis SSc, (6.8%) late overlap syndromes and 1 (0.9%) SSc sine sclerodermia. Most (92.3%) were ANA positive, with 53.8% having ACA, 26.5% anti-Scl70, 3.4% anti-U3 RNP, 2.6% anti-U1 RNP, 1.7% anti-PM/Scl and 0.9% anti-RNA polymerase III and 0.9% anti-Th/To.

Positivity for ACA was significantly associated with female gender (OR: 1.18 95% CI 1.04–1.34) and SSc phenotype (OR: 9.43 95% CI 3.86–23.03). ACA was also associated with older age at disease onset (p<0.008). Vascular involvement, defined by current/previously digital ulcers and/or telangiectasias, was also more prevalent in this group (OR: 5.59 95% CI 2.47–12.66). Pulmonary arterial hypertension (group 1 ERS/ESC 2013 classification) was present in 6.3% of pts with ACA. Oesophageal involvement was the second commonest manifestation and occurred in 57.1% of pts with ACA, although this association was not statistically significant. ACA seemed to have a protective effect for intestinal lung disease (ILD) (OR: 0.027 95% CI 0.004–0.213). Anti-Scl70 positivity was associated with dcSSc phenotype (OR: 9.29 95% CI 3.26–26.5) and ILD (OR: 10.39 95% CI 3.86–27.92).

From the 4 pts with anti-U3 RNP, 3 had dcSSC subtype. The only patient with renal manifestations was anti-U3 RNP positive and had rapidly progressive cutaneous involvement.

Legend: ACA – anticientromere antibody; anti-Scl70 – antitopoisomerase I; dcSSc – limited cutaneous systemic sclerosis; dcSSc – diffuse cutaneous systemic sclerosis; PAH – pulmonary arterial hypertension; GI – gastro-intestinal; MS – muscular-skeletal

AB0727
Anti-U1RNP was associated with muscle-skeletal manifestations (OR: 10.7 95% CI 9.02–20.44) and with overlap syndromes (OR: 15.2 95% CI 4.7–59.1). Pts with anti-Th/To and anti-RNA-polymerase III had lcSSc subtype. Vascular manifestations, oesophageal involvement and calcinosis cutis were the main manifestations, respectively. Table 1 shows detailed clinical manifestations and antibody profile.

Conclusions: In our cohort, ACA and anti-Scl70 were the commonest antibodies and were associated with lcSSc and dsSSc phenotype, respectively. ACA positivity conferred a higher risk of vascular disease and had a protective effect for ILD, while anti-Scl70 was associated with ILD.

Pts with anti-U1 RNP and anti-PM/Scl had mainly muscle-skeletal manifestations. This study confirms an association between immunological profile and clinical manifestations, reinforcing the importance of antibody profile and raising awareness for possible disease complications. Larger national studies would be desirable, specially for a better understanding of major organ involvement associated with least common antibodies.

AB0728 NAILFOLD CAPILLAROSCOPY IN SYSTEMIC SCLEROSIS – SIX YEARS IN REVIEW

A.C. Duarte, A. Cordeiro, M.J. Santos. Rheumatology, Hospital Garcia de Orta, Almada, Portugal

Background: Microvascular dysfunction is a dynamic process that is crucial in systemic sclerosis (SSc) pathogenesis. Nailfold capillaroscopy(NCP) is a rapid, non-invasive exam that illustrates the early capillary changes in SSc and monitor their evolution. It is extremely useful in clinical practice and has been recognised in 2013 ACR/EULAR classification criteria for SSc.

Objectives: Evaluate the prevalence and evolution of NCP scleroderma pattern in SSc patients and analyse possible associations with disease-phenotype.

Methods: NCP of SSc patients followed in our centre were reviewed; clinical and demographic features were collected. A descriptive analysis was performed and nonparametric tests compared patients with and without SSc pattern.

Results: In total, 70 out of 117 SSc patients had at least 1 NCP available during the last 6 years. Most of these patients(62.9%) had limited cutaneous SSc, 21.4% diffuse cutaneous SSc, 11.4% very early diagnosis SSc and 4.3% overlap syndrome; mean disease duration was 10.7±9.6 years.

At the moment of the first NCP, 46 patients(39.4%) had a scleroderma pattern, 12 (10.3%) had non-specific(NS) NCP abnormalities and 12 had a normal NCP. During the 6 years follow-up, NCP changed in 5 patients as illustrated in figure 1. However, none had concomitant development/worsening of other clinical manifestations. At the end of the follow-up, 49 (70%) patients had a NCP scleroderma pattern. Early pattern was present in 13 (26.5%) patients, active pattern in 21 (42.9%), active/late pattern in 3 (6.1%) and late pattern in 12 (24.5%). When comparing patients with and without scleroderma specific patterns (table 1), the presence of scleroderma pattern was associated with the presence of current/previous digital ulcers/OR 1.49 95% CI 1.17–1.92. However, this difference was not confirmed between the different scleroderma patterns.

Regarding, major organ involvement, although there were no statistical differences between both groups, patients with scleroderma pattern had a higher prevalence of oesophageal involvement.

AB0729 QUALITY OF LIFE ASSESSMENT IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION: A LONGITUDINAL STUDY

A.L.C. Guimarães1, K. Costa-Pereira2, J.B. Elias3, D.A. Marques3, E.A. Oliveira-Cardoso1, J.T. Garcia1, M.C. Oliveira1, V. Leopoldo2, A.F. Zombrilli3, T.M. Costa2, M. Vasconcelos2, M.C. Oliveira2, Ribeirão Preto School of Philosophy, Sciences and Literature; 2Division of Clinical Immunology, Ribeirão Preto Medical School; 3Ribeirão Preto School of Nursing, University of Sao Paulo, Ribeirão Preto, Brazil

Background: Autologous Hematopoietic Stem Cell Transplantation (AH SCT) has been explored as a therapeutic option for patients with systemic sclerosis (SSc) that do not respond to conventional treatment.

Objectives: To investigate changes in quality of life of severe and rapidly progressive SSc patients treated with AH SCT.

Methods: This is a longitudinal and comparative study. Patients were evaluated before (n=27), and at 6 (n=27) and 12 months (n=21) after AH SCT. The Generic Questionnaire for Evaluation of Quality of Life Medical Outcomes Study 36 Item Short-Form Health Survey (SF-36) was applied individually, face-to-face, under patient written consent. This questionnaire evaluates eight domains: physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), social functioning (SF), vitality (VT), role-emotional (RE) and mental health (MH). Results were transformed into a 0–100 scale, where zero corresponds to a worse health condition and 100 to the best possible score, and submitted to statistical analysis. Significance was defined as p<0.05.

Results: Most participants were females (n=24), with mean age of 33 years (standard deviation, SD=10.33) and mean time from diagnosis of 34.4 months (SD=34.89). Before AH SCT, the mostly impaired aspects were: PF (mean=8.33, SD=18.34), and RP (mean=35.82, SD=21.56), while MH (mean=61.63, SD=15.46) and SF (mean=56.87, SD=27.17) were mostly preserved. At 6 and 12 months post-AH SCT, there was a significant improvement of the SF-36 scores in the following domains: PF (6 months, p<0.01, 12 months, p<0.01); RP (6 months, p<0.01, 12 months, p<0.01); BP (6 months, p<0.01, 12 months, p<0.01); GH (6 months, p<0.01, 12 months, p<0.02); VT (6 months, p<0.01, 12 months, p<0.01); MH (6 months, p<0.01, 12 months, p<0.01). The SF domain showed significant increase only at 12 months (p<0.02). The only domain in which there was no significant change was RE.

Conclusions: Increases in the physical components of quality of life are more evident in the initial periods that follow AH SCT, while improvements in mental state, which are also associated with social aspects, are detected on longer follow-up. These data reinforce the relevance of AH SCT upon patient quality of life, signalling the importance of psychotherapeutic evaluations and follow-up.

Disclosure of Interest: None declared

Background: The idiopathic inflammatory myopathies (IIM) are rare systemic autoimmune diseases that affect the muscle and other organs. Traditionally, IIM encompasses polymyositis (PM) and dermatomyositis (DM), but progressively inclusion body myositis (IBM), Immune-mediated necrotising myopathy (IMNM), the antisynthetase syndrome (ASS) and connective tissue diseases-overly myositis (CTD-OM) have been recognised within the IIM spectrum.

Objectives: To compare the clinical characteristics and treatment in a IIM cohort from an Argentinian university hospital with the international IIM cohort EUROMYOSITIS.

Methods: Descriptive, retrospective study. IIM patients defined by expert opinion followed in our centre between October 2007 and October 2017 were included. ASS was defined by the presence of arthritis, Raynaud’s phenomenon, mechanic hands, elevated CK, muscle weakness, interstitial lung disease and/or presence of antisynthetase antibodies and, as in EUROMYOSITIS, patients with IIM with positive antisynthetase antibodies were reclassified as ASS. CTD-OM was defined as patients with IIM fulfilling classification criteria for other CTD.

Demographic data, accumulated clinical features, time interval between disease onset and diagnosis, IIM subtype, treatment and presence of neoplasm were evaluated.

Ethnicity was defined using the same classification as in EUROMYOSITIS.

Results: 58 patients were included: DM 24, PM 4, ASS 10, CTD-OM 20. 89.6% Hispanic, mean age 48.4±15.2 years, median time interval between disease onset and diagnosis 5 months (IQR 2–11 months), been higher in AAS (8.5 months, IQR 1.5–18.2 months). 6.89% (4/58) patients presented associated neoplasm, 3 with DM and 1 with CTD-OM. Table 1 shows the demographic and clinical features of our IIM cohort and EUROMYOSITIS. Table 2 shows treatments received in our cohort and EUROMYOSITIS.

Conclusions: DM was the most frequent IIM subtype in both cohorts. In our group, CTD-OM was second and ASS was third. Muscle weakness was found less frequently in our DM and AAS than reported in EUROMYOSITIS. However, calcinosis was more frequent. This could be explained by our mostly Hispanic population and/or by frequent Systemic Sclerosis overlap in our patients. It’s important to remark that the ethnic variety defined as Hispanic in EUROMYOSITIS has a complex composition in Latin America, due to interbreeding.

No difference was found in terms of most frequent treatments between both cohorts. However, use of IVIg was more frequent in our patients. To our knowledge, this is the first comparative report of an argentinian single-centre IIM cohort and an international multi-centre cohort.

Disclosure of Interest: None declared

AB0733

ASSOCIATION OF HAEMATOLOGICAL PARAMETERS WITH DISEASE MANIFESTATIONS, ACTIVITY, AND SEVERITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

1. Department of Rheumatology, Ankara University Faculty of Medicine, Ankara; 2. Department of Rheumatology, Trakya University Faculty of Medicine, Edirne, Turkey

Background: Neutrophil-to-lymphocyte ratio (NLR), monocyte-to-lymphocyte ratio (MLR), eosinophil-to-lymphocyte ratio (ELR), basophil-to-lymphocyte ratio (BLR), and mean platelet volume (MPV) may potentially reflect inflammatory status in systemic autoimmune diseases.

Objectives: The aim of this study is to investigate the association of NLR, MLR, ELR, BLR and MPV with disease manifestations, activity and severity in patients with systemic sclerosis (SSc).

Methods: 59 patients with SSc and 50 healthy controls were included in the study. All patients were diagnosed according to the 2013 ACR/EULAR systemic sclerosis classification criteria. Adult patients with SSc and healthy controls were compared in terms of NLR, MLR, ELR, BLR and MPV.

Results: SSc and control groups had similar ages and genders. Lymphocyte number was lower in SSc group compared to controls (p<0.001). SSc group also have higher NLR and MLR (table 1). There were no significant differences in ELR and BLR ratios between SSc patients and controls. Patients with active disease (2.9 [IQR 2.13], p=0.042), pulmonary hypertension (PHT), digital ulcers, and tendon friction rubs (TFR) had higher NLRs (table 2). MLR was also higher in dcSSc patients (0.28 [IQR 0.3] vs 0.15 [IQR 0.3], p=0.001). Patients with digital ulcers (p=0.02) and arthritis (p=0.013) had higher ELRs and patients with tendon friction rubs had higher ELRs (p=0.014) and BLRs (0.036) compared to those without. There was no significant relation between MPV and disease manifestations (table 2). There were no relationships between dysmotility and haematological parameters.

AB0732

EFFICACY AND SAFETY OF RITUXIMAB IN SYSTEMIC SCLEROSIS: FRENCH RETROSPECTIVE STUDY AND LITERATURE REVIEW

Background: Interstitial lung disease occurs in 42% of diffuse SSC patients and have a major impact on the overall survival.1 Cyclophosphamide and mycophenolate mofetil can allow the lung disease stabilisation.2-4 Recently several case-reports and little series reported the efficacy of rituximab in SSC, showing a possible improvement of pulmonary involvements.5-8 Large studies are lacking to determine the factors associated with rituximab response, the maintenance regimen and the long term efficacy of rituximab in SSC.

Objectives: To describe safety and efficacy of rituximab in patients with systemic sclerosis.

Methods: We included 13 patients with systemic sclerosis treated with rituximab and pooled with 40 additional patients from the literature. SSc rituximab untreated patients were matched to rituximab treated ones.

Results: Thirteen patients who received rituximab and 26 rituximab-untreated patients were included. In comparison to 26 patients who did not received rituximab, FVC changes were not significantly different, whereas DLCO improved in 13 patients while Venticil increased from 71% to 63% at M12 (p=0.04). Consdering 7 rituximab treated and 14 untreated diffuse SSc, FVC was improved during median mRSS from 18% to 32 at baseline to 9% at M6 (p=0.007), 13% at M12 (p=0.006) and 16% at the last follow-up (p=0.002). FVC increased from 71% to 63% at baseline to 84% at M6, 90% at M12 (p=0.001). DLCO increased from 58% to 63% at M0 to 63% at M12 (p=0.04).

Conclusions: Our personal data and pooled literature analysis suggest the efficacy of rituximab in the subset of diffuse SSC in particular in skin and interstitial disease involvements. The safety of rituximab seems to be reasonable and similar to previous data in other autoimmune diseases.

REFERENCES:

Disclosure of Interest: None declared

Background: Interleukin (IL)–35 is a member of the IL-12 family. Studies show that IL-35 is an important anti-inflammatory cytokine and suppresses effector T cell activity. Systemic sclerosis (SSc) is a chronic disease characterised by vascular damage, autoimmunity and fibrosis.

Objectives: In this study, we aimed to evaluate serum IL-35 level in SSc patients and its potential relation with disease findings.

Methods: Fifty-five SSc patients and 25 healthy controls were included in the study. All patients were diagnosed according to 2013 ACR/EULAR systemic sclerosis classification criteria. Serum IL-35 was measured using a commercial ELISA kit (Cloud-Clone Corp, Wuhan, China).

Results: SSc patients and healthy controls had similar ages and genders. The mean of serum IL-35 level was significantly higher in SSc patients (8.2±1.3 pg/ml) than in healthy controls (6.9±0.7 pg/ml) (p<0.001). Serum IL-35 levels were similar in lcSSc (n=44) and dcSSc (n=11) groups (8.3±1.2 and 8.0±1.6 pg/ml, respectively). There were no significant relationships between serum IL-35 level and digital ulcer, interstitial lung disease, pulmonary hypertension, tendon friction rub, gastrointestinal motility disorder, cardiac involvement and Anti-SCL70, anti-CENP-B positivity (table 1). There was no significant correlation between IL-35 level and disease duration, modified Rodnan skin score, Valentini disease activity score, Medsger disease severity score, erythrocyte sedimentation rate and C-reactive protein (CRP) levels. Serum IL-35 levels between patients treated with or without immunosuppressives didn’t differ significantly.

Conclusions: It has been reported that serum IL-35 level is higher in SSc patients than healthy volunteers and is associated with interstitial lung disease. In our study, the level of IL-35 was higher in SSc patients than healthy controls. There is no relationship between clinical parameters and IL-35 levels, this may be due to small sample size. Our results suggest that IL-35 may have a role on the pathogenesis of SSc. Further investigations are needed in large sample size of SSc patients.

NAILFOLD CAPILLARY COUNTS CORRELATE MOST WITH COMPLICATIONS OF SYSTEMIC SCLERODERMA IN JAPANESE PATIENTS

A. Kondo1, H. Dobashi1, T. Kameda2, M. Izumikawa2, S. Nakashima2, H. Shindai2, R. Wakiya3, M. Kato3, N. Kadawaki3. 1Kagawa university, Kita, Japan; 2Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa university, Kita, Japan

Background: Connective tissue diseases (CTD) patients have various clinical manifestation including pulmonary hypertension (PH) and digital ulcer (DU). Especially, Raynaud’s phenomenon (RP) is one of the common symptoms. On the other hand, “abnormal nailfold capillaries” are important as the findings that suggest RP associated with CTD. They are included in one of the items of classification criteria for Scleroderma (SSc) in 2013 Classification Criteria for Systemic Sclerosis (ACR/EULAR)1. Recently, some reports presented the usefulness of nailfold capillaroscopy (NFC) in SSc2,3. NFC findings showed enlarged/giant capillaries, fresh or old haemorrhages, avascular areas, ramified/bushy capillaries. These findings are known as “scleroderma pattern” features. Additionally, there are some reports that nailfold capillary density in SSc related with DU, PH and interstitial pneumonia (IP).

In this study, we clarify the association between nailfold capillary density and clinical manifestation by analysis of the case in our institution.

Objectives: To clarify the association between nailfold capillary density and clinical manifestation.

Methods: We enrolled Japanese SSc patients from May 2016 to May 2017 in our institution. We measured total nailfold capillary count per 1 μm from second to fifth finger by NFD “OptiPiX Capillaroscopy Clinic 1.7.x”. In addition, we investigated relationship with NFC findings and clinical manifestation such as current and previous DU, PH and IP.

Results: We enrolled 42 SSc patients. Total nailfold capillary counts significantly decreased, especially in SSc patients with, previous DU (μ=0.4122, p<0.0054), and PH (μ=0.3229, p<0.0022). In addition, there is significant difference between DU and existence of giant capillaries (μ=0.3019 p=0.0464), existence of avascular areas (μ=0.4057 p=0.0063). On the other hand, there is no significant difference between IP, PH and other “scleroderma pattern” features.

Conclusions: Our study revealed that total nailfold capillary counts were associated with PH and DU in SSc patients. We suggest that nailfold capillary density may most predict complications with SSc patients.

SYSTEMIC SCLEROSIS SINE SCLERODERMA: CHARACTERISTICS OF A SOUTH INDIAN COHORT FROM A TERTIARY CARE CENTRE

B. Chilukuri1,2, S. Chinnadurai2, B. Mahendran3, R. Ramamoorthy2, B. Selvakumar4, R. Sankaranarayanan1. 1Dept of Rheumatology, Parvathy Hospital, 2Institute of Rheumatology, Madras medical college, Chennai; 3Dept of Rheumatology, KIMS Hospital, Trivandrum; 4Dept of Rheumatology, SRMC, Chennai, India

Background: Systemic Sclerosis is a complex disorder characterised by autoimmunity, vasculopathy and fibrosis. The hallmark of Systemic Sclerosis is skin thickening. Systemic Sclerosis sine scleroderma is a variant of Systemic sclerosis which shares visceral, serological and vascular manifestations but lacks skin thickening. Systemic Sclerosis sine scleroderma still remains a rarely reported subtype of Systemic Sclerosis unlike commonly reported limited cutaneous and diffuse cutaneous types.

Objectives: Aim of this study was to analyse the characteristics of patients with Systemic Sclerosis sine scleroderma from a cohort of Systemic Sclerosis patients.

Methods: This study was done at Institute of Rheumatology, Madras Medical College, Chennai, India. It was a retrospective observational study (January 2006 to November 2016). Patients satisfying ACR/EULAR 2013 Classification criteria for Systemic Sclerosis were included in this study. Patients with overlap syndromes, MCTD, UCTD, children and pregnant women were excluded. Poornomglim criteria was used for diagnosis of Systemic Sclerosis sine scleroderma.Absent skin
Conclusion: The most common pattern of Systemic Sclerosis sine scleroderma observed in our cohort was oesophageal dysfunction (78%) followed by lung involvement in the form of interstitial lung disease (52.1%) and pulmonary hypertension (47.8%). Renal involvement was not observed in any of the patients. Most common autoantibody detected among patients with Systemic Sclerosis sine scleroderma was anti-centromere antibody (78.2%) followed by anti-scl70 antibody (21.8%). Nine patients (39.1%) received pulse cyclophosphamide therapy and 3 patients received rituximab therapy in view of interstitial lung disease.

Disclosure of Interest: None declared

Abstract AB0736 – Figure 1

Conclusions: The most common pattern of Systemic Sclerosis sine scleroderma observed in our cohort was Oesophageal dysfunction +Raynauds Phenomenon +Anti centromere antibody positivity +Interstitial lung disease with or without pulmonary hypertension which are usually the characteristics of limited cutaneous type of Systemic Sclerosis. Hence Systemic Sclerosis sine scleroderma could be a subset of limited cutaneous type without the phenotypic skin involvement.

AMINAPHTONE INCREASES SKIN BLOOD PERFUSION AND IMPROVES CLINICAL SYMPTOMS IN PATIENTS WITH RAYNAUD’S PHENOMENON INDEPENDENTLY FROM DIFFERENT TREATMENT BACKGROUNDS

B. Ruaro, C. Pizzorni, E. Gotelli, J. Alsheyyab, E. Alessandri, A. Sulli. Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy

Background: Aminaphtone is a vasoactive drug that was recently demonstrated to improve both peripheral blood perfusion (BP) and clinical symptoms of Raynaud’s phenomenon (RP) in patients with either primary or secondary RP to systemic sclerosis (SSc).1–2

Objectives: The aim of this study was to evaluate possible interferences of different treatment backgrounds on both skin BP and RP-related clinical symptoms in patients treated with aminaphtone, during a six-month follow-up.

Methods: Forty-six patients with active RP were enrolled during routine clinical assessment after informed consent (11 primary RP, mean age 49±19 SD years, mean RP duration 6±3 years; and 35 secondary RP to systemic sclerosis, mean age 61±17 years, mean RP duration 11±9 years). Aminaphtone was orally administered 75 mg twice daily in addition to current treatments, and all patients were on a stable drug regimen for at least two months, which remained unmodified during the follow-up. All patients were taking cardiaoaspirin. Six groups of treatment backgrounds were identified: 1) no further treatments (12 patients); 2) hydroxychloroquine (2 patients); 3) colchicine (5 patients); 4) methotrexate (3 patients); 5) cyclosporine A (6 patients); 6) mycophenolate (6 patients); 7) proton-pomp inhibitors (12 patients). Blood perfusion was measured by Laser Speckle Contrast Analysis (LASCA)2 at the level of fingertip, periangual areas, dorum and palm of hands, and face at baseline (T0), after one (T1), four (T4), twelve (T12) and twenty-four (T24) weeks of treatment. Raynaud’s condition score (RCS) and both frequency and duration of Raynaud’s attacks were assessed at the same time. Statistical analysis was performed by non-parametric tests.

Results: During aminaphtone treatment, a progressive statistically significant increase of skin blood perfusion, as well as an improvement of RP clinical symptoms (decrease of RCS, frequency and duration of RP attacks/day), were observed in all above reported seven groups of RP patients with different treatments backgrounds from T0 to T12 in all skin areas (p<0.01). There were no statistically significant difference between the seven groups of patients concerning skin BP at different times (p>0.60). The results were similar in both primary and secondary SSc RP patients (p>0.40). Aminaphtone administration had to be stopped in 2 patients due to headache, and one patient was lost during follow-up.

Conclusions: This study demonstrates that the increase of skin blood perfusion and the improvement of RP clinical symptoms is not influenced by different treatment backgrounds in RP patients treated with aminaphtone. These preliminary results should be further confirmed by a randomised blind clinical trial.

IMPROVEMENT OF DERMAL THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH ENDOTHELIN RECEPTOR ANTAGONIST: LONG TERM STUDY BY HIGH FREQUENCY ULTRASOUND

B. Ruaro1, A. Sulli1, C. Pizzorni1, M. Ghio2, V. Smith2, V. Tomatis1, M. Cuto1.1 Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium

Background: Systemic sclerosis (SSc) is a connective tissue disorder characterized by skin involvement, which may be evaluated by both modified Rodnan skin score (mRSS) and skin high frequency ultrasound (US).1–3 Endothelin-1 (ET-1) seems implicated in the development of dermal fibrosis in SSc.3 Bosentan, a dual ET-1 receptor antagonist seems effective in reducing skin fibrosis in SSc patients.4,5

Objectives: The aim of this study was to evaluate by US the long-term effects of bosentan on dermal thickness (DT) in SSc patients, in combination with long-term cyclic intravenous iloprost versus iloprost monotherapy.

Methods: Thirty-eight SSc patients were enrolled during their standard treatment for digital ischemia. At baseline (T0), 19 patients already receiving cyclic intravenous infusion of iloprost (5 continuous days, average 80 mcg/day, every two...
months), continued the treatment for further 4 years (T4) (ILO group). Other 19 patients, although they continued the same cyclic intravenous iloprost treatment (mean disease duration 6±4 SD years) were receiving a wide range of drugs, including vasodilators, immunosuppressive agents and endothelin receptor antagonists. Statistical analysis was performed by both US and mRSS. The treatment with ET-1 receptor antagonists was evaluated by continuous capillaroscopic patterns (NVC) at the same reported areas. The capillarangiopathy evolution score (MES) was used to evaluate DT at the above mentioned skin sites. The examination was performed in 65 healthy subjects.

Methods: Twenty-three female patients affected by SSc according to the LeRoy criteria (mean age 63±4 SD years, mean disease duration 6±4 years) were enrolled and followed for five years (T5), after informed consent. Laser speckle contrast analysis (LASCa), skin high frequency ultrasound (US), modified Rodnan skin score (mRSS), and nailfold videocapillaroscopy (VNC) were yearly performed. Blood perfusion (BP), assessed by LASCa at the level of fingertips, perungual areas, dorsum and palm of both hands, was calculated as perfusion units (PU). Dermal thickness (DT) was assessed by both US and mRSS in the same reported areas. The capillarangiopathy evolution score (MES) and the CN per linear millimetre at first distal row were evaluated by NVC. Patients were receiving a wide range of drugs, including vasodilators, immunosuppressive agents and endothelin receptor antagonists. Statistical analysis was performed by non-parametric tests. Results: A progressive statistically significant decrease of both BP (p<0.0001) and nailfold CN (p<0.0001) was observed from T0 to T5 at the level of all areas, as well as a progressive statistically significant increase of DT (p<0.0001), mRSS (p<0.0001) and MES (p<0.001) values. The progressive decrease of BP was positively correlated over time with the worsening of nailfold CN (p=0.03, r=0.62), MES (p<0.05, r=0.62), mRSS (p=0.002, r=0.72) and DT (p=0.002, r=0.64).

Conclusions: This study demonstrates a negative correlation between BP and DT as evaluated by both US and mRSS at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects. In healthy subjects, there was no statistically significant correlation between BP and DT as evaluated by both US and mRSS at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects. In healthy subjects, there was no statistically significant correlation between BP and DT at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects.

AB0740 EVALUATION OF HAND DERMAL THICKNESS AND PERIPHERAL BLOOD PERFUSION IN SYSTEMIC SCLEROSIS PATIENTS

B. Ruaro1, A. Sulli1, T. Santiago2,3, J.A. Pereira da Silva2,3, C. Pizzorni2, Y. Tomatis1, M. Cutolo1, 1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Systemic sclerosis (SSc) is characterised by progressive skin involvement. The modified Rodnan Skin Score (mRSS) is the gold standard to assess skin damage, but it has significant limitations. Recently, several studies demonstrated the utility of skin high frequency ultrasound (US) as an alternative.

Objectives: The aim of this study was to identify possible correlations between peripheral blood perfusion (BP) and ultrasonic dermal thickness (US-DT) at either skin sites and healthy subjects. In healthy subjects, there was no statistically significant correlation between BP and DT as evaluated by both US and mRSS at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects. In healthy subjects, there was no statistically significant correlation between BP and DT as evaluated by both US and mRSS at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects.

Results: BP was negatively correlated with both US-DT (r=−0.45) and mRSS (r=−0.07) in SSc patients at the finger sites, but not at the level of dorsum of the hands. In healthy subjects, there was no statistically significant correlation between BP and DT at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects. In healthy subjects, there was no statistically significant correlation between BP and DT at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects.

AB0741 T-REG AND TH17 LEVELS IN PATIENTS WITH SYSTEMIC SCLERODERMA

D. Üsküdar Čansu1, H. Üsküdar Tekeli2, C. Kerimoğlu3. 2Internal Medicine, Rheumatology, 3Internal Medicine, Hematology, Eskişehir Osmangazi University, Eskişehir, Turkey

Background: Regulatory T-cells (T-reg) may play an inhibitory role in the development of autoimmune diseases (AID) by suppressing the immune response to autoantibodies. T-reg impaired or decreased T-reg and/or increased Th17 cells may be responsible for the development of AID. However, studies about the association of T-reg and systemic scleroderma (SSc) are limited and conflicting.

Objectives: Our aim is to determine whether there is a relationship between T-reg and Th17 levels and disease activation in patients with SSc.

Disclosure of Interest: None declared

Methods: 17 patients with SSc who met 2013 ACR/EULAR SSc criteria were included in the study. Clinical and laboratory parameters, Rodnan skin scores, Valienti disease activity index, were evaluated in detail. Concurrent peripheral blood T-regs (CD4+CD25+FoxP3+ T reg) and TRIM21 (IL-17 producing T cells) were studied. Age and sex matched 11 subjects were included as healthy control (HC) in this study.

Results: Fifteen of seventeen patients were female, median age was 52.8±9.36 years, median disease duration was 5.41±4.51 years. While skin involvement and Raynaud’s phenomenon were determined in all of the patients, esophageal involvement was determined in 13 of the patients (76.5%), digital ulcer in 2 patients (11.7%), and lung involvement in 14 (94.1%) patients. Median ESR level was 31.29±12.7 mm/hour, median CRP level was 0.57±0.474 mg/dl, median Valienti disease activity index was 3.23±1.53. The medications of the patients during the follow up period were as; nifedipine n=15 (88.2%), hydroxychloroquine n=14 (82.4%), corticosteroids n=14 (82.4%), azathioprine n=7 (58.6%), mycophenolate mofetil n=1 (5.9%), cyclophosphamide n=7 (41.2%). In comparison of SSc and HC, all the T-reg cell levels were significantly higher in SSc group than HC (p<0.0001, p<0.0001 and p<0.0001). However, the levels of CD4+IL-17 cells in SSc group were high compared to HC, it was not significant (p<0.100). A positive correlation between CD4+IL-17 cells and CRP (r=0.613, p=0.009), a negative correlation between CD4+CD25+T reg cell levels and dosage of corticosteroid (r=−0.513, p=0.035), a negative correlation between CD4+CD25+T reg cell levels and platelet levels (r=−0.560, p=0.019) and a negative correlation between CD4+CD25+FoxP3+ T reg cell levels and platelet levels (r=−0.500, p=0.041) were determined.

Conclusions: In a cross-sectional study, it is rather difficult to explain the mean-ingly increased T-gard in SSc patients. These results may be due to modification of the cells by immunosuppressive treatment. It might be more meaningful to evaluate T-reg cell before and after the treatment.

HANDED X-RAY LESIONS ARE FREQUENT IN ANTI-Ro52/TRIM21 bSs PATIENTS WITH ARTHRALGIA AND INCREASE WITH THE RADIOGRAPHIC FOLLOW-UP, WHATEVER THE EXTRA-ARTICULAR FEATURES AND THE SEROTYPE OF ANTI-Ro52/TRIM21 bSs PATIENTS

C. Guillarch-Petrunkevich1, G. Bierry2, F. Maurier3, N. Alli4, L. Messer5, J.-E. Gottenberg6, J. Sibilia3, A. Meyer4, R. Rheumatology, Hôpitaux universitaires de Strasbourg, Strasbourg, France; 2Internal medicine, Hôpitaux privés de Metz, Metz, France; 3Rheumatology, Centre hospitalier de Mulhouse, Mulhouse, France; 4Rheumatology, Hôpitaux civils de Colmar, Colmar, France; 5Physiology and functional explorations, Hôpitaux universitaires de Strasbourg, Strasbourg, France

Background: Arthritis is frequent in antisyntehse syndrome (ASS) but the prev- alence, the characteristics and the risk factors of radiographic lesions have been poorly assessed.

Objectives: To report prevalence, characteristics and risk factors of radiographic abnormalities in ASS patients with arthralgia.

Methods: A mono-centric cohort of 101 patients with ASS and arthralgia was screened for hand X-ray availability. Patients with osteoarticular lesions were excluded from the analysis. ASS patients with radiographic lesions were com- pared to ASS patients with normal X-ray.

Results: Thirty-one patients were included. Thirty patients (41.9%) had radio- graphic lesions on hand X-ray, including periarticular calcifications (53.8%), joint pinching (46.1%), erosions (23%), and subluxations (15.3%). Age (54.15±4.5 vs 49.17±3.3 years old, p=0.17) and sex ratio were similar in both groups. Duration of ASS was two-fold longer at first hand X-ray with radiographic lesion compared to the ASS patient without radiographic lesion at last radiographic follow-up (10.08±2.4 years vs. 4.83±1.6, p=0.06). However, the cumulative num- ber of immunomodulatory drugs at first hand X-ray with radiographic lesion or last hand X-ray if normal tended to be lower in patients with radiographic lesions (0.818 vs 1.28, p=0.55). History of extra-articular involvements (including myositis, interstitial lung disease, skin lesions and Raynaud phenomenon) were not different in both groups, although mechanic’s hand tended to be less frequent in patients with radiographic lesions (23.1% vs 61.1%, p=0.07).

Patients with radiographic lesions had more frequently anti-EJ (31% vs. 0%, p=0.05). Other anti-RNA antibodies were not significantly associated with abnormal hand X-ray which were found in 50% of anti-PL-7 positive patients (2/4), 33.3% of anti-PL-12 positive patients (1/3), 30% of anti-Jo1 positive patients (6/20), and 0/1 anti-OJ positive patient (one patient was positive for anti-Jo1 and anti-PL7). ACPA (27.3% vs. 7.1%, p=0.29) and rheumatoid factor (50% vs 14.2%, p=0.09) were more frequently positive in case of radiological abnormality.

Conclusions: Hand X Ray lesions are frequent in ASS patients with arthralgia, whatever the extra-articular features and the ASS serotype was and was a longer duration of ASS.

Disclosure of Interest: None declared

THE CLINICAL MANIFESTATIONS IN ANTI-Ro52 ANTIBODY-POSITIVE PATIENTS WITH SYSTEMIC SCLEROSIS: A RETROSPECTIVE CASE CONTROL STUDY

C. Kawata, S. Miyauchi, M. Kimura, Y. Rikitake, K. Iwao, M. Rikitake, A. Aizawa, T. Kawaguchi, Y. Kariya, M. Matsuda, K. Umekita, K. Takajo, I. Takajo, A. Okayama. Department of Internal Medicine, Rheumatology, Infectious Diseases and Laboratory Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan

Background: Autoantibodies (abs) directed against Ro52/TRIM21 are common in systemic sclerosis (SSc) but their clinical significance remains uncertain. Some reports suggested that anti-Ro52/TRIM21 abs-positive SSc patients present interstitial lung disorders (SSc-ILD). However, it is not clear whether positive for anti-Ro52/TRIM21/abs related to other clinical manifestations in patients with SSc.

Objectives: The aim of this study is to clarify the prevalence of anti-Ro52/ TRIM21 abs in patients with SSc. Then, we investigated the clinical manifestations between anti-Ro52/TRIM21 abs-positive and negative patients with SSc.

Methods: This study is a retrospective case-control study. The medical records of 42 patients who were diagnosed as having SSc admitted to our hospital were reviewed. We evaluated the clinical manifestations at the first-onset of SSc such as Rodnan skin score, digital ulcer, abnormal subcutaneous calcification, esophag- eal reflux, pulmonary hypertension, myositis and arthralgia. Co-existing rheu- matic diseases were also reviewed such as Sjogren syndrome (SSjs), rheumatoid arthritis (RA), and polymyositis. All subjects underwent SSc –associated assess- ing using EUROLINE immunoassay. The autoantibodies include anti-Scl-70, anti-centromere A and B (CENP-A, CENP-B), anti-RNA polymerase III (RP-11, RP-155), anti-fibrillarin (U3RNP), anti-90-kd nucleolar protein (NOR-90), anti-Th/To, anti-PM-Scl100, anti-PM-Scl75, anti-Ku, anti-platelet-derived growth factor receptor (PDGFR), and tripartite motif–containing protein 21 (Ro-52). The associa- tions between clinical features and autoantibody profile were also evaluated.

Results: Thirty-five patients with SSc were female (87%). Twenty-one and nine- teen patients with SSc are positive and negative for anti-Ro52/TRIM21 abs, respectively (47 v.s 52%). There is no difference in population of diffuse type of SSc between anti-Ro52/TRIM21 abs-positive and negative SSc patients. In addi- tion, the prevalence of ILD is not different between two groups (57 v.s 52%, p=0.76). The prevalence of SSjs is tended to be higher in anti-Ro52/TRIM21 abs-positive SSc patients than in negative SSc patients (68 v.s 33%, p=0.05). Unex- pectedly, 57% of anti-Ro52/TRIM21 abs-negative SSc patients present poly- arthralgia at the onset of SSc. In addition, there were no any complications such as osteoartithitis and RA in anti-Ro52/TRIM21 abs-negative SSc patients. The prevalence of arthralgia was higher in anti-Ro52/TRIM21 abs-negative SSc patients than in positive SSc patients (p=0.02).

Conclusions: The prevalence of anti-Ro52/TRIM21 abs in SSc patients of this study seems to be high compared to other reports. In addition, there seems to be no difference in the prevalence of ILD regardless of existence of anti-Ro52/ TRIM21 abs in SSc patients. Anti-Ro52/TRIM21 abs-negative SSc patients were tended to present poly-arthritis, compared to the present poly-arthritis of anti-Ro52/ TRIM21 abs-negative SSc patients may be not associated with other rheumatic diseases such as SSjs and RA in this study. It is necessary the large number study to clarify whether anti-Ro52/TRIM21 abs involve in the pathogenesis of musculos- keletal disorders in patients with SSc.

AB0744
A "LOSE-TO-FOLLOW-UP" AUTOANTIBODY FOR THE DIAGNOSIS OF AUTOIMMUNE DISEASE: PREVALENCE AND CLINICAL CHARACTERISTICS OF ANTI-NOR90/HUBF POSITIVE PATIENTS

C. Koutsianas1, K. Levasseur2, M. Rutter1, C. Webber3, M. Bhole4, C. Bell5, K. Douglas1,1Department of Rheumatology, The Dudley Group NHS Foundation Trust, Dudley; 2Department of Rheumatology, Worcestershire Acute Hospitals NHS Trust, Worcester; 3Department of Immunology, The Dudley Group NHS Foundation Trust, Dudley, UK

Background: Anti-nuclear antibody (ANA) patterns in indirect immunofluorescence testing (IFT) have been valuable in the diagnosis of autoimmune diseases. A pattern of speckling with fluorescent mitotic dots is considered to represent autoantibodies against nucleolar organising regions (NORs). Anti-NOR90 anti-bodies target the human upstream binding factor (hUBF) which activates RNA polymerase I-activated ribosomal RNA transcription. They have been anecdotally associated with systemic sclerosis (SSc), Sjögren’s Syndrome (pSS) and rheumatoid arthritis (RA).

Objectives: To analyse the prevalence and clinical characteristics of patients found to be anti-NOR90 positive by immunology at The Dudley Group NHS FT (DGH) which also serves Worcestershire Acute Hospitals NHS Trust (WAH).

Methods: Clinical letters and electronic patient records of anti-NOR90 positive patients identified in the DGH immunology laboratory between July 2016 and October 2017 were reviewed. Advice was sought regarding ethical approval and consent; this was deemed unnecessary for this clinical survey. Anonymized patient data was collected on Excel. Anti-NOR90 was tested for when the characteristic ANA pattern was observed and as part of an extended SSc blot (EIROLINE SSc (Nucleoli) profile (IgG) – EUROIMMUN).

Results: We identified 11 anti-NOR90 positive patients among 8000 positive ANA results (estimated prevalence 0.0137%). Patient demographics, diagnoses and immunology are illustrated in Table 1. Patients were in their vast majority female (10/11, 91%) and had a median age of 63 (IQR:53–74) years. The median anti-NOR90 titre was 111 (IQR:14–139) intensity units. 6/11 (54.5%) had a confirmed diagnosis of rheumatoid disease. The most common clinical features were Raynaud’s phenomenon (83.6%), sicca symptomatology (36.4%) and polyarthritids (36.4%). Intestinal lupus disease (ILD) and oesophageal dysmotility (OD) were predominant clinical features in two cases (SSc, pSS). In general, patients lacked skin involvement (scleroderma, telangiectasias, calcinosis).

Abstract AB0744 – Table 1. Demographic, clinical and immunological characteristics of anti-NOR90 positive patients

Conclusions: Literature regarding anti-NOR90 auto-antibodies has been scarce and in the age of automated IIF ANA testing, it is plausible that their specific nucleolar pattern is frequently missed. In our survey, they were observed in the context of several rheumatic diseases and linked to Raynaud’s, sicca symptoms and polyarthritis. Studies in larger relevant patient cohorts are needed to further clarify their clinical value.

MECHANICS OF EARLY VENTRICULAR IMPAIRMENT IN SYSTEMIC SCLEROSIS AND THE EFFECTS OF PERIPHERAL VASCULOPATHY

C. Toutrel1,2, V.-K. Bournia1, S. Panopoulos1, A. Goumisikakasi2, D. Beldekas2, M. O. Tetensdal1, A.D. Protogerou2, P.P. Stiakaki2. 1First Department of Propaedeutic and Internal Medicine/Joint Rheumatology Program, “Laikon” Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens; 2Cardiology Department, Tzanio Hospital, Piraeus, Greece

Background: Multiple mechanisms commonly lead to severe cardiac involvement in systemic sclerosis (SSc), an autoimmune disease characterised by microvascular lesions, systemic inflammation and fibrosis.

Objectives: To examine the mechanics of right and left ventricles (RV, LV) at the early stage of possible impairment and test the hypothesis that peripheral arterial hemodynamics are associated with early LV compromise.

Methods: Ninety-five asymptomatic SSc patients free of cardiovascular disease (88% women, 53±14 years) and 54 apparently healthy controls matched for age, gender, arterial hypertension, dyslipidaemia, and diabetes mellitus underwent echocardiography, including multilayer speckle-tracking, and tonometry-based pulse wave analysis of the peripheral arteries; 68 SSc patients were prospectively assessed after 32±7 months. Indices of ventricular and arterial structure and function, as well as LV-arterial coupling, were calculated.

Results: At baseline, patients presented RV diastolic/systolic impairment, as well as LV remodelling and diastolic/systolic impairment in terms of reduced deformation parameters versus controls. No association was evident between RV and LV strain within individual patients, whereas by multivariate analysis including age, gender, and SSc characteristics we found that the global longitudinal strain of RV tissue wall was associated only with the presence of diffuse skin involvement (b=−2.63, p=0.042) and both global longitudinal and circumferential strain of LV were correlated only with disease duration (b=0.14, p=0.001 and b=0.17, p=0.032, respectively). Both RV and LV abnormalities progressed independently during follow-up. Moreover, in the absence of differences in aortic stiffening and LV-arterial coupling between patients and controls, arterial pressure wave reflections assessing small vessel function and/or microcirculation were abnormal in SSc patients and strongly correlated with impaired indices of LV diastolic function and remodelling.

Conclusions: These novel findings show the mechanics of RV early impairment in SSc that develops and progresses independently from the concomitant LV impairment, which, in turn, may be influenced by peripheral microvascular abnormalities in the absence of macrovascular damage.

FREQUENCY AND CLINICAL ASSOCIATION OF RARE ANTIBODIES IN A LARGE CONNECTIVE TISSUE DISEASE COHORT

C. Camponchiaro, C. Clark, L. Host, A. Sari, S. Nihiyanova, C. Fonseca, C. Denton, V. Ong. Centre for Rheumatology and Connective Tissue Diseases, The Royal Free Hospital, London, UK

Background: Connective tissue diseases (CTDs) are characterised by the presence of specific antibodies (Abs). These are useful in diagnosis and prognostic stratification. Rare Abs have been reported but their clinical significance is currently not as clear.

Objectives: to assess the diagnosis, and frequency of clinical features within each rare antibody subgroup in our CTD cohort

Methods: The immunology results for 5828 patients obtained over the past 17 years and patients positive for 1 of the rare Abs (Jo-1, PONAXR,PL-4,PL-7,PL-12,SRP,Ku,Mi-2,EJ,SL,PMsc,RF,RNrP,Th/To,NU-Ma-1,DJ and hRNP) were identified. Diagnosis and frequency of major organ involvement were reported.

Results: 758 patients (12.5%) were positive for at least one rare Abs. Clinical information confirming a diagnosis of a CTD was available for 514 patients. The most frequent rare Ab in our cohort was PONAX(3.10%). The majority of patients had clinical features of overlap syndrome (33%), the 2nd most common diagnosis was systemic sclerosis (ScS)(31.10%). Interstitial lung disease (ILD) was more commonly seen in patients with PL-7(82.4%), PL-12(75%), Jo-1(70.8%) and SRP(66.7%). ILD was not reported in PCNA+PL-4, NuMa+1 and hRNP+. Pulmonary arterial hypertension(PAH) was most frequently seen in patients with XRo(31.8%). Inflammatory myositis(IM) was found in all Jo1+ and SRP+ patients, and in the majority of PL-7(88.2%) patients. Inflammatory arthritis was commonly reported in patients with PCNA+(57.1%), NuMa+1(50.0%) and rRNP+(40%). Renal involvement was classified as either glomerulonephritis(GMN) or scleroderma renal crisis(SRC). GMN was more common in patients with rRNP+(60%), PL-4+(45.4%) and PCNA+(42.9%) patients. SRC was diagnosed in patients with SL+(3.2%), PMsc+(5.5%) and ThTo+(2.5%) (table 1).

INTERSTITIAL LUNG DISEASE IS INDEPENDENTLY ASSOCIATED WITH INCREASED FAECAL CALPROTEIN LEVELS IN SYSTEMIC SCLEROSIS
C. Caimi1, E. Bertoldi1, A. Venturini1, P. Caramaschi1, L. Frulloni2, R. Ciccocioppo2, S. Brunelli2, L. Idolazzi1, D. Gatti1, O. Viapiana1, M. Rossini1.
1Rheumatology Unit; 2Gastroenterology Unit, University of Verona, Verona, Italy
Background: Intestinal lung disease (ILD) is one of the leading cause of death in systemic sclerosis (SSc).
Objectives: The aim of this paper was to evaluate the relationship between faecal calprotectin (FC) and ILD.
Methods: 129 outpatients with SSc were enrolled. Data about disease characteristics, in particular lung involvement, were collected and FC was measured.
Results: Eighty-seven patients (67.4%) had a limited subset with a mean disease duration of 13.3 (7.1) years. Anti-Scl70 antibodies were found in 35 (27.1%) patients. GI tract involvement was severe/end stage in 3 cases (2.4%). ILD affected 35 patients (27.1%). Median levels of FC were 80 ug/g (157 ug/g). FC was found to be higher in patients with a moderate/severe/end stage score for gastrointestinal tract (p=0.046) and on steroids (p<0.015). In addition, it positively correlated with age (p<0.001).
Other than well-known risk factors such as higher mRSS or diffuse subset, patients with ILD had higher values of FC (p<0.001). In multivariate analysis correcting also for factors affecting FC levels (i.e. disease duration, mRSS, Valenti activity score, total Medsger severity score, proton pump inhibitor, anti-Scl-70 antibody, diverticulosis, limited cutaneous subset, faecal calprotectin levels, steroid treatment), diffuse disease subset (p<0.001), higher mRSS (0.04), longer disease duration (0.046), higher severity scores (0.026), higher FC levels (p<0.003) and steroid treatment (0.014) were associated with increased risk of ILD, while diver-
ticulosis was protective. In addition, we ran a second multivariate analysis considering the 110 cases with FC level <275 μg/g, in order to correct for a possible small intestine bacterial overgrowth. Increased FC levels (p=0.019), steroid treatment (p=0.03), higher severity scores (p<0.016) and diffuse disease subset (p=0.002) were confirmed to be associated with ILD.
Conclusions: In this paper we have found a possible link between gut inflammation and ILD. Many hypothesis may be done but it is intriguing that these data further support what previously found by other authors (Andreasson et al. 2016), that is a correlation between gut inflammation and dysbiosis and non-gastrointestinal disease manifestation. Our study may support the hypothesis of a role of gut dysbiosis in triggering a pathologic immune response leading to ILD. It may also be that increased FC simply reflects a more severe disease but this still doesn’t explain why only ILD was found to be linked with FC. Is it because lung is a filter of molecule (i.e. antigens, cytokines, metabolites, etc.) produced in the gut? Further studies with longitudinal evaluation are warranted.

Background: Systemic sclerosis (SSc) is a disorder with a well-known autoimmune base. There is evidence suggesting a common background with other connective tissue diseases, thus predisposing to the development of other autoimmune disorders in these patients, that is, poliautoimmunity (PAI).
Objectives: To assess PAI in a cohort of SSc patients.
Methods: A nationwide, cross-sectional study was performed including the 1928 patients enrolled in the Spanish SSc Registry (REGESCLE). Ethics Committee approval was obtained by all participating centres.
Results: Prevalence of PAI was 45%, with 32% having more than one association. Most of these patients were women (93%, p<0.001), with older age at diagnosis (53.7±14.7 years, p<0.007). Regarding subtypes, PAI was significantly more frequent in limited cutaneous SSc (48%, p<0.004) and pre-SSc (47%, p<0.001). Sjögren’s syndrome was by far the most common association (55%), followed by global autoimmune thyroid disorders (31%), autoimmune liver disorders (17%) and inflammatory myopathies (12%). Clinical features are shown on table 1.

Disclosure of Interest: None declared
We found no significant differences concerning capillaroscopy patterns, or causes of death, neither SSc-related nor non-SSc-related.

Finally, a multivariate analysis with logistic regression was performed to evaluate the risk factors for PAI, which are shown on the table 2.

Conclusions: PAI in SSc is a frequent condition that special attention in these patients. We found a rather higher prevalence compared with those published in the literature, even though the distribution of those associated disorders was similar. In our cohort, there were no remarkable differences between both groups concerning clinical manifestations (although not always statistically significant); Finally, certain circumstances should make us aware of a possible associated condition to SSc.

DON'T FORGET THE CAREGIVERS OF PATIENTS WITH SYSTEMIC SCLEROSIS

M. Boonstra1, D.F. Stoop1, T.W. Huizinga1, T.P. Vliet Vlieland2, J.K. de Vries-Bouwstra1. 1department of Rheumatology; 2department of Orthopedics, Leiden University Medical Center, Leiden, Netherlands

Background: Systemic sclerosis (SSc) is a disease with considerable physical and psychosocial impact. Previous studies among partners of patients with other chronic diseases, such as Parkinson’s and stroke, showed that 6%–25% of caregivers experience high levels of stress related to caregiving. To our knowledge, the burden experienced by caregivers of patients with SSc has not been determined so far.

Objectives: To evaluate perceived strain, quality of life and health care needs among SSc caregivers.

Methods: During a patient information meeting, companions of SSc patients were invited to complete 3 questionnaires: 1. The Caregiver Strain Index questionnaire (CSI), in which a score >7 indicates high care burden, 2. Short Form-36 (SF-36): a measure of self-reported Quality of Life (QoL) and 3. a self-designed questionnaire on the needs and preferences for caregiving support. Caregivers with and without high care burden were compared regarding their general characteristics and QoL.

Results: Thirty-six SSc caregiver filled out questionnaires (n=31 completed the CSI questionnaire). Respondents were mostly men (64%), on average 62 years old (SD 14), 35% (n=11) had a paid job, and 50% (n=18) suffered from chronic disease. The majority was in a spousal relationship (75%) with the SSc patient and 56% of patients had been diagnosed with SSc more than 5 years ago. Nineteen percent of patients (n=7) needed daily personal caregiving and 25% (n=9) was transport-dependent. Median CSI was 2 (range 0 to 5), and 6/31 (19%) perceived high care burden (CSI >7). Caregivers with high care burden were significantly more often involved in daily personal caregiving of the patients (3/6 vs. 2/25). Although not statistically significant, all caregivers perceiving a high burden were spouses, while the remaining caregivers had varying relationships with SSc patients. SF-36 summary scale scores were similar in both groups (table 1).

Regarding needs and preferences of caregivers, 15% (n=5) reported a need for additional individual information, and 21% (n=7) a need for contact with fellow caregivers of patients, preferably during information meetings.

We refer to the abstract for more details.
Antibodies against EBV appear to be more frequent in SSc than in healthy controls, and equally prevalent with MS, a disease known to be associated with anti-EBV antibody responses and a known risk factor for MS. Whether an EBV-specific response is also an initiating trigger of SSc remains to be investigated.

Disclosures of Interest: None declared

COMPARATIVE STUDY OF SYSTEMIC SCLEORS WITH OTHER AUTOIMMUNE DISEASES FOR HEALTH-RELATED QUALITY OF LIFE

E.H. Pad1, V. Strand2, Y.J. Oh1, H. Kwon3, Y.W. Song1, B.E. Lee1, 1Seoul National University Hospital, Seoul, Korea, Republic of Ireland, 2Stanford University, California, USA, 3Gangnam Sungshin Hospital, Seoul, Korea, Republic of Ireland

Background: Systemic sclerosis (SSc) is a rare autoimmune disease characterised by fibrosis of the skin and multiple internal organ involvement. Previous studies reported a poorer health-related quality of life (HRQoL) in patients with SSc compared to the general population. However, very little is known about HRQoL of SSc as compared with other systemic autoimmune diseases, including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and Sjögren’s syndrome (SSJ).

Objectives: To compare the HRQoL of patients with SSc and other systemic autoimmune disease and general population.

Methods: HRQoL was captured by the Korean short form-36 health survey version 2 (SF-36), short form-6D (SF-6D) and 3 level version of EuroQol five-dimensional (EQ-5D) descriptive system (EQ-5D-3L). Between March and July 2017, consecutive patients with SSc, and randomly chosen patients with RA, SLE and SJ were recruited from the outpatient rheumatology clinics of Seoul National University Hospital, and were asked to answer SF-36 and EQ-5D. Disease activity of RA was evaluated by Disease Activity Score 28-ESR (DAS28-ESR), SLE by Systemic Lupus Erythematosus Disease Activity Index-2k (SLEDAI-2k), and SJ by European Sjögren’s syndrome activity index (ESSAI).

Results: A total of 480 patients with SSc (n=120), RA (n=120), SLE (n=120) and SJ (n=120) and 600 healthy controls were included. The demographic features of patients were similar to the known features of each rheumatic disease group. Patients with rheumatic diseases had significantly lower SF-36 scores (p<0.001 in all domains), SF-6D scores (p<0.001), EQ-SD-3L index scores and EQ-VAS (p<0.001) than the healthy controls; adjustments for age and sex did not change those results. Patients with SSc showed significantly lower scores in the mental component summary scores compared with patients with RA (age and sex-adjusted scores, 43.0±9.0 vs. 48.9±9.0; p<0.001). Specifically, domain of mental health was lower in SSc patients than RA patients (age and sex-adjusted scores, 61.3±1.8 vs. 71.7±1.8; p<0.001). Among the physical domains, SSc
patients showed lower score in general health domain than RA patients (age and sex-adjusted scores, 41.4±1.8 vs 51.3±1.8, p<0.001). Moreover, SSc patients reported remarkably lower scores of EQ-SD-3L index scores than all comparative rheumatic disease groups (RA, SLE, SJL) (p<0.001). HRQoL of patients with SSc was associated with HAQ-DI and SSc HAQ-DI.

Abstract AB0753 – Table 1. Comparisons of the SF-36, SF-6D and EQ-5D-3L, adjusted by age and sex in study subjects.

Conclusions: HRQoL of patients with systemic autoimmune diseases is significantly worse and affects all health domains in comparison to healthy controls. Patients with SSc have poorer HRQoL than patients with other rheumatic diseases. Specifically, SSc patients have more impaired mental health than RA patients, and the perception of an individual’s general health is also poor compared to RA.

AB0754
LONG-TERM FOLLOW-UP OF 214 PRIMARY RAYNAUD S PHENOMENON PATIENTS

Background: Raynaud’s phenomenon (RP) is frequently associated with the presence of scleroderma or other connective tissue diseases (CTD). Identify the presence of secondary RP is important to perform an adequate therapeutic management and to achieve the early control of these patients. Nailfold capillaroscopy is safe, economic, and relatively easy to perform and has proven to be useful in identifying patients with secondary RP.

Objectives: To assess a long-term follow-up primary RP patient’s series.

Methods: Retrospective observational study of a wide and unselected series of patients diagnosed as primary RP from a single university hospital from January 2012 to August 2017. Patients were classified as primary RP after the presence of CTD at the onset was excluded.

Results: We studied 214 patients (85.98% were female), with a mean age of 47.6±16.7 years (range 15–88). After a mean follow-up period of 48.4±23.3 months, 8 patients were diagnosed of a CTD (2 Scleroderma/Systemic sclerosis, 3 Systemic Lupus Erythematosus, 1 Rheumatoid arthritis and 2 Sjogren’s syndrome). The remaining 206 patients continued classified as primary RP. The main capillaroscopic patterns observed were: Normal (n=157), unspecific (n=49), scleroderma pattern (n=2) and suggestive of other rheumatic diseases pattern (n=6).

All patients who developed a CTD during the follow-up, showed changes in successive nailfold capillaroscopic examinations. 20 of 206 patients who remained primary RP showed minor changes at successive nailfold capillaroscopy. The main capillaroscopic changes detected on this group were: presence of capillary tortuosity (n=4), presence of a decreased capillary density2 and the presence of capillary bleeding (n=16). Antinuclear antibodies (ANA) were positive at the onset in 34 patients and after follow-up in 39 patients.

Conclusions: After a mean follow-up period next to four years, most of our primary RP patients remained free of CTD. A minority of our patients showed changes at nailfold capillaroscopy exam or positivity of ANA.

Disclosure of Interest: None declared

AB0755
SKIN SCORE PROGRESSION AFTER DISCONTINUATION OF MYCOPHENOLATE TREATMENT IN SYSTEMIC SCLEROSIS PATIENTS

F.A. Mendoza1, C.P. Lee Ching1, S.A. Jimenez2, 1Scleroderma Center and Division of Rheumatology, 2Scleroderma Center and Jefferson Institute of Molecular Medicine, THOMAS JEFFERSON UNIVERSITY, Philadelphia, USA

Background: Rapid progressive skin involvement in diffuse Systemic Sclerosis (rp-dcSSc) is associated with higher mortality and internal organ involvement. Treatment with Mycophenolate Mofetil (MMF) has been shown to halt the progression of the disease. However, the optimal duration of therapy is unknown and has not been studied. We follow up a known cohort of rp-dcSSc patients treated with MMF after discontinuation of therapy.

Objectives: To describe the progression of skin involvement in rp-dcSSc patients after discontinuation of MMF

Methods: Twenty-five previously untreated consecutive patients with recent-onset (<24 mo) rp-dcSSc received MMF as the only disease-modifying therapy. Their Modified Rodnan skin score (mRSS) and Pulmonary function tests were followed after discontinuation of MMF after 2 years of treatment. Patients were followed up every 3–6 months. Therapy was re-initiated if their mRSS increased more than 20% or worsening respiratory symptoms with progression of restrictive lung disease were reported.

Results: Six patients lost follow up after terminating the open label trial with MMF. From the 19 patients followed up after MMF discontinuation, 26.3% required to resume MMF. All these patients presented active skin disease recurrence within 6 months after discontinuation. All of them presented increase in mRSS. Two of them (10.5%) presented respiratory symptoms associated with restriction pattern at PFTs. Skin score returned to baseline in 80% of the patients after resuming therapy.

Abstract AB0755 – Figure 1. mRSS after MMF discontinuation.

Conclusions: Recurrent skin progression occurs in up to 26.3% of patients with rp-dcSSc after discontinuation of 2 years of MMF, requiring longer term immuno-suppression. In this group, all patients presented active skin disease recurrence within 6 months of treatment discontinuation. Ergo, slow decrease of MMF dose over time and very close follow up is recommended in patients with rp-dcSSc discontinuing MMF even after a prolonged period of time. In addition, these findings support the therapeutic effect of MMF in rp-dcSSc.

AB0756
MDA 5 DERMATOMYOSISTIS AND RESPONSE TO
RITUXIMAB IN A SMALL COHORT AT OUR INSTITUTION
F. Berinugu, V.J. Maya, B. Wang, MAYO CLINIC, Jacksonville, USA

Background: Treatment for anti-melanoma differentiation-associated gene 5 antibody (MDA 5) Dermatomyositis is posing challenging to clinician and there is currently no consensus on therapy. The MDA5 was recently classified as a myositis-specific antibody (MSA), and has been associated with rapidly progressive interstitial lung disease (ILD), amyopathic dermatomyositis (aDM), mechanic’s hands, ulcerations, inflammatory arthritis, and increased mortality.

Objectives: This study sought to characterised response to Rituximab in a small cohort of patients with MDA 5 DM at our institution.

Methods: A retrospective chart review was done to identify all MDA5 positive patients who were evaluated at our centre from 2015 to 2017 with suspected myositis and had myositis-associated autoantibodies tested using a commercial panel (MyoMarker Panel 3). For all patients who were positive for MDA5, we collected clinical information on the presence of myopathy, skin involvement and ILD, data on the autoantibody profile, PFTs and high resolution CT pattern along with therapeutic response.

Results: 11 were positive for MDA5. 7 were females and 4 were males, with mean age 56.6 years. Eight patients were treated with Rituximab from which seven had ILD at presentation: 4 NSIP, 2 with organising pneumonia, one had UIP and one had fatal acute interstitial pneumonitis 2 months after onset of mechanics’ hands and inflammatory arthritis. Three patients without ILD were treated with other DMARDs. All had responded well to Rituximab with improvement in skin ulceration, inflammatory arthritis and mechanic’s hands and most patients had stable ILD except for one patient with fulminant interstitial pneumonitis for which Cytoxan was added without any additional benefit.

Conclusions: Rituximab is a good management option for all manifestation of MDA 5 DM. Further studies are needed to elucidate the association of MDA5 and the clinical manifestation and response to treatment response of patients with inflammatory myopathies.

AB0757
PERSISTENT CRP ELEVATION IS ASSOCIATED WITH HIGH MORBIDITY IN SYSTEMIC SCLEROSIS
A. Mitev1, D. Feldmann2, A.-M. Kanne1, T. Hugl1, P.M. Villiger3, R.E. Völl1, S. Finzel1, P. Kulier1, 1Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany; 2Service de diagnostique immunologique, CHUV, Lausanne; 3Department of Rheumatology, Immunology and Allergology, University Hospital Bern Inselspital, Bem, Switzerland

Background: Elevated levels of C-reactive protein (CRP) in systemic sclerosis (SSc) have been linked to early inflammatory stages of the disease. Objectives: This study has been set to investigate CRP levels in a longitudinal cohort of SSc patients and to correlate these findings to comorbidities and disease characteristics.

Methods: In this retrospective study patients with SSc were recruited from the outpatient clinic of the Department of Rheumatology and Clinical Immunology, University Medical Centre Freiburg. Only patients with at least three consecutive visits at our centre over at least one year were included in this study. CRP serum levels were measured at every visit and categorised as positive if CRP concentrations were ≥5 mg/L. Subjects with elevated CRP levels at more than 80% of visits were defined as being persistently positive. The longitudinal CRP profile was correlated to comorbidities and disease characteristics.

Results: A total of 1852 consecutive visits of 131 SSc patients were analysed. Over the observed time span (9136–56 months) 19% (n=25) of patients had continuously elevated CRP levels, whereas in 29% (n=38) CRP levels were always in the normal range. There was no association between disease duration and CRP levels at first visit (p>0.5). Persistent CRP elevation was associated (p<0.05) with anti-topoisomerase I antibodies, diffuse cutaneous SSc (dcSSc), modified Rodnan skin score (mRSS), pulmonary fibrosis, and cardiac arrhythmia, whereas no associations with arthritis or malignancy were found (p=0.1). In a patient with dcSSc and persistent elevated CRP even cyclophosphamide and autologous stem cell transplantation did not alter CRP levels.

Conclusions: Persistently elevated CRP levels characterise a more severe fibrotic phenotype and a higher prevalence of cardiac arrhythmias.

EVALUATION OF NAILFOLD VIDEO CAPILLAROSCOPY IN 296 PATIENTS WITH CONNECTIVE TISSUE
DISEASES
G. Kumárovics, G. Nagy, L. Cziráik. Rheumatology and Immunology, University of Pécs, Medical School, Pécs, Hungary

Background: The influence of the presence of Raynaud’s phenomenon (RP) on microangiopathy is not well characterised in connective tissue diseases (CTDs). Objectives: To characterise capillary density and capillary morphology by nailfold video capillaroscopy (NVC) in different CTDs with a special focus on the presence/absence of Raynaud’s phenomenon (RP) and overlap syndromes.

Methods: 296 patients with systemic sclerosis (SSc), systemic lupus erythematosus (SLE), idiopathic inflammatory myopathies (IIM), Sjogren’s syndrome (SS), antiphospholipid syndrome (APS), rheumatoid arthritis (RA), systemic vasculitis and undifferentiated connective tissue disease (UCTD) were investigated by NVC. Control groups consisted of 25 healthy controls (HC) and 22 primary RP (PRP) cases.

Results: The mean capillary density was significantly decreased in SSc, SLE, SS, IIM and APS either compared to HC or PRP cases. Mean microangiopathy evolution score (MES) was higher in SSc, SLE, SS, IIM and APS compared to both HC and PRP cases. SSc, SLE, SS patients had a significantly higher giant capillary number compared to either HC or primary RP control cases. Average haemorrhage score was significantly higher in SSc and SS but not in SLE, RA, IIM and APS compared to HC. Average dilatation point was higher in all investigated CTDs compared to HC. Except RA, all investigated CTDs showed significantly higher capillary loss score compared to either PRP controls or HC. RA cases showed such a difference only compared to HC. Average disorganisation score was significantly higher in all CTDs compared to HC but not compared to PRP cases. Ramification score was significantly elevated in SSc and IIM compared to PRP and HC, but no difference was observed in SLE, SS, APS and RA. The mean capillary density was decreased, and MES was higher in RP associated cases compared to patients without RP in cases with SLE, IIM, and RA. Conversely, the presence of RP did not influence these particular parameters in cases with APS and SS. Except SSc, the impact of overlap features was not remarkable on major capillaroscopic findings. SSc capillary pattern was present in 75.3% of all SSc cases, most commonly SSc late pattern was observed (58.43%). SSc pattern was present in other CTD cases too (15.4%–40.7%). SSc patients with a DLCO<70% had significantly more giant capillaries, avascularity, late SSc pattern, increased MES, and lower capillary density compared to cases with DLCO>70%, but in the other CTDs decreased DLCO was not associated with similar pronounced capillary damage.

Conclusions: Microangiopathy with decreased capillary density and increased MES were present in all CTDs compared to controls. RP caused most pronounced impairment in SLE, IIM and RA compared to non-RP patients, but had no major effect on SS, and APS. Except SSc, the presence of overlap syndrome did not show a remarkable influence on the microvascular abnormalities compared to pure idiopathic cases. SSc late pattern was most frequently observed in CTDs other than SSc, and it may appear even in patients without RP. Previous associations shown by other authors of decreased DLCO and capillary damage in SSc was confirmed. Capillaroscopy is useful not only in IIM and SSc patients but also in all SLE cases and RP associated SS and RA patients. Capillary density and MES are the most valuable parameters.

THE ASSESSMENT OF GASTROINTESTINAL TRACT INVOLVEMENT THROUGH UCLA SCTC GIT 2.0 QUESTIONNAIRE IDENTIFIES SCLERODERMA PATIENTS WITH REDUCED BONE MINERAL DENSITY

G. Natalioli, E. De Lorenzo, G.B. Canestrari, L. Gigante, L. Verardi, L. Mirone, S. L. Bosello, G. Ferraccio, E. Gremske. Rheumatology Unit, Fondazione Policlinico Universitario A. Gemelli – Catholic University of the Sacred Heart, Rome, Italy

Background: Gastrointestinal (GI) symptoms are seen in majority of patients with Systemic Sclerosis (SSc) and are a common presenting feature of disease. Severe GI involvement may lead to malabsorption which represents a poor prognostic factor. Accordingly, a regular monitoring of gastrointestinal tract involvement and nutritional status appears crucial in SSc patients. Previous studies reported low values of bone mass density (BMD) in SSc patients. While no specific relationship has emerged between the two conditions, it’s likely that disease-related GI involvement may contribute to the alterations in BMD.

Objectives: To determine if GI-related clinical status was associated to low bone density in our cohort of SSc patients.

Methods: Two-hundred-and-ten unselected SSc patients have been enrolled. The 7-items UCLA SCTC GIT 2.0 questionnaire and Malnutrition Universal Screening Tool (MUST) were administered to each patient. A comprehensive medical history was collected. A blood panel for nutritional status was also performed. T-scores and Z-scores at lumbar spine, femoral neck, Ward’s and total hip measured by dual-energy X-ray absorptiometry (GE Lunar Prodigy) were measured.

Results: In our cohort, 86.7% of patients reported some GI symptoms. The mean UCLA GIT total score was 0.34±0.50 in patients (24.2%) who were at risk of malnutrition according to MUST score (<1). 53.7% patients had BMD values <1, and 12.5% had BMD values <−2.5 at any of the considered sections. Patients with reduced BMD (<−1) showed similar levels of selected nutritional blood markers compared to subjects with normal BMD, including vitamin D and albumin.

Patients with spine T-score <−1 had lower BMI (23.2±3.9 vs 25.2±4.8; p=0.011) and reported higher UCLA GIT reflux (0.66±0.63 vs 0.42±0.48; p=0.016), distension (0.80±0.72 vs 0.53±0.56; p<0.15) and total score (0.42±0.37 vs 0.27±0.30; p=0.006) compared to patients with normal BMD. Similar significant differences were observed in the same domains for patients with full hip T-score values <−1. Femoral neck T-score <−2.5 was associated with higher UCLA GIT reflux (0.88 ±0.78 vs 0.48±0.50; p=0.022), soilage (0.50±0.78 vs 0.14±0.52; p=0.041) and total score (0.50±0.37 vs 0.31±0.33; p=0.012).

On the other hand, the comparison of patients with severe, moderate and mild symptoms according to UCLA GIT total score showed an association between progressively lower values of spine and total hip T-score and increasing severity of GI symptoms (ANOVA for spine T-score: p=0.015; for total hip T-score: p=0.048).

Patients at risk of malnutrition (MUST score >1) presented significant lower T-score for all the considered sections (spine and hip) and significant lower total hip Z-score.

Conclusions: In our SSc cohort gastrointestinal symptoms were frequent and were associated with low BMD. Considering the heterogeneity of GI involvement, UCLA SCTC GIT 2.0 emerged as a useful and feasible tool to assess GI involvement and other associated comorbidities. In particular, SSc patients who report remarkable GI symptoms and are at risk of malnutrition according to MUST may benefit from a stricter control of BMD to promptly detect osteopenia and osteoporosis.

ADVANCED OXIDATION PROTEIN PRODUCTS IN SERUM OF PATIENTS WITH SYSTEMIC SCLEROSIS: A POSSIBLE INDICATOR OF CLINICAL EVOLUTION

G. Sighinolfi, M. Colaci, A. Spinella, F. Lumetti, E. Artoni, C. Salvarani, D. Giuggioli. Chair and Rheumatology Unit, University of Modena and Reggio Emilia, Policlinico of Modena, Modena, Italy

Background: Systemic sclerosis (SSc) is a chronic, multysystem connective tissue disease characterised by immune dys-regulation, obliterative microvascularopathy and fibrosis. Endothelial dysfunction, immune system imbalance and fibroblast activation constitute the three major factors of the pathogenic process. In this context, oxidative stress could play a significant role through direct damage of endothelial cells and the persistent activation of the immune system. 1,2

Objectives: This study investigated the presence of advanced protein oxidation products (AOPP) in serum of patients with SScs and its correlation with disease’s features.

Methods: 50 patients with SSc (M:F 1:7, mean age 57±11.2 SD, mean duration of disease 10±9.1 SD years), were screened for AOPP in the serum, using the AOPP OxiSelect Kit of CELL BIOLABS (San Diego, CA, USA). Among 50 SSc patients, 39 had limited cutaneous subset, while 11 had the diffuse one. Anamnestic and clinical data were collected for all SSc patients. As a control group 50 consecutive healthy subjects, sex and age matched, were recruited.

Results: We found serum levels of AOPP increased in the SSc group compared with the controls (p<0.0001) with mean values of 336±167.8 mmol/L and 167.5 ±59.2 mmol/L, respectively. In addition, higher levels of AOPP directly correlated with the diffuse cutaneous subset (p=0.0242), presence of digital ulcers (p=0.005), esophagopatgy (p<0.006) and pulmonary fibrosis (p=0.0128).

Conclusions: Serum AOPP levels are significantly higher in patients with SSc than in controls. In addition, the correlations of AOPP with SSc diffuse cutaneous subset, digital ulcers, and pulmonary involvement (indicative of progressive disease and worse prognosis) suggest a possible role of this marker in the identification of the cases with worse clinical evolution. The data of this preliminary study should be confirmed on larger case series and analysed in prospective studies, in order to understand its eventual usefulness during the follow-up of SSc patients.

FOLLOW UP OF NAILFOLD MICROVASCULAR DAMAGE IN MIXED CONNECTIVE TISSUE DISEASE VERSUS SYSTEMIC SCLEROSIS PATIENTS

G. Ferrari, A. Sulli, C. Prizzi, M. Ghio, M. Patanè, S. Paulino, A.C. Trombetta, M. Cutojo. Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, GENOA, Italy

Background: Nailfold videocapillaroscopy (NVC) is a non invasive diagnostic technique useful for evaluating microvascular status in patients with connective tissue diseases. 1 In systemic sclerosis (SSc) capillary abnormalities, when evaluated by NVC, evolve in a clearly defined sequence called the “sclerodermat patterns” (Early, Active, Late). 2 On the contrary, mixed connective tissue disease (MCTD) doesn’t show characteristic either nailfold capillary abnormalities or typical sequence.1,2 Until today, few studies described the main NVC changes in MCTD.3

Objectives: To retrospectively study nailfold microangiopathy by NVC in MCTD patients with a follow-up of three years and to compare capillaries abnormalities between patients affected by MCTD and SSc.

Methods: Ten patients (mean age 50±19 years) affected by MCTD with Raynaud phenomenon (Kasukawa’s criteria) who performed their first NVC were enrolled. Among these, complete capillaroscopic and clinical data at three years were available for 7 patients (disease duration 6.4±4.2 years). Main NVC parameters (absolute number of normal and total capillaries and scores of capillary ramifications, enlarged capillaries, giant capillaries, microhemorrhages, number of capillaries) were evaluated by NVC at baseline (T0, first NVC), and after one (T1) and three years (T2). Possible variations of clinical parameters along with capillary findings were analyzed. Significant correlations among capillaroscopic and clinical parameters. Furthermore, we compared main NVC parameters at T0 of ten above mentioned MCTD patients versus ten random SSc patients with the same disease duration (6.4±4.2 years) and similar age (51±17 years). Statistical analysis was performed by non parametric tests.

The patients were receiving different immunosuppressive treatments.

Results: No statistically significant variation of the scores as well as of the absolute value of the above reported capillary parameters was observed during the 3 years of follow-up. No statistically significant correlation was observed between capillary parameters and MCTD clinical aspects (Raynaud phenomenon, dysphagia, dyspnoea, sclerodactyly, sicca syndrome, telangiectasies and arthralgia) at first visit and during follow-up. The scores of enlarged capillaries and giant capillaries were found significantly higher (p<0.05) in patients with SSc versus MCTD patients at T0. Moreover, the absolute number of total capillaries and normal capillaries were found significantly lower (p<0.05) in SSc patients versus MCTD patients. On the contrary, no statistically significant difference was observed for
the other capillary parameters (capillary ramification, microhemorrhages) between the two groups of patients.

Conclusions: In a limited cohort of MCTD patients with an average disease duration of 6.4 years and a follow-up of three years, the nailfold microangiopathy does not seem to be significantly progressive. Patients with MCTD seem to show less enlarged/giant capillaries, and larger absolute number of total and normal capillaries than SSc patients. Still difficult to identify a defined NVC pattern in MCTD patients.

AB0762
RELATIONSHIP OF THE SIX MINUTE WALKING TEST AND QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS
G. Cuomo, K. Gjeloshi, F. Masini, F. Danzo, C. Romano, L.E. Adinolfi. UOC Medicina Interna, UNIVERSITA DEGLI STUDI DELLA CAMPANIA, NAPOLI, Italy

Background: The six minute walking test (6MWT) is a standardised measure of submaximal exercise capacity. It is a surrogate measure of heart and lung involvement. There are no studies on relationship between 6MWT and quality of life evaluated by Short form 36.

Objectives: To evaluate the relationships between the 6 min walking distance (6MWD) and each items of SF36

Methods: Fifty consecutive SSc patients were investigated. They underwent 6MWT and complete the SF-36 (assessed the 8 domains of the questionnaire as well as the physical component score-PCS and mental component score-MCS). 6MWD ranged from 253 to 582 (median 420); we listed the correlations from 6MWT and only the statistically significant features of SSc and the items of SF36

Age: median 48 (range 20–72); Rho −0.51; p<0.00001
EScSG Activity index: median 0.5 (range 0–5); Rho −0.33; p<0.009
HAG-DI: median 0.375 (range 0.2–2.75); Rho −0.26; p=0.048
mRSS: median 2 (range 0–17); Rho 0.35; p<0.007
Pulmonary hypertension (echocardiography): median 30 (range 13–80); Rho −0.26; p=0.048
SF36: PCS: median 43 (range 20–65); Rho 0.41; p=0.0016
PF: median 75 (Range 0–100); Rho 0.40; p=0.002
GH: median 50 (range 10–92); Rho 0.43; p=0.0007

Conclusions: Our study first demonstrates that 6MWT is correlated to some aspects of quality of life as measured by SF36 in the SSc patients. This results must be considered when assessing 6MWT in SSc.

AB0763
BIOELECTRICAL IMPEDANCE ANALYSIS FOR THE ASSESSMENT OF BODY COMPOSITION IN PATIENTS WITH SYSTEMIC SCLEROSIS
G. Cuomo, G. Guarino, F. Danzo, C. Romano, F. Masini, R. Ferrara, S. Gentile, L. E. Adinolfi. UOC Medicina Interna, UNIVERSITA DEGLI STUDI DELLA CAMPANIA, NAPOLI, Italy

Objectives: The aim of the present study was to evaluate the body composition by bioelectrical impedance analysis (BIA) and to assess the nutritional status by BMI and possible correlations with epidemiological and clinical characteristics in patients with SSc

Methods: Malnutrition was defined as BMI <18.5 kg/m² or unintentional weight loss >10% in combination with a fat-free mass index (FFMI) <15 kg/m² for women or <17 kg/m² for men or BMI <20.0 kg/m² (age <70 years) or <22 kg/m² (age >70 years). Body composition was assessed in 40 patients (female) (age mean ±sd: 45.2±12.2) and 20 healthy controls (age mean ±sd 41.5±5.3) with BIA (Akern, Italy) and BMI. The manufacturer’s equation and the Geneva equation were used to estimate fat mass (FFM).

Results: Malnutrition was found in 10% of patients vs 8% of healthy controls; and low FFMI in 30% of patients compared to controls (46.8±7.6 vs 53.6±6.3 respectively; p<0.01). Furthermore, with the same instrument a lower basal metabolic rate was found in patients compared to controls: 1462±145 vs 1720±69 calories (p=0.001). The correlations between FFM and basal metabolism with the clinical features of the patients were not statistically significant

Conclusions: This study confirm the study of Spanjer MJ et al and shows a relatively low prevalence of malnutrition in comparison with other studies, but a high prevalence of low FFMI, underlining the necessity of measuring body composition in SSc patients with a standardised and validated method. Furthermore, Cappori et al,² have shown an alteration of the nutritional status of patients of SSc probably related to a gastro-intestinal commitment. In our patients despite the presence of an apparent good nutritional status the use of bioimpedanceometry revealed a different body composition, a lower share of muscle mass, in patients compared to controls, related, in part, to musculoskeletal involvement by systemic sclerosis (increase in muscle catabolism and/or poor nutrient supply due to malabsorption phenomena). The early detection of such alterations could be useful to insert subjects at risk in physiological rehabilitation programs.

AB0764
COMPARISON OF DISEASE CHARACTERISTICS IN PATIENTS WITH JUVENILE-ONSET AND ADULT-ONSET PROGRESSIVE SYSTEMIC SCLEROSIS
G. Karatemiz¹, A. Androvic², S.N. Esatoglu², S. Sahin³, K. Barut³, G. Hatemì ¹, V. Hamuryudan¹, O. Kasapcopur², E. Seyahi², ¹Rheumatology, Istanbul University of Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Progressive systemic sclerosis (PSSc) has been known to affect mainly adults of 30–50 years of age. Juvenile–onset has been reported to be rare and studies comparing clinical differences between juvenile-onset and adult-onset form have been limited.¹ These studies were coming from European and North American countries.¹,² As there would be also effects of ethnic differences, we aimed to clinical differences between the two forms of pSSc of paediatric and adult rheumatology centres of a tertiary centre, in Turkey.

Methods: Adult onset patients were defined as those who were registered and followed as ‘sclerodermia’ at the departments of adult and paediatric rheumatology at Cerrahpasa Medical Faculty, Istanbul, between 2005 and 2017. Only those with at least 2 follow-up visits were included. Patients’ charts were re-evaluated retrospectively.

AB0765 DEVELOPMENT AND ASSESSMENT OF A STRUCTURED TRAINING PROGRAM FOR PATIENTS WITH SYSTEMIC SCLEROSIS

H. Ahrens¹, E. Siegert², M. Kraft¹, K. Loewe³, M. Worm⁴. ¹Department of Dermatology, Venerology and Allergology, Charité University Medicine; ²Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany

Background: Structured patient education programs are a key element of patient care in many chronic diseases. They are often based on the Stanford University chronic disease self-management program and aim to empower patients and to improve compliance and coping abilities. However, we are not sure whether self-management education programs yield the expected benefit.¹

Objectives: To develop a structured patient education program for SSc patients and to prove training-specific effects on patients’ quality of life and disability.

Methods: We developed a structured patient education program. The content of the program was created by a team of rheumatologists and dermatologists. The program consists of three modules focusing on general knowledge about the disease, gastrointestinal involvement, digital ulcers (DU), skin and wound care and a patient diary on disease symptoms. Patients were either included in the intervention or in the control group. Disease symptoms and severity as well as clinical parameters were assessed at baseline (intervention and control), at the follow-up visit at month 3 (intervention only) and at the final follow-up visit at month 6. In the intervention group satisfaction with the education program was analysed.

Primary outcome measures were SHAQ-SF, SF-12, BFI, SHAQ_DU. Secondary outcome measure was the satisfaction survey. For comparisons between different times analysis of variance for repeated measures was used. For description of cohorts Mann-Whitney Wilcoxon test was used.

Results: 58 SSc patients were included, 27 received the educational program (intervention group) and 31 patients served as a control group. Both groups were matched regarding demographics and disease subtype. Incidence of DU’s was significantly higher in patients from intervention group resulting in a more frequent administration of vasoactive therapies. SHAQ-SF, SF-12, BFI, SHAQ_DU were comparable between control and intervention group. However, patients in the intervention group rated the training program as helpful and reported an increased in knowledge about their disease afterwards. A positive impact of the training program on SHAQ-SF, SF-12, BFI, SHAQ_DU was observed in individual patients.

Conclusions: Patients who participated in the training were overall satisfied with the program. However, no significant effects on quality of life after the intervention were observed. One reason for this finding might be the disease duration (mean 11.5 years). This needs to be further analysed in a consecutive study considering patients with shorter disease duration.

AB0766 INITIAL CHARACTERISATION OF WOMEN WITH BREAST IMPLANTS IN A GROUP OF PATIENTS WITH SYSTEMIC SCLEROSIS REFERRED FOR AUTOLOGOUS HSCCT

H. Khoun⁵, R. Burt⁵. ¹Sainte Justine Hospital, Montreal, Canada; ²Immunotherapy and Autoimmune Diseases, Northwestern University, Chicago, USA

Background: The causal relationship between breast implants (BI) and systemic sclerosis (SSc) is still strongly contested.

Objectives: To add further input to this medical controversy, we studied the initial clinical characteristics of patients with breast implants and systemic sclerosis that are referred to our centre for autologous hematopoietic stem cell transplant.

Methods: From 163 patients, with the diagnosis of systemic sclerosis (SSc), limited SSc, CREST, Morphea or scleroderma sine scleroderma, referred to our centre for autologous hematopoietic stem cell transplantation, 132 were found to be females. To identify those with breast implants (BI) or have a history of breast implants, we performed a systemic chart review for all patients. Once the patients with actual breast implant devices or have history of breast implants were identified, alive patients were contacted to check the type of their breast implants (silicone vs saline), the year of insertion, the local complications, whether they were removed or replaced and the year of removal and replacement, and the type of replacement if applicable. Clinical and biological data were collected for all patients and were compared between those who have breast implants or history if breast implants and those who do not have.

Results: From 132 patients with SSc or SSc variants, thirteen had history of BI (9.8%). In 12, the breast augmentation therapy preceded the development of SSc, with median time between BI insertion and the emergence of initial symptoms of SSc of 12 years (range 7–29). The remaining patient showed acceleration of her disease after BI surgery. Surprisingly, in all 12 patients for whom we could know the type of initial implants, the prostheses were saline. When we compared the clinical characteristics of those with BI and those without. Patients with BI appeared to have higher age (mean 49.95 vs 44.42 years, p=0.012, shorter time from initial symptoms to diagnosis (mean 4.76 vs 12.24 months, p<0.001), more frequently positive ANA (13/13 vs 89/114, p=0.06) and more frequently positive anti RNA polymerase III (7/10 vs 20/78, p=0.004).

Conclusions: Our data may support the hypothesis of a possible association between BI and SSc. Furthermore, these results raise questions regarding the safety of saline breast prosthesis. Finally, our finding may indicate a possible difference in the initial characteristics of SSc patients with BI and those without.

Disclosure of Interest: None declared

AB0767 EFFICACY OF SUBCUTANEOUS TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC SCLEROSIS OVERLAP SYNDROME

H. Wakabayashi¹, S. Kino¹, M. Hasegawa¹, A. Sudo¹. ¹Orthopaedic Surgery, MIE University Graduate School of Medicine, Tsu; ²Orthopaedic Surgery, Kino Orthopaedic Clinic, Nabari, Japan

Background: Systemic sclerosis (SSc) is a connective tissue disease that develops sclerotic changes in the skin and visceral organs. SSc is a disease of uncertain etiology, characterized by fibrotic changes in the skin, cardiac, gastrointestinal, and renal complications contribute to patient morbidity and decreased survival¹. And patients present with stiffness of the limbs because of joint and swelling in the skin and periartricular connective tissues. Interleukin-6 (IL-6) is a pleiotropic factor that plays a major role in inflammation; furthermore, IL-6 overexpression and pathogenicity in SSc have been demonstrated². IL-6 expression is reportedly high in both the skin and serum of SSc patients, and its elevation depends on the skin score. And it is a candidate factor that can reproduce the pathological conditions of SSc as well as RA.

Objectives: We report the cases of rheumatoid arthritis (RA) patients with SSc who was administered anti-interleukin-6 receptor antibody tocilizumab (TCZ).

Methods: Two RA with refractory SSc patients were administered tocilizumab at 162 mg/kg twice a month for 12 months. RA disease activity is evaluated by DAS28-ESR and CDAI. Skin condition of SSc is evaluated by pinching the skin according to the modified Rodnan total skin score (mRTSS).

Results: They were both female, and age at the time of SSc diagnosis was 74 (patient 1) and 51 (patient 2) years old. The time lapse since SSc diagnosis was at first visit and 14 years, respectively. And it since RA diagnosis was 14 years and 6 years, respectively. Tocilizumab was administered at 162 mg every 2 weeks, which is equal to the dosage used for RA. Administration of prednisolone at 5 mg/day and DMARDs were continued. Overall, TCZ was well tolerated, and both patients experienced a general improvement in coping with normal daily activities. During the 12 month tocilizumab therapy, both RA disease activity and mRTSS decreased. The patient global assessment improved by 70 (75 to 5) and 44 (88 to 24) in patients 1 and 2 in 12 months, respectively. In RA disease activity, DAS28 decreased from 5.66 to 1.73 in 12 months in patient 1 and 7.14 to 4.43 in
OSTEOMYELITIS COMPLICATING DIGITAL ULCERS IN SYSTEMIC SCLEROSIS

I. Chiapparini1, F. Locatelli2, P. Orsolini3, R. Caporal4, C. Montecucco4, V. Coudoulière1,2, *RIJCCS Policlinico San Matteo Foundation, Pavia, Italy; 2Rheumatology Unit, IRCCS Policlinico San Matteo Foundation; Department of Infectious Diseases; 3Rheumatology Unit, University of Pavia, Pavia, Italy

Background: Skin ulcers are a frequent manifestation of systemic sclerosis (SSc). Skin ulcers are painful, represent a cause of disability and heavily affect patients’ quality of life. The presence of local infection may be responsible for osteomyelitis (OM) of the underlying bone. If gangrene develops, surgical amputation may be required. At the moment is not clear if there are predisposing factors to osteomyelitis development.

Objectives: To describe a population of SSc patients affected by cutaneous ulcers and osteomyelitis

Methods: We collected data of SSc patients satisfying the 2013 ACR criteria for SSc referring to our outpatient clinic from January 1st 2016 to December 31st 2017. The patient’s data were evaluated on the basis of individual clinical records, including demographic, clinical and serological findings. Cutaneous ulcers were defined as epithelial loss and loss of dermis; post-traumatic skin lesions were excluded. In cases suspected of infection, microbiological investigations were carried out. We have diagnosed OM by clinical, radiological and laboratory means, in particular the presence of pain, swelling, fever, erythema, purulent secretions, blood chemistry alterations and typical radiological characteristics at either plain X ray and/or MRI. Statistical analysis was performed using STATA software for descriptive analysis and groups comparisons. Given the low number of events only univariate analysis was conducted.

Results: A total of 189 patients were enrolled in the study. Of them, 21 (11.1%) were males, mean age was 64.39±12.5 years and median disease duration 11.59 (5.6–19.3) years. A diffuse cutaneous (dcSSc) involvement was present in 50 (26.5%), limited cutaneous (lcSSc) in 131 (69.3%) and a limited disease in 8 patients (ISSc) (4.2%). Digital ulcers (DU) were present in 29 patients (15.3%) and in 5 cases (2.6%) were complicated by the occurrence of OM. The pathogens responsible of the infections were isolated in 3/5 (60%) cases and were representative of: Methicillin-sensitive Staphylococcus aureus (2 cases) and P. Aeruginosa, also multisensitive. OM affected the third finger of right hand in 2 (40%) patients, the second finger of right hand in 1 (20%) patient and the third finger of left hand in 2 patients (40%). In 2 cases (40%) surgical amputation had to be performed. Patients with OM were significantly younger (54.9±16.07 vs 64.65 ±12.34, p=0.0432) and had higher CRP levels than the rest of the patients (1.27 ±0.59 vs 0.42±0.74, p=0.0061). In patients with DU, the only predictive factor for the development of OM was the total number of ulcers in the single patient (OR 2.27, 1.39–3.71, p<0.001) while no significant influence was found for other demographic or disease specific parameter.

Conclusions: OM is a severe complication of DU in SSc. In most cases the aetiological agents are community-acquired pathogens. SSc patients with OM were younger but did not show any other obvious distinguishing feature. The number of ulcers in the single patients were predictive of OM development. Further and larger studies are needed to address this aspect of the microvascular involvement of SSc.

SCLERODERMA MIMICS IN COHORT FROM AN EUSTAR CENTRE

I.R. Dobrotna 1, L. Damian 2, A. Petcu 1, I. Felea 2, I. Filipsescu 2, S.P. Simon 2, 3, S. Rednic 1, 4, *Rheumatology, Emergency County Hospital; 1Rheumatology, Iuliu Hatageanu University of Medicine and Pharmacy, Cluj Napoca, Romania

Background: The differential diagnosis of systemic sclerosis (SSc) can be sometimes challenging, especially when you have symmetrical skin thickening, Raynaud’s phenomenon (RP) or acroosteolysis. When symptoms and signs are unclear, patients should be referred to a specialist centre for assessment to differentiate between scleroderma and its mimics.

Objectives: Assessing the types of scleroderma mimics presenting in a tertiary care centre and underlining the diagnosis difficulties.

Methods: We evaluated a cohort of 140 patient admitted in our clinic with the suspicion of SSc from January 2007 until December 2017. 130 of them are with SSc and 10 patients with scleroderma mimics. The patients were evaluated for quality and distribution of skin involvement, the presence of systemic complications, the presence of scleroderma specific antibodies and the capillaroscopic pattern. If they haven’t met any criteria for SSc, they underwent further specific investigations.

Results: From the 140 patients evaluated, 10 (7,14%) were with scleroderma mimics. All these 10 patients were admitted in our clinic with the suspicion of SSc. 3 of them had severe RP, one had acroosteolysis and 6 had symmetric skin thickening. There were 4 males and 6 females. All the patients had no organ involvement (pulmonary arterial hypertension or pulmonary fibrosis), normal capillaroscopic pattern and negative antinuclear antibodies and negativespecific scleroderma antibodies. The patients with RP had no skin sclerosis or other clinical or laboratory changes and the diagnostic was primary RP. The patient with acroosteolysis had no skin sclerosis or RP and after genetic testing a diagnosis of Hajdu-Cheney syndrome was made. The 6 patients with skin thickening had no RP. There were 2 patient with solvent induced scleroderma, 2 with scleroderma adultorum, 1 with scleromixidema, 1 with eosinophilic fasciitis. The 2 patients with solvent induced scleroderma had sclerodactyly and one of them the "prey sign" and they had a complete resolution of skin sclerosis after eliminating the solvent exposure after a few years of follow up. The 2 patients with scleroderma adultorum had no underlying gammapathy or infections. The patient with eosinophilic fasciitis had extended skin thickening with eosinophilia ant typical aspect on MRI, with partial clinical resolution after immunosupression. The patient with scleromyxedema had associated hypothyroidism. The period from first symptoms to diagnosis was variable from months to years.

Conclusions: Even though are rare, scleroderma mimics can be a challenging diagnostic even in tertiary care centre and sometimes diagnostic can be delayed. A correct diagnostic is necessary to avoid unnecessary immunosupression.

18 FDG PET/CT PREDICTS DECLINE IN FUNCTIONAL RESPIRATORY TESTS IN SYSTEMIC SCLEROSIS PATIENTS BUT NOT IN RHEUMATOID ARTHRITIS PATIENTS

J. Ibors1, M. Martinez2, J.L. Lolaizas3, M. Garcia4, J.J. Allegr6, S. Herren5, I. Chalmeta1, L. Gonzalo1, R. Neguerol2, C. Aiarz2, K.A. Arevalo5, I. Canovas1, C. Feced6, J.J. Fraigo1, R. Gonzalez1, E. Grau1, E. Labrador1, I. Martinez2, C. Najera1, J.E. Oliver1, F.M. Ortiz1, E. Vicenis1, M. De la Rubia1, D. Hervas1, J.A. Roman1, *Rheumatology Department, 2Respiratory Department, 3Nuclear Medicine Department, HUP La Fe, Valencia; 4Rheumatology Unit, H Leon Leon; 5Rheumatology Department, H. Peset; 6Biostatistical Unit, IIS La Fe, Valencia, Spain.

Background: Intestinal lung diseases (ILD) is a frequent complication in connective tissue diseases (CTD) such as rheumatoid arthritis (RA) or systemic sclerosis (SS), but the lung is the only affected organ in the idiopathic pulmonary fibrosis (IPF). Nonspecific interstitial pneumonia (NSIP) is the more frequent form in SS while usual interstitial pneumonia (UIP) predominates in RA patients and in the IPF form. Some studies suggested that 18-FDG-PET/CT could help to detect zones of activity in lung tissue in IPF and this in turn could predict the disease

Disclosure of Interest: None declared

Scientific Abstracts
progress, but results are inconclusive. Moreover, little is known about the value of 18-FDG PET uptake in ILD associated to RA or SS.

Objectives: The purpose of this study is to evaluate the predictive value of 18-FDG PET/CT scan images in functional pulmonary progression of ILD associated to RA or SS.

Methods: We conducted a 12 month prospective observational study on patients diagnosed with ILD associated to SS or RA between January 2015 and May 2017. ILD diagnosis was based on clinical assessment, pulmonary function test (PFTs) and expert HRCT evaluation. We performed three visits: basal, 6 month and 12 month. On all visits a general exploration, forced vital capacity (FVC) and diffusing capacity of the lungs for carbon monoxide (DLCO) were carried out. On basal and 6 month visit a 18-FDG PET/TC was performed within a period of three months from the PFTs. Participants continued with their treatment (corticosteroids, DMARDs or immunosuppressants). The nuclear medicine physician identified the maximum and mean standardised uptake value (SUVmax and SUVmean) in the three areas with the most FDG uptake, and adenopathies uptake. PET/CT images were reviewed by 2 combined radiologist/nuclear medicine physicians in consensus.

Results: We included 17 patients, 10 had UIP associated with RA and 7 NSIP related to SS. It appeared that RA patients had longer lung illness evolution and worse FVC than SS patients (table 1), in spite of not having found statistical differences. We detected significant statistical relation between the highest SUVmax and FVC (p=0.009) or DLCO progression (p=0.006) in SS patients, independently of the basal FVC and DLCO, and duration of lung illness in a multivariable linear mixed model. We didn’t find any relation between SUVmax and FVC or DLCO progression in RA patients.

Conclusions: In our cohort of patients with SS, 18 FDG PET/TAC can aid in predicting the progression of ILD associated disease, which does not occur in RA patients.

AB0772 PROSPECTIVE STUDY OF CARDIOVASCULAR RISK ASSESSMENT IN SYSTEMIC SCLEROSIS

J. J. Gonzalez Martin1, M. Novell-Navarro2, J. L. Cabrera Alarcón2, O. Camiòn2, A. Abdeldaker3, E. Calvo3, P. Aloceno4, F. Aramburu5, C. Main2, F. Gairdner6, P. García de la Peña7, on behalf of HM Sanchinarro. 1Rheumatology, Hospital HM Universitario Sanchinarro; 2Centro de Biología Molecular Severo Ochoa; 3Angiology and Vascular Surgery, Hospital HM Sanchinarro; 4Angiology and Vascular Surgery, Hospital HM Universitario Sanchinarro; 5Rheumatology; 6Angiology and Vascular Surgery, Hospital HM Universitario Madrid, Madrid. Spain

Objectives: Evaluate evolution of cardiovascular risk (CVR) in a cohort of systemic sclerosis (SSc) in one year of follow-up.

Methods: Prospective longitudinal study of a cohort of 45 patients with SSc during a period of one year. Sociodemographic and analytical variables were analysed at the time of inclusion in the study (baseline) and after 12 months of follow-up. The vascular protocol with carotid ultrasound was performed, including the determination of carotid intima-media thickness (IMT) and the evaluation of atheromatous plaques; in addition to the performance of the ankle-brachial index (ABI) and the determination of endothelial dysfunction (ED) through the measurement of flow-mediated vasodilation (FMVD), all at baseline and at one year.

Results: 45 patients were included, 94% of them female, with a mean age of 52.2 ±11.5 years and mean evolution time of 4.6±5.1 years. The distribution by subgroups was 44.4% limited SSc, 35.5% diffuse SSc, 4.4% pre-scleroderma, 4.4% sine scleroderma SSc, 6.8% MCTD, and 4.4% overlap syndrome. Classical CVR variables were collected as smoking habit, DM, HTN, obesity, DLP, hyperhomocisteinaemia, and clinical variables of the SSc were added such as modified Rodnan Skin Score (mRSS), pulmonary arterial hypertension (PAH), interstitial lung disease (ILD), capillaroscopic pattern, SSc specific antibodies and previous treatments.

A bivariate analysis was performed using binomial logistic regression, both at baseline and at one year. Pathological IMT (>0.9 mm) was significantly associated with hyperhomocysteinemia (p=0.024, OR=3.03, CI 1.33–9.58). The presence of atheromatous plaque was associated with corticosteroid treatment (p=0.048, OR=0.58, CI 0.28–0.97). Pathological ITB (>0.9) was significantly associated with the 25-OH-vitamin D deficit (p=0.031, OR=0.25, CI 0.06–0.77). ED did not show a statistically significant association with the parameters studied.

To evaluate the effect of time, a binomial model was adjusted by linear regression of mixed effects for the variables of CV affection considered (see table 1). Time proved to be a risk factor to present pathological ITB values, since it was evidenced at baseline in 4.4% of the sample compared to 20% in the one-year study. Consequently, a multivariate analysis was performed showing pathological ABI was significantly associated to time (p<0.001, OR=5.97, CI 59.64–59.75) and mRSS, although with little effect (p<0.001, OR=0.042, IC 0.036–0.047). Time was not a risk factor for the appearance of pathological IMT, ED or plaques.
Conclusions: In our study, we observed the significant variation in ABI in one year, this may be due to the fact that this measurement has a high sensitivity for the detection of early peripheral arterial disease, in those patients who have not manifested signs and symptoms of arterial disease due to more evolved time of evolution.

AB0774 IMPACT OF STANDARDISED EDUCATION PROGRAM ON THE ACCURACY OF MODIFIED RODNAN SKIN SCORING IN PATIENTS WITH SYSTEMIC SCLEROSIS

J.W. Park1, J.-B. Jun2, L. Czirják3, Y. Allanore4, M. Matucci-Cerinic5, E.B. Lee6,
1Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine; 2Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of Ireland; 3Department of Rheumatology and Immunology of Medical Centre, University of Pecs, Hungary; 4Paris Descartes University and Cochin Hospital, AP-HP, Paris, France; 5Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; 6Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of Ireland

Background: Modified Rodnan skin score (mRSS) has been used as not only a primary outcome in many clinical trials, but also as an important surrogate marker of disease activity in patients with systemic sclerosis (SSc). Therefore, establishment of well-organised training program of mRSS is essential for the proper management of patients. Recently, Scleroderma Clinical Trials Consortium and the World Scleroderma Foundation published the recommendation for 2-phase mRSS training and emphasised assessing scoring accuracy after the training.

Objectives: To investigate the effect of modified Rodnan skin scoring (mRSS) education on improving its accuracy

Methods: Ten rheumatologists (6 professors and 4 fellows) received an education program composed of video education and live demonstration by master instructor (Marco Matucci-Cerinic) at (Seoul in June, 2017). Physicians measured mRSS of 8 patients with SSc 1) before the education, 2) after the video education and 3) after live demonstration without any clinical information of the patients. Accuracy of skin scoring was estimated by the difference from the pre-defined gold-standard skin score measured by master instructor. Change in accuracy of mRSS during the education course was analysed using linear mixed model. Intra-observer reliability of the mRSS and its change was assessed by intraclass correlation coefficient (ICC).

Abstract AB0774 – Table 1. Multivariable analysis indicating effect of the education program on the accuracy of modified Rodnan skin scoring

<table>
<thead>
<tr>
<th>Variable</th>
<th>Coefficient</th>
<th>Standard Error</th>
<th>P value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Examiner’s skin score – gold-standard skin score</td>
<td>0.56</td>
<td>0.23</td>
<td>0.01</td>
</tr>
<tr>
<td>Exam's skin score</td>
<td>0.56</td>
<td>0.23</td>
<td>0.01</td>
</tr>
</tbody>
</table>

*, Dependent variable = (Examiner’s skin score – gold-standard skin score). Regression coefficient indicates the difference in dependent variable as compared with reference.

1. This clinical factor consistently influence the dependent variable irrespective of education course.

2. Indicates P value for type 3 fixed effect

3. (Physician’s skin score – gold-standard skin score) (95% CI) was estimated as 7.66 (6.03 to 9.29) before the education.

Results: The number of SSc patients ever experienced by each physician was significantly higher in the professors than fellows but the number of mRSS ever performed was comparable between the two groups. Median (IQR) skin score
measured by master instructor was 10.5 (9.0). Mean (SD) difference between skin scores by physicians and master instructor was 7.7 (9.5) units. In the univariable analysis, video education significantly reduced the difference from the gold-standard score (β=–1.96, 95% CI –3.83 to –0.10) whereas live education did not show additional enhancement in scoring skill. Effect of education program was significantly different according to the physician’s status and patient’s disease type (diffuse vs. limited). In addition, male patient, shorter disease duration and higher gold-standard skin score was associated with more accurate skin scoring irrespective of the education. In the multivariable analysis where above clinical factors were adjusted, video education also led to significantly accurate skin scoring (β=0.10). When the educational effect was stratified by individual site of examination, face and distal extremities showed greater enhancement of scoring accuracy whereas difference from gold-standard score in proximal extremities was rather increased. ICC of physicians’ skin scores was acceptable over all scoring times (0.63 to 0.88) but was not significantly changed after the education.

Conclusions: The mRSS education program can significantly enhance the accuracy of mRSS, which is mainly achieved by video education.

AB0775 CHARACTERISTICS OF PATIENTS WITH SCLERODERMA (SSC) TREATED WITH VARIOUS DRUGS IN THE CLINICAL ASSESSMENT AND TGF B AND IL13 CONCENTRATION IN COMPARISON TO THE HEALTHY GROUP
1Department of General and Experimental Pathology, CEPT laboratory, Medical University of Warsaw; 2Department of Polyclinic of Systemic Connective Tissue Diseases; 3Department of Molecular Biology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland

Background: Scleroderma (SSc) is a rare multisystem chronic disease the treatment of which is still challenging. Until now, there is no effective therapy that can modify the overall disease course. However, the main aim of SSc treatment is directed toward managing organs involvement and providing symptomatic relief. Effective drug therapy should inhibit three components of the disease: tissue fibrosis, vascular abnormalities and autoimmunity. Moreover, potential drug needs to be considered in the context of specific four subsets of the disease: fibroproliferative, inflammatory, limited, and normal-like. It was shown that various subsets could have different profile of specific cytokines: TGFβ – associated with fibroproliferative and inflammatory type of disease and IL-13 – mediator of fibrotic and vascular pathology.

Objectives: The aim of the study was to assess the level of TGFβ and IL-13 in SSc pts with various treatment regimens comparing to healthy control.

Methods: 55 patients (71% were women) with SSc diagnosed according to EULAR/ACR 2013 criteria were divided into 5 treatment groups: 1st group – 6 pts treated with methotrexate (MTX), 2–13 pts with mycophenolate mofetil (MMF), 3–5 pts with cyclophosphamide (CYC), 4th group– 7 pts with azathioprine (AZA), 5th group- 22 pts without immunosuppressive treatment. All patients have been treated based on a scheme required for organs involvement in accordance with the update of EULAR recommendations from 2016. Mean age of patients was 54.56 ±13.97. The blood and serum samples have been collected for basic examination. TGFβ and IL-13 concentration in serum was quantitated by ELISA. Differences in cytokine concentration were determined using non-parametric Kruskal-Wallis test. The level of statistical significance was set at p<0.05. The modified Rodnan Skin Score (mRSS) examination was taken by one assessor at the beginning of the study and six months later. There were measured DLCO, HRCT, echocardiography and capillaroscopy.

Results: In 82% pts positive antinuclear antibodies have been revealed: in 16% positive results for CENPB were obtained and in 44% for SC170. Capillaroscopy showed in 23% pts early pattern, in 38% – active pattern, and in 27% – late pattern. 32% of SSc pts had confirmed pulmonary fibrosis, while 90% – Raynaud’s syndrome. The median of mRSS in CENPB (+) pts was 5.4 ±0.4 in SC170 (+) pts – 12.7. Statistically significant differences were found between IL13 and TGFβ levels in patients treated with immunosuppressants and healthy subjects. There was no correlation between IL13 or TGFβ with lung fibrosis progression or skin involvement.

Conclusions: In conclusion, our findings indicate that IL13 and TGFβ are characteristic cytokines in scleroderma, but these parameters did not correlate with severely progressive course of SSc.

Disclosure of Interest: None declared

AB0776 MUSCLE ULTRASONOGRAPHY: A POTENTIAL NEW DIAGNOSTIC TOOL FOR INFLAMMATORY MYOPATHIES
K. Bhansing1, C. Saris2, J. Fransen1, F. van den Hoogen1, A. Verrips2, R. Cooper4, P. van Riel3, B. van Engelen2, S. Pillen3, M. Vork1. 1Rheumatology, Radboud University Medical Center; 2Neurology, Canisius Wilhelmina Hospital, Nijmegen, Netherlands; 3Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, UK; 4Scientific Institute for Quality of Healthcare, Radboud University Medical Center, Nijmegen, 5Child Development and Exercise Center, University Medical Center Utrecht, Utrecht, Netherlands

Background: Quantitative muscle ultrasound (QMUS) imaging has proven to be a useful, non-invasive technique to visualise normal and pathological skeletal muscle tissue. 1 Electromyography (EMG) findings are not always disease specific in patients suspected of dermatomyositis inflammatory myopathies (IIM).

Objectives: To assess diagnostic value of QMUS in patients suspected for IIM and to compare results with EMG.

Methods: In 57 patients, suspected for IIM, panel diagnosis blinded for QMUS was used as reference standard. QMUS results were used to classify patients according an ultrasound neuromuscular disorder (NMD) algorithm (normal/borderline/abnormal). The predictive value of QMUS and EMG was assessed in a two by two table and a multivariate logistic regression model.

Results: Twenty-two patients (39%) were diagnosed with IIM; 8 polymyositis, 4 dermatomyositis, 4 necrotizing myopathy, 3 inclusion body myositis and 3 non-specific myositis. Sixteen patients were classified with other NMD. We found an increased echointensity of the sternocleidomastoid, biceps, forearm flexor and tibialis anterior in the IIM group. Sensitivity, specificity, positive and negative predictive values (PPV/ NPV) were 82%, 51%, 51%, 82% for ultrasound NMD algorithm and 63%, 64%, 50%, 75% for EMG. Multivariate analyses showed area under the curve (AUC) (0.81) (0.69–0.92) for ultrasound NMD algorithm, EMG (0.79) (0.67–0.92) and ultrasound NMD algorithm plus EMG (0.82) (0.70–0.93).

INFLAMMATORY MYOSITIS ASSOCIATED WITH MYASTHENIA GRAVIS WITH AND WITHOUT THYMIC PATHOLOGY: CASE SERIES AND LITERATURE REVIEW

K. Huang1, M. Mezei2, K. Shojania1, K. Chapman4, N. Amir1, N. Dehghan1.
1Rheumatology, 2Neurology, University of British Columbia, Vancouver, Canada

Background: Inflammatory myopathies (IM) and Myasthenia gravis (MG) are two well-recognised and distinctive neuromuscular diseases. The association of myasthenia gravis (MG) and inflammatory myositis (IM) is rare and often only one of the diseases is diagnosed. The coexistence of MG and IM might be associated with thymoma. Even less common is the association of IM (polymyositis or dermatomyositis) and myasthenia gravis in the absence of thymoma.

Objectives: Here, we report a case series of 6 patients with concurrent MG and IM who were followed at the Neuromuscular Disease Unit (NMDU) at a tertiary referral centre in Vancouver, British Columbia. We also conducted literature review on clinical characteristics, diagnostic challenge and management of this entity.

Methods: In this study, we retrospectively examined patients seen at NMDU from 2004 to 2017 who had diagnosis of concurrent MG and IM. We reviewed medical records to access their clinical presentations, laboratory findings, imaging studies and electrophysiological features. The data is presented descriptively.

Results: We identified 6 patients with MG-IM overlap. Three patients had simultaneous onset of MG and IM, 2 of whom presented with myasthenia crisis and fulminant myositis. In the other 3 patients, MG was the initial presentation and IM occurred 3–11 years after MG. Diagnosis of MG was confirmed with clinical features, electromyography and/or serology. All had symptoms of MG with predominant ocular or bulbar weakness. Among these 6 patients, 3 had underlying thymic pathology including two benign thymoma and one stage IV thymoma; all 3 patients had Acetylcholine Receptor (AChR) antibody and 2 were negative.

Four patients had biopsies confirming the diagnosis of dermatomyositis or polymyositis. The other 2 patients declined biopsy; however, their MRI and EMG findings were consistent with IM. Only one patient had typical dermatomyositis rash. Among the 3 patients with underlying thymic pathology, thymoma were resected; all 3 were treated with high dose glucocorticoids, IVIG, and methotrexate with complete remission after 2 years. Of the 3 patients with no thymic pathology identified, one patient (AChR+), was in remission on mycophenolate and passed away from pancreatic cancer; two patients (AChR+) had refractory MG and IM, and both responded to rituximab.

Conclusions: In summary, this is one of the largest case series with MG-IM overlap with or without thymic pathology. It is very important to recognise such association and the different pattern of muscle involvement because therapies may be adjusted to treat both conditions. In patients with thymic pathology, conventional disease modifying agents, IVIG and glucocorticoids in addition to thymoma resection appear to be effective. In patients with refractory MG and myositis who were AChR negative, rituximab may be effective.

AB0779

LONG TERM FOLLOW-UP OF A SYSTEMIC SCLEROSIS GROUP TREATED WITH BOSENTAN

I. Grosecieu1,2, F. Berghesi1,2, V. Bojinca3,2, A. Balanscescu2, A. Borangiu4, D. Mazuli2,3, S. Dais-Ilieescu2,4, D. Opris-Belinicki1,2, I. Saulescu2,4, C. Constantinescu3,2, M. Abobului1, R. Ionescu2,3, I. Bucilu1,2, I. Bucilu2,3, Internal Medicine and Rheumatology, Sf Maria Clinical Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background: Prospective studies with Bosentan have shown short term efficacy, while it is not clear whether long-term treatment may be effective or whether ulcers may recur once treatment is discontinued.

Objectives: Our objective was to evaluate the long term efficacy and tolerability of bosentan in patients with systemic sclerosis (SSc) who develop digital ulcers (DU).

Methods: In the present prospective, observational, non-controlled study, we followed 26 SSc patients treated with Bosentan from Sept 2014 to Dec 2017 Number of DU. semiquantitative capillaroscopic scoring, VAS (visual analog scale) for Raynaud, VAS for DU and HAQ were evaluated every 6 month. Results are presented as mean±SD. The difference between efficacy measures at follow-up visits was tested with the Wilcoxon’s signed-rank test.

Results: The group included 26 patients, 16 females, 11 diffuse subsets, age 48.08 (9.8) years, disease duration was 84.35 (76.04) months, number of DU was 4.27 (3.71), most of them had a late scleroderma pattern pattern (16/26),
Microangiopathy evolution score was 5.19 (2.04), VAS for DU was 75.52 (16.17), VAS for Raynaud was 67.43 (14.16), HAQ was 1.62 (0.55). 5 patients received Bosentan less than 6 months, so they were excluded from the statistical analysis. 6 month evaluation revealed significant decrease in the number of DU (p<0.01), the VAS for DU (p<0.01), the VAS for Raynaud (p=0.03) and the HAQ (p=0.04), but not of the microangiopathy evolution score. No significant difference was noticed of the above mentioned parameters at the next follow-up evaluations.

Regarding Bosentan safety: 6 patients died during the follow up (3 cases of severe pulmonary arterial hypertension, 1 scleroderma renal crisis, 1 heart failure, 1 post vascular surgery), Bosentan was stopped due to lack of efficacy in 2 case and due to side effects in 3 cases: 2 elevated liver enzymes, 1 severe trombocytopenia and 1 dyspepsia aggravation.

12 patients had a follow up after a 6 months Bosentan stop. We did not notice any significant increase in the number of DU, the VAS for DU or Raynaud, the capillary density, nailfold capillaroscopy or the HAQ.

Conclusions: We noted a significant decrease in the number of DU, patients perception of Raynaud and of DU after 6 months of treatment and the effect was maintained in the 3 years follow-up, even 6 months after Bosentan was stopped. In this long-term follow-up no new unidentified adverse reactions were found, except for the unexpected severe trombocytopenia. The present study is limited due to the small sample size, to the observational nature and should be viewed as descriptive. Questions rise about drug costs (6 months or long term treatment), but it also has to be emphasised that most of these lesions were chronic and non-responsive to previous treatments.

PROLONGED PROTON PUMP INHIBITOR EXPOSURE IS ASSOCIATED WITH DEVELOPMENT OF CALCINOSIS IN SYSTEMIC SCLEROSIS

L.V. Host, C. Campochiaro, S.I. Nihyanova, V.H. Ong, C.P. Denton, Centre for Rheumatology and Connective Tissue Diseases, The Royal Free Hospital, London, UK

Background: Long-term use of proton pump inhibitors (PPI) has been associated with some safety concerns, including potential vascular calcification. In a previous retrospective analysis, we noted a possible association between PPI use and calcinosis in scleroderma (SSc).

Objectives: To investigate the association between PPI use and the presence and extent of calcinosis in SSc patients.

Methods: Data from prospectively recruited patients were collected by patient survey, physician assessment and medical records. Calcinosis was graded; size (0 <=1 cm, 1+>1–3 cm, 2+=>3 cm) and number of sites involved (NSI) (I=1 body site, II=2–3, III>=3). A total daily PPI equivalent dose (TDED) was calculated for each patient. We calculated PPI exposure score (PPE) by multiplying the total duration of use by TDED. For analysis, PPE was categorised into four groups: 0=no exposure, 1-up to 5 years, 2–6–10 years, 3>10 years. Fisher’s exact test was used to assess categorical variables. Logistic regression assessed association between calcinosis and independent variables.

Results: 216 patients were recruited, 81.5% females, mean age 57.46 (SD 13.5) years, 56.5% had limited, 31.5% diffuse SSc, 9.7% had overlap features or 2.3% other CTD. Mean disease duration was 10 years (SD 9), ANA subtypes were defined: ACA positive (31.5%), ATA (25.5%), ARA (12.0%), ANA +ENA- (11.6%), URSNP (5.1%), ANA - (4.2%), PmScl (3.7%) and 6.5% other antibodies. Gastroesophageal reflux symptoms occurred in 83.3% of patients, most were on PPI (81%) and 14.8% had previously been on PPI. Current calcinosis (CC) was present in 30.1% patients, 9.7% reported past calcinosis. 39.6% had calcinosis at any time (CAT), 60.2% of patients never had calcinosis. Of those with CC, 47.7% had >1 site involved. The most frequent sites affected were: finger (70.8%), elbow (35.4%) and knee (18.5%).

Univariable analysis found an association between disease duration and calcinosis, with odds of CAT increased by 7% per year (OR 1.07, CI 1.04–1.11, p=0.001). Similarly, every year of PPE increased odds of CAT by 3% (OR 1.03, CI 1.01–1.05). Increasing age associated with CAT (odds increasing by 2% per annum, p=0.043). Exposure to a standard dose of PPI for over 10 years increased the odds of calcinosis by 4 times (OR 4.07, CI 1.68–9.55, p=0.002) compared to no exposure. PPE category associated with NSI (p=0.04). 73.3% of patients with large volume calcinosis (>3 cm) had a PPE for >10 years and all with calcinosis >3 cm had exposure to PPI.

Multivariable logistic regression found that disease duration (OR 1.07, CI 1.03–1.11, p=0.001) and antibody specificity strongly associated with calcinosis. Presence of ATA (OR 0.32, CI 0.14–0.75 p=0.008), ANA- (OR 0.13, CI 0.02–0.79 p=0.026), and ANA +ENA- (OR 0.17, CI 0.05–0.52, p=0.002) reduced odds of calcinosis. Although the effect of PPIs on calcinosis was attenuated after adjusting for disease duration and antibodies, higher exposure to PPIs remained a significant predictor of calcinosis, with PPI category (>10) increasing risk of CAT (OR 3.34, CI 1.16–9.17, p=0.025).

Conclusions: Our data support a novel association of PPI exposure with calcinosis and confirm association of disease duration and antibody profile. Given the clinical impact of calcinosis, a potentially modifiable risk factor for PPI exposure warrants further study.

AB0781

GLUCOCORTICOID DOSE AND CARDIAC INVOLVEMENT MIGHT BE POTENTIAL RISK FACTORS FOR SCLERODERMA RENAL CRISIS

X.-N. Wei, D.-H. Zheng, J.-J. Liang, L. Dai, Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Background: Scleroderma renal crisis (SRC) is a rare but life-threatening complication of systemic sclerosis (SSc). SRC remains a major risk factor for mortality in SSc. It is important to identify potential risk factors for SRC, and avoid developing overt SRC.

Objectives: To perform a retrospective case series analysis of the characteristics, management and outcomes of SRC in Chinese SSc patients.

Methods: SSc patients hospitalised at Sun Yat-Sen Memorial Hospital from January 1992 to December 2017 were recruited. Clinical data were collected. SRC was defined as new onset, with blood pressure (BP) >140/90 mmHg or >30 mmHg rise in BP from baseline, rising serum creatinine (Scr) levels and/or oliguria. Data were showed as mean ± standard deviation.

Results: 1 There were 749 SSc patients recruited and 16 patients (2.1%) of them were hospitalised for SRC. Among these 16 patients, 56% were women, age was 54.6±13.6 years, mean duration from SSc onset to SRC occurred was 4 years. 2 SRC developed in 14 patients (87.5%) with diffuse cutaneous SSc (dcSSc), and in 2 patients (12.5%) with limited cutaneous SSc (lcSSc). Eleven patients (68.8%) were under glucocorticoid treatment before SRC onset: 4 patients received >30 mg/d prednisone, 6 patients received >7.5 mg/d prednisone and 1 patient received <7.5 mg/d prednisone. No patient was treated with angiotensin-converting enzyme (ACE) inhibitors before SRC.

2 All 16 patients manifested progressive renal failure, with Scr levels increase to 420±256 μmol/L. Ten patients manifested new onset hypertension, with systolic BP 175±21 mmHg and diastolic BP 108±13 mmHg. Five patients who had a history of well-controlled hypertension manifested accelerated increase in BP 178±17/108±7 mmHg. One patient was normotensive, but manifested rapidly progressive oliguric renal failure with Scr increase to 969±114 μmol/L, massive proteinuria and hemolytic anemia.

3 Twelve patients (75%) had pulmonary fibrosis, 11 patients (68.8%) had cardiac involvement, 6 patients had pulmonary arterial hypertension (PAH) and 6 patients had gastrointestinal dysfunction. Cardiac involvement was common, manifested pericarditis, myocardial damage and heart failure (n=7, 43.8%, respectively). All 5 dead patients were accompanied by cardiac involvement.

Eleven patients had Raynaud’s phenomenon, 8 patients had digital ulcers, 5 patients had arthritis and 2 patients had oedema. Thirty patients (81%) manifested anemia, 8 patients (50%) manifested thrombocytopenia, and 8 patients (50%) manifested microangiopathic haemolytic anaemia (MAHA).

Eleven patients (68.8%) received ACE inhibitor treatment. Fifteen patients were treated with glucocorticoid and 12 patients with immunosuppressant (Cyclophosphamide n=10, Azathioprine n=2). After treatment, renal recovery in 4 patients (25%), kidney function improved and developed to chronic kidney disease (CKD) without dialysis in 5 patients (31%), 2 patients required permanent dialysis (13%). Five patients (31%) died.

Conclusions: The ILD is a frequent manifestation and the main cause of death in the patients with anti-Jo1 of our cohort. The presence of anti-Jo1/anti-Ro52 ‘doubled’ seems to lead to a worse prognosis in these patients.

CLINICAL CHARACTERISTICS OF A COHORT OF PATIENTS WITH ANTI-JO1 ANTIBODIES

M.C. Carrasco Cubero1, S.M. Rojas Herrera2, M.L. Vargas Pérez2, M.I. Alcalá Peña3, M. Esparrago Rodriáñez4, E. Chamarro Carmenáñez4, Rheumatology, CHU Infanta Cristina; 2Rheumatology, Hospital de Mérida; 3Immunology, CHU Infanta Cristina; 4Immunology, Hospital de Mérida, Badajoz, Spain

Background: Anti-synthetase syndrome (ASSD) is characterised by myositis associated with anti-synthetase antibodies, fever, arthritis, Raynaud’s phenomenon, “mechanic’s hands” and diffuse intestinal lung disease (ILD); 80% of patients present incomplete forms. The most frequently detected anti-synthetase antibody is anti-Jo1 (anti-histidyl-tRNA synthetase), which usually leads to a greater lung involvement. In some cases of myositis, the simultaneous presence of anti-Jo1 and anti-Ro52 antibodies has been described, and it is debated whether the presence of both antibodies is accompanied by more severe pulmonary involvement.

Objectives: To compare the clinical manifestations of the positive anti-Jo1 patients, with and without associated anti-Ro52 antibodies.

Methods: This is a retrospective observational study of anti-Jo1 positive patients confirmed in the Immunology Laboratory, between 2009 and 2018. Two techniques were used to identify the anti-Jo1 and anti-Ro52 antibodies: Western blot (EUROLINE Myositis Profile 3 (IgG)) and Fluorozenimmunoassay (EliA, Thermofisher).

Results: In this study, 22 patients with anti-Jo1 antibodies were included, 16 (72.7%) women and 6 (27.2%) males. There was no association with FR or ACPA. The mean age was 57.3 years (SD:14.6) and the mean time of follow-up was 4.01 years (SD: 2.1). Of all patients, 5 had ASSD, the rest expressed the clinical picture of incomplete form. The most frequently clinical manifestations associated with anti-Jo1 were: muscular involvement (n=18, 81.8%), ILD (n=13, 59.1%), arthritis (n=9,400.9%), Raynaud’s phenomenon (n=4, 18.2%). No patient developed lesions of mechanic’s hands. The majority of patients with muscular involvement (83.3%), had histological confirmation of inflammatory idiopathic myopathy (Dermato or Polymyositis). The most frequently found X-ray pattern (HRCT) in patients with ILD was Non-specific interstitial pneumonia (NSIP) (n=9, 69.2%), followed by 2 Respiratory bronchiolitis interstitial lung disease (RB-ILD) and 2 Idiopathic interstitial pneumonia (IIP). Nine patients presented ILD and Myositis concomitantly (40.9%), more than half had fibrosing pulmonary involvement. 50% (n=11) also had criteria for other autoimmune diseases (2 rheumatoid arthritis, 4 polymyositis, 4 dermatomyositis, and 1 overlap). Half of the patients with anti-Jo1 presented also anti-Ro52, which 27.3% exclusively developed myopathy, 18.2% ILD and both entities 54.5%. Half of the ILD presented a radiological fibrosing radiological pattern. During follow-up, 7 patients (31.8%) died, 2 of metastatic cancer (one renal and one ovarian) and 5 of complications of the ILD, of which 80% were anti-Jo1/anti-Ro52 ‘doubled’ positives.

4. Minier T, Guiducci S, Bellando-Randone S Preliminary analysis of the very early diagnosis of systemic sclerosis (VEDOSS) EUSTAR multicentre study: evidence for the role of T helper (Th) Th17/T17 lymphocytes. 2.9-fold higher frequency than that observed in general population (3%). Psoriasis with a first-degree relative. For all the psoriatic patients except one, BMI was calculated; 50% had a BMI of >20 (average: 23.7). A metabolic syndrome was present in 3 out of 11 (27.2%), and in ten patients there were data available to calculate the presence of average moderate cardiovascular (CV) risk (11.5%).
MYOCARDIAL FIBROSIS DETECTED BY MAGNETIC RESONANCE IMAGING IN SYSTEMIC SCLEROSIS—PATHOPHYSIOLOGICAL SIGNIFICANCE

M. Funauchi, K. Kishimoto, Y. Nozaki. Hematology and Rheumatology, Kindai University Faculty of Medicine, Osaka, Japan

Background: Systemic sclerosis (SSc) is characterised by chronic fibrosis in various organs such as skin, lung and heart leading to poor prognosis. Myocardial fibrosis is one of factors of pulmonary hypertension (PH) as well as pulmonary arterial hypertension or interstitial lung disease (ILD). Detection of cardiac lesions has progressed much using imaging techniques such as echocardiography (UCG) in combination with measurement of various biomarkers such as BNP. Recently, cardiac magnetic resonance imaging (CMR) has been shown to be sensitive to detect even subclinical cardiac lesions. However, it is unclear what subtype of SSc is prone to myocardial fibrosis, when it manifests in the clinical course, or whether fibrosis occurs simultaneously in various organs.

Objectives: To clarify the pathophysiological significance of myocardial fibrosis in SSc, CMR was performed in the patients with limited ( lc) and diffuse ( dc) cutaneous SSc with or without PH.

Methods: Twelve patients (male 2, female 10) who fulfilled ACR/EULAR criteria (2013) for SSc were enrolled. Eight patients were diagnosed as having lcSSc and 4 dcSSc. In addition to CMR, chest CT scan, UCG and laboratory tests including serum autoantibodies specific for SSc, blood brain natriuretic peptide (BNP) and pulmonary function test (%FVC, %DLCO) were performed in all patients. Right heart catheterization was performed in patients whose systolic right ventricular pressure estimated by UCG was higher than 30 mmHg. Positivity of late gadolinium enhancement (LGE) was compared with clinical findings and these parameters. Difference between the patient groups were tested using Student’s t-test.

Results: LGE was positive in 6 out of 12 patients. Patient composition of dc/lc in LGE (+) and LGE (-) group was 1/5 and 3/3, respectively. Complication of ILD was present in 3 among LGE (+) patients, while esophageal involvement in 3 among LGE (+) patients. The mean age of LGE (+) group tended to be higher than that of LGE (-) group (73.8±5.8 vs 68±6.4), duration of disease (year) tended to be shorter in LGE (+) group than those of LGE (-) group (1.8±3.0 vs 7.7±5.5), and BNP level (170.6±150.0 vs 90.1±69.9 pg/ml) and RVP (33.5±8.1 vs 29.7 ±8.1 mmHg) tended to be higher in LGE (+) than in LGE (-) group, although difference was not statistically significant. There was no tendency of positivity of autoantibodies and pulmonary function test, while patients with low%DLCO (<70) and without fibrosis on CMR tend to be positive in the patients whose E/e’ ratio determined by UCG or pulmonary capillary wedge pressure by RHC was elevated.

Conclusions: Since myocardial fibrosis was found rather in the cases without ILD, there might be difference in the progression of fibrosis depending on the organ, although it accelerates by ageing. If LGE is seen, PH, especially that asso-ciated with left heart disease, might occur in future. This study suggests that CMR might be useful to detect cardiac lesions from early period of clinical course, as well as in the cases with some abnormalities in biomarkers such as BNP or DLCO regardless of existence of ILD, although further study is needed to clarify the indication of CMR using more cases of SSC.

ROLE OF CALCIUM ANTAGONISTS IN THE CANCER OF SYSTEMIC SCLEROSIS, AN ASSOCIATION UNDER DISCUSSION

Background: The use of calcium channel blockers (CCB) is widespread in systemic sclerosis (SSc) for the treatment of Raynaud’s phenomenon, present in 95% of patients. CCB can alter apoptosis, a mechanism for the destruction of cancer cells. In SSc the risk of cancer is increased, but the role that CCB can play is not clear, with contradictory data obtained so far.1,2

Objectives: To analyse the role of CCB in the appearance of cancer in a cohort of patients with systemic sclerosis.

Methods: Encoded patients under the diagnosis of SSc in our hospital from 1985 until December of 2017 were collected. Medical records were reviewed, recording clinico-epidemiological data and treatments used.

Results: 120 patients have been diagnosed of SSc (103 females, 17 males), 22 of whom (18.3%) have developed cáncer. The type of cáncer were (in order of frequency): breast (12 patients, 57%), gastrointestinal (4 patients, 33%), one hypernephroma, one endometrial carcinoma, one lyphma, one skin cáncer and one epidermoid of tongue. Adenocarcinoma was the most frequently histologic pattern found (16 patients, 76%). Interestingly, the diagnosis of SSc was made at an older age in those patients diagnosed of cáncer (66±11.7 vs 54.8±17.3 years old, p=0.019); An age older than 55 years old conferred a relative risk (RR) of cáncer of 1.69 (95% CI 1.18-2.35) in the female cohort. Although the association cancer and CCB did not reach statistical significance, the association CCB and female patients older than 55 years elevate de RR of cáncer to 4.16 (0.96–17.95). All other characteristics (epidemiological, clinical, analytical and another treatments) analyzed did not reach statistical significant differences.

Conclusions: CCB increase in our series the risk of cáncer in women over 55 years old. CCB could be implicated in the patogenia of cáncer in SSc. Due to the broad use of this in the SSc population, it may be require to study in a large number of patients in order to explore this association.

THE EULAR SYSTEMIC SCLEROSIS IMPACT OF DISEASE (SCLEROID) SCORE – A NEW PATIENT-REPORTED OUTCOME MEASURE FOR PATIENTS WITH SYSTEMIC SCLEROSIS

Background: Patient reported outcome measures (PROs) are increasingly important for clinical practice and research. Given the unmet need for a comprehensive PRO for systemic sclerosis (SSc), the ScleroID questionnaire was developed by a joint team of patients with SSc and medical experts in the field. This approach was designed as a brief, specific, patient-derived, disease impact score for research and clinical use in SSc. A preliminary analysis was previously reported. Here, we present the first computation of the ScleroID score and an extended pre-final analysis from the ongoing ScleroID validation study.

Methods: This EULAR-endorsed project involves 11 European expert SSc centres. Patients fulfilling the ACR/EULAR 2013 criteria were prospectively included since 05/16 in the ongoing observational cohort study. Patients completed the ScleroID questionnaire (figure 1), as well as the selected comparators (mSHAQ, EQ5D, SF36). Additionally, they weighted 10 dimensions of ScleroID by distributing 100 points according to the perceived impact on their health. The final score calculation was based on the ranking of the weights. The study included a reliability arm (follow-up questionnaire 7-10 days from baseline), as well as a longitudinal arm, looking at sensitivity to change at follow-up visits (n=10 days from baseline).

Results: As of January 2018, the study cohort included 417 patients with valid baseline data, 80 patients also had a reliability visit and 42 patients a follow-up visit. 84% of patients were female, 62% had limited cutaneous SSc, mean age was 56 years, and median disease duration 10 years. 19% of patients were not able to work. The highest weights by the patients were assigned to Raynaud’s phenomenon, fatigue, hand function and pain, in accordance with our previous results. The total ScleroID score showed good Spearman correlation coefficients with the comparators (mSHAQ: 0.59; EQ5D: -0.62; Patient’s global assessment, VAS: 0.75; SF36 physical score: -0.62; each p<0.001). The internal consistency was good with a high Cronbach’s alpha of 0.96. Conclusions: The EULAR ScleroID score is a promising, novel PRO tool designed for use in clinical practice and clinical trials to display the disease impact of SSc, showing good performance in this pre-final analysis. Importantly, Raynaud’s phenomenon, impaired hand function, pain and fatigue were the main patient reported drivers of disease impact. To date the recruitment has reached more than 80% of the targeted number, the study is ongoing.

OSTEOARTICULAR INVOLVEMENTS IN PATIENTS WITH SYSTEMIC SCLEROSIS

M. Tououri1, T. Ben Salam, I. Ben Ghobbel, M. Lamlaoum, M.H. Hourman. Internal medicine, Rabta Hospital, Tunis, Tunisia

Background: Osteoarticular involvements are common in systemic sclerosis (SSc) and are considered as an important cause of disability.

Objectives: The aim of this study was to assess clinical, radiological and immunological characteristics of patients with systemic sclerosis and who present with osteoarticular involvements at any time of the disease course. Patients with arthralgia and/or arthritis and/or imaging abnormalities were included.

Methods: A retrospective descriptive and comparative study was performed in an internal medicine department. One hundred thirty one patients who fulfilled 2013 ACR/EULAR criteria for SS were studied.

Results: We identified 101 patients with osteoarticular involvements (77.1%); 92 women and 9 men. Mean age at SS diagnosis was 47.6±12.4 years. Disease was revealed by joint manifestations in 10.7% of cases. Arthralgia and arthritis were observed in 61.8% and 21.4% of cases respectively. Flexion deformities with disability were noted in 26 cases. X-Ray investigations revealed distal phalanges resorption (n=24), dystrophic calcifications (n=10) and joint space narrowing (n=9). Tendinitis was observed in one patient. Patients with osteoarticular manifestations developed more frequently digital ulcers (100% vs 78.3%; p<0.001). Osteoarticular involvements was associated to diffuse cutaneous sclerosis (37.7% vs 12.5%; p=0.002) and to telangectasia (91.3% vs 70%; p=0.027), gastrointestinal manifestations (90.1% vs 54.5%; p<0.001) and interstitial lung disease (92.7% vs 67.9%; p=0.001). SS was associated to sJogren syndrome (n=20), to systemic lupus erythematosus (n=15) and to rheumatoid arthritis (n=2). Patients received non-steroidal anti-inflammatory drug (n=26), corticosteroids (n=8) and methotrexate (n=8).

Conclusions: Osteoarticular involvement in systemic sclerosis has heterogeneous aspects. Its frequency ranges from 40% to more than 85% of cases in some studies. Early screening and treatment associated with physiotherapy session are essential to avoid complication and loss of function.

Abstract AB0787 – Figure 1. The EULAR Scleroderma Impact of Disease Score (ScleroID)}
**AB0789**

HOW DOES THE DURATION OF THE DISEASE INFLUENCE THE QUALITY OF LIFE?

N. Locht-Chiprut, S. Vetrii, L. Mazur-Nicorici, V. Salaru, M. Mazur. Internal Medicine, Family Medicine, SUMF'Nicolae Testemitanu, Chisinau, Moldova, Republic of

**Background:** It is noticed that over the last decades the prognostic in patients with Idiopathic Inflammatory Myopathies (IIM) – a group of autoimmune disease characterised by muscle involvement, has improved along with increaseamnt of disease duration and thus affects the quality of life.

**Objectives:** To assess the patient’s quality of life related to the duration of the disease.

**Methods:** We performed a cross-sectional study from December 2015 to December 2017, the patients included fulfilled the Bohan and Peter criteria for IIM.

Consistent with the objective the study group was divided in two subgroups by disease duration 1 less than 24 months and second subgroup more than 2 years. In order to estimate the quality of life (QoL) was applied Short Form-8 with 8 items for 8 domains and two components: mental and physical. Statistical data was analysed using MedCalc software version 12.

**Results:** There were 67 patients enrolled in the study, including 51 females and 16 males with a M:F ratio of 3:2:1, mean age 53.1±12.5 (range 25-78). The disease mean disease duration was 8.3±5.7 (range 0.5-12) years, there were 16 patients in the subgroup with the disease duration less than 2 years. The mean physical component was 36.48±9.05 and the mental component – 41.69±9.62 points, determined as reduced quality of life. Regarding the QoL of patients from subgroup 1, we found the physical component – 38.15±8.83 and the mental component 40.95±22 points. In the second subgroup we appreciated the physical and the mental component – 35.77±9.14 and 42.01±9.86 points, respectively. It was identified moderate correlation (r=0.49 p<0.005) between the both domains of the QoL and disease duration till 2 years, for the duration of more than 2 years we found moderate correlation (r=0.51 p<0.005) between the both domains of the QoL and disease duration.

**Conclusions:** Patients with idiopathic inflammatory myopathies had reduced quality of life by both domains. Disease duration in patients with early idiopathic inflammatory myopathies – less than 2 years, has a greater impact on patient’s quality of life.

FREQUENCY OF OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN WITH SYSTEMIC SCLEROSIS

O. Dobrovol’skaya, N. Demin, A. Smirnov, O. Koneva, N. Toropovska. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** The prevalence of low bone mass or osteoporosis in patients with systemic sclerosis (SSc) varies significantly between studies performed in different countries and vary from 3% to 51% (Omar MA et al. 2013).

**Objectives:** To determine the frequency of osteoporosis (OP) in postmenopausal women with SSC in comparison with healthy control.

**Methods:** 163 postmenopausal women were enrolled in the study: 83 with SSc (mean age 58.5±8.1 years, mean disease duration 9.7±6.8 years) and 80 healthy controls (mean age 59.2±6.6 years, mean disease duration 8.3±5.3 (range 0.5-12) years). There were 16 patients in the subgroup with the disease duration less than 2 years, the mean physical component was 58.5±8.1 and the mental component – 61.6±10.06 points, determined as reduced quality of life. Regarding the QoL of patients from subgroup 1, we found the physical component – 61.6±10.06 and the mental component – 59.2±6.6 points, respectively. It was identified moderate correlation (r=0.51 p<0.005) with mental component and a weak correlation (r=0.49 p<0.005) between the both domains of the QoL and disease duration till 2 years, for the duration of more than 2 years we found moderate correlation (r=0.51 p<0.005) with mental component and a weak correlation (r=0.49 p<0.005) between the both domains of the QoL and disease duration.

**Conclusions:** Patients with idiopathic inflammatory myopathies had reduced quality of life by both domains. Disease duration in patients with early idiopathic inflammatory myopathies – less than 2 years, has a greater impact on patient’s quality of life.

SPECIFIC FEATURES OF SKIN INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS AND ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

N. Yudkina, A. Volkov, T. Martynyuk, E. Nasonov, V.A. Nasonova Scientific Research Institute of Rheumatology, *Cardiology Scientific Medical Research Center, Moscow, Russian Federation*

**Background:** Pulmonary arterial hypertension, associated with systemic sclerosis (SSc-PAH), is a severe irreversible manifestation of the disease, potentially fatal in its late stage. It was shown that survival in SSc-PAH pts is much worse than in pts with idiopathic pulmonary arterial hypertension (IPAH). Unfavourable outcomes due to late recognition can be explained by predominance of subtle, clinically poor manifest SSC types, especially in terms of cutaneous and vascular syndromes.

**Objectives:** To assess the clinical features and survival rates in pts with systemic sclerosis sine scleroderma (ssSSc), associated with PAH.

**Methods:** 14 pts with ssSSc-PAH were analysed in comparison with 54 pts with clinically manifest skin involvement SSc-PAH (3 pts with diffuse (dcSSc-PAH) and 51 pts with limited cutaneous involvement (lcSSc-PAH), and 48 pts with IPAH.

**Results:** Pts with IPAH were younger than both type SSc-PAH – 37 (28; 44), 48 (37; 56) and 54 (48; 62) y, respectively. In SSc-PAH pts skin involvement and the diagnosis of PAH was established earlier (within 10; 44) mo than in pts with ssSSc (23 [15; 47] mo), although differences are not statistically significant. The PAH functional class was slightly higher in ssSSc-PAH than in IPAH and SSc-PAH, the differences are not significant. Raynaud’s phenomenon (RP) was present in all SSc-PAH pts, although in cutaneous SSc pts diastolic ischaemic lesions were more frequent (51% vs 14%, p<0.03), as well as contractures (53% vs 7%, p=0.006). There were no other differences in clinical features between the groups. Anticentromere antibodies (ACA) were present in 7 (50%) pts with ssSSc-PAH and in 36 (65%) pts with cutaneous SSc. Anti-topoisomerase-I antibodies (anti-Scl-70) were found only in 2 pts with lcSSc. More than 1 type of autoantibodies was detected in the majority of SSc pts. A wide range of antinuclear antibodies was found in pts with ssSSc-PAH with prevailing ARA (in 7 pts), as well as anti-Sm, anti-La, anti-nucleosome antibodies (in one case), anti-Ro antibodies (in 5 pts), anti-RNP-70 antibodies – in 4 pts, anti-DsDNA antibodies – in 2 pts, RF – in 3pts. SSc diagnosis was established according to ACR-EULAR 2013 classification criteria. The following diagnostic criteria were present in ssSSc-PAH pts: RP (in all pts), ulcers (3), scars (2), telangiectasia (10), PAH (14), SSc-associated ABs (7), capillaroscopic lesions (12). The mean total score was 11 (9;12) while ≥9 scores are required for SSc diagnosis, 100% pts with ssSSc-PAH met ACR-EULAR 2013 criteria, thus, justifying the SSc confirmation in this group of pts. There were significant differences in survival rates between IPAH pts and pts with various types of SSc-PAH (log-rank test, p=0.06). 5 year survival in ssSSc-PAH was somewhat lower, than in SSc-PAH – 50.6% vs 64.9%, respectively; IPAH pts had the best survival rates of 82.5%, and these differences are close to significant.

**Conclusions:** Clinical features and survival ssSSc-PAH are very similar to those in pts with cutaneous SSc-PAH with the exception of skin involvement and associated symptoms (diastolic ischaemia and contractures). Rheumatologists
should be aware of such specific features as similar survival rates in cutaneous and ssSSc pts, and late recognition of PAH in pts with ssSSc, as well as its similarity with IPAH.

AUTOIMMUNE AND INFLAMMATORY DISTURBANCES IN PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH SYSTEMIC SCLEROSIS

N. Yudkina1, A. Volkov1, T. Martynyk2, E. Nikolaeva1, E. Nasonov2, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; 2Cardiology Scientific Medical Research Center, Moscow, Russian Federation

Background: The prognosis of patients with pulmonary arterial hypertension associated with systemic sclerosis (SSc-PAH) is significantly worse, than other forms of PAH, and mechanisms of this phenomenon are unknown. Therefore, the isolation of autoimmune disorders is of great importance for early diagnosis and differential diagnosis, as well as the search for new therapeutic targets.

Objectives: To identify the autoimmune disorders in patients with SSc-PAH.

Methods: The study includes 52 pts with idiopathic pulmonary arterial hypertension (IPAH), 51 pts with SSc-PAH, 65 pts with SSc without PAH. Serum concentrations of the C-reactive protein (CRP), anticytome antibodies (ACA) and antibodies to topoisomerase-I (anti-Scl-70) were routinely measured. The control group consists of 146 volunteers. Statistical analysis includes univariable logistic regression, ROC analysis and Kaplan-Mayer method.

Results: The average age of patients with IPAH was 37.9±10.5 years, SSc-PAH – 52.3±12.7 years, SSc without PAH – 51.2±13.2. Patients did not differ in functional class (FC), which was the main criterion of comparability. Mean values of FC in groups with SSc-PAH and IPAH also did not differ (2.7±0.8 and 2.6±0.7, respectively). ACA was associated with a 15.2-fold increased odds of developing PAH in SSc (OR 15.2, 95% CI 5.4–43.0), on the contrary, prensence of anti-Scl-70 associated with low risk of PAH (OR 0.5, 95% CI 0.10 to 0.21). The level of CRP in the serum was significantly higher in patients with PAH than in the control group; 4.1 (1.9, 10.0) and 0.61 (0.25, 1.9), p<0.00001, and also in comparison with patients without PAH (1.9 (0.8, 6.4), p=0.02). In pts with PAH, the level of CRP correlated with FC and right atrium pressure and 6 min walk test distance. The level of CRP was significantly higher in patients with FC III-IV compared with FC I-II and in non-surviving patients. The Kaplan-Mayer analysis showed that pts with CRP level more than 4.75 mg/L at the time of diagnosis of PAH had a significantly lower survival rate (median 48 months) than pts with normal values (median 91 months) (p<0.005), with 67% sensitivity and 61% specificity.

Conclusions: SSc-PAH is a unique phenotype combining the manifestations of SSc and PAH, the pathogenetic mechanisms of which modify the course of these states. It is based on a feature of autoimmunity with the predominance of ACA and antibodies to topoisomerase-I (anti-Scl-70) were routinely measured. The control group consists of 146 volunteers. Statistical analysis includes univariable logistic regression, ROC analysis and Kaplan-Mayer method.

DESCRIPTIVE ANALYSIS OF A COHORT OF PATIENTS DIAGNOSED WITH INFLAMMATORY MYOSITIS IN A TERTIARY HOSPITAL

O. Barqueroncillo1, E. Ruiz1, M.L. Garcia1, S. Kapetanovic2, O. Fernandez2, I. Torre1, A.R. Inchurbe1, C. Perez1, J.M. Blanco1, I. Calvo1, E. Guerrero1, D. Montero1, E. Galindez1, 1Rheumatology, Basurto University Hospital, Bilbao, Spain

Background: Inflammatory myopathies are a group of rare systemic diseases characterised by muscle weakness and inflammation. Clinical manifestations, course and prognosis of these pathologies are very heterogeneous.

Objectives: The aim is to describe the main characteristics of patients diagnosed with inflammatory myositis fulfilling Bohan and Peter criteria.

Methods: Descriptive analysis of a cohort of 34 patients from the same hospital with follow-up between January 2010 and December 2017. We recorded demographic characteristics, clinical manifestations, treatment, comorbidity and mortality.

Results: 34 patients (73% female) were recruited with an average age at diagnosis of 56.3 years among adults and 10 years among children. Most of them were Caucasian (94%), 18% were smokers and 15% previous smokers. The most frequent type was dermatomyositis (DM) (40%) followed by antisynthetase syndrome (ASS) (15%), necrotizing myopathy (12%), inclusion body myopathy (12%), overlap myasthenia (9%) and polymyositis (9%). 2 patients (out of 4) with necrotizing myopathy were treated with statins.

Conclusions: Inflammatory myopathies have frequent multiorgan involvement and represent a heterogeneous group of systemic diseases as shown in our registry and in the literature. Most patients need chronically combined immunosuppressive treatment and few achieve sustained remission. In consequence the collaboration of several specialties is necessary for the diagnosis and management of these pathologies.

MYOSITIS DAMAGE INDEX IN A MYOSITIS POPULATION COHORT

O. Enriquez, A. Lilia, I. Fedra, on behalf of Hospital Centro Medico Nacional 20 de Noviembre. Reumatologo, Hospital Centro Medico Nacional 20 de Noviembre, Ciudad de Mexico, Mexico

Background: Idiopathic inflammatory myopathies (IM) are a heterogeneous and uncommon group of diseases characterised by muscular involvement and many systemic manifestations. They usually have a chronic course, and despite treatment they often develop functional impairment. MDI-MYODAM a score to assess damage has been recently developed. Few publications in this regard have reported a prevalence of 92%. There are no studies in Mexican-mestizo population describing the extent of damage and its main determinants.

Objectives: To investigate the prevalence of damage measured with the MDI-MYODAM tool in patients with IM and its relationship with characteristics of the disease and treatment.

Methods: A cross-sectional study was conducted in an IM cohort from a national reference hospital. MDI questionnaire was applied to all patients. Demographic, disease characteristics, IM subgroup (dermatomyositis, polymyositis and overlap), comorbidities (Charlson index), medical treatment were collected. Descriptive statistics were applied. Bivariate Pearson correlation test was conducted to...
analyse associations between MDI score and clinical characteristics. P value<0.05 was considered as a statistically significant.

Results: Fifty subjects participated, 75% were women, mean age at diagnosis was 40.7 years (SD±) and mean duration of the disease was 11.8±3.3 years. Thirty-one percent of patients had polymyositis, 31% dermatomyositis, 12% juvenile dermatomyositis, 10% overlap myositis (mainly systemic lupus erythematosus, scleroderma and rheumatoid arthritis). The mean Charlon index was 2.7±2.4. Eighty-one percent had a score greater than 0 for at least one category; majority within the endocrinological systems (55%), skeletal (51%), gastrointestinal (35%). The mean total damage score (MDI) was 3.6±2.9. The mean score for the total damage according to the MYODAM score was 6.9±5.1. A moderate correlation between the MDI score and the use of glucocorticoids (r 0.3, CI 95% 0.1–0.6, p<0.01). No associations between damage and activity of the disease or IIM subgroup were observed.

Conclusions: Most patients with IIM develop some kind of damage, with greater impact on the endocrinological, skeletal and gastrointestinal systems. There increases with the time of evolution and the use of steroids in a non-linear way. Therefore, these results should be taken into account in the decision-making process in long-term treatment.

AB0795 LONG-TERM EFFICACY AND SAFETY OF RITUXIMAB IN SYSTEMIC SCLEROSIS REFRACTORY TO CONVENTIONAL IMMUNOSUPPRESSANTS

P. Pollo, E. Zanatta, M. Favarò, M. Felicetti, F. Oliviero, E. Pigatto, F. Cozzi, A. Doria. Rheumatology Unit, Department of Medicine – DIMED, Padova University, Padova, Italy

Background: Recent studies1 2 have shown that B-cells are involved in the pathogenesis of systemic sclerosis (SSc) suggesting that B-cell depletion might have a role in the treatment of the disease2. 

Objectives: To describe the long-term efficacy and safety profile of Rituximab (RTX) in SSc patients who failed previous conventional immunosuppressive drugs.

Methods: We retrospectively analysed medical records of all SSc patients treated with Rituximab in our Rheumatology Unit from July 2011 to December 2017. Disease manifestations, particularly skin, pulmonary and articular involvement, were evaluated at baseline (T0), at 8±2 months (T1) and at the last follow-up visit (T2).

Results: Thirty patients, 11 females and 2 males, were treated with 32 RTX cycles (median per patient 2,5, range 1–4). Eleven patients had diffuse and 2 limited cutaneous form; all had positive ANA, 9 anti-Topol, 2 anti-RNA polII, and 1 anti-SSA. The mean age at first RTX infusion was 49.3±13.6 years and the mean disease duration was 6.5±3.3 years. The main indications to RTX were: interstitial lung disease (11/13), worsening of skin involvement (6/13) and arthritis (6/13). Refractory to at least one previous immunosuppressive drug (median 2, range 1–3). Twelve patients were treated with mycophenolate mofetil, 5 with cyclophosphamide, 4 with methotrexate and 2 with azathioprine.

All patients were treated with RTX (1000 mg twice, two weeks apart). Twelve patients received more than one cycle; the interval between cycles was 12.7±5.4 months. The mean follow-up period was 41.4±21.9 months. Five patients had arthritis and we observed complete remission of arthritis in all of them. 8 months after the first RTX administration arthritis relapsed in 4 patients who were successfully retreated. We did not observe a significant decrease in modified Rodnan Skin Score over time (T0: 15.6±6.9, T1: 14.8±7.8, and T2: 13.1±8.3; p=n.s.). Lung involvement, detected in 11/13 patients, remained radiologically stable in 8 patients and worsened in 3. No significant changes in the pulmonary function tests was observed from T0 to T2. Five patients had a follow-up longer than 33 months after the last RTX cycle: 3 patients had a stable disease, 1 developed severe PAH and 1 lung neoplasia.

CD19 cell depletion (<2%) was observed after each RTX cycle, without significant changes in immunoglobulin levels. No infusion reactions were observed. We registered only one severe side effect: hand cellulitis in a patient with digital ulcer, requiring hospitalisation.

Conclusions: Our experience suggests that RTX is well tolerated and could be effective in the management of severe and refractory SSc manifestations.

AB0796 SHORT TERM TREATMENT RESPONSE TO INTRAVENOUS PULSE CYCLOPHOSPHAMIDE TREATMENT IN CONNECTIVE TISSUE RELATED INTERSTITIAL LUNG DISEASE

P. T. Antony. clinical Immunology and rheumatology, AMALA institute of medical sciences, thrissur, India

Background: Interstitial lung disease (ILD) is a major cause for morbidity and mortality in patients suffering from connective tissue diseases. Early detection and prompt recognition of symptoms with appropriate treatment is necessary for effective control of the disease and for better prognosis and long-term survival. Various treatments have been approved based on observational studies. We have very few studies as regards ILD treatment from the Indian subcontinent. In a resource constrained country like India, we mainly rely on cheap drugs like cyclophosphamide. We have done a study to assess the short-term treatment response of connective tissue related interstitial lung disease to cyclophosphamide in a tertiary centre in India.

Objectives: 1. To assess short treatment outcome for Connective tissue disease related interstitial lung disease treated with intravenous pulses of cyclophosphamide (CYP) based on improvement in: Lung function 1) Forced vital capacity (FVC)%; predicted, forced expiratory volume in first second (FEV1)% predicted 2) Dyspnoea Borg scale 3) Cough visual analogue score
2. To determine the factors affecting treatment outcome like age, sex, duration of the connective tissue disease, type of connective tissue disease, HRCT type and presence of PAH.

Methods: A cohort study was conducted in the Department of General Medicine, Rheumatology and Pulmonology in Amala Institute of Medical Sciences, Thrissur, Kerala from November 2015 to June 2017, that evaluated 74 patients who were having connective tissue disease related ILD. Detailed history and a thorough clinical examination was done. Treatment with 6 intravenous pulses of cyclophosphamide was done and response was assessed after 6 months. Response to treatment and associations were analysed using SPSS software (version 15). Method used for statistical analysis was Chi-Square test and paired t test.

Results:
There was no association between treatment response and age, sex or type of connective tissue disease. Following treatment there was a definite improvement in the clinical aspects of the patient which was assessed by dyspnoea Borg score and cough visual analogue score. Following treatment there was a definite improvement in PFT (FVC, FEV1) as well as 6 min walk test which was also statistically significant. CT pattern of Non specific interstitial pneumonitis also had a better outcome.

Conclusions: Our study proves that there is definite clinical and FVC improvement in CTD-ILD patients after giving treatment with cyclophosphamide. Determinants that can predict treatment outcome are duration of disease, HRCT type, presence of Pulmonary artery hypertension(PAH). Poor treatment response should be anticipated in those with longer duration of disease and UIP type in HRCT, presence of PAH.

CLINICAL ASSOCIATIONS OF VASCULAR ENDOTHELIAL GROWTH FACTOR AND ITS RECEPTOR 2 TYPE IN SYSTEMIC SCLEROSIS

R. Alekperov1,2, E. Alexandrova3, A. Novikov4, L. Ananyeva5. 1Moscow Regional Research and Clinical Institute (MONIKI); 2NASCNOVA RESEARCH INSTITUTE OF RHEUMATOLOGY; MOSCOW, RUSSIA; Moscow, Russian Federation

Background: Systemic sclerosis (SSc) is characterised by impaired angiogenesis and peripheral microvasculopathy. A major role in the regulation of angiogenesis attributed to vascular endothelial growth factor, which performs its functions through interaction with its receptor 2 type (VEGFR2).

Objectives: The aim of our study was to assess the levels of VEGF in serum and its associations with clinical manifestations in patients with SSc.

Methods: We studied 46 patients with SSc who underwent clinical examination, pulmonary function tests and echocardiography. Serum VEGF-A and VEGFR2 levels were determined by ELISA in 46 SSc patients and 20 healthy controls.

Results: Mean VEGF levels were increased in SSc patients compared to controls (212.35±253.93 and 97.74±71.46 pg/ml, respectively; p=0.032). Patients with limited cutaneous SSc (n=23) had higher levels of serum VEGF than those with diffuse cutaneous SSc (n=23) (267.11±268.74 vs 120.40±141.09 pg/ml; p=0.012). Patients with fingertip ulcers (n=19) were found to have higher levels of VEGF than pts without fingertip ulcers (n=27) (214.25±265.93 vs 162.88±198.97 pg/ml) but this difference wasn’t significant. Serum VEGF levels were higher in SSc patients with sPAP >30 mmHg than in those with sPAP ≤30 mmHg (286.51±287.42 vs 92.88±108.06 pg/ml; p=0.0042) and correlated with sPAP values (R=0.40; p=0.007). Mean VEGF levels in patients with DLOC ≤50% (n=14) were significantly higher than those with DLOC >50% (n=30): 364.20±381.95 vs 126.55±142.70 pg/ml, respectively (p=0.034). There weren’t significant differences in VEGF levels between patients with FVC <80% (n=11) and those with FVC >80% (219.15±252.57 vs 154.26±208.91 pg/ml, respectively).

Mean VEGFR2 levels were also increased in SSc pts compared to controls (758.84±477.38 and 1552.6±272.8 pg/ml, respectively; p<0.0001). There weren’t any differences between pts with diffuse or limited SSc. In pts with digital ulcers, or normal levels of sPAP, or DLOC >50% mean VEGFR2 levels didn’t differ from those without digital ulcers, or sPAP >30 mm Hg, or DLOC <50%, respectively.

Serum VEGF levels directly correlated with sPAP (R=0.40; p=0.007).

Conclusions: Our findings show significantly higher circulating levels of VEGF and VEGFR2 in SSc patients. Associations of VEGF with some clinical signs indicate its role in pathology of SSc.

ALTERATIONS OF BODY COMPOSITION IN SCLERODERMA PATIENTS ARE ASSOCIATED WITH DISEASE ACTIVITY AND PHYSICAL ACTIVITY BUT NOT WITH LUNG INVOLVEMENT

S. Oreska1, M. Spiritovic1,2, P. Cesak1, M. Cesak1, H. Storkanova1, H. Smucrova1, B. Hermankova1, O. Ruzikova1, H. Mann1, K. Pavelka1, L. Senolt1, J. Vencovsky1, R. Bevac1, M. Tomcik1. 1Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology; 2Department of Physiotherapy, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

Background: Systemic sclerosis (SSc) is characterised by fibrosis of the skin and visceral organs, especially digestive tract, and musculoskeletal and lung involvement, which limit mobility/self-sufficiency of patients and can have a negative impact on body composition and physical activity.

Objectives: To assess body composition and physical activity of SSc patients and healthy controls (HC).

Methods: 59 patients with SSc [50 females; mean age 52.5; disease duration 6.7 years; limited cutaneous (sSc); 34/diffuse cutaneous (dcSSc); 25] and 59 age-/ sex-matched HC (50 females, mean age 52.5) without rheumatic diseases were
Changes of Body Composition in Myositis

S. Tomcik

Purpose:

To assess body composition and physical activity of IIM patients and controls. The study had some limitations due to absence of control group or according cutaneous diffuse (dcSSc) or limited (lcSSc) systemic sclerosis.

Conclusions:

This pilot study suggests that sarcopenia seems present in almost 25% of the SSc patients, particularly in a condition of advanced microcirculation damage, as characterised by the NVC late pattern. However, no statistically relevant correlations were observed between RSMI, BMI, age, disease duration, CRP, and mRSS. SSc patients fulfilled ACR/EULAR 2013 criteria. These results suggest that sarcopenia is present in SSc patients and seems to be associated with decreased quality of life and physical performance. Further studies need to be conducted to confirm these results and to determine the impact of sarcopenia on the clinical course of SSc.

BONES AND BONE MINERAL DENSITY IN SYSTEMIC SCLEROSIS PATIENTS: A PILOT STUDY

Department of Internal Medicine, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, Genoa, Italy

Background:

Systemic sclerosis (SSc) patients may present muscle involvement in the form of myositis or non-inflammatory myopathy with different degree of weakness and muscle atrophy. Sarcopenia is described as a multifactorial syndrome with muscle mass and function correlated to functional impairment; according to the anthropometric equation by Baumgartner et al. sarcopenia was defined as relative skeletal muscle mass index (RSMI) <5.5 Kg/m² for women and 7.2 Kg/m² for men. The impact of sarcopenia on the clinical course of SSc is not well documented.

Aim:

To assess the association between sarcopenia and muscle involvement, and physical activity, and could reflect their impaired nutritional status and worse muscle predispositions for physical exercise, aerobic fitness/performance. Increased EBCM in SSc patients positively correlated with disease activity (ESSG: r=0.273, p=0.043) and skin score (mRSS:r=0.371, p=0.0045) and inflammation (CRP:r=0.292, p=0.0278; ESR:r=0.302, p=0.0226). Increased EBCM was also associated with worse quality of life (HAQ:r=0.438, p=0.0007; SHAQ: r=0.268, p=0.0436; fatigue (FSS:r=0.366, p=0.0400), and worse ability to perform physical activity (HAP:r=0.644, p<0.0001). Disease activity (ESSG) negatively correlated with BF% by DEXA (r=-0.324, p=0.0138). Physical activity (HAP) positively correlated with BMD (r=0.280, p=0.032). There was no significant correlation of lung involvement with alterations of body composition.

Conclusions:

Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our SSc patients, which are associated with their disease activity and physical activity, and could reflect their nutritional status, and gastrointestinal and musculoskeletal involvement. We found no significant association between lung involvement and changes of body composition.

A REAL LIFE EXPERIENCE ON THE EFFICACY AND SAFETY OF MYCOPHENOLATE MOFETIL IN CONNECTIVE TISSUE DISORDER ASSOCIATED INTERSTITIAL LUNG DISEASE – A RETROSPECTIVE STUDY

S. Santhanam1, V. Rahulan2. 1Rheumatology; 2Pulmonology, Glenaeages global hospital, chennai, India

Background: Interstitial lung disease (ILD) is one of the common extra articular manifestations of various connective tissue disorders (CTD). We don’t have enough evidence on the drugs used, except for ILD in systemic sclerosis and the results of the same has been extrapolated to other diseases. Mycophenolate mofetil (MMF) has antiproliferative and anti fibrotic action in addition to anti inflammatory property and hence we wanted to study the efficacy and safety of MMF in CTD-ILD.

Objectives: To study the efficacy and safety of mycophenolate mofetil (MMF) in a diverse cohort of patients with connective tissue disease (CTD) associated interstitial lung disease (ILD).

Methods: This is a retrospective observational study with records of outpatients with CTD associated ILD were screened from Oct 2014 to Dec 2017. Among them, patients with imaging (HRCT chest) documented ILD were included. All patients underwent detailed clinical assessment, serological investigations (baseline blood test, erythrocyte sedimentation rate, C – reactive protein, rheumatoid factor, ACPA Ab, antinuclear antibody, ANA profile, complements), urine routine, pulmonar y function test(PFT), HRCT chest and echocardiogram. The response of ILD to treatment (follow up of 2 years) was assessed clinically, radiologically and by PFT.

Results: 54 patients were identified with CTD-ILD of which 33 patients were on MMF. 13 patients were diagnosed with MCTD, 12 with RA, 3 with diffuse cutaneous systemic sclerosis, 2 with SSC/mysitis overlap, 1 with primary sjogren’s syndrome, 1 with SLE/Sjogren’s overlap and 1 with lung dominant CTD(Scl 70+ve). The cohort was divided in to 3 groups – MCTD, RA and others (SSc predominant), Among patients with MCTD, 10 had NSIP pattern of ILD, 3 UIP. In RA, 7 had NSIP and 5 UIP and among others 7 NSIP and 1 UIP. The mean FEV1 and FVC values over 2 years and the treatment response has been discussed in table 1 and Figure 1. FEV1 and FVC had high positive correlations (Pearson correlation, p<0.05) with treatment for all groups of diseases. The values go together in the positive direction with treatment. Among the groups, all patients who improved had NSIP pattern and all who worsened had UIP. Though there were numerical differences in the mean values of FEV1 and FVC between two groups (NSIP and UIP), it was not statistically significant (paired t test, p>0.05). There was no significant difference in FEV1 and FVC values with treatment between the three groups (one way ANOVA test).

Conclusions: Osteoporosis was associated with SSc-related factors such as: articular, digestive and respiratory involvements, and associated auto-immune diseases. Usual OP risk factors where not significantly different between osteoporotic SSc patients and non-osteoporotic patients.

THE RELATIONSHIP BETWEEN AUTOANTIBODIES AND CLINICAL SYMPTOMS IN PATIENTS WITH INFLAMMATORY MYOPATHY

S. Nakashima1, H. Nakashima2, T. Kameda1, M. Izumikawa1, H. Shimada1, R. Wakiya1, K. Atsushi1, M. Kato1, N. Kadowaki1, H. Dobashi1. Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine; 2Clinical Laboratory, KAGAWA UNIVERSITY, Kagawa, Japan

Background: Myositis-specific autoantibody (MSA) and myositis-associated autoantibody (MAA) are often detected in dermatomyositis (DM) and polymyositis (PM), and are useful diagnostic markers. In addition, autoantibodies are reportedly related to clinical symptoms, including skin findings, muscle symptoms, and interstitial lung disease, and provide information useful for medical treatment. However, the clinical significance of the presence of multiple MSA/MAA and anti-Ro52 autoantibodies has not been determined. The purpose of our study was to clarify the clinical significance of multiple MSA/MAA and anti-Ro52 autoantibodies.

Methods: We enrolled 58 patients diagnosed with DM and PM at Kagawa University Hospital. PM and DM were diagnosed according to the Bohan and Peter criteria. The patients were analysed for MSA (anti-nR-2, anti-Jo-1, anti-SRP, anti-PL-7, anti-MDA5, anti-TIF1γ, anti-PL-12, anti-EJ, and anti-OJ) and MAA (anti-RNP, anti-Ku, and anti-PM-Scl) by ELISA (MESA/CUP anti-ARS, MDA5 and TIF1 test, MBL, Nagoya, Japan) and Line blot (EUROLEUR Myositis Profile 3, EUROMIM, Lübeck, Germany). We extracted MSA/MAA(+) and anti-Ro52(+) patients and analysed the association between the presence of multiple MSA/MAA or anti-Ro52 autoantibodies and patients' clinical features (skin findings such as Gottron papule, heliotrope rash and mechanic's hand, interstitial lung disease, malignancy, and arthritis).

Results: 53/58 patients were positive for MSA/MAA, followed by anti-Ro52(n=27), anti-PL-12(n=7), anti-Jo-1(n=8), anti-PM-Scl75(n=7), anti-Ku(n=6), anti-SRP(n=4), anti-EJ(n=4), anti-TIF1γ(n=4), anti-MDA5(n=4), anti-Mi2(n=3), anti-PL12(n=1), anti-PM-Scl100(n=1), and five cases were MSA/MAA(-). Five patients had multiple MSA/MAA (+) and anti-Ro52(+) and analysed the association between the presence of multiple MSA/MAA or anti-Ro52 autoantibodies and patients' clinical features (skin findings such as Gottron papule, heliotrope rash and mechanic's hand, interstitial lung disease, malignancy, and arthritis).

Conclusions: We hypothesise that the presence of multiple MSA/MAA may be useful for predicting ILD. However, in this study, anti-Ro52 autoantibodies did not correlate with ILD and myositis.

THE IMPACT OF DYSPHAGIA IN IDIOPATHIC INFLAMMATORY MYOTISIS: AN ONLINE SURVEY OF HIGHLY-SPECIALISED CENTRES

S. Bertoli1, 2, G. Cavazzana1, R. Neid1, L. Cavagna2, F. Iannoni1, C. Montecucco1, A. Tincani1, F. Franceschini1, M. Mosca1, 3Department of Medical Biotechnologies, University of Siena, Siena, 2Rheumatology Unit, University of Pisa, Pisa, 3Rheumatology Unit and Chair, ASST Spedali Civili and University of Brescia, Brescia; 4Rheumatology University and IRCCS, Policlinico S. Matteo Foundation, Pavia; 5Rheumatology Unit – DETO, University of Bari, Bari, Italy

Background: Dysphagia represents a frequent and disabling symptom in patients with idiopathic inflammatory myopathies (IIM). Despite this, there are not widely accepted diagnostic and therapeutic guidelines for dysphagia in IIM.

Objectives: This study is aimed at surveying the approach to dysphagia in IIM patients at European and worldwide highly-specialised centres.

Methods: An anonymous on-line survey was designed and criticized by clinicians from European Union (EU) countries, and countries from North and Central America and South Korea were invited via email to participate. The questionnaire included 11 items about the characteristics of the hospital of the responder, the evaluation of the impact of dysphagia on disease severity assessed on a visual analogue scale (10 VAS), the techniques used for the assessment of dysphagia, the use of validated patients reported outcome (PRO) and the therapeutic approach of dysphagia.

Results: Between December 2017 and January 2018, 52 clinicians from different centres working in 21 different countries (18 EU countries, 3 non-EU countries) completed the survey. The total numbers of patients followed in the participating centres were 5817 with an average number of patients followed in each centre of 75 (±83). The majority of centres followed only adult patients, only paediatric patients (<18 years) and 5 both. The impact of dysphagia on disease severity was considered severe by all the participants with a mean VAS score of 7.3. All but one centre routinely ask the patients for the presence of dysphagia during the clinical examination. The assessment of dysphagia is performed using validated PRO questionnaires in only 7 centres (SWAL-QOL 2 centres, EAT-10 2 centres, MDAI 2 centres). 12 centres evaluate dysphagia using a graduate dysphagia scale by means a 10 cm VAS, and 2 routinely screen patients by a functional test (time necessary to drink a glass of water).

In all the centres an instrumental evaluation of esophageal motility is performed: esophageal manometry in 24 centres, videofluoroscopic swallowing exam in 17, esophageal barium x-rays in 16, and pharynx and functional endoscopy in 14 each. Esophageal scintigraphy and esophageograms were respectively performed in 5 and 3 centres. The presence of dysphagia greatly influences the therapeutic approach to IIM in 49 centres leading to an increase of the corticosteroids dosage (11 centres), a change of the immunosuppressive treatment or the initiation of intravenous immunoglobulins (IVlg).

Conclusions: This study suggests that the approach to dysphagia is variable, but dysphagia has an impact on IIM patients and influences the therapeutic
PLATELET INDICES AS MARKERS OF INFLAMMATION IN SYSTEMIC SCLEROSIS

S. Eldessouki Ibrahim1, C. Morad2. 1 Ain shams University, Cairo, Egypt. 2 Internal medicine, Ain shams University, Cairo, Egypt

Background: Systemic sclerosis (SSc) is a connective tissue disease involving multiple organs with an unknown etiology. Platelet function may be associated with endothelial dysfunction and immune regulatory mechanisms. Recently, an increased tendency to platelet aggregation and enhanced platelet activation have been described in SSc patients, suggesting a role for platelets in the disease itself.

Objectives: To evaluate platelet indices in systemic sclerosis (SSc) patients and identify their clinical significance as novel inflammatory biomarkers in correlation to markers of endothelial dysfunction: vascular endothelial growth factor (VEGF) and flow mediated dilatation (FMD).

Methods: Thirty-five SSc patients were enrolled in addition to thirty-five age and sex matched healthy volunteers as controls. All patients and controls underwent full medical history taking, thorough clinical examination, assessment of severity extent of skin sclerosis using the modified Rodnan skin score, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), complete blood count with special consideration to mean platelet volume (MPV), platelet distribution width and plateletcrit count, assay for serum VEGF concentration, and branial FMD assessment by colour duplex sonography.

Results: There was a highly significant decrease in the mean MPV in SSc patients compared to the controls (8.65±0.6 fl vs. 9.55±0.52 fl). There was a significant increase in the mean platelet count in SSc patients compared to controls (331.63±64.66 × 10^3/μl vs. 297.60±44.48 × 10^3/μl). In SSc patients, a significant negative correlation was found between the mean MPV and each of ESR, CRP and VEGF (r=−0.42–0.368 and −0.55 respectively, p<0.05); and a significant positive correlation was found between the mean MPV and mean FMD (r=0.378, p<0.05). Linear regression test, showed an association between mean MPV and each of ESR and CRP (r=−3.312–2.92 respectively, p<0.05).

Conclusions: MPV levels could be an easily measurable parameter to reflect the inflammatory condition and disease activity in systemic sclerosis patients.

MULTICENTRIC STUDY OF SYSTEMIC SCLERODERMA IN TUNISIA

S. Hammami1, S. Boumoun2, O. Berrihe3, A. Barhoumi4, on behalf of The group for Scleroderma, STMI.

1 Department of Internal Medicine, CHU F Bourguiba Monastir, Monastir; 2 Internal medicine, medical hospital Gabes, Gabes; 3 Department of Internal Medicine, CHU T Star Mahdia, Mahdia; 4 CHU F Bourguiba, University of Internal Medicine, Monastir, Tunisia

Background: Scleroderma is an autoimmune connective tissue disorder which is characterised by fibrosis of visceral organs, skin and blood vessels. This condition can be localised or systemic. Its estimated prevalence is 250 cases in a million and it is more common in women than in men.

Objectives: The aim of this retrospective multicenter study was to analyse demographic, clinical, laboratory features, and outcome of SSc in Tunisia throughout 8 Departments of Internal Medicine and to compare them with those of other geographic groups.

Methods: One hundred and eight cases of SSc were recorded (American College of Rheumatology criteria) during a 15 years period. They were 93 women and 15 men with an average age at SSc onset of approximately 46.9 years.17-25

Results: Only 18 patients had limited cutaneous SSc, 11 patients had a CREST syndrome. Our Tunisian patients were characterised by a high frequency of cutaneous signs: sclerodactyly (80.6%), proximal sclerosis (81%), telangiectasia (34.3%), Raynaud’s syndrome (91%), pigmentation disorders (36%), ulceration (24%) and subcutaneous calcification (4.8%). The other clinical manifestations were dysphagia in 54% (n=59), pulmonary involvement in 55.6% (n=60), cardiac manifestation in 27% (n=29), arthritis in 19.4% (n=21), renal involvement in 13.8% (n=15), and neurological involvement in 12 cas. 78.7% were antinuclear antibody (ANA) positive, 25% were Antithrombomerase-I antibodies (anti-Scl-70 antibodies) positive and 10% with anti-centromere antibodies. SSc was associated to Sjögren’s syndrome n=27, systemic lupus erythematosus (n=8), Polymyositis (n=5) and Rheumatoid arthritis (n=1)

Treatment regimen included, calcium channel blockers (85.7%), steroids (47%), Colchicine (47.2%), D penicillamine (21%), immuno suppressive therapy was added in patient with partial control (n=13). Median follow-up period was 3.7 years. With the above treatment protocol, (29.6%) patients achieved disease control on treatment, (43.3%) had partial control while (26.8%) showed no response or progressive disease. Six patients died, three of them with scleroderma renal crisis.

Conclusions: The findings of this study documents The high frequency of extensive cutaneous sclerosis, Potential limitations and biases in our study need discussion. Specific recruitment of patients in tertiary referral centres may be the source of selection bias. Patients were evaluated by different doctors. The therapeutic management and outcome monitoring were heterogeneous. This study remains the most representative of Tunisian Scleroderma patients recruited from all parts of Tunisia.

A NEW SCORE TO PREDICT DIGITAL ULCERS COMBINING CLINICAL DATA, IMAGING AND PATIENT HISTORY IN SYSTEMIC SCLEROSIS

S. Friedrich1,2, S. Lüders1,3, G.-R. Burmester1, G. Reumkens1, S. Ohndorf1.

1 Department of Rheumatology and Clinical Immunology; 2 Department of Radiology; 3 Department of Gastroenterology and Rheumatology, Charité Universitätmedizin Berlin, Berlin; 4 Department of Rheumatology and Clinical Immunology, University of Schleswig-Holstein, Lübeck, Germany

Background: Ischaemic complications such as digital ulcers (DU) are a common complication in systemic sclerosis (SSc) patients.

Objectives: The aim of this study was to combine clinical characteristics and imaging methods to a composite predictive score.

Methods: Seventy-nine SSc patients received a clinical examination and their patient history was taken. Furthermore, we performed nailfold capillaroscopy (NC), colour Doppler ultrasonography (CDUS) and fluorescence optical imaging (FOI) of the hands at baseline. Newly developed digital ulcers over a period of approximately 12 months were registered. We used criteria with significant OR values above 3.5 in regard to the development of these new DU to create the score (CIP-DUS).

Results: Twenty-nine percent of the patients developed new DU during follow-up (48.1% diffuse SSc, 18.4% limited SSc). The following criteria were used: SSc diffuse subtype (OR 4.127, p=0.0087), modified Rodnan skin score >8 (OR 9.429 [95% CI: 3.0–29.2], p<0.001), pulmonary arterial hypertension (OR 6.854 [95% CI: 1.6–32.9], p=0.0088), present digital ulcers or pitting scars at baseline (OR 15.71 [95% CI: 3.3–74.3], p<0.001), history of digital ulcer or pitting scars (OR 36.15 [95% CI: 2.1–626.9], p<0.0001), NC pattern (OR 18.6 [95% CI: 1.1–326.4], p=0.0035), reduced capillary density (n<7/mm) in digit III of the right hand in NC (OR 9.0 [95% CI: 1.1–73.6], p=0.0266), missing initial enhancement in FOI in digit III of the right hand (OR 3.857 [95% CI: 1.2–12.8], p=0.0323), percentage of pathologic (i. e. narrowed or occluded) vessels>35% in CDUS (OR 4.286 [95% CI: 1.5–12.4], p=0.0099). Criteria with greater OR should impact the score to a higher degree so we appointed three points to dichotomous criteria with OR >10, two points for criteria with OR between 5–10, and one point for criteria with OR <5. Regarding the NC pattern, 3 points were given to patients with late pattern, 2 points for active and 1 point for early pattern.

Best results were found for a cut-off of >10 points with obtained sensitivity levels of 95% and specificity levels of 74% in regard to new DU (AUC=0.8867, p<0.0001). In the absence of CDUS and FOI data, specificity levels dropped slightly to 72% with unchanged sensitivity values of 95%.

AB0808

AB0809
Conclusions: A new score was introduced with the aim to predict digital ulcers. If applied correctly and with the new imaging techniques proposed, 95% of patients at risk of digital ulcers throughout 12 months could be identified.

A COMPARISON OF CLINICAL PRESENTATION AND INCIDENCE RATE OF CARDIOPULMONARY INVOLVEMENT BETWEEN MALE AND FEMALE PATIENTS WITH EARLY SYSTEMIC SCLEROSIS

S. Wangkawelt, S. Tungeerabundlikul, V. Sawangduan, N. Prasertwattikan, J. Euathrongchit

Background: During the follow-up period, the IR of right ventricular dysfunction was significantly higher in patients with SSc than in HC (0.853±0.701 cutoff index [COI], 0.325±0.111 COI, respectively; p=0.00001). Receiver operating characteristic (ROC) curve analysis indicated that serum M2BP correctly differentiated between SSc patients and HC with a sensitivity of 81.1% and specificity of 87.5%. In patients with SSc, a significant correlation was not found between serum M2BP levels and age, sex, mRSS, ILD, pulmonary artery hypertension (PAH), SSc-types, dermatomyositis findings. In multivarient analysis, disease duration was a only independent factor for higher serum M2BP levels more than 0.64 COI, serum M2BP median (odds ratio 0.935, 95% CI 0.879–0.996, p=0.0385). We detected the protein level of M2BP in SSc patient’s fibroblast of skin and SSc Patient’s proliferating type II alveolar cells adjacent to fibrotic lesions of lung tissue.

Conclusions: In this study, for the first we demonstrated that M2BP is expressed in skin and lung tissue in SSc patients in IHC and more over the serum M2BP level tends to be higher in patients with short disease duration. It is reveal that M2BP play an important role of fibrosis in early stage of SSc. The serum level of M2BP may be a novel biomarker of SSc.

ULTRASONOGRAPHY FOR THE ASSESSMENT OF SKIN IN SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW

T. Santiago, M. Santiago, B. Ruaro, M. J. Salvador, M. Cutojo, J. A. Pereira da Silva, R. de Freitas; Faculdade de Medicine, University of Coimbra, Portugal

Background: Skin involvement is the clinical hallmark of systemic sclerosis (SSc). A palpation-based semi-quantitative tool, the modified Rodnan skin score, is the current gold standard for the assessment of skin involvement. However, this method has significant limitations, with emphasis on low sensitivity to change and a high inter-observer variability. Ultrasound has been explored, in the past decades, as a basis for more objective, sensitivity and reproducible measure of skin involvement.

Objectives: To identify and synthesize the best available evidence on the use of ultrasound as a source of skin outcome measures in patients with SSc.

Methods: Two independent reviewers systematically searched PubMed MEDLINE and Embase (up to December 2017). A study was eligible if it included at least one defined group of patients with SSc and reported a structured evaluation of the skin with ultrasound and/or ultrasound elastography. This search was augmented by review of bibliographic references from the included studies. The two reviewers independently extracted the data and classified the quality of evidence of the included studies by the Effective Public Health Practice Project system.

Results: A total of 30 studies (21 observational cross-sectional and 9 longitudinal) were included. They enrolled a total of 1171 SSc patients, mostly middle-aged, female and with a limited form of SSc (59.0%). The most common ultrasound outcome measure used was skin thickness (in 28 studies), although the definition of this parameter was a highly heterogeneous. Other outcome measures were echogenicity (in 7), and/or stiffness (in 6) and/or vascularity (in 1). There was a substantial discordance in the number and exact location of skin sites examined. The main comparator was global and site specific mRSS. There was a lack of consensus on which patients should be measured (the correspondence between ultrasound measures and histological findings). Few studies reported information about inter- and intra-rater reproducibility, but when reported, it showed excellent results. Data regarding evidence for responsiveness to change and feasibility were also scarce.

Conclusions: This systematic review highlights a remarkable literature heterogeneity and limited quality of most reported studies. This hinders the evidence currently supporting the use of skin ultrasound evaluation in clinical practice, but the very promising data (e.g. good reliability and early detection of skin involvement) support its use in clinical research. Further well-designed and dimensioned studies are needed to support the role of skin ultrasound assessment in the early diagnosis and monitoring SSc patients. These may be crucial to improve our
understanding the disease process and to foster the development of much-needed new intervention strategies.

AB0813

SEVENTEEN MYOSITIS AUTOANTIBODIES: SEROLOGICAL PROFILE OF HISPANIC PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Background: The idiopathic inflammatory myopathies (IIM) are a heterogeneous group of subacute, chronic, or acute acquired diseases of skeletal muscle, they can be classified into the following clinical pathologic groups: dermatomyositis (DM), polymyositis (PM), and inclusion body myositis (IBM) which differ in clinical presentation, season of onset, genetics, and prognosis. Moreover, the seropositivity of antibodies in these diseases can help to predict the evolution of the disease, and influence therapeutic strategies. Anti-Mi-2 is a classic marker for IIM at the north of Mexico.

A cross-sectional, retrospective descriptive study cohort of 95 patients attended the rheumatological clinic in the period from January 2016 to January 2018 in a Rheumatology Service from a University (Hospital Jose E. Gonzalez) from UANL and a centre for rheumatology.

From a cohort of 95 patients, 68.42% were women and 31.75% were men. The average age was 47±15.42. A prevalence of seropositive antibodies (MMDA) was performed by the Immunoblot technique with Euroimmun kit. The following antibodies was observed for Mi2: 29 (30.52%), 14 (14.73%) in Tif gamma, 21 (22.29%) in Jo-1, 2 (2.11%) in MDA-5, 17 (18.02%) in TIF gamma and 12 (12.63%) has positive Mda 5.

SODIUM THIOSULFATE 10% INTRALESIONAL TO TREAT CALCINOSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS AND DERMATOMYOSITIS: CASE SERIES

A.F. Tonial1, M.P.M. Cathcart1, T.A.F. G. Santos1, P.M. Azvedo1, T.L. Skare1, P. Martin2. 1Departamento de Reumatología, Hospital Universitario Evangélico de Curitiba; 2Escola de Medicina, Pontificia Universidade Católica do Paraná, Curitiba, Brazil

Background: Calcinosis is a frequent complication of systemic sclerosis and dermatomyositis, causing local pain, joint mobility reduction, ulcerations, secondary infections and disability. Currently, there is no effective treatment to calcinosis, but the use of topical dressing or intralesional sodium thiosulfate (STS) has showed promising results.

Objectives: To evaluate efficacy of intralesional STS 10% in calcinosis of patients with dermatomyositis and systemic sclerosis.

Methods: Prospective and open-labeled study including dermatomyositis and systemic sclerosis patients with calcinosis. The primary endpoints were: pain relief evaluated through visual analogue scale (VAS) and reduction of major diameters of calcinosis in x-ray. The secondary endpoints were: improvement in the quality of life and function evaluated by SF12 and HAQ respectively.

Results: A total of 10 calcinosis from 7 patients, one with dermatomyositis and 6 with systemic sclerosis were treated. The average dosage of STS per application was 9.27 mg at intervals ranging between 15 and 30 days (mean=17.85) between each injection. The number of injections per each calcinosis ranged between 3 and 8 (mean 3.3). All patients reported improvements in pain, however the results were not statistically significant (table 1). There were no reductions in calcinosis diameters, nor improvement of quality of life and function.

Conclusions: Low doses of sodium thiosulfate applied through intralesional injections, in a restrict number of applications and long intervals were not effective to treat calcinosis.

HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS TREATED WITH TWO DIFFERENT INTRAVENOUS ILOPROST REGIMENS

T. Schioppo1, L. Scala1,2, P. Cozzolino1,2, M. Mantovani1, G. Cesana2, O. De Lucia1, A. Murgo1, F. Ingegnoli1,2, *Rheumatology, Pini, Milan, Italy; 1CESP, University of Milan Bicocca, Monza; 2University of Milan, Milan, Italy

Background: In systemic sclerosis (SSc), Raynaud’s phenomenon (RP) and digital ulcers (DU) can decrease health related quality of life (HRQoL). Intravenous (IV) iloprost (ILO) is administered for RP, after oral therapy failure, and DU healing. HRQoL is considered fundamental to assess the impact of the disease and therapy on patients: EQ-5D-5L has been satisfactory used to assess the general HRQoL in SSc.

Objectives: Aim of our study was to estimate HRQoL in SSc patients treated with two different IV ILO regimens and in patients not requiring IV ILO.

Methods: This was a monocentric, prospective, pragmatic and non-randomised study. Enrolled SSc patients were divided into 3 groups: no IV ILO (group A), IV ILO once monthly (B) or IV ILO for 5 consecutive days every 3 months (C). HRQoL was assessed using EQ-5D-5L through a telephone interview. Group A patients were evaluated at baseline and after 3 months; group B 2 days before each therapy cycle, and after 2 weeks after the first cycle of therapy. The EQ-5D-5L describes health state with a 0 to 1 utility and values health with a utility index. Multiple regression analyses was performed to calculate VAS and mean utility index in each group (confounders: age, sex, treatment group, baseline utility or VAS score, average outdoor temperature the week before the evaluation at patient’s place of residence).

Results: 96 patients were enrolled: 52 in group A, 24 in B, and 20 in C. Of these 35, 21 and 16 completed the study respectively. Utility and VAS score at the end of the three months, as adjusted for the possible confounders, were not statistically different in the three groups.

Conclusions: Utility and VAS, at 3 months follow-up, were not different in the 3 groups as if IV ILO was able to make patients requiring IV ILO as similar as patients not requiring IV ILO. Moreover, in this model there was no difference between the two ILO regimens (1 days monthly vs 5 every 3 months). These results suggest that our therapeutic approach, based on various criteria such as demographic, clinical characteristics, logistic aspects and patients’ preferences, allows to reach or to maintain HRQoL at comparable levels between the three groups considered.

PROLIFERATIVE NAILFOLD CAPILLARY AVASCULAR AREA PREDICTS MALIGNANCY IN PROGRESSIVE SYSTEMIC SCLEROSIS

W.-N. Huang1,2, Y.-M. Chen1,2,3, W.-T. Hung1, C.-W. Hsieh1, C.-T. Lin1, Y.-H. Chen1,2,3, *Allergy, Immunology And Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China; 1Allergy, Immunology And Rheumatology, Taichung Veterans General Hospital, Taichung; 2Faculty of Medicine, National Yang Ming University, Taipei; 3Institute of Biomedical Science, National Chung Hsing University, Taichung, Taiwan, Province of China

Background: Systemic sclerosis (SSc) is an autoimmune disease characterised by proximal scleroderma and internal organ involvement. Observational studies demonstrated increased incidences of cancer in SSc patients1. Nailfold capillaroscopy is useful for the diagnosis and disease activity assessment of SSc.

However, whether the nailfold capillaroscopy pattern is distinct in SSc patients with malignancy remained unknown.

**Objectives:** The aim of this study was to investigate the incidence rate of malignancy in SSc patients. Nailfold capillaroscopy morphology patterns in SSc patients with cancer were also compared to those without cancer.

**Methods:** During 2009 to 2014, consecutive 310 SSc patients who visited outpatient clinics at Taichung Veterans General Hospital, Taiwan were enrolled. Nailfold capillaroscopy was performed at a magnification of 200x. Abnormal morphology description were analysed and categorised by the scoring system proposed by Dr. Cutolo. SSc with malignancy was defined if the subject had a cancer diagnosis during the follow-up period.

**Results:** Among 310 SSc patients, 28 (10.9%, 13 males, 15 females) patients had cancer. The mean age of SSc with malignancy is 62±10.9 years. Sixty-four percent SSc patients with cancer is diffuse type, but only 42% of them were tested positive for anti-Scl-70 antibodies. The most common cancer were genitourinary tract and gastrointestinal tract, accounting for almost two-thirds patients. Cancer and SSc were frequently diagnosed at the same year. In SSc patients with cancer, 19 patients received nailfold capillary microscope exams when SSc was diagnosed. The assessment of nailfold capillaroscopy morphology patterns in SSc patients with cancer demonstrated neither enlarged loop, giant loop, microhemorrhage nor angiogenesis. However, prominent avascular areas could be observed universally in SSc patients with malignancy.

**Conclusions:** Rheumatologists should be aware of malignancy in SSc patients, especially those with diffuse type and within the 1st year of symptoms onset. SSc patients with malignancy tend to present atypical capillaroscopic pattern of prominent avascular area without loop dilatation, microhemorrhage and angiogenesis.

**THE COMPARATIVE STUDY OF SYSTEMIC SCLEROSIS AND SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION**

Y. Feng, J. Wang, Y. Lei, X. Zhang. Department of Rheumatology, Guangdong Academy of Medical Sciences/Guangdong General Hospital, Guangzhou, China

**Background:** Systemic Sclerosis (SSc) is the main cause of Connective Tissue Disease-associated pulmonary arterial hypertension (CTD-PAH) in western countries, while Systemic Lupus Erythematosus (SLE) is the first cause in Asian. Systemic Sclerosis (SSc) is the main cause of Connective Tissue Disease-associated pulmonary arterial hypertension (CTD-PAH) in western countries, while Systemic Lupus Erythematosus (SLE) is the first cause in Asian.

**Objectives:** This study aimed to identify the clinical difference between SSc-PAH and SLE-PAH. This study aimed to identify the clinical difference between SSc-PAH and SLE-PAH.

**Methods:** SSc and SLE patients with pulmonary arterial hypertension who visited Guangdong General Hospital in China from 2009 to 2017 were recruited. PAH was diagnosed by transthoracic echocardiography or right heart catheterization and clinical data of patients was collected. Comparative study between SSc-PAH and SLE-PAH was conducted to identify the difference. SSc and SLE patients with pulmonary arterial hypertension who visited Guangdong General Hospital in China from 2009 to 2017 were recruited. PAH was diagnosed by transthoracic echocardiography or right heart catheterization and clinical data of patients was collected. Comparative study between SSc-PAH and SLE-PAH was conducted to identify the difference. SSc and SLE patients with pulmonary arterial hypertension who visited Guangdong General Hospital in China from 2009 to 2017 were recruited. PAH was diagnosed by transthoracic echocardiography or right heart catheterization and clinical data of patients was collected. Comparative study between SSc-PAH and SLE-PAH was conducted to identify the difference.

**Results:** Twenty-nine SSc-PAH and 55 SLE-PAH patients were enrolled. The baseline characteristics of two groups was shown in table 1. In comparative study: the gender(p=0.018), the age of PAH diagnosis(p=0.001), Raynaud’s phenomenon(p=0.001), WHO function state(p=0.019), PASP (p=0.013), the diameter of RA(p=0.045) and RV(p=0.029) showed significant difference between SSc and SLE-PAH. TTE: transthoracic echocardiography; PASP: pulmonary arterial systolic pressure; RA: right atrium; RV: right ventricle; LVEF: left ventricle ejection fraction; RHC: right heart catheterization; PAP: pulmonary arterial pressure; PVR: pulmonary vascular resistance; CI: cardiac index.

**Conclusions:** The SSc-PAH patients tend to be older, have more angioopathic characteristics and more silent clinical course than SLE patients, which might bring some insight into the different pathophysiological process between SSc and SLE-PAH. The SSc-PAH patients tend to be older, have more angioopathic characteristics and more silent clinical course than SLE patients, which might bring some insight into the different pathophysiological process between SSc and SLE-PAH.

**TFH CELLS CONTRIBUTE TO ABNORMAL B CELL PROFILES IN DERMATOMYOSITIS**

X. Zhang. X. Ma, H. Wang, Z. Chen. L. Sun. Department of Rheumatology And Immunology, THE AFFILIATED DRUM TOWER HOSPITAL, NANJING UNIVERSITY MEDICAL SCHOOL, NANJING, CHINA., Nanjing, China

**Background:** CD4+CXCR5+PD-1+ T follicular helper (Tfh) cells assist B cells in their proliferation, differentiation and antibody class switch. Several studies indicate that Tfh cells play important roles in autoimmune diseases such as SLE, RA and pSS, which are characterised by the production of multiple antibodies. The frequency of Tfh cells in the peripheral blood from patients with dermatomyositis(DM) and whether they participate in the development of DM remain to be elucidated.

**Objectives:** To investigate the frequencies of Tfh cells and B cell profiles in DM patients. To further determine the association of Tfh cells and B cells in DM patients and clarify the possible mechanism.

**Methods:** Peripheral blood mononuclear cells (PBMCs) were isolated from DM patients and age, gender-matched healthy controls (HCs), respectively. The frequency of Tfh (CD4+CXCR5+PD-1+) cells, total B (CD19+) cells naive B (CD19+CD27-) cells, memory B (CD19+CD27+) cells and plasmablasts (CD19+CD38+) were examined by flow cytometry. The serum levels of IgA were tested by enzyme linked immunosorbent assay (ELISA).
Results: The percentages of circulating Th cells are significantly higher in DM patients than HCs (p<0.0001). Compared to HCs, the absolute numbers of circulating Th cells also increase markedly in DM patients. The miRNA expression levels of Bcl-6, a typical transcription factor of Th cells, increase apparently in PBMC from DM patients (p<0.05). Serum levels of IL-21, a Th-specific cytokine, are obviously higher in DM patients (p<0.01). The percentages of total B cells (p<0.01) and Naïve B cells (p<0.01) upregulate significantly in DM patients while Memory B cells (p<0.05) downregulate markedly when compared with HCs. The absolute numbers of plasmablasts (p<0.05) and Naïve B cells (p<0.05) increase notably while memory B cells decreased obviously (p<0.01). Serum levels of IgG (p<0.01), IgM (p<0.0001), IgE (p<0.01) and IgA (p<0.05) are obviously higher in DM patients (p<0.05). The frequencies of Th cells are positively correlated with total B cells (r=0.633, p<0.001) and Naïve B cells (r=0.643, p<0.01).

Conclusions: Th cells may contribute to abnormal B cell profiles and antibodies production in DM and participate in the pathogenesis of DM. Th cell-targeted therapy might be a potential strategy for DM.

AB0820 ANTI-KS AUTOANTIBODY IS ASSOCIATED WITH SICCA SYNDROME AND INTERSTITIAL LUNG DISEASE

Y. Kondo, S. Sasaki, T. Kurabayashi, Y. Koyama, S. Sato. Division of Rheumatology, Department of Internal Medicine, Tokai University School of Medicine, Kanagawa, Japan

Background: Anti-a-minocyclin-RNA synthetase (anti-ARS) autoantibodies have been found in patients with polymyositis/dermatomyositis (PM/DM). Anti-KS, an anti-ARS antibody, often presents with interstitial lung disease (ILD) without other clinical symptoms of connective tissue disease (CTD). However, the clinical manifestations of anti-KS-positive patients are not well studied.

Objectives: To clarify the clinical and laboratory characteristics of Japanese patients with antibodies against anti-KS antibody.

Methods: Sera from 326 patients with CTD (including PM/DM) or ILD at Tokai University were screened for anti-KS antibody using RNA and protein immunoprecipitation assays. Demographic data, clinical symptoms, laboratory findings and chest computed tomodiography (CT) scan results were retrospectively reviewed from medical charts.

Results: Five patients with anti-KS autoantibody were identified. All five patients were female with a mean age (±SD) of 59.4 (±13.9) years at onset, presenting with respiratory symptoms without any sign of myositis. In all patients, ILD was chronic and chest CT scan revealed a non-specific interstitial pneumonia pattern in three patients and the remaining two showed a usual interstitial pneumonia pattern. Three patients (60%) had arthritis, mechanic’s hand, while one (20%) had Gottron’s sign and was diagnosed as amyopathic DM with ILD. Interestingly, three patients (60%) showed symptoms of the Sicca syndrome with presence of anti-SSA antibody and two of those were diagnosed as Sjögren’s syndrome. The frequency of Sicca syndrome in anti-KS-positive patients was significantly higher compared with other anti-ARS antibody-positive patients (50% vs. 14%, respectively, p=0.031).

Conclusions: These results highlight that the presence of anti-KS antibody is associated with the Sicca syndrome as well as ILD without muscle symptoms.

AB0821 EARLY DETECTION OF THE CHANGES IN PULMONARY ARTERIAL PRESSURE AND VASCULAR FUNCTIONS IN SYSTEMIC SCLEROSIS: EXPLORING NON-INVASIVE CLINICAL TEST METHODS AND UNDERLYING GENE EXPRESSIONS

Y. Koyama1, S. Fukue2, T. Ohno3, Y. Sato4, T. Higuchi1. 1. Center for Autoimmune Diseases, Division Of Rheumatology, 2. Department of Cardiology, 3. Department of Dermatology, Japanese Red Cross Okayama Hospital, Okayama, 4. DNA Chip Research Inc, Tokyo, Japan

Background: Pulmonary arterial hypertension (PAH) is prominent as a vascular involvement in systemic sclerosis (SSc), which remains a leading cause of death in spite of current best treatments. Although recent studies focused on early diagnosis of established PAH, it is known that more than a half of the pulmonary circulation is impaired before early PAH is detected. However, there is little study about the changes of vascular functions or the underlying gene expressions during its subclinical stage.

Objectives: I. To detect the pathological changes in pulmonary arterial pressure (PAP) and vascular functions before PAH is manifested. II. To explore the changes in its underlying gene expressions of peripheral blood.

Methods: Total of 103 cases without PAH symptoms (NYHA I) with either Raynaud phenomenon (RP: n=87), skin sclerosis (n=65) or SSc-related autoantibody (n=68) were enrolled. To detect the pathological change of PAP, exercise Doppler echocardiography was carried out, and exercise induced pulmonary hypertension (exPH) group was segregated from normal response group (exN) with using the definition described in R. Naeije et al.1 Vascular function was evaluated with thermography after 0°C-stress and determination of ankle-brachial index (ABI) and cardio-ankle vascular index (CAVI), Furthermore, reactive hyperemic index (RHI), augmentation index (AI) and second derivative of photoplethysmogram aging index (SDPTGAI) were assessed with using EndoPAT. Micro-vascular changes were also recorded with nailfold videocapillaroscopy. Meanwhile, genome-wide gene expression analysis was performed with using whole peripheral blood. The genes correlated with each vascular function tests were analysed by weighted gene co-expression network analysis (WGCNA) and pathway enrichment analysis (PathVisio).

Results: There were significant differences between exPH and exN group in the result of thermography after 0°C-stress test, CAVI and AI normalised to heart rate of 75bpm (AI75bpm). As the CAVI and AI are known to correlate positively with age, careful interpretation was necessary because the mean age of exPH group was higher as compare with exN group (69.05±11.04 vs. 60.23±14.73). However, the fact that recovery of blood-flow from RP was significantly delayed in exPH group suggested the additional pathological changes of vascular and endothelial functions. Gene expression analysis revealed that several mutual pathways such as “type2 interferon signalling”, “oxidative damage” and “fatty acid omega oxidation” seemed to underlie some vascular changes. The on the other hand, gene expression analysis showed that many factors such as ageing, arteriosclerotic and immunological mechanisms were involved in the changes of these vascular functions. Although further prospective study is required to select appropriate set of the tests, it is possible that evaluation of these vascular functions may be useful as a non-invasive test to assess the pulmonary vascular disease before PAH is manifested.

AB0822 A MEASUREMENT OF ANTI-ARS ANTIBODES, ANTI-MI-2 ANTIBODY, ANTI-TIF1 GAMMA ANTIBODY AND ANTI-MDA5 ANTIBODY BY ENZYME-LINKED IMMUNOSORBENT ASSAY AS A DIAGNOSTIC TOOL OF IDIOPATHIC INFLAMMATORY MYOPATHY: RHEUMATOLOGY DAILY PRACTICE

Y. Miyoshi1,2, T. Kise1, N. Yokogawa1, K. Shimada1, S. Sugii1. 1. Department of rheumatic diseases, Metropolitan Tama Medical Center, Fuchu, Tokyo; 2. Department of rheumatic diseases, Tama-Hokubu medical center, Higashimurayam, Tokyo, Japan

Background: Enzyme-linked immunosorbent assay (ELISA) tests of anti-ARS antibodies, anti-Mi-2 antibody, anti-TIF1γ antibody and anti-MDA5 antibody
became available at daily clinical practice on Oct. 2016 in Japan. Diagnostic accuracy of myositis-specific autoantibodies (MSAs) except for anti-Jo-1 antibody in daily clinical practice is scarce. 1

Objectives: This study investigated the diagnostic utility of newly available myositis-specific autoantibodies (ELISA) in idiopathic inflammatory myopathy (IM) suspected patients at a rheumatology clinic with muscle and skin biopsy as a reference standard.

Methods: This study is a retroactive, cross-sectional study. The electrical medical records of patients who visited the department of rheumatic diseases at Tokyo Metropolitan Tama Medical Centre between Nov. 2016 and Aug. 2017 were retrospectively searched for clinical variables and laboratory data. Patients with serum creatine phosphokinase (CK) greater than two-fold of normal upper limit (over 300 IU/ml) or suspected dermatomyositis skin rash were included. Anti-ARS antibodies, anti-phosphokinase (CK) greater than two-fold of normal upper limit (over 300 IU/ml) ELISA without immunosuppressive therapy were assumed negative. IIM diagnosis was with interface-dermatitis were considered positive. The biopsy results of patients who did not have biopsy procedure but whose symptoms and signs improved without immunosuppressive therapy were assumed negative. IM diagnosis was based on 2017 EULAR/ACR classification criteria. 2 We calculated likelihood ratio of MSAs for biopsy results and IIM diagnosis.

Results: Eight hundred and eighty-six new patients visited an outpatient clinic of rheumatic disease department and 38 patients met inclusion criteria. 14 patients were excluded because of apparent causes (1 each for sepsis, rhabdomyolysis, macro CK, serotonin syndrome, motor neuron disease, statin myopathy, SSc, idiopathic IP, seborrheic dermatitis, 3 for symptoms not compatible with IMs.) and no biopsy results (2 patients). 17 (71%) of 24 patients analyses were female. The median age was 56.5 (IQR 41–65) years, median CK 658 (IQR 105–1866) IU/ml. 11 (46%) patients had the positive biopsy result (6 muscle biopsy and 5 skin biopsy) and IIM diagnosis. 10 (42%) patients were positive for MSAs (anti-ARS antibodies in 3, anti-Mi-2 antibody in 1, anti-TIF1γ antibody in two, anti-MDAS antibody in 3 and double positive for anti-ARS and anti-MDAS antibody in 1). The positive likelihood ratio of MSAs for the biopsy result and IIM diagnosis was ∞ (95% CI cannot be calculated). The negative likelihood ratio was 0.091 (95% CI 0.086–0.907).

Conclusions: Our analysis demonstrated that MSAs measured by ELISA efficiently differentiated biopsy-proven IMs from other medical conditions at rheumatology daily practice.

AB0824 EVALUATION OF THE DETECTION OF MYOSITIS-SPECIFIC ANTIBODIES BY LINEBLOT AS A TOOL FOR THE CHARACTERISATION OF A PROSPEROUS MULTICENTER CORHOT

Y. Piette1,2, C. Bonrocy1, J. Dehoorne3, J. De Bleecker1, M. De Sloovere2, Y. Pan1, D. Lin3, P. Smits1

1Rheumatology, AZ St.-Jan, Brugge
2Rheumatology, AZ KU-Leuven; 3Laboratory Medicine, University Hospital, Gent, Belgium

Background: Traditionally, the diagnosis of idiopathic inflammatory myopathies (IM) is based on clinical findings, muscle enzyme levels, electromyography and biopsy. Newer approaches include the detection of myositis-specific autoantibodies (MSA), with MSA identified in about 50% of patients.

Methods: A total of 225 samples (118 consecutive routine samples for which MSA were requested and 107 controls [50 systemic sclerosis (SSc), 29 systemic lupus erythematosus (SLE) and 28 rheumatoid arthritis patients (RA)]) was analysed on indirect immunofluorescence (HEp-2000, Immunocbins) and lineblot (MYO12 blot, D-Tek). All consecutive samples were retrospectively categorised by the treating medical specialist as definite IM (n=16), probable IM (n=10), immune mediated inflammatory disease (IMID) – myositis overlap not excluded (n=28), myopathic features without IM (n=1), IM excluded (n=44), and lost from follow-up data available (n=19). Data to calculate the EULAR/ACR probability score were also collected.

Results: MSA were detected in 12% of the 225 samples, showing no multiple reactivities. A sensitivity of 50% in the IM patients (definite and probable n=13/26 – based on judgement of the clinician) was observed, with the highest frequencies observed for anti-HMGCR (15%, n=4), anti-M2 (12%, n=3) and anti-Jo-1 (12%, n=3). Less frequent antibodies were anti-EJ (n=1), anti-MDAS (n=1) and anti-NXP2 (n=1). All these patients had a MSA-compatible clinical IM subtype. The median minimal EULAR/ACR probability score was 97% (range 6%–100%, no biopsy data entry), with the lowest score observed in the anti-EJ patient. In contrast, MSA were also observed in 8 patients with no convincing clinical diagnosis of IM or myositis overlap syndrome (anti-TIF1γ in 4 [5 SSc and 1 SLE], anti-SRP in 1 [1 RA], anti-SAE in 1 [1 SSc, 1 RA and 1 IM excluded], mostly showing low anti-body titres (n=6/8) and no compatible immunofluorescence pattern on HEp-2000 (n=7/8). For 2 other positive samples the results were not conclusive (anti-PL7 in patient with myopathic features and anti-SRP in an unspecified IMID patient).

Conclusions: The detection of MSA by lineblot will be useful for the prospective serological characterisation of patients with clinical suspicion of IM. Nevertheless, careful interpretation in correlation with the clinical findings and other technical examinations is necessary in case of low titres and absence of a compatible immunofluorescence pattern.

Disclosure of Interest: None.

AB0823 PATIENTS WITH CONNECTIVE TISSUE DISEASE HAVE MORE ANXIETY IN COMPARISON WITH PATIENTS WITH OTHER RHEUMATIC DISEASES

Y. Jiang1, D. Lin1, P. Zhang1, X. Zhang1, Z. Liao1, Y. Pan1, J. Gu1

1Rheumatology, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Rheumatic diseases often coexist with psychological disorders. Psychological symptoms not only have a substantial negative impact on the quality of life, but also on the course and outcome of the chronic diseases. 2

Objectives: Our study was to investigate psychological disorders in Chinese patients with rheumatic diseases and to compare the differences of psychological disorders among different diseases.

Methods: Patients with rheumatic diseases were enrolled from July to December in 2017 in rheumatology department of the Third Affiliated Hospital of Sun Yat-sen University. Participants were required to complete a set of questionnaires and examinations, including demographic and clinical information, Zung self-rating anxiety scale (Zung SAS), and Zung self-rating depression scale (Zung SDS). The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis. The Mann-Whitney U test and Student’s t test were used to compare patients with different rheumatic diseases and psychological status in these patients.

Results: Of all the 153 patients, 49 (32%) were male patients, 14.4% had only primary education, while 32% received education in university. Numbers of the patients were stated as follows. Lupus, 44; rheumatoid arthritis, 11; Sjogren’s syndrome, 11; systemic sclerosis, 9; myositis, 7; vasculitis, 6; spondyloarthritids, 10; gout, 10; other diseases 46. Mean age was 37.6±15.23 years. Mean disease duration was 3.78±5.07 years. Mean SAS scores were 43.44±18.51, and mean SDS scores were 46.6±12.43. 35 (22%) of the patients had anxiety, while 6 (3.9%) had moderate anxiety, 50 (32.7%) patients suffered from depression, of which 5 (3.3%) had severe depression, and 13 (8.5%) had moderate depression. Patients with connective tissue diseases had more anxiety (30.5%) than average score (p<0.05), especially in patients with lupus. SDS (B=1.073, p<0.001), educational scale (B=–2.147, p<0.05) contributed to SAS scores.

Conclusions: Psychological disorders could concur with rheumatic diseases, especially in connective tissue diseases. Physicians should be aware of psychological status in these patients.

AB0825 MANAGING SYSTEMIC SCLEROSIS: ASSESSING THE EDUCATIONAL NEEDS OF RHEUMATOLOGISTS
Z. Ahmad, S. Johnson. Toronto Scleroderma Program, Division of Rheumatology, Department of Medicine, Sinai Health System, University Health Network, University of Toronto, Toronto, Canada

Background: Systemic sclerosis (SSc) is an uncommon, complex and heterogeneous condition, making it challenging to manage. Individual rheumatologists see relatively few cases and patient surveys identify numerous gaps in clinical care. There are no published data on the educational needs of rheumatologists caring for patients with SSc. We aimed to determine rheumatologists’ self-rated knowledge and learning needs.

Methods: Survey questions were adapted from the EUALAR Recommendations for the Treatment of SSc with reference to patient-identified care gaps. The survey was conducted on paper and on SurveyMonkey (a cloud-based online survey development software program). The target audience was Ontario rheumatologists, serving a population of 13.6 million. We sought to explore self-reported knowledge, experience, attitudes and perceived barriers in caring for SSc patients. Physician demographics and preferred educational methods were also collected. Gaps between perceived and desired knowledge were calculated to identify the greatest unmet learning needs.

Results: One hundred and eighteen responses were received with a response rate of 54%. The greatest unmet learning needs were seen in the management of muscular disease (average gap of 1.4 on a 5-point scale), pulmonary hypertension (average gap of 1.3), interstitial lung disease (average gap of 1.1) and gastrointestinal manifestations of the disease (average gap of 1.0). The smallest learning gap concerning screening recommendations (average gap of 0.7) was observed in the management of fatigue. Rheumatologists agree that “scleroderma is an autoimmune disease.” Agreement with this statement was high (93.3%) among the rheumatologists who treat relatively small numbers (≤10) of scleroderma patients.

Conclusions: We have identified several unmet learning needs regarding the management of SSc among rheumatologists. These can be used to inform future educational resources and programs for rheumatologists regarding SSc and to direct further research into their needs.

Z. Chen, X.-P. Li, X.-M. Li. Rheumatology and Immunology, The First Affiliated Hospital of University of Science and Technology of China, Hefei, China

Background: Myositis-specific antibodies (MSAs) have been found to be associated with distinct clinical phenotype and prognosis in patients with Idiopathic Inflammatory Myopathy (IIM).

Objectives: To assess the profile of MSAs in Chinese patients with polymyositis (PM)/dermatomyositis (DM) and explore association of antibody profile with clinical characteristics, laboratory findings and prognosis.

Methods: 90 patients with PM/DM were enrolled. 12 MSAs (mi-2b, b2m, TIF1γ, MDAS, SAE1, Jo-1, SRP, PL-7, PL-12, EJ, OJ) were measured by immunoblotting. Associations between antibody profile and clinical manifestations and outcome were explored.

Results: The study population comprised 20 patients with PM and 70 patients with DM, in which 17 DM patients were identified as clinically amyopathic dermatomyositis (CADM). Anti-Jo-1 antibody was associated with more frequent anti-MDA5 positivity. Anti-PL-7 was well tolerated, and no significant complications (e.g. serious infections or tuberculosis) were observed. No prosthesis was indicated for any patient with DM. Anti-MDA5 is predominantly seen in patients with CADM and closely associated with rapidly progressive ILD and high mortality thus serve as a marker of poor prognosis. Anti-TIF1γ positive patients routinely screened for tumours will be of clinical significance.

Spondyloarthritis – treatment

AB0827 HIP ARTHRITIS REMAIN FREE FROM RADIOGRAPHIC PROGRESSION FOR 24 MONTHS FOLLOWING TREATMENT OF ANKYLOSING SPONDYLARThRITIS WITH TNF-A INHIBITORS: A PROSPECTIVE STUDY

Background: Hip involvement is the most frequent extra-skeletal arthritic manifestation of ankylosing spondylitis (AS). It can be severe and may worsen outcomes for patients. There is a large body of high quality evidence for clinical efficacy of TNF-α inhibitors at treating this condition. However, their structural hip benefit remains unknown.

Objectives: In this prospective study undertaken in Algeria, we aimed to evaluate clinical and structural efficacy of TNF-α inhibitor therapies on non-synostosante hip involvement in AS, for a 24 months period.

Methods: This study pursued a follow-up of patients SA using modified New York criteria or ASSAS criteria. Patients were TNF-α inhibitors naïf diagnosed with SA, with hip involvement (identified using clinical and/or radiological findings). Patients were treated with one of the following: adalimumab, infliximab or etanercept.

Exclusion criteria were: history of tuberculosis, serious infections, hepatitis, neoplasms, other inflammatory conditions, and hip involvement due to any other causes. The following data were collected: clinical rating of hip involvement using the Harris Hip scoring system, biological characteristics (CRP), and radiological characteristics of hip lesions using Bath Ankylosing Spondylitis Radiology Index of the hip (BASRI hip). Specific disease indexes such as BASDAI and BASFI were also collected. Follow up was undertaken at the following time periods in months: 0, 3, 6, 12 and 24. Statistical analysis of findings was performed using SPSS 11.0 software.

Results: The study recruited a total of 30 patients, 22 males and 8 females. Mean age was (24.1±3.6 years). Bilateral and unilateral hip involvement were identified in 67% and 33% of patients, respectively. Mean time for appearance of hip lesions was (3.9±2.1 years), HLAB27 was present in 30% of this study population. Baseline characteristics of hips examined have shown an altered function (Harris Hip mean score of 56.1±5.1) and a relatively advanced structural score (BASFI hip mean score 2.4±1.1). These scores correlated with high disease activity (BASDAI mean score 5.5±1.2) and a poor mean BASFI score (5.4±2.0). This was accompanied by a mean CRP score of 22.1±8.1. Non-steroidal anti-inflammatory drugs were ineffective. During the 24 months treatment period using TNF-α inhibitors, there was a statistically significant improvement in hip scores from the third month onwards with mean Harris Hip scores of 70.3±21.5 (p<0.001), and 81.3±11.5 (p<0.001) at months 3 and 6, respectively. This was maintained until the end of the study period at 94.2±10.5 (p<0.001). There have also been statistically significant improvements in BASDAI and BASFI scores as well as CRP (all p<0.001). Mean BASRI score, however, remained unchanged after 24 months. Treatment was well tolerated, and no significant complications (e.g. serious infections or tuberculosis) were observed. No prosthesis was indicated for any patient

Conclusions: Hip involvement is associated with severe and rapidly evolving AS. In this study, we have demonstrated improved outcomes and stability of radiographic lesions of hip arthritis for a period of 24 months, when SA was treated with TNF-α inhibitors.

AB0829
PERSISTENCE ON GOLIMUMAB AS SECOND LINE BIOLOGICAL THERAPY IN PATIENTS WITH SPONDYLOARTHRITIS (AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS). GO-BEYOND, A RETROSPECTIVE STUDY

Objectives: In this retrospective study we assess the 1 to 3 year probability of persistence on golimumab in patients with spondyloarthritis (SpA), axial SpA or psoriatic arthritis (PsA) who started treatment with golimumab as second biological (after withdrawal of a first anti TNF-alpha drug).

Methods: GO-BEYOND was a retrospective study undergone in 20 Spanish rheumatology clinics. Information was collected on all axial SpA and PsA patients who initiated golimumab between January 2013 and December 2015 as second anti TNF-alpha (i.e. after discontinuation of a first anti TNF-alpha drug). Centres in which all the patients could not be included were excluded from the analysis. The probability of persistence was calculated with a Kaplan-Meier test and comparisons were done with the log-rank test.

Results: 210 patients were included (131 with axial SpA and 79 with PsA, mean age 49 years [SD=14]; 40% women, median duration of disease at the initiation of golimumab 80.5 months). Reasons for discontinuation of the first anti TNF-alpha were loss of efficacy (71.4%), poor tolerability or adverse event (11.0%) and patient or physician preference (17.6%). During a median follow-up of 29.3 months, 72 of 210 patients (34.3%) discontinued golimumab, due to primary failure (n=21), disease reactivation or secondary failure (n=29), poor tolerability (n=4), adverse events (n=10), inactive disease or patient-physician agreement (n=8). The probability of persistence on golimumab since treatment initiation was 80% at year 1 (95% CI 75–86), 70% at year 2 (62–77) and 65% at year 3 (59–72). The figures were similar in patients with axial SpA or PsA, and in patients who discontinued the first anti TNF-alpha due to loss of efficacy or to other reasons (p=0.121 and p=0.835, table 1).

Conclusions: After discontinuation of a first anti TNF-alpha, patients with spondyloarthritis showed a high probability of persistence on golimumab. The probability of persistence was similarly high in patients with axial SpA or PsA, and in patients who discontinued the first anti TNF-alpha due to loss of efficacy vs other reasons. Real life effectiveness of golimumab as second anti TNF-alpha is high and durable in SpA patients.

MRI EVALUATION OF THE EFFECT OF ANKYLOSING SPONDYLITIS TREATMENT ON HIP JOINT INVOLVEMENT

E. Agafonova1, T. Dubinina2, A. Dyomina2, O. Rumyantseva1, S. Erdes1

1Laboratory Spondyloarthritis, 2Laboratory of Scientific Organizational Problems in Rheumatology, V.A. nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Coxitis is one of the leading causes of early disability in ankylosing spondylitis (AS) patients. There’s no mild course of the disease as soon as hip joints (HJ) are involved, but epidemiological surveys in Russia show that only 7% of AS associated hip damage require total hip replacement.

Objectives: To evaluate case follow-up data in treated AS patients with hip involvement using hip MRI and radiography for dynamic assessment.

Methods: 30 AS patients (mean age of 27.7±7.7 yrs) meeting modified 1984 N-Y criteria with MRI signs of HJ inflammation were followed up for 2 years. Patients’ mean age at the onset of the disease was 22.3±18.3 years. 77% of the population were HLA-B27 positive. Median AS duration was 47 (12–144) months, and median BASDAI score was 5.9±3.1. The median duration of clinically manifest coxitis by the time of the study was 45 months. (25%, 75%), and pain intensity by numeric ranking scale (NRS) was 6 (2; 8). HJ MRI using T1 and STIR modes was performed in all participants in addition to clinical and radiological examinations. All patients were grouped into three arms based on therapeutic regimens: Group I was administered non-steroidal anti-inflammatory drugs (NSAIDs), Group II – genetically engineered biological agents (GEGA) +NSAIDs, and Group III was treated with combination of NSAIDs+DMARD (methotrexate or sulfasalazine). In case of baseline regimen failure patients from Group II were switched to NSAIDs+DMARD GEBA combination at Mo 6 after initiation of treatment.

Results:...
THE INFLUENCE OF REMISIVE AND ANTI-INFLAMMATORY TREATMENT ON AXIAL MOBILITY IN PATIENTS WITH ANKYLOSING SPONDYLARthritis

F. Russi, L. Chisari, R. Larisa, V. Cazac. Rheumatology and Nephrology, SMPU "Nicolae Testemițanu", Chisinau, Moldova, Republic of

Background: In advanced ankylosing spondylarthritides (AS), bone ankylosis or ossification of the involved joints can make the chest practically immobile, decrease its compliance, or even lead to intercostal muscle atrophy.

Objectives: The purpose of the study was to evaluate chest involvement in AS by measuring toracoabdominal movements during quiet breathing, by dividing the chest and abdominal contribution to the current volume, by inductive plethysmography methods.

Methods: 60 consecutive patients were recruited from the Rheumatology Department of the Republican Clinical Hospital. They were selected based on AS diagnosis, with no existing cardiovascular or neuromuscular diseases that would alter respiratory mechanisms and the absence of severe obesity.

Results: Monotherapy with DMARD was 27 out of 60 patients (45%) (Sulfasalazine 3 g/day) for a period of 1–48 months (mean value=19.4 (15.5) months). There were no differences in the angle of the Ct-Abd curve between patients with DMARD and DMARD-naïve treatment (39.2 (14.5)° and 34.7 (19.5)° for sitting position, 49.3 (18.1)° and 47.2 (23.1)° in orthostatism, and 19.1 (15.6)° and 16.1 (14.6)° for cinostatism, p<0.05). In the baseline study, the Ct-Abd patient angle was lower than the control group in sitting position (36.3 (17.3)° and 51.5 (8.9)°, p<0.0002) in orthostatism (48.1 (20.8)° and 62.4 (12.5)°, p<0.01) or orthostatism (17.4 (15.0)°) and 24.5 (9.8)°, p<0.05). In the entire patient group, the Ct-Abd angle correlated negatively with BASFI in all three body positions (r=−0.50, p<0.0001 in the sitting position, r=−0.36, p<0.01 in orthostatism, r=−0.47, p<0.0001 in cinostatism); did not correlate with BASDAI, BASMI, or the modified Schoeber test in either of the three body positions.

In 15 AS patients who underwent repeated measurements of toracoabdominal movements while receiving their associated DMARD treatment (Methotrexate 15 mg/week and Sulfasalazine 3 g/day) 3 months after treatment, the angle of the Ct-Abd slope was significantly higher than that of the fundamental study, in all bodily positions. The Ct-Abd angle continued to increase, with increments less pronounced and reaching significant value only between measurements of 3 months and 12 months. Improvements in standardised clinical signs following associated DMARD treatment followed a similar pattern, with scores at each interval significantly different from those measured in the baseline study, improvements continuing at a faster pace slowly after the third month.

In the control group, the angle of the slope of the Ct-Abd curve was not different in the two measurements in any of the body positions (51.4 (8.9)° and 50.7 (9.3)° in the sitting position, 62.4 (12.4)° and 61.6 (11.8)° in orthostatism, and 24.6 (9.8)° and 24.8 (10.4)° in cinostatism, p<0.05). In orthostatism, the difference between the measurements was 0.8° (confidence interval 95%: 0.2 to 2.52, upper and lower boundaries of 6.6° and 8.2°).

Conclusions: The slope of the Ct – Abd curve during quiet breathing correlates negatively with BASFI and responds significantly to associated DMARD treatment and NSAIDs. Our data suggest that this measure can be targeted for further evaluation of its usefulness in monitoring chest involvement and its response to treatment in AS patients.

Disclosure of Interest: None declared

REAL-WORLD EFFICACY AND SAFETY OF SECUKINUMAB: DATA FROM VERONA’S COHORT

F. Martins, C. Cami, A. Carletto, E. Fracassi, M. Rossini. Rheumatology, AOUI Verona, Verona, Italy

Background: Secukinumab has been approved for the treatment of active ankylosing spondylitis (AS) and psoriatic arthritis (PsA). Its efficacy has been demonstrated in phase III trials where eligibility criteria ensured a homogeneous population. Although this strategy reduces confounding factors, it does not guarantee the same results in the real world, where clinicians deal with advanced disease, comorbidities, adherence and persistence challenges.

Objectives: Aim of this study was to assess efficacy and safety of Secukinumab in real-world clinical practice.

Methods: Patients received Secukinumab (150 or 300 mg) at weeks 0, 1, 2, 3 as induction therapy and then every 4 weeks as maintenance therapy. Assessments included clinical outcomes, comorbidities, adherence and persistence challenges.

Results: 61 patients affected by PsA (65% females, 35% males) and 29 affected by AS (70% males, 30% females) were included. 64% of patients reached 12 months follow up. Baseline characteristics of both groups are shown in the tables below.

In the PsA cohort, the median DAPSA at baseline was 19.5 (IQR 9.6), at 6 months 9.09 (IQR 2.7) to 4.5 at 12 months (IQR 2). No differences emerged among PsA groups. Clinical trials did not assess efficacy of Secukinumab in patients previously treated with biologic agents other than anti-TNF agents, due to exclusion criteria. We performed subgroup analysis to evaluate its efficacy in patients previously treated with biologic agents other than anti-TNF agents, due to exclusion criteria. We achieved a retrospective descriptive and comparative monocentric study, on 49 patients, with SpA including ankylosing spondylitis (AS), psoriatic arthritis (PsA), enthesopathic arthritis (EA), reactive arthritis (ReA) and undifferentiated spondyloarthritis (usSpA) (according to Amor criteria, ASAS 2009 and CASPAR criteria), during 12 years (2004–2015). The patients were treated with at least one anti-TNF, during at least 6 months. Disease activity was assessed by the BASDAI, ASDAS, ESR and CRP. To compare mean differences between time points (week 0 versus week 24), a Wilcoxon test was applied. To compare efficacy between the 3 anti-TNF, a Mann-Whitney test was applied.

Results: Twenty three patients (47%) had AS, 13 patients (27%) had PsA and 11 patients (22%) had EA. One patient had an usSpA, and 1 patient had a ReA. The mean age was 42.81 years±11.77. The median age at disease onset was 29.41 years±11.29. The mean disease duration was 10.16 years. Nineteen patients received etanercept (ETN), 16 infliximab (IFX) and 12 adalimumab (ADA). At six months, the 3 anti-TNF showed improvement in the disease activity scores: BASDAI (p<0.0001), ASDAS CRP (p<0.0001), ESR (p<0.0001) and CRP (p<0.0001). Sixty two percent of the patients have reached BASDAI 50 response at 6 months.

Disclosure of Interest: None declared

Conclusions: In this first real-world cohorts of patients with PsA and AS Secukinumab has proven to be effective, regardless of PsA subtype, radiographic progression in AS and previous exposure to biologic therapy. The safety profile was favourable and similar to previous studies.

AB0834
BETTER IMPROVEMENT OF ASDAS WERE ACHIEVED IN 841 AS PATIENTS AMONG 6 MONTHS OF ANTI-TNF USERS COMPARED TO NON-ANTI-TNF USERS: RESULTS FROM A REAL WORLD PROSPECTIVE COHORT MANAGED BY SMART PHONE SYSTEM

X. Ji, J. Zhu, J. Zhang, F. Huang, on behalf of SMSP co-authors. Rheumatology, Chinese PLA General Hospital, Beijing, China

Background: Ankylosing spondylitis (AS) is a chronic and progressive condition of the spine, which is the most common form of spondyloarthritis (SpA). Although anti-TNF agents are the most effective therapy for AS or SpA, it is recommended as the second-line treatment for individuals who have persistently high disease activity despite treatment with at least 2 non-steroidal anti-inflammatory drugs (NSAIDs), intolerance or contraindication to NSAIDs. Changes in ankylosing spondylitis disease activity score (ASDAS) are often measured to reflect outcomes in AS trials. However, anti-TNF does not always maintain long-term remission. There is limited evidence about remission rate of 6 months treatment from real-world AS cohorts.

Objectives: The purpose of this study is to compare the remission rate of AS patients among biologics users or non-biologics users from China Ankylosing Spondylitis/Spondyloarthritis Prospective Imaging Cohort (CASPIC).

Methods: CASPIC is an ongoing prospective cohort established by a smart management system (Smart Management System for Spondyloarthritis (SMSP)). Clinic visits were scheduled based on visits reminder set by rheumatologists (1~6 months). Anti-TNF users were defined as patients who used biological agents during the follow-up period and the baseline was defined as the start time to use the biological agents. Non-biologics users were served as control groups. ASDAS was calculated to assess disease activity in AS. Generalise additive mixed model (GAMM) and curve fitting were used to show the difference between two groups.

Results: There were 841 AS patients in this cohort, 83.4% were male, with mean (±SD) age 30.8 (±8.8) years, mean time since diagnosis 8.3 (±6.1) years (table 1). Mean duration of anti-TNF treatment was 4.1 (±3.5) months. Significant improvements were observed in ASDAS (table 2). Anti-TNF users had more serious disease activity despite treatment with at least 2 non-steroidal anti-inflammatory drugs (NSAIDs), intolerance or contraindication to NSAIDs. Changes in ankylosing spondylitis disease activity score (ASDAS) are often measured to reflect outcomes in AS trials. However, anti-TNF does not always maintain long-term remission. There is limited evidence about remission rate of 6 months treatment from real-world AS cohorts.

AB0835
COMPARISON OF LONG TERM ANTI-TNF SURVIVAL IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS; DATA FROM TURKBIO REGISTRY

G. Can1, E. Dakilić2, Y. Pehlivan3, S. Senel3, S. Akar4, D. Solma2, S.S. Koca2, N. İnanı5, P. Atagunduz6, A. Yazıcı7, A. Çelte7, B. Gökay6, B. Zengin1, S. Uulu1, N. Akkoç5, F. Önen1, 1Rheumatology, Dokuz Eylül University, İzmir, Turkey; 2Rheumatology, Uludağ University, Bursa; 3Rheumatology, Erciyes University, Kayseri; 4Rheumatology, Kafıpınar University, İzmir; 5Rheumatology, Fatih University, İzmir; 6Rheumatology, Marmara University, İstanbul; 7Rheumatology, Kocaeli University, Kocaeli; 8Rheumatology, Gazi University, Ankara; 9Rheumatology, Private Doctor, İzmir, Turkey.

Background: Limited data are available on anti-TNF survival in non-radiographic axial spondyloarthritis (nr-axSpA) patients and their long-term survival in ankylosing spondylitis (AS).

Objectives: The aim of the study was to evaluate long term survival of the first anti-TNF drug treatment among patients with AS and nr-axSpA enrolled in the TURKBIO database and to compare the discontinuation rates for infliximab (INF), etanercept (ETN), and adalimumab (ADA) in each of the two groups.

Methods: All AS and nr-axSpA patients receiving biological therapies registered in the TURKBIO database between the dates of October 2011 and April 2017 were included in the study. AS diagnosis was made according to modified New York classification criteria and nr-axSpA according to ASAS AxSpA classification criteria. Demographic and clinical data, the date of starting to use biological drug, using frequency and dose of biological drugs, BASFI, BASDAI, BASM, ASDAS scores, date and reason for discontinuing to use drug were collected. Baseline characteristics and drug survival rates were compared between AS and nr-axSpA patients. Drug survival was calculated by the Kaplan-Meier method and risk for discontinuation among treatment groups compared by Long Rank test.

Results: A total of 924 patients were included in the study (AS, n=871 and nr-axSpA, n=53). More than half of the patients with AS were male (60.7% in AS vs 34.0% in nr-axSpA group, p<0.001). AS patients had longer symptom duration (104.90±79.06 vs 75.11±45.29 months, p<0.036) compared to nr-axSpA. Median levels of CRP and ESR were similar for nr-axSpA (CRP: 27.03±34.71, ESR: 50.50±25.77) and AS (CRP: 22.32±29.95, ESR: 35.40±22.91). The scores of
BASFI, BASMI and ASDAS were found to be similar in both groups. Median BAS-DAI scores at first TNF initiation were higher in patients with nr-axSpA than in patients with AS (58.6±18.21, 51.06±18.91, p=0.039). Cumulative drug survival rates did not show significant difference among INF (at 59. months:18.5%), ADA (at 71. months: 39.5%) and ETN (at 51. months: 24.2%) in nr-axSpA group (p=0.699) (figure 1). Similarly, drug survival rates at 78, 77, 78, months for 3 anti-TNF drugs had shown no difference in AS patients (INF (at 78. months: 38.1%), ADA (at 77. months: 52.4%), ETN (at 78. months: 39.0%)) (p=0.151) (Figure 2). Cumulative survival rates in AS patients (at 78. months:42.2%) were found to be significantly higher than that (at 71. months:28.2%) in nr-axSpA patients (p<0.001) (Figure 3).

Conclusions: In contrast to the literature that revealed similar short term survival rates for anti-TNF drugs in patients with AS and nr-axSpA, we found higher survival rates in patients with AS compared to patients with nr-axSpA in this long-term observational study. A limitation of the study may be the low number of nr-axSpA patients using anti-TNF, related to the requirements of social insurance system.

Disclosure of Interest: None declared

AB0836 – Figure 1. Drug survival rates anti-TNF in nr-axSpA. Abstract AB0835 – Figure 2. Drug survival rate by anti-TNF in AS. Abstract AB0835 – Figure 3. Overall drug survival on first anti-TNF in nr-axSpA and AS patients.

AB0837 – THE EFFECT OF ANTI-TNF ON RENAL FUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A PROSPECTIVE COHORT STUDY

I.A. Swart, M. Heslinga, I.M. Visman, I.E. van der Horst-Bruinsma, C. van Denderen, M.T. Nurmoshamed. AMSTERDAM RHEUMATOLOGY AND IMMUNOLOGY CENTER / READE, Amsterdam, Netherlands

Background: Impaired renal function is common in patients with ankylosing spondylitis (AS) and patients also have an increased risk of cardiovascular disease (CVD). Previous studies have demonstrated that biological, such as anti-Tumour Necrosis Factor (anti-TNF) reduce CVD in patients with inflammatory rheumatic diseases. Impaired renal function is a known predictor of CVD (also elevated in AS). We postulated that the beneficial cardiovascular effect of anti-TNF might be mediated by improving renal function. However, data about the effect of biologicals on renal function in patients with AS are lacking.

Objectives: To assess the effect of anti-TNF on renal function in patients with AS.

Methods: Biological naïve consecutive AS patients treated with etanercept or adalimumab were prospectively followed from 2005 to 2014. Renal function was determined by calculation of the estimated Glomerular Filtration Rate (eGFR), which was estimated with the abbreviated Modification of Diet in Renal Disease (MDRD) formula. Patients were divided into two groups: patients with normal renal function at baseline and patients with impaired renal function at baseline, to investigate whether the effect is different for these groups. Normal renal function was defined by eGFR ≥90 mL/min/1.73 m2 at baseline and impaired renal function was defined by eGFR <90 mL/min/1.73 m2 at baseline. The effect of anti-TNF on eGFR was analysed using mixed model analysis.

Results: 211 AS patients were followed for a median of 156 (36 – 286) weeks. 153 patients had normal renal function and 58 had impaired renal function at baseline. In patients with normal renal function at baseline eGFR decreased significantly over time (β=-0.041, p<0.001), although this association did not remain significant after adjustment for disease activity (β=-0.015, p=0.212). Patients with impaired renal function at baseline did not have a significant change in eGFR over time (β=0.022, p=0.087) and this association remained not significant after adjustment for alcohol consumption, BMI, disease duration and disease activity (β=0.008, p=0.593). The change in eGFR on average over time after starting anti-TNF in AS patients with normal and impaired kidney function are presented in figure 1.

Conclusions: Effectiveness of TNFi, estimated by drug survival, seems to be lower in patients with nr-axSpA than those affected with axSpA. The reason of these findings remain to be elucidated. However, a possible explanation may be searched in the limit of the classification criteria for nr-axSpA. In addition overweight and high disease activity negatively impact the persistence on first line anti-TNF treatment in axSpA patients in real life setting.

REFERENCES:

Disclosure of Interest: None declared

Conclusions: This study demonstrates that anti-TNF is not associated with renal function in AS patients, which means that use of anti-TNF is safe concerning renal function in patients with AS. From our results it seems that the effect of anti-TNF on CVD in AS patients is not mediated by an effect on renal function.

Disclosure of Interest: None declared

THE EFFICACY OF ADALIMUMAB AND SULFASALAZINE IN ALLEVIATING AXIAL AND AORTIC INFLAMMATION DETECTED IN PET/CT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

J.-P. Kajisala1, A. Kerola1, R. Tuompo2, M. Kauppi3, H. Relas4, A. Loimala4, H. Koivu5, J. Schidt6, T. Kerola1, K. Eklund7, T. Nieminen8. 1Internal Medicine, Päijät-Häme Central Hospital; 2Medical Imaging Center, Helsinki University Hospital; 3Rheumatology, University of Tampere School of Medicine, Tampere; 4Medical Imaging Center, Helsinki University Hospital, Helsinki; 5Department of Nuclear Medicine, Päijät-Häme Central Hospital, Lahti; 6Heart and Lung Center, Helsinki University Hospital, Helsinki, Finland

Background: Inflammatory pathways are likely the central link from axial spondyloarthritis to the known increased risk of cardiovascular morbidity. Literature on positron emission tomography imaging together with computed tomography (PET/CT) in the context of spondyloarthritis is limited.

Objectives: The aim was to grade the inflammatory signals in the sacroiliac joints and aorta in the PET/CT imaging before and after antirheumatic treatment of clinically active axial spondyloarthritis with either sulfasalazine (SSZ), the first-line anti-rheumatic drug in Finland for axial spondyloarthritis, or adalimumab (ADA).

Methods: Fourteen patients aged 18–75 years with axial spondyloarthritis and radiologic sacroiliitis as detected either by MRI or X-ray and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and visual analogue scale (VAS) ≤4 have been recruited to the pilot study. DMARD-naïve patients started SSZ for 16 weeks. Those who failed to reach remission (BASDAI and VAS ≤4) were shown before and after treatment with either sulfasalazine (five patients) or adalimumab (nine patients). Each colour depicts one unique patient.

Conclusions: As detected by reduced 18F-FDG uptake, SSZ reduced inflammation in sacroiliac joints. There was also clear trend towards reduction of inflammation in aorta. ADA and SSZ both reduced clinical symptoms, but only ADA reached statistical significance. PET/CT could not show any reduction in FDG uptake in the ADA group. This may be due to the fact that ADA was used as the second line treatment, when the inflammation had already been reduced to the limit detectable by the method.

RADILOGIC PARAMETERS OFankylosing SpONDylORTHIS PAtIENTS TREATED WITH ANTI-TNF-a VERSUS NON-STEROIDAL ANTI-INFLAMMATORY DRUGS AND SULFASALAZINE

S.M. Son1, J.S. Lee2, T.S. Goht3, W. Park4. 1Orthopaedics, Pusan National University Yangsan Hospital, Yangsan; 2Orthopaedics, Pusan National University Hospital, Busan, Korea, Republic of Ireland

Background: The introduction of anti-tumour necrosis factor-α (anti-TNF-α) has significantly altered the treatment landscape of inflammatory arthritis. It has proven to be an excellent treatment option for reducing Ankylosing spondylitis(AS) symptoms. The impact of anti-TNF-α on the radiographic progression of AS has been difficult to characterise, in part because of the relatively slow rate of radiographic change in AS and the hurdles it imposes on longer-term placebo-controlled trials. Despite symptomatic improvement, conclusions concerning effect of anti-TNF-α treatment on radiographic progression in patients with AS remain inconsistent. Furthermore, while many studies have reported the impact of anti-TNF-α on radiographic progression, limited data are available on the relationship between treatment agents and sagittal balance in AS.

Objectives: Limited data are available on the relationship between treatment agents and sagittal balance in AS. We investigated radiological features related to treatment agents and compared sagittal balance between patients treated with anti-tumour necrosis factor-α (anti-TNF-α) or non-steroidal anti-inflammatory drugs (NSAIDs) and sulfasalazine.

Methods: We prospectively enrolled 133 consecutive AS patients. Patients were eligible for the trial if they were under medical treatment with the same treatment agents for at least 1 year. All patients were treated initially with NSAIDs and...
sulfasalazine. Sixty-nine patients were achieved an excellent pain control outcome with these agents (Group A). Sixty-four patients who complained of intractable low back pain were switched to anti-TNF-α treatment (Group B). Twelve radiographic parameters were measured. Clinical outcome was assessed with the Bath AS Disease Activity Index (BASDAI), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP). All parameters were measured at enrolment, upon changing treatment agents, and every 6 months during follow-up.

Results: Mean ESR, CRP, BASDAI, and thoracic kyphosis at baseline were significantly higher in group B. After treatment, group B had significantly higher lumbar lordosis and significantly better clinical outcomes. Correlation analysis revealed significant relationships between radiologic parameters and BASDAI. On multiple regression analysis, lumbar lordosis was a significant predictor of BASDAI.

Conclusions: This study demonstrated a clear association between treatment agents and radiologic parameters in AS. Anti-TNF-α treatment improved lumbar lordosis and slowed thoracic kyphotic progression with improvement of clinical outcomes. Lumbar lordosis was a significant predictor of clinical outcome in AS patients treated with anti-TNF-α.

AB0841 ASSOCIATION OF RELATIONSHIP BETWEEN LONELINESS, PERCEIVED SOCIAL SUPPORT, DEPRESSION AND MEDICATION ADHERENCE IN ANKYLOSING SPONDYLITIS PATIENTS

E. Öksüz1, F. İ. Cinar2, M. Cinar3, E. Telkoz2, S. Yılmaz3. 1University of Health Sciences, Gülhane Faculty of Nursing; 2University of Health Sciences, Gülhane Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

Background: Ankylosing spondylitis (AS) is a chronic, progressive, inflammatory disease which can cause labour loss and deformities and requiring long-term treatment. Loneliness, perceived social support, depression, patients’ beliefs about medicines and treatment may affect their medication adherence and treatment success.

Objectives: In this study, we aimed to investigate the relationship between loneliness, perceived social support, depression and medication adherence in AS patients.

Methods: This cross-sectional study was conducted in a tertiary rheumatology outpatient clinic. One hundred and nineteen AS patients were enrolled to the study. The socio-demographic and clinical features of the patients agreeing to participate were recorded to the “Patient Assessment Form”; The patients’ disease activity and functional status were determined with the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), the Bath Ankylosing Spondylitis Functional Index (BASFI), respectively. The pain and global assessment of the patients were assessed with a numerical visual analogue scale (nVAS; 0–10 cm). The medication adherence of the patients was assessed with the Morisky Green Levine Scale (MGLS). The UCLA Loneliness Scale, the Multidimensional Scale of Perceived Social Support (MSPSS) and the Beck Depression Inventory (BDI) were used to determine loneliness, perceived social support, depression and medication adherence in AS patients.

Results: One hundred five patients (88.2%) were male, the mean age was 35.80 ±9.08 years, and the mean disease duration was 9.88±6.34 years. The mean BASDAI, BASFI and patient global assessment scores were: 4.57±2.63, 3.23 ±2.76, and 4.13±3.23, respectively. According to the MGLS medication adherence groups, patients with low medication adherence had higher BASDAI, spinal pain, spinal pain at night, fatigue and patient global assessment scores and had lower mean ages (p<0.05). Among the MGLS medication adherence groups, patients with low medication adherence had lower MSPSS scores, and had higher UCLA Loneliness Scale and Beck Depression Inventory scores (p=0.037, p<0.001, p=0.022, respectively) (table 1).

Disclosure of Interest: None declared

AB0840 DETERMINATION OF SERUM LEVELS OF AND ANTIDRUG ANTIBODY PRODUCTION AGAINST TNF INHIBITORS IN ANKYLOSING Spondylitis: TESTING MAY BE USEFUL FOR THE ASSESSMENT OF COMPLIANCE BUT NOT THAT OF TREATMENT EFFECTIVENESS

K. Gulyas, A. Medele, N. Bodnar, Z. Szekanecz, S. Szanto. Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

Background: Targeted therapies, such as TNF-alpha inhibitors revolutionised the treatment of spondyloarthritides including ankylosing spondylitis (AS).

Objectives: To determine the correlation between serum TNF-alpha inhibitor levels of patients receiving biological therapy and concentration of anti-drug antibodies, disease activity (treatment effectiveness), age of patients and elapsed time since the onset of the diagnosis and from the initiation of the therapy.

Methods: Serum levels of TNF-alpha inhibitors (mg/ml) and concentration of anti-drug antibodies (AU/ml) were measured in 37 AS patients. Altogether 12 patients were treated with infliximab (IFX), 15 received adalimumab (ADA) and 10 received etanercept (ETN). Demographic data and parameters measuring disease activity (BASDAI) were also included in the analysis.

Results: A strong negative correlation was found between the concentration of anti-drug antibodies and drug serum levels (IFX: R²=0.833; ADA: R²=0.426; ETN: R²=0.587). On the other hand, similar correlation could not be demonstrated between serum concentrations of IFX, ADA or ETN and other factors, such as age of the patient (IFX: R²=0.050; ADA: R²=0.090; ETN: R²=0.016), BASDAI (IFX: R²=0.099; ADA: R²=0.071; ETN: R²=0.015), disease duration (IFX: R²=0.024; ADA: R²<0.001; ETN: R²=0.182) and time since the initiation of therapy (IFX: R²=0.008; ADA: R²=0.052; ETN: R²=0.062).

Conclusions: As anti-TNF-alpha antibodies decrease the serum concentration of TNF inhibitors. In our study, drug serum levels and anti-drug antibody concentrations significantly correlated with each other. However, similarly to some other reports, drug levels did not correlate with treatment efficacy. Therefore, routine assessment of serum drug and anti-drug antibody levels should not be recommended in the everyday practice in order to determine treatment effectiveness. However, the parallel evaluation of drug and anti-drug antibody levels may be effectively used in order to determine patient compliance in the case of subcutaneously administered drugs.

F: One-way ANOVA. Statistically significant between a and c, and b and c (p<0.05). * It shows the lowest-highest scores that can be taken from the scale and its sub-dimensions.

Conclusions: In this study, it was shown that as the average age and social support scores of patients decreased, and as the BASDAI, spinal pain, spinal pain at night, fatigue, patient global assessment, loneliness and depression scores increased, adherence to treatment were decreased. It is thought that patients should be handled holistically in terms of biopsychosocial aspect in order to improve adherence to medical treatment.

Abstract AB0842 – Figure 1

Conclusions: LoSpA patients were almost 10% of all biological registry. LoSpA patients were predominantly female, and they had relatively higher baseline disease activity and lower biological treatment response. On the other hand the drug survival rate and discontinuation reasons of TNF inhibitors in the LoSpA group was comparable to that in the younger group.

Abstract AB0843

EFFECT OF TNF INHIBITORS ON BONE MICROARCHITECTURE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A LONGITUDINAL STUDY BASED ON HIGH-RESOLUTION PERIPHERAL QUANTITATIVE BASED (HRPQCT)

N. Nilgi Haroon1, E. Szabo2, A.M. CHEUNG3, R. Inman4, 1Medicine, Northern Ontario School of Medicine, Sudbury; 2Osteoporosis program, UHN; 3Medicine, Univ of Toronto; 4Medicine, unit of Toronto, Toronto, Canada

Background: Ankylosing spondylitis (AS) is associated with high risk of fractures. BMD, bone microarchitecture and strength are negatively affected in AS. TNF inhibitors such as etanercept, adalimumab, golimumab and infliximab are the mainstay of treatment in AS. However no data is available on the effect of TNF inhibitors on bone microarchitecture and strength.

Objectives: This study aimed to assess the effect of TNF inhibitors on bone microarchitecture in patients with AS.

Methods: AS was defined by Modified New York criteria. Areal BMD was measured by DXA. Volumetric BMD (vBMD) and bone microarchitecture were measured using highresolution peripheral quantitative CT (HRpQCT) at the radius and tibia at baseline and after one year of treatment with TNF inhibitors. Intake of calcium and vitamin D were optimised.

Results: There were 31 subjects (58% men). Mean (±SD) age and BASDAI were 40±14 years and 4.1±2.1 respectively. Mean duration of disease was 14 (IQR: 6.5–25.5) years. Mean duration of follow-up was 15 months. Areal BMD (n=22) at lumbar spine (1.053±0.235 vs. 1.049±0.202;p=0.89), total hip (0.944±0.152 vs. 0.912±0.164,p=0.5), and femoral neck (0.955±0.151 vs. 0.954±0.191,p=0.2) did not change significantly. HrpQCT (n=31) on follow-up demonstrated that total, trabecular and cortical volumetric BMD were unchanged at both radius and tibia (table 1). Also, HrpQCT based trabecular parameters such as trabecular number, thickness and separation, BV/TV and cortical parameters such as cortical porosity and thickness remained stable (table 1). FEA estimates of bone stiffness and

**Conclusions:** This is the first study to document the changes in bone strength in AS patients with the use of TNF inhibitors. Treatment with TNF inhibitors might maintain bone microarchitecture at cortical and trabecular sites in patients with AS.

---

### ABSTRACT AB0844

**Background:** Certolizumab pegol (CZP) is available for patients with axial spondyloarthritis (axSpA), including ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritiiss (nr-axSpA). The efficacy and the safety of CZP are well established from clinical trials. However, evidence of its effectiveness in regular clinical practice is limited.

**Objectives:** To evaluate the effectiveness and safety of CZP in a real-word setting in nr-axSpA patients.

**Methods:** Multicentric cohort of SpA patients treated with CZP according to routine clinical practice. The study was approved by the local Ethics Committee. Maximum follow-up was 12 months. Clinical response was evaluated through BASDAI, ASDAS, BASFI and MASES scores. Safety variables: discontinuation rate.

**Results:** 336 patients with axSpA were included: 56.5% male, mean age 45.8 (±12.1) years, median disease time 4.3 (0, 49.5) years, 58.5% of patients were HLAB27 positive, and never smokers 64.7%. Prior bDMARD received (27.2% none; 37.9% 1, 35%-2). At baseline 38.6% had concomitant DMARDs and 82.8% NSAIDs. 31.8% of patients had peripheral arthritis and 42.7% enthesitis at baseline. CZP retention time 10.3 months. Statistically significant differences in BASDAI, BASFI, ASDAS and MASES were observed at the last visit comparing to baseline (table 1). In the last observation, 41.0% of the patients achieved BASDAI50, 34.6% were in ASDAS remission (ASDAS <1.3) and 49% presented a minimal clinical improvement (ASDAS at least 1.1). 46.3% of patients had resolution of the enthesitis (MASES=0). According to Kaplan-Meier analysis, the drug survival of CZP was 83.3%, and no differences were observed in retention rates when CZP were used as first option (83.3%) or after failure to other biologics (79.1%) (figure 1). 56/336 (16.7%) withdrawn CZP treatment: 34/336 (10.1%) due to lack of effectiveness, 16/336 (4.8%) due to adverse event and 6/336 (1.8%) for other reason. Serious adverse event was found in 23/336 (6.8%) patients.

**Conclusions:** Real life experience from this nationwide rheumatology study, demonstrated the effectiveness and safety of CZP in patients with axSpA, with a significant reduction of BASDAI, BASFI, ASDAS and MASES scores. No differences were observed in the retention rate regardless previous biological treatment.

### ABSTRACT AB0845

**S. Rodrigues-Manica**1, J. Leite Silva2, A.R. Machado3, C. Coelho4, J. Duarte5, E. Vieira-Sousa6, J. Tavares-Costa2, F.M. Pimentel-Santos1,2,3, C. Cezar Moniz, Centro Hospitalar de Lisboa Ocidental, Lisbon; 2Unidade Local de Saúde do Alto Minho, Ponte de Lima; 3Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre; 4Genetics Laboratory, Instituto of Environmental Health, Lisbon School of Medicine, University of Lisbon; 5Medical Department, Novartis Pharma, Pharmaceutical products, Lisbon, Portugal

**Background:** Patient reported outcomes (PROs) have gained relevance in the evaluation of several diseases such as axial spondyloarthritis (axSpA). They allow the clinician to have a quantitative measurement of several aspects of the disease, according to the patient perspective.

**Objectives:** In this review we intended to evaluate the efficacy of different biologic disease-modifying anti-rheumatic drugs (bDMARD) in achieving the minimum clinically important difference (MCID) in several PROs’ data. From randomised controlled trials (RCT) conducted in radiographic axSpA (r-axSpA) and non-radiographic axSpA (nr-axSpA) patients were included.

**Methods:** A systematic literature review (SLR) was performed using the MEDLINE database (August 17 2017) with the filters “published in the last 10 years” and “humans”. Abstracts from the EULAR 2017 were also considered. The PICO (P,
Personalising Care: Using Infliximab Drug Trough and Anti-Drug Antibody Levels Improves Clinical Treatment Decisions and is a Cost Effective Strategy in Spondyloarthritis

S. Dubash1,2, D. Bryer3, J. Fitton1,2, A. Ban1,2, C. Vandevelde1,2, H. Marzo-Ortega1,2, J. Freeston1,2, Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 1Rheumatology, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, UK

Background: Personalised medicine tailors treatment to the individual’s needs. The advent of biosimilars has led to therapy reappraisals driven by healthcare commissioning bodies’ demand for cost-effective interventions. Yet, biologic drug dosing is standardised and little is known about the rationale and efficacy of dose adjustment.

Objectives: As part of a service evaluation exercise, we measured serum drug trough levels (DLs) and anti-drug antibodies (ADAbs) in our cohort of patients with axial spondyloarthritis (axSpA) and Psoriatic arthritis (PsA) receiving bio-originator infliximab with the aims of a) informing our decision making when switching to a biosimilar and b) assessing the impact of this approach to our clinical practice.

Methods: Eligible subjects identified, were counselled and consented by an experienced specialist nurse on DLs and ADAb testing and possible associated outcomes including change in drug class, dose, infusion time interval and switching from bio-originator infliximab to the biosimilar infliximab CT-P13. A treatment algorithm was developed to guide the treating physician. Clinical and outcome data were recorded as per routine practice including disease status, DLs and ADAb titre, and clinical outcome.

Results: We identified 53 subjects. Based upon disease activity, DL and ADAb level, bio-originator infliximab was discontinued in 3 (6%) subjects, the infusion interval was extended in 8 (15%), shortened in 3 (6%), and the dose reduced in 3 (6%) subjects. Four patients (8%) changed to an alternative biologic due to persistent high disease activity on infliximab. ADAbs were absent in 20/28 (71%) subjects. Four patients (8%) changed to an alternative biologic due to persistence of high disease activity on infliximab. ADAbs were absent in 20/28 (71%) subjects. Four patients (8%) changed to an alternative biologic due to persistence of high disease activity on infliximab.

Conclusions: These data from a small cohort suggest that measuring ADAb and DLs to characterise treatment response, tailor treatment regime and inform biosimilar switching is a clinically efficacious and cost-effective strategy in infliximab-treated SpA patients. We anticipate further significant savings with our biosimilar switch of £41,184 per annum. DOI: 10.1136/annrheumdis-2018-eular.5857
cohort receiving subcutaneous therapies. This approach unlocks the potential of “personalised medicine” which supports individualised treatment and brings significant savings to the healthcare provider.

AB0847
IMPACT OF SPONDOYLOARTHRITIS ON LIFE QUALITY: BEFORE AND AFTER TREATMENT
X. Grapton1, on behalf of CREER, P. Lemesle2, on behalf of CREER, L. Arabian3, on behalf of CREER, V. Stroz4, on behalf of CREER. 1Private Rheumatology Practice, Colombes; 2Private Rheumatology Practice, Bois-Colombes; 3Private Rheumatology Practice, Clamart; 4Private Rheumatology Practice, Antony, France

Background: Life quality issues in spondyloarthritis (SPA) are often spontaneously mentioned by patients or identified by rheumatologists. Besides classic follow up parameters, we have to consider those issues to improve our patients life quality.

Objectives: Explore and quantify the impact of SPA on life quality via everyday’s life and psychological items and the effect of treatment on them.

Methods: SPA cases were collected by a group of 14 private practice rheumatologists (Rh) in the Paris area. Basic informations about the patient and his disease were provided by his rheumatologist. Questionnaire including 12 themes and 41 items was filled in by the patient.

Results: 50 cases collected, 59.5% men, mean age 45 years, 82% working. Axial SPA 42%, peripheric 4%, mixt 52%. Mean duration before study: 14 years. Moderate disease 57%, severe 26.5%. HLA B27 positive 84%. Drugs: NSAIDs 96%, classic DMARDS 31%, biological DMARDS 84%, corticosteroids 36%, combination therapy 42%. Associated measures were suggested by the Rh: Physical activity (62%), rest (56%), psychological support, physiotherapy, yoga, adapting professional activity and environment…

Life quality issues are spontaneously mentioned by 40% of the patients. Before treatment, 72% of the patients report consequences on their hobbies, 68% on their psychological well-being, 54% on their getting about, 50% on their family relations. The less impacted items are food (26%) and economy (24%).

Life quality is mostly altered by pain (71%), then fatigue (17%), handicap (7%) and other people’s attitude (5%).

After treatment, social repercussions diminish by 47%, then getting about, house-work, family relations, holidays, sexual life, psychological well-being, hobbies and work (between – 21% and – 44%).

Drug intolerance: 36%.

The items improving by more than 50% after treatment are in this order: cultural life, transports, house-keeping, do-it-yourself, sleep, going out, work (53% less sick leave).

The treatment is less efficient (<22%) on economy, dependance, disillusion, depression and sexual life.

Family circle lacks empathy in 66% of the cases, family relations stay difficult after treatment.

Conclusions: SPA diminishes quality of life in 75% of our patients, but only 40% mention it spontaneously. All the parameters impacted by SPA were significantly improved after treatment. The best improvement concerned hobbies, including culture, do-it-yourself and going out. One patient of two found correct sleep and felt psychologically better. Sick leave was reduced by half, but, unfortunately, family relations didn’t improve.

The rheumatologist has to track, in a trusting patient-physician relation, the daily situation impacted by the SPA.

Spondyloarthritis – clinical aspects (other than treatment)

AB0848
FOUR YEARS OF DELAY IN THE DIAGNOSIS OF SAPHO SYNDROME: SINGLE TERTIARY CENTRE EXPERIENCE
A. Erdes1, M. Ekcioğlu1, B. Armagan1, A. Sarı1, G.K. Yardımoğlu1, L. Kılıç1, S. Apras Bilgen1, A. Akdoğan1, O. Karadag1, S. Kiraz1, I. Erteler1, U. Kalyoncu1. 1Division of Rheumatology, Department of Internal Medicine; 2Department of Internal Medicine, Hacettepe University, Ankara, Turkey

Background: SAPHO syndrome is a chronic disease with bone, joint and skin involvement characterised by synovitis, acne, pustulosis, hyperostosis and osteitis. It is a rare disease and its diagnosis may depend on detailed clinical examination as well as radiological evaluation.

Objectives: In this study, we aim to present clinical features and diagnostic course of patients with SAPHO syndrome who are followed in our tertiary referral clinic.

Methods: All patients with SAPHO syndrome diagnosed since February 2014 have been registered with a standard form. Patients are prospectively monitored since then. Diagnosis was based on the criteria by Benhamou et al.1. In the questionnaire, demographic data (age, sex, duration of illness), clinical features (skin and joint involvement), laboratory characteristics (acute phase reactants, HLA-B27), radiological imaging (bone scintigraphy (increased activity in the sternum, bilateral sternoclavicular joints and clavicles), MRI) disease activity parameters (BASDAI, BASFI) were questioned. There were 24 patients with SAPHO syndrome. The data of 21 patients were presented because the clinical findings of 3 patients were insufficient.

Results: Data of 21 patients with SAPHO syndrome were available and 11 (52.4%) patients were female. Mean age at diagnosis was 39.9±12.9, mean age of symptom onset was 35.2±12.9, mean follow-up duration was 18.1±25.1 months. The mean delay time of diagnosis SAPHO syndrome was calculated as 49.0±82.5 months. Thirteen patients (61.9%) were followed up with another clinical diagnosis before SAPHO diagnosis. The clinical characteristics of the patients are shown in Figure 1. HLA-B27 was positive in 3 of 13 patients. Mean activity scores of our patients at initial visit were: BASDAI: 4.8±2.8, BASFI: 4.6±2.2, CRP2.3±4.2 mg/dL, and erythrocyte sedimentation rate 23.8±22.6 mm/h. Scintigraphy findings were positive in 16 (94.1%) of 17 patients. The diagnosis of 2 patients was supported by MRI. The remaining 2 patients were diagnosed with X-ray and clinic findings.

Abstract AB0848 – Figure 1. Clinical characteristics of patients at diagnosis

PPT: palmoplantar pustulosis, IBP: Inflammatory Back pain

Conclusions: There is a certain diagnostic problem in the SAPHO syndrome. Delay of SAPHO diagnosis was almost 4 years and 62% of patients had wrong diagnosis before SAPHO syndrome. Anterior chest wall involvement with dermatological findings should be alerting to the physicians. Bone scintigraphy can be helpful to diagnose SAPHO syndrome. It is important to distinguish SAPHO syndrome from other spondyloarthritis and/or psoriatic arthritis because of the potential different treatment strategies.

CORRELATION BETWEEN RAPID3 AND PROMIS10 IN PATIENTS WITH ANKYLOSING SPONDYLITIS
A. Ogdie1, W.B. Nowell1, R. Reynolds1, K. Gavigan2, S. Venkataramalingam2, M. de la Cruz2, E. Flood3, E.J. Schwartz4, B. Romero4, Y. Park5. 1Perelman School of Medicine at The University of Pennsylvania, Philadelphia; 2Global Healthy Living Foundation, Upper Nyack; 3ICON, Gaithersburg; 4Novartis Pharmaceuticals Corporation, East Hanover, USA

Background: Patient-reported outcome (PRO) measures are important in managing and improving the quality of care in patients with chronic rheumatic conditions including ankylosing spondylitis (AS). The RAPID3 was developed for use in patients with rheumatoid arthritis, but it has shown good correlation with the BASDAI and ASDAS in patients with AS. The PROMIS10 is a universal (non-disease specific) PRO measure that quantifies physical and mental health quality of life (QoL). RAPID3 has not been examined in patients with AS.

Objectives: To evaluate the relationship between RAPID3 and PROMIS10 in patients with AS.

Methods: US patients aged ≥18 years with a self-reported diagnosis of AS were recruited through CreakyJoints (www.CreakyJoints.org), an online patient support community comprising patients with arthritis and arthritis-related diseases and their caregivers and via outreach on social media. Respondents completed a web-based survey designed to collect data on socio-demographics and clinical symptoms, RAPID3, and PROMIS10. The RAPID3 score consists of three patient self-reported scores (0–10): functional impairment, pain, and patient global assessment; total scores:3.0= near remission, 3.1 to 6.0=low disease severity, 6.1 to 12.0= moderate disease severity, and >12.1 = high disease severity. PROMIS10 is a 10-item questionnaire measuring, mental, and social domains; physical and mental health domain scores are transformed to T-score distributions normalised to the general population (mean score=50). PROMIS10 individual scores and global physical and mental health T-scores were stratified by RAPID3 disease severity and compared across RAPID3 severity levels using Kruskal-Wallis or ANOVA or tests, respectively. Spearman’s correlation coefficient was calculated between the RAPID3 total score and the PROMIS10 physical health and mental health T-scores, respectively.

Results: Among 235 respondents, 174 (74%) were female, with a mean (SD) age of 49.8 (10.7) years. The mean (SD) PROMIS10 cumulative score was 15.4 (5.4). The mean (SD) PROMIS10 global physical and mental health T-scores were 35.60 (7.39) and 39.89 (8.76), respectively, with individual domain scores and global T-scores decreasing with worsening RAPID3 disease activity (table 1; p<0.001 for all). PROMIS10 physical and mental health T-scores showed a strong correlation with RAPID3 (r=−0.84 and −0.63, respectively).

DO SYMPTOMS OF DEPRESSION AND ANXIETY INFLUENCE TREATMENT RESPONSE AND LONG-TERM PHYSICAL HEALTH OUTCOMES IN ANKYLOSING SPONDYLITIS?
M. Eustebio1, C.A. Lopez2, M. Bernardes3, P. Pinto4, H. Santos5, J.L. Gomes2, M. Tavares-Coelho2, J. Dias2, A. Bernardo6, L. Domingues7, C. Crespo8, S. Maia6, F. Martins6, J.C. Branco9, F.M. Pimentel-Santos10, F. Venkatachalam11, M. de la Cruz12, E. Flood13, E. Schwartz14. 1Perelman School of Medicine at The University of Pennsylvania, Philadelphia; 2Global Healthy Living Foundation, Upper Nyack; 3ICON, Gaithersburg; 4Novartis Pharmaceuticals Corporation, East Hanover, USA; 5Rheumatology, Hospital Egas Moniz – CHLO; 6CEDOC, NOVA Medical School, NOVA University of Lisbon, Lisbon; 7Rheumatology, Centro Hospitalar São João, Porto; 8Rheumatology, Centro Hospitalar Vila Nova de Gaia/Espinho, Gaia; 9Rheumatology, Instituto Português de Reumatologia, Lisbon; 10Rheumatology, Unidade Local de Saúde de Alto Minho, Ponte de Lima; 11Rheumatology, Centro Hospitalar Médio Tejo, Torres Novas, Portugal

Background: Psychological disturbances, frequently observed in inflammatory rheumatic diseases, seem to negatively influence patient’s clinical status and treatment response.

Objectives: The aim of this study was to examine the longitudinal impact of depression (D)/anxiety (A) in treatment response, disease activity, physical disability and quality of life in patients with Ankylosing Spondylitis (AS).

Methods: Data from patients who fulfilled the modified New York criteria for AS were collected at baseline, weeks 2 and 14 post-treatment with Adalimumab. The Hospital Anxiety and Depression Scale (HADS) was used to evaluate D/A symptoms severity. The primary outcomes were AS disease activity score – C reactive protein (ASDAS-CRP), Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI) and AS Quality of Life (ASQoL) Scale. Secondary outcomes were patient and physician global assessment by Visual Analogue Scale (VAS), erythrocyte sedimentation rate (ESR), CRP and BASDAI question 1 (fatigue). Difference-in-differences estimation took into account the covariates gender, age at baseline and disease duration.

Results: Data from 54 patients were included. At baseline, D/A symptoms significantly influenced the mean value of BASFI (p=0.006; p=0.003) and ASQoL (p=0.001; p=0.004). On the other hand, BASDAI (p=0.009), CRP (p=0.017), patient’s VAS (p=0.003) and fatigue (p=0.015) were only influenced in the individuals with A symptoms, while the physician’s VAS (p=0.005) was only influenced in patients with D symptoms. After 14 weeks of treatment, significant differences in ASQoL mean values were found in patients with both D/A symptoms at baseline (p=0.005; p=0.022) and in BASFI (p=0.044) and patient VAS (p=0.006) for the population showing only A symptoms at the baseline. Apart from the physician VAS (p=0.023), D/A baseline symptoms did not affect the treatment’s response.

AS, ankylosing spondylitis; PROMIS10, Patient-Reported Outcome Management Information System Global Health short form; RAPID3, Routine Assessment of Patient Index Data 3.

* Disease severity classified by RAPID3 scores:<3.0= near remission; 3.1 to 6.0=low severity; 6.1 to 12.0=moderate severity; >12.1= high severity.

Conclusions: RAPID3 and PROMIS10 are relatively short questionnaires that can be used in the real world to track and monitor disease symptoms and health-related quality of life in patients with AS. RAPID3 and PROMIS10 were strongly correlated in patients with AS; although, the PROMIS mental health T-score likely measures a slightly different construct than RAPID3.

REFERENCES:
Conclusions: In patients with SpA, different disease manifestations between genders are observed already from the first stages of the disease. In patients with axSpA, males have worse prognostic factors compared with females. However, in pSpA, females report poorer functionality despite being diagnosed earlier than male patients. This difference in phenotypes may be relevant when therapeutic decision-making.

AB0853

THE ASSOCIATION OF VITAMIN D RECEPTOR LEVELS WITH DISEASE ACTIVITY PARAMETERS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

T. Kültürel1, D. Öztekin2, D. Keskin3, G. Keskin3, A. İnal4, H. Kara5, P. MIR, Kinkikale University, Kinkikale; 2Public Health, Yıldırım Beyazıt University, Istanbul; 3Immunology, Ankara University, Ankara; 4Immunology, Baskent University, Istanbul; 5Pharmacology, Yıldırım Beyazıt University, Ankara, Turkey

Background: Ankylosing Spondylitis (AS) is a chronic, systemic, inflammatory disease that involves sacroiliac, axial and peripheral joints with an unknown etiology. The role of vitamin D receptor (VDR) in the regulation of multiple pathophysiologic processes, like inflammation, infection and malignancies and systemic disease is not fully understood.

Objectives: The aim of this study, was to investigate the relationship between serum VDR levels and disease activity parameters in patients with AS.

Methods: Sixty-two patients with AS and 32 healthy volunteers were included into the study. Demographic features like age, duration of illness, medication, history of uveitis and peripheral involvement of the patients were recorded. Erythrocyte sedimentation rate (ESR), serum C-reactive protein (CRP) levels were recorded. The Bath AS Disease Activity Index (BASDAI) scores were calculated to determine disease activity. Serum Vitamin D receptor (VDR) level was measured by ELISA.

Results: There was no difference in Serum VDR levels between the patient and the control group (p=0.658). In patients with active AS (BASDAI score ≥4) serum VDR level was significantly high (p=0.002). Also serum VDR levels were statistically significantly high in patients with peripheral joint involvement and enthesis (p=0.001, non-steroidal anti inflammatory drugs (NSAID) compared to patients treated with biological agents (p=0.000). Serum VDR levels were also significantly correlated with BASDAI, CRP and ESR in the patient group (p=0.000, r=0.751, p=0.001, r=0.751 respectively).

Conclusions: In our study, serum VDR levels are related with disease activity, clinical parameters, peripheral joint involvement and enthesis in patients with AS.

Our results suggest that serum VDR level may be used to predict disease activity and prognosis. Further studies in large cohorts are needed to determine the role of Serum VDR level in the pathophysiology of AS.

Dysfunctional Pain Component in Ankylosing Spondylitis Patients

F. Filatova, S. Erdes. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

Background: As a result of chronic inflammation, repetitive activation of primary afferent fibres changes the functional state and activity of Central nervous pathways. On this patients when describing their complaints use neuropathic pain descriptors in combination with anxiety disorders, resulting in the conclusion that, relationship between DCP and the intensity of the pain in VAS back, as well as clinically significant anxiety and lack of it in group II (10,09±2,86 vs 6,17±3,35, p=0,07). Correlation analysis revealed a significant points, but lesions of the somatosensory nervous system in these patients was not detected, hence 14,7% of patients were identified DCP. When comparing patients with the presence of TCS group I (22 people) and no DCP group II (128) it has been found that statistically significantly in patients in group I had higher pain intensity on VAS (6,09±1,85 vs 4,55±2,06, p=0,001, respectively); active disease BASDAI index of 7.05±vs 1,58 4,87±2,16, p=0,001, respectively); the expression of functional impairment index BASFI (6,46±2,24 vs 4,05±2,81, p=0,001); the indicators of the questionnaire HADS in group I, consistent with the presence of clinically significant anxiety and lack of it in group II (10,09±2,86 vs 6,17±3,35, p=0,0001). However, duration of disease distinguish authentic in the groups was not (9,4±1,68 6,81 vs ±6±1,3 ±p=0,07). Correlation analysis revealed a significant relationship between DCP and the intensity of the pain in VAS back, as well as with the severity of anxiety, disease activity, functional disorders (p=0,05)

Conclusions: The study identified 22 patients, the presence of neuropathic pain descriptors in combination with anxiety disorders, resulting in the conclusion that, along with nociceptive component of pain in 14.7% of cases detected by the DCT. So the pain of some AS patients should be considered as a multicomponent syndrome, providing a comprehensive approach with the use of antidepressants (TCA and SSRIs).

AB0855

Identifying Patients with Axial Spondyloarthritis by Data Mining MRI Radiology Reports

F. Reilly, A. Szauchowicz, R. Sengupta. Royal National Hospital for Rheumatic Diseases, Bath, UK

Background: Axial Spondyloarthritis (axSpA) encompasses ankylosing spondylitis (AS) and non radiographic axSpA (nr-axSpA) as part of the ASAS classification criteria. The role of MRI is now central in identifying patients early in the disease course, but our use of this needs to be standardised to ensure appropriate requesting and correct interpretation of MRI axSpA features.

Objectives: To describe the prevalence of axSpA associated spinal lesions in patients with back pain

Conclusion: Through data mining of MRI reports, we have found that appropriate MRI sequences are being requested when features of AxSpA are suspected. The rate of chronic features of AxSpA such as ankylosis was low, suggesting this cohort may have short disease durations. Multiple features of AxSpA were identified in patients without an existing diagnosis prior to imaging. 16 new cases of AxSpA were identified.

AB0854

Dysfunctional Pain Component in Ankylosing Spondylitis Patients

E. Filatova, S. Erdes. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

Objectives: To identify the MRI protocols used to investigate patients with axial spondyloarthritis (AS) and to describe the prevalence of axial spondyloarthritis (axSpA) associated spinal lesions in patients with back pain and their relevance in subsequently diagnosed axSpA

Methods: MRI reports between 4th January 2015 and 25th February 2017 containing the key words ‘ankylosing spondylitis’ (AS), ‘bone marrow oedema’ (BMO), ‘spondyloarthritids’ and ‘sacroiliitis’ were identified using a computerised word finding programme, in a tertiary referral hospital for Rheumatology.

Results: 194 patients had MRI features of axSpA. 60.8% were female; mean age 39.3 years (SD 13.3). 96.4% (n=187) contained the term ‘sacroiliitis’ with AS, BMO and spondyloarthritis in 2.6%, 0.5% and 0.5% respectively, 63.4% were referred by a rheumatologist, and 19.1% from primary care. Musculoskeletal radiologists reported 16.0%, general radiologists 37.1%, and external radiology services 46.4%. The most common MRI protocol was the inflammatory spinal protocol (ISP-MRI, 57.2%), with sacroiliac (SIJ) MRI in 17.8%. ISMR MRI were requested by Rheumatology. GPs requested more ISP-MRI than other sequences (29.7% of their total MRIs). 144 cases had a diagnosis stated on the MRI report: 100 (69.4%) had an existing diagnosis of axSpA, and 20 (13.9%) of a peripheral arthritis. In patients with known AxSpA, the most frequent findings were BMO (70.3%), and erosions (67%). Ankylosis was only seen in 4 patients. Features of axSpA were identified in 26 MRIs requested for mechanical back pain, and 11 for unrelated medical reasons. 33 cases of BMO and 29 of SIJ erosions were identified in patients who did not have a pre existing diagnosis of AxSpA, and one showed ankylosis. 16 patients went on to have a diagnosis of axSpA.

Abstract AB0854 – Table 1. Radiological features seen on MRI imaging, and by diagnosis
THE IMPACT OF SYSTEMIC INFLAMMATION AND RADIOLOGICAL CHANGES ON MOBILITY IN ANCHYLOSING SPONDYLITIES

F. Russo, L. Chisari, R. Larisa, V. Cazac. Rheumatology and Nephrology, SMPU “Nicolaie Testemitanu”, Chisinau, Moldova, Republic of

Objectives: The purpose of the study was to investigate the relationship between disease activity, structural lesions and physical function by testing the hypothesis that the level of structural lesions contributes independently to physical impairment.

Methods: For this analysis, the database of Rheumatology Department was used and included 78 consecutive SA patients who have been observed for many years, implying that they have used NSAID’s and DMARD for progression disease, no one has used TNF blocking agents.

Results: BASFI and DFI correlated significantly (ρ=0.88). The correlation coefficient for mSASSS and BASFI was 0.508 and for mSASSS and DFI equal to 0.464, suggesting a moderate correlation relationship. The correlation coefficient for the relationship between BASDAI and BASFI was equal to 0.79 and for BASDAI and DFI equal to 0.69 suggesting a moderate to significant correlation. The correlation between mSASSS and BASFI or DFI was dependent on the BASDAI level.

To further investigate the relationship between mSASSS and BASFI/DFI concurrently adjusting for BASDAI and other covariates, a multivariate analysis was performed using GEE with BASFI or DFI as dependent variables, and mSASSS and BASDAI as covariates, concurrently adjusting for age, sex, duration of illness, HLA-B27 status and hip involvement.

Both BASDAI and mSASSS contributed independently to the BASFI and DFI explanations with significant parameter estimates. Regression coefficients describe the independent relationship between the explanatory variables and the dependent variable: in the environment, compared to a patient with mSASSS 40, a patient with the mSASSS score 50 has a BASFI of 0.57 times greater, independent of BASDAI.

All mSASSS subscripts contributed independently to the explanation of BASFI variations (p<0.001). Compared to the mSASSS model, which had the best result, the model with the total score of the syndesmofite, the number of the affected vertebral units, the number of vertebral vertebral units, and the model with the non-spondysmophy sumary score, it was deduced that the syndesmophites are in much but not exclusively responsible for explaining variations in BASFI. A model with the syndesmophites summary score (p<0.001) and the non-spondysmophy (p=0.002) shows that both components contribute significantly to the explanation of BASFI variations. Results with DFI were similar.

Using mSASSS, the syndesmophyte subservices, the affected vertebral units or vertebral vertebral units, we showed that lumbar and cervical spine involvement contributed independently and almost similarly to explaining variations in BASFI and DFI.

Conclusions: The study conducted by us demonstrates that the patient’s physical function is not only dependent on signs and symptoms reported by the patient (activity of the disease), but also on the degree of structural lesions. Optimal AS treatment should not only include strategies aimed at removing pain, redness and swelling, but also strategies aimed at preventing the formation and growth of syndesmophyte.

THE BURDEN OF DISEASE IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLARTHROSIS IS NOT INFERIOR TO THAT OF ANKYLOSING SPONDYLITIS. THE PROOF STUDY

Objectives: To compare disease burden between patients fulfilling criteria for AS and axSpA-nr.

Methods: Sub-analysis of Spanish patients from the PROOF study, an international prospective observational longitudinal study conducted in rheumatology clinics. All patients who attended rheumatology clinics due to CLBP (>3 months, start <45 years of age) from 2017 to 2018 not previously diagnosed were consecutively included. The ASAS criteria were applied to all, with centralised image reading. Patients with AS and axSpA-nr were compared.

Results: 192 patients with CLBP were included, of whom 151 (79%) met criteria of SpA-ax, 56 (43%) of AS and 74 (57%) of axSpA-nr (21 patients had X-ray missing or no central reading had been done so far). The table shows the description of patients with AS and axSpA-nr and their comparison.

IMPACT OF APPLICATION OF ASAS CRITERIA FOR AXIAL SPONDYLOARTHRITIS ON THE DIAGNOSTIC DELAY IN EGYPTIAN PATIENTS

F.I. Abdelrahman, M. Mortada. Rheumatology, ZAGAZIG UNIVERSITY, zagazig, Egypt

Background: Diagnostic delay is a major challenge in axial spondyloarthritides (SpA). The 2009 Assessment of SpondyloArthritis international Society
OBJECTIVES: To evaluate the period from symptoms onset to diagnosis in Egyptian patients with axial SpA before and after application of ASAS criteria for axial SpA and to examine possible reasons for delayed diagnosis.

Methods: The study included all axial SpA patients attending a university tertiary referral centre for regular follow up in the period between May 2016 to November 2017. The patients were divided into 2 groups; group 1 included patients with a diagnosis of axial SpA before the beginning of 2010 (when ASAS criteria became widely available and in use) and group 2 included patients with a diagnosis of axial SpA after the beginning of 2010. A face-to-face interview was applied for both groups to take medical history, and a questionnaire that contains some clinical aspects of disease was used. Diagnosis delay was described as the gap between first SpA symptom and correct diagnosis of axial SpA. Clinical and functional assessment of axial SpA measured by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI). The direct medical cost during years of delay (including costs of medical consultations, medications, investigations, physiotherapy and surgical treatment) had been estimated.

Results: As presented in table 1; more axial SpA cases were in group 2 (diagnosed after the beginning of 2010) with significantly narrower gap of delay, younger age at diagnosis, lesser number of doctor visits, lesser number of unnecessary spinal surgeries, lower total direct estimated costs and better BASDI, BASFI and BASMI.

Conclusions: Application of ASAS criteria for axial SpA has resulted in a significant decrease in the diagnostic gap which is reflected in a significant decrease in the costs of unnecessary medications. On the other side, the gap is still large and more sensitive criteria are still needed.

Problem Total Activity Impairment. *P*values from 2-sided t test for scale variables and Fisher exact test for categorical variables; statistical comparison between nr-axSpA and AS; *p*<0.05, **p**<0.001.

**Conclusions:** Clinical features and disease burden were generally similar between nr-axSpA and AS pts in the Chinese PROOF subpopulation. AS pts were more frequently men, had higher inflammatory burden (CRP and ASDAS-CRP), more functional impairment, and were more frequently treated with TNF inhibitors.

### ACUTE PHASE REACTANT CHANGE IN ANKYLOSING SPONDYLITIS PATIENTS

F. Deimer, G. Kenar, B. Zengin, H. Yarkan, S. Capan, M. Britik, F. Ocen, N. Akkoc, G. Can. **Rheumatology, Department of Statistics, Dokuz Eylul University, Izmir, Turkey**

**Background:** The aim of this study is to investigate the levels of acute phase reactants (APRs) in patients with ankylosing spondylitis (AS) at the time of diagnosis and during follow-up. We also evaluated the associations between APR levels and disease activity.

**Methods:** The study included 948 patients with AS who were followed-up at Dokuz Eylul University School of Medicine Rheumatology outpatient clinic. The patients’ erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels across all visits were retrospectively reviewed through the Turkbio registry and the hospital’s database. Disease activity and follow-up parameters as BASDAI, ASDAS, BASFI and BASM1 were taken from Turkbio visit charts. The correlation between APR and follow-up parameters were evaluated with Spearman correlation coefficient analysis.

**Results:** There were 948 AS patients (69% male, mean age 46.6±12.1 years) who fulfilled the 1984 modified New York criteria. At first visit, high levels of CRP and ESR were observed in 626 (68.5%) and 578 (64.6%) patients respectively. During follow-up 84.6% of patients had high CRP and 69.5% patients had high ESR at any visit (figure 1). However in 10% of AS patients APRs did not increase at any visits.

There was good correlation between ESR and CRP (r=0.666, p<0.001). A better correlation was observed at first visit between CRP and BASDAI (r=0.31, p=0.23) or ASDAS (r=0.468, p<0.001) compared to ESR and BASDAI (r=0.11, p=0.02) or ASDAS (r=0.334, p<0.001) (table 2). Compared to BASDAI, ASDAS with either CRP (r<0.001) or CRP (very high disease activity p<0.01, inactive disease, p=0.001) had better performance in evaluating the activity of the patient in inactive and very high levels of severe disease (table 2).

**Conclusions:** There is no correlation between APRs and disease activity in majority of AS patients. However, CRP had better performance in measuring a change in disease activity compared to ESR.

### HEALTH STATUS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS (AXSAP) AS DETERMINED BY THE ASSESSMENT OF SPONDYLOARTHRITIS INTERNATIONAL SOCIETY HEALTH INDEX (ASAS-HI)

R. Burgos-Vargas1, G. Alva Medina2,3, on behalf of Sacroiliacos, I. Peláez3

**Rheumatology, CMN LA RAZA, CDMX, Mexico**

**Background:** The ASAS-HI is a new instrument based in the International Classification of Functioning, Disability and Health to assess the impact of axSpA; ASAS-HI has been validated in Mexican patients.

**Objectives:** To investigate the status of health in Mexican patients with axSpA using the ASAS-HI

**Methods:** This is multicenter, cross-sectional study of 377/423 patients with axSpA (ASAS criteria) referred by 64 rheumatologists with private or institutional practice across the country in a period of six months. Sociodemographic and clinical data were collected at each site and analysed centrally.

**Results:** The ASAS imaging arm were fulfilled 87.5% and the clinical by 61.8%; sociodemographic data were collected at each site and analysed centrally. The ASAS-HI associated with those patients who elevation only ESR/CRP or with both elevation together at any visit.

**Conclusions:** In over 80% patients with AS had elevated levels of CRP, the most frequently used laboratory parameter, during follow-up. CRP is well correlated with ESR, and disease activity parameters as BASDAI, ASDAS, BASFI and BASMI. Compared to BASDAI; ASDAS had better agreement between activity and APRs. Interestingly, in 10% of AS patients APRs did never increase in follow-up.

ANTEORIOR THORACIC FATTY CORNER LESIONS ARE USEFUL IN AXIAL SPONDYLOARTHRITIS (SPA) DIAGNOSIS – DATA FROM A MULTICENTER BACK-PAIN-MRI COHORT IN HONG KONG

H.Y. Chung, S.W.R. Yu, H.H.L. Tsang. 1The University of Hong Kong; 2QUEEN MARY HOSPITAL, Hong Kong, Hong Kong

Background: A fatty corner lesion (FCL), as defined by fat infiltration at the vertebral corner in T1 Magnetic Resonance Imaging (MRI) sequence, has been reported to be useful in Spondyloarthritis (SpA) diagnosis.

Objectives: Our objective is to systematically evaluate the diagnostic utility of FCLs in a large, multicenter back-pain-MRI cohort in Hong Kong.

Methods: Three hundred and one patients with back pain were recruited from 3 rheumatology centres. Clinical, biochemical and radiological parameters were collected and all patients underwent a whole spine and sacroiliac (SI) joints MRI. FCLs from C4 to L5 levels were scored. Results were compared to expert-diagnosed axial SpA to determine the usefulness of FCLs in disease diagnosis.

Results: Anterior FCLs of whole or thoracic spine were found to be useful in axial SpA diagnosis. (AUC 0.622; p=0.003, AUC 0.640; p=0.001 respectively) Applying FCLs to the Modified New York (MNY) criteria and Assessment of SpondyloArthritis international Society (ASAS) axial SpA criteria, a minimum of 5 FCLs at whole spine level had a sensitivity of 66.4% and 91.6%, specificity of 98.4% and 91.9% respectively. Applying a minimum of 3 FCLs at thoracic spine level to the MNY criteria and Assessment of SpondyloArthritis international Society (ASAS) axial SpA criteria yielded a sensitivity of 68.5% and 92.0%, specificity of 93.8% and 91.9% respectively. Applying a minimum of 3 FCLs at thoracic spine level to the Modified New York (MNY) criteria and Assessment of SpondyloArthritis international Society (ASAS) axial SpA criteria, a minimum of 5 FCLs at whole spine level had a sensitivity of 66.4% and 91.6%, specificity of 98.4% and 91.9% respectively. Applying a minimum of 3 FCLs at thoracic spine level to the MNY criteria and ASAS axial SpA criteria yielded a sensitivity of 68.5% and 92.0%, specificity of 93.8% and 91.9% respectively. Three FCLs improves both classification criteria.

Conclusions: FCLs are useful in axial SpA diagnosis. A minimum of 3FCLs at the thoracic level is useful for the disease diagnosis.

ANALYSIS OF THE FREQUENCY OF UVEITIS IN SPONDYLOARTHITIS PATIENTS AND ASSOCIATIONS WITH CLINICAL PARAMETERS OF THE DISEASE

I.M.S. Vale, M.D.S. Mastella, R.B. Trevisol, M.M. Pereira, M.J. do Carmo, I. A. Pereira. Universidade do Sul de Santa Catarina (UNISUL), Florianopolis, Brazil

Background: Acute anterior uveitis is the most common extra-articular manifestation of spondyloarthritis (SpA). The ocular inflammation in SpA is restricted to the uvea, usually unilateral and in some cases may precede the clinical characteristics of SpA.

Objectives: The aim of this study is to analyse if the presence of uveitis is associated with a different clinical manifestation, laboratory, radiological and therapeutic among spondyloarthritides patients.

Methods: This was an observational retrospective study with 153 patients with spondyloarthritis included in the period from 1997 to 2017 in Florianopolis, Brazil. It was analysed demographics, laboratory, clinical and therapeutic data in spondyloarthritis patients with or without uveitis.

Results: 26.8% of the patients with spondyloarthritides presented uveitis. The presence of complications was rare, but cataract occurring in only four patients and glaucoma in two of them. A higher frequency of acute anterior uveitis in males (p=0.06) was observed in patients with a family history (p=0.19) and HLA-B27 positive (p=0.14). Patients with spondyloarthritides and uveitis more frequently used anti-TNF (p=0.04) and presented sacroiliitis on imaging tests (p=0.02). There was no association between uveitis and cardiovascular (p=0.44), cutaneous (p=0.13) or gastrointestinal involvement (p=0.10).

Conclusions: Uveitis in patients with spondyloarthritides is common, predominantly in males and more frequently, in HLA-B27 positive patients. Ocular manifestation in spondyloarthritis has a degree of complication when compared to uveitis from other etiologies. The use of immunobiological agents such as anti-TNF is common in patients with uveitis.

THE IMPACT OF DISEASE ACTIVITY, STRUCTURAL DAMAGE, AND FATIGUE ON PHYSICAL FUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: DIFFERENCES IN EARLY AND LATE DISEASE

J. He, S., L. Sarl1, R. Inman, N. Haroon. 1Rheumatology, Toronto Western Hospital; Toronto; 2Rheumatology, Western University, London, Canada

Background: In patients with ankylosing spondylitis (AS), the physical function impairment caused by the disease is among the biggest concerns for both patients and clinicians. Previous studies have shown that disease activity and structural damage are the main underlying causes for physical function impairment. There is accumulating evidence that suggests fatigue as well contributes to functional limitations. However, the differential impact of these factors on physical function at early and late stage of disease remains unclear.

Objectives: Study the strength of association in AS patients with varying disease duration, between physical function and the three potential determinants of interest: disease activity, structural damage, and fatigue.

Methods: AS patients satisfying the modified New York criteria were followed from 2003 to 2017. Patients completed a standardised annual protocol including demographic and clinical factors, with radiographic data collected biennially. Baseline physical function (BASFI) was analysed for association with factors including disease activity (BASDAI), radiographic changes (mSASSS), and fatigue (FSS). The same analysis was conducted again with patients sub grouped with respect to disease duration (<5 years, 5–9 years, 10–20 years, >20 years), and again with respect to change in BASFI between the first and last patient visit.

Multivariable regression analysis was performed to identify independent predictors of physical function at baseline and the change with time.

Results: A total of 611 patients were followed and completed the standard protocol (mean age at initial visit 38.2 years; 74% male; 76.5% HLA-B27+). At baseline BASFI was independently associated (table 1) with BASDAI (p<0.0001), CRP (p<0.0001), mSASSS (p<0.0001), and FSS (p<0.0001). In the disease duration subgroup analysis, BASFI was independently associated with BASDAI (p<0.05) and mSASSS (p<0.05) in all disease durations, but in subgroups with disease duration of 5 years or greater (p<0.05). In the longitudinal analysis, change in BASFI was independently associated with changes in BASDAI (p<0.0001) and FSS (p<0.05), but not with change in mSASSS (p=0.283).

</table>
Conclusions: The study demonstrated that disease activity and structural changes consistently contribute to physical function impairment in both early and late stages of disease. Fatigue does not associate with physical function at early stages of the disease, but it increases in contribution to functional impairment as disease duration increases.

AB0865

DO ASAS, ASDAS AND BASDAI THERAPY RESPONSE EVALUATION TRANSLATE THE SAME INFORMATION?

Background: The ASAS-EULAR recommendations for the continuation of biological Disease-Modifying Anti-rheumatic Drugs (DMARD) suggest the evaluation of patients after at least 12 weeks of treatment by either the Anti-Tumour Necrosis Factor (AS) Disease Activity Score – C reactive protein (ASDAS-CRP) or by the Bath AS Disease Activity Index (BASDAI). For ASDAS-CRP, a Minimal Clinical Important Difference (MCID) ≥1.1 is necessary, while for the total BASDAI score a 50% reduction or a change of >2.0 points is considered clinically relevant. In clinical trials, the Assessment in Ankylosing Spondylitis (ASAS) response criteria – ASAS 20, ASAS 40 and ASAS 70 – are still the most frequent outcome measures to evaluate improvement in treatment response. However, in clinical practice the BASDAI is still routinely used.

Objectives: The aim of this work was to assess the concordance/agreement between different therapeutic outcome measures, such as the ASAS response criteria, ASDAS-CRP and BASDAI 50.

Methods: Data from 54 patients who fulfilled the modified New York criteria for AS were collected at baseline, weeks 2 and 14 post-treatment with Adalimumab. Pearson’s correlation (PCCs) and the Cohen’s Kappa coefficients were calculated for the three scores.

Results: A strong correlation was found between the three scores throughout the visits: rho=−0.676 for ASDAS/ASAS, rho=−0.807 for ASAS/BASDAI, and rho=−0.786 for BASDAI/ASDAS (all PCCs with p<0.001). Additionally, when the categorization in different disease activity states and response levels was performed, PCCs revealed significant concordance/agreement between the three scores’ cut-offs (see table 1).

The individuals categorised as responders, by either BASDAI50 or ASDAS ≥1.1, have shown similar clinical characteristics (Erythrocyte Sedimentation Rate, CRP, AS Quality of Life Scale and Bath AS Functional Index) importantly, when more stringent measures of ASAS response criteria and ASDAS were used (i.e. ASAS 70 and ASDAS ≥2.1) the agreement with BASDAI values decreased.

Abstract AB0865 – Table 1. Summary information of the Agreement and Cohen’s kappa.

</tr>
</tbody>
</table>

Conclusions: Our results suggest that the ASAS response criteria, ASDAS-CRP and BASDAI 50 report the same clinical information. Hence, the clinician’s decision should still be consistent independently of the score adopted. However, this study also highlights the importance of establishing a new and more stringent BASDAI cut-off, in alignment with ASDAS-CRP ≥2.1 and ASAS 70.

ADVANCED METROLOGY IN PATIENTS WITH AXIAL SPONDYLOARTHROPATHIES: LUMBAR OR THORACIC? LUMBAR MEASUREMENTS FOR SPINAL MOBILITY ASSESSMENT?

I.C. Aranda-Valera1, L. Garcia-Luque2, S. Alcaraz-Cliarina3, J.L. Garrido-Castro4, I. Martinez-Sanchez4, C. Gonzalez5, P. Gardiner6, P.M. Machado7, E. Collantes8, on behalf of ImMaxSpA Study Group, HU Reina Sofia, IMIBIC, Cordoba, Spain; WHSCT, London, UK

Background: Advanced technologies for measuring human mobility have recently emerged: motion capture, inertial measurement units (IMU) and wearable devices. Some of them are used for mobility assessment of rheumatic patients. Certain devices analyse only lumbar mobility of the patients. Axial Spondyloarthri-

‡ devices suggest the evaluation of lumbar mobility at all levels and not only at the lumbar level.

Objective: To analyse what is the contribution of the thoracic spine to spinal mobility, and if this contribution should be taken into account in the metrological assessment of patients with axSpA.

Methods: 20 patients with axSpA and 20 age, BMI and sex-matched healthy subjects were recruited. An IMU sensor-based system (ViMove©) was used to measure spinal mobility. This system uses two IMU sensors and the angle between both is obtained in real time. Two tests were recorded: one with the recommended anatomical location (pelvis and L1) and another one aimed at combining lumbar +thoracic movement (pelvis and T3). Conventional metrology, radiographic structural damage (axSpA patients) and PROs were also collected.

Results: The table shows the results obtained for measuring only lumbar or lumbar + thoracic mobility, in both groups. The contribution of the thoracic spine is expressed in % of the total movement. Pearson correlation coefficients (only for patients) with conventional metrology (BASMI), PRO questionnaires (BASDAI, BASFI and ASQoL) and structural damage (mSASSS) scores are also presented.

**p<0.001; ***p<0.01; *p<0.05.

Conclusions: Thoracic + lumbar results reflect better the spinal mobility impairment of axSpA patients compared to lumbar spine assessments only. Compared to isolated lumbar spine assessment, the combined assessment showed better correlations with conventional metrology, disease activity, physical function, health-related quality of life and spinal structural损害. Despite this, the magnitude of the differences is not enough to reject the use of a system that only considers assessment of lumbar spinal mobility.

AXIAL SPONDYLOARTHRITIS POSTURE ASSESSMENT USING INERTIAL SENSORS

J.L. Garrido-Castro1, I.C. Concha-Aranda2, P. Gardiner3, P.M. Machado4, J. Williams5, E. Collantes-Estevez6, on behalf of iMaxSpa Study Group. 1IMIBIC; 2HU Reina Sofia, Cordoba, Spain; 3WHSCST, Londonderry; 4UCL, London; 5BU, Bournemouth, UK

Background: Axial Spondyloarthritis (axSpA) often causes spinal deformity in patients, most commonly a flared kyphotic posture. In the early stages a flattening of the lumbar spine or reduced lordosis may become apparent. Kyphosis of the thoracic and cervical spine is also common in severe cases, resulting in an increased ‘tragus to wall distance’ as clinically assessed in the BASMI score. No other measurement related to posture is routinely recorded in clinical practice. Inertial Measurement Units (IMU) is a new technology that can measure angles of anatomical regions where the sensor is located.

Methods: To compare the spinal curvature of axSpA and healthy individuals to other measurement related to posture is routinely recorded in clinical practice. AxSpA patients and healthy age, BMI and sex matched controls, were recruited. An IMUs system (ViMove©) was used to obtain angles at key anatomical regions where the sensor is located. Results: Pelvis lordosis was increased in the axSpA group, resulting in a decrease in the lumbar lordosis. Schöber measurement was increased, but the lordosis correction could also be a very important factor contributing to pain, stiffness and structural damage in the lumbar spine that reduces their mobility and quality of life. The biomechanical features of axSpA have not been investigated in detail, but could prove to be a very important factor contributing to pain, stiffness and mobility.

Conclusions: IMU based sensors are a useful new tool for the assessment of axSpA patients. This is the first formal evaluation of posture in axSpA and seems to be a promising tool in the functional evaluation of axSpA patients. More studies (reliability, feasibility, sensitivity to change, etc.) are needed for validating these measures.

AXIAL SPONDYLOARTHRITIS IS ALTERED IN COMPARISON WITH HEALTHY SUBJECTS

I.C. Aranda-Valera1, S. Alcaraz-Clariana2, L. Garcia-Luque3, J.L. Garrido-Castro4, I. Martinez-Sanchez2, C. Gonzalez3, P. Gardiner3, P.M. Machado4, E. Collantes5, on behalf of iMaxSpa Study Group. 1HUS, Cordoba, Spain; 2IMIBIC, Cordoba, Spain; 3WHSCST, Londonderry; 4UCL, London, UK

Background: Axial Spondyloarthritis (axSpA) patients have inflammation and/or structural damage in the lumbar spine that reduces their mobility and quality of life. The biomechanical features of axSpA have not been investigated in detail, but could prove to be a very important factor contributing to pain, stiffness and mobility.
Conclusion: axSpA increases lumbar muscle stiffness with respect to healthy individuals. Muscle stiffness, as measured by myotonometry, was related to loss of movement and could be contributing to a loss of function independently of structural damage and inflammation in axSpA. These new outcome measures could be helpful for understanding the evolution of the disease and for the functional assessment.

Conclusions:

The results obtained suggest that the follow-up of a cohort of patients with spondylarthropathy in a specialised monographic medical centre allows a control of the symptoms, with a low recurrence of extra-axial manifestations. We can conclude from this study that most patients with spondylarthropathy (75%) could have good control of their disease with NSAIDs in the long term.

PREDICTIVE VALUES OF INFLAMMATORY LOW BACK PAIN, POSITIVE HLA B 27 ANTIGEN, INCREASED C-REACTIVE PROTEIN, POSITIVE MAGNETIC RESONANCE AND OTHER FEATURES IN AXIAL SPONDYLOARTHRITIS (SPA). A PROSPECTIVE 2 YEARS FOLLOW UP

J.Y. Komsajova, A. Valdivia, P.M. Salinas, 1 Rheumatology; 2 Epidemicology and preventive medicine; 3 Radiology department; Hospital Marina Salud, Denia, Spain

Background: Diagnosis of Spondyloarthritides remains challenging in the daily practise. Inflammatory back pain might be a good tool for early diagnosis.

Objectives: To analyse sensitivity, specificity and predictive values of inflammatory back pain (IBP), positive HLA B27 antigen, increased C-reactive protein (CRP), positive sacroiliac joints (SI) magnetic resonance (MRI) imaging, additional features (AF) such as peripheral arthritis, dactylitis, psoriasis, uveitis, inflammatory bowel disease (IBD) and familiar history (FH) and assess probabilities to develop SPA.

Methods: We prospectively collected and follow up 82 patients referred to our department with suspicion of SPA from September 2014 to December 2016. Data such as IBP, HLA B27, additional features, familiar history of SPA, increased CRP, sacroiliac x-Rays and sacroiliac MRI imaging was performed for each patient. Each MRI image was separately and independently evaluated by rheumatologist and radiologist.

Results: The average age in our study was 39.8 years with male/female ratio 0.4/1. 37 (45.1%) patients were diagnosed with axial SI. Radiographic sacroiliitis had only 5 (6.1%) patients. AF had 21 (25.8%) patients. IBD was found in 36 (43.9%) patients, positive HLA B27 antigen in 24 (29.3%) and increased CRP in 22 (26.8%). Sacroiliac joints (SI) MRI images were assessed as clearly positive if patients had more than 2 highly specific for SPA bone marrow oedema (BME) lesions, at least 3 fatty lesions and more than 1 erosion, positive MRI image if patients had at least 2 highly specific BME lesions, and clearly negative MRI images if patients had not got any of those features. We found 83.76% sensitivity and 88.89% specificity for IBP, 37.84% sensitivity and 89.55% specificity for positive HLA B27 antigen, 43.24% sensitivity and 88.1% specificity for increased CRP, AF such as peripheral arthritis, dactylitis, psoriasis, uveitis and IBD, evaluated together reached sensitivity 37.84% and specificity 84.44%. Positive FH only contributed to the diagnosis with 13.51% sensitivity, but showed higher specificity (84.44%). Sensitivity for positive SI MRI imaging were poor (51.35%) but reached excellent specificity (100%). Predictive values in our study were as follows: 86.11% predictive positive values (PPV) and 86.96% predictive negative value (PNV) for IBP, 63.64% PPV and 59.65% PNV for HLA B27, 76.19% PPV and 63.79% PNV for increased CRP, 66.67% PPV and 62.30% PNV for AF.

Positive FH contributed to the diagnosis with 66.67% PPV and 62.30% PNV. Positive MRI reached 100% PPV and showed high PNV – 71.43. Multivariate analysis displayed 81.8% likelihood to be diagnosed for SPA if only IBP without AF at the onset of the diagnosis and 94.8% if both IBP and AF were present.

Conclusions: At the onset, IBP may be a good indicator for SPA with high sensitivity and acceptable specificity. Additional feature such as peripheral arthritis, dactylitis, psoriasis, uveitis and IBD might increase the possibility of SPA. HLA B27 antigen, increased CRP and FH brings low sensitivity for SPA nevertheless, specificity is better. Positive SI MRI imaging is highly specific but lacks sensitivity. Normal SI radiography at the onset does not rule out diagnosis of SPA.

AB0872

QUANTIFERON TB GOLD TEST IN DIAGNOSIS OF LATENT TUBERCULOSIS INFECTION AMONG A MOROCCAN POPULATION WITH SPONDYLOARTHROSIS

J. Eddarami, L. Ichchou. Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco

Background: Patients treated with anti-tumour necrosis factor-alpha (anti-TNF-α) are at increased risk for latent tuberculosis reactivation. However, the best method for latent tuberculosis infection (LTBI) detection before initiation of anti-TNF therapy remains to be determined.

Objectives: The aim of this study is to investigate the role of Quantiferon-TB Gold test as one of the interferon-gamma release assays (IGRAs) in detecting LTBI before initiation of biotherapy in a population of Moroccon patients suffering from spondyloarthritides (SpA).

Methods: We have conducted a cross-sectional study over two months in our department of rheumatology. All SpA patients fulfilled ASAS 2009 criteria. Tuberculin skin test (TST), Quantiferon-TB Gold in Tube (QFT-GIT) assay and chest radiographs were performed before starting anti-TNF-alpha. Computed tomography was performed in patients with abnormal chest radiographs.

Results: We included ninety two patients with SpA. Among them, 35 (38%) received anti-TNF-α therapy. A history of tuberculosis disease was noted in 6 patients (6.6%) (3 Pulmonary TB and 3 extrapulmonary TB). Two patients (2.2%) had contagious tuberculosis. The positive QFT-GIT rate was 15.2% (14/93). The TST was negative in 16.3% of cases (15/93). The results of QFT-GIT and TST performed in the same patients were discordant in 5 cases (5.4%). Sputum smears were negative. Chest CT performed in 29 patients had shown bronchiectasis in 3 cases (3.7%), interstitial syndrome in 2 cases (2.5%) and was normal in 24 cases (29.6%).

The chemoprophylaxis was prescribed in 14 persons with a positive QFT-GIT. It was based on isoniazid (INH) alone in 12 cases (13%), a triple therapy (RH2) in one case (1.1%) and a quadrithrapy (RHZE) in another case with active tuberculosis. The duration of chemoprophylaxis varied between 6 and 9 months in the case of monotherapy, 2 months in the case of triple therapy because of biologic hepatotoxicity, and 6 months in the case of quadrithrapy because of active TB occurring during anti-TNF alpha therapy. The delay in initiating biotherapy varied between 1 and 6 months. At the time of blood sampling for QFT-GIT, patients were receiving: steroids in one case (1.1%), Methotrexate (MTX) and steroids in 3 cases (3.3%), Sulfasalazine (SSZ) in 2 cases (3.3%), MTX in 4 cases (4.3%) and MTX and SSZ in 2 cases (2.2%).

Conclusions: QTB-G may be a more sensitive screening tool for LTBI before initiating anti-TNF therapy in immunocompromised patients, especially in a TB endemic country.

US RHEUMATOLOGISTS HAVE MIXED PERCEPTIONS ABOUT MANAGING PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS AND ANKYLOSING SPONDYLITIS

J. Robinson, L. Price, Advanced Analytics Group, Spherix Global Insights, Exton, USA

Background: Non-radiographic axial spondyloarthritis (nrAxSpA) is a relatively new term used to describe patients who clinically appear to have ankylosing spondylitis (AS) but do not exhibit radiographic sacroiliitis. Though several biologics are currently FDA approved for the treatment of AS, there are no agents approved for patients in which there is not radiographic evidence of sacroiliitis. With several agents under investigation with the hopes of gaining a line-extension label for nr-axSpA, it is important to understand how the current treating rheumatologists view these two diseases and their current and future plans for spondyloarthritis management.

Objectives: The study sought to (a) evaluate the differences between AS and nr-axSpA diagnosis and treatment patterns (b) highlight the challenges clinicians face in managing patients with nr-axSpA and (c) understand rheumatologists’ willingness to use biologic agents to treat nr-axSpA.

Methods: An independent market analytics firm collaborated with US rheumatologists (n = 98) to learn about current and anticipated changes to the management of Ankylosing Spondylitis and Non-radiographic Axial Spondylitis. Participants were administered an online survey, lasting approximately 30 min in length and respondents were compensated for their professional time. Following the fieldwork, data were analysed in SPSS, a statistical software, to determine significant differences.

Results: 87% of the surveyed rheumatologists agree that AS and nr-axSpA are part of a spectrum, and 37% report that they often find it challenging to differentiate between the two conditions. The majority of the respondents report that they treat these conditions in a very similar manner. In fact, 40% agree that distinguishing between the two has no relevance to their treatment decisions. Use of biologics is significantly more pronounced in AS (56% vs. 39%, respectively), largely because there is currently no FDA indicated biologic for nr-axSpA and because many rheumatologists view nr-axSpA simply as a less severe precursor to AS, where aggressive treatment with a biologic is not warranted. In order to gain reimbursement for a biologic in patients with nr-axSpA, rheumatologists frequently classify patients as having AS (as opposed to nr-axSpA). Although adalimumab is the most frequently prescribed biologic in both conditions, rapid adoption of an IL-17 inhibitor (secukinumab) is occurring in the US market.

Conclusions: There is a need to educate both primary care physicians and rheumatologists about the differences between AS and nr-axSpA. The official FDA approval of biologic agents in nr-axSpA is anticipated to lead to more aggressive treatment of these patients earlier in the spectrum.

MENTAL HEALTH DISORDERS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: INCREASING OUR UNDERSTANDING OF THE DISEASE. RESULTS FROM THE ATLAS-2017

M. Garrido-Cumbres1,2, V. Navarro-Compán3, D. Gálvez-Ruiz1, C. Delgado-Dominguez1, P. Font Ugalde4, O. Braña1, P. Zarcó1, J. Chacón-García1, P. Plazuelo-Ramos1,1 Universidad de Sevilla, Sevilla, Spain; 2CEADE, 3Rheumatology, Hospital La Paz, IdiPaz, Madrid, Spain; 4Medicina, Universidad de Córdoba, Córdoba, Spain; 5Rheumatology, Hospital Fundación Alarcón, Madrid, Spain

Background: Depression and other mental disorders are among the most prevalent comorbidities in patients with axial spondyloarthritis (axSpA). The study sought to (a) evaluate the differences between sociodemographic and mental health comorbidity with risk of mental disorders (RMD).

Objectives: To assess the association between sociodemographic characteristics, disease progression, and mental health comorbidity with risk of mental disorders (RMD).

Methods: In 2016 a sample of 680 axSpA patients was interviewed as part of the Spanish Atlas. To quantify the RMD, GHQ-12 scale was employed. Possible RMD predictors taken into account in the analysis were: sociodemographic characteristics (age, gender, being part of a couple, patient association membership, job status); disease characteristics (BASDAI, spinal stiffness, functional limitation in 18 daily activities; and mental health comorbidities. All clinical variables showed a Cronbach’s alpha coefficient guaranteeing the reliability of the scales used. First, a descriptive analysis was employed to describe the sample and study variables. Second, univariate correlation and homogeneity analyses between each predictor (independent variable) and RMD (GHQ-12) were performed.

Results: All variables except educational level and thoracic stiffness showed significant univariate correlation with RMD. BASDAI, functional limitation and age showed higher coefficient (r = 0.543, p < 0.001; r = 0.378, p < 0.001; r = -0.174, p < 0.001, respectively).

Multiple hierarchical regression analysis showed as sociodemographic variables explained in great detail the RMD (R² = 83.2%). By contrast, having established sociodemographic as a control variable, the inclusion of depression and anxiety to the model increased the R² value to just 0.6% (p < 0.001), while the inclusion of variables related to the disease characteristics add 5.5% (p < 0.001) to the GHQ-12 punctuation variability. The only variables presenting a significant coefficient different from 0 were BASDAI (0.52, p < 0.001) and functional limitation (0.14, p < 0.01). This suggests that once the sociodemographic and mental comorbidity variables are established, a change in BASDAI levels or functional limitation impacts the GHQ-12 score.

In the stepwise regression analysis, four variables (BASDAI, functional limitation, association membership, cervical stiffness) showed a significant relation to GHQ-12 and explained the majority of RMD variability. BASDAI displayed the highest explanatory degree (R² = 0.875, p < 0.001).

Conclusions: In axSpA, patients at certain sociodemographic levels are more prone to present a higher BASDAI. Taking these conditions for granted, the degree of disease progression measured by BASDAI is a good indicator of RMD. Therefore, in those patients with higher disease activity, psychiatric evaluation and intervention should be considered within the medical treatment.

QUALITY OF LIFE IMPROVEMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS TREATED WITH NSAIDS AND BIOLOGICAL THERAPY FROM THE PATIENT’S PERSPECTIVE: RESULTS FROM THE ATLAS-2017

M. Garrido-Cumbres1,2, D. Gálvez-Ruiz1, J. Gratacos2,3, C. Blanch Mur2, V. Navarro-Compán3,4, Universidad de Sevilla, Sevilla, Spain; 2CEADE, Madrid; 3Rheumatology, Hospital Universitari Parc Taulí, Sabadell, 4I3PT, UAB; 5Novartis, Barcelona; 6Rheumatology, Hospital Universitario La Paz, IdiPaz, Madrid, Spain

Background: In patients with axial spondyloarthritis (axSpA), the main long-term outcome is quality of life. Clinical trials and observational studies have shown the efficacy of biological therapy (BT) on improving the signs and symptoms of the disease. However, data assessing the impact of BT on quality of life is scarce and mainly comes from clinical trials.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2018-eular.7240
**Objectives:** To assess in clinical practice the improvement in quality of life from the patient’s perception as a result of pharmacological treatments in axSpA.

**Methods:** A sample of 680 patients diagnosed with axSpA was interviewed through an online survey as part of the Spanish Atlas-2017, which aimed to promote early referral, improve healthcare, and the use of effective treatments in patients with axSpA. For this study, self-reported data from patients who had received both NSAIDs and BT were analysed. Patients were asked about the improvement they had experienced on 7 different aspects of quality of life after starting treatment with NSAIDs or BT: independence, leisure and free time, social relations, sport and physical activity, and mood and sexual relations. Improvements were measured on a 0 to 10 Likert Scale and classified as low (<5) and high (≥6). Non-parametric (Wilcoxon) tests were used to compare the degree of improvement between patients with biological therapy and those with NSAIDs.

**Results:** A total of 189 patients who had received both types of drugs were included. The mean (SD) age was 44.03 (±10.11) years, 50.3% were females, 70.9% married and 47.1% belong to a patients’ association. The mean (SD) disease duration was 21.3±10.7 years and 67.7% were HLA-B27+. A higher percentage of patients perceived a high level of improvement after receiving a BT than after receiving an NSAID, for both overall quality of life assessment (57% vs 22%, respectively) and the different quality of life-related aspects. Additionally, the mean degree of improvement for overall quality of life assessment and the different aspects related to this were reported to be significantly higher after receiving BT than after NSAIDs (overall improvement: 5.46±2.59 vs 3.19±2.45; p<0.001, respectively).

**Abstract AB0875 – Table 1:** Mean improvement degree and percentage of patients who reported high improvement (>6 in 0–10) in different aspects related to quality of life after receiving biological therapy and NSAIDs

**Conclusions:** In clinical practice, patients’ self-reported satisfaction overall and related to different aspects of quality of life is substantially greater after being treated with BT than with NSAIDs. However, these results need to be confirmed in a longitudinal study.

[1] UNISUL, Florianópolis, Brazil

**Objectives:** Patients with SpA present peripheral involvement, such as arthritis and enthesitis, or only axial involvement, such as sacroiliitis and spondylometaphyseal. The differentiation of the peripheral and axial presentation is important, being able to guide different therapeutic strategies.

**Methods:** This is a retrospective observational study, conducted in two clinics in Florianópolis. The population was composed of patients with AS and non-radiographic and peripheral axial SpA, according to the criteria of modified New York and ASAS group, respectively, served from 1997 to 2017.

**Results:** 153 patients were analysed, 82 were male (53.59%), 71.29% were HLA B27 positive (77/108 tested), 87.3% had sacroiliitis detected on x-ray, CT or MRI, 104 presented peripheral involvement (67.97%) and 49 (32.02%) purely axial involvement. Arthritis occurred in 86 (56.2%) and enthesitis in 57 (37.3%) patients. The use of synthetic DMARD occurred in 78.4% of the patients, more frequently in the group with peripheral involvement, with methotrexate being used in 74% versus 56.3% of those with purely axial involvement (p=0.05). The use of biological DMARD occurred in 104 (68%), in the majority of the anti-TNF class (96.1%), with the highest frequency of use in patients with axial involvement (77.1% versus 64.4%), but not statistically significant (p=0.05). Extra-articular manifestations were found in 72 (47.1%) of the patients, with uveitis being the most frequent (28.6%). The presence of uveitis occurred in 68.3% of patients with isolated axial involvement versus 31.7% of patients with peripheral involvement (p=0.017). The cutaneous involvement occurred in 18.3% of patients with peripheral involvement compared to 8.3% of those with an isolated axial condition. Regarding bowel involvement and cardiovascular impairment, there was no significant difference in prevalence between the two groups.

**Conclusions:** Extra-articular manifestations are frequent in SpA, but are not more frequent in patients with peripheral involvement versus patients with pure axial involvement. Peripheral involvement is associated with greater use of synthetic DMARDs when compared to purely axial involvement.

Comparisons of Clinical Features in Patients with Psoriatic Arthritis and Patients with Spondyloarthritis with Inflammatory Bowel Disease

M. Uematsu1,2, K. Inui1, T. Okano1, Y. Yamada1, K. Manda1, Y. Sugikokai1, K. Mamoto1, T. Kiko3, H. Nakamura1, M. Department of Orthopedic Surgery, Osaka City University Graduate School of Medicine; 2Department of Orthopedic Surgery, Higashisumiyoshi morimoto hospital; 3Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka; 4Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama, Japan

Background: Spondyloarthritis (SpA) is one of the representative comorbidity in patients with psoriasis (PsO) and inflammatory bowel disease (IBD) disease. However, the difference of clinical features between SpA due to PsO (PsA) and SpA due to IBD (IBD-SpA) are unclear.

Objectives: The purpose of this study is to compare the clinical features between patients with PsA and IBD-SpA.

Methods: Overall, 192 patients with PsO and 37 patients with IBD were included in this cross-sectional study. Clinical classification of PsA and IBD-SpA were performed according to the CASPAR1 criteria and ASAS criteria.2 Disease activity (DAS28-CRP), C-reactive protein (CRP), matrix metalloproteinase-3 (MMP-3), anti-cyclic citrullinated peptide antibody (ACPA), rheumatoid factor (RF), biologic disease modifying anti-rheumatic drugs (bDMARDs) use, and proportion of peripheral and axial disease were evaluated in patients with PsA and IBD-SpA.

Results: In this analysis, 74 patients were classified as PsA, 65 patients as PsO, 17 patients as IBD-SpA and 20 patients as IBD. The mean age was 56.0±14.7 years in PsA, 44.7±10.9 years in IBD-SpA (p=0.003). The mean BMI was 24.2±4.5 kg/m² in PsA, 23.3±7.2 kg/m² in IBD-SpA (p=0.18). DAS28-CRP was 3.26 ±1.26 in IBD-SpA (p=0.12). Axial SpA was observed in 4 (5.4%) in PsA, 29 (24.9%) in IBD-SpA (p<0.001). Biologics were used in 29 (39.2%) patients in PsA, 13 (76.5%) patients in IBD-SpA (p=0.007). Proportion of seropositive ratio was not significant in this two groups.

Conclusions: The clinical features between patients with PsA and IBD-SpA were compared. The patient with IBD-SPA was younger than patient with PsA and the prevalence of axial disease was more frequent in IBD-SpA.

# The Objective Automated Measurement of Fluorescence-Signal Intensities in Fluorescence-Optical Imaging Technique Discriminates Between Disease Activity and its Response in AntitNF Treated Psoriatic Arthritis Patients – an Interim Analysis of the Xplore-Study

M. Köhler1,2, S. Ohmdorf1, T. Rossmannith1, A. Ermens3, U. Heine4, G. Schmittat1, J. Berg5, H. Burkhardt6, F. Behrens2, M. Sahli, O. Saidane, I. Mahmoud, A. Ben Tekaya, R. Tekaya, L. Abdelmoula. Rheumatology, Charles Nicole Hospital, Tunis, Tunisia

Background: Spondyloarthritis (SpA) is an inflammatory rheumatic disease, characterised by spinal involvement, peripheral arthritis, or enthesitis with marked pain, stiffness, and fatigue. Fibromyalgia (FM) may be associated with SpA, and shares some common symptoms.

Objectives: We aimed to estimate the prevalence of FM in SpA and its influence on the assessment of SpA disease activity.

Methods: This single-centre cross-sectional study included consecutive patients with SpA according to the Assessment of SpondyloArthritis International Society criteria. FM was diagnosed according to the 2010 American College of Rheumatology criteria. All patients underwent clinical evaluation of disease activity using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), the Bath Ankylosing Spondylitis Functional Index (BASFI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS) and then compared in patients with and without FM.

Results: The study included 100 patients with SpA, 67 males and 33 females with a median age of 44.65 years. The prevalence of fibromyalgia was 20%. Patients fulfilling the criteria of FM presented a higher total BASDAI (5.86±1.97 vs. 3.15±1.99, p<0.01), higher ASDAS-CRP (3.43±1.13 vs. 2.41±1, p<0.01), higher ASDAS-ES (3.5±1.12 vs. 2.5±1.02, p<0.01) and poorer functional scores (BASFI) (6.76±1.97 vs. 3.8±2.59, p<0.01).

Conclusions: FM is a frequent comorbidity in patients with SpA. In patients with SpA-FM, disease activity may be overestimated and this overestimation could lead to inappropriate treatment escalation.

ASSOCIATION OF RS12218 POLYMORPHISM IN SAA1GENE WITH LUMBAR SPINE SYNDROMESYMPHIES IN THE RUSSIAN ANKYLOSPONDYLITIS POPULATION. A PILOT STUDY

M. Krivov1, S. Erdes1, A. Starkova1, E. Samarkina1, I. Guseva1, N. Konvalova2, D. Varlamov2. V.A. Nasonova Research Institute of Rheumatology, "All-Russian Research Institute of Agricultural Biotechnology, Moscow, Russian Federation

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease from the group of spondyloarthritides (SpA). Earlier studies showed a correlation between SAA1 gene polymorphism, encoding serum amyloid A, and the development of secondary AA-amyloidosis in familial Mediterranean fever and rheumatoid arthritis in Caucasian and Asian populations. The Moriguchi et al (2005) study showed that the −13 T/C polymorphism in the gene 5′-flanking region (rs12218) is a better marker of AA-amyloidosis than mapping of polymorphisms in SAA1 exon 3 (SAA1.1 and SAA1 1.3). Data on rs12218 polymorphism contribution into predisposition to AS and its clinical phenotypes are very scarce. One of the clinical phenotypes, determining the severity of spine damage, is associated with presence of syndromesympties (SM) in the lumbar (SMl), thoracic (SMt) and cervical (SMc) spine, confirmed by x-ray data.

Objectives: To study potential associations of rs12218 polymorphism in SAA1 gene with AS and phenotypes of radiographic progression, with the presence of SMl, SMt and SMc, and correlation with BASDAI, BASFI and ASAS indices.

Methods: rs12218 polymorphism was studied in 112 subjects: 47 AS patients (37 males and 10 females, mean age 40y, mean disease duration 213 weeks, mean age at onset 22y, positive for HLA-B27), and 65 healthy volunteers (controls). Genotyping was performed using allele-specific polymerase chain reaction in real-time (PCR-RT).

Results: The Pearson Correlation analysis showed negative correlation between rs12218 polymorphism and presence of SM, as well as BASDAI, BASFI scores (r=-0.39, r=-0.35 and r=-0.36, p<0.006, p=0.017, p=0.014, respectively). There were no correlations between rs12218 and pts' age, AS duration and pts' age at AS onset. There were similar rs12218 allele distribution rates between AS patients and the controls. rs12218C allele rates were significantly higher in SM positive group (n=23) compared to subjects without SM (n=24) [50.0% vs. 15.2%, p=0.001]. No association was established between C allele and presence of SM in other parts of the spine. A correlation between BASDAI and BASFI scores and SAA1 gene rs12218 polymorphism was established. Mean BASDAI score was significantly higher in carriers of T/C and CC genotypes compared to carriers of TT genotype (5.6±1.3 vs. 3.9±2.3,p=0.004). The mean BASFI scores in carriers of the respective genotypes were (6.1±2.3 vs 4.1±2.8, p=0.012). No significant correlation was found between rs12218genotypes and mean ASDAS score values.

Conclusions: Therefore, this pilot study is the first to show the possible participation of rs12218 polymorphism in SAA1 gene in AS pathogenesis in Russian population. We suggest that C allele may be a risk factor for radiographic disease to SM [OR 5.14, 95% CI(1.75–16.17), p=0.001]. The data obtained on a limited sample of patients require further validation on larger samples of patients involving different population groups.

ACHILLES ENTHESITIS IN THE PATIENTS WITH SPONDYLOARTHITIS: RELATIONSHIP WITH MUSCLE STRENGTH ACTIVITIES OF DAILY LIVING AND QUALITY OF LIFE

Ö. Kuru, B. Farsıogulları, G. Alayk, A. Bilgici, D. Durmuş, Physical Medicine and Rehabilitation, Ondokuz Mayıs University Medical Faculty, Samsun, Turkey

Background: Enthesitis is a central feature of spondyloarthritides (SpA). In SpA, entheses of the lower extremities are more commonly involved than those of the upper limbs, and the heel is the most frequent site. Investigation of peripheral enthesitis in SpA is based on clinical findings and/or imaging findings. The involvement of Achilles tendon may lead to pain, movement restrictions, decrease in muscle strength, and eventually a diminished quality of life (QoL).

Objectives: In the present study, we aimed to evaluate clinical enthesopathy and muscle strength of the lower extremities, activities of daily living (ADLs) and foot and ankle related QoL in the patients with SpA.

Methods: Sixty SpA patients fulfilling the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for SpA (M=F=39/21) (35.8±11.85 years) and 50 healthy controls (M=F=32/18) (35.40±10.62 years) were enrolled in the study. Clinical enthesopathy was defined by the presence of at least one of the spontaneous pain, tenderness elicited by pressure, mobilization and contraction against resistance of the corresponding tendons and local swelling of the enthesis. Pain by visual analogue scale (VAS), disease activity by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional capacity by Bath Ankylosing Spondylitis Functional Index (BASFI), enthesitis severity by SPARCC index was assessed in the patients. Isokinetic measurements of ankle dorsiflexion and plantarflexion were performed by the isokinetic dynamometer. The patients were tested at 30° and 120°/sec angular velocities. Pain, other symptoms (stiffness, swelling, range of motion), ADLs, sport and recreational activities, and foot and ankle-related QoL were evaluated by the Foot and Ankle Outcome Score (FAOS) in which higher scores indicate lesser problems and/or functional limitations.

Results: There was no significant difference between the patients and controls regarding age, sex, and body mass index. Clinical enthesopathy was detected in 36.7% of the SpA patients. Although ankle plantarflexion and dorsiflexion muscle strength in all angular velocities were lower in the SpA patients, the difference did not reach statistical significance (p>0.05). All of the FAOS subscales were found to be significantly lower in the patients with SpA than in the controls (p<0.001). When the SpA patients were divided into two groups as with clinical enthesopathy (n=22) and without clinical enthesopathy (n=38), there were significant differences between the groups regarding VAS pain, BASDAI, BASFI and SPARCC scores whereas there was no significant difference in muscle strength. Also, all FAOS subscale scores were significantly lower in the patients in clinical enthesopathy. Additionally, in the patients with SpA, while there were negative correlations between VAS pain, BASDAI, BASFI, SPARCC and FAOS subscale scores, there was a positive correlation between ankle muscle strength and FAOS scores (p<0.05).

Conclusions: We found that all the FAOS subscale scores were lower in the SpA patients and they were correlated with clinical findings. The results of our study indicate that even though there was not a significant decrease in the muscle strength, ADLs, sport and recreational activities, foot-related QoL are poorly affected in the SpA patients with Achilles enthesis.

ASSESSMENT OF EARLY MYOCARDIAL DYSFUNCTION USING SPECKLE TRACKING ECHOCARDIOGRAPHY IN PATIENTS WITH RADIOGRAPHIC AND NONRADIOGRAPHIC AXIAL SPONDYLOARTHROPATHY

V. Emren1, O. Gercik2, E. Ozdemir, D. Solmaz, S. Gucenmez, N. Eren1, M. Tokac1, G. Kabayaz1, S. Akar1, C. Caklar1, T. Aksoy, Health Sciences University, Izmir Katip Celebi University School of Medicine, Izmir, Turkey

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease that mainly affects axial skeleton. Although some differences like sex and objective signs of inflammation were described between these two subgroups, overall disease burden was found to be similar in radiographic (r-) and non-radiographic (nr-) axSpA patients. The association of chronic inflammation with cardiac dysfunction was well documented in many inflammatory rheumatic diseases. However, it was not assessed in the subgroups of axSpA patients. Advanced two-dimensional (2D) speckle tracking echocardiography analysis is more sensitive and accurate method of early detection of myocardial dysfunction than the conventional 2D transthoracic echocardiography (TTE).

Objectives: To evaluate the left ventricular function by using speckle tracking echocardiography in patients with both r- and nr-axSpA.

Methods: In total 64 patients with r-axSpA (70% male) and age- and sex-matched 27 patients with nr-axSpA (63% male) and 30 healthy control subjects...
(83% male) were included in the analysis. Patients with hypertension, diabetes and known cardiac disease were excluded. All patients underwent detailed echo-cardiographic examination including M-mode, pulsed-wave Doppler imaging, pulsed-wave tissue Doppler imaging and 2D speckle tracking.

Results: Age and sex distribution were not different between groups. Some demography and disease related characteristics were shown in the table. BASDAI, BASFI, global assessment of disease activity and ASAS-HI scores were found to be similar between r-axSpA and nr-axSpA patients. Although ejection fraction (EF) (p=0.112) and the other echocardiographic variables were similar between groups, global longitudinal strain (GLS) (p=0.045) were found to be different among groups (table 1). Post-hoc analysis showed that GLS was similar between nr-axSpA and control groups however GLS was significantly low in r-axSpA patients. In univariate analysis GLS was correlated with age (p=0.025), EF (p<0.001), peripheral arthritis (p=0.047), and smoking (p=0.019). However in regression only peripheral arthritis (p=0.032) and EF (p=0.015) were found as the independent predictors of GLS.

Conclusions: The results of the present study showed that left ventricular function had impaired in r-axSpA patients and speckle tracking echocardiography may be a useful tool for early demonstration of left ventricular dysfunction.

SERUM FIBROBLAST GROWTH FACTOR-23 LEVELS WERE HIGHER IN PATIENTS WITH AXIAL SPONDYLOARTHROPATHY AND MAY BE ASSOCIATED WITH DISEASE ACTIVITY

O. Gercik1, E. Coban2, B. Ozbek Ipek3, G. Avcioglu4, D. Solmaz1, O. Bayindir1, G. Kabasdy5, D. Koza6, S. Akar7, 1Rheumatology, 2Internal Medicine, 3Izmir Katip Celebi University School of Medicine, 4Izmir, 5Medical Biochemistry, Ankara Yildirim Beyazit University School of Medicine, Ankara, Turkey

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease that mainly affects axial skeleton. The disease is characterised by new bone formation; it usually starts with the bony fusion of sacroiliac joints (SIJs) and also causes syndesmophyte formation in the intervertebral space, enthesophytes in the tendon and ligament insertion sites. Underlying mechanisms of new bone formation in axSpA patients is not completely understood and low levels of sclerostin may be associated with the development of syndesmophyte in patients with ankylosing spondylitis (AS). Beside sclerostin another osteocyte factor is fibroblast growth factor-23 (FGF-23) and it has been first described as a phosphaturic hormone. It was also shown that FGF-23 may inhibit osteoblast differentiation and growth factor-23 (FGF-23) and it has been first described as a phosphaturic hormone. It was also shown that FGF-23 may inhibit osteoblast differentiation and growth factor-23 (FGF-23) and it has been first described as a phosphaturic hormone. Our results suggested that serum FGF-23 is increased in axSpA patients and also disease activity may contribute to an up-regulation in serum FGF-23 levels.

Conclusions: Our results suggested that serum FGF-23 is increased in axSpA patients. And also disease activity may contribute to an up-regulation in serum FGF-23 levels.

AB0885

CHARACTERISTICS OF JUVENILE ONSET HIP ARTHRITIS IN PATIENTS WITH SPONDYLOARTHRITIS

W. Hamdi, R. Ben Saad1, H. Riahi, K. Maatallah, D. Kaffel, T. Bouazziz, L. Ledab, M. Kchiri, 1Institut national de Mohamed el Kassab, tunis, Tunisia

Background: Axial spondyloarthritis (AS) is a chronic inflammatory rheumatic disease that affects the axial skeleton. It typically occurs in the late teens or early twenties and rarely in childhood, defining the juvenile onset (JoAS). The adult-onset AS (AoAS) and Juvenile-onset (JoAS) may share many common features including hip involvement. But their impact on function and quality of life may differ.

Objectives: To compare demographic, clinical and functional outcome of patients with hip involvement in JoAS, with that of patients with AoAS

Methods: Cross-sectional study including patients with AS according to the ASAS criteria of 2009 with hip involvement. The juvenile onset of coxitis was defined by an onset before 16 years of age. An analysis of demographic and clinical comparisons between the two groups was performed including HLA B27 status. Mobility spine outcomes were assessed by the Bath AS Metrology Index (BASMI) and radiographic disease severity by the Bath AS Radiology Index (BASRI).

Results: There were 100 AS ages of average 36.4±12.2 years old [10-70]. The sex ratio was 4.6. The mean duration of progression of AS was 10.9±3.9 years (0.5–24). It was a JoAS in 15 cases. All patients had a hip involvement. The juvenile onset of hip arthritis was associated with male gender (p=0.042), younger age of patient with AS at the time of recruitment (p=0.007), less severe clinical spinal involvement assessed by schober index (p=0.029) and more frequent and severe enthesitis assessed by MASES (p=0.024). Extra-articular manifestations were significantly more frequent in patients with juvenile onset of hip arthritis (p=0.008). Otherwise the comparison of the two groups showed no difference in the presence of uveitis (p=0.407) and pulmonary involvement (p=0.097). HLAB27 antigen was significantly more common in JoAS (p=0.037). BASRI and BASMI as well as ESR and CRP, were comparable between the two groups (p=0.976, p=0.626, p=1.000, respectively).

Conclusions: Hip involvement is common in the AS, particularly in JoAS. Our study showed that juvenile onset hip arthritis was associated with male gender, less severe spine involvement, enthesitis and the presence of HLA B27. This would help physicians to identify patients at higher risk of developing hip involvement, to enable early diagnosis.

DOES RADIO-ANATOMIC FEATURE OF HIP ARTHRITIS IN SPONDYLOARTHRITIS PREDICT FUNCTIONAL IMPAIRMENT?

W. Hamdi, P. Ben Saad, H. Riahi, K. Maatallah, D. Kaffel, T. Bouaziz, L. Ledab, M. Khiri. Institut National de Mohamed El Kassab, Tunis, Tunisia

Background: Axial spondyloarthritis (AS) is a chronic inflammatory disease that primarily affects the axial skeleton. Hip involvement is common in AS patient. The reported prevalence of clinical hip involvement in AS ranges from 24% to 36% and prevalence of radiographic hip arthritis ranges from 9% to 22%. 1, 2 Several radio-anatomic feature are described with often significant clinical impact.

Objectives: To assess for an association between the radio-anatomic feature of hip arthritis and its clinical impact in patients with AS.

Methods: Cross-sectional study including patients with AS according to the ASAS criteria of 2009 with hip arthritis. All patients had pelvic X-rays. The delay in X-ray was distributed the patients according to five radio-anatomic feature of the hip arthritis: destructive, protractive, ankylosing, mimicking osteoarthritis and early hip arthritis. To evaluate the functional impairment, two clinical indices were calculated: Lequesne index and intermalleolar distance between the two medial malleoli in centimetre. The comparison of qualitative variables was performed with the Chi square test and the comparison of quantitative variable and quantitative ones was performed with the Student’s test. The significance level was set at 0.05.

Results: One hundred patients were included with 176 hips arthritis. The delay between onset of AS and hip arthritis was on average 5.6 years [0–34]. The distribution of coxitis according to the radio-anatomic feature was as following: destructive (110 cases), protractive (10 cases), mimicking osteoarthritis (29 cases), ankylosing (7 cases) and early hip arthritis (20 cases).

According to the Larsen classification for destructive hip arthritis: a grade 4 was found in 41 cases, a grade 2 in 33 cases, a grade 3 in 33 cases and a grade 1 in 3 cases.

The destructive form had the most important functional impairment with the highest Lequesne index in comparison with other forms (13.05 vs 9.7, p=0.000) and the smallest intermalleolar distance (74.40 cm vs 87.29 cm, p=0.010).

The early hip arthritis and protractive forms had the least important functional impact in with the following scores: Lequesne index (8.83 vs 12.29, p=0.015) and (10.78 vs 11.96, p=0.000) and the intermalleolar distance (76.36 cm vs 65.00 cm, p=0.015) and (105.56 cm vs 70.22 cm, p=0.002) respectively.

Scores were comparables for osteoarthritis and ankylosing forms.

Conclusions: Our study showed that radio-anatomic feature of hip arthritis could influence functional impairment. Distinguishing these forms may allow the rheumatologist to select the hip arthritis that deserves more attention because of the highest risk of functional impairment.

AB0088

PLATELET COUNT IN ANKYLOSING SPONDYTIS: CAN IT SHOW THE DISEASE ACTIVITY ?

S. Rahmoui, M. Stourma, R. Dharhi, L. Metoui, N. Boussetta, N. Guedidche, F. Laajili, I. Ghasallah, B. Louzir. Internal Medicine, Military Hospital of instruction of Tunis, Tunis, Tunisia

Background: C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are the main inflammatory biomarkers used in assessment of disease activity in numerous inflammatory diseases such as ankylosing spondylitis (SA).

In recent years, it has been shown that Platelet count (PC) provided additional information on inflammatory status.

Objectives: The present study aimed to investigate the correlation between PC and clinical activity indices assessed by Bath ankylosing spondylitis disease activity index (BASDAI).

Methods: The study included 68 patients who fulfilled Assessment of Spondyloarthritides International Society Criteria. A cell blood count, including platelet count, ESR (mm/h), CRP (mg/L) and albumin (g/L), was obtained for each patient.

Disease activity measures at the time of blood sampling were obtained using the BASDAI. Statistical Package for Social Sciences (SPSS) was used for analysis.

Results: Of the 68 patients, 73.5% were male (Sex Ratio: 2.7). The mean age was 36±12.9 years. The mean disease duration was 40 months (0–192). The average age of the onset of the disease was 36.6±11.9 years. No patient had ongoing infection at time of study. The mean BASDAI score was 5.1 [1.95–9.2]. Forty-one percent of our patients (n=28) had active AS (BASDAI >4).

The mean ESR, CRP, albumin and PC were 39.4 (mm/h), 34.1 (mg/L) and 39.34 g/L, respectively.

There was no significant difference in laboratory parameters (ESR, CRP, albumin, PC, Hg) between patients with active AS (BASDAI >4) and those with inactive AS (BASDAI ≤-4).

Conclusions: Although acute phase reactant such as ESR, CRP and PC mirror disease activity in AS, their values were not associated with disease activity assessed by BASDAI in our study. However, new prospective studies including larger study groups are required to verify the findings of the present study.

JIA PATIENTS WITH HIGH DISEASE ACTIVITY HAVE INCREASED ACTIVITY OF BOTH THE IDO AND GTP-CH1 PATHWAY, BUT DECREASED BH4 EFFICACY: CONSEQUENCES FOR FATIGUE AND WELL-BEING

S. Korte1, E. Abers2, W. van den Bogaard2, G. Korte-Bouws1, S. de Rook3, S. Vasten1. 1Dept of Pharmacology, Onderwijscentrum Farmacie, Utrecht University; 2Paediatric Rheumatology, Wilhelmina Children’s Hospital, University Medical Center, Utrecht, Netherlands

Background: Juvenile idiopathic arthritis (JIA) patients suffer from an inflammatory condition, resulting in painful joints. In addition, JIA patients often report symptoms of sickness behaviour, including depressive symptoms and fatigue. Recent animal studies suggest that proinflammatory cytokines produce sickness behaviour by increasing the activity of indoleamine-2,3-dioxygenase (IDO) and guanosine/ phosphate-cyclohydrolase-1 (GTP-CH1). Here it is hypothesised that inflammation in JIA patients affects the enzymatic activity of IDO and GTP-CH1 and the co-factor BH4. These compounds play a crucial role in the metabolism of the neurotransmitters serotonin and dopamine.

Objectives: The aim of our study was to reveal whether inflammation affects BH4, IDO and GTP-CH1 (enzymatic) activity in JIA patients.

Methods: Serum samples were collected of twenty-four JIA patients. In these samples, the concentrations of tryptophan, kynurenine, tyrosine, neopterin and phenylalanine were measured. An HPLC method with electrochemical detection was developed to quantify tryptophan, kynurenine and tyrosine. Neopterin and phenylalanine were quantified by ELISA. Kyn/trp ratio was measured as an index of IDO activity, while Phen/Tyr ratio was measured as an index of BH4 activity. Neopterin concentrations were used as an indirect measure of GTP-CH1 activity.

Results: JIA patients with high disease activity showed higher levels of both neopterin and kynurenine, and a higher ratio of both Kyn/Trp and Phen/Tyr and lower tryptophan levels than clinically inactive patients.

Conclusions: Altogether, these data support our hypothesis that inflammation increases the enzymatic activity of both IDO and GTP-CH1 and decreases the efficacy of the co-factor BH4. Further animal studies are needed to investigate whether inflammation-induced changes in these enzymatic pathways and co-factor lower the levels of the brain neurotransmitters dopamine and serotonin, and consequently produce sickness behaviour and fatigue.

**CLINICAL CHARACTERISTICS OF 88 PATIENTS WITH PUSTULOCUTANEOUS ARTHRO-OSTEITIS (PAO) IN JAPAN**

S. Tsui1, Y. Ishihara2, H. Nishikawa3, Y. Taniguchi4, M. Kishimoto5. 1Department of Rheumatology and Allergology, National Hospital Organization, Osaka Minami Medical Center, Kawanachi City, Osaka; 2Department of Orthopaedic Surgery, Kasumigaseki Urban Clinic, Tokyo; 3Department of Nephrology and Rheumatology, Kochi Medical School Hospital, Kochi; 4Immuno-Rheumatology Center, St. Luke’s International Hospital, Tokyo, Japan

**Background:** The prevalence rate of PPP in Japan is somewhat as 0.13%1), accounting for 61% of cutaneous manifestations diseases associated with SAPHO syndrome2). SAPHO syndrome3) is not a new disease concept in which the cause of the disease has been clarified but is a name that classified diseased groups by collecting known diseases. On the other hand, PAO is a concept of disease that is a ‘proper subset’ of SAPHO syndrome and is the smallest unit disease concept. Therefore, detailed information on PAO was sought.

**Objectives:** To examine the clinical features and treatment of PAO

**Methods:** We conducted a multicenter, non-intervention retrospective study of 88 PAO patients who were able to visit directly in 4 hospitals in Japan from January to June 2017. The criteria of PAO patients who were able to visit directly in 4 hospitals in Japan from January to June 2017. The criteria of PAO in Japan is not sufficient, and it is necessary to try to elucidate further disease condition.

**Results:** The average age at the time of visit was 55.4 years old, palmomplantar pustulosis/PAO onset age was 44.4 years old, 49.3 years old, the onset pattern was skin leading type/simultaneous onset/joint advanced type (66.7/25.6/7.7%). The clinical features were pain joints of 33.0% of the thoracic joints, 22.7% of the shoulder joints and 10.2% of the joints of the ankle joints, and the adhesion flame was the most abundant in the Achilles tendon at 21.4%. ASDAS-CRP was 1.4 ±0.8 on average, breakdown was inactive disease 52.3%, moderate 22.7%, severe 22.7%, very high disease activity 2.3%, and insufficient disease activity remained in 25% of cases. Radiographic change showed in 81.8% of the sternum/the sternocostoclavicular joint, 33.0% of the spine, 31.0% of the sacroiliac joint (NY II or more), and 9.8% of the peripheral joint. MRI findings showed changes in intraosseous luminance in 76.9% around the sternum, 52.2% in the shoulder joints, and 10.2% of the joints of the ankle joints, and the adhesion flame was skin leading type/simultaneous onset/joint advanced type (66.7/25.6/7.7%). The clinical features were pain joints of 33.0% of the thoracic joints, 22.7% of the shoulder joints and 10.2% of the joints of the ankle joints, and the adhesion flame was the most abundant in the Achilles tendon at 21.4%. ASDAS-CRP was 1.4 ±0.8 on average, breakdown was inactive disease 52.3%, moderate 22.7%, severe 22.7%, very high disease activity 2.3%, and insufficient disease activity remained in 25% of cases. Radiographic change showed in 81.8% of the sternum/the sternocostoclavicular joint, 33.0% of the spine, 31.0% of the sacroiliac joint (NY II or more), and 9.8% of the peripheral joint. MRI findings showed changes in intraosseous luminance in 76.9% around the sternum, 52.2% in the spine and 65.2% in the sacroiliac joint. Bone scintigraphy showed abnormal findings in the anterior chest 96.4%, spine 23.6% and sacrum 30.9%. Blood biochemical examination showed CRP 0.35±0.52 mg/dl, RF positive rate 9.4%, ACPA positive rate 5.1%. First-line drugs (NSAIDs, biotin, anti-bacterial drugs) and second-line drugs (glucocorticoids, methotrexate MTX) were selected as therapeutic agents. For other treatments, 64.8% of topical therapy, 12.5% of phototherapy and 18.6% of tomsistectomy were performed.

**Conclusions:** In this study, we reported the clinical features, radiological findings and treatments in 88 Japanese patients with PAO in Japan. The treatment outcome for PAO in Japan is not sufficient, and it is necessary to try to elucidate further disease condition.

AB0890

**EFFICIENCY OF 8-YEAR EDUCATIONAL PROGRAMS FOR PRIMARY CONTACT PHYSICIANS IN DIAGNOSIS AND TREATMENT OF AXIAL SPONDYLOARTHRITIS IN KAZAN**

S. Lapshina1, L. Myasoutova2, R. Mukhina3, 149 Butlerov street, Kazan State Medical University; 2Clinic Hospital # 7, Kazan, Russian Federation

**Background:** In recent years, there have been cardinal changes in terminology, understanding of pathogenesis of axial spondylitis (AxSpA) and anklyosing spondylitis (AS), early diagnosis has improved. An important role is played by the level of awareness of primary care physicians in the early diagnosis of AxSpA and AS.

**Objectives:** To evaluate the effectiveness of educational activities for primary contact physicians in AxSpA (including AS) diagnostics for a long time.

**Methods:** From 2010 to the present time, educational activities are conducted for primary care physicians in diagnostics and tactics of managing patients with AS with discussion of the criteria for inflammatory back pain, options for onset and the algorithm for diagnosis and examination of patients with AxSpA for primary contact physicians in Kazan. Since 2014, educational modules have been integrated into the system of continuing education of doctors. Assessment of the results of educational schools was carried out according to the analysis of reports of out-patient admission to rheumatologist of the City Rheumatological Centre in Kazan (Clinical Hospital # 7) and the analysis of medical records of patients sent to a rheumatologist in 2009 (base year) in comparison with 2010–2017 in the process of schools.

**Results:** In the process of conducting schools (2010–2017) the number of patients with AxSpA and AS significantly increased for the first time this year. In 2010–2011, the number of patients almost doubled (575 pts in 2010, 683 pts in 2011) compared to 2009 (378 pts). The second sharp increase in the number of patients was observed in 2016 (1178 pts) and in 2017 (1298 pts). The same dynamics was observed for AxSpA patients (including AS) who applied for the first time to rheumatologist with a significant increase in patients in 2010–2011 (2009–118 pts, 2010–190 pts, 2011–204 pts) and in 2016–506 pts, 2017 year – 711 patients “Peak” increase in the number of patients in 2010–2011 can be explained by the beginning of educational activities for doctors; in 2016–2017 – an increase in the number of activities (including remote ones), the amount of information, increased availability of MRI examinations for patients with AxSpA.

Primary care physicians were more likely to refer patients with suspected AxSpA or diagnosed AS, the percentage of discrepancies between diagnoses (referral and rheumatology) decreased from 78% in 2009 to 18.1% in 2011, 8.9% in 2013, 2.1% in 2015 and 3.3% in 2017. The number of patients coming from the primary contact physician to rheumatologist with the required volume of examination (description of back pain, laboratory tests, HLAB27 determination, radiographs and/or MRI) increased significantly from 23.7% in 2009 to 87% in 2017, which allows to verify diagnosis without repeated consultations.

**Conclusions:** Educational programs for primary care physicians (lectures, schools, remote programs) have great importance for the timely diagnosis of AxSpA, reducing the number of consultations before the diagnosis and with the subsequent appointment of adequate therapy.

AB0891

**DISEASE ACTIVITY PREDICTS FUNCTIONAL IMPAIRMENT AND SPINAL MOBILITY IN AXIAL SPONDYLOARTHRITIS**

T. Williams1, A. Wadeley2, C. Cavi1, M. Freeth1, J. Hole1, R. Sengupta1. 1Rheumatology, Royal National Hospital for Rheumatic Diseases; 2College of Liberal Arts, Bath Spa University, Bath, UK

**Background:** Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease, mainly affecting the spine and sacroiliac joints. This results in progressive spinal immobility and can result in a level of disability comparable to Rheumatoid Arthritis1. The natural history of axSpA and relationships between active inflammation,
structural damage and functional impairment remain poorly understood. Previous
studies have hypothesised that functional impairment and spinal mobility in
axSpA are independently influenced by disease activity and radiographic
damage.1,2,3

Objectives: To define the relationship between disease activity, spinal mobility
and radiographic damage with other patient-reported outcome measures in
axSpA.

Methods: We performed a cross-sectional analysis of axSpA patients attending
the Royal National Hospital for Rheumatic Diseases, Bath. The most recent out-
come measures for each patient were compared. Spinal mobility was assessed
using the BASMI; structural radiographic damage by the mSASSS; disease activ-
ity by the BASDAI; functional impairment by the BASFI; fatigue by the FACIT
score; work disability by the WPAI-overall; quality of life by the ASQoL; overall
health by the EQ5D. We analysed the correlation between these variables, sepa-
ratey for patients with Ankylosing Spondylitis (AS) and non-radiographic axSpA
(nr-axSpA).

Results: 721 axSpA patients were included for analysis (548 AS; 42 nr-axSpA; 39
inflammatory bowel disease-related SpA; 47 juvenile-onset SpA; 24 psoriatic
SpA; 3 reactive SpA; 18 undifferentiated SpA). Results are summarised in table 1:

**Correlation is significant at the 0.01 level (2-tailed); *Correlation is significant at the 0.05 level (2-tailed)

Conclusions: Spinal mobility and disease activity are both correlated with func-
tional impairment, along with other measures of disability and poor health in
axSpA, with BASDAI the strongest predictor of BASFI. Consistent with other stud-
ies, BASDAI was more predictive of spinal mobility in nr-axSpA than AS patients
(p=0.002, 1-tailed). Structural radiographic damage is the strongest predictor of
spinal mobility in AS. BASMI scores merit further investigation to ascertain their
potential as a surrogate for radiographic disease burden in axSpA.

INFLUENCE OF INFLAMMATION AND STRUCTURAL
DAMAGE ON GLOBAL FUNCTIONING IN PATIENTS
WITH AXIAL SPONDYLOARTHROSIS – USING THE ASAS
HEALTH INDEX IN ROUTINE CARE

U. Kitz, T. Wiatr, X. Baraliakos, J. Braun. Rheumatology, Rheumazentrum
Ruhrgebiet, Herne, Germany

Background: Global functioning of patients with spondyloarthritis (SpA) can be
influenced by many different factors. ASAS Health Index (ASAS HI) has aims to
measure global functioning in patients with SpA. So far, its association with inflam-
matory spinal changes and structural damage has not been examined.

Objectives: To investigate the relationship between spinal mobility and self-
reported global functioning as assessed by the ASAS HI, and to study the influence
of structural and inflammatory spinal changes on global functioning.

Methods: Patients from the outpatient clinic of our hospital suffering from axial or
peripheral SpA completed questionnaires assessing disease activity and func-
tioning (ASAS HI, pain, BASDAI, ASDAS, BASFI). Axial inflammation as detected
by magnetic resonance imaging (MRI) was assessed by the Berlin score, struc-
tural damage by the modified Stokes ankylosing spondylitis (AS) Spine Score
(mSASSS) and spinal mobility by the Bath AS Metrology Index (BASMI). Imaging
were scored by two independent readers. Correlations between the ASAS HI and
other health outcomes were analysed by Spearman’s test. Logistic regression
analyses were performed to investigate the association between functioning and
other clinical characteristics.

Results: A total of 203 patients (76 non-radiographic (nr)-axSpA, 115 AS
patients, and 12 with peripheral SpA (pSpA) were included: 63.5% male, mean
(SD) age 46.6 (14.1), symptom duration 18.8 (12.8) years, and 76.4% HLA-B27
positive. The mean values of clinical assessments were ASAS HI 7.9 (4.0), BAS-
DAI 5.0 (2.2), ASDAS 2.8 (1.1), BASMI 3.3 (1.8), pain 6.0 (2.6), and BASFI 5.0
(2.6). Elevat CRP levels were found in 37.4% of the patients, while 59.1% of the
AS patients had syndesmophytes and 11.3% a bamboo spine. The median (IQ9)

AB0892

PREDICTING SYNDESMOPHYTE FORMATION IN AXIAL
SPONDYLOARTHRITIS

T. Anachebe, G. Fitzgerald, F.O. Shea. Rheumatology Department, St James
Hospital, Dublin, Ireland

Background: Axial spondyloarthopathy (axSpA) is a chronic inflammatory
arthritis affecting the sacroiliac joints and spine. The consequence of inflammation
in axSpA is new bone formation, or syndesmophytes, which can result in complete
ankylosis of the spine. The pathogenesis of syndesmophyte formation is incom-
pletely understood. It is agreed that presence of baseline syndesmophytes pre-
dicts further syndesmophytes, but other predictive factors have been difficult to
define. In particular, the impact of extra-articular manifestations (EAMs) on syn-
desmophyte formation is unclear.

Objectives: 1. To assess the burden of radiographic disease in a well-character-
ised axSpA cohort.
2. To investigate demographic and disease-related variables associated with syn-
desmophytes (specifically EAMs).

Methods: A cross-sectional study of AxSpA patients was performed, comprising
standardised clinical assessment and structured interviews. Validated measures
of disease severity were used: BASDAI and ASDAS-CRP (disease activity),
BASMI (spinal mobility), HAQ (disability), BASFI (function). Lateral x-rays of
the lumbar and cervical spine were performed to quantify syndesmophytes using a
validated score (mSASSS) ranging from 0–72, with higher numbers indicating a
higher burden. BASRI-hp was used to determine hip involvement, assessed on x-
ray of pelvis.

Results: One hundred and four patients with axSpA were included: 78.8% (n=82)
males, 98.1% (n=102) Caucasian, average (SD) age 50.8 (12) years and average
disease duration 26.15 years. Modified New York (mNY) criteria were fulfilled by
84.6% (n=88) of the cohort. An EAM was present in 29.1% (n=30) of patients.
Uveitis was the most prevalent EAM (29%), followed by inflammatory bowel dis-
ease (IBD) (18.4%) and psoriasis (17.5%). Average (SD) BASDAI was 3.9 (2.2),
ASDAS-CRP 2.3 (1), BASMI 4.2 (1.9), indicating a mild to moderate disease bur-
den in the cohort.

Median (IQR) mSASSS was 9.5 (33.8), 1.6% (n=11) of patients had an mSASSS
of >0% and 7.7% (n=8) had a bamboo spine. There was no significant difference
in the median cervical and lumbar spine mSASSS scores (4 v 6, p=0.05). The distri-
bution of mSASSS was similar in males and females. HLA-B27 status had no
effect on mSASSS scores.

Increasing mSASSS correlated significantly (p<0.05) with increasing age
(rho=0.6), longer disease duration (rho=0.5), rising BASMI (rho=0.8), higher
BASFI (rho=0.4) and higher HAQ (rho=0.3). Worsening hip disease, as measured
by BASRI, also correlated with an increasing mSASSS (rho=0.4, p<0.01). There
was also a statistically significant difference between patients who met mNY crite-
reria compared to those that didn’t (median 14.4 v 2.5, p<0.01).

Patients with hypertension had a significantly higher median mSASSS score than
patients without (25.4 v 7, p<0.01). Smoking status, hypercholesterolaemia,
ischaemic heart disease and diabetes had no impact on mSASSS.

The presence or absence of uveitis, psoriasis or IBD had no effect on syndesmo-
phyte formation. Equally, peripheral arthritis had no effect. Patients with moder-
ate or severe hip disease were more likely to have a higher mSASSS score (OR 3.8,
95% CI 1.5–9.3).

Conclusions: In keeping with previous literature, higher mSASSS was associ-
ated with more severe disease. However, in contrast to other published studies,
gender had no effect on the severity of mSASSS in our cohort. EAMs did not affect
the mSASSS score, but worse hip disease did. It remains a challenge to predict
which patients will develop syndesmophytes.

A COMPARISON OF CLINICAL FEATURES IN PATIENTS WITH SPONDYLOARTHRITIS AND UNILATERAL OR BILATERAL HIP ARTHRITIS

W. Hamidi, S. Zidri, H. Rahi, K. Maatallah, D. Kaffel, M. Chelli Bouazziz, M. F. Ladeb, M.M. Kchir, 1 Rheumatology, 2 Radiology, Institute Mohamed Kassab, Ksar Saïd, Manouba, Tunisia

Background: Axial spondyloarthritis (AS) is a frequent chronic and progressive disease that affects mainly young adults and is characterised by inflammation of the axial skeleton, but peripheral joints such as hips may also be involved. The incidence of hip involvement in AS is around 30%. Nevertheless, data concerning clinical features in patients with spondyloarthritis comparing unilateral and bilateral hip arthritis are lacking.

Objectives: To compare clinical, functional and radiologic outcomes in patients with AS with unilateral or bilateral hip arthritis.

Methods: Cross-sectional study on 100 patients with AS according to the ASAS criteria of 2009 who had unilateral and bilateral hip joint lesions defined by hip pain, limited joint motion and radiographic hip abnormalities. Demographic and clinical outcomes were performed including HLA B27 status. Spinal mobility outcomes were assessed by Schöber index and Bath Ankylosing Spondylitis Metrology Index (BASMI). Radiographic measurements were performed and included Bath Ankylosing Spondylitis Radiology Index (BASRI) and modified Stoke Ankylosing Spondylitis Spine Score (mSASSS).

Results: Bilateral hip joint lesion was reported in 76% of patients which 14 were women and mean age was 37.14 years. Bilateral hip involvement was associated with less height (p=0.002), more long disease duration (p=0.015), more several clinical spinal involvements with more spinal stiffness (p=0.000) and less spinal mobility (p=0.004). Extra-articular manifestations were comparable in patients with unilateral and bilateral hip arthritis (p=0.55), however HLA B27 antigen was significantly more common (p=0.003) in patients with bilateral hip arthritis. BASRI hip (p=0.042) and mSASSS (p=0.009) scores were used to assess structural damage on plain radiographs and were significantly more important in bilateral involvement. Nevertheless, protrusive form was more frequent in patient with unilateral hip involvement (p=0.05).

Conclusions: Bilateral hip arthritis seems to be more frequent and more severe than unilateral involvement in patients with AS.

AB0895 ARE LATERAL SPINE BONE MINERAL DENSITY MEASUREMENTS USEFUL IN AXIAL SPONDYLOARTHRITIS?

W. Hamidi, D. Ben Nesso, H. Rahi, A. Kasraoui, K. Maatallah, M.D. Kaffel, M. Bouazziz, M.F. Ladeb, M.M. Kchir, 1 Rheumatology, 2 Radiology, Kassab Hospital, Tunis, Tunisia

Background: Bone loss leading to osteoporosis (OP) is a well-known feature of axial spondyloarthritis (AS) although this disease is characterised by calcification in extra osseous tissues and new bone formation. In fact, dual-energy X-ray absorptiometry (DEXA) is the most common imaging method used to measure the bone mineral density (BMD). However, many studies have shown an inferiority of the postero-anterior (PA) spine measurements in reflecting the bone loss compared to lateral spine measurements because of the bridging syndesmophytes which may overestimate the BMD.

Objectives: Our aim is to evaluate the Lateral spine BMD (L-BMD) in AS and to assess its association with the disease features.

Methods: Seventy-five patients who met the Modified New York Classification criteria for AS were enrolled in this cross-sectional study. BMD was measured using DEXA at PA lumbar spine and lateral lumber and hip regions.

Results: Sixty-two men and 13 women were enrolled with an average age of 36.8 ±11.8 years. Bone loss (osteopenia or OP) was noted in 65% of the patients (n=46) in PA lumbar and in 63% in lateral lumber (n=45). In L-BMD, BMD was correlated with early menopause and vitamin D level (p<0.01 and p=0.04 respectively). T-score in lateral spine was correlated with coffee consumption (p=0.02), physical inactivity (p=0.037), sexual hormones disorders (p=0.02), hip arthritis (p=0.017), BASMI (p=0.001), BASFI (p=0.03) and ASDAS (p=0.03) scores, ESR (p=0.003) and CRP (p=0.03) levels, and hip (p=0.007) and total (p=0.001) BASRI.

Conclusions: L-BMD seems to be a reliable measurement in AS, and may avoid the overestimation of the BMD values and allows consequently to detect spinal osteoporosis and prevent fractures in AS.

AB0896 ASSOCIATION OF IGA ANTIBODIES AGAINST CD74 WITH PRODUCTION OF IL17A BUT NOT OF TNFALPHA IN PATIENTS WITH ACTIVE AXIAL SPONDYLOARTHRITIS

X. Barajalakos, K. Knesch, N. Baerlecken, J. Braun, T. Witte, 1 Rheumazentrum Ruhrgebiet, Herne; 2 Medizinische Hochschule Hannover, Hannover, Germany

Background: Axial spondyloarthritis (axSpA) is strongly associated with HLA-B27. Recently, IgA antibodies (Abs) against CD74 (IgA-anti CD74) and T-cells carrying CD-74-specific T-cell receptors were also found to be associated with axSpA, especially in patients with ankylosing spondylitis, the radiographic form of axSpA. Tumour necrosis alpha (TNFα) inhibitors and IL-17 antagonists are efficacious in patients with active axSpA.

Objectives: To investigate whether IgA-anti-CD74 Abs are associated with pro-inflammatory cytokines in the sera of patients with HLA-B27-positive and -negative patients with active axSpA.

Methods: Blood samples of 62 HLA-B27-positive and 58 HLA-B27-negative patients with axSpA (44% AS) prior to starting a biologic therapy were collected. A cytometric bead-array (CBA Flex Set) was used to measure serum levels of interleukin (IL)-17A, IL-6, IL-1α, TNFα, and interferon (INF)γ. IgA-anti CD74 Abs were measured by ELISA, using the predefined cut-off of 15 U/ml. Their mean concentrations were compared between groups using T-tests. The patients who were positive or negative for IgA-anti CD74 Abs were compared using chi-square test.

Results: IgA-anti CD74 Abs were detected in 54/120 axSpA patients (45%). There were no differences in the baseline demographics and clinical assessments in patients with or without IgA-anti CD74 Abs. The presence of IgA-anti CD74 Abs
was associated with higher serum concentrations of IL-17A (p=0.01), irrespective of the presence of HLA-B27, CRP and IL-6 (both p<0.05) but not TNFα (p=0.2).

Conclusions: In a cross-sectional study, the presence of IgA Abs against CD74 was associated with serum levels of pro-inflammatory biomarkers such as CRP (and IL-6) and IL-17 but not TNFα irrespective of HLA-B27 status. Longitudinal prospective studies are needed to show that the measurement of IgA anti-CD74 Abs and/or serum cytokines can help to guide treatment decisions.

AB0897 THE RELATIONSHIP BETWEEN DISEASE-SPECIFIC INDICES AND BALANCE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Y. Acar1, N. Iičin1, B. Gürpınar1, G. Can2, F. Öner2. Physical Therapy and Rehabilitation, Dokuz Eylül University, İzmir, Turkey

Background: Axial and periferal joint stiffnes, impaired joint mobility and postural deformities may affect balance in AS. However factors affecting balance in AS patients are still unclear. There is limited literature investigating balance-related factors in patients with AS and the results are contradictory.

Objectives: The aim of the study was to investigate relationship between disease-specific indices and balance in patients with AS.

Methods: 72 patients (46 male, 26 female) with AS were included in the study. The demographic and anthropometric features (age, weight, height, body mass index (BMI)) of patients were recorded. Disease-specific indices used in the study were Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Mobility Index (BASMI). BASDAI for disease activity, BASFI for functional capacity, BASMI for spinal mobility were used. Static and dynamic balance was evaluated with Biodex Balance System SD. Limits of stability and bilateral stance (stable platform) postural stability test results were recorded. Overall stability (OA) indices were used. A high score in the OA index indicates poor balance. Spearman correlation test used for statistical analysing. Correlation analyses were performed between BASDAI, BASFI, BASMI scores and Biodex test results.

Results: The mean age of patients was 39.95±8.84 years and mean BMI was 26.55±3.82 kg/m2. BASDAI, BASFI and BASMI scores of patients are shown in table 1.

Comparison of improvement rates in I and III trimesters, p=0.05. Worsening of underlying disease (as compared to the condition 3 months prior to pregnancy) during whole pregnancy was reported by 3 (3.5%) women, absence of noticeable changes was reported by 13 (15.1%) patients, and AS improvement – by 9 (10.4%) participants.

Conclusions: Therefore, the majority of participants reported the diverse fluctuations in AS course during pregnancy, although 50% of responders reported the improvement in the course of the disease at least during one trimester (more often in the first). Nevertheless, almost 70% of responders reported AS worsening with exacerbations rates increasing in parallel with increasing gestation age. 50% of participants noticed worsening back pain, although special attention should be given to correct evaluation of AS activity in these patients keeping in mind the increased physiological load on the backbone during the second half of pregnancy.

Psoriatic arthritis

AB0909 DESCRIPTIVE STUDY OF PSORIATIC ARTHRITIS IN A HISTORICAL COHORT OF 383 PATIENTS AT A UNIVERSITY HOSPITAL

A. Prior Español1, L. Mato1, M. Mihaylov1, J. Roca2, Y. García Mira1, J. Camins1, I. Casabó1, L. Gil1, A. Rivero1, S. Helgado1, M. Martínez Morillo1, M. Aparicio1, A. Olivé1, J. Rodríguez1, Y. García Miranda1

Badalona, Spain

Background: There are few recent large cohort epidemiological studies that analyse the clinical profile of patients with psoriatic arthritis (PsA) who require biological treatment, as well as pharmacological survival and reasons for the suspension of different biological treatments.

Methods: The aim of this study is to investigate the recently interested adipokines vaspin and lipocalin2 levels in PsA. In our knowledge, this is the first study comparing the vaspin and lipocalin2 in PsA. We have calculated the means and standard deviations of the results. We compared the vaspin and lipocalin2 levels in two groups: before and after the AS onset. We have used two-sample t-tests to compare the means.

Conclusions: Therefore, data from questionnaire survey of females with AS demonstrates that presence of AS does not increase the incidence of unfavourable maternal outcomes of pregnancies, or negatively affects anthropometric parameters of neonates. Of notice is the fact, that women’s choice abortions become more rare after AS diagnosis is established. The rate of Cesarean sections is higher in AS patients. Fear of potentially harmful effects of the disease and it’s therapy on the fetus and the baby underlies 30% of all not getting pregnant cases among AS female patients of child-bearing age.

Disclosure of Interest: None declared

AB0901 VASPIN AND LIPOCALIN2 LEVELS IN PSORIATIC ARTHRITIS

S. Colak1, A. Ömm2, S. Can Sandıkçı2, C. Yuce1, T. Turhan3, I. Rheumatology, Ankara Numune Training and Research Hospital, 2Rheumatology, Diskapi Yildirim Beyazit Training and Research Hospital, 3Biochemistry, Ankara Numune Training and Research Hospital, Ankara, Turkey

Background: Psoriatic arthritis (PsA) is a type of spondiloarthropathies which is affiliated with psoriasis. Metabolic syndrome, diabetes mellitus and cardiovascular diseases are comorbid conditions associated with psoriatic arthritis. Adipokines are suggested to be playing proinflammatory or antiinflammatory roles in the proceeding of inflammatory situations.

Objectives: The aim of this study is to investigate the recently interested adipokines vaspin and lipocalin2 levels and their association with disease activity of patients diagnosed with psoriatic arthritis.

Methods: The study was conducted between October 2017 and January 2018 at the Rheumatology Clinic of Ankara Numune Training and Research Hospital, Turkey. The vaspin and lipocalin2 levels of 50 PsA patients, diagnosed according to the Classification Criteria for Psoriatic Arthritis (CASPAR), and 30 age and sex matched healthy subjects were analysed in current study. The disease activity was assessed by using Psoriasis Area Severity Index, Bath Ankylosing Spondylitis Functional Index, Bath Ankylosing Spondylitis Disease Activity Index and Disease Activity Index for Psoriatic Arthritis. Indexes were applied to the patients in order to evaluate the disease activity.

Results: No significant difference was found between groups with respect to age, sex and body mass index. There was significant difference between vaspin (p=0.001) and lipocalin2 (p=0.014) levels among the PsA patients and control groups. There was no significant difference between the groups in terms of disease activity (p>0.05).

Disclosure of Interest: None declared

**AB0902**

**EFFICACY OF TOFACITINIB BY BACKGROUND METHOTREXATE DOSE IN PATIENTS WITH PSORIATIC ARTHRITIS: A POST-HOC ANALYSIS OF POOLED DATA FROM 2 PHASE 3 TRIALS**

A.J. Kivitz1, O. FitzGerald2, P. Nash3, S. Pang4, V.F. Azevedo5, E. Kudlac2, C. Wang2, D. Graham2, L. Takiya,6 Department of Rheumatology, Altonna Center for Clinical Research, Burlingame, CA, USA; 7Department of Rheumatology, St Vincent’s University Hospital, Dublin, Ireland; 8Department of Medicine, University of Queensland, St Lucia, Brisbane, Australia; 9St Jude Medical Center, Fullerton, CA, USA; 10Universidade Federal do Paraná, Curitiba, Brazil; 11Pfizer Inc, Grooton, CT; 12Pfizer Inc, Collegeville, PA, USA

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). The efficacy of tofacitinib has been evaluated in 2 Phase 3 studies in patients (pts) with PsA.

**Objectives:** To describe the efficacy of tofacitinib by background methotrexate (MTX) dose in pts with PsA.

**Methods:** This post-hoc analysis utilised efficacy data pooled from 2 Phase 3 randomised, double-blind, placebo-controlled studies (OPAL Broaden [12 months; NCT01877668] and OPAL Beyond [6 months; NCT01882439]) in pts with a diagnosis (>6 months) of active PsA (>3 swollen and >3 tender joints). Pts in OPAL Broaden were tumour necrosis factor inhibitor (TNF)-naive and had an inadequate response (IN) to ≥1 conventional synthetic disease-modifying antirheumatic drug (csDMARD). Pts in OPAL Beyond had an IR to ≥1 TNFi. Pts were randomised to tofacitinib 5 or 10 mg twice daily (BID), placebo or adalimumab 40 mg subcutaneous every 2 weeks (OPAL Broaden); adalimumab data not shown. All pts received a stable dose of 1 csDMARD (eg MTX, leflunomide or sulphasalazine) as background therapy. The maximum dose of MTX allowed per protocol was 20 mg/week. Efficacy outcomes for tofacitinib at Month 3 were evaluated by background MTX dose (<15 vs ≥15 mg/week) and included: ACR20/50/70 response rates (>20/50/70% improvement from baseline, respectively); Health Assessment Questionnaire-Disability Index (HAQ-DI) response rate (reduction from baseline ≥0.35 points) and mean change from baseline in HAQ-DI score. Analyses were based on the full analysis set for pts receiving MTX on Day 1; pts with missing data were considered as having a non-response for binary endpoints. No statistical testing was performed.

**Results:** In total, data from 556 pts who received tofacitinib plus MTX only or placebo plus MTX only (tofacitinib 5 mg BID, n=186; tofacitinib 10 mg BID, n=178; placebo, n=192) were included in this analysis. Most pts were treated with background MTX at doses:15 mg/week (n=371, 66.7%; mean [SD] dose, 12.6 [3.1] mg/week) vs >15 mg/week (n=185, 33.3%; mean [SD] dose, 19.8 [0.8] mg/week). Baseline demographics and disease characteristics were generally similar between arms in MTX dose groups (table 1). At Month 3, tofacitinib 5 and 10 mg BID were generally associated with numerically greater ACR and HAQ-DI response rates and greater changes from baseline in HAQ-DI score compared with placebo. The magnitude of tofacitinib effects on efficacy outcomes appeared broadly similar between background MTX dose groups (table 1).

**Abstract AB0902 – Table 1.** Patient demographics and disease characteristics at baseline, and efficacy outcomes at Month 3 by MTX dose

*Among pts with baseline HAQ-DI score ≥0.35

*The maximum permitted dose of MTX was 20 mg/week. The analyses included all pts who received MTX as background therapy only on Day 1 or >1 mg/week.

**Conclusions:** The results of this pooled analysis suggest that the efficacy of tofacitinib in pts with PsA was greater than placebo and does not differ when evaluated by background MTX dose (<15 vs ≥15 mg/week), although small pt numbers in some groups may limit the conclusions that can be made. These results are consistent with findings from similar analyses of tofacitinib in pts with rheumatoid arthritis.

**AB0903**

**EFFICACY OF TILDRAKIZUMAB IN ETANERCEPT PARTIAL OR NONRESPONDERS**

**Background:** Etanercept (ETN) is an anti–tumour necrosis factor (TNF) medication that was among the first biologics approved for psoriasis. Additional medications have been developed or are in development for psoriasis, and patients who do not adequately respond to ETN may benefit from these more recent biologics.

**Objectives:** Here we report the efficacy of tildrakizumab (TIL), a humanised anti–IL-23p19 monoclonal antibody, as evaluated in patients with moderate to severe chronic plaque psoriasis who were partial (Psoriasis Area and Severity Index [PASI]: 50–75) or nonresponders (PASI <50) to ETN and subsequently rerandomized to TIL in the phase 3 RESURFACE 2 trial (NCT01729754).

**Methods:** Patients with psoriasis (>10% body surface area, Physician’s Global Assessment [PGA], and PASI >12) participated in RESURFACE 2, a 3-part, 52 week, randomised controlled trial. In Part 1 (Weeks 0–12), patients were randomised to subcutaneous TIL 200 mg, TIL 100 mg, or placebo (PBO) administered at Weeks 0 and 4, or ETN 50 mg administered twice weekly. In Part 2 (Weeks 12–28), TIL and ETN patients remained on the same treatment (TIL administered at Week 16; ETN once weekly), whereas PBO patients were rerandomized to TIL 100 or 200 mg. In Part 3 (Weeks 28–52), ETN responders (PASI >75) were discontinued, and partial and nonresponders were switched to TIL 200 mg (administered at Weeks 32, 36, and 48). For this post hoc analysis, the proportion of partial responders (PR) with PASI response (score of 0 [clear] or 1 [minimal] with at least a 2-grade score reduction from baseline) were determined at Week 52. Primary results from the trial have been previously reported.

**Results:** In total, 1090 patients were randomised. Of the 313 patients randomised to ETN, by Week 28 there were 83 partial responders and 39 nonresponders. At Week 52 (after 20 weeks of TIL treatment) for ETN partial responders, 75%±5%, 54%±5%, 15%±4%, and 5±4% had achieved PASI 75, 90, 100, and PGA response of 0/1, respectively, with TIL 200 mg treatment. At Week 52 for ETN nonresponders, 54%±6%, 31%±5%, 10%±3%, and 56%±5% had achieved PASI 75, 90, 100, and PGA response of 0/1, respectively, with TIL 200 mg treatment. Adverse events were similar in patients switched from ETN to TIL at Week 28, compared with the patients who were maintained on TIL through Week 52.
Conclusions: A substantial portion of patients with moderate to severe chronic plaque psoriasis who were partial or nonresponders to ETN may respond after switching to treatment with TIL 200 mg. TIL may be a reasonable option for those who do not achieve adequate response to ETN.

AB0904 CORRELATION OF RAPID3 AND PROMIS10 IN PATIENTS WITH PSORIATIC ARTHRITIS

Background: In addition to clinician assessment and laboratory tests, patient-reported outcomes (PROs) are important for managing and improving the quality of care in patients with psoriatic arthritis (PsA). The RAPID3 was originally developed for use in patients with rheumatoid arthritis, but it may be used in clinical practice to assess disease activity in patients with PsA.1 The PROMIS10 is a general (nondisease-specific) PRO instrument that measures physical, mental, and social health.2 Developed for the general population, PROMIS10 has not yet been specifically validated in PsA.

Objectives: To evaluate the relationship between RAPID3 and PROMIS10 in patients with PsA.

Methods: US adults with a self-reported diagnosis of PsA were recruited through CreakyJoints (www.CreakyJoints.org), an online patient support community comprising patients with arthritis and arthritis-related diseases and their caregivers. Respondents completed an online survey that was designed to collect data on socio-demographics and clinical symptoms and included the RAPID3 and PROMIS10 to evaluate disease activity and health-related quality of life (HRQoL), respectively. The RAPID3 and PROMIS10 are relatively short questionnaires that can be correlated in patients with PsA. PROMIS10 mental health scores moderately correlated with RAPID3, suggesting the mental health questions add a different construct. PROMIS10 and RAPID3 are relatively short questionnaires that can be used in the real world to track and monitor disease symptoms and HRQoL in patients with PsA.

Abstract AB0905 – Table 1. PROMIS10 Scores and Impact of PsA on Work by RAPID3 Disease Activity in Patients with PsA

* Disease severity classified by RAPID3 scores: £3.0=low remission; 3.1 to 6.0=moderate remission; >6.1=high severity.

Conclusions: RAPID3 and PROMIS10 physical health T-scores were strongly correlated in patients with PsA. PROMIS10 mental health scores moderately correlated with RAPID3, suggesting the mental health questions add a different construct. PROMIS10 and RAPID3 are relatively short questionnaires that can be used in the real world to track and monitor disease symptoms and HRQoL in patients with PsA.
Objectives: To describe the long-term (5 year) efficacy and safety of APR monotherapy in DMARD-naive subjects with active PsA from the phase 3 PALACE 4 study.

Methods: Subjects were randomised (1:1:1) to receive placebo, APR 30 mg BID (APR30), or APR 20 mg BID (APR20). At Week 16, subjects were eligible for early escape; placebo subjects were re-randomised to APR treatment, and APR subjects remained on their assigned dose. At Week 24, all subjects remaining on placebo were re-randomised to APR. Double-blind treatment continued to Week 52, with open-label APR treatment for up to 4 additional years.

Results: A total of 527 subjects were randomised and received ≥1 dose of placebo (n=176), APR30 (n=176), or APR20 (n=175). Among subjects randomised to APR30 at baseline, 45.5% (80/176) completed the Week 260 visit. At Week 52, modified ACR20, ACR50, and ACR70 responses were achieved by 58.0%, 29.8%, and 15.5% of subjects receiving APR30, respectively, regardless of when APR was started (baseline, Week 16, or Week 24). Rates of improvement in PsA signs and symptoms and physical function were sustained up to Week 260 with continued APR30 treatment, including reduction in SJC of 84.8% and in TJC of 76.4% (table 1). At Week 260, 65.8%, 39.0%, and 20.3% of subjects achieved a modified ACR20, ACR50, and ACR70 response, respectively, and 71.2% of APR30 subjects with baseline enthesitis achieved a MASES of 0; 95.1% with baseline dactylitis achieved a dactylitis count of 0. At Week 260, 52.9% of subjects achieved a HAQ-DI MCID ≥0.35, 60.3% achieved a PASI-50 response, and 47.6% achieved a PASI-75 response (table 1). No new safety concerns were identified with APR up to 260 weeks. During Weeks>208 to>260, the most common adverse event (AEs) among APR30-exposed subjects was nasopharyngitis (6.9%). Serious AEs occurred in 5 APR30 subjects; serious infections were reported in 2 APR30 subjects (pelvic abscess and bacterial urinary tract infection), and no opportunistic infections were reported during Weeks>208 to>260.

Conclusions: APR monotherapy demonstrated sustained response or improvement in PsA signs and symptoms, including SJC and TJC, enthesitis, dactylitis, physical function, and psoriasis in the population of subjects continuing treatment over 260 weeks. APR continued to demonstrate a favourable safety profile and was generally well tolerated.

AB0907 TREATMENT PATTERNS IN PSORIATIC ARTHRITIS IN US AND EUROPE: RESULTS FROM A REAL-WORLD INTERNATIONAL SURVEY

Background: With the availability of a greater range of Psoriatic Arthritis (PsA) treatment options, it is increasingly necessary to understand their use and impact on disease control in real-world practice.

Objectives: To assess treatment patterns and their impact on clinical outcomes among PsA patients currently receiving conventional/targeted synthetic disease-modifying anti-rheumatic drugs (cs/tsDMARD) or biologic DMARD (bDMARD).

Methods: A point in time survey was conducted in 2015 across the US, France, Germany, Italy, Spain and UK. Patients had physician-confirmed PsA and had to have been receiving their current cs/bDMARD (bio naive) or bDMARD (1st or 2nd line) for ≥6 months. Physicians provided information on demographics, treatment history, disease severity, clinical measures included body surface area (BSA), joint count, flare/remission status. Student t-tests, Pearson line) for

Results: 519 physicians (331 rheums, 188 derms) provided data for 2467 PsA patients, 1463 of whom met the inclusion criteria (1136 EU, 327 US). No significant differences were observed between EU and US patients in demographics (male 52.6%, mean age 49.0 years), disease duration 6.3 years; disease severity 29.1% moderate to severe. In the EU, 32.3% were patients on cs/tsDMARDs, 55.4% 1st-line bDMARD, 12.3% 2nd-line bDMARD vs 21.7%, 58.4%, 19.9% respectively in the US.

Time in months (mo) from diagnosis to first csbDMARD was similar in the EU and US (EU mean 4.7 mo; US 8.1 mo, p=0.24), from 1st cs/bDMARD to 1st bio (EU 37.4 mo; US 29.4 mo, p=0.15). Patients in the EU received more cs/ tsDMARDs prior to bDMARD initiation than US patients (mean 1.4 v 0.8; p<0.001). US patients were more likely to have bDMARD without combination cs/bDMARD (US 65.1% vs EU 52.3%; p=0.004).

Patients receiving cs/bDMARDs had a worse clinical profile than those on 1st-line bDMARD in all areas other than joint count. Patients on 2nd-line bDMARD had more symptoms, more affected joints and more likely to flare vs 1st-line bDMARD. They had more affected joints but were less likely to flare vs cs/DMARD. These findings were directionally similar in the EU and US (table 1). BSA was higher for cs/tsDMARD patients than for any bDMARD patients.

Conclusions: Only 39%-60% of patients were considered by physicians as in remission, revealing a considerable unmet need in both the EU and US in patients treated with cs/DMARDs and bDMARDs. Further research is needed to identify patients on cs/DMARDs who may be a candidate for advanced therapy and to recognise patients who might fail on bDMARD who therefore may benefit from a different therapeutic alternative.

AB0908 ABILITY OF THE REDUCTIVE X-RAY SCORE FOR PSORIATIC ARTHRITIS (REXSPA) TO DETECT CHANGE IN AN OBSERVATIONAL COHORT OF PATIENTS WITH PsA

A. Antony1, A. Allard1, G. Shaddick2, D. Jadon3, C. Cavil1,4, E. Korendowych1, N. McHugh1,4, W. Tillet1,4, *Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath; 2Mathematical Sciences, University of Exeter, Exeter; 3Rheumatology, Cambridge University Hospitals, Cambridge, 4Pharmacy and Pharmacology, University of Bath, Bath, UK

Background: The measurement of radiographic joint damage is important in characterising disease severity, progression, and prognosis in psoriatic arthritis (PsA). Existing radiographic measures are time-consuming to perform, leading to limited data collection from existing longitudinal observational studies.

Objectives: We have previously proposed a Reductive X-ray Score for Psoriatic Arthritis (ReXSPA) as more feasible method, and in this study set out to examine the sensitivity of ReXSPA in a new cohort of patients.

Methods: A retrospective sample of 28 patients who had hand and foot radiographs at 3 time points (5 years before [T0], at the time of [T1], and 5 years post [T2] commencement of anti-TNF treatment) were taken from the Bath longitudinal PsA cohort. Radiographs were scored for erosion, joint space narrowing and proliferation to calculate the Sharp-van der Heijde modified method (VDH) and ReXSPA scores. A sample of 9 radiographs were scored by all assessors (WT, AA and AA) to determine inter- and intra-rater reliability using intra-class correlation coefficients (ICC). Sensitivity to change was determined from timepoint T0 to T2 using the Standardised Response Mean (SRM) and Smallest Detectable Change (SDC).

Results: The patients’ mean age (SD) at T0 was 61 years (13.4), the mean disease duration was 11.2 years (11.14). Patients were followed up for a mean (SD) of 10.2 years (2.76). Overall inter- and intra-rater reliability for ReXSPA and VDH were 0.80 and >0.92 and 0.91 and >0.90 respectively. The median (IQR) of ReXSPA score was 8.5 (1–36) at T0, and 5 years post T2 using the Standardised Response Mean (SRM), and Smallest Detectable Change (SDC).

CERTOLIZUMAB PEGOL’S EFFECTIVENESS, RETENTION RATE AND SAFETY IN PSORIATIC ARTHRITIS. ROUTINE CLINICAL PRACTICE DATA

Background: Certolizumab pegol (CZP) is the only antiTNF pegylated without Fc fragment. CZP is the only antiTNF pegylated without Fc fragment.

Methods: Multicentric cohort of PsA patients treated with CZP according to routine clinical practice. Study approved by local Ethics Committee. Maximum time of observation was 12 months. Effectiveness variables: SJC, TJC, PtGA (Patient Global Assessment) and DAS28-CRP. Safety variables: discontinuation rate.

Results: 262 patients with PsA were included: 43.5% male, mean (SD) age 49.9 (11.9) years, mean (Q1-Q3) disease duration 6.9 (1.9–9.3) years, 14.9% of patients HLAB27 positive, mean (SD) IMC (kg/m²) 26.9 (4.7), never smokers 70.3%. Extra-articular manifestations ever: Psoriasis (90%; PASI 10 40.9%), arthritis mutilans (4.9%). 37.3% of the PsA patients had bone erosions and 3% arthritis mutilans. 48.9 patients received 1 prior csDMARD and 52.1% at least 2 csDMARD. Prior bDMARD: 28.4% none; 38.1% 1, 33.5%> 2. 29.6% of PsA patients received CZP in monotherapy. Mean time on treatment with CZP 10 months.

Conclusions: The RexSPA is a reliable and sensitive alternate scoring method for the detection of radiographic progression in an observational cohort of patients with PsA, but not as sensitive to change as the VDH method.

*p<0.001, Wilcoxon’s test

Conclusions: In this study of routine clinical practice CZP was effective in patients with PsA, with a significant decrease in DAS28-CRP and the percentage of patients with enthesitis and dactylitis. The retention rate of certolizumab pegol was not affected by the number of previous biologics treatments.

LONG-TERM GOLIMUMAB RETENTION RATE IN PATIENTS WITH PSORIATIC ARTHRITIS: IS CONCOMITANT DMARD IMPORTANT?

B. Serrano-Benavente1,2, C.M. González-Fernández1,2, L. Valor1, I. Janta1, R. D. González-Benitez2, C. Sáenz Tenorio1, J.C. Nieto-González1, J.O. Ováles-Bonilla1, J. Martínez-Barrío1,3, M. Correya Plaza1, L. García-Montoya1, F.J. López-Longo1, I. Montagudo Saez1.

Background: The efficacy of Golimumab treatment in psoriatic arthritis (PsA) patients has been widely documented.

Objectives: The aim of this study was to analyse the long-term retention rate of golimumab and to identify independent predictors of drug retention in patients with PsA including concomitant synthetic disease-modifying antirheumatic drugs (sDMARD).

Methods: Prospective monocentric cohort of PsA patients treated with golimumab according to clinical practice. Study was approved by local Ethics Committee. Demographic and clinical variables were analysed with Cox proportional hazard regression model.

Results: 48 patients were included, 20/48 (41.7%) oligoarticular, 19/48 (39.6%) polyarticular and 9/48 (18.7%) with peripheral and axial PsA. The baseline characteristics of the patients are shown in table 1.

Follow-up time was 89.25 patients-year. Mean survival time was 40.3 months (95% CI: 32.0–48.5). Age, mean evolution time and previous biological use were significant in the univariate analysis. Concomitant sDMARD had no influence on golimumab retention rate (HR: 1.3; 95% CI: 0.5–3.2; p: 0.6). Figure 1. When golimumab was used as first or second biologic treatment, it had a better retention rate than when it was used as third or fourth, but did not reach statistical significance (HR: 2.3; IC 95%: 0.8–6.2; p: 0.4). 18/48 patients (37.5%) withdrew golimumab treatment. 13/18 (72.2%) due to lack of efficacy, 1/18 (0.6%) due to adverse events and 4/18 (22.2%) due to other reasons.

CONCLUSIONS: Real-world Golimumab retention rate in patients with PsA was good and did not depend on concomitant treatment with sDMARD. When used as first or second biologic, Golimumab retention rate tended to be better.

THE RELATIONSHIP BETWEEN NEUROPATHIC PAIN AND DISEASE ACTIVITY, SLEEP, FATIGUE, QUALITY OF LIFE IN PATIENTS WITH PSORIATIC ARTHRITIS

C. Unal1, F. Ulutatar1, M.T. Duruaz2, 1PMR Department; 2PMR Department, Rheumatology Division, Marmara University School of Medicine, Istanbul, Turkey.

Background: Neuropathic pain (NP) is composed of several abnormal sensations, including burning, prickling hyperalgesia and allodynia. NP is a common problem in rheumatic diseases such as rheumatoid arthritis and ankylosing spondylitis due to inflammatory processes. Previous studies showed that NP in other rheumatic diseases had a negative influence on sleep and quality of life.1, 2

Objectives: To examine the relation of neuropathic pain symptoms in Psoriatic Arthritis (PsA) with demographic, clinical and functional parameters.

Methods: PsA patients according to CASPAR criteria were recruited into the study. Demographic and clinical parameters were noted. PainDETECT measurement tool was used for evaluation of NP. Physical examination such as manual muscle testing and sensory examination for hyperalgesia and allodynia was performed (pinprick and light touch test). Disease Activity Score-28 (DAS-28) was noted for disease activity. Associations of NP with quality of life, sleep and fatigue were analysed by filling out Psoriatic Quality of Life (PsAQoL), Pittsburgh Sleep Quality Index (PSQI), Multidimensional Assessment of Fatigue (MAF). PainDETECT scores were categorised as no NP (<12 points), ambiguous NP (13–18 points), probable NP (>19 points). Group analysis was performed with Independent-Samples Kruskal-Wallis test. Spearman correlation coefficient (rho) was used for correlations between functional parameters. p<0.05 was accepted as significant.

Results: Forty-eight PsA patients (31 female, 17 male) with a mean age 50.4 years (SD:10.0) and mean disease duration 92.2 months (SD: 90.2) were recruited into the study. The number of patients with ambiguous NP was 6 patients (4 female, 2 male) and probable NP was 12 patients (10 female, 2 male). The mean scores of PSQI, PsAQoL and MAF were significantly higher in patients with NP (p<0.05). There was no difference in mean scores of DAS-28 and disease duration among groups. The correlations between PainDETECT and other functional parameters were found moderate-strong as PSQI (rho=0.43, p=0.002), MAF (rho=0.44, p=0.002), PsAQoL (rho=0.66, p=0.0005). Also, the probability of NP existence increased with the age (rho=0.40, p=0.01). There was no significant correlation between and clinical parameters such as disease duration and DAS-28 (p<0.05).

Conclusions: These findings suggest that a substantial number of PsA patients suffering from NP. The neuropathic pain symptoms are found to be associated with worse self-reported quality of life and sleep disturbances. It is important to consider the existence of NP in the assessment and treatment process of PsA.

TWO-YEAR EFFICACY AND SAFETY OF GUSELKUMAB FOR TREATMENT OF MODERATE-TO-SEVERE PSORIASIS: PHASE 3 VOYAGE 1 TRIAL

C.E. Griffiths1, K.A. Papp2, A.B. Kimball3, B. Randazzo4, Y. Wad6, S. Li4, Y. K. Sherr4, A. Blauvelt1. 1U of Manchester, Manchester, UK; 2K. Papp Clinical Research and Probit Research Inc, Waterloo, Canada; 3Harvard Medical Faculty Physicians at Beth Israel Deaconess Medical Center, Inc, Boston; 4Janssen Research and Development, LLC, Spring House; 5Oregon Medical Research Center, Portland, USA

Background: Gusekumab (GUS) is an interleukin-23 inhibitor recently approved in the US for treatment of moderate-to-severe psoriasis.

Objectives: Efficacy and safety data for up to 100 wks of GUS treatment are reported.

Methods: In the VOYAGE 1 Phase 3, randomised, double-blind, placebo/active comparator-controlled trial, 837 patients were randomised at baseline to placebo (PBO) at wks0/4/12 then GUS 100 mg at wks16/20 and q8w (n=174); GUS at wks0/4/12, and q8w (n=329); or adalimumab (ADA) 80 mg at wk 0, 40 mg at wk 1, and q2w through wk47 then GUS at wk52 and q8w (n=334). Efficacy was assessed using nonresponder imputation through wk48 and treatment failure rules from wks52–100.

Results: Among patients randomised to GUS, or PBO—GUS at wk16, efficacy (PASI, Psoriasis Area and Severity Index; IGA, Investigator’s Global Assessment) was maintained from wks52–100 with continuous GUS treatment. Among those
randomised to ADA (–GUS at wk52), efficacy improved from wk52–100. Similar findings were observed for patient-reported outcomes (PSSD, Psoriasis Symptom and Signs Diary; DLQI, Dermatology Life Quality Index; table 1). Through wk100, there were no disproportionate increases in rates of Adverse Events (AEs) compared with rates through wk48. Serious AE rates were low and remained stable; no TB, opportunistic infections, or serious hypersensitivity reactions were reported.

Bone mineral density and fracture

Conclusions: In patients with PA, the presence of psoriasis skin involvement correlates with higher 25OH-D3 serum levels. This finding could be explained by the treatment received in these patients for moderate-severe skin involvement, which includes topical vitamin D analogues and phototherapy that could increase 25OH-D3 serum levels. After oral supplements, there was no statistically significant difference in the percentage of patients that reached sufficiency levels in both groups.

BONE MINERAL DENSITY AND FRACTURE FREQUENCIES IN PATIENTS WITH PSORIASIS OR PSORIASIS ARTHRITIS

D. Freier1, K. Zeiner1, R. Biesen1, E. Wieve1, T. Buttgereit2, S. Hermann1, F. Buttgerlei1, 1Rheumatology and clinical Immunology, 2Dermatology, Charité University Medicine, Berlin, Germany

Background: Reports on the prevalence of osteoporosis, osteoporotic fractures and risk factors for osteoporosis in patients with Psoriasis or Psoriasisarthritis are scarce, and the published results on this are, at least in part, contradictory. Additionally, there is no firm understanding of the impact of potential risk factors such as smoking and low Vitamin D (Vit D) levels have on the occurrence of osteoporotic fractures in this patient group.

Objectives: Rh-GIOP is an ongoing prospective study monitoring glucocorticoid (GC)-induced osteoporosis of rheumatic patients, established in 2015 at the Charité University Hospital. To date, the database comprises clinical data and bone mineral density data measured by dual x-ray absorptiometry (DXA) of 592 patients with inflammatory rheumatic diseases. (ClinicalTrials.gov Identifier NCT02719314) The objective of this cross-sectional analysis was to evaluate the prevalence of osteoporosis and frequency of fractures in patients with Psoriasis (PSO) or Psoriasisarthritis (PSOA). Additionally, smoking and Vit D status were investigated as possible risk factors for low BMD.

Methods: We evaluated the initial visit of 55 patients with PSO (80% female) or PSOA (60% female). Descriptive analyses were performed, and values are displayed as means and standard deviations. For subgroup analyses non-parametric tests were used.

Results: Overall mean age was 60 years (±12 years), and 69% of the patients were female. The mean disease duration was 16±13 years and patients generally showed a good functional status as quantified by the Health Assessment Questionnaire (HAQ) mean: 1.0±0.8. While osteoporosis and osteopenia were present in 16% and 38%, respectively, osteoporotic fractures were found in 33% of all patients. However, the family history for osteoporosis was positive in 20% of the patients. The prevalence of osteopenia and osteoporosis was higher in PSO compared to PSOA patients (70% vs. 45%) without reaching statistical significance. 27% of all patients were treated with glucocorticoids: mean daily dose 3±8 mg, mean cumulative dose (GCCD) 10.9±20.3 g. No significant difference was seen comparing medians of BMD in patients with a GCCD >10 g versus a GCCD <10 g. In terms of risk factors, 27% were smokers and 32% former smokers. 60% of all patients showed Vit D levels<75 nmol/L. Yet, in subgroup analyses neither smoking nor Vit D deficiency could be identified to have a measurable effect on the BMD. The mean body mass index (BMI) was 28.9 (±5.9), and a higher BMI correlated positively with BMD (p=0.01).

Conclusions: In our patient cohort, the GCCD does not have a measurable impact on the BMD. Additionally, according to current literature the prevalence of osteoporosis seems to be in the same range as in the normal population. Keep in mind the (still) small number of patients, neither smoking nor Vit D deficiency could be identified as possible risk factors for low BMD, but further investigations are necessary to corroborate these observations.

REFERENCE:

Efficacy and Predictive Factors of Clinical Response to TNF Inhibitors in Patients with Axial and Peripheral Psoriatic Arthritis

D. Benavent1, C. Plasencia1, V. Navarro-Compán1, B. Hernández-Breijo2, A. Villalba1, D. Peleado1, M. de Diego1, P. Boga1, E. Fernández1, A. Balasa1.
1Rheumatology; 2Immunology, Hospital Universitario La Paz, Madrid, Spain

Background: Patients with psoriatic arthritis (PsA) may have predominant axial (axPsA) or peripheral (pPsA) manifestations. The development of TNF inhibitors (TNFi) has changed the course of PsA. However, most published data is focused on pPsA but almost no data is available for TNFi response in axPsA.

Objectives: to analyse the efficacy and the predictive factors of clinical response in patients with axPsA and pPsA starting treatment with TNFi in clinical practice.

Methods: An observational study analysing data from a prospective cohort including 93 patients (pts) with axPsA or pPsA treated with TNFi from 2002–2018 was conducted. Demographic information, disease activity indexes (ASDAS for axPsA and DAS28 for pPsA) and laboratory tests were collected before starting TNFi (baseline visit) and 6 months later (6 m visit). At 6 m, the percentage of pts achieving inactive disease (ASDAS <1.3) for axPsA or remission (DAS28 <2.6) for pPsA as well as the percentage of pts achieving clinical improvement (defined as ASDAS-clinically important improvement=delta-ASDAS >1.1 or delta-DAS28 >1.2) were determined. Baseline predictor factors of inactive disease/remission and clinical improvement at 6 m were identified using a univariable and multivariable binary regression models adjusted for confounder factors.

Results: Of out 93 included pts, 45 pts had predominant axPsA and 48 pPsA. Administered TNFi was etanercept for most pts (42%), infliximab in 29%, adalimumab in 22% and golimumab in 7%. Baseline characteristics are shown in table 1. Male sex was more frequent in axPsA vs pPsA (62% vs 42%; p=0.04, respectively). In axPsA, 55% clinically improved and 32% pts achieved inactive disease. After multivariable analysis, male gender (OR 25.8, p=0.01) and higher baseline ASDAS (OR 6.3, p=0.01) were associated as independent predictors of clinical improvement at 6 m. Also, male gender (OR 15.7, p=0.03) and lower BMI (OR
Conclusions: In clinical practice, 1 out of 3 pts with PsA is on remission 6 m after initiating a TNFi, and 1 out of 2 clinically improve; both proportions are similar for axPsA and pPsA. Male gender, higher baseline disease activity and lower BMI are associated with more probability to achieve inactive disease or an important clinical improvement in axPsA.

Disclosure of Interest: None declared

No significant differences were found in reference to the presence of extra-articular involvement (dactylitis, uveitis, psoriasis, onychopathy), nor in reference to the presence of related family history (spondyloarthritis, psoriasis, uveitis).

Conclusions: Patients with axial PsA with sacroiliitis according to ASAS criteria of positive MRI/unilateral grade II X-ray sacroiliitis presented more peripheral joint involvement, and less association with HLA B27 compared to patients who did meet mNY criteria. A smaller proportion of patients with axial PsA that meet the mNY criteria suggests a less aggressive structural sacroiliac involvement.

Disclosure of Interest: None declared
MTX mono-therapy, combination therapy with MT + adalimumab 40 mg s/c every 2 weeks was started. At baseline and after 1 year of therapy the following PROs were analysed: trends in fatigue (according to FACIT and RAPID3) were studied in 64 pts, trends in patient’s global disease activity (PGA) and in patient’s pain VAS were studied in 78 pts, trends in levels of anxiety and depression (HADS) were studied in 49 pts. The data acquired was analysed with the use of Spearman’s correlation.

Results: After 1 year of therapy, there was a significant improvement in the following scores: anxiety changed from 5.7±3.1 to 4.3±3.2 (p<0.003), fatigue from 35.3±9.8 to 41.3±9.9 (p<0.001), RAPID3 from 13.4±5.1 to 6.2±5.2 (p<0.001), PGA from 56.0±17.8 to 18.9±17.1 (p<0.001), pain from 53.7±18.6 to 16.9±16.6 (p<0.001). Depression scores had also changed though not significantly: from 3.8 ±3.0 to 3.2±3.1 (p<0.235). The dynamics of anxiety and depression indexes correlated with the dynamics of fatigue (r=0.64 and r=0.39, accordingly), as well as with RAPID3 indexes (r=0.36). Correlation of the dynamics of PROs indexes with DAS (r=0.45 and DAS28 (r=0.41) activity reduction was found. Association of RAPID3 dynamics with the achievement of remission according to DAS (p<0.001) and DAS28 (p<0.001) was detected. Interrelation between RAPID3 dynamics and the achievement of MDA (p<0.001) was found. Correlation between dynamics of anxiety and depression indexes and the reduction of tender joint count (TJC) was found (r=0.38 and r=0.36, accordingly). There is correlation between the dynamics of fatigue indexes and TJC, swollen joint count (SJC) and PGA (r=0.30, r=0.25 and r=0.35, accordingly). Dynamics of RAPID3 correlated with TJC and SJC dynamics (r=0.33, r=0.25), as well as PGA and pain dynamics (r=0.49 and r=0.58). PGA and pain dynamics correlated with TJC and SJC dynamics (r=0.34 and r=0.26, r=0.43 and r=0.39, accordingly).

Conclusions: The T2T strategy in the Russian cohort of peripheral early PsA pts demonstrated the improvement of PROs indexes and decrease in PsA activity. Interrelation between the improvement of psychological status according to PROs (anxiety, depression and fatigue) and improvement in joint status (TJC and SJC) was found. RAPID3 is a reliable tool for evaluating patient’s status: RAPID3 indexes correlate with the achievement of MDA and DAS/DAS28 remission.

VALIDATION OF PROTEOMIC BIOMARKERS OBSERVED IN MONOZYGOTIC TWINS CONFIRMS TWO PROTEINS ASSOCIATED WITH PSORIATIC DISEASE

E. Genereu1, N. Isailovic1, A. Cerbelli1, F. Sacrin1, M. De Santis1, M. Meroni1, G. M. Guidelli1, M. Caprioli1, A. Costanzo2,3, C. Selmi1,4. 1Rheumatology and Clinical Immunology, 2Dermatology Unit, University of Milan, Milan, Italy

Background: Skin psoriasis affects 3% of the general population and as much as 20%-40% of patients will develop psoriatic arthritis (PsA), with the two conditions representing a clinical and immunological continuum within a prototype for chronic inflammation. Different from most rheumatic diseases, no serum autoantibody is associated with PsA, and there are currently no biomarkers for an early diagnosis and prediction of PsA onset in psoriasis, frequently causing a delayed diagnosis. Monozygotic twins discordant for psoriasis/PsA represent a unique setting to investigate the influence of environmental and stochastic factors on disease phenotype. Through a high-throughput proteomic analysis (SomaLogic) we have previously identified a set of 13 proteins differentially expressed in the serum of monozygotic twins discordant for PsA versus controls, in a recently described and from 70 unrelated patients with psoriatic disease (psoriasis without PsA 34%-49%, PsA with/without psoriasis 36%-51%; women 46%, median age 52 years, interquartile range 41–59) followed at Humanitas Research Hospital, and 25 healthy subjects (52% women, median age 52 years, IQR 44–62). Candidate serum proteomic biomarkers obtained by SomaLogic analysis were validated using commercially available ELISA kits and proteins are herein anonymized due to a pending patent request.

Results: We found a significant correlation between SomaLogic results in monozygotic twins and ELISA results in unrelated psoriatic cases in the serum levels of 2 proteins (figure 1), which are involved in inflammatory and immune response, and one has been previously reported in psoriatic plaques. Four proteins showed a significantly different expression between psoriasis and PsA versus controls, in particular two proteins have a potential role in disease pathogenesis, as protein #1 acts as cell-surface receptor and regulates differentiation, proliferation and survival of dendritic cells, while protein #2 is involved in regulation of UV radiation-induced apoptosis and protein folding.

Conclusions: Two serum proteomic biomarkers, previously identified in a cohort of monozygotic twins discordant for psoriatic disease, can discriminate psoriatic disease, thus representing potential biomarkers of disease and possibly playing a pathogenetic role in disease.

TUMOUR NECROSIS FACTOR INHIBITORS PERSISTENCE IN PSORIATIC ARTHRITIS PATIENTS

E. Vieira-Sousa1, M. Eusébio2, P. Ávila-Ribeiro1, N. Khmelnikis1, A.R. Machado1, T. Martins Rocha1, M. Bernardes2, D. Santos-Faria1, J. Leite Silva1, H. Santos1, C. Migueis2, P. Carvalho2, T. Costa1, L. Teixeira1, T. Meinhos1, P. Niero2,3, M. J. Santos4. 1Rheumatology and Metabolic Bone Diseases Department, Hospital de Santa Maria, CHLN and Rheumatology Research Unit, Instituto de Medicina Molecular, Faculty of Medicine, University of Lisbon, Lisbon; 2Portuguese Society of Reumatology, Lisbon; 3Rheumatology Department, Centro Hospitalar São João do Porto and Faculdade de Medicina da Universidade do Porto, Porto; 4Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima; 5Instituto Português de Reumatologia, Lisbon; 6Rheumatology Department, Hospital Sénior de Vila Nova de Gaia, Vila Nova de Gaia; 7Rheumatology Department, Hospital de Évora, Évora, Portugal; 8Rheumatology Department, Hospital Garcia de Orta, Almada; 9Rheumatology Department, Centro Hospitalar do Baixo Vouga, Aveiro, Aveiro, Portugal

Background: Tumour necrosis factor inhibitors (TNFi) lead to a dramatic improvement in the management of psoriatic arthritis (PsA). Nevertheless, a significant proportion of patients still do not respond and/or are intolerant to TNFi, requiring treatment switch for an adequate control of disease activity.

Objectives: To assess TNFi’s drug retention and the main reasons for TNFi discontinuation in PsA patients.

Methods: This was a non-interventional study of PsA patients registered at the Rheumatic Diseases Portuguese Registry (Reuma.pt), with at least one TNFi prescription. Drug retention for a first, second and third line TNFi was assessed by Kaplan-Meier survival analysis. The reasons for discontinuation were described as frequencies.

Results: 750 PsA patients were included, with a mean age of 47.6 years (+11.6) and 50.3% (n=377) female. 200 patients (26.7%) treated with adalimumab, 335 (44.7%) with etanercept, 114 (12.2%) with golimumab and 101 (13.5%) with infliximab, as first line TNFi. The majority (67.6%) were receiving concomitantly conventional synthetic disease modifying anti-rheumatic drugs (62.3% MTX) and 33.9% corticosteroids. The mean duration of TNFi retention was of 48.5±40.1 months, when treated with a 1st TNFi, decreasing to 35.5±33 months for the 2nd TNFi, and to 22.7±22.9 months for the 3rd TNFi (figure 1). After being treated with a 1st TNFi, the majority of discontinuers (35.9% of the total population), withdrew due to lack of effectiveness (53.9%) and due to adverse events (24.4%). The rates of discontinuation for the 2nd and 3rd TNFi were of 39% and 54%, respectively. Lack of or loss of effectiveness and adverse events were maintained the two main reasons of withdrawal for the 2nd (62.3%; 21.6%) and 3rd TNFi (63%; 22.2%).
Conclusions: PsA patients registered at Reuma.pt treated with a 1st TNFi had an overall drug retention of 49 months. We observed a decrease in the average retention of TNFi therapy of 13.0 months in PsA patients who switched to a 2nd TNFi or a 3rd TNFi. Lack or loss of response were the main reason for TNFi discontinuation, independently of TNFi position, responsible for more than half of the discontinuations. The observed short survival of TNFis in PsA, and the inability to maintain drug expectancy when switching to another TNFi, highlights the limitations from recycling between TNFis when aiming at long-term disease remission.

AB0921

IMPACT OF BASELINE DEMOGRAPHICS, DISEASE ACTIVITY AND CONCOMITANT MEDICATION ON AMERICAN COLLEGE OF RHEUMATOLOGY 20 RESPONSE RATE AND HEALTH ASSESSMENT QUESTIONNAIRE-DISABILITY INDEX SCORE WITH TOFACITINIB IN ACTIVE PSORIATIC ARTHRITIS: A POOLED SUBGROUP ANALYSIS OF 2 PHASE 3 STUDIES

F. Behrens1, J. Gomez-Reino2, P. Nash2, D.D. Gladman4, O. FitzGerald5, C. Ritchlin6, E. Kudlac7, J. Wu1, C. Wang7, A.B. Romero8. 1CIRI/Rheumatology and Fraunhofer Institute IME, Translational Medicine and Pharmacology, Goethe University, Frankfurt, Germany; 2Hospital Clinico Universitario, Santiago de Compostela, Spain; 3University of Queensland, St Lucia, Brisbane, Australia; 4University of Toronto, Toronto, ON, Canada; 5St Vincent’s University Hospital, Dublin, Ireland; 6University of Rochester Medical Center, Rochester, NY; 7Pfizer Inc, Groton, CT, USA; 8Pfizer Inc, Barcelona, Spain

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). In a pooled analysis of data from 2 Phase 3 trials in patients (pts) with active PsA, tofacitinib 5 and 10 mg twice daily (BID) significantly improved American College of Rheumatology (ACR) 20 response rates vs placebo (PBO) (50.0, 53.0 vs 28.0%, respectively; p<0.001) and least squares mean (LSM) change from baseline (BL) in Health Assessment Questionnaire-Disability Index; PsA, psoriatic arthritis; pts, patients; ROW, rest of world (Brazil, Mexico and Taiwan); SPARCC, Spondyloarthritis Research Consortium of Canada (enthesitis index)

Objectives: To compare the efficacy of tofacitinib 5 and 10 mg BID vs PBO in predefined pt subgroups based on differences in BL demographics, disease activity and concomitant medication.

Methods: This was an analysis of pooled efficacy data from 2 Phase 3, randomised, double-blind, PBO-controlled studies (OPAL Broaden [12 months; NCT01877668] and OPAL Beyond [6 months; NCT01882439]) in pts with active PsA (defined as ≥3 swollen and ≥3 tender joints). Pts in OPAL Broaden were tumour necrosis factor inhibitor (TNFi)-naive with an inadequate response (IR) to ≥1 conventional synthetic disease-modifying antirheumatic drug (csDMARD). Pts in OPAL Beyond had an IR to ≥1 TNFi. Pts were randomised to receive tofacitinib 5 or 10 mg BID, subcutaneous adalimumab 40 mg every 2 weeks (OPAL Broaden; data not included) or PBO. Pts continued to receive a stable dose of a single csDMARD. ACR20 response rates and LSM change from BL in HAQ-DI at Month 3 (primary endpoint data) were evaluated by subgroup category (demographic and disease characteristics at BL or at screening). Analyses were based on the full analysis set (table 1).

Results: In total, 238, 236 and 236 pts received tofacitinib 5 mg BID, 10 mg BID, or PBO, respectively. Across all subgroups analysed, tofacitinib 5 and 10 mg BID were generally associated with greater improvements at Month 3 in ACR20 and change from BL in HAQ-DI score than PBO (table 1). In pts classified as current smokers, slightly lower ACR20 response rates and similar changes from BL in HAQ-DI score to corresponding PBO at Month 3 were observed relative to never- or ex-smokers; however, the sample size was small.

Conclusions: In this analysis of pooled data from 2 Phase 3 studies in pts with active PsA, tofacitinib 5 and 10 mg BID consistently improved efficacy at Month 3 compared with PBO across all predefined subgroups evaluated, with the exception of current smoking; however, as this was not a pre-specified analysis and some subgroups (including smoking status) were small, interpretation should be made with caution.
The aim of this study is to investigate its relationship with disease activity in patients with psoriatic arthritis (PsA) by using several parameters including BASFI and BASMI.

Methods: This study included patients with PsA followed in the Rheumatology outpatient clinic at Dokuz Eylul University. Age-matched patients with Takayasu arteritis (TA), an inflammatory systemic disease, were enrolled as diseased controls.

Results: More patients with MetS had higher BASDAI, BASFI, BASMI, VAS, ASqOL, CPDAI, respectively, p<0.001). In the comparison of PsA patients with and without MetS, no differences were found regarding treatment frequencies of NSAIDs, glucocorticoids, DMARDs and anti-TNFs.

Conclusions: This study demonstrates a higher prevalence of MetS in PsA patients compared to TA. It also suggests that MetS might be associated with high disease activity and more severe disease especially in patients with axial involvement.

Disclosure of Interest: None declared

AB0922 METABOLIC SYNDROME IS ASSOCIATED WITH ACTIVE DISEASE IN PSORIATIC ARTHRITIS AND MAY CONTRIBUTE TO DEVELOPMENT OF SYNDROMEPHYES

P. Sanç1, G. Kenar1, B. Zengin2, S. Uslu1, A. Koken2, H. Yarkani2, H. Ellidokuz2, G. Can1, M. Birlik2, F. Onen1

Background: An increased prevalence of metabolic syndrome (MetS) has been reported in psoriatic arthritis (PsA) suggesting an association between the inflammation and MetS.

Objectives: The aim of this study is to investigate its relationship with disease activity in patients with PsA. We also evaluated whether an association exists between MetS and axial involvement in PsA.

Methods: This study included patients with PsA followed in the Rheumatology outpatient clinic at Dokuz Eylul University. Age-matched patients with Takayasu arteritis (TA), an inflammatory systemic disease, were enrolled as diseased controls. The NCEP-Act III criteria were used to identify subjects with MetS. Disease activity was assessed in patients with PsA by using several parameters including BASDAI, ASDAS, VAS, patients’ and physician’s global, tender and swollen joint assessment (28/68), DAS28, DAPSA, CPDAI and SPARC Enthesitis Index. ESR and serum CRP levels were measured. BASFI and BASMI were used to evaluate functional status and HAQ, ASQoL and DLQI to evaluate health and quality of life.

Results: There were 104 PsA patients (83.5% F; mean age: 50.9±13.0 years) who fulfilled the CASPAR criteria and 28 TA patients (89% F, mean age: 46.3±9.1 years) who fulfilled the ACR 1990 criteria. The prevalence of MetS was found to be considerably higher in PsA patients compared to TA patients (45.2% and 21.4%, respectively, p<0.001).

Conclusions: This study demonstrates a higher prevalence of MetS in PsA patients compared to TA. It also suggests that MetS might be associated with high disease activity and more severe disease especially in patients with axial involvement.

Disclosure of Interest: None declared

AB0923 AUTONOMIC DYSFUNCTION IN PSORIATIC ARTHRITIS PATIENTS AND PSYCHO-EMOTIONAL DISORDERS FREQUENCY

I. Biaginina1, O. Rebrova1, A. Blagodareiko1, N. Budova1, I. Pokryshka2

Background: Progressive autonomic dysfunction syndrome development is a characteristic for the most of immune inflammatory processes. Pain syndrome chronization in patients with psoriatic arthritis (PsA) is one of the leading factors contributing to the development of psycho-emotional disorders. They, in turn, exacerbate the disorders of the autonomic nervous system.

Objectives: to evaluate function of the autonomic in PsA patients and the presence of psycho-emotional disorders in them

Methods: 73 patients with PsA (≥5 SJC and ≥5 TJC; CRP<0.3 mg/dL) were examined by psycho-emotional testing using the Spielberger anxiety and Hamilton depression scales. Autonomic disorders were detected by "Vein-Patient"-VP questionnaire, filled by the patient (when more than 15 points – autonomic dysfunction is possible (AD)) and "Vein-Doctor"-VD questionnaire, filled by the doctor (more than 25 points – confirmation of the presence of AD); studied the general indicators of heart rate variability (HRV) – mode (Mo), mode amplitude (AMO), autonomic equilibrium index (AEI), activity index of regulatory systems (AIRS); spectral characteristics – standard deviation of normal RR intervals (SDNN); square root of the mean of the sum of the squares of the differences between consecutive RR-intervals (RMSSD) and the ratio of balance between sympathetic and parasympathetic nervous systems (LF/HF) of autonomic nervous system (ANS). All the patients received MTX in a stable dose for 6 months at least, prior the time of the study.

Results: in 39 PsA patients (53.4%) increased reactive anxiety (37.0±1.5 points) and personal anxiety (45.4±1.5 points) levels were determined as results of testing. They made up the 1st observation group, and the remaining 34 patients – the 2nd observation group. In the first group, according to the questionnaire VP and VD more significant excess of the norm was defined (19.7±0.54 points and 29.8±0.77 points respectively) than in the 2nd group (16.9±0.62 and 27.1±0.8 points).

Conclusions: Emotional disorders of the anxiety-depressive spectrum contribute to the regulatory mechanisms tension increase and adaptive capabilities

REFERENCE:
Efficacy of Subcutaneous Ustekinumab Therapy in Patients with Psoriatic Arthritis: A Single Centre-Study

Background: Ustekinumab is a monoclonal antibody that inhibits IL-12 and 23 and has demonstrated efficacy and safety for the treatment of patients with psoriatic arthritis, plaque psoriasis and Crohn’s disease.

Methods: Descriptive, prospective, longitudinal and open study of 66 patients diagnosed with psoriatic arthritis: 63 patients received subcutaneous USTE 45 mg and 3 patients received USTE 90 mg every 12 weeks, both groups received a first dose of induction according to technical specifications. The following variables were collected: age, sex, years of evolution, previous treatment with Synthetic Disease Modifying Anti-Rheumatic Drugs (DMARDs) and/or biologic DMARD, counting of painful and swollen joints, determination of C-reactive protein, presence of dactylitis, enthesopathy and cutaneous psoriasis. Clinical efficacy was evaluated by EULAR response criteria and Disease Activity Score (DAS28) according to low activity criteria (DAS28 >2.6 –3.2) and remission clinical activity (DAS28 <2.6) at 6 and 12 months of treatment. Efficacy was compared between 2 subgroups; one group was: patients with USTE monotherapy vs USTE in combination therapy with DMARDs and the other group was: naïve patients vs patients who received previous treatment with biologic DMARD. Enthesitis affection was evaluated with the MASES index.

Results: 66 patients were included, 51.5% were female. The mean age was 47.2 ±11.3 years and the mean disease duration was 6±7.76 years. USTE was prescribed in 44% as a first line therapy and was administered in combination with DMARDs in 51.5% of the patients (mostly, methotrexate). In our cohort, 74.2% of patients had exclusively peripheral involvement, 10.6% had axial involvement and 15.2% had mixed involvement. 21% of our patients had dactylitis and 36% enthesitis, as well as cutaneous psoriasis (74%) and onicopathy (42%). At 6 and 12 months of treatment, we observed a statistically significant decrease in the count of painful and swollen joints, in the DAS28 index and in the MASES index. DAS28 low disease activity rates were 38% at 6 months and 21% at 12 months of treatment. DAS28 remission rates were 21% and 14% at 6 and 12 months respectively. When comparing efficacy by subgroups, we observed higher EULAR response rates in patients with USTE in combination therapy with DMARDs (figure 1) and biologic DMARD-naïve patients (figure 2) at 6 and 12 months of treatment.

Conclusions: Ustekinumab is effective for the treatment of psoriatic arthritis and constitutes an alternative to treatment with anti-TNFα. The dose of Ustekinumab 90 mg may improve the response to treatment in some patients, but we would need a greater number of studies in clinical practice.

Comparison of Psoriatic Arthritis Therapeutic Targets – PSA-MDA and DAPSA Remission/Low Disease Activity in Patients Treated in the Institute of Rheumatology Prague

J. Stolfi1,2, L. Sedova1,2, Z. Mares1. 1Institute of Rheumatology; 2Clinic of Rheumatology, First Medical Faculty, Charles University, Prague, Czech Republic

Background: According to the Czech Society of Rheumatology guidelines for therapy and monitoring of psoriatic arthritis from 20161 which are based on the EULAR recommendations 2015(2) the target of the therapy is to attain either minimal disease activity (MDA)(3) or remission/low disease activity according to DAPSA(4). In fact, the majority of our patients have only mild skin disease and that’s why DAPSA, which is more feasible to use could be sufficient as a target of therapy, even though these two indices assess the disease from different points of view (MDA being more comprehensive, including also entheses, skin and function and DAPSA only joint disease).

Objectives: To compare the ability of these two indices in the evaluation of the response to treatment.

Methods: We compared both indices from 206 visits in 32 patients with PsA from our database of 247 patients. At first we took the patients who complied with MDA criteria and looked at what percentage of them were in remission/low disease activity, moderate, or high activity respectively at the same time. Then, we took the patients, who did not comply with MDA criteria and again looked at the level of activity according to DAPSA.

Results: In the group of patients who fulfilled the MDA criteria (5/7), 99.5% were also in the state of remission or low disease activity according to DAPSA. In only 1 case the activity was assessed as moderate and no patient was in high disease activity state. In the group of patients who did not comply with MDA criteria, 42.6% of patients were in mild disease activity state and only 57.4% of patients were in moderate, or high activity according to DAPSA – Tab. 1

105 patients fulfilled MDA criteria. EULAR response rates (%) at 6 (p=0.027) and 12 months.
Conclusions: DAPSA correlates well with MDA in patients with mild skin disease and can be used in these patients instead of MDA. In patients who fail to respond to therapy according to MDA there can be a substantial proportion of patients with mild joint disease, due to more severe skin disease and/or presence of enthesis-dies, which are nevertheless vaguely defined.

EFFECTIVENESS OF CERTOLIZUMAB PEGOL IN PSORIATIC ARTHRITIS. RELATIONSHIP WITH SMOKING STATUS AND BMI

J. Campos Esteban1, A. Conesa Mateos2, M. Fernandez-Prada3, R. Expósito-Moliner4, P. Rubio Muñoz5, J.R. Lamua-Riazuelo6, P. Navarro-Alonso1, P. Ahijado Guzmán8, R. García-Portales8, A. Urruticoechea-Arana9, C.M. Gonzalez Fernandez10,10 on behalf of RENACER Study Group. 1Rheumatology, Hospital Universitario Puerta de Hierro, Madrid, Spain; 2Rheumatology, Hospital Clínico Universitario, Valencia; 3Rheumatology, Hospital Universitario de Guadalajara, Guadalajara; 4Rheumatology, Hospital Comarcal de Laredo, Laredo, Cantabria; 5Rheumatology, Hospital Universitari Germans Trias i Pujol, Badalona; 6Rheumatology, Hospital del Henares, Alcalá de Henares; 7Rheumatology, Hospital de Fuenlabrada, Fuenlabrada; 8Rheumatology, Hospital Virgen de la Victoria, Malaga; 9Rheumatology, Hospital Can Misses, Ibiza; 10Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Previous literature have investigated that tobacco and weight in psoriatic arthritis (PsA) is associated with a poorer response to antiTNF.

Objectives: To investigate the response and survival of Certolizumab pegol (CZP) in PsA patient in daily clinical practice according to their baseline smoking status and Body Mass Index (BMI).

Methods: Multicentric cohort of PsA patients treated with CZP according to routine clinical practice. This study was approved by local Ethics Committee. Maximum observation time was 12 months. Effectiveness variables: DAS28 (CRP), Survival rate: Kaplman-Meier.

Results: 262 patients with PsA were included: 43.5% male, mean (SD) age 49.9 (11.9) years, mean (Q1-Q3) disease duration 6.9 (1.9–9.3) years, and 14.9% of patients were HLAB27 positive. Among these, 229 (87.4%) had known smoking status (29.7% smokers and 70.3% never smokers) and 85 (32%) had known BMI (median 26.9 kg/m², SD 4.7). Statistically significant differences in DAS28 were observed at last visit comparing to baseline in both groups according to BMI and smoking status (table 1). CZP retention rate was 78.5% in non-smokers and 76.7% in smokers. In patients with BMI <25 kg/m² CZP retention rate was 78.6% compared to 78.9% in patients with BMI ≥25 kg/m² (figure 1). No statistical differences were observed in both sub-groups.

<0.05, Wilcoxon test; #p<0.001 T-Student’s test (last visit vs basal).

Conclusions: In this daily clinical practice study of patients with PsA treated with certolizumab pegol there was a significant decrease in DAS28-CRP independent of smoking status and BMI. No differences were found in the retention rate of certolizumab pegol based on these two variables.

AB0927

PROBABILITY AND IMPACT OF ACHIEVING LOW DISEASE ACTIVITY OR REMISSION IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH APREMILAST: POOLED ANALYSIS OF THE PALACE 1–3 PHASE 3 TRIALS

I. Molnár1, P.J. Mease2, F. Behrens3, A.-M. Otba4, M. Bronfman5, L. Teng5, B. Guerre2, J. Smole2,3, University of Glasgow, Glasgow, UK; 2Swedish Medical Center and University of Washington School of Medicine, Seattle, USA; 3Goethe University, Frankfurt, Germany; 4Johns Hopkins Arthritis Center and Johns Hopkins University School of Medicine, Baltimore; 5Celgene Corporation, Summit, USA; 6University of Vienna, Vienna, Austria

Background: Baseline (BL) disease characteristics and short-term response status and its implications for long-term achievement of low disease activity (LDA) or remission (REM) in pts with active psoriatic arthritis (PsA) treated with apremilast (APR) are unknown.

Conclusions: In this daily clinical practice study of patients with PsA treated with certolizumab pegol there was a significant decrease in DAS28-CRP independent of smoking status and BMI. No differences were found in the retention rate of certolizumab pegol based on these two variables.

Objectives: 1) To assess BL clinical Disease Activity for Psoriatic Arthritis (cDAPSA) levels associated with achieving cDAPSA LDA or REM at Week 52 (Wk52); 2) predict cDAPSA response categories at Wk52 based on BL or Wk16 cDAPSA; 3) assess disease activity in different PsA domains associated with cDAPSA categories at Wk52.

Methods: Pooled analyses (PALACE 1–3) were performed of pts assigned to receive APR 30 mg Bid (APR30) at BL who completed Wk52 and had cDAPSA components available to calculate responses. Pts were grouped according to the cDAPSA categories reached at Wk52 (REM: LDA, A4 – 13; MDA: 13 – 27; HDA > 27). Shifts of cDAPSA response categories from BL to Wk16 to Wk52 were reported and provided the predictability of BL status or early response to the achievement of cDAPSA categories at Wk52. Mean disease activity in core PsA domains, including swollen (0–76)/tender joint (0–78) (SJ/TJ), enthesitis (MASES), dactylitis count, Patient Global Assessment of Disease Activity (PtGA), Patient Assessment of Pain (PAP), Psoriasis Activity Severity Index (PASI), and Physical Function (HAQ) were reported longitudinally, allocated by cDAPSA category at Wk52. To better describe predictors associated with pts potentially being considered for APR in routine clinical practice, analyses were repeated removing pts in HDA at BL.

Results: 374 APR30 pts were included in the analyses. Pts who achieved MDA, LDA or REM at Wk52 indicated sustained improvements in cDAPSA over time; Means of BL cDAPSA scores at Wk52 were associated with achievement of MDA, LDA and REM at Wk52 (figure 1). At BL, pts in HDA had 42%, 24% and 5% chances of achieving MDA, LDA or REM at Wk52, respectively. Pts in MDA at BL had 41% and 12% chances of achieving LDA or REM. Pts in LDA had 20% chances of achieving REM. At Wk16, pts in HDA had 43%, 8% and 1% chances of achieving MDA, LDA or REM. Pts in MDA had 38% and 2% chances of achieving LDA or REM. Pts in LDA at BL had a 20% chance of achieving REM and pts in REM a 67% chance of staying in REM. Achieving cDAPSA LDA or REM at APR with Wk52 was associated with residual disease activity as follows: SJ (1.2 vs. 0.24); TJ (2.6 vs. 0.52); MASES (1.2 vs. 0.43); dactylitis (0.47 vs. 0); PGA (28.0 vs. 7.7); PAP (25.1 vs 7.2); PASI (4.0 vs. 2.7); HAQ (0.62 vs. 0.14). Removing pts with HDA at BL suggested that a mean cDAPSA 21 was associated with achieving LDA or REM at Wk52, corresponding to 5.5 in mean SJ and 9 in mean TJ at BL.

Conclusions: Changes of achieving LDA or REM were greater for pts in MDA at BL or Wk16 vs. HDA. Achieving LDA or REM at Wk52 with APR was associated with good outcomes across core PsA domains. Results suggest that pts with BL moderate cDAPSA disease activity may be particularly suitable for APR therapy.

AB0929

BURDEN OF SKIN AND JOINT SYMPTOMS OF
PSORIATIC DISEASE: RESULTS OF A MULTI-NATIONAL
PATIENT SURVEY

J.F. Merola1, D. Shrom2, J. Eaton2, C. Dworkin3, C. Kresbach3, B. Shah-Manek3,
J. Birt2. 1Brigham and Women’s Hospital, Boston; 2Eli Lilly and Co; 3Ipsos
Healthcare, Indianapolis, USA
Background: Psoriatic Arthritis (PsA) and Psoriasis (PsO), have a significant
impact on health-related quality of life and work productivity loss. In patients with
both PsA and PsO, the full extent of the physical and emotional burden due to
either joint related or skin related symptoms is not well understood from the perspective of the patient.
Objectives: To evaluate the patients’ perspective on the overall burden of skin
and joint related symptoms of PsA in a cross-sectional online survey.
Methods: A 20 min web based survey was developed based on analysis of 1-on1 interviews with 30 PsA patients from the US, France and Germany. The final survey contained validated instruments including the PSA Quality of Life (PSAQoL)
and Work Productivity and Activity Impairment (WPAI) questionnaires as well as
custom questions designed to capture emotional burden of PsA and its impact on
daily activities/situations. Additional data collected included demographics,
severity of PsO by patient-reported body surface area involvement (BSA), severity
of PsA by RAPID3, impact of PsO and PsA by a Patient Global Assessment scale
with focus on skin or joint symptoms. In total, 439 psoriatic arthritis (PsA) patients
from the US (68%), Germany (20%) and France (12%) were recruited to complete
the survey.
Results: Among all participants, 30% had mild and 70% had mod-severe PsA
based on RAPID-3 cutoffs, while 51% had mild and 48% had mod-severe PsO
based on BSA cutoffs. According to multiple regression analyses, severity of joint
symptoms and skin symptoms were signifcantly associated with lower PsAQoL
(p<0.0001) as was age (p<0.0001). In patients with mild joint severity, impact of
skin symptoms was significantly associated with PsAQoL (p<0.0001) as well as
age and gender (p<0.05). Joint severity and impact of joint symptoms were the
strongest contributors to the WPAI scores (p<0.05). When asked to select the 2
emotions most associated with the impact of their joint symptoms, patients most
often chose fatigue (36%), worry/concern (19%) and depression (17%), and with
respect to their skin symptoms, patients most often chose embarrassment (24%),
fatigue (23%), worry/concern (14%) and depression (12%). When asked to rate
the impact of their disease in certain scenarios or situations, more than 25% of
patients reported that their joint symptoms had a severe impact (a choice of 8, 9 or
10 on a 10-point scale with 0=no impact and 10=severe) on fatigue (32%) “leisure
activities” (26%), “how they think of themselves” (25%) and “how others felt about
them” (26%). More than 25% of patients reported that their skin symptoms had a
severe impact on fatigue (28%) “how they think of themselves” (27%),“how others
thought of them” (27%) and “making a first impression” (28%).

Conclusions: In this survey of patients with PsA, we evaluated the patient‘s perspective on the burden of both skin-related and joint-related symptoms with the
PsAQoL and WPAI as well as with a set of novel questions. Both skin and joint
symptoms have a broad and meaningful impact on patient QoL, work productivity
and patients reported a range of emotions as well as a variety of impacts on their
daily activities with respect to skin and joint symptoms. This data highlights that
there is a unique impact of PsA for each patient.

AB0930

REAL-WORLD EFFECTIVENESS AND SAFETY OF
APREMILAST IN GERMAN PATIENTS WITH PSORIATIC
ARTHRITIS: ANALYSIS OF AN ONGOING
MULTICENTRE, PROSPECTIVE, NON-INTERVENTIONAL
STUDY

J. Wollenhaupt1, T. Klopsch2, H. Strothmeyer3, S. Morys4, C. Bach4, N. NunezGomez4. 1Schoen Klinik Hamburg Eilbek, Klinik für Rheumatologie, Hamburg;
2
Praxis Dr. med. Thilo Klopsch, Neubrandenburg; 3Rheumatologische
Gemeinschaftspraxis Düsseldorf, Düsseldorf; 4Celgene GmbH, München,
Germany
Background: Apremilast (APR) has been studied extensively in phase III randomised, controlled trials. However, there is a lack of real-world evidence of effectiveness and safety in a broad population of pts with psoriatic arthritis (PsA).
Objectives: To assess effectiveness and safety of APR in pts with active PsA
from routine clinical practice settings in Germany.
Methods: In this multicentre, prospective, non-interventional study, the primary
endpoint was the proportion of pts reaching 1 point (20%) improvement from
baseline (BL) in the Physician’s Global Assessment of Disease Activity (PhGA)
score. Other endpoints included effects on tender and swollen joint counts, psoriasis-affected body surface area (BSA), enthesitis, dactylitis, Patient’s Global
Assessment of Disease Activity score (PtGA), Psoriatic Arthritis Impact of Disease
tool (PsAID), pain and pruritus. The current analysis is based on observed data.
Results: The first 202 of a planned 500 German pts receiving APR for 4 month
(1 month [V1],4 month [V2]) and 127 pts receiving APR for 7 months (V3)
were evaluated. Mean age was 54 years, mean BMI was 29 kg/m2 and 61% were
female. The mean duration of psoriasis was 25 years and of PsA was 18 years;
»30% of pts were biologic-experienced. The mean (SD) PhGA was 2.5 (0.56) at
BL. After V1, 60% of pts achieved 1 point improvement in PhGA, which
increased to 76% (V2) and 87% (V3). Mean (SD) PhGA decreased to 1.7 (0.69),
1.4 (0.73) and 1.1 (0.74) at V1, V2, and V3 respectively. Achievement of a PhGA
of 0–1 increased from 0% of pts at BL to 36.8% (V1), 65.0% (V2) and 77.2% (V3).
Median improvements in tender and swollen joint counts from BL to V3 were
57.1% and 60.0%, respectively. BSA improved from 11.4% at BL to 8.3%, 5.1%
and 3.5% at V1, V2 and V3, respectively. At BL, 48.4% of pts had enthesitis based
on Leeds Enthesitis Index; 46% reached a score of 0 by V1, 57% by V2% and
60% by V3. At BL, 27.3% of pts had dactylitis; a score of 0 was achieved by
40.0%, 66.7% and 71.9% of pts by V1, V2, and V3, respectively. BL mean PsAID
score (5.33; max=10.00) decreased to 4.40 (V1), 3.85 (V2) and 3.36 (V3).
Improvements were also seen in PtGA, overall pain and pruritus. A sub-analysis
suggests that APR was associated with greater benefits in biologic-naive pts compared with pts who previously received biologic therapies. The observed safety
and tolerability after V3 was consistent with the known overall safety profile of
APR. Common AEs in clinical trials were similar, with a lower incidence: diarrhoea
(10.4%), nausea (5.6%), headache (4.0%), and respiratory tract infection (1.2%).
Conclusions: The first results from this real-world PsA study reinforce findings
from previous clinical trials of APR. In pts with 4 and7 months of follow-up,
APR was associated with improvements in both physician-assessed and patientreported outcomes, with possibly a greater benefit in biologic-naïve compared
with biologic-experienced pts. Safety and tolerability were similar to the known
profile of APR.

PERSISTENCE WITH SUBCUTANEOUS ADMINISTERED BIOLOGICS AMONG PATIENTS WITH PSORIATIC ARTHRITIS: ANALYSES FROM A US CLAIMS DATABASE

K. Oelke1, O. Chambenoit2, A. Majhoo3, S. Gray4, K. Higgins5, P. Hur.1
Rheumatic Disease Center, Glendale, WI; 2Novartis Pharmaceuticals Corporation, East Hanover, NJ; 3Shores Rheumatology, St. Clair Shores, MI; 4Truven Health Analytics, an IBM Company, Cambridge, MA, USA

Background: Persistence with biologic therapies among patients with psoriatic arthritis (PsA) provides insight into the real-world effectiveness of biologics in routine clinical practice. With different dosing schedules and durations of action of currently available biologics, measuring persistence using varying treatment gap cutoffs may better guide physicians in their treatment decisions.

Objectives: To evaluate the persistence of subcutaneously (SC) administered biologics in patients with PsA.

Methods: Patients with ≥1 pharmacy claim for an FDA-approved SC biologic (adalimumab, certolizumab pegol, etanercept, golimumab, and secukinumab) for the treatment of PsA between 01/15/2016 and 07/31/2017 were identified in the Truven Health Analytics MarketScan Commercial and Medicare Supplemental Databases. Eligible patients were aged ≥18 years at the time of biologic initiation (index date) and continuously enrolled with medical and pharmacy claims ≥12 months prior to (baseline period) and ≥12 months after the index date. Patients had ≥1 PsA diagnosis (ICD-9-CM 696.0 or ICD-10-CM L40.5x) and no pharmacy claims for the index biologic during the baseline period. Persistence over 12 months was measured as the discontinuation rate and number of days persistent on the biologic from the index date to reported treatment gaps of ≥45, >90, and >180 days based on clinical expert opinion, or the end of follow-up if no gap was observed. The median time to discontinuation of the index biologic over 12 months was assessed by Kaplan-Meier analysis for each treatment gap cutoff.

Results: A total of 1558 patients with PsA enrolled in the analysis initiated SC biologics, including adalimumab (n=720), certolizumab pegol (n=93), etanercept (n=435), golimumab (n=64), and secukinumab (n=255). Overall, 680 patients (43.6%) discontinued their index biologic therapy during 12 month follow-up. The 12 month discontinuation rate for each treatment gap cutoff was lowest with secukinumab compared with other SC biologics (51.8%, 36.5%, and 21.6% for patients with treatment gaps >45 days, ≥90 days, and ≥180 days, respectively). Mean days persistent on the index biologic was highest with secukinumab for each treatment gap cutoff (254.5, 282.8, and 307.5 days for patients with treatment gaps: ≥45 days, ≥90 days, and ≥180 days, respectively) and etanercept (270.7 days for patients with a treatment gap ≥180 days; Table 1). The median (95% CI) time to discontinuation for patients with a treatment gap ≥45 days was the highest with secukinumab (308 [238 to 365] days) and lowest with certolizumab pegol (216 [155 to 274] days). Median time to discontinuation could not be calculated for patients with treatment gaps ≥90 days or ≥180 days due to low event rates and limited follow-up.

AB0932
HELIcobacter PYLORi ANTIgen SPECiFiC ANtIBOdIES iN PSORiATIC ARTHRiTIS

1Rheumatology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece; 2Institute of Immunology, EUROMMUN, Lübeck, Germany

Background: The role of Helicobacter pylori (Hp) infection in the aetopathogene- sis of psoriatic arthritis (PsA) and psoriasis (Ps) is currently inconclusive, as studies reported increased, decreased or comparable to controls frequency of anti-Hp antibodies.

Objectives: To test antigen-specific Hp antibodies in a well-defined cohort of PsA patients and demographically matched Ps patients and healthy controls (HCs).

Methods: A total of 140 serum samples (48 PsA, 37 Ps, and 55 HCs) were tested for anti-Hp antibodies by a western blot immunoassay using whole Hp extract as antigenic source.

Results: Overall, anti-Hp seropositivity was similar in PsA (19/48, 39.6%) and Ps (16/37, 43.2%, p=0.05) but significantly lower compared to HCs (33/55, 60%, p=0.039). Overall, IgG anti-CagA and VacA, the most diagnostically relevant anti-Hp antibodies, were present in 26/48 (54.2%) and 5/48 (10.4%) PsA patients, respectively, compared to 15/57 (40.5%) (p<0.01) and 1/37 (2.7%) (p=ns) Ps patients, respectively as well as in 39/55 (70.9%) (p<0.01) and 4/55 (7%2) (p=ns) HCs, respectively. Compared to HCs, patients with PsA had higher reactivity to n99 (UreA) (31/48, 64.6% vs 24/55, 43.5%, p=0.033) and to p54 (24/48, 50% vs 15/55, 27.2%, p=0.017) and tended to have higher positivity against p75 antigen (9/48, 18.9% vs 3/55, 5.4%, p=0.062). Reactivity to p50 (15/48, 31.3% vs 50.9, p=0.042) and p33 antigen (3/48, 6.3% vs 10/55, 18.2%, p=0.061) was lower in PsA than in HCs. No differences on anti-Hp antigen specific antibodies was found between PsA and Ps.

Conclusions: Although overall reactivity to Hp in PsA and Ps is lower than HCs, Hp infection cannot safely be considered a protecting microbial agent for these diseases, as reactivities to some Hp antigens are more frequently recognised to these diseases than in HCs.

AB0933
SURVIVAL AT 6 AND 12 MONTHS OF USTEKINUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS IN CONDITIONS OF CLINICAL PRACTICE

Introduction: Psoriatic arthritis (PsA) is a chronic inflammatory disease associated with skin psoriasis. Ustekinumab is a monoclonal antibody which inhibits IL12/23 and has proven efficacy and safety in the treatment of patients with PsA.

Objectives: To determine the survival rate and the reasons for Ustekinumab discontinuation in a patient cohort with PsA in conditions of clinical practice.

Methods: Descriptive, prospective, longitudinal and open study including 66 patients diagnosed with PsA and treated with Ustekinumab at dose according to the data sheet (45 mg in the 0, 4 and every 12 weeks), except for 3 patients who were administered a 90 mg dose with the aforementioned regimen. The patients were monitored at 6 and 12 months. The following variables were collected: age, sex, years of evolution, previous treatment with Synthetic Disease Modifying Anti-Rheumatic Drugs (DMARDs) and/or biologic DMARD. All the adverse events (AE) which caused the discontinuation of the drug in patients who had received at least one dose of Ustekinumab were also collected. The Kaplan-Meier method was used to analyse the survival rate. The survival rate in naïve patients with biologic DMARD was compared with those who had received at least one biologic DMARD treatment before; and patients treated with Ustekinumab in monotherapy with those who were in a combined therapy with DMARDs. The Log-Rank Test was used for the comparative analysis of both subgroups.

Results: Out of the 66 patients of our cohort, 34 (51.5%) were women, whose mean age was 47.2±11.3 years. 49 presented only peripheral affectation (74.2%), mainly in polynartic form, and 10 had mixed affectation. The rest presented axial affectation exclusively. Our patients had been suffering from this disease for
an average of 6.7±7 years, and had received an average of 1.2±1.45 previous biologic DMARD. 51.5% were receiving Ustekinumab in a combined therapy with DMARD (most of them Methotrexate) and 48.5% were in monotherapy. The survival rates at 6 and 12 months were 85% and 74.6% respectively. Comparing the subgroups, the naïve patients with biologic DMARDs presented higher survival rates at 6 (91.6% vs 80.7%) and at 12 months (85.1% vs 66.7%), a statistically significant difference with the group that received previous biologic DMARD (p=0.036). The patients in combined therapy with DMARDs presented higher rates of survival than the patients in monotherapy with Ustekinumab (80% vs 80%; 78% vs 71.1% at 6 and 12 months respectively), although the differences were not statistically significant. The main reason for discontinuation was the decrease of efficacy (14 patients; 21.2%), mostly in patients who had received previous treatment with biologic DMARD. 5 patients (7.6%) did not continue due to AE (2 due to relapsing herpes zoster; 1 patient deceased, with a personal history of neoplasms and a previous treatment with anti-TNF; and 2 had reactions at the injection site).

Conclusions: Ustekinumab is a safe drug, presenting high rates of drug retention, especially in patients who have not received any previous biologic therapy.

OBESITY IN PATIENTS WITH PSORIATIC ARTHRITIS IN OUR AREA

L. Montolio-Chiva1, M. Robustillo-Villarino2, A. Sendra-García2, A. Martínez-Ferrer1, C. Vergara-Dangond1, M. Aguilar-Zamora1, A.V. Orenes-Vera1, E. Valls-Pascual1, D. Ybáñez-García1, V. Núñez-Monje2, I. Torner-Hernández1, J.J. Alegre-Sancho1, C. Vergara-Dangond1, M. Aguilar-Zamora1, A.V. Orenes-Vera1, E. Valls-Pascual1, D. Ybáñez-García1, V. Núñez-Monje2, I. Torner-Hernández1, J.J. Alegre-Sancho1

Background: Obesity is a comorbid condition in patients with psoriasis which tends to be less common in patients with psoriatic arthritis (PsA). In the general population, obesity is associated with increased inflammatory load and vascular risk, and with hypovitaminosis D.

Objectives: To explore the relationship between obesity and disease activity, vascular damage, serum concentrations of vitamin D (25OHD) and bone mineral density (BMD) in patients with PsA.

Methods: Descriptive cross-sectional study. Patients with PsA patients and peripheral joint involvement were consecutively included. Demographic (age, sex), clinical (duration of the disease, BMI (body mass index), and to have mMDA (MDA 1) and [ii] 5 of the following 6 criteria (MDA 2): TJC $\geq$ 1, SJC $\geq$ 1, BSA $\geq$ 3%, pain VAS $\geq$ 1, DAPSA 28 $\geq$ 15, and high DAPSA disease activity (50.8% vs 39.3%, p=0.015). A higher proportion of nbDMARD patients had dactylitis (36.1% vs 25.3%, p=0.023). No differences were observed between groups in enthesitis, overall EAMs, or QoL at baseline.

Disclosure of Interest: None declared

AB0935

CANADIAN ADALIMUMAB POST-MARKETING OBSERVATIONAL EPIDEMIOLOGICAL STUDY ASSESSING THE EFFECTIVENESS OF ADALIMUMAB VS NON-BIOLOGIC DMARDS IN PSORIATIC ARTHRITIS (COMPLETE-PSA): 12-MONTH EFFECTIVENESS DATA

M. Khraishi1, L. Bessette2, A. Chow3, B. Harauzi4, V. Pavlova5, J. Stewart2, V. Remple1, 1Memorial University of Newfoundland, St. John's; 2Laval University, Centre Hospitalier de l'Université Laval, Quebec; 3University of Toronto, Toronto; 4Centre Hospitalier de l'Université de Montréal, Montreal; 5McMaster University, Hamilton; 6University of British Columbia, Penticon; 7AbbVie Corporation, Montreal, Canada

Background: To date, observational studies comparing the effectiveness of adalimumab (ADA) to non-biologic DMARDs (nbDMARD) in psoriatic arthritis (PsA) are not available. The aims of this study were to 1) assess the effectiveness of ADA vs nbDMARDs within 1 year of treatment and 2) compare the effectiveness of ADA in prior treatment failure vs naive patients.

Objectives: This analysis aimed to describe the baseline demographic and disease parameters of patients initiating nbDMARD or ADA and compare the 12 month real-life effectiveness of both treatments.

Methods: Patients eligible for COMPLETE PsA are anti-TNF naïve adults, with active PsA who require change in their treatment regimen, per the judgment of the treating physician. In the current analysis patients enrolled during Jul 2011–Jun 2016 were included. Outcome measures analysed were: DAS28, SF-12, DLQI, presence of extra-articular manifestations (EAMs; enthesitis and dactylitis), psoriasis BSA, achievement of modified MDA (defined as achievement of [i] 4 of 6 (MDA 1) and [ii] 5 of the following 6 criteria (MDA 2): TJC $\leq$ 1, SJC $\leq$ 1, BSA $\geq$ 3%, pain VAS $\leq$ 15 mm, PtgA $\geq$ 20 and HAQ $\leq$ 0.5), modified remission (defined as SJC=0, TJC=0, absence of enthesitis and dactylitis, BSA $\leq$ 3% and HAQ $\leq$ 0.5), DAPSA LDA ($\leq$ 14), and DAPSA remission (REM=$\leq$4). Analyses were conducted by initial group assignment (intent-to-treat approach).

Results: 406 patients were included (nbDMARD n=146, ADA n=260). Baseline demographics were comparable between treatment groups. However, patients initiating ADA were more likely to be unemployed (47.3% ADA vs 34.9% nbDMARD, p=0.015), had higher DAS28 (4.8 vs 4.4, p=0.002) and total DLQI score (6.1 vs 4.3, p=0.007), and were more likely to have BSA $\geq$ 3% (44.6% vs 39.5%, p=0.043) and high DAPSA disease activity (50.5% vs 42%, p=0.015). A higher proportion of nbDMARD patients had dactylitis (36.1% vs 25.3%, p=0.023). No differences were observed between groups in enthesitis, overall EAMs, or QoL at baseline.

Upon 12 months of treatment, mean adjusted DAS28 (2.6 vs 3.4, p<0.001) and DLQI (2.2 vs 2.9, p<0.050) scores, but not SF-12, were lower in the ADA group. Furthermore, although statistical significance was not always met, patients treated with ADA had lower DAPSA score (p=0.025) (LDA/REM: 64.9% vs 58.6%; REM: 37.7% vs 17.1%), were more likely to be in modified remission (14.7% vs 9.7%, p=0.031), and to have mMDA (mMDA1 1.56% vs 12.6%, p=0.529; mMDA2: 17% vs 11.5%, p=0.253) and BSA $\leq$ 3% (89.3% vs 83.9%, p=0.207). Also, EAM prevalence decreased in both groups but was significantly lower in the ADA group (35.8% vs 55.8%, p=0.001).

Over time, 9.6% of ADA patients initiated another biologic and 32.2% of patients in the nbDMARD group initiated biologic treatment (p<0.001).

Conclusions: PsA patients initiating ADA in Canadian routine clinical care have significantly greater baseline disease severity compared with those initiating nbDMARDs. However, 12 month treatment improved disease control and EAMs. DAPSA-REM evaluation seems more sensitive than mMDA in differentiating both populations.

GOLIMUB IMPROVES DISEASE SIGNS AND SYMPTOMS, CONCOMITANT DISEASES AND CONCOMITANT DRUG USE IN PATIENTS WITH PSORIASIS ARTHRITIS IN A REAL-LIFE SETTING IN GERMANY

K. Krüger¹, G.R. Burmester², S. Wassenberg³, A. Thiele⁴, M.H. Thomas⁵
¹Rheumatologisches Praxiszentrum, München; ²Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin, Berlin; ³Rheumazentrum Ratingen, Ratingen; ⁴Krankenhaus St. Josef, Wuppertal; ⁵Medical Affairs, MSD Sharp and Dohme GmbH, Haar, Germany

Background: Golimumab (GLM) has demonstrated efficacy and safety in several randomised clinical trials in Psoriatic Arthritis (PsA) patients. Data on disease signs and symptoms, concomitant diseases and concomitant drug in daily clinical practice are rare.

Objectives: The aim of this subanalysis was to assess the effectiveness of GLM in patients with established PsA in a real-world setting in Germany.

Methods: Descriptive post-hoc analysis of the non-interventional, prospective, 24 month study GO-NICE. Patients with established PsA starting with GLM 50 mg SC once monthly under routine clinical care conditions. Endpoint measures were: Physician’s Global Assessment (PGA) of patient’s health status (visual analogue scale VAS: 0 no discomfort → 10 strong discomfort), change in concomitant diseases, concomitant drug use, inflammatory markers (CRP/ESR), improvement of the skin (PfGA-score: 0–none → 3–severe).

Results: A total of 501 patients with PsA were included at 121 sites and 231 (46.1%) completed the 24 month observation period. At baseline (BL) mean age 50.2 (±12.1) years, 271 (54.1%) females, mean time since first diagnosis 13.0 ±11.5 years, BMI 28.1 (±5.4) kg/m². 169 (73%) patients received basic therapeutics, 286 (57.1%) had none previous biologics use, 136 (27.1%) one, and 79 (15.8%) at least two biologics. 439 (87.8%) had extra-articular diseases manifestations at BL. The most common were psoriasis (n=394, 78.8%), nail involvement (n=197, 39.4%), dactylitis (n=106, 21.2%), and enthesitis (70, 14.0%) at BL. The three most concomitant diseases were: psoriasis (n=151, 30.1%), depressive disorder (n=60, 12.0%), and diabetes mellitus (n=52, 10.4%). On GLM treatment, remarkable improvements were seen (table 1):

Additionally, the percentage of patients with severe psoriatic symptoms decreased from 11.8% (BL) to 1.8% (M12) to 0.4% (M24), and the percentage of patient without any symptom increased from 8.8% (BL) to 31.8 (M12) to 36.2% (M24). An increase in any of the prespecified concomitant diseases was not observed. No new safety signals were detected.

Conclusions: GLM SC once-monthly, administered to PsA patients according to routine clinical practice in Germany, showed remarkable improvements in Physician’s Global Assessment of patient’s health status, decrease in the number of concomitant diseases and concomitant glucocorticoids use, inflammatory markers (CRP/ESR) and skin symptoms over 24 months of treatment.

EFFICACY OF NEW TREATMENTS ON DACTYLITIS OF PSORIATIC ARTHRITIS: UPDATE OF SYSTEMATIC LITERATURE REVIEW

M. Sondag, F. Verhoeven, X. Guillot, C. Prati, D. Wending. Rheumatology, Hopital Jean Minjoz, Besançon, France

Background: Dactylitis is a frequent disabling feature of psoriatic arthritis (PsA). Therapeutic strategy on dactylitis is not really codified.

Objectives: The objective of the study was to evaluate efficacy on dactylitis of different treatments actually available in PsA.

Methods: We performed a literature review from June 2014 to October 2017 based on Pubmed, using the search terms “psoriatic arthritis” and “treatment” with only clinical trials. 89 articles were identified (English-language reports only). Thus, we selected only randomised, double-blind placebo-controlled trials in which analysis of dactylitis was exposed: 11 articles were selected for full review.

Results: Significant improvement of dactylitis (p<0.05) compared to placebo was observed with the use of golimumab in GO-VIBRANT, ustekinumab in PSUMMIT-1/PSUMMIT-2 trial, with apremilast 30 mg only in PALACE 3, with ixekizumab and adalimumab in SPIRIT-P1 (post hoc analysis).

For secukinumab, results are different: Molnnes et al. (FUTURE 2) found no significant efficacy with 47% of dactylitis resolution at 24 weeks for secukinumab vs 11% for placebo (p=0.9195). At the opposite, Kavanaugh et al. (FUTURE 2) demonstrated secukinumab efficacy on anti-TNF-naïve (300 mg and 150 mg dosages) and anti-TNF-exposed patients (only 300 mg).

For Mc Innes et al., clazakizumab permitted great decrease in the mean number of dactylitis from baseline to weeks 16 and 24 but no statistical data are available in the report. Similarly, in a recent publication, promising results were found for tofacitinib and abatacept, but no statistical data are available.

At the opposite, no significant efficacy was demonstrated in a randomised controlled trial with brodalumab.

Calculating of effect size was possible and available only in one study: secukinumab’s effect size was 4.35 in Molnnes study (FUTURE 2). Calculation of Odds Ratio (with of residual dactylitis between treatment and placebo groups was possible on part of studies with significant results for clazakizumab (200 mg dosing) and secukinumab in patients TNF exposed (figure 1).

Conclusions: Dactylitis was always used as secondary outcome criteria with heterogeneous results. So conclusions need to be cautious. This invalidating clinical manifestation need to be evaluated as a primary outcome in the future.

Disclosure of Interest: None declared

Background: The initial treatment of Psoriatic Arthritis (PsA) is largely based on the extent of musculoskeletal involvement and disease severity according to the stepwise approach of EULAR and GRAPPA recommendations for PsA management, but without regard to the age of onset.

Objectives: This prospective observational study aimed to describe treatment prescribing patterns in PsA over the first 2 years of follow-up and to determine if the treatment patterns are conditioned by the age of onset.

Methods: Patients with at least 2 years of follow-up within the PsArT (Psoriatic arthritis Age-related Treatment patterns) study were included. Patients with a diagnosis of early (symptom duration <52 weeks) PsA, made by rheumatologists with long-standing expertise in PsA, were consecutively recruited and divided into Adult-Onset (AOPsA) (age <60 years) and Late-Onset (LOPsA) (onset age >60 years). PsA according to the age at the onset of musculoskeletal manifestations.

For the aim of this study, patient’s data were collected at the enrolment (baseline) (T0), at 12 months (T12) and at 24 months (T24). Clinical, laboratory features and treatment patterns, over 2 years were described according to the age stratification.

Results: 46 PsA patients (22 M, 24 F; age 49±16, range 16–90 years) with a disease duration of 20±15 weeks (range 1–52) were enrolled. Compared to the 31 patients with AOPsA, the 15 patients with LOPsA had a significant shorter disease duration (17±15 vs. 21±15 weeks, p<0.05) and showed more frequently increased levels of ESR (75% vs. 43%, p<0.05) and CRP (87% vs. 52%, p<0.01). In addition, patients with LOPsA developed more frequently inflammatory extremity swelling with pitting oedema (IESPE) over the dorsum of hands and/or of the feet (56% vs. 13%, p<0.01). There were no other significant differences between the 2 groups even though more males were observed in the LOPsA group (56% vs. 42%, p=0.05). The sensitivity of the CASPASAR criteria was similar in AOPsA (78%) and LOPsA (75%). Of 46 patients during the first year 80.4% received non steroidal anti-inflammatory drugs, 32.6% received oral corticosteroids, 13.0% received local corticosteroids, 19.5% received synthetic disease-modifying anti-rheumatic drugs (sDMARDs) and 6.5% received biologics (bDMARDs: IFX, ADA, GOL, ETN). During the second year of follow up 37.3% received non steroidal anti-inflammatory drugs, 50.0% received synthetic disease-modifying anti-rheumatic drugs (sDMARDs), 15.2% received biologics (IFX, ADA, GOL, ETN) and received 30.4% local corticosteroids. (see figure) About the drug intake the only statistical significant difference between the two groups was the rate of patients using NSAIDs in LOPsA group during the first year (100% vs. 70.9%, p value 0.02). There were no other significant differences in drug intake, therapy changes, discontinuation, add-on therapy according to the age of PsA onset.

Conclusions: During the two years of follow up period a high proportion of patient received NSAIDs in LOPsA group during the first year. The main limit of our study is the low number of patients, therefore a greater number could help to understand whether the age of onset may affect the use of specific type of drugs.

OFF-LABEL SECUKINUMAB DOSE ESCALATION IN THE TREATMENT OF MODERATE-TO-SEVERE PSORIASIS: A MULTICENTER, RETROSPECTIVE STUDY

M. Phung1, A. Ighani2, J.R. Georgakopoulos3, R. Vender4, L. Giroux5, P. Lansang6, J. Yeung1, 2, Department of Pharmacology and Toxicology, 3Faculty of Medicine, University of Toronto, Toronto; 4Schulich School of Medicine and Dentistry, Western University, London; 5Division of Dermatology, Department of Medicine, McMaster University, Hamilton; 6Division of Dermatology, The Northern Ontario School of Medicine, Sudbury; 7Division of Dermatology, Sunnybrook Health Sciences Centre, 8Division of Dermatology, Faculty of Medicine, University of Toronto; 9Probiotic Medical Inc., Waterlo, Canada

Background: There have been significant advancements in the development of biologics over the past decade that revolutionised treatment for psoriasis and psoriatic arthritis. Interleukin (IL)–17A is a pro-inflammatory cytokine that plays a pivotal role in the pathogenesis of psoriatic disease, and is therefore a target for biologic drug development. Secukinumab is an IL-17A antagonist approved in 2015 for the treatment of psoriatic arthritis and moderate-to-severe psoriasis in adults. Its current approved dosing schedule for psoriasis patients is 300 mg subcutaneous weekly for 5 weeks, followed by monthly maintenance dosing.

Some psoriasis patients in clinical practice exhibit a suboptimal response to secukinumab or experience relapse with the approved dosing schedule. In these cases, clinicians may use off-label secukinumab dose escalation regimens, which involve increasing the maintenance dosing frequency to every 2 or 3 weeks, or increasing the monthly dose to 450 mg. No guidelines currently exist for high dose secukinumab regimens.

Objectives: The objective of this study was to assess the efficacy and safety of off-label high dose secukinumab regimens in adults with moderate-to-severe psoriasis.

Methods: We performed a retrospective chart review for adult patients diagnosed with moderate-to-severe psoriasis treated with an off-label secukinumab up-dose regimen. Efficacy was measured using Psoriasis Area and Severity Index (PASI)–75 or a Physician Global Assessment (PGA) score of 0 or 1 after dose escalation. To assess safety, adverse events (AEs) were recorded.

Results: Twenty-five patients were included in this study, 13 (52%) of which also had psoriatic arthritis. The mean treatment time with secukinumab prior to dose escalation was 44.5 weeks. Twelve patients had PASI recorded prior to dose escalation, with a mean score of 5.7. Of the remaining 13 patients, 1 had no documentation of disease severity and 12 had PGA scores of 0 (n=2), 1 (n=1), 2 (n=5), 3 (n=2), and 4 (n=2). These patients then increased their dose to 300 mg secukinumab every 3 weeks (n=10), 300 mg every 2 weeks (n=9), or 450 mg monthly (n=6). Mean follow-up time was 15.9 weeks after dose escalation, where 4 patients achieved PASI-75 and 10 achieved PGA 0 or 1. Therefore, 14 out of 25 (56%) patients had effective outcomes from secukinumab dose escalation based on our study endpoints. AEs included one case of the common cold and an upper respiratory tract infection after dose escalation.

Conclusions: This study provides evidence of safety and moderate efficacy for high dose secukinumab regimens in psoriasis patients who display an inadequate response to the approved regimen. Increased dosing did not result in more AEs compared to secukinumab phase 3 clinical trials that used the approved regimen. As such, there may be a role for increased dosing in psoriatic arthritis patients.

HEALTH SERVICES RESEARCH PROJECT FOR THE EARLY DIAGNOSIS OF PSORIATIC ARTHRITIS: MONOCENTRIC QUESTIONNAIRE-BASED STUDY TO IDENTIFY PATIENTS WITH ARTHRITIS AND DETECT SIGNS OF DEPRESSION IN 150 PATIENTS

N. Fred1, S. Schauer1, C. Schemp2, S. Finzel1, F. Röthé1, R. Volf1, J. Thiel1, N. Venhoff1, 1Department of Rheumatology and Clinical Immunology, 2Department of Dermatology, Medical Center – University of Freiburg, Freiburg, Germany

Background: Psoriatic arthritis (PsA) is an inflammatory rheumatic disease affecting approximately 30% of psoriasis (PsO) patients. Despite increased awareness there is still a considerable delay in diagnosis. Untreated PsA may lead to irreversible joint destruction associated with a high rate of disability and depression. A timely diagnosis and initiation of treatment are therefore essential.
Objectives: In order to minimise diagnostic delay and improve patient care, we have implemented a questionnaire-based screening procedure in the dermatology outpatient clinic to identify patients with suspected PsA.

Methods: A questionnaire-based screening (PEST, FFHB, WHOOL-BREF, PHQ-9, GHQ-12) was used to assess PsO patients for PsA, depression, comorbidities, and quality of life (QOL). The corresponding results for PaGl vs. pain was 4.9 (bias), –17.1 (LLoA), and 22.0 (UloA), and for pain vs. PhGl 18.9 (bias), –23.0 (LLoA) and 60.8 (UloA). PaGl was significantly but weakly correlated with PhGl (R=0.42, p<0.0001) with a high standard error of estimation (SEE)=21.2. PaGl was independently predicted by pain (beta=-0.76, p<0.0001) and HAQ-DI (beta=0.19, p<0.01) and was not predicted by PhGl (p=0.61) (R=0.78, SEE=10.5, p<0.0001), PhGl was independently predicted by SJC (beta=-0.43, p<0.0001) followed by pain (beta=0.41, p<0.0001) and CRP (beta=0.20, p<0.05) (R=0.70, SEE=14.4, p<0.0001) with no significantly contribution by PaGl (p=0.49).

Conclusions: In patients with active PsA initiating biological treatment, PaGl was in general scored considerably higher than PhGl. On the individual patient level, differences between PaGl and PhGl varied substantially. PaGl was best explained by pain, and PhGl by SJC. The findings reflect strongly diverging attitudes between PsA patients and their rheumatologists to severity of disease and to the relative importance of different outcome measures.

AB0942  CONCORDANCE BETWEEN FATIGUE, PAIN AND PATIENT GLOBAL ASSESSMENT IN INDIVIDUAL PATIENTS WITH PSORIATIC ARTHRITIS

O. Rintek Madsen. Center for Rheumatology and Spine Diseases and the DANBIO Registry, Copenhagen University Hospital Rigshospitalet/Gentofte, Høllerup, Denmark

Background: Associations between fatigue (FTG), pain and patient global assessment (PaGl) have been examined on the group level in patients with psoriatic arthritis (PsA), but studies focusing on the concordance between these patient-reported outcome measures (PROMs) in individual patients are missing. A better understanding of how tight the measures are bounded in individuals may improve our ability to deal with them in the daily clinic.

Objectives: To examine associations on the group level and concordance on the individual patient level between FTG, pain and PaGl as scored on 0–100 visual analogue scales (VAS) in the daily clinic by patients with PsA. The influence of other clinical disease activity measures on these measures was also examined.

Methods: Data on 132 outclinic PsA patients treated with biological agents were extracted from the Danish registry for biological treatment in rheumatology (DANBIO). Data comprised VAS FTG, pain, PaGl and physician global assessment (PhGl), and HAQ-DI, swollen and tender joint counts (66/88), CRP, DAS28-CRP and age. Simple linear regression analyses were used to assess the association between FTG, pain and PaGl. Independent predictors of FTG, pain and PaGl were identified using stepwise multiple regression analysis. Degrees of association were expressed by coefficients of correlation, beta-values and standard errors of estimation (SEE). Concordance between FTG, pain and PaGl on the individual patient level was estimated using the Bland-Altman method yielding 95% lower and upper limits of agreement (LLoA and ULoA) and corresponding biases (mean of intra-individual differences).

Results: Mean age was 54±13 years, mean DAS28 3.7±1.5 and mean PaGl 56 ±28. FTG, pain and PaGl were strongly inter-associated but errors of estimation were substantial: (r-range 0.80–0.94, p<0.0001, SEE-range 11.5–16.9), FTG, pain and PaGl were only poorly correlated with objective measures of disease activity (for example, r-range for swollen joint count 0.19–0.25, p<0.05). FTG was independently predicted (beta, p-value) by PaGl (0.51, p<0.001) and pain (0.31, p<0.05) (R²=0.66, p<0.05, SEE=16.7), pain by PaGl (0.82, p<0.0001) and HAQ-DI (0.15, p<0.005) (R²=0.88, p<0.005, SEE=10.5) and PaGl by pain (0.80, p<0.001) and fatigue (0.17, p<0.001) (R²=0.89, p<0.001, SEE=12.4). Swollen and tender joint count, CRP and PhGl did not add to the explanation of the patient-reported VAS scores. The bias [LLoA; ULoA] for FTG versus pain was 8.5±19.1 (p<0.0001) [–29.1; 45.9], for FTG versus PaGl 4.1±19.4 (p<0.05) [–34.0; 42.2] and for PaGl versus pain 4.4±11.5 (p<0.0001) [–18.1; 26.9]. Thus biases were small but limits of agreement were pronounced.

Conclusions: In patients with PsA, VAS FTG, pain and PaGl were nearly identi-cal and were strongly inter-associated on the group level with no explanatory influ-ence of more objective measures. However, on the individual patient level substantial discrepancies between the VAS scores were observed. The findings emphasise the complexity of understanding and dealing with PROMs in the daily clinic.

SUSTAINED IMPROVEMENTS WITH UP TO 104 WEEKS OF APREMILAST MONOTHERAPY IN BIOLOGIC-NAÏVE SUBJECTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM A PHASE 3B, RANDOMISED, CONTROLLED TRIAL

P. Nash1, F. Behrens2, A.-M. Orba3, S. Rathmann4, D. Adams5, O. Benichou6, A. Deodhar7. 1Univ. of Queensland, Brisbane, Australia; 2Goethe Univ., Frankfurt, Germany; 3Johns Hopkins Univ., Baltimore; 4Eli Lilly, Indianopolis; 5Oregon Health and Science Univ., Portland, USA

Background: SPIRIT-P2 is a phase 3, multi-centre, randomised, double-blind, placebo-controlled trial of IXE in adults with active PsA and prior TNFi therapy. Among IXE-treated patients, higher proportions of patients achieved clinically important differences.

Conclusions: In biologic-naïve subjects treated with APR, early onset of effect was observed across PsA manifestations, including morning stiffness severity and enthesitis, with sustained improvements through Week 104 in the subjects continuing APR therapy. AEs were consistent with those reported for other APR phase 3 PsA and psoriasis studies.

Efficacy and Safety of Ixefzumab When Used Alone or in Combination With Conventional Disease-Modifying Antirheumatic Drugs (CDMARDs) in TNF-Experience Patients With Psoriatic Arthritis

P. Nash1, F. Behrens2, A.-M. Orba3, S. Rathmann4, D. Adams5, O. Benichou6, A. Deodhar7. 1Univ. of Queensland, Brisbane, Australia; 2Goethe Univ., Frankfurt, Germany; 3Johns Hopkins Univ., Baltimore; 4Eli Lilly, Indianopolis; 5Oregon Health and Science Univ., Portland, USA

Background: Registry studies1,2 suggest that cDMARDs do not improve TNFi efficacy in the treatment of psoriatic arthritis (PsA), but studies of novel biologics are warranted. In SPIRIT-P2, TNF-experienced patients with active PsA were treated with ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets IL-17A.

Objectives: We conducted post-hoc analyses of SPIRIT-P2 data to investigate the efficacy and safety of IXE relative to placebo (PBO) when used alone or in combination with background MTX or cDMARDs in patients with PsA.

Methods: SPIRIT-P2 (NCT02349295) is a phase 3, multi-centre, randomised, double-blind, placebo-controlled trial of IXE in adults with active PsA and prior TNFi-inadequate response or intolerance. Patients were randomised 1:1:1 to receive PBO, 80 mg IXE either every 4 weeks (Q4W) or every 2 weeks (Q2W), after receiving a 160 mg initial IXE dose. Eligible established background cDMARD therapy was allowed in the double-blind treatment period (Week 0–24), but no changes were allowed unless for safety reasons or due to inadequate response at week 16. Efficacy and safety were assessed at week 24. Efficacy outcome measurements included ACR 20/50/70 responses, achievement of minimal disease activity (MDA), 28-joint disease activity score using CRP (DAS28-CRP), disease activity in psoriatic arthritis (DAPSA), and HAQ-DI. All comparisons were made relative to PBO by Fisher’s exact test for categorical end points and analysis of covariance models for continuous end points.

Results: At baseline, 185 (51%) patients received background cDMARDs. Of these patients, 149 received background MTX. ACR20, ACR50, and MDA response rates were significantly higher in patients treated with IXE versus PBO regardless of background cDMARD use (table 1). Disease activity improved significantly with IXE versus PBO in each subgroup, as measured by DAS28-CRP and DAPSA. Likewise, physical function improved with IXE versus PBO as indicated by significantly more profound decreases in HAQ-DI with IXEQ4W with or without background cDMARDs, and with IXE-Q2W monotherapy. HAQ-DI improvements were significantly more profound versus PBO in patients treated with IXE-Q4W with or without background cDMARDs, and with IXE-Q2W monotherapy. Among IXE treated patients, higher proportions of patients achieved HAQ-DI MCID in all subgroups versus PBO, but these were only significantly higher in patients treated with IXE-Q4W or IXE-Q2W monotherapy. Regardless of background cDMARD use, efficacy outcomes were significantly improved with both IXE groups versus PBO, except for HAQ-DI for IXE-Q2W in combination with cDMARDs and HAQ-DI MCID in all background cDMARD subgroups. The proportions of patients who experienced ≥1 treatment emergent adverse events (AE), serious AEs (including serious infections), or discontinuations due to AEs were comparable to the overall trial population.3

Scientific Abstracts
Secukinumab has demonstrated rapid, significant and sustained improvement in the signs and symptoms of psoriatic arthritis (PsA) in multiple trials. Secukinumab was administered at starting doses of 150 mg or 300 mg subcutaneously, or 150 mg without load, with or without background methotrexate (MTX) use from four Phase 3 studies: FUTURE 2, FUTURE 3, FUTURE 4 and FUTURE 5, respectively. Secukinumab 300 mg was associated with higher responses compared to 150 mg dose particularly for TNF-naïve pts and in pts with no concomitant MTX use. Earlier responses were observed with secukinumab with load compared to without load primarily across ACR, DAS28-CRP and PASI endpoints.
RESULTS FROM A PHASE 3B, RANDOMISED, CONTROLLED STUDY IN BIOLOGIC-NAIVE SUBJECTS WITH ACTIVE PSORIATIC ARTHRITIS

Methods: Subjects were randomised (1:1) to receive APR 30 mg BID or placebo (PBO). Subjects who did not improve by >10% in swollen and tender joint counts at Week 16 were eligible for early escape. At Week 24, all remaining PBO subjects were switched to APR. Work productivity and activity impairment were assessed at baseline (BL) and Week 16 using the 6-item, self-administered Work Productivity and Activity Impairment Questionnaire: Psoriatic Arthritis (WPAI:PsA). WPAI: PsA includes 4 subscale scores (Absenteeism, Presenteeism, Work Productivity Loss, and Activity Impairment), each ranging from 0% to 100%; higher scores indicate greater impairment. Work-related subscales were evaluated only among employed subjects, while activity impairment was evaluated among all subjects, regardless of employment. Correlations were examined at Week 16 between WPAI:PsA subscale scores and the SF-36v2 domain scores for Physical Functioning (PF), Bodily Pain (Pain), and Vitality (VIT), as well as associations with ACR20 response. Improvement in work productivity was assessed through Week 104.

Results: BL characteristics were similar between APR and PBO subjects with WPAI:PsA scores included in this analysis. At Week 16, APR significantly improved work productivity and the ability to carry out daily activities vs PBO, with significantly greater mean improvements observed in the overall Work Productivity Loss (p<0.001) and Activity Impairment (p<0.001) scores (table 1). Estimated mean change in the Absenteeism score was similar with APR vs PBO (p=0.079). By contrast, the Presenteeism score showed significant improvement with APR vs worsening with PBO (−10.8% vs 4.1%; p<0.002). At Week 16, statistically significant correlations were observed between WPAI:PsA subscale scores (except Absenteeism) and the SF-36v2 domain scores for PF, Pain, and VIT, as were associations with ACR20 response. Among subjects randomised to APR at BL, improvements in Week 16 WPAI:PsA subscale score were generally maintained through Week 104 in those continuing APR.

Abstract AB0946 – Figure 1

Results are from an analysis of covariance model, adjusted with BL WPAI: PsA subscale score, BL prednisone use (yes/no), and previous DMDAR use (yes/no). LS mean is estimated using the observed margins of the covariates. WPAI: PsA scores were evaluated for subjects with values at both BL and Week 16. Absenteeism, Presenteeism, and Work Productivity Loss were evaluated only among employed subjects. Activity Impairment scores were evaluated among all randomised subjects with scores at BL and Week 16, regardless of employment status. CI=confidence interval; LS=least square.

Conclusions: In biologic-naive subjects with PsA, APR monotherapy contributed to an overall improvement in work productivity at Week 16, which correlated with SF-36v2 PF, Pain, and VIT scores and was associated with ACR20 response; improvements in WPAI:PsA subscale scores were generally maintained to Week 104.

AB0947 IMPACT OF CLINICAL SPECIALTY SETTING ON DISEASE MANAGEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM A CROSS-SECTIONAL OBSERVATIONAL STUDY IN THE UNITED STATES

Methods: LOOP was a multi-centre, cross-sectional observational study conducted across 44 sites in US. Adult pts with a suspected or an established diagnosis of PsA who were routinely visiting a rheumatologist (rheum) or a dermatologist (derm) were eligible to participate in this study. Each enrolled pt was assessed by both rheum and derm. The association between enrolling or diagnosing clinical specialty setting and time from symptom onset to PsA diagnosis and to different disease management steps were examined.

Abstract AB0947 – Table 1. Current Disease Activity and Disease Burden by Clinical Specialty in US Patients with PsA from LOOP Study

Results are from an analysis of covariance model, adjusted with BL WPAI: PsA subscale score, BL prednisone use (yes/no), and previous DMDAR use (yes/no). LS mean is estimated using the observed margins of the covariates. WPAI: PsA scores were evaluated for subjects with values at both BL and Week 16. Absenteeism, Presenteeism, and Work Productivity Loss were evaluated only among employed subjects. Activity Impairment scores were evaluated among all randomised subjects with scores at BL and Week 16, regardless of employment status. CI=confidence interval; LS=least square.

Conclusions: In biologic-naive subjects with PsA, APR monotherapy contributed to an overall improvement in work productivity at Week 16, which correlated with SF-36v2 PF, Pain, and VIT scores and was associated with ACR20 response; improvements in WPAI:PsA subscale scores were generally maintained to Week 104.

Disclosure of Interest: P. Mease Grant/research support from: Abbott, Amgen, Biogen Idec, BMS, Celgene Corporation, Genentech, Janssen, Eli Lilly, Novartis, Pfizer, Roche, UCf, Consultant for: Abbott, Amgen, Biogen Idec, BMS, Celgene Corporation, Genentech, Janssen, Eli Lilly, Novartis, Pfizer, Roche, UCB, Publisher: AbbVie, Amgen, BMS, Celgene Corporation, Janssen, Novartis, Pfizer, and UCB, Speaker: AbbVie, Amgen, BMS, Celgene Corporation, Janssen, Novartis, Pfizer, and UCB, Consultant for: Abb-Vie, Amgen, BMS, Celgene Corporation, Janssen, Novartis, Pfizer, and UCB, E. Davenport: None declared, X. Zhou: None declared, B. Guertte Employee of: Celgene Corporation, E. Teng Employee of: Celgene Corporation, S. Kaura: Employee of: Celgene Corporation, P. Nash Grant/research support from: Celgene Corporation

Results: Of 681 pts enrolled, 513 pts with a confirmed diagnosis of PsA were included in this analysis. PsA diagnosis was established prior to study entry in 404 pts (positive ESR), while diagnosis was confirmed during the study in 197 pts (suspected pts). In established pts, PsA was first diagnosed in 352 (87.1%) pts by a rheumatologist and 40 (9.9%) pts by a dermatologist. Among suspected pts, 87 (79.8%) and 15 (13.8%) pts were being managed by a rheumatologist and a dermatologist, respectively. Pt demographics and disease characteristics were comparable between PsA pts enrolled by a rheumatologist and a dermatologist. Current disease activity and disease burden were also mostly similar between rheumatologist and dermatologist (table 1); though pts enrolled by a dermatologist had higher scores on skin and enthesis. The median (95% CI) time from symptom onset to PsA diagnosis was 1.0 (0.5, 1.1) and 2.6 (1.7, 4.1) years (y) in pts enrolled by a rheumatologist and dermatologist, respectively (p<0.001). However, the median time to PsA diagnosis was 0.9 (0.5, 1.0) and 1.0 (0.0, 2.0) y in pts diagnosed by rheumatologists and dermatologists, respectively. After PsA diagnosis, the median time to first csDMARD and to first bDMARD was 1.0 and 2.4 y, respectively. Overall, 282 (55.0%) and 354 (68.0%) pts received csDMARDs and bDMARDs, respectively. Treatment with first csDMARD occurred in 106 (20.7%) pts before PsA diagnosis and 176 (34.3%) pts after diagnosis; for first bDMARD, it was 121 (23.6%) and 233 (45.4%) pts, respectively.

Conclusions: The duration from symptom onset to PsA diagnosis was longer in pts enrolled by dermatologists and was similar in pts diagnosed by both rheumatologists and dermatologists. The median time was longer for treatment with first bDMARD compared to first csDMARD. Current disease activity and disease burden highlight the delay in PsA diagnosis and the need for appropriate management of PsA pts, irrespective of clinical specialty setting.

AB0949

TUMOUR NECROSIS FACTOR INHIBITORS AND THEIR IMPACT ON DIABETES MELLITUS AMONG PATIENTS WITH PSORIATIC ARTHRITIS

S. Mantravadi1,2, M. George3, A. Ogdie2. 1Thomas Jefferson University, 2University of Pennsylvania, Philadelphia, USA

Background: Tumour necrosis factor is a key inflammatory cytokine in the pathogenesis of psoriatic arthritis (PsA) and diabetes mellitus (DM). Tumor necrosis factor inhibitors (TNFi) have been shown to be associated with a decreased incidence of DM, but it is unknown whether treatment of PsA with TNFi has off-target therapy benefits for patients with DM. 2

Objectives: To determine whether initiation of a TNFi, compared to initiation of methotrexate (MTX) or metformin, results in a decrease in Haemoglobin A1c (HbA1c) in patients with PsA, DM, and elevated HbA1c.

Methods: A retrospective cohort study was conducted in OptumInsight, a de-identified administrative claims database that includes laboratory values for approximately 10% of patients. Data from 2000–2014 was included. We identified patients with PsA and DM (defined by ICD-9CM codes), with an HbA1c>7 and examined change in HbA1c among new initiators of a TNFi (etanercept, adalimumab, golimumab, or golimumab), MTX, and metformin (positive control). A base-line period of 12 months prior to the index date was required to capture potential confounders. All patients were required to have one HbA1c in the six months prior to and one HbA1c in the 6 months after drug initiation. We evaluated median HbA1c change in each group and then assessed statistical differences using the Wilcoxon Rank Sum test (unadjusted). We then used linear regression models to determine the relative differences in HbA1c change using MTX as the reference and adjusted for age, sex, baseline A1c, DM medications, and comorbidities in the baseline period, with clustering to account for multiple new drug initiations per patient.

Results: Among 914 drug initiations in 756 patients with PsA and available HbA1c values, HbA1c was >7 before 125 (44%) of TNFi initiations, 90 (43%) of MTX initiations, and 233 (55%) of metformin initiations. The average time between baseline and follow-up HbA1c values was 231 days. Median HbA1c change was -0.50 (IQR – 1.30, 0.30) after TNFi initiation, -0.40 (IQR – 1.50, 0.10) after MTX initiation, and -0.90 (IQR – 1.80, 0) after metformin initiation (figure 1). In adjusted analyses, TNFi initiators had a similar decrease in HbA1c compared to MTX initiators, β 0.02 (95%CI: –0.29, 0.33). Metformin initiators had a significantly greater change in HbA1c than MTX patients, β -0.43 (95%CI: -0.72, -0.13).

Conclusions: TNFi and MTX initiation lead to a decline in HbA1c by half as much as metformin. Changes in HbA1c were not different among patients initiating TNFi versus MTX.

AB0949

SERUM 25-HYDROXYVITAMIN D STATUS IN PATIENTS WITH PSORIATIC ARTHRITIS

S. Tsui1, J. Hashimoto1, T. Noguchi2, S. Akita2, K. Yachi2, S. Ohshima1, Y. Saeki3, M. Hagaishiyama4. 1Department of Rheumatology and Allergology, 2Department of Orthopaedic Surgery, 3Department of Clinical Research, NATIONAL HOSPITAL ORGANIZATION, OSAKA MINAMI MEDICAL CENTER, Kawachinagano City, Osaka, 4Department of Dermatology, Nissay Hospital, Osaka city, Japan

Background: Vitamin D has been recognised not only in calcium metabolism and bone metabolism but also in the physiological activities of a wide variety of cells, and its deficiency is caused by fractures/falls, osteoporosis and other various disease risks have been reported.

Objectives: To clarify vitamin D satisfaction status of patients with PsA, which is one of spondyloarthritides, by measuring serum 25OHD concentration.

Methods: 180 patients with PsA satisfying CASPAR criteria during the visit to our hospital between August 2016 and June 2017, 125 males, averaging age 54.1 y.o., BMI average 24.2, mean disease duration of PsA and psoriasis were 8.1 years, 19.3 years, respectively. The type of psoriatic arthritis was 79 spondylitis type and 101 peripheral type. MTX was 51.7% as an agent for treating PsA, and the average dose was 8.35±3.1 mg/week. The number of biologies use was 37.2%. There were 9 cases of osteoporosis and 21 cases of osteopenia, 20 patients who were undergoing treatment for osteoporosis, and all patients were treated with activated VD3. 110 patients (61.1%) had active type VD3 paint applied to psoriasis eruption. The ACPA positive rate was 7.4%, the rheumatoid factor positive was 17.7%, and

Abstract AB0948 – Figure 1
average CRP was 0.25±0.36 mg/dl. The test method for the serum 25OHD concentration was measured with the CLIA antibody method (SRL, Inc.). Regarding the judgment criteria of deficiency, although various discussions are in progress, "the index of serum 25OHD deficiency less than 20 ng/ml" prepared by the institute of medicine (IOM) in 2011 was used. As a study item, firstly, the degree of satisfaction of vitamin D using serum 25OHD concentration was determined. Second, it divided into VE deficient group and non-deficient group age, sex, disease duration, psoriatic arthritis type, blood biochemical test, presence of active VE administration, presence or absence of active type VE coating for skin, present or absence of enthesitis or arthritis mutilans. The results of the study were presented in tables, figures, and p values. The results showed that the mean serum 25OHD concentration in patients with PsA was 16.4±6.3 ng/ml and serum 25OHD deficiency was observed in 134 cases (74.4%). Factors that showed significant differences between the two groups (VD deficient group/normal group) were age (54.4±9.9 y.o., p=0.032), gender (female rate) 35.0%/11.9%, p=0.040, ACPA negative rate 97.0%/85.2%, p=0.010, serum MMP-3 (69.0/98.4 ng/ml, p=0.030), active vitamin D top coating use rate for skin 54.0%/88.9%, p=0.001, Biologics treatment rate 49.3%/11.1%, p<0.001. Conclusions: 74.4% of patients with PsA had vitamin D deficiency. In the vitamin D deficient group, low age, high female rate, ACPA negative, low serum MMP-3, VE coating low use rate for skin, biological product high usage rate were significant. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2018-eular.4822

Abstract AB0950 – Figure 1. The distribution of all MDA domains in patients achieving MDA and patients not achieving MDA. TJC: tender joint counts; SJC: swollen joint counts; TEP: tender enthesal points; BSA: body surface area; PGA: patient global activity; VAS: visual analogue scale; HAQ: Health Assessment Questionnaire.

Disclosures: The MDA criteria provide an objective target for treatment in trials and clinical practice; however in real life PROs are the most significant barriers to achieve MDA in all domains. Leeds enthesis index was not able differentiate MDA, for being negative in the vast majority of the patients. Monoarthritis subtype is a good prognostic factor whereas DIP joint disease and history of enthesis are poor prognostic factors to achieve MDA. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2018-eular.2729

Results: In January 2018, 1283 patients from Turkey and 119 patients from Canada were recruited, 317 of whom had full data for MDA and were included in this analysis. The demographics, disease characteristics and patterns in patients with MDA achieved vs not are summarised in the table. There were no differences regarding demographics in both groups. The monoarthritis subtype (RR: 2.01, 95% CI: 1.579–2.559), the absence of enthesis (RR: 1.570, 95% CI: 1.027–2.398) and the absence of distal interphalangeal joint disease (RR: 1.1, 95% CI: 1.001–1.25) were associated with higher probability of achieving MDA. Across different domains included in MDA, pain VAS≤15 and PGA ≤20 could less frequently be achieved even when MDA is fulfilled as 44.5% and 26.5% of patients respectively still did not fulfil these domains (figure 1). On the other hand, for patients that did not achieve MDA, the body surface area (51.2%) and swollen joint count (53.5%) domains could be achieved in the majority of the patients and 93.5% of them had no enthesis using the Leeds enthesis index. Physician global assessment (>21 vs<20) and BASDAI (>41 vs<40, only for axial disease) had only moderate agreement with MDA (achieved or not) (kappa=0.47, p=0.05 and kappa=0.469, p=0.072; respectively). All data were given in n/total n (percentage (%)) or median (first-third percentiles%). MDA: minimal disease activity; PsA: Psoriatic Arthritis; DIP: distal interphalangeal.

AB0952 HIGH PREVALENCE OF INFLAMMATORY AND NON-INFLAMMATORY LIVER AND GASTROINTESTINAL DISEASES IN YOUNG PATIENTS WITH PSORIATIC ARTHRITIS: A HOSPITAL-BASED STUDY

N. Batakova¹, E. Batakova², T. Korotova³. ¹Dermatology, Peoples’ Friendship University of Russia (RUDN University); ²Dermatology, Peoples’ Friendship University of Russia (RUDN University); ³Research Institute of Rheumatology n. a. V. A. Nasonova, Moscow, Russian Federation

Background: Psoriatic arthritis (PsA) is associated with numerous comorbidities, including gastrointestinal (GI) and liver diseases (LD). But there is limited data about the prevalence of these disorders among patients (pts) with PsA and severe psoriasis (PsO) in Russian population.

Objectives: to evaluate the prevalence of LD and GI comorbidity in a hospital-based cohort of PsA pts.

Methods: 417 (304 Male (M.)/113 Female (F.) out of 417 pts (54.9%) had LD and GIT disorders. Soft tissue swelling around nail was observed.

Results: Seventy (78.6% female) patients were analysed, mean age was 45.5 (12.0). Mean follow-up duration was 18.3 (12.6) months, and total of 213 clinical visits were performed, median 3 (1–12) control visits were done. At baseline, the mean (SD) DAS-28 4.07 (1.22), HAQ-DI 0.86 (0.53), pain-VAS 6.9 (2.1), PGA-VAS 6.4 (1.7), and PsAID-12 6.6 (1.5) were as follows. Anti-TNF treatments were stopped due to inefficacy in 43/210 (20.5%) outpatient visit during the follow-up period. The results of anti-TNF stopped and continuing patients; ΔPsAID-12 were 0.38 (1.71), and 3.12 (2.14), respectively and PsAID-12 baseline/control visits 0.96 (0.29) vs 0.50 (0.33), respectively. Level of favourable response and achieving to goal according to ΔPsAID-12 and PsAID-12 Baseline/control visit were shown table 1. On the follow up visits, among measured parameters one of the highest SRM was detected in PsAID-12; PsAID-12 (1.10), DAS-28 (1.14), PGA (0.88), Pain (0.85), and HAQ-DI (0.51), respectively.

Conclusions: Having 3.5 unit or 50% decrease in the PsAID-12 score indicates a favourable response to anti-TNF treatment, 4 unit or 70% decrease indicates level

AB0953 PSAID-12 CAN BE USED TO DETERMINE THE ANTI-TNF TREATMENT DECISION IN THE PSORIATIC ARTHRITIS REGISTRY

U. Kalyoncu, S. Kiraz, S. Agra Bilgen, O. Karadaag, A. Akdogan, L. Kilic, A. Erden, B. Armagan, A. Sarı, I. Ertenli, Hacettepe University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey.

Background: Psoriatic Arthritis Impact of Disease (PsAID-12) score has 12 questions and each question has its own weight. PsAID-12 is developed to be used in daily practice. However, in the daily practice, there has been no information on the utilisation of determining the response of the biological DMARD treatment.

Objectives: The assessment of utilisation of PsAID-12 for PsA patients on determination of the efficacy and inefficiency of anti-TNF treatment in a biological registry.

Methods: In this study patients were taken from Hacettepe University biological database (HUR-BIO). Since January 2013 PsAID-12 score was built in HUR-BIO database. PsAID-12 score was known for 116 patients before starting off the first anti-TNF treatment and 88 patients whose PsAID-12 score was 4 and above were included in the enquiry. Overall, 70 PsA patients included to analysis. Demographic data before anti-TNF treatment of PsA patients were noted. The decision of continuation, stopping or switching to another anti-TNF drugs were performed by both clinicians and the patients agreement. According to baseline evaluation, decrease of 20 mm and above on pain-VAS score and PGA, improvement of 0.22 unit and above on HAQ-DI score, or decrease of 1.2 unit and above on DAS-28 score were considered favourable to the anti-TNF treatment. Stopping or switching the anti-TNF treatments due to inefficiency was definitely a negative response. Pain-VAS score being under 15 mm or below, global-VAS score being 20 mm and below, HAQ-DI score being 0.5 and below, DAS-28 score being 2.6 and below were determined as targeted goals. Changes were analysed comparing to baseline level in PsAID-12 score, in compliance with the favourable and unfavourable responses to Anti-TNF treatments. In determining the response of the treatment, standardised response mean (SRM) was used.

Results: Seventy (78.6%) female patients were analysed, mean age was 45.5 (12.0). Mean follow-up duration was 18.3 (12.6) months, and total of 213 clinical visits were performed, median 3 (1–12) control visits were done. At baseline, the mean (SD) DAS-28 4.07 (1.22), HAQ-DI 0.86 (0.53), pain-VAS 6.9 (2.1), PGA-VAS 6.4 (1.7), and PsAID-12 6.6 (1.5) were as follows. Anti-TNF treatments were stopped due to inefficacy in 43/210 (20.5%) outpatient visit during the follow-up period. The results of anti-TNF stopped and continuing patients; ΔPsAID-12 were 0.38 (1.71), and 3.12 (2.14), respectively and PsAID-12 baseline/control visits 0.96 (0.29) vs 0.50 (0.33), respectively. Level of favourable response and achieving to goal according to ΔPsAID-12 and PsAID-12 Baseline/control visit were shown table 1. On the follow up visits, among measured parameters one of the highest SRM was detected in PsAID-12; PsAID-12 (1.10), DAS-28 (1.14), PGA (0.88), Pain (0.85), and HAQ-DI (0.51), respectively.

Conclusions: Having 3.5 unit or 50% decrease in the PsAID-12 score indicates a favourable response to anti-TNF treatment, 4 unit or 70% decrease indicates level
A RANDOMISED, DOUBLE-BLIND TRIAL COMPARING THE EFFICACY, SAFETY AND IMMUNOGENICITY OF MSB11022 VS. ADALIMUMAB, VERSUS ADALIMUMAB ORIGINATOR IN PATIENTS WITH MODERATE-TO-SEVERE PLAQUE PSORIASIS

J. Hercogová1, K.A. Papp2, C.J. Edwards1, V. Chrykó4, T. Haladý3, M. Ullmann3, P. Vlachos5,1, Charles University, Prague, Czech Republic; 2Probity Medical Research Inc, Waterloo, ON, Canada; 3University of Southampton, Southampton, UK; 4Fresenius Kabi, Aubonne, 5Cyted, Geneve, Switzerland

Background: Adalimumab is a fully human anti-TNF mAb, indicated for the treatment of multiple inflammatory disorders. MSB11022 is a proposed adalimumab biosimilar that has shown analytical similarity [1] and bioequivalence to US-licensed and EU-approved adalimumab originator, as well as comparable safety, tolerability and immunogenicity in a phase I trial [2].

Objectives: The aims of this multicentre, double-blind, parallel-group, 52-week phase III study (AURIEL-PsO, NCT02660580) were to demonstrate equivalence in efficacy (Psoriasis Area and Severity Index [PASI] 75) and to compare the safety and immunogenicity of MSB11022 vs. adalimumab originator in patients with moderate-to-severe chronic plaque psoriasis. This study was designed in-line with the biosimilar regulatory framework as part of the totality of evidence to confirm similarity and rationale for extrapolation.

Methods: A total of 443 eligible patients (391 evaluable, including 43 with psoriatic arthritis) from 69 sites in 12 countries were randomised 1:1 and treated with MSB11022 (n=202) or adalimumab originator (n=189) (80 mg subcutaneously [SC] on day 1; 40 mg SC every other week from weeks 2–14). The primary endpoint was PASI 75 at week 16: equivalence was established if the 95% confidence interval (CI) for the treatment difference was within ±18%. Secondary endpoints included % change from baseline in PASI (equivalence confirmed if 95% CI within ±15%), Physician Global Assessment (PGA), quality of life (QoL), immunogenicity and safety. Interim results at week 16 are presented.

Results: Patient baseline characteristics were comparable between MSB11022 and adalimumab originator groups: mean age 44.8 ± 42.4 years, male 66.8% vs. 68.3%, mean PASI score 20.7 vs. 21.2, respectively. PASI 75 scores were 89.6% for MSB11022 and 91.5% for adalimumab originator (difference –1.9% [95% CI –7.82–4.16]). Mean % change from baseline in PASI was –90.6% for MSB11022 and –91.7% for adalimumab originator (difference –0.1% [95% CI –1.23–2.98]). PGA and QoL scores were comparable between treatment groups. The incidence of treatment-emergent adverse events (TEAEs)/serious TEAEs was 51.3/6.6% for MSB11022 and 53.2/7.7% for adalimumab originator. Immunogenicity profiles of MSB11022 and adalimumab originator were also similar and consistent.

Conclusions: Week 16 results of this phase III confirmatory study demonstrated equivalent efficacy and similar safety and immunogenicity profiles for MSB11022 vs. adalimumab originator at 16 weeks in patients with moderate-to-severe chronic psoriasis.

TILDRAKIZUMAB EFFICACY OVER TIME BY WEEK 28 RESPONSE LEVELS IN TWO PHASE 3 CLINICAL TRIALS IN PATIENTS WITH CHRONIC PLAQUE PSORIASIS

A. Blauvelt1, H. Sofen2, K. Papp3, M. Gooderham2, Y. Zhao1, S. Lowry1, A. Mendelsohn1, J. Pampl0, Q. Li1, C.L. Rosa1, K. Reich2, Oregon Medical Research Center, Portland; 2Medicine, University of California at Los Angeles, Los Angeles, USA; 3Probity Medical Research, Waterloo; 4Skin Centre for Dermatology, Peterborough, Canada; 5Sun Pharmaceuticals, Princeton, 6Merck and Co., Inc., Kenilworth, USA; 7ScI Derm Research Institute and Dermatologikum, Hamburg, Germany

Background: Tildrakizumab (TIL), a high affinity, humanised, IgG1/k monoclonal antibody for IL-23p19, recently demonstrated efficacy in patients with chronic plaque psoriasis in two, phase 3 clinical trials.

Objectives: To examine efficacy from baseline to week 52 among TIL patients achieving various Psoriasis Area and Severity Index (PASI) responses at week 28.

Methods: ReSURFACE 1 (NCT01722331) and reSURFACE 2 (NCT01729754) were double-blind, randomised controlled trials in subjects with moderate-to-severe chronic plaque psoriasis. Part 1 (0–12 weeks) was placebo controlled; Part 2 (12–28 weeks) re-randomised placebo patients to TIL; Part 3 (28–64 weeks, reSURFACE 1; 28–52 weeks, reSURFACE 2) patients with >PASI 50 were re-randomised to continue or increase TIL dose or to placebo based on response at week 28. In this post-hoc pooled analysis, patients on TIL 100 mg and 200 mg from baseline to week 52 were classified in 5 mutually exclusive groups based on their week 28 PASI response: PASI 50–PASI 75–PASI 75–99, PASI 90–99, and PASI 100. Baseline characteristics and % PASI improvement from baseline up to week 52 (observed data) were examined for each group.

Results: This analysis included 575 (TIL 100 mg) and 581 (TIL 200 mg) patients; the overall pooled Week 28 PASI 75/90/100 responses were 77%/54%/23% (TIL 100 mg) and 76%/58%/29% (TIL 200 mg). At week 28, 133 (23.1%), 175 (30.4%), 137 (23.8%), 82 (14.3%), and 48 (8.3%) TIL 100 mg patients and 170 (29.3%), 169 (29.1%), 82 (14.3%), and 48 (8.3%) TIL 200 mg patients achieved PASI 100, 90–99, 75–89, 50–74, and <50, respectively. On average, PASI 100 patients were younger, lighter, and had shorter disease duration at baseline compared to other response groups. For TIL 100 mg, % PASI improvement was highest for PASI 100 and least for PASI <50 for all visits up to week 28 (week 4: 53%, 46%, 38%, 30%, and 16%; week 28: 100%, 95%, 83%, 64%, and 33% for PASI 100, PASI 90–99, PASI 75–89, PASI 50–74, and PASI <50 categories, respectively). Among patients achieving PASI >50 at week 28 and continued up to 52 weeks, % PASI improvement remained consistent or improved from week 28 to week 52. Similar results were observed for TIL 200 mg as well as subgroup analysis with bio-naïve and bio-experienced patients, respectively.

Conclusions: The majority of TIL 100 and 200 mg patients achieved PASI response at week 28, and PASI improvement was maintained from week 28 to week 52. Among patients achieving >PASI 90 at week 28, TIL 100 and 200 mg were associated with rapid improvement by week 4.

LEUCINE-RICH ALPHA-2 GLYCOPROTEIN IS A PREDICTABLE BIOMARKER FOR THERAPEUTIC RESPONSE AND CLINICAL RELAPSE TO BIOTHERAPEUTICS, BUT NOT TO APREMILAST IN PATIENTS WITH PSORIASIS

Y. Shibata1, S. Serada2, M. Fujimoto3, H. Nakajima4, S. Sano5, T. Nakajima6

1Department of Dermatology, 2Department of Dermatology, 3Department of Dermatology, 4Department of Dermatology, 5Department of Dermatology, 6Department of Dermatology

Background: Leucine-rich alpha-2 glycoprotein (LRG) is a 50 kDa protein produced by hepatocytes, endothelial cells, neutrophils and macrophages, and it was identified as an inflammatory biomarker that correlates with the disease activity of autoimmune diseases such as inflammatory bowel disease and rheumatoid arthritis. We recently reported that LRG could also be a biomarker of psoriasis, which correlated with the clinical severity scores such as Psoriasis Area and Severity Index (PASI), Disease Activity Score 28 (DAS-28) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) more closely than common inflammatory markers like C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). The biologics are innovative therapies for psoriasis, however they can cause side effects and increase medical cost. Recently, apremilast, a small molecule inhibitor of phosphodiesterase 4, was approved for treatment of psoriasis in Japan, yet the precise mechanism remains unknown.

Objectives: To explore the eligibility of serum LRG for a biomarker to monitor the responses to biologics and apremilast in psoriasis.

Methods: Antibodies to TNF-α, IL-12/IL-23p40, IL-17A and IL-17 receptor A and apremilast were administered in patients with psoriasis vulgaris and psoriatic arthritis (n=15, 6, 14, 4 and 8 respectively). Serum LRG levels were measured by enzyme-linked immunosorbent assay. Serum CRP and ESR, and PASI, DAS-28 and BASDAI were also recorded.

Results: Serum LRG decreased along with the improvement of clinical scores after the administration of biologics, and reflected the change of scores more accurately than CRP and ESR. Furthermore, the LRG levels predicted the changes of clinical symptoms and predicted both primary and secondary treatment failure at the early time point, allowing us to determine if we should increase the doses, discontinue or switch to another drug. In some patients with PASI clear, complete regression of eruption, after biologics, serum LRG rerose from the baseline while their PASI scores remained stable; however, they later relapsed. On the other hand, LRG did not reflect the therapeutic effectiveness of apremilast.

Conclusions: Serum LRG in psoriasis patients would be a sensitive biomarker for predicting the effectiveness and treatment failure of biologics, but not of apremilast. Monitoring LRG levels may enable us to decide the timing of bio-attenuation and to detect the relapse after discontinuation of biologics.

AB0957 SEVERE SKIN SYMPTOMS ARE NOT ASSOCIATED WITH MUSCULOSKELETAL MANIFESTATIONS IN PATIENTS WITH PSORIASIS

Y. Yamada1,2, K. Inui1, T. Okano1, Y. Sugikawa1, H. Yoshimura2, K. Mamoto3, T. Koke4, M. Tada5, C. Tateno6, E. Yonezawa7, A. Natsumi8, Y. Fukunaga9, D. Tsuruta10, H. Nakamura11, Department of orthopedics surgery, Osaka City UNIVERSITY; 2Department of orthopedics surgery, Yokogawa Christian Hospital; 3Center for Senile Degenerative Disorders (CSDD), Osaka CITY UNIVERSITY, Osaka City; 4Shirahama Foundation for Health and Welfare; 5Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama; 6Department of orthopedics surgery, Osaka City General Hospital; 7Department of Dermatology, Osaka CITY UNIVERSITY, Osaka City, Japan

Background: Among patients with psoriasis, risk factors for developing musculoskeletal manifestations, known as psoriatic arthritis (PsA), are not recognised well.

Objectives: The aim of this study is to clarify the relationship between severity of skin disease and arthritis.

Methods: Psoriasis patients referred from dermatologists for assessment of musculoskeletal manifestations between June 2015 and July 2017 were enrolled. Their age, comorbidity, disease duration and treatment were collected. Presence of inflammatory back pain, sacroiliac joint tenderness or enthesitis were examined. Severity of skin symptoms were evaluated by dermatologists in Psoriasis area and severity index (PASI), Psoriatic arthritis screening and evaluation (PASE) and disease activity score (DAS28 ESR) were also evaluated. PsA was diagnosed by the Classification for Psoriatic Arthritis (CASPAR) criteria assisted with musculoskeletal ultrasound examination.

Results: Among 107 patients with psoriasis referred from dermatologists during designated period, 63 patients were diagnosed as PsA. These PsA patients were compared with 44 patients who had no arthritis (PsO). Multiple logistic regression analysis showed neither of age, sex, PASI, disease duration, rheumatoid factor (RF), CRP or Matrix Metalloproteinase-3 (MMP3) had no association with presence of PsA (table 1). Among 63 patients with PsA, those using NSAIDs (p=0.028), those with inflammatory back pain (p=0.002) and male patients (p=0.017) had significantly high PASI. PASI significantly correlated with age (Spearman’s correlation coefficient R=−0.303: p=0.016), body height (R=0.301: p=0.019) and weight (R=−0.383: p=0.002), but not with DAS28 ESR, MMP3 or disease duration (table 2).

Conclusions: PASI did not associate with presence of arthritis. Furthermore, even DAS28 ESR, reflecting musculoskeletal manifestations, or disease duration did not correlated with PASI among patients with PsA. These indicates severity of skin symptoms is not associated with musculoskeletal manifestations in patients with psoriasis.

KNEE PAIN IN OSTEOARTHRITIS: CORRELATION WITH SONOGRAPHIC FINDINGS

A. Radwan, A. Radwan, M. Khalil, A.M. Elsamad, Rheumatology and Rehabilitation, Sohag University, Sohag, Egypt

Background: Osteoarthritis (OA) is a common joint disorder, with the knee being one of the most frequently involved sites. Knee OA causes pain and stiffness and can lead to considerable disability and consequently to a reduced quality of life (Wideman et al. 2014). The level of radiographic knee OA is, at most, moderately associated with the level of pain. Therefore, it is unlikely that pain is predominantly caused by only bone and cartilage pathology. Mechanical, structural, inflammatory, bone-related, neurological and psychological factors play a role in the process that results in painful knee OA (Wenger et al. 2013). As OA is a disease of the entire joint that is characterised by cartilage breakdown, subchondral bone alterations and formation of osteophytes, as well as soft tissue abnormalities including meniscal degeneration, bursitis, tendinitis, Baker’s cyst and synovial inflammation; information about these soft tissue structures might provide more insight into their potential role in the complex process of pain in knee OA (Cook 2016).

Musculoskeletal ultrasonography (US) is a relatively new imaging tool that is non-invasive, safe and relatively inexpensive and is able to create static as well as dynamic images. In addition, it has been shown to be more sensitive than clinical examination in picking up peri- and intra-articular soft tissue lesions (Bever et al. 2014). The objective of this cross-sectional study was to compare clinical knee OA and pain score in patients with OA fulfilling ACR clinical criteria. They were divided into two groups. Group A (53) patients with knee pain (VAS 33 mm) during physical activity once at least in the previous 3 days prior to inclusion. Another (42) patients without knee pain for at least 1 month prior to inclusion (VAS 0 mm). All of the participants were subjected to the following:

- Full history (demographic data and personal history, detailed history of general health condition and chronic or current diseases).
- Knee clinical examination (including varus deformity angle assessment).
- Sonographic evaluation: of Effusion, Synovial hypertrophy, Baker’s cyst, Enthesitis, Power Doppler by SOLAR score, menisci protrusion, bursitis, sonographic signs of Gout or CPPD and scoring of the osteophytes and cartilage.

Results: Our study showed that the painful OA group are more obese, more varus deformities, effusion, synovial hypertrophy, cartilage changes, and higher grading of osteophytes than the control group. On the other hand, Baker cyst and meniscal protrusion ecogenic foci, double contour, erosions, meniscal and cartilage calcification showed a non-significant difference between the two groups. We included all of the demographic, clinical and sonographic factors in a univariate regression analysis, and this analysis showed that synovial hypertrophy, effusion, the degree of cartilage changes, the degree of osteophytes, bursitis, and weight may be possible risk factors for pain among OA patients.

Abstract AB0958 – Table 1. Multivariate logistic regression analysis of the possible independent risk factors for pain among painful OA group compared to the non-painful OA group.

Conclusions: Cartilage degeneration, osteophytes, effusion, synovial hypertrophy, bursitis, and overweight respectively, are the leading causes of pain in knee OA.

Disclosure of Interest: None declared.

CONSUMPTION OF DAIRY PRODUCTS IN RELATION TO PRESENCE OF CLINICAL KNEE OSTEOARTHRITIS: THE MAASTRICHT STUDY

K. Denissen1,2, A. Boonen2,3, J. Nielen1,2,4, A. Feitsma4, E. van den Heuvel5, P. Emans3, S. Sep1,2,4,5, C. Stehouwer7,10, M. van Dongen7,2,8, P. Dagnelie1,2,6, S. Eussen7,9, 1Department of Epidemiology, 2CAPHRI Care and Public Health Research Institute, Maastricht University; 3Department of Internal Medicine, Division of Rheumatology; 4Department of Clinical Pharmacy and Toxicology, Maastricht University Medical Center+, Maastricht; 5Friesland Campina, Amersfoort; 6Department of Orthopaedics; 7Department of Internal Medicine, Maastricht University Medical Center+; 8Department of Rehabilitation Medicine, Maastricht University, Maastricht; 9CAPHRI Care and Public Health Research Institute, Maastricht University, Amersfoort; 10CARIM School for Cardiovascular Diseases, Maastricht University, Maastricht, Netherlands

Background: Observational studies showed inverse associations between milk consumption and knee osteoarthritis (knee OA).1,2 There is lack of information on the role of specific other dairy product categories.

Objectives: To explore the association between dairy consumption and presence of clinical knee OA in individuals aged 40–75 year participating in the Maastricht Study.

Methods: Presence of clinical knee OA was defined according to a slightly modified version of the American College of Rheumatology (ACR) clinical classification criteria.1 Data on dairy consumption was appraised by a 253-item Food Frequency Questionnaire covering 47 dairy products with categorization on fat content, fermentation or dairy type. Multivariable logistic regression analyses were performed to estimate odd ratios (ORs) and 95% confidence intervals (95% CI), while correcting for relevant factors.

Results: Of the 9010 participants included in this study, 427 individuals (14%) were classified as having clinical knee OA. Significant inverse associations were observed between presence of clinical knee OA and intake of full-fat dairy and Dutch, primarily semi-hard, cheese, with OR for the highest compared to the lowest tertile of intake of 0.88 (95%CI 0.50–0.92) for full-fat dairy, and 0.75 (95%CI 0.56–0.99) for Dutch cheese. No significant associations were found for other dairy product categories.

Conclusions: In this Dutch population, higher intake of full-fat dairy and Dutch cheese, but not milk, was cross-sectionally associated with lower presence of clinical knee OA. Prospective studies need to assess the relationship between dairy consumption, and in particular semi-hard cheeses, with incident knee OA.

POLYMORBIDITY AND COGNITION IN AMBULATORY POSTMENOPAUSAL HIP AND KNEE OSTEOARTHRITIS PATIENTS

A.A. Popovy1, N.V. Izmozheneva2, N.A. Getmanova2, 1Hospital Therapy Dept, 2Pharmacology and Clinical Pharmacology Dept., Urals State Medical University, Ekaterinburg, Russian Federation

Background: Osteoarthritis (OA) has been reported to be a risk factor of morbidity, disability and premature cardiovascular mortality.

Objectives: to assess the impact of polymorbidity on cognitive function in postmenopausal women with primary OA.
Methods: cross-sectional study included ambulatory 682 postmenopausal women aged 48 to 62 (median 56; 25%–75%: 52.0 / 60.0). Inclusion criteria were: confirmed postmenopausal status and Kellgren stage 2 or 3 OA of the knee and hip joints fulfilling ARA criteria. Cognitive impairment (CI) was verified by MMSE scale (Mini Mental State Examination). For all patients expected individual risk of premature death and Charlson index were calculated.

Results: Median Charlson comorbidity index in women with OA was 4 (3 / 4). None of the patient had a comorbidity index of 0. The most frequent comorbidities were chronic heart failure (364 women (53.4%) and type 2 diabetes mellitus (180 women, 26.4%).

Charlson index increase was associated with decline of cognitive function (see table 1) with incline of quantity and severity of CI cases.

Conclusions:
- Hip and knee joints OA in postmenopausal women is associated with polymorbidity.
- Polymorbidity in OA patients is associated with cognitive impairment.

Disclosure of Interest: None declared

| AB0961 | CARDIORESPIRATORY RESPONSE ACCORDING TO BODY WEIGHT SUPPORT AND GAIT VELOCITY VIA ANTI-GRAVITY TREADMILL AFTER BILATERAL TOTAL KNEE ARTHROPLASTY |
|-----------------------------------------------|
| B.R. Kim. JEJU NATIONAL UNIVERSITY HOSPITAL, Jeju, Korea, Republic of Ireland |

Background: Patients undergoing total knee arthroplasty (TKA) may benefit from early focused postoperative rehabilitation, and progressive weight-bearing activities, such as walking, are routinely recommended during rehabilitation to facilitate return to normal gait function. Not all patients are capable of full weight-bearing activity in the early postoperative period and assistive devices such as walkers, crutches, and canes, are routinely employed. The anti-gravity treadmill, consisting of a treadmill enclosed within an airtight chamber, applies air pressure to a patient’s lower body to alter body weight support and can reduce the forces at the knee during weight bearing exercise. The anti-gravity treadmill could be a useful device for early postoperative rehabilitation of TKA, especially for those patients with reduced physical strength and cardiovascular fitness. However, so far, there have been no reported investigations of the physiologic cardiorespiratory responses via anti-gravity treadmill in patients following TKA.

Objectives: This study was conducted to investigate cardiorespiratory response according to body weight support and gait velocity elicited using an anti-gravity treadmill during walking and to find specific gait velocity and body weight support combinations early after bilateral TKA.

Methods: Twenty five patients who underwent a primary TKA were enrolled in this study. Subjects walked with 2.5 km/h and 3.5 km/h on an anti-gravity treadmill at 3 levels (50%, 75%, 100%) of body weight (BW). Each trial was performed for 2 min with at least 1 min rest between trials. For cardiorespiratory responses, oxygen consumption (VO2), Heart rate, systolic (SBP) and diastolic blood pressure (DBP), respiratory exchange ratio (RER) and rate pulse product (RPP) were measured continuously with average values. The VO2, heart rate and RER were measured by using the KO2 (Cosmed, Rome, Italy), which is a wireless cardio-pulmonary diagnostic device, and the values of these exercise variables were defined as the averages of values recorded during the last 30 s of exercise. The RPP was calculated (heart rate x SBP/100). In addition, Borg’s rating of perceived exertion scale (RPE) and visual analogue scale (VAS) of knee pain were recorded immediately after each condition.

Results: There were 20 females and 32 men, with the average age being 71.3 ± 5.4 years. In the two-way repeated measures ANOVA, VO2 levels (p<0.01), HR (p<0.01), RPP (p<0.01), RPE (p<0.01), RER (p<0.01) and VAS (p<0.01) were significantly increased in proportion to 3 levels (50%, 75%, 100%) of BW. In the post-hoc analysis, all other conditions except comparison of RER values between 50% level of BW and 75% level of BW under a speed of 2.5 km/h and a speed of 3.5 km/h were statistically significant. Meanwhile, SBP (p=0.65) and DBP (p=0.39) were not influenced by difference of BW levels.

While walking with a speed of 3.5 km/h at same fraction of BW level, VO2 (p<0.03), RPE (p<0.01) and RER (p<0.01) values were statistically greater than 2.5 km/h. In the post-hoc analysis, all other conditions except comparison of RER values between a speed of 2.5 km/h and a speed of 3.5 km/h under 100% level of BW was statistically significant.

In addition, multiple linear regression analysis was performed to defining VO2 as functions of gait speed and fraction of BW under each condition. Based on BW and gait velocity settings of the LBPP treadmill, the equations were VO2=1.46 v +0.09BW-3.13 (adjusted R²=0.34).

Conclusions: This study demonstrated that cardiorespiratory responses were variably computed by combination of weight support and gait velocity during anti-gravity treadmill walking, and these cardiorespiratory responses and knee pain were more significantly influenced by body weight support than gait velocity. These findings suggest that body weight support and gait speed should be considered for gait training program for cardiovascular fitness early after bilateral total knee arthroplasty.

| AB0962 | IRISIN LEVELS ARE ASSOCIATED WITH EXERCISE, PAIN AND FUNCTION IN PATIENTS WITH KNEE OSTEOARTHRITIS |
|-----------------------------------------------|
| C. Creljana, J. Calvet, N. Navarro, C. Galisteo, J. Gratacos, M. Larosa. Rheumatology, Parc Taulí Sabadell Hospital Universitari, Sabadell, Spain |

Background: Muscle strengthening and aerobic exercise have been shown to improve joint pain and function in patients with knee osteoarthritis (OA). Irisin is a hormone-like myokine synthesized by skeletal muscle and its secretion appears to be related to physical activity in healthy people.

Objectives: To determine the levels of irisin synovial fluid and plasma and evaluate their association with exercise level and pain and function in patients with symptomatic knee OA.

Methods: Cross-sectional study with systematic inclusion of 108 symptomatic primary knee osteoarthritis patients (VAS>4) with ultrasound-confirmed joint effusion. Age, physical exercise, knee osteoarthritis symptoms duration and different anthropometric measurements were collected. Radiographic severity was evaluated according to Kellgren-Lawrence scale. Physical exercise was categorised as never, occasional (less than 150 min per week) or regular (more than 150 min per week. Pain and disability were assessed by the Lequesne algo-functional questionnaire. Irisin was measured by ELISA in synovial fluid and plasma. Summary of clinical data and laboratory parameters and their association with Lequesne scale were performed using non-parametric methods. Medians and Spearman correlation (r) were used for continuous measures, and Mann-Whitney test was applied to categorical variables. This study was approved by the local ethics committee.

Results: Plasma and synovial irisin levels were strongly related (r=0.7). Plasma and joint irisin levels showed an inversely significant association with the level of exercise in patients with symptomatic knee OA: no exercise 763.3 ng/mL, occasional exercise 631.8 ng/mL and regular exercise 523 ng/mL (p<0.01). Patients with severe pain and disability (Lequesne algofunctional score >11) had higher plasma (791.5 vs 680.4 ng/mL, p<0.05) and synovial (711.4 vs 468.7 ng/mL, p<0.05) irisin levels compared to patients with less disability and pain. No relationship was found between irisin concentration in plasma or synovial fluid and radiographic severity.

Conclusions: Irisin levels were associated with pain and function in patients with knee osteoarthritis. Irisin levels were negatively associated with exercise level in this population.

Disclosure of Interest: None declared

| AB0963 | CALPROCTIN AS A USEFUL MARKER OF INFLAMMATION IN KNEE OSTEOARTHRITIS |
|-----------------------------------------------|
| J. Calvet, C. Creljana, N. Navarro, C. Galisteo, J. Gratacos, M. Larosa. Rheumatology, Parc Taulí Sabadell Hospital Universitari, Sabadell, Spain |

Background: Low-grade synovial inflammation is known to be present in many patients with knee osteoarthritis and appears to have clinical and prognostic implications. Calprotectin seems to be more sensitive than CRP to detect minimal inflammatory activity in many inflammatory rheumatic diseases and could be a biomarker in osteoarthritis with inflammatory features.

Objectives: To determine the levels of synovial calprotectin in patients with knee osteoarthritis showing inflammatory traits and their relationship with clinical and ultrasonographic features and other proinflammatory markers.

Methods: Cross-sectional study with systematic inclusion of 108 symptomatic primary knee osteoarthritis patients (VAS>4) with ultrasound-confirmed joint
THE ROLE OF MTOR GENE EXPRESSION, APOPTOSIS MEDICAMENTAL AND NON-MEDICAMENTAL THERAPY

Methods:

Background: Metabolic osteoarthritis (OA) has been identified in rheumatology as a specific phenotype due to the growing rates of obesity and other comorbidities, with meta-inflammation as the key factor in its pathogenesis. On the other hand, OA progression is associated with altered regulation of chondrocytes’ metabolism, namely, with up-regulated expression of genes encoding m-TOR, apoptosis, cartilage degeneration and inflammation.

Objectives: To measure the expression levels of genes encoding m-TOR, apoptosis (caspase-3), cartilage destruction (cathepsin K), and inflammation (TNF-α) in patients with knee OA (KOA) and obesity.

Methods: 50 female patients (45–65 y.o.) with Kellgren-Lawrence stage II-III KOA and obesity (BMI >30 kg/m²;) were randomised into 2 groups. Pts in Group 1 (n=25) were administered orlistat as a specific therapy for obesity for the period of 12 months. Peripheral blood samples were obtained at Mo12 to evaluate possible correlation with the dynamics of body weight. Up-regulated expression (p<0.05) of genes encoding inflammation (TNF-α), cartilage destruction (cathepsin K), apoptosis (caspase-3), and cell proliferation (m-TOR) was documented in KOA obese pts from Group 1, gaining body weight during the second stage of the study, as compared to the expression values in pts from Group 2 (figure 1). The analysis demonstrated direct positive correlation (p<0.05) between expression of genes encoding inflammation, cartilage destruction and apoptosis and pain intensity in knee joints assessed by VAS and WOMAC scales.

Conclusions: Therefore up-regulation of m-TOR, caspase-3, TNF-α and cathepsin K gene expression is observed in obese pts with KOA following weight gain and worsening of clinical parameters, which is suggestive of aggravated apopotic inflammation, cartilage destruction and apoptosis and pain intensity in knee joints assessed by VAS and WOMAC scales.

AB0965 MEDICAMENTAL AND NON-MEDICAMENTAL THERAPY PREGNANT WOMEN WITH HIP OSTEOARTHRITIS

E. Trofimov, V. Mazurov, A. Trofimova, E. Melnikov, I. Gaydukova. North-West II Mechnikov State Medical University, Saint-Petersburg, Russian Federation

Objectives: The management of patients with severe pain caused by primary or secondary osteoarthritis (OA) of the hip joint (TBS) has not been developed. The aim of the present work was to evaluate the impact of NSAIDs, glucocorticoids (GCS), analgesics and non-drug treatment methods on pregnancy outcomes in patients with primary and secondary OA TBS

Methods: The study included 99 pregnant women aged 35 to 49 with an intensive pain (>4.0 points for VAS) due to primary or secondary OA TBS. Depending on the form of OA, the severity of the pain and the patient's opinion, the therapy was prescribed – ibuprofen up to 800 mg per day orally (n=31) or paracetamol up to 1000 mg per day orally (n=20) or methylprednisolone up to 12 mg per day orally (n=27) or non-pharmacological methods (n=21). The efficacy of the treatment was evaluated within a month from the start of the therapy, pregnancy outcomes for the mother and fetus and pathology of the child after 12 months after the birth. The factors, associated with low efficacy of treatment, were evaluated.

Results: In 50 (51%) women was established primary OA TBS, in 49 (49%) – secondary OA TBS. A decrease of pain in TBS in patients of all treatment groups (p>0.05 for comparison with baseline) was registered. Patients with secondary OA, who received Methylprednisolone, showed a statistically significant (p<0.05) improvement in pain compared to patients in other clinical groups. A correlation was found between the intensity of pain syndrome (VAS) and BMI. 85 (85%) patients had urgent deliveries, 14 (14%) had premature, natural delivery (n=27) or non-pharmacological methods (n=21). The cases of ante- and perinatal fetal death were not recorded. Pathological conditions were absent in 28 (84.8%) of newborns, whose mothers refused medical treatment, in 28 (80.32%) newborns, who received ibuprofen, in 15 (75%) – paracetamol, and in 23 (85.19%), who were on methylprednisolone therapy (differences between groups are unreliable, p>0.05). In 12 months after birth in the group of newborns receiving antenatal ibuprofen, pathological conditions were observed in 3 children, paracetamol – in 5, metiprednisolone – in 4 children who were “without therapy” – in 5 children.

Conclusions:

- The use of non–medicamental and medicamental (non-selective NSAIDs or GCS in small doses or analgesics) treatment in pregnant woman with hip osteoarthritis has equal efficiency and safety for the health of the mother and fetus.
- Children, born to mothers with primary or secondary hip osteoarthritis, treated with NSAIDs or analgesics or GCS by medical treatment in age of 12th month do not differ from children, born to mothers with osteoarthritis of hip joints, receiving non–medicamental therapy.
- An increase of the body mass index of a pregnant woman with osteoarthritis of the hip joints is a predictor of refractoriness to any form of drug and non–drug therapy.

Disclosure of Interest: None declared

Abstract AB0964 – Figure 1. Body mass dynamics. Abstract AB0964 – Figure 2. Gene expression in obese pts with knee OA
CROSS-CULTURAL ADAPTATION AND VALIDATION OF THE KOREAN VERSION OF THE FUNCTIONAL INDEX FOR HAND OSTEOARTHRITIS (FIHOA)

G.Y. Ahn1, S.-K. Cho1, S.J. Cha2, E. Nam2, J.-E. Lee1, R.L. Dreiser3, E. Maheu5, Y.K. Sung1, 2Rheumatology, Hanyang University Hospital for Rheumatic Diseases; 3Internal medicine, Hanyang University College of Medicine; 2Biostatistical Consulting and Research Lab, School of Medicine, Hanyang University, Seoul, Korea, Republic of Ireland; 1Rheumatology, Bichat Hospital, AP-HP, 4Rheumatology, Saint-Antoine Hospital, AP-HP, Paris, France

Background: Osteoarthritis (OA) is one of the most common type of arthritis and it most frequently involves joints of the hands. Measuring functional ability of hand OA patients is important in terms of assessment of treatment response, patient management and improvement of quality of life. The functional index for hand osteoarthritis (FIHOA) is one of the most frequently utilised questionnaire to assess the physical function of hand OA patients. The FIHOA has been translated into 17 languages, however, no Korean version of FIHOA is yet available.

Objectives: To translate the FIHOA into Korean, and establish the reliability and validity of the cross-culturally adapted Korean version of FIHOA (K-FIHOA) in patients with hand OA.

Methods: The FIHOA was translated into Korean following cross-cultural adaptation guidelines. The K-FIHOA was pretested in 40 hand OA patients (defined by ACR classification criteria). The adapted K-FIHOA was then administered to 100 consecutive hand OA patients together with the modified Health Assessment Questionnaire (mHAQ) and visual analogue scale (VAS) for hand pain. The test-retest reliability of each item and total scores were assessed using Spearman’s correlation coefficient and intraclass correlation coefficient (ICC). The internal consistency reliability was evaluated as the Cronbach’s alpha. The external construct validity was assessed using correlation between K-FIHOA and mHAQ and hand pain VAS.

Results:

Values are given as mean ± standard deviation.

Abbreviations: K-FIHOA, the Korean version of functional index of hand osteoarthritis; ICC, intra-class correlation coefficient.

The mean total score of the K-FIHOA was 4.39 (Standard deviation (SD)=5.56) in the first assessment and 4.04 (SD=5.22) in the second assessment. The test-retest reliability for the total score was strong (r=0.87 and ICC=0.75). Spearman’s rho for single item correlation ranged from 0.58 to 0.85 and ICC between single items were good or excellent (0.54–0.80). Cronbach’s alpha was high (0.88) suggesting a strong internal coherence in the items of the questionnaire. We identified significant correlations between K-FIHOA and hand pain VAS (r=0.53, p<0.01), mHAQ (r=0.52, p<0.01), and mHAQ hand function score (r=0.57, p<0.01).

Discussion: The K-FIHOA is a reliable and valid instrument for evaluating functional disability in Korean hand OA patients. The ICOAP questionnaire is easy to use clinically, with the majority of patients approached willing to participate. Respondents with both OA and RA also commented on the lack of complication and ease of understanding of questions. It was responsive to changes in management, proving to be a useful tool in general practice to follow disease progression. The findings demonstrate that the ICOAP has a potentially wider clinical utility in measuring pain in patients with both OA and RA. The similarities in responses of the majority of respondents with knee OA and long-standing RA also strongly suggest that ICOAP might be likely detecting under-reported secondary OA. Future research will examine the effects of variables like pain catastrophizing on pain perception and response.

Abstract AB0967 – IS THE ICOAP A VALID TOOL FOR MEASURING PAIN AND FUNCTION IN PATIENTS WITH KNEE OA AND RA IN CLINICAL PRACTICE?

J. Obire, A. Harrison, N. Sofat. St Georges University of London, Tooting, UK

Background: Osteoarthritis (OA) is primarily managed in general practice however, care is provided on an ad hoc basis, and a structured approach to continuing care is not offered. Studies have demonstrated the high prevalence of secondary OA of the knee in patients with RA, however, about 52% of these cases are under-reported or under graded by general radiological reports. With its increasing prevalence, it is important to use valid and responsive instruments to evaluate the effectiveness of interventions and to understand the pathology’s impact on functioning and general health status.

Objectives: We hypothesised that the ICOAP can accurately measure the severity of pain in patients with OA in the clinical setting and can equally detect secondary OA in patients with pre-existing RA.

Methods: Patients with longstanding knee OA or RA from outpatient rheumatology clinics alongside GP surgeries were recruited. The ICOAP’s formatting was modified and brief abstract was added to the top of the questionnaire to aid patient comprehension. After its modification, it was tested for internal consistency, reliability and construct validity by correlating its yield with other disease activity parameters including the WOMAC and DAS. To examine the test-retest reliability patients were asked to fill out the ICOAP questionnaire again after two weeks.

Results: The study included 57 patients with OA and 45 with RA. Total ICOAP-C was 42 with patients with OA compared to 56 in patients with RA while ICOAP-I was 49 in patients with OA compared with 53 in patients with RA. Subgroup analysis of ICOAP-C and ICOAP-I identified that while intermittent pain had a greater impact on QOL in patients with OA, constant pain had a greater impact on OA patient QOL. Patients with RA for more than 10 years had more similar results to patients with OA.

Conclusions: The ICOAP questionnaire is easy to use clinically, with the majority of patients approached willing to participate. Respondents with both OA and RA also commented on the lack of complication and ease of understanding of questions. It was responsive to changes in management, proving to be a useful tool in general practice to follow disease progression. The findings demonstrate that the ICOAP has a potentially wider clinical utility in measuring pain in patients with both OA and RA. The similarities in responses of the majority of respondents with knee OA and long-standing RA also strongly suggest that ICOAP might be likely detecting under-reported secondary OA. Future research will examine the effects of variables like pain catastrophizing on pain perception and response.
EVALUATION OF OSTEOARTHRITIS OF TEMPOROMANDIBULAR JOINT BY COMPUTED TOMOGRAPHY, CLINICAL FEATURES AND CORRELATIONS

M. Salokhiddinov, G. Haydarova, TASHKENT MEDICA ACADEMY, Tashkent, Uzbekistan

Background: Osteoarthritis (OA) of the temporomandibular joint is a unilateral, degenerative disease of the jaw joint. It is characterised by breakdown of the articular cartilage, architectural changes in bone, and degeneration of the synovial tissues causing pain and/or dysfunction in functional movements of the jaw.

Objectives: To determine the prevalence and relationship between clinical signs, symptoms and computed tomography (CT) manifestations of temporomandibular joint (TMJ) osteoarthritis.

Methods: The study included 56 patients with osteoarthritis of the TMJ, including 25 unilateral and 31 bilateral lesions, a total of 87 joints with degenerative changes. Clinically, there was a significant restriction of the movement of the lower jaw and chewing efficiency and a significant increase in articular sounds and general complaints of pain.

Results: CT data of the most frequent bone changes were erosions of the joint surfaces of the condyles (70 joints, 81%), osteophytes (73 joints, 87%), then their smoothing (67 joints, 77%), hypoplasia (24 joints, 27.6%), sclerosis (6 joints, 6.8%) and subchondral cysts (4 joints, 4.8%). Smoothing of the joint elevation and pneumatisation were observed in five joints. Thirty-one patients had bilateral degeneration. In 25-one-sided degeneration. Hypermobility is found in 37 degenerative joints. Chewing efficiency was negatively correlated both with the degree of smoothing of condyles. Sclerosis and the general complaints of pain positively correlated with the smoothing of condyles.

Conclusions: Conjunctural erosion, flattening, osteophytes, revealed with CT, along with pain, noise in the joint, restriction of the jaw movement and deterioration of the chewing movement were characteristic signs of the TMJ. A correlation was found between bone changes and the severity of the clinical signs and symptoms of the TMJ. CT is a powerful diagnostic tool for the diagnosis of TMJ osteoarthritis.

CONVENTIONAL AND BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS FOR OSTEOARTHRITIS: A META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

M.S.M. Persson1,2, A. Sarmanova1,2, M. Doherty1,2, W. Zhang1,2, Academic Rheumatology, Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, UK

Background: The role of inflammation in osteoarthritis (OA) is controversial. Some perceive OA as a reparative process where modest inflammation is secondary to largely biomechanical insult.1 In contrast, others believe synovial inflammation to be a central driver of OA pain and progression.5 This has encouraged randomised controlled trials (RCTs) of conventional and biologic disease modifying anti-rheumatic drugs (DMARDs) in OA. However, it is unknown whether these treatments that are primarily used for rheumatoid arthritis are effective for OA.

Objectives: To examine the efficacy of DMARDs, including biologics, in people with symptomatic OA.

Methods: A systematic literature search was conducted (to November 2017) for placebo-controlled RCTs of DMARDs in OA. Data extraction and Cochrane’s risk of bias assessments were conducted independently by two reviewers (MP, AS). Pain relief at treatment peak time-point was combined using a random-effects meta-analysis. All DMARDs were pooled and sensitivity analysis was undertaken for high-quality trials and subgroup analyses for DMARD type, biologic target, joint site, OA subtype, and publication type.

ES, effect size; CI, confidence interval

Results: Eleven RCTs (n=1205), including six (n=757) for conventional and five (n=448) for biologic DMARDs, were included in the meta-analysis (7 full texts, 4 abstracts). Overall, conventional and biologic DMARDs were marginally superior to placebo. However, statistical superiority was not observed in high-quality studies (table 1) or subgroup analysis for conventional or biologic DMARDs separately (figure 1). Furthermore, no differences were observed between erosive versus non-erosive hand OA, hand versus knee OA, anti-IL1 versus anti-TNF biologics, or full text versus abstract-only publications (table 1).

Conclusions: No significant pain relief was observed from either conventional or biologic DMARDs compared to placebo. Combining all DMARDs gave statistical separation from placebo, but this was below the minimal clinically important difference threshold (0.5 SD) used in the UK.2 Furthermore, the analysis is based on peak time point for the intervention, so even at their most effective timepoints these treatments do very little over placebo. Lack of efficacy of DMARDs supports the perspective that inflammation is not an important driver for OA pain and differs fundamentally from that in rheumatoid arthritis.

INVESTIGATION OF THE EFFECTS OF BALANCE TRAINING ON BALANCE AND FUNCTIONAL STATUS IN PATIENTS WITH TOTAL HIP ARTHROPLASTY DUE TO OSTEARTHRITIS: A RANDOMISED CONTROLLED PILOT STUDY

N. Elblo1, B. Unver, V. Karatosun,1, Physiotherapy and rehabilitation, European of Lefke University;2 Physiotherapy and rehabilitation;3 Orthopaedics, Dokuz Eylul University, Izmir, Turkey

Background: Osteoarthritis (OA) of the hip is one of the most common disorders in musculoskeletal system. The hip osteoarthritis is painful and this causes disability of various degrees, postural and gait disorders.1 Total hip arthroplasty (THA) has been to one of the most frequent elective surgical procedures that can effectively reduce pain and improve the function in patient with hip OA.2 It was reported that patients with coxarthrosis and THA have decreased proprioception with motor control and balance disorders, compared to healthy subjects.3

The purpose of current study was to investigate the effects of balance exercises on balance and functional level with objective assessment methods until the 26th week of surgery in patients with THA.

Objectives: The purpose of our study is investigating of the effects of balance training on balance and functional status in patients with THA.

Methods: Sixteen patients with unilateral elective THA were randomised to 2 groups: conventional rehabilitation (CR, n=8) or conventional rehabilitation plus balance training (CR + BT, n=8) groups. The CR group completed typical surgery-specific joint range-of-motion and muscle strengthening exercises, while the CR + BT group completed the CR plus balance exercises during 6 weeks.

The patients were evaluated by single leg stance test, Tetrax balance system, Harris hip scoring, lower extremity function scale, 5 times sit to stand test and 50-foot timed walk test preoperatively and 8, 14, and 26 weeks after THA.

Results: While there was significant improvement, in terms of on the right extremity eyes closed single leg stance test in the CR group (p<0.05), there was no significant difference in terms of other assessment parameters between CR and CR + BT groups (p>0.05). There were significant improvement after THA surgery in both groups (p<0.05).

Conclusions: The results of our study indicate that there were similar improvements in the balance and functional parameters in the CR and CR + BT groups. There was no additional benefit of the balance exercises in balance in the 14 and 26 weeks after THP. Significant differences could be found between groups by continuing balance training with more patients for 1–2 years following THA.

THE EFFECTIVENESS OF PHYSICAL ACTIVITY INTERVENTIONS FOR PEOPLE WITH OSTEARTHRITIS AND OBESITY: A META-ANALYSIS
S. Mckevitt, C. Jinks, E.L. Healey, J.G. Quicke. Primary Care and Health Sciences, Keele University, Keele, UK

Background: Osteoarthritis (OA) is one of the diseases with the highest prevalence in developed countries. Clinical guidelines recommend physical activity (PA) for people with OA irrespective of comorbidity. Research investigating the effectiveness of PA interventions in OA and comorbidity is needed.

Objectives: To synthesise existing evidence investigating the effectiveness of PA interventions in adults with OA and obesity.

Methods: A systematic review with meta-analysis was conducted (PROSPERO CRD42017055582). Six electronic databases: MEDLINE, EMBASE, AMED, CINAHL, SportDiscus and CENTRAL were searched for studies from their inception to 29.03.17. Inclusion criteria were: randomised controlled trials (RCTs) comparing the effectiveness of any PA intervention to non-PA control group; including adults aged 45 years old and over with clinical or radiographic OA at any site; at least one of the comorbidities of interest (COPD, depression, diabetes, hypertension, obesity, T2DM); and measuring pain, physical function, quality of life, global health post intervention and adverse events. Included study risk of bias (ROB) was assessed using the Cochrane risk of bias tool. Two reviewers screened titles, abstracts and full text articles, checked data extraction, and carried out ROB assessment. Random-effects model meta-analysis pooled outcomes from sufficiently homogeneous studies to calculate effect sizes (Standardised Mean Difference (SMD) with 95% confidence interval (CI)). Meta-analysis findings of the OA and obesity subgroup are reported.

Results: The literature search retrieved 8171 citations of which 14 studies (n=4422 participants) were included in the full review, with 9 (n=1382 participants) analysed for the OA and obesity subgroup. PA interventions included: aquatic, aerobic, strengthening and functional activity; of 1–18 months in duration. Four studies of OA and obesity measuring either Western Ontario Osteoarthritis Index (WOMAC) pain, WOMAC function or Six Minute Walking Test (6MWT) and were included in these three meta-analyses. Best estimates showed PA to improve WOMAC pain (n=3 studies; n=547 participants; SMD = -0.09 (95% CI) -0.65, 0.47), improve WOMAC function (n=3 studies, n=415 participants; SMD = -0.35 (95% CI) -0.89, 0.16) and the 6MWT (n=4 studies, n=573 participants; SMD = -0.93 (95% CI) -0.49, 2.35). However, results were not statistically significant. There was substantial between-trial outcome heterogeneity (I²=89.4% (p=0.000); 77.5% (p=0.012); 97.8% (p=0.000); respectively); results should be interpreted with caution.

ROB domain judgements were generally either low or unclear. A small minority of judgements were at high risk of bias.

Conclusions: Best estimates suggest small beneficial effects of physical activity on WOMAC pain, WOMAC function and the 6MWT. Mixed effectiveness among individual RCTs was likely due to heterogeneous intervention types, intensity and duration.

Background: Isometric exercises play important role in treatment of Knee OA and are easy to do by the growing elderly population. Electromyographic (EMG) biofeedback devices are designed to enhance patient’s participation in these exercises by giving them feedback signals of visual or auditory nature, so that it can affect the subject’s voluntary activity.

Objectives: The aim of this survey was to study the effect of EMG biofeedback on pain, function, thickness of the vastus medialis oblique muscle and maximal electrical activity of this muscle in isometric contraction, in patients with knee OA.

Methods: In this single-blinded clinical trial, 46 patients aged between 45 to 70, referring to Shohadaye Tajrish and Shahid Modarres hospitals with diagnosis of knee OA, were recruited. Patients were randomly assigned to two groups of case (23 patients), with EMG biofeedback associated exercise, and control (23 patients), with sham biofeedback associated exercise. The exercise program includes 12 sessions of 15 min isometric quadriceps exercise. Data were gathered via VAS score, the Persian version of WOMAC and Lequesne questionnaires, ultrasonography of VMO muscle and surface electromyography of this muscleat baseline and at the end of 2 months period of this study. Variables compared before and after exercises program in each group and between the two groups.

Results: At the end of the study, there were no significant differences between the two groups regarding VAS score, VMO muscle thickness, WOMAC and Lequesne questionnaires scores including overall scores and scores in each subcategories. Although all assessed parameters, except for VMO muscle thickness, were found to be improved significantly in each group, the changes were not more significant in case group except for the VAS score. VMO muscle thickness didn’t change significantly after 12 sessions of exercise in either of the groups.

Conclusions: Isometric exercises accompanied by EMGBF and the same exercises with sham biofeedback for 2 months both lead to significant improvements in pain, and function of patients with knee OA. Real EMG biofeedback was not superior to sham biofeedback. The only parameter found to be improved to a greater extent in the EMGBF group was the subjective measure of VAS score.

Disclosure of Interest: None declared

Conclusions: BTA showed promising effects in improving knee pain, ROM and functional status. Therefore this single session method could be considered as an alternative to other intra articular injections in knee OA patients who did not respond to primary conservative treatments. Further data is necessary to assess long-term effects and cost-benefit analysis of BTA against other similar choices.

AB0976  Efficacy of intra-articular injection of PRP-driven growth factor (PRP without platelet and WBC) versus hyaluronic acid on pain and function of patients with knee osteoarthritis: a single-blinded randomised clinical trial

S.A. Raeissadat, A. Gharooee Ahangar, S.M. Rayegani. Physical Medicine and Rehabilitation, Shahid Beheshti University of Medical Science, Tehran, Iran, Islamic Republic of Ireland

Background: Knee osteoarthritis is the most common joint disease. Objectives: We aimed to compare the efficacy and safety of intra-articular injection of PRP-driven growth factor versus hyaluronic acid (HA) on pain and function of patients with knee osteoarthritis.

Methods: In this single-blinded randomised clinical trial, patients with symptomatic osteoarthritis of knee were assigned to receive 2 intra-articular injections of PRP-driven growth factor in 3 weeks or 3 weekly injections of HA. Our primary outcome was the mean change from baseline until 2 and 6 months post intervention in scores of visual analogue scale, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), and Lequesne index. The secondary outcome was the mean change from baseline until 2 and 6 months post intervention in scores of pain function stiffness and total WOMAC index.

Results: A total of 69 patients entered final analysis. The mean age of patients was 58.2 ± 7.41 years and 81.2% were women. Total WOMAC index decreased from 42.9 ± 13.51 to 26.8 ± 13.45 and 24.4 ± 16.54 at 2 and 6 months in the PRGF group (within subjects p < 0.0001), and from 38.8 ± 12.62 to 27.8 ± 11.01 and 27.4 ± 11.38 at 2 and 6 months in the HA group (within subjects p < 0.0001), respectively (between subjects p = 0.631). There was no significant difference between PRP-driven growth factor and HA groups in patients’ satisfaction and minor complications of injection, whereas patients in HA group reported significantly lower injection-induced pain.

AB0977  Correlation of the level of C-reactive protein and bone mineral density in patients with gonarthritis

T. Tarasenko. Polyclinic, Regional Clinical Hospital named after I.I. Mechnikov, Dnipro, Ukraine

Background: The results of recent studies also indicate a link between loss of bone mineral density (BMD) and progressive loss of articular cartilage in patients with knee joint osteoarthritis (OA). The presence of correlation of changes in bone tissue and degradation of cartilage in OA is due to the possible presence of common pathogenesis chains, including activation of proinflammatory mediators.

Objectives: Determine the relationship between the level of C-reactive protein (CRP) and the level of BMD in patients with gonarthritis.

Methods: We conducted a cross sectional study including confirmed radiographic knee osteoarthritis according to Kellgren-Lawrence scale, with normal and reduced BMD according to the classification of Report of a WHO Study Group. The structural and functional status of bone tissue in patients was...
evaluated using the method of ultrasonic densitometry and DEXA at the beginning of treatment and 12 months. The CRP level was determined at the beginning of the observation and after 1, 3, 6, 9 and 12 months. The two groups were compared on the level of BMD, radiological grade, the level of CRP and WOMAC function after adjusting for significant covariates. Multiple regression analysis was used to identify the independent effects to each specific component for level of CRP on knee osteoarthritis parameters.

**Results:** One hundred forty women were included. The mean age was 55.28 ±0.89[177–179] years. Overweight had 86.42% of patients. The body mass index averaged 30.18±0.43[37–39] kg/m2. According to Kellgren-Lawrence classification, 55% of patients had II and 45% of patients – III radiological stage of gonarthritis. 55.7% of knee OA patients had reduced bone mineral density. Multiple regression analysis showed, after adjusting for significant covariates, that the CRP level was significantly higher (p<0.0001) in patients with reduced BMD compared to normal (6.32 ±1.67 mg/L and 4.74±0.75 mg/L respectively), an average of 33.3%, which was associated with a more severe course of the disease.

**References:**

[1] It is recommended to study the severity of the progression and progression of OA to study the level of CRP and mineral density of bone tissue.

D ECREASED P AIN AND I MPROVED DYNAMIC K NEE I NSTABILITY M EDIATE THE B ENEFICIAL E FFECT OF W ARING A SOFT K NEE B RACE ON A CTIVITY L IMITATIONS I N P E RSONS W ITH K NEE OSTEARTHRITIS

T. Cudekio, M. van der Eschj, J. van den Noortj, J. Rijnhartj, M. van den Leedenh, L.D. Roorda, W. Lemsj,1, G. Harlaur,1, G. Waddingtonj, J. Dekkerj.1 VU University Medical Center;2 De Boelelaan 1117, Afdeling revalidatiegeneeskunde;3 Amsterdam Rehabilitation Research Center Reade, Amsterdam, Netherlands;4 University of Canberra, Canberra, Australia

**Background:** We have previously shown that wearing a soft knee brace reduced activity limitations in persons with knee osteoarthritis (OA).1 Several underlying mechanisms have been proposed via which a soft knee brace reduces activity limitations in persons with knee OA.2,3 However, to our knowledge, no study has identified mechanisms explaining this effect.

**Objectives:** The aim of the study was to identify mechanisms explaining the beneficial effect of wearing a soft knee brace on activity limitations in persons with knee OA.

**Methods:** This was an exploratory analysis of data from 44 participants with knee OA from Amsterdam Osteoarthritis cohort, who enrolled in a single-session within-subject cross-over design study, comparing a soft brace with no soft brace, and comparing a non-tight soft brace with a tight soft brace (GENUTEX A2, Genutec NV, Human L). A mediation analysis was performed and the mediation effect was calculated based on the product of coefficients approach. Confidence intervals were calculated with a bootstrap procedure. The outcome measures were activity limitations assessed with the 10-metre walk test and the Get up and Go test. The studied mediators were the changes in: knee joint proprioception, pain, pressure pain threshold (PPT) and objective dynamic knee instability. Knee joint proprioception was assessed by the active movement extent discrimination assessment; pain with the Numeric Rating Scale (NRS); PPT with a hand-held pressure algometer, and dynamic knee instability with the Perturbation Response i.e. a measure reflecting deviation in the mean knee varus-valgus angle after a controlled mechanical perturbation on the treadmill, in respect to level walking.

**Results:** Both a decrease in pain during walking and a decrease in dynamic knee instability mediated the association between wearing a soft knee brace and reduction in time to complete both 10 m walk test and the GUG test (p<0.05). Changes in proprioception and PPT did not mediate these associations (p>0.05). Magnitudes of the mediation effects were similar for a non-tight and a tight soft knee brace.

**Conclusions:** The decrease in activity limitations in persons with knee OA who wear a soft knee brace might be explained by a decrease in self-reported pain and a reduction in dynamic knee instability.

ULTRASOUND-MEASURED RADIAL DISPLACEMENT OF THE MEDIAL MENISCUS AS AN INDIRECT SIGN OF MRI-DETECTED CARTILAGE DAMAGE IN PATIENTS WITH MEDIAL TIBIOFEMORAL OSTEOARTHRITIS

T. A. Georgiev, M. Ivanova, R. Rashkov, R. Stoilov.1,2 Rheumatology clinic, University Hospital “St. Ivan Rilski”,1,2 Medical Faculty, University Medicine – Sofia;2 Radiology department, University Hospital “St. Ivan Rilski”, Sofia, Bulgaria

**Background:** Exudation of the medial meniscus is a consequence of the complex interactions among joint structures and altered tissue mechanics involved in the osteoarthritis (OA) process.1 Potential contributing factors are cartilage loss, meniscal tears, obesity and knee malalignment – features strongly associated with knee OA. Ultrasound (US) measurement of medial meniscal radial displacement (MRD) is an easy to implement procedure that may serve as a starting point for assessment of the cartilage loss in patients with knee osteoarthritis.

**Objectives:** The aim of the study was to investigate the correlation between ultrasound-measured MRD and magnetic resonance imaging (MRI)-detected cartilage damage, as a referent method, in patients with medial femorotibial knee OA.

**Methods:** 60 osteoarthritic knees of 48 patients (83% female) aged 40 to 80 years, meeting the ACR criteria for knee osteoarthritis, were included in the study. Patients with severe malalignment (varus or valgus deformity ≥20 degrees) were excluded. Radiographic stage was assessed according to the Kellgren-Lawrence (KL) grading system, as only KL I–III knees were included. MRD was measured in millimetres using diagnostic US with patients in the supine (non-weight-bearing) position. Magnetic resonance images were acquired by using 1.5 T MRI and were evaluated by a trained radiologist using Whole-Organ Magnetic Resonance Imaging Score (WORMS) for cartilage abnormalities of the medial femorotibial joint (MFTJ) and medial meniscal tears.

**Results:** There was a significant difference in values of MRD among studied radiographic groups (p<0.001). The mean (SD) levels of MRD were 2.70 (1.43) mm, 3.97 (1.25) mm and 6.03 (1.30) mm for KLI, KLII, and KLIII, respectively. All knees that were KLI/KLII (n=41) had MRD higher than 1.8 mm (range 1.8–8.7 mm), MRD correlated significantly and positively with WORMS grades for cartilage abnormalities of MFTJ (r=0.756), WORMS grades for medial meniscal tears (r=0.315). Correlation between KL and MRI-detected cartilage damage remained significant after adjustment for age, BMI and medial meniscal tears score.

**Conclusions:** Joint space narrowing (KL ≥2) on radiography is associated with higher level of meniscal extrusion. Higher values of measured MRD by ultrasound may be indicative of greater cartilage damage of MFTJ.

FACTORS ASSOCIATED WITH LOSS OF CARTILAGE IN KNEE OSTEOARTHRITIS

V. Vardanyan1, V. Mukuchyan2, A. Kirakosyan2. Internal Medicine, Yerevan State Medical University, 2Rheumatology, Erebouni Medical Center, Yerevan, Armenia

Background: Osteoarthritis (OA) is one of the leading causes of pain and disability worldwide. The structural changes in knee OA are characterized mainly by the progressive loss of cartilage, which is associated with additional structural changes such as subchondral bone lesions and alterations in the menisci. Unfortunately, these changes cannot be effectively treated conservatively. Further determination of modifiable risk factors of cartilage loss is extremely important for improvement of OA management.

Objectives: The main objective of the study was the determination of factors associated with loss of cartilage in knee OA.

Methods: 294 patients (277 female, 17 male, mean age 55, 09±56 years) with newly diagnosed mild to moderate primary knee osteoarthritis were investigated. X-ray and ultrasound examinations of knee joints were performed. The thickness of cartilage and synovial layer, as well as presence of synovitis, tendinitis, osteophytes, Baker’s cysts, tear of meniscus were determined. For determination of factors associated with loss of cartilage both univariate and multivariate analyses were performed. The data is introduced as odds ratios (OR) with 95% confidence interval (CI). The results were considered significant when p<0.05.

Results: Expressed thinning of cartilage (≤2 mm) was observed in 216 (73.5%) patients, abnormal thickening of synovial layer (≥3 mm) – in 76 (25.9%), synovitis – in 88 (29.9%), tendinitis – in 38 (12.9%), osteophytes – in 273 (92.9%), Baker’s cysts – in 93 (31.6%), tears of meniscus – in 93 (31.6%) patients.

Univariate analysis had shown that loss of cartilage (≤2 mm) was significantly (p<0.05) associated with age >55 (OR=95\% CI=2.0;1.3–3.4), p<0.05), thickening of synovial layer (OR=95\% CI=2.9;1.5–6.2, p<0.01), synovitis (OR=95\% CI=2.6;1.3–5.0, p<0.01) and osteophytes (OR=95\% CI=14.8;4.8–45.5, p<0.01). Following factors were then stepwise included in the model of multivariate logistic regression: age >55, thickening of synovial layer and osteophytosis. According to results of analysis, age >55 had lost its significance, was evaluated as confounding factor (OR=95\% CI=1.2;0.7–2.2, p=0.4) and excluded from the model. Finally, loss of cartilage (thickness ≤2 mm) was found to be significantly and independently associated with abnormal thickening of synovial layer (OR=95\% CI=2.8;1.3–6.0, p<0.05) and osteoarthritis (OR=95\% CI=12.8;3.9–41.6, p<0.01).

Conclusions: A positive association of cartilage loss with abnormal thickening of synovial layer (with further development of synovitis) and presence of osteophytes was determined. While cartilage loss and meniscal damage are not yet clearly treatable, treatments targeting inflammation within the joint are available. Thereby, forehanded treatment of secondary inflammatory conditions of joint, as well as strategies, directed toward dissection of osteophytes, can decrease cartilage loss and structural damage in OA.

PRIORITY FOR OSTEOARTHRITIS RESEARCH SHOULD BE DONE IN CHINA

Y. Mei1, S. Guan1, Y. Shi2, D.J. Hunter2, Z. Zhang1. The First Affiliated Hospital of Harbin Medical University, Harbin, China

Background: Osteoarthritis (OA) exacts a tremendous toll on patients and society due to its impact on function, quality of life, and health care costs. As OA morbidity and mortality increases, the search for effective and safe treatment options has accelerated. Unfortunately, the OA etiology and pathogenesis are unclear. The prevalence of osteoarthritis of subtypes of joints is different, whereas the most common osteoarthritis occurs in knees. In China, the prevalence of osteoarthritis is about 15%, the prevalence of the patients over 40 years old is 10%-17%, and 50% over the age of 60, while over 75 years old was as high as 80%. Few data exist regarding the prevalence of OA in plateau in China.

Objectives: To investigate the prevalence of osteoarthritis (OA) in Jiuhu village, which is located about 3.5 kilometres high of Gonggyai County of Tibet and the associated factors in order to provide the guidance for the prevention and treatment of OA.

Methods: The participants in this analysis were all the resident people aged 50 years and above in Jiuhu village, Gonggyai County of Tibet. All subjects were invited to completed an questionnaire, physical examination and radiographic examination. The questionnaire included sex, age, body mass index(BMI) and dietary habit.

Results: A total of 136 participants aged 50–86 years were enrolled, including 47 males with mean age of 62.0±9.11 years, and 89 females with mean age of 61.3±9.52 years. Altogether 102 knee OA can be diagnosed, the total prevalence of knee OA was 75.00%. Knee OA occurred in 78.72% of male and 73.03% of female. The prevalence of knee OA combined with hand OA was 19.12%, and 21.28% for male and 17.98% for female. The prevalence of knee OA combined with hand OA increased with age in the female, no such trend was observed in male or in only knee OA patients. No significant difference was found about sex, BMI, drinking between the OA patients and the controls.

Conclusions: The prevalence of osteoarthritis in Jiuhu village, plateau of Tibet was significantly high. The prevalence in male is higher than that in female. The prevalence of knee OA combined with hand OA increased with age in the female.

Background: Intra-articular injections of hyaluronan represent one of the well-accepted standard of care for treating symptomatic knee osteoarthritis (OA). Until now, not much is known about the structural-modifying effect of this treatment justifying this pilot study.

Objectives: This exploratory non-controlled study aims to study effects of HYMOVIS on imaging, biological and clinical variables.

Methods: Forty six patients with symptomatic knee OA (mean age 61.4 years [min.35-max.80; 67.4% female; Kellgren and Lawrence grade II and nd III (63% ratio Coll2 changes in AGG, COMP, PIINP, MMP-3, MPO and IL-6 serum biomarkers, the after Hymovis treatment versus baseline. Secondary endpoints included levels of –statistically significant decrease in comparison to group I or group II #statistically significant decrease in comparison to group I

Conclusions: Results of the present study revealed that: there are harmful effects of smoking on the bone mineral density and it may be occurred by direct (increased blood and urinary levels of both cadmium and lead) or indirect effects (effects of both renal and liver functions) of cadmium and lead.

CADMIUM TOXICITY AS A PROBABLE CAUSE OF SMOKING INDUCED BONE LOSS

A.A. Elbeialy1,2, H.A. Eldosouky1, 1 Rheumatology, Al-Azhar Faculty of Medicine, Cairo, Egypt; 2 Rheumatology, St Thomas Hospital, London, UK

Background: Cigarette smoking supposed to be a risk factor for osteoporosis. There is an inverse relationship between smoking and both bone mass and fracture risk. Tobacco smoking is the most important single source of cadmium exposure in the general population. The absorption of cadmium from the lungs is much more effective than that from the gut.

Objectives: This study was designed to evaluate the effect of cigarette smoking on bone mineral density, due to cadmium toxicity.

Methods: This study was carried on 100 persons, selected from AL-Azhar university hospital and divided into three groups: group I: included 40 persons with active smokers; group II: included 40 persons with passive smokers and group III included 20 nonsmokers. All persons were subjected to full history taking, thorough clinical examination, routine lab tests, serum and urinary cadmium and lead, and bone mineral density was measured by DEXA.

Results: Serum and urinary cadmium and lead were statistically significantly higher in group I in comparison to groups II or III and in group II in comparison to group III. Also, there was statistically significant decrease of BMD in group I in comparison to either group II or group III and in group II in comparison to group III.

There was an inverse statistically significant correlation between serum and urinary cadmium and bone mineral density.

PERSISTENCE AND ADVERSE EVENTS IN PATIENTS TREATED WITH DENOSUMAB

Background: Denosumab (DNS) is a human monoclonal antibody directed against RANKL, which blocks the maturation of the osteoclast, inhibiting bone resorption. The binding of DNS to RANKL suppresses bone resorption mediated by osteoclasts and decreases bone turnover.

Disclosure of Interest: None declared
Objective: To evaluate the survival rate of DNS, adverse events and reasons for the DNS discontinuation. Methods: This was a prospective observational study in patients with OP who initiated treatment with DNS, between January 2013 and December 2017. Patients included were followed up in the Rheumatology Nurse Clinic every six months. Demographic data, disease features, concomitant disease and treatments, adverse events and reasons for discontinuation were collected. Results: We included 220 patients (80.5% women) with a mean age (range, SD) of 67.19 (30–89, 12.2) years. In average (range, SD), patients received 3.85 (1–11, 2.2) doses of DNS, with a mean duration of treatment (range, SD) of 23.03 (6–66, 13.3) months. 191 (86.8%) patients received also treatment with calcium and vitamin D supplements. Before the start of the treatment with DNS, 123 (55.9%) patients had received another specific treatment for OP with mean previous treatment duration of 51.6 months. Previous fragility fractures were reported in 150 (68.1%) patients, of whom 91 (41.3%) patients had two or more fractures before starting treatment with DNS. Of all included the patients, 108 (49%) patients had an inflammatory autoimmune disease (IAD) diagnosed. In addition, 100 (45.4%) patients had concomitant biological and/or synthetic treatment and 77 (35%) patients received concomitant treatment with corticosteroids. During the treatment with DNS, 30 (13.6%) patients had new fractures, 5 (2.3%) patients had 2 fractures. Eleven fractures were vertebral, 3 of femur, one of radius and 21 other locations. There were no differences between patients with or without glucocorticoid treatment (0.234). The most frequent adverse events (AE) were infections in 88 (40%) patients, muscle pain in 15 (0.6%) patients, fatigue in 7 (0.3%) patients, itching, heat and fever in 2 (0.9%) patients and osteonecrosis of the jaw in 2 (0.9%) patients. The 2 patients with osteonecrosis of the jaw had previous treatment with bisphosphonates for more than 24 months. At 60 months, 185 (84.1%) patients continued with DNS. In 37 (1.6%) patients, DNS was discontinued; in 4 patients DNS was restarted. The reasons for suspension were hypercalcemia 1 (0.04%), hypercalcinemia 1 (0.04%), local hypersensitivity reactions 4 (0.18%), normalisation of BMD 5 (0.2%), dental problems 11 (0.4%) and others 17 (0.7%). The mean (SD, 95% CI) of DNS survival was 51.2 (21.9; 47.3–55.1) months. There are no differences in the survival rates of DNS between patients with and without concomitant biologic therapy (p=0.995). Conclusions: The majority of patients who started treatment with DNS continue the treatment with good tolerance. The most frequent adverse effects were infections but they have not led to suspension of treatment. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2018-eular.5531

MANAGEMENT OF OSTEOPOROSIS AFTER MAJOR FRACTURE IN A COHORT OF WOMEN AGED OVER 50 IN A REAL LIFE SETTING
A. Nuti1, S. Bastide2,3, F. Fiaisler1, C. Gaujoux-Viala1,2
1Rheumatology, Nîmes University Hospital, NIMES; 2EA4215, Montpellier University, MONTPELLIER; 3Biostatics, Epidemiology, Public Health and Innovation in Methodology (BESIPIM), Nîmes University Hospital, NIMES, France
Background: Osteoporosis is the most common metabolic bone disease. Fractures constitute a major health concern because prior fractures are associated with an increased risk of subsequent fracture. Moreover, osteoporotic fractures have been associated with increased mortality risk.1 Hence secondary fracture prevention is recommended. Anti-osteoporotic drugs are available, but in the last decade an alarming decrease of anti-osteoporotic therapy use was observed.2 Objectives: The aim of this study was to analyse the management of osteoporosis after major fracture (hip, vertebral and humerus fractures) in women aged over 50 in a real life setting. Methods: We conducted an observational study on all women over 50 years of age who experienced a major fracture at Nîmes University Hospital in 2015 identified by informatic codes. Only fragility fractures were included. Data collected prospectively in the computerised medical files were extracted: prescription of a postmenopausal osteoporosis therapy; therapy initiation; prescription and completion of generalised bone mineral density testing; and prescription and completion of blood sample tests to look for secondary osteoporosis. We also recorded the department in which the hospitalizations occurred and the fracture localization. Results: Of 375 women over 50 with a registered fracture in 2015, 264 were included. The exclusion criteria were women with traumatic fracture or minor osteoporotic fracture. The median age was 84 years old. The most common major fractures were hip (52.3%), humerus (20.8%) and spine (18.9%). Forty-five (17.0%) patients had experienced a fracture prior to the 2015 fracture. Only 12 patients (4.5%: IC95%[2.4–7.8]) had an anti-osteoporotic drug prescription at the end of the hospitalisation and only 45 women (17%) had anti-osteoporotic drug prescription planned later. The median period until anticipated prescription was 9 days and the median period until prescription in practice was 18 days. Assessment of bone mineral density was planned later in only 23 patients (8.7%: IC95%[5.6–12.8]). Blood sample tests were realised in 49 women (16.6%: IC95%[14.1–23.8]). In surgical department, anti-osteoporotic drug prescription was planned in only 3 women (1.5%) compared with 40 women (56.3%) in medical departments. Conclusions: A large majority of women with osteoporotic major fracture are not receiving appropriate therapy and recommended management in 2015 in Nîmes University Hospital. The rate is dependent on the department in which patients are hospitalised. The results of our study highlight the urgent need for optimisation of osteoporotic fracture management, especially in the surgical department.

FREQUENCY OF UTILISATION OF THE CENTRAL DXA BONE DENSITOMETRY IN PATIENTS WITH MULTIPLE SCLEROSIS
A.N. Klimo, Specialized hospital of rehabilitation "Banja Kanjiža", Kanjiža, Serbia
Background: Multiple sclerosis patients can have a higher risk from occurrence of osteoporosis. Reduced bone mass density can be related to a cumulative effect of different factors, most common ones being physical inactivity, reduced intake of vitamin D and use of medications such as glucocorticoids.
Objectives: The aim of this research was to explore the level of awareness in patients and physicians on the significance of the utilisation of DXA bone densitometry in patients with multiple sclerosis.
Methods: The observational analytical cross-section study included 366 multiple sclerosis patients on stationary treatment at the Special rehabilitation hospital "Banja Kanjiža" in Kanjiža in the period between 2013 and 2017. The following parameters were observed in patients: sex, age, duration and form of basic disease, the level on the Kurtzke Expanded Disability Status Scale, utilisation of glucocorticoids, occurrence of pathological fractures and intake of vitamin D, i.e. of medication for the treatment of osteoporosis in order to determine their impact on the frequency of the low bone mineral density (BMD). Statistical data processing and analysis was conducted in the SPSS ver 20.0 program by IBM corporation.
Results: In the period in question, an average of 128 multiple sclerosis patients were treated, out of those 62.3% (n=228) with relapsing-remitting type of disease, and n=366 first time patients. Within the given period, 36% more women than men were rehabilitated (f=249 vs. m=117). During the five-year long period of observation of said patients, only 8.5% (n=31) of patients with different levels of bone metabolic disorders established underwent central DXA bone densitometry. Pathological fracture on a small trauma was suffered in 6.8% (n=25) patients. Of the abovementioned parameters, only the female sex (X2=84.492; p<0.001) and analysis was conducted in the SPSS ver 20.0 program by IBM corporation.

Background: Patients affected by Rheumatoid Arthritis (RA) show an increased risk of bone loss, as a result of multiple-system disorders including toxic drug, low vitamin D levels, use of glucocorticoids and physical inactivity. Trabecular Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) images, that provides an indirect measurement (Score) of bone axial microarchitecture and allows to get information about bone quality.1,2

Objectives: The aim of this investigation was to evaluate by TBS the bone quality in RA patients (high risk population) receiving vitamin D supplementation from at least 3 months (1000IU/die).

Methods: 108 female patients (mean age 61±8 years) affected by RA and 60 age- matched controls (CNT) (mean age 64±11 years) were analysed in winter time. Bone Mineral Density (BMD, g/cm²) of the lumbar spine (L1-L4) was analysed using a DXA scan (GE, Lunar Prodigy), Lumbar spine TBS (TBS Insight Medimaps) was derived for each spine DXA examination. All patients were evaluated for serum 25 hydroxvitamin D (25(OH)D) serum concentrations.

Results: RA patients showed lower 25(OH)D concentrations (18.4±1.3 ng/ml) than CNT (26.2±0.9 ng/ml; p<0.04) possibly due to low dosage and short treatment. Seventy-eight RA patients (80% of study population) presented a bone loss that was significant when compared to the control group (p<0.001). In particular, BMD was found significantly lower in RA patients compared with matched control group (respectively, Lumbar spine: 0.882±0.194 g/cm² vs 1.240±0.932 g/cm²; Femoral neck: 0.685±0.141 g/cm² vs 0.845±0.164 g/cm²; Ward: 0.846±0.221 g/cm² vs 0.657±0.106 g/cm²; Trochanter: 0.598±0.231 g/cm² vs 0.725±0.143 g/cm²; Total hip: 0.764±0.244 g/cm² vs 1.033±0.161 g/cm², all p<0.01). Likewise, lumbar spine TBS score was found significantly lower in RA patients when compared to CNT (0.604±0.148 vs 1.061±0.126, both p<0.001).

Conclusions: This study shows in RA patients a reduction of TBS values that seem placed side by side with reduced BMD values and in presence of serum 25 (OH)D insufficiency. A more careful analysis of the clinical status/treatments should be let to better identify RA patients at higher risk of bone loss.

Osteoporosis and Fractures in Patients with Cirrhosis. Can FRAX Be Useful for Screening?

E. Casado1, M. Arévalo1, J. Próftö2, A. Lira3, L. Del Río1, O. Valero1, M. Larrosa1, J. Sánchez-Delgado2, J. Gracados2,1, Rheumatology, University Hospital Parc Taulí, IDPT, UAB, Sabadell, Sabadell, 2Gastroenterology and Hepatology, Consorcio hospitalar de Terrassa, Terrassa, 3Gastroenterology and Hepatology, University Hospital Parc Taulí, IDPT, UAB, Sabadell, Sabadell, 4Radiology, CETIR Centre Médic, Barcelona, 5Statistics, Universitat Autònoma Barcelona (UAB), Bellaterra, Spain

Background: Osteoporotic fractures are a serious complication in patients with cirrhosis. In addition to the high morbidity and mortality of the patients who suffer them, fragility fractures represent a high cost for Healthcare systems.

However, there are very few studies that evaluate the prevalence of osteoporosis and fractures in patients with liver cirrhosis different than primary biliary cirrhosis (non-PBC cirrhosis). There are also no clinical guidelines with recommendations for osteoporosis screening in these patients.

Objectives: To assess the prevalence of osteoporosis and fragility fractures in patients with non-PBC cirrhosis in our environment, and the associated risk factors.

To analyse if the FRAX tool can be useful in the diagnostic screening of these patients.

Methods: From November 2015 to September 2017, outpatients older than 40 years diagnosed with non-PBC cirrhosis (any Child stage) were randomly included.

Demographic, clinical and analytical data (calcium, phosphorus, 25-hydroxyvitamin D and PTH) were collected from all patients. A bone densitometry, GE, Lunar Prodigy (DXA) and vertebral fracture assessment (VFA) were also performed, for the diagnosis of osteoporosis (T-score ≤−2.5), and vertebral fracture. The 10 year absolute fracture risk was calculated using FRAX (https://www.sheffield.ac.uk/FRAX/tool.aspx?country=4).

A descriptive statistic of the main variables was carried out, with univariate and multivariate analysis to assess which predictive factors could be related to the presence of osteoporosis and/or fragility fractures.

Results: Ninety-two patients were included (71% male and 29% female). Age 63 ±11 years. The etiology of cirrhosis was: alcohol (52%), hepatitis C virus (27%) and alcohol +hepatitis C virus (9%). Stage: Child A (80.4%), B (17.4%) and C (2.2%). Mean 25-hydroxyvitamin D was 18.5±18.8 ng/ml and PTH 51.8±23.0 pg/ml.

16 patients (17%) had osteoporosis by DXA, 54 patients (59%) osteopenia and 22 (24%) had a normal bone mineral density (BMD). 8 patients (9%) had suffered some fragility fracture (vertebral fracture in 6 cases). The 10 year absolute risk for major fracture (vertebra, humerus, femur or radius) by FRAX without BMD was 5.7±4.5; and with BMD 4.7±4.9. Age and female sex were associated with the presence of osteoporosis, and a BMI higher than 30 was found to be a protective factor. A BMI in the range of osteoporosis was the only factor associated with fracture.

FRAX for major fracture without BMD higher than 6.6% in this population had a high sensitivity (69%) and specificity (85%) for the diagnosis of osteoporosis, which implies a negative predictive value of 93%. Using this FRAX cut-off for indicating DXA in cirrhotic patients could expect a saving of 76% of DXA scans.

Conclusions: The prevalence of osteoporosis and fractures in patients with non-PBC cirrhosis, even in mild stages, is higher than in the healthy population, being more frequent in women and older patients.

The FRAX tool can be useful in the selection of patients with cirrhosis to be assessed by a bone densitometry.

Pain Relief Management of Acute Osteoporotic Vertebral Fracture in a Real Life Study

F. Bertoldo1, G. Gandolini2, A. Venturini2, C. Cisari3, R. Lovato3, M. Longhi4, S. Farina4, E. Bertoldo1, R. Nuli5, on behalf of Servatius GISMO study group.

1Internal Medicine, University of Verona, Verona; 2rheumatology, IRCCS Don Gnocchi, Milan; 3Rhebilitation Unit, University of Padua, Padua; 4Orthopedic Unit, University of PO, Novara; 5Internal Medicine, Villa Berica Hospital, Vicenza; 6Orthopedic Unit, Galeazzi Institute, Milan; 7Rhebilitation Unit, Crema Hospital, Crema; 8Rheumatology Unit, University of Verona, Verona; 9Internal Medicine, University of Siena, Siena, Italy

Background: Among all osteoporotic fractures the painful vertebral fractures (PVF) are the minority and their management is challenging for the clinician because the evidences about the best approach are conflicting and of low quality. Moreover there are no guidelines or consensus of experts. A real life picture of the management of the PVF is lacking in the literature.

Objectives: The primary end point of the study is to describe the pharmacological and/or non-pharmacological management of PVF through the record of use of individual classes, associations and sequences of drugs or procedures. Secondary end point is the outcome of treatment in term of pain, disabilities and quality of life.

Methods: We present the interim analysis results of a multicentric cross-sectional observational study. 400 interviews will be collected consecutively about pain, disabilty, pharmacological, spinal orthoses and orthopaedic surgery after the diagnosis of PVF in postmenopausal women treated by orthopaedics, endocrinologists, geriatricians, physiatrists, neurosurgeons and E.R. pycians. Pain and disability were quantified by NRS scale and by QUALEFFO-41. Data collected from the first 100 patients have been analysed.

Results: One hundred postmenopausal women aged 73.1±7.49 y.o. (age of menopause 48.6±3.9 years, L1-L4 T-score −2.75±0.92. Total hip T-score −2.35±0.98) with a new or first PVF were recorded. About 49% of them had a previous vertebral fracture and 22% a previous non-vertebral fragility fracture, 27% was not on osteoporosis treatment. The interviews were collected 135±114 days from diagnosis of PV,174±141 days from onset of pain. 92.3%±12% of subjects were treated for pain relief for a mean time of 98±12 days. Only 1.6% of cohort fractures has been noted as well, probably due to predisposing factors related to HIV infection, apart from the traditional risk factors.

Objectives: To assess the relationship between mean values of bone biomarkers P1NP and b-CTX and incidence of vertebral fractures (VF) in a HIV infected population; and compare such values with those of a Spanish healthy population of reference.

Methods: We performed a cross-sectional study with HIV infected patients followed up in the Infectious Diseases Department of our centre from 2014 to 2016. P1NP and b-CTX values were determined and lumbar and thoracic spine radiographs made to assess presence of VF (Gentam grading scale). Other clinical and demographic data were collected retrospectively. P1NP and b-CTX values in the presence (VF group) and absence of fractures (non-FV group) were compared. Mean values were also compared with the Camargo cohort, comprised of 1080 healthy postmenopausal Spanish women, used as reference. Statistical analysis were made with STATA. All patients signed and informed consent, previously approved by the Hospital’s Ethics Committee.

Results: A total of 144 patients were included, 38 were women with a mean age of 56.4 years old64–77 and 106 men with mean age of 56.5 years old64–86 of the patients had at least one VF. No statistically significant differences were found between P1NP mean levels in the FV and the non FV groups, with values of 45.30 ng/ml (±17.59 ng/ml) and 49.48 ng/ml (±32.92 ng/ml) respectively, (p=0.52). Mean levels of b-CTX were 0.38 ng/ml (±0.18 ng/ml) in the VF group and 0.43 ng/ml (±0.22 ng/ml) in the non-FV group, again without significant differences (p=0.35).

Mean general b-CTX values in our population were 0.41 ng/ml (±0.21), 0.46 ng/ml (±0.20) in women and 0.39 ng/ml (±0.20) in men. Higher levels were found in HIV infected women than in the Camargo cohort (0.38±0.19 ng/ml), with statistical significance (p=0.03). Mean general P1NP values were 48.34 ng/ml (±29.47), 58.63 ng/ml (±32.9) in women and 44.95 ng/ml (±27.56) in men, with no statistically significant differences found when HIV infected women were compared with those of the Camargo cohort, (47.7±19.9 ng/ml) (p=0.06), although a trend towards higher levels in HIV infected women was observed.

Conclusions: In the present study no correlation between P1NP and b-CTX levels in HIV infected patients and incidence of vertebral fracture was found. P1NP and b-CTX mean values in HIV infected women in our study are higher than those of healthy postmenopausal Spanish women, which means a higher bone turnover in this population. More studies are needed to clarify the extent and clinical impact of this finding.

Disclosure of Interest: None declared

underwent to percutaneous vertebroplasty while 84.6%±17.1% had spinal orthoses. Pharmacological treatment for pain was prescribed to 98.2±7.1% of subjects: acetaminophen (42%), tapentadol (24%), opioids (24%), NSAID (6%) and codeine with acetaminophen (4%). In 95% of patients with spinal orthoses drugs for pain were assumed. In about 40% of cases NSAID was switched to acetaminophen, in 18% opioid and tapentadol switched to NSAID or acetaminophen. Only a few titration of opioids/tapentadol were reported. Not adequate pain relief (NRS scale 6.2±3.1; QUALEFFO-41 pain score 70±14.2) and impairment quality of life (mean total QUALEFFO-41 score 65.1±20.1) were reported.

Objectives: A definition of optimal management of acute vertebral fracture is missing due to preliminary data seem to confirm an inadequate pain relief in PVF. The emerging critical issues across all categories of physicians are the lag of diagnosis, the inappropriate use of acetaminophen, the missing titration of opioids or tapentadol. A definition of optimal management of acute vertebral fracture is missing due to conflicting and scarce evidences in this field predisposing to chronic pain and disability.

AB0994 IMPACT ON THE ADHERENCE AND PERSISTENCE OF DENOSUMAB VS WEEKLY BISPHOSPHONATE IN HEALTH-RELATED QUALITY OF LIFE IN POSTMENOPAUSAL OSTEOPOROSIS

G. Carlino1, R. Cinzia1, R. Maggio2, 1Rheumatology, ASL LE, Casarano; 2Internal Medicine, “Vera Delli Ponti” Hospital, Scorrano, Italy

Background: Long term adherence and persistence in patients undergoing treatment for postmenopausal osteoporosis remains poor despite the proven efficacy of the therapy.

Objectives: In this study, we evaluated whether greater adherence and persistence in treatment can lead to an improvement in the quality of life.

Methods: A cohort of 268 patients, all women, in postmenopausal osteoporosis divided into two groups was evaluated: “DEN Group” (DEN) in treatment with denosumab (n=131) and “BIS Group” (BIS) in treatment with bisphosphonates (n=137). Table 1 shows demographic and clinical data. Patients were followed for 3 years with baseline, 6 month, 18 month, and 36 month evaluation. The evaluation criteria were the persistence in therapy and the self-related treatment compliance, as well as the quality of life assessed with the 41-item Quality of Life questionnaire for osteoporosis (QUALEFFO-41) performed at baseline, at 18 and at 36 months.

Results: Table 2 shows the percentage of patients who abandoned treatment at different times with a statistical significance towards both 18 and 36 months. In the BIS the main reason for abandonment were the adverse events (gastrointestinal, dental interventions, etc.), in the DEN the abandonment was due to drop-out. In BIS, the most frequent reason for non-compliance with therapy was oversight, and most patients who continued treatment always used the drugs regularly on the recommended days and dosages. In the period of time considered the majority of patients both BIS and DEN said they were satisfied with the treatment and wanted to continue it. The QUALEFFO scores (Fig 1) of patients from the baseline visit were significantly improved in the 36 month visit (BIS 79.6±25.4 vs 65.4±14.6; DEN 80.2±18.5 vs 55.8±16.4) (p<0.001); the difference was not significant between BIS and DEN groups at both baseline visit and 36 month visit, but in the DEN group there was significance between baseline and 36 month visit.

Conclusions: In conclusion, the observation, although numerically limited, notes that the use of denosumab in patients with postmenopausal osteoporosis leads to a greater persistence in treatment and a statistically significant adherence to therapy, which allows to obtain the maximum therapeutic effect of the therapy, also determining in 36 months of treatment an improvement in the quality of life, which is not achieved in subjects treated with bisphosphonates.

AB0995 VERTEBRAL FRACTURES CASCADE: POTENTIAL ETIOLOGIES AND RISK FACTORS

H. Che1, V. Breuil2, B. Cortet3, J. Pacquet4, L. Chausis5, F. Debias6, R.M. Javier7, N. Mehsen Cetre1, S. Loiseau Peres2, T. Thomas3, G. Roux2, K. Broit8, 1CHU Lapeyronie, Montpellier; 2CHU Nice, Nice; 3CHU Lille, Lille; 4CH du Vitré, Vitré; 5CHU Poitiers, Poitiers; 6CHU Hautepiere, Strasbourg; 7CHU Bordeaux, Bordeaux; 8CHR Orleans, Orleans; 9CH Saint Etiennel, Saint Etiennel; 10CHU Cochin, Paris, France

Background: Vertebral fracture (VF) is the most common osteoporotic fracture, and a strong risk factor of subsequent vertebral fracture. Prospective studies have shown that a recent VF increases an imminent risk of a subsequent one, and attention has been paid recently to a possible cascade phenomenon i.e. the occurrence of multiples VFs in less than one year.

Objectives: This cascade could have severe consequences, and we prompted a study to identify potential causes of osteoporosis and risk factors.

Methods: Vertebral fractures cascade (VFC) observations were collected retrospectively between January 2016 and April 2017. VFC was defined as the occurrence of at least 3 vertebral fractures within one year. Patients with other etiologies than osteoporosis (i.e. malignant or traumatic VFs) were excluded. The cause of osteoporosis associated with VFC was the one retained by the physician at the time of diagnosis.

Results: Ninety-five observations of VFC (80% of women, mean age of 71 years) were collected in 10 centres (9 tertiary centres and 1 outpatient centre). The median number of incident VFs over 1 year was 4.2-11 Forty-five patients (45.9%) had a previous major fracture before the VFC and 65 (70.7%) had densitometric osteoporosis (T-Score ≤-2.5 SD either at lumbar or femoral site). Eighteen (19%) patients currently received oral glucocorticoids treatment at the time of VFC, with a mean daily dose of 20 mg. Thirty-three (35.1%) patients received systemic glucocorticoids in the past. The main comorbidities were history of cancer (n=19) and chronic inflammatory diseases (n=21) including asthma (n=7), chronic obstructive pulmonary disease (n=7) and rheumatoid arthritis (n=7).

A secondary osteoporosis associated with the cascade was diagnosed in 54 patients (54.5%) with the following causes: glucocorticoid-induced osteoporosis (n=22, 23.7%), benign hemopathies (malignant or non-malignant) (n=20, 21.1%), pregnancy and lactation-associated osteoporosis (n=2, 2.1%), primary hyperparathyroidism (n=2, 2.1%) and hypercorticism (n=1, 1.1%). In addition, 11 cases (11.3%) were reported following a vertebroplasty procedure. Primary either postmenopausal or idiopathic osteoporosis was diagnosed in 48 patients (51.6%). A total of 29 (29.6%) patients previously received an anti-osteoporotic treatment. In six patients (6.3%), VFC occurred early (in the year) following discontinuation of an anti-osteoporotic treatment: 5 after denosumab and one 12 months after an infliximab injection.

Conclusions: The results of this retrospective study show that almost half of VFC occurred in patients with secondary osteoporosis. While they suggest that a careful management has to be given to these patients in order to prevent VFC in these circumstances, prospective studies are needed to further explore the determinants of such a severe complication of osteoporosis.

AB0996 BONE MINERAL DENSITY AT DIFFERENT SITES AS A PREDICTOR OF RIB FRACTURES: A CASE-CONTROL STUDY

H.L. Wu, M. Bukhari. Rheumatology, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, UK

Background: Rib fractures commonly occur as a result of direct trauma, though pathological causes have also been identified. Literature on the specific risk factors of rib fractures is scarce. There was an American prospective cohort study
which highlighted the relationship between risk factors of osteoporosis and rib fractures in older men aged 65 or above. It was observed that the incidence of rib fractures was 3.5/1000 years. Only 3% of rib fractures occurred with absence of trauma. Bone mineral density (BMD) is an important measure for predicting various bone fractures. However, prediction of rib fractures using BMD measurement in different body sites is not reported.

**Objectives:** To determine if reduction in femoral neck and lumbar spine BMD are predictive of rib fractures.

**Methods:** Patients referred from primary care to a DEXA scanner in the north west of England between January 2006 and December 2016 were used in this study. Patients with a history of rib fractures at first scan were matched with controls who did not have any indication for scanning. Cases and controls were matched for age and gender. Differences in BMD at L1-L4 spine and the femoral neck were analysed using two-sample t test. Logistic regression models were fitted to analyse the association between lumbar spine and femoral neck BMD and rib fracture occurrence. The fit of each model was compared using receiver operating characteristic (ROC) curves.

**Results:** A total of 1554 patients were included in the study (777 cases of rib fractures and 777 controls). Mean age for both cases and controls were 62.5 years (SD 12.0). 605 patients (77.9%) were female in both the case cohort and the controls. The mean T score in the lumbar spine was 1.00 in cases versus 1.10 in controls (diff 0.100 95% CI 0.048, 0.142 p<0.001). The mean T score in the femoral neck is 0.812 in cases versus 0.935 in controls (diff 0.123 95% CI 0.108, 0.137 p<0.001). The odds of lumbar spine BMD and femoral neck BMD were 0.111 (95% CI 0.0640, 0.194, p<0.001) and 0.00209 (95% CI 0.000903, 0.00485, p<0.001) respectively. The areas under ROC curve (AUC) for lumbar spine BMD and femoral neck BMD were 0.623 and 0.733.

**Conclusions:** This study demonstrated that reduction in BMD at the lumbar spine and femoral neck positively correlated to the risk of rib fractures. Reduction in femoral neck BMD is a stronger predictor of the two. Prediction of rib fractures could be affected by other factors influencing lumbar spine and femoral neck BMD. Further work in different demographic groups should be done for comparison and analysis.

**AB0997** CLINICAL CHARACTERISTICS OF NON-RESPONDER TO DENOSUMAB TREATMENT FOR POSTMENOPAUSAL OSTEOPOROSIS IN JAPANESE WOMAN

**Yoshi** Orthopaedics, YOSHI HOSPITAL, Shimanto City, Japan

**Background:** Denosumab (d-mab), an anti-receptor activator of nuclear factor kappa-B ligand (RANKL) monoclonal antibody, is now widely used in postmenopausal osteoporosis (OP) treatment. It can attain reliable increase of bone mineral density (BMD) despite any OP drugs previously used, and that can be predicted in a long period. However, sometimes we observe BMP decrease. Factor that suppresses BMD gain is still unclear.

**Objectives:** This study investigates non-responder to d-mab, and attempted to evaluate factors that concerns non-responder in clinical practice retrospectively.

**Methods:** 212 postmenopausal OP patients have been treated with d-mab continuously for more than two years under vitamin D supplement and calcium since June 2013. These patients were enrolled, and their clinical background (CBs), such as age at start of d-mab, past history of bone fragility fracture, alcohol habit, current smoking being treated for rheumatoid arthritis (RA), glucocorticoid steroid thrown, OP drug naive, length of administration (LA), concurrence of lifestyle disease (LSD) such as diabetes mellitus, hypertension, and chronic obstructive lung disease (N.Com), were investigated (table 1a). BMD of lumbar spine (LS), femoral neck (FN), greater trochanter (GT), and whole femur (WF) at the start and every six months thereafter were measured. Tartrate-resistant Acid Phosphatase 5b (TRACP5b) and total dose of type-one pro-collagen –N-pro-peptide (P1NP) at the same time of BMD measurement, and reduction ratio (RR) of them compared to the first shot were calculated. Patients were divided into two groups whether BMD increased. BMD in each part at final measurement was compared statistically with paired t-test. CBs were statistically evaluated between the two BMD groups (Res and n-Res; Responder and non-Responder) with Mann-Whitney U-test (MWT), and then correlation between the BMD groups and factors of CB that had demonstrated significantly different, and TRACP5b and P1NP was also evaluated statistically with Binary Logistic Analysis (BLR). Statistical significance was set less than 5%.

**Results:** For all patients, BMD in LS, WF, and GT demonstrated significant increase at final measurement than at start (p<0.001), while FN demonstrated no significant increase. However, n-Res counted 30, 89, 44, and 44 for LS, FN, WF, and GT, respectively. LA demonstrated negative significant correlation for being n-Res in all part, while LSD, N.Com, TRACP5b at start and, RR of TRACP5b at second shot and last shot, demonstrated significant positive correlation in LS with MWT. However, with BLR, only RR of TRACP5b at second shot demonstrated significant negative correlation with n-Res in LS (OR:0.0702, 95% CI:0.0051–0.9655) with 0.39 cut-off index (COI), while no other factors but LA demonstrated significant negative correlation with n-Res in WF (OR:0.9669, 95% CI:0.9433–0.9911) and GT (OR:0.9632, 95% CI:0.9391–0.9878) with 26 and 24 months COI, respectively (table 1b).

**Table 1a Patient’s background. Age at Start, Length Administered, Number of Chronic Comorbidities, and Bone Mineral Density, show average value and standard deviation. The other parameters show numbers.%YAM:% of young adult mean value. LS: lumbar spine, FN: femoral neck, WF: whole femur, GT: greater trochanter, SERM: selective oestrogen receptor modulator. Table 1b Parameters that demonstrated significant difference between responder and non-responder to denosumab, and their p-values, and results of these parameters with binary logistic regression analysis. LS: lumbar spine, FN: femoral neck, WF: whole femur, GT: greater trochanter, LSD: concurrence of lifestyle disease, LA: length of administration, N.Com: number of concurrent comorbidities, TRACP5b at start; tartrate-resistant acid phosphatase 5b (TRACP5b) at start of administration, TRACP5b@1stP: reduction ratio of TRACP5b of second shot compared to the first, TRACP5b@1stP: reduction ratio to TRACP5b of last shot compared to the first. Drug Naive: initial drug as osteoporosis treatment, PINP: total dose of type-one pro-collagen –N-pro-peptide.

**Conclusions:** These results suggest that non-responder to d-mab exists. Length of administration works for BMD to increase in femur, and concurrence of LSD, and N.Com are suggested to be risk factors in LS. Less reduction ratio of TRACP5b of second shot is referred for prediction of non-responder. However, there is no parameter that predicts non-responder before administration.

**AB0998** OSTEOPOROSIS PREVALENCE IN POST-MENOPAUSAL PATIENTS TREATED WITH AROMATASE INHIBITORS USING BONE MINERAL DENSITY VALUES FROM A SPANISH POPULATION

**J. Loarca-Martos** University of Zaragoza, Department of Clinical Biochemistry, Medical University Hospital of Zaragoza, Zaragoza, Spain

**Background:** The majority of cases of breast cancer (BC) are hormone receptor positive and are sensitive to endocrine therapy. For postmenopausal women, adjuvant hormonal therapy with an aromatase inhibitor (AI) is the standard of care, and is associated with greater prevalence of osteoporosis (OP)1. Definition of osteoporosis is made depending on the T-Score value, which is calculated according to the bone mass peak obtained from a reference population; in our country, BMD reference values in clinical practice are obtained from the National Health and Nutrition Examination Survey cohort (NHANES III) for femoral neck (FN) and those proportionated by the commercial brand Hologic for lumbar spine (LS), which may not be representative of our population and could be distorting the assessment of OP in our patients.

OPPORTUNISTIC SCREENING FOR OSTEOPOROSIS USING THORACO-ABDOMINO-PELVIC COMPUTED TOMOGRAPHY FOR ASSESSMENT OF VERTEBRAL DENSITY IN RHEUMATOID ARTHRITIS PATIENTS

J. Perrier-Cornet, I. CHARY-VALCKENAERE, D. LOEUILLE, A. Y. OMOROU.
1 Rheumatology; 2INSERM CIC-1433 Clinical Epidemiology, CHU NANCY, NANCY, France

Background: Screening for osteoporosis is crucial in rheumatoid arthritis (RA) patients. Computed tomography (CT) attenuation assessment has been proved to be of interest in general population for detection of osteoporosis.

Objectives: To assess the value of thoraco-abdomino-pelvic CT-derived bone mineral density (BMD) in L1, compared with dual energy X-ray absorptiometry (DXA) for osteoporosis screening in rheumatoid arthritis patients.

Methods: Consecutive RA patients who underwent a CT-scan and a DXA within a two-year period are retrospectively included. CT sagittal images are evaluated from T4 to L5 for vertebral fractures according to Genant classification. CT attenuation values (in Hounsfield units [HU]) of trabecular bone in L1 are measured on axial images and compared to DXA results.

Results: One hundred and five patients (mean age 61.1 years ±9.5; 78.1% women) were included. Twenty-eight patients (26.7%) have DXA-defined osteoporosis and 32 (30%) have osteoporotic fractures (vertebral and/or non-vertebral). According to CT assessment, mean (SD) vertebral L1 attenuation is 142.2 HU ±18.5. The diagnostic performance for vertebral CT-attenuation measurement was good, with an AUC of 0.67 for predicting osteoporotic fractures and of 0.68 for predicting vertebral fractures. Among 31 patients with osteoporotic fractures, 23 (74%) patients are categorised as osteoporotic with L1 CT-attenuation of 135 HU or less, whereas only 13 patients (42%) with DXA.

Conclusions: This technique offers a combined opportunistic screening for osteoporosis by assessing both vertebral fractures and bone density on routine CT-scans. This seems of particular interest in RA patients who are at high risk for osteoporosis.

ASSOCIATION OF SERUM URIC ACID LEVEL WITH BONE MINERAL DENSITY AND OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

1 Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan; 2Microbiology and Immunology, Pusan National University School of Medicine, Yangsan; 3Internal Medicine, Kosin University College of Medicine, Busan, Korea, Republic of Ireland

Background: Previous studies have reported that higher serum uric acid (SUA) levels are associated with higher bone mineral density (BMD) in men and postmenopausal women, and lower risk of fragility fracture in men. However, whether this association is also present in patients with rheumatoid arthritis (RA) has not yet been investigated.

Objectives: To examine the association of SUA levels with BMD and osteoporosis in postmenopausal women with RA.

Methods: We retrospectively evaluated 447 postmenopausal female RA patients (mean age 61.1 years) who underwent measurement of L1–4, femoral neck, and total hip BMD using dual energy X-ray absorptiometry, in addition to SUA levels at a university rheumatology centre in South Korea between 2004 and 2017. Osteoporosis was defined as a T-score of ≤−2.5 according to the World Health Organisation classification.

Results: The median (interquartile range) SUV level was 4 (3.3–4.8) mg/dL. The mean (±SD) L1–4, femoral neck, and total hip BMD were 0.93±0.16 g/cm2, 0.75±0.12 g/cm2, and 0.81±0.12 g/cm2, respectively, and the frequencies of osteoporosis in the spine, hip, and either site were 25.6%, 15.9%, and 32.5%, respectively. SUA levels were positively correlated with L1–4 (r=0.102, p=0.032), femoral neck (r=0.123, p=0.011), and total hip BMD values (r=0.146, p=0.002) and body mass index (r=0.231, p=0.001), and negatively correlated with glomerular filtration rate (r=−0.363, p=0.001) in Spearman correlation analysis. In multivariable linear regression models adjusted for confounding factors, SUA levels showed a significant positive association with femoral neck BMD (β=0.0099, p=0.015) and total hip BMD (β=0.0086, p=0.159) as shown in table 1. In addition, multivariable logistic analysis revealed that the third (OR=0.44, p=0.038) and fourth SUA quartiles (OR=0.37, p=0.021) were associated with lower risk of hip osteoporosis, as compared with the first SUA quartile. However, this association was not observed in lumbar spine osteoporosis.

Disclosure of Interest: None declared
AB1001 MANAGEMENT OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS IN RHUmatoid ARTHRITIS: THE EXAMPLE OF THE ‘RIC NORD DE FRANCE’ COHORT

J. Cortel, G. Baudens2, R. M. Filipo, B. Cortel, on behalf of RIC-Nord de France. 1Rheumatology, CHRU Lille, Lille; 2Rheumatology, Valenciennes, Valenciennes, France

Background: Glucocorticoid-induced osteoporosis (GIOP) is the most common cause of secondary osteoporosis. Patients followed for Rheumatoid Arthritis (RA) are particularly exposed to OP and have a greater risk of fracture, which must be prevented. The newest French guidelines for GIOP management were published in 2014 and it is not known yet how they are applied in real life.

Objectives: The objective of our study was to investigate the treatment of glucocorticoid-induced osteoporosis in the Rhumatismes Informatiachines – Nord de France (formerly known as RIC-NPC) network in 2016 for patients with rheumatoid arthritis (RA).

Methods: In this observational study, the patients studied were followed in the RIC network for RA from 2004 until June 2016, had at least one bone mineral density (BMD) assessment and glucocorticoid therapy during follow-up. Demographic characteristics of patients, BMD results, fractures and treatments implemented were collected from network data completed during consultations by practitioners.

Results: 647 patients were enrolled, including 511 women (79%). The average age of patients was 65.5 years (SD=12) with a mean DAS28 of 3.91 (SD=1.44), mean dose of steroid of 7.6 mg (SD=6.6) and a mean duration of treatment of 49 months (SD=53.7). The average T-score at the first BMD assessment was −0.99 at the spine and −1.03 at the total hip. 298 patients received an anti-osteoporotic treatment (46%). Treated patients were older (p<0.0001), with lower weight (p=0.001) and had a lower T-score at both the spine and the total hip (p<0.0001 for both sites). They most often underwent a prior fracture (p<0.0001), and an initial T-score less than −1.5 SD (p<0.0001).

Conclusions: Our study has the advantage of reflecting the management of GIOP in a ‘real life’ cohort. Almost half of our patients followed for RA who received corticosteroids had received treatment. According to French guidelines the number of patients requiring an anti-osteoporotic treatment should be higher.

AB1002 DIFFERENCES IN BONE METABOLISM BETWEEN INTERMITTENT AND CONTINUOUS TREATMENT WITH LHRR AGONISTS IN PROSTATE CANCER PATIENTS

K.R. Arevalo1,2, J. Ivorra1, C. Vera1, E. Grau1, I. Chalmets1, L. Gonzalez1, R. Negueruela1, C. Alcazar1, I. Canovas1, C. Feced1, J.J. Frigo1, R. Gonzalez1, E. Labrador1, I. Martinez1, C. Najera1, J.E. Olle1, F.M. Ortiz1, E. Vicens1, M. Dela Rubia1, D. Hervas1, J.A. Roman1. 1Rheumatology Department, 2Urology Department, HUP La Fe, Biostatistical Unit, IS La Fe, Valencia, Spain

Background: Prostate cancer is a hormone dependent neoplasia, therefore androgenic inhibition by LHRR agonists is the mainstay of treatment. There are different treatment regimen options: continuous or intermittent in order to decrease side effects. As for the bone effects, therapy with LHRR agonists increases bone resorption and decreases bone mineral density (BMD) all together increasing the risk of fracture. The influence of the different treatment regimen in bone metabolism has not been studied enough.

Objectives: To evaluate the effect of the LHRR agonists therapy different regimens on bone metabolism in prostate cancer patients, and whether antiresorptive treatment influences the evolution of BMD according to LHRR agonists treatment schemes. Patients without antiresorptive treatment under an intermittent LHRR agonists regimen might have a better evolution in BMD values compared to those under a continuous scheme. In patients without antiresorptive treatment the evolution of BMD values was related to beta-CTX levels during follow up.

Methods: One hundred-five prostate cancer patients with bone metastasis with 12 months follow up were selected. The mean age at cancer diagnosis was 65.92 (8.44) years old, with a mean Gleason score of 7.4. 81% of patients had LHRR agonists active treatment, 81% of them were under continuous treatment scheme. 39% of patients initiated antiresorptive therapy, 24% with intermittent LHRR agonists and 76% with continuous LHRR agonists. At the basal evaluation 12% of patients had osteoporosis and the 32% had osteopenia. 43% of patients displayed vIdt values under 20 ng/mL. Antiresorptive treatment influenced lumbar spine, femoral neck and hip BMD values (p<0.001). In patients with antiresorptive treatment, LHRR agonists intermittent scheme did not have an independent effect in any locations of BMD. In patients without antiresorptive treatment elevated beta-CTX levels were related to a decrease of BMD values (p<0.017).

No fractures were reported during the follow up period.

Conclusions: In our patients there is a high prevalence of vId deficiency. Antiresorptive therapy had a positive effect in the BMD on both LHRR agonists treatment schemes. Patients without antiresorptive treatment under an intermittent LHRR agonists regimen display show significant differences in the evolution of BMD values compared to continuous scheme. In patients without antiresorptive treatment the evolution of BMD values compared to continuous scheme. In patients without antiresorptive treatment the evolution of BMD values was related to beta-CTX levels during follow up.

AB1003 USEFULNESS OF DOPPLER ULTRASOUND EXAMINATIONS FOR DETECTING DEEP VENOUS THROMBOSIS DURING THE PERIOPERATIVE PERIOD IN PATIENTS WITH OSTEOARTICULAR FRACTURES OF THE PROXIMAL FEMUR

K. Nakaseko, N. Mayumi. Department of Orthopaedic Surgery and Rheumatology, KUWANA CITY MEDICAL CENTER, Ksukana Me, Japan

Background: Deep venous thrombosis (DVT) can lead to a venous thromboembolism and increase the risk of a pulmonary thromboembolism (PE). PE is one of the most common causes of death in hospitalised surgical patients. Although there have been some prospective studies regarding the prevalence of DVT on Doppler ultrasound examinations of the lower extremities, there have not been any prospective studies in which three consecutive Doppler ultrasound examinations were performed to detect DVT during the perioperative period. The purpose of the present study was to prospectively evaluate the occurrence of DVT in patients with osteoarticular fractures of the proximal femur, based on the results of examinations involving three consecutive ultrasound scans. In addition, the usefulness of the d-dimer level as a predictor of DVT was investigated.

Objectives: This study was a single-centre prospective study. One hundred-five patients (18 males and 87 females) between the ages of 46 and 97 years with osteoarticular fractures of the proximal femur were enrolled. All patients were asymptomatic in terms of their clinical DVT findings.

Methods: Three Doppler ultrasound examinations of the lower extremities were conducted in each case: on admission, one day before surgery, and one week after surgery. The period from admission to surgery ranged from 2 to 8 days (mean: 5.4 days). The d-dimer level was measured at one week after surgery and its relationship with the presence/absence of DVT was evaluated by calculating sensitivity, specificity, positive predictive, and negative predictive values.

Results: DVT was detected in 20 patients (2 patients on admission, 9 patients one day before surgery, and 9 patients one week after surgery). The overall prevalence of DVT in the perioperative period was 19.0% (20/105). As for the characteristics of the patients that did and did not develop DVT, there were no significant differences between the two groups. When the d-dimer cut-off level was set at 4.3 µg/ml, the sensitivity and negative predictive value reached 100%, while the specificity was 16.5%, and the positive predictive value was 22.0%. A receiver operating characteristic (ROC) curve was drawn, and the optimal d-dimer cut-off level was examined. The ROC curve was closest to the upper left corner when the d-dimer cut-off level was 12.2 µg/mL. At that point, the sensitivity, specificity, positive predictive value, and negative predictive value were 55.0%, 69.4%, 28.9%, and 86.8%, respectively.
Conclusions: In this prospective study, DVT was detected in 2 patients on admission, 9 patients one day before surgery, and 9 patients one week after surgery. As DVT can occur at any moment, performing repeated Doppler ultrasound examinations in the perioperative period is useful for quickly detecting DVT, which can cause PE. As for the d-dimer level, its sensitivity and negative predictive value reached 100% at a cut-off level of 4.3 μg/ml. Therefore, d-dimer assays could be a useful screening tool for DVT and might be a suitable substitute for Doppler ultrasound examinations.

OSTEOPOROSIS SCREENING IN A TERTIARY RHEUMATOID ARTHRITIS CLINIC. WHO’S SCREENING NOW?

L. Ku1, T. Kovitwanichkanont1,2, D. Wang3, N. Wapla2, S. Raghunath1,3, S. Pignataro1, S. Morton1, M. Leech3, T. Badajoz, D. Wang, S. Morton, M. Leech, S. Pignataro, S. Wapla, S. Raghunath, S. Wapla, S. Pignataro, S. Morton, M. Leech

Background: Osteoporosis is a complication of rheumatoid arthritis (RA) due to inflammatory disease and treatment with glucocorticoids. Screening and management of osteoporosis (OP) is shared amongst General Practitioners (GP) together with subspecialists including rheumatologists.

Objectives: To assess the adequacy of osteoporosis screening in a tertiary RA clinic in Melbourne, and to determine where most screening is occurring.

Methods: A cross-sectional study of patients at a tertiary RA clinic was undertaken. Osteoporosis screening, therapy and related factors were evaluated. This was compared to best practice screening ACR/GIOP guidelines.

Results: 116 RA patients, 66% female (median age 58 years) were included. OP screening occurred in 61.2% of patients with 40.5% and 20.7% performed by their rheumatologist and by the GPs respectively. The remainder 38.8% of patients recalled no recent screening.

36.2% of patients were taking prednisolone, while 74% reported prior exposure. 58.6% of patients had prednisolone for over 3 months. Calcium or vitamin D supplementation was noted in 62% of the population. 21.6% reported a history of minimal trauma fracture and alarmingly only 10% reported currently taking anti-resorptive therapy.

47% of patients had a DEXA scan performed within the last 3 years. Of the 53% that did not have a recent DEXA scan, three quarters had indications for osteoporosis screening based on the 2010 ACR/GIOP guidelines. 35 patients had indications based on age, 11 patients based on glucocorticoid exposure and 1 patient based on history of minimal trauma fracture.

RESEARCH BETWEEN AUTOIMMUNITY AND OSTEOPOROSIS IN RHEUMATOID ARTHRITIS

M.C. Carnisco Cubero1, S.M. Rojas Herrera2, J. Malave Calzada2, P. Pérez David2, I. Braña Abascal3, E. Chamizo Carmona3, 1Rheumatology, CHU de Badajoz, Badajoz; 2Rheumatology, Hospital de Mérida, Mérida, Spain

Background: Osteoporosis (OP) is more prevalent in patients with rheumatoid arthritis (RA) than in the general population. Positive anti-citrullinated peptide antibody (ACPA) has been related with juxta-articular OP, but their relationship with systemic OP in RA is controversial.

Objectives: To determine if RA autoantibodies (FR and ACPA) are associated with bone mineral density (BMD) in a cohort of patients with established RA diagnosed following the criteria.

Methods: Observational study. We analysed the relationship between RF and/or ACPA with the DXA BMD values of the femoral neck (FN) and lumbar spine (LS) (GE LUNAR Prodigy). We performed the analysis using logistic regression, bi and multivariate models, and correlation models. The control variables were sex, body mass, age, duration of RA, prednisone and vitamin D.

Results: We included 294 patients with RA who had all the tests, with a mean age of 63.4 (±10.9) years and duration of RA of 9.8 (±7.8) years. There were 229 (77.9%) women, 229 (77.9%) positive-RF, 196 (66.7%) positive-ACPA, 109 (37.1%) deficient in 25-OH cholecalciferol (<20 ng/ml) and 59 (20.1) smoker patients. They received corticosteroids at low doses 207 (70.4%) and suffered some bone fracture 42 (14.3%) patients. In the BMD, 98 (33.3%) reached T-score < -1, of who 86 (27.6%) reached a T-score < -2.5 in LS and/or in FN.

Disclosure of Interest: None declared
Lumbar OP was associated with the female sex (OR=3.6). The FN T-score (and, to a lesser extent, lumbar T-score), showed a correlation with age (r=−0.515, p<0.01). No differences were found in the mean values of BMD, T-score, and Z-score of FN and LS between positive or negative patients for FR or ACAP (t-student), neither between their possible combinations (one-way ANOVA). Association between positivity of RF, ACAP, or their combinations and T-score < −1 (osteopenia) or T-score < −2.5 (OP) in LS or FN were not found. A negative weak correlation was found between the RF and lumbar BMD values (r=−0.121, p=0.04) and a positive weak correlation between ACAP and FN (0.136 with BMD, 0.131 with T-score and 0.018 with Z-score; p<0.05 for all).

Conclusions: OP was very common in our RA population, especially in women and elderly. Any association was demonstrated between OP and the presence/ titer of autoantibodies (RF and ACAP) and low dose of corticosteroids treatment.

Disclosure of Interest: None declared

Abstract AB1007 – Figure 1

Conclusions: Linear correlation between levels of 25OH-D3 and PTH could not be established in our study, not even using levels classified as vitamin D deficiency. 25OH-D3 levels tended to increase from winter to summer whereas PTH levels decreased inversely during these seasons, without any linear correlation.

Disclosure of Interest: None declared

AB1008
COMPARISON OF BONE MINERAL DENSITY BETWEEN RHEUMATOID ARTHRITIS PATIENTS AND HEALTHY INDIVIDUALS OVER SEVEN YEARS FROM THE TOMORROW STUDY

M. Tada1, K. Inou2, Y. Sugio3, T. Okano2, Y. Yamada2, K. Mandai2, K. Mamoto2, T. Koke3, N. Nakamura3, 1Orthopaedic Surgery, Osaka City General Hospital; 2Orthopaedic Surgery, 3Center of Senile Degenerative Disorders, Osaka City University Graduate School of Medicine, Osaka, Japan

Background: Despite advances in treatment, rheumatoid arthritis (RA) remains a key cause of secondary osteoporosis and is also a risk factor for fragility fracture. We have previously reported that bone mineral density (BMD) was lower in patients with RA than in healthy individuals (HI) and examined changes in BMD over 3 years.

Objectives: To observe BMD changes over 7 years and identify factors that affect BMD changes in patients with RA.

Methods: We analysed data from the TOMORROW study (UMIN000003876), a prospective cohort for patients with RA and age- and sex-matched HI. BMD was measured at three parts (whole body, lower limb, lumbar spine) using dual-energy X-ray absorptiometry (DXA). We compared the percentage change in BMD (%BMD) at the three parts in RA and HI from 2010 to 2017. Factors affecting %BMD in RA were analysed.
Results: Participants comprised 172 HI and 119 RA, after excluding those who dropped out (HI, n=21; RA, n=19) or underwent implant surgery (HI, n=12; RA, n=60). Height and weight reduced significantly over 7 years (p<0.001) in both groups (table 1). The%BMDs of RA were -2.6% (whole body), -3.6% (lower limb), and 1.8% (lumbar spine), compared to -2.0%, -2.7%, and 0.6%, respectively, for HI. No significant differences in BMD for the whole body or lower limb were seen during 7 years, while BMD of the lumbar spine was significantly increased in both groups (p<0.0001). No significant differences between groups were identified. In patients with RA, DAS28ESR improved significantly over 7 years (p=0.008; table 1) and%-

Conclusions: BMD of the whole body and lower limb tended to decrease slightly over 7 years in both groups. However, BMD of the lumbar spine increased significantly. Continued osteoporosis treatment is important for increasing BMD at the lumbar spine in patients with RA.

CONCORDANCE BETWEEN VERTEBRAL FRACTURE ASSESSMENT AND CONVENTIONAL RADIOGRAPHY IN DETECTION OF VERTEBRAL FRACTURE

Background: Vertebral fractures (VFs) are considered as severe fractures, but often asymptomatic. The VFA (Vertebral Fracture Assessment) performed at the same time as the bone mineral density (BMD) measure, allows the detection of these fractures. Nevertheless, standard radiography remains the reference technique in the diagnosis of VFs.

Objectives: Our objective is to compare the contribution of VFA and the standard thoraco-lumbar spine X-ray in the diagnosis of FVs in patients at risk.

Methods: This is a cross sectional study, including women referred in rheumatology department for measurement of bone mineral density (BMD). During the same examination, a vertebrographic assessment (VFA) and an X-ray of the dorsal and lumbar spine were done. The interpretation of the two methods was to diagnose asymptomatic vertebral fractures (VFs) which are defined according to Genant’s semi-quantitative classification.

Results: The mean age of our patients (31 patients) was 61.3±11.3 years with an average body mass index (BMI) of 27.65±4.8 Kg/m², 7.18–40.1. According to the WHO classification, 17 women (54.8%) had osteoporosis, 10 (32.3%) had osteopenia and 4 (12.9%) had normal BMI. The indications for VFA practice were: age over 60 years with T scores < -2 SD, historical height loss >4 cm, a history of VF, a long-term corticosteroid therapy, and aromatase inhibitors therapy in 25.8%, 12.9%, 8.5%, 45.2% and 9.7% respectively. VFA objectified 15 FVs in 6 women (19.4%) which were grade 1, 2 and 3 in respectively 2, 5 and 8 vertebrae. However, plain X ray showed 21 FVs in 10 women (32.2%) which were grade 1, 2 and 3 in respectively 5, 7 and 9 vertebrae. The concordance between the two methods was found in 87.1% of cases, with a coefficient of Cohen (kappa) at 0.76 (strong agreement). A significant correlation (p=0.000) was found between the two methods concerning the detection of VFs grade II and III.

Conclusions: Our study proved the good agreement between the VFA and the standard X-ray in the detection of VFs. This shows the sensitivity of this technique which has the advantages of low cost and less irradiation.

AB1010

RISK OF INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS TAKING DENOSUMAB CONCURRENT WITH BIOLOGIC THERAPY

M. Zabihyeganeh1, A.M. Mirzaie2, S.A. Jafeh3. 1Rheumatology, Bone and Joint Reconstruction Research Center, Shafa Orthopedic Hospital, Iran University of Medical Sciences; 2Endocrinology, Diabetes Advisory Committee, Gabric Diabetes Education Association, Tehran, Iran, Tehran, Iran, Islamic Republic of Ireland

Background: Apart from Denosumab effects on bone, there are some promising data on its inhibitory effect on structural damages in patients with rheumatoid arthritis (RA). Despite some clinical concerns on its potential harm for increasing risk of infections, Denosumab is officially approved for the treatment of postmenopausal osteoporosis. Still there are even greater debates on its use and predisposing patients to infection in cases receiving immunosuppressive therapy. Considering the importance of infection in such cases, lack of sufficient convincing safety data has prevented, at least in part, the current guidelines to recommend Denosumab in treatment of osteoporosis in patients on immunosuppressive agents.

Objectives: We aimed to compare the infection risk in patients with RA taking biologic agents. Considering the importance of infection in such cases, lack of sufficient convincing safety data has prevented, at least in part, the current guidelines to recommend Denosumab in treatment of osteoporosis in patients on immunosuppressive agents.

Methods: Using records from the files covering January 2013 to May 2016, a retrospective comparative study was performed on two groups of postmenopausal RA patients, group A including 40 patients receiving Denosumab+bDMARDs (Etanercept, Rituximab, Adalimumab), and group B consisting of 44 patients receiving bDMARDs alone. Patients were included if the current therapeutic regimen was used for at least one year. All patients were also on a daily dose of prednisolone (2.5–7.5 mg) and folic acid, and a weekly dose of Methylprednisolone. Occurrence of serious bacterial or viral infections was extracted from recorded files of the patients’ routine visits.

Results: The mean age of the patients was 63.1±11.2 years and 62.6±11.7 years in group A and B, respectively (p=0.42). The mean disease duration was 7.2±2.9 years in group A and B, respectively (p=0.39). Type 2 diabetes mellitus was present in four and five patients of group A and group B, respectively (p=0.35). In total, four infections occurred in our study groups, two in each group (p=0.94). In group A, the first one was an osteomyelitis of the first metatarsal bone in a diabetic patient receiving Etanercept+Denosumab. The second one was a herpes zoster infection in a patient receiving Adalimumab+Denosumab. In group B two cases of herpes zoster were recorded in two patients receiving Adalimumab.

Conclusions: This study showed that the potential infection risk of concurrent use of Denosumab and bDMARDs was not significantly different from using bDMARDs alone. Denosumab seems safe in the treatment of osteoporosis in RA patients receiving bDMARDs.

Background: Osteoporosis (OP) is a systemic bone disease characterised by decreased bone mass and deterioration of bone microarchitecture with increased brittleness and a higher risk of fracture associated with higher morbidity and mortality for patients and has a high impact on health expenditure. Bone marrow stromal mesenchymal stem cells (BM-MSC) give rise to osteoprogenitor cells and osteoblasts and influence bone homeostasis. However after their intravenous (i/v) infusion their osteotropism is limited. Our group has demonstrated that the exofucosylation of the CD44 membrane antigen in MSC improves their homing to bone tissue and that the infusion of these cells is safe in a murine model.

Objectives: To evaluate the safety of i/v infusion of fucosylated BM-MSC in patients with OP, and secondarily assess their ability to improve the course of the disease.

Methods: 10 women between 50 and 75 years old diagnosed with osteoporosis disease patients with OP, and secondarily assess their ability to improve the course of the disease.

Results: Seven patients have been recruited to date. Two left the study for lack of interest in the follow-up of the study and consecutive patients. The four first patients were treated with a dose of 2 × 10⁶ cells/kg body weight and the other 6 with 5 × 10⁶ cells/kg body weight. A 24 month follow-up will be conducted to evaluate the rate of severe and non-severe adverse events and secondary endpoints (decreased fracture rate, pain scores, functional status and quality of life, biochemical indexes of bone metabolism, quantitative computed tomography for morphometric and mechanical analysis of bone quality, densitometry, and histomorphometry).

Conclusions: Our preliminary data indicate that clinical and GMP-grade production of BM-MSC is feasible. We have not observed any short-term adverse effects associated with treatment in infused patients.

Disclosure of Interest: None declared.

AB1013 PREDICTION OF BONE MINERAL DENSITY CHANGES IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Tomizawa1, H. Ito1, M. Furu1, M. Hashimoto1, M. Tanaka1, T. Mimori1, S. Matsuda1.

1Orthopedic Surgery; 2Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, Kyoto-City, Japan

Background: Osteoporosis and its related fractures is one of the most dominant, troublesome complications in rheumatoid arthritis (RA). Newly-introduced drugs such as methotrexate and biological and targeted synthetic disease modifying anti-rheumatic drugs have decreased disease activity drastically, but the improvement of osteoporosis remains to be investigated.

Objectives: To find useful factors for bone mineral density (BMD) management of RA patients under the current treatment.

Methods: We consecutively recruited 370 RA patients treated at Kyoto University Hospital in 2012. We prospectively collected the BMD values of the lumbar spine and the distal forearm measured by dual-energy X-ray absorptiometry (DXA), blood sampling test, urinalysis including bone metabolic biomarkers and clinical parameters of the RA patients in 2012 and 2014. Multivariate regression analysis was performed after adjustment by age, sex, body mass index (BMI), steroid use, anti-osteoarthritis medication. We set the annualised BMD change as an outcome variable and allotted the other parameters as explanatory variables by a stepwise procedure.

Results: The average values (minimum-maximum value) of age and BMI were 63.3 (32.8–85) years and 22.1 (12.3–30.0), respectively. Female patients and steroid users accounted for 91.1%, and 41.0%, respectively. Coincidentally, anti-osteoarthritis drug-user also reached 41.0%. User of biological accounted for 30.0%. The average of disease activity score (DAS) 28-erythrocyte sedimentation rate, Health Assessment Questionnaire was 2.6 (0.1–5.9) and 0.8 (0–2.9), respectively. The average of total Sharp score was 122.6 (0–443). Laboratory data showed serum tartrate-resistant acid phosphatase (TRACP)–5b, serum homocysteine, serum undercarboxylated osteocalcin, bone specific alkaline phosphatase, and urinary pentosidine were 320.0 (68–877) mU/dl, 9.7 (3.2–28.7) ng/ml, 4.8 (0–23) nmol/l, 561 (0.04–43.6) μg/l, and 50.0 (11.5–561) pmol/l, respectively. Next, we describe by the result of multiple regression analysis. The levels of serum homocysteine (β= 0.19; 95%CI: 0.24 to 1.75; p=0.01) and anti-osteoarthritis drug (β= –0.19; 95%CI: –0.26 to –0.04; p=0.009) were consistently significant predictive variables of annualised BMD change of the lumbar-spine.

Conclusions: Anti-osteoarthritis medication may be particularly important for lumbar spine BMD for RA patients, regardless of steroid-use. Specific biomarkers would be useful such as homocysteine as lumbar spine BMD and TRACP-5b as...
the forearm BMD. These findings would be helpful for osteoporosis management in RA patients.

EPIDEMIOLOGICAL FEATURES OF PERIPHERAL FRAGILITY FRACTURES IN WOMEN IN REPUBLIC OF MOLDOVA

V. Cazac, L. Groppa, E. Russu, L. Rotaru, L. Chislari, Rheumatology and Nephrology, State University of Medicine and Pharmacy "Nicolea Testemitanu", Chisinau, Moldova, Republic of

Background: Osteoporosis is a disease which is frequently asymptomatic until fragility fractures occur. The study of risk factors in osteoporosis is continuously developing, considering that there is a tremendous geographic variety in osteoporosis occurrence. We present the results of an epidemiological study of fragility fracture cases in Republic of Moldova, trying to underline differences in fragility fracture epidemiology, based on residence region, and possibly lifestyle factors, in a female population.

Objectives: The purpose of the study was to determine the incidence and prevalence of fragility fractures in women, with comparison of epidemiological indexes between urban and rural areas in Republic of Moldova.

Methods: Approximately 6% of the state population was included in the study. Data regarding peripheral fragility fracture cases was collected from all specialised and primary medical institutions from the defined area. Fragility fractures of proximal humerus, distal forearm, proximal femur and distal calf, in women aged over 40 years old were collected. Using population statistics provided by the National Bureau of Statistics, epidemiological indexes regarding fracture incidence and prevalence were derived, with further comparison of derived epidemiological indexes for urban and rural areas, as well as separate epidemiological indexes for the four fracture regions.

Results: A general incidence of 1033.4 peripheral fragility fractures per 1 00 000 female population >40 years was determined, with a significantly higher incidence in urban areas (1216.7 vs 980.1, p<0.05). The incidence of proximal humerus fracture was 149 per 1 000 000 female population >40 years, with a small, but significantly higher incidence in urban areas (159.5 vs 145.9, p<0.05). The incidence of distal forearm fractures was 393.4 per 1 000 000 population >40 years, significantly higher in urban areas (528.5 vs 354.1, p<0.05). The incidence of proximal femur fracture was 208.5 per 1 000 000 population >40 years, significantly higher in urban areas (227.9 vs 202.9, p<0.05). The incidence of distal calf fractures was 292.5 per 1 000 000 population >40 years, with a small, but significantly higher incidence in urban areas (300.7 vs 277.2, p<0.05).

Conclusions: There was an overall higher incidence of fragility fractures in the urban female population compared to the rural one, with a similar relationship in all four fracture groups. The association between urban residence and increased incidence of fragility fractures in women, could be attributed to a less active physical lifestyle (known risk factor in osteoporosis) in urban areas. Distal forearm fractures showed a greater prevalence both in urban and in rural areas, compared to other fracture types. Moreover, the incidence difference between urban and rural areas was most prevalent in the distal forearm fracture group. The latter observation was not determined in a similar study in men, in the same population and period of time.

AB1015
BONE MINERAL DENSITY IN PATIENTS WITH CHRONIC KIDNEY DISEASE

V. Vasilkova1, T. Mokhort2, N. Filipsova3, A. Naumerkas3, 1GOMEL STATE MEDICAL UNIVERSITY, Gorom, 2Belarusian State Medical University, Minsk; 3The Republican Research Center for Radiation Medicine and Human Ecology, Gorom, Belarus

Background: Chronic kidney disease (CKD) is commonly associated with disorders of mineral and bone metabolism. However, the relationship between renal function and bone mineral density (BMD) is controversial.2,3

Objectives: We aimed the relationship between markers of renal function and BMD in patients with CKD.

Methods: 95 patients both sexes with CKD aged 55.49±10.07 years were studied. Control group included 84 healthy subjects the same age. Standard laboratory analyses were performed in all patients. Renal function was assessed by the estimated glomerular filtration rate (eGFR), which was calculated using an equation based on creatinine (eGFRcr) and cystatin C (eGFRcys_c). Osteoporosis was defined as a femoral neck BMD T-score below −2.5.

Results: The serum cystatin C level was negatively correlated with BMD and T-score right and left femoral neck (p<0.05), but not with BMD T-score lumer spine. The level of creatinine was negatively correlated only with BMD and T-score right femoral neck (r=−0.653, p<0.05). Higher cystatin C levels were associated with a higher prevalence of osteoporosis in CKD patients (OR 3.54; 95% CI 1.63–7.85; p=0.002). In logistic regression analysis, after adjusting for age, body mass index, calcium, only cystatin C showed a negative correlation with femoral BMD. In addition, the eGFRcys_c showed a stronger positive correlation with femoral BMD than the eGFRcr.

Conclusions: Our findings suggest that serum cystatin C level could be a marker for femoral BMD and might help identify patients with osteoporosis who are susceptible to fractures.

AB1016
OSSEOINTEGRATED IMPLANTS FOR LOWER LIMB AMPUTEES: EVALUATION OF BONE MINERAL DENSITY

S. Thomson1, W. Lu1, M. Al Muderis2,3, 1The Osseointegration Group of Australia; 2Macquarie University; 3The University of Notre Dame, Sydney, Australia

Background: The use of dual-energy X-ray absorptiometry (DXA) is a standard clinical procedure for the evaluation of bone mineral density (BMD). Amputee patients are known to have decreased BMD and an increased risk of osteoporosis in the affected proximal femur and hip region. The major cause of these issues in these patients is the absence adequate loading leading to bone resorption in accordance to Wolff’s law.

Objectives: In this paper, we present a prospective study reporting changes in BMD among amputees who received osseointegrated implants to determine if the loading through the Osseointegrated implant can overcome the bone resorption issues.

Methods: This is a prospective study of 33 patients, consisting of 24 males and 9 females, aged 22–77 (mean=51.0±2.0) years with one and two-year follow-up. Selection criteria included age over 18 years, unilateral amputees with socket-related problems. All patients received osseointegrated implants press-fitted into the amputated limb. BMD was assessed using DXA in the femoral neck (operative and contralateral) and lumbar spine (L2-L4) regions, and corresponding Z-scores were generated. DXA scans were taken preoperatively as well as one-year and two-years following osseointegration surgery.

Results: Mean BMD and Z-scores of spine, and operative and contralateral sides were generated for all patients. Independent t-tests were used to test for significant differences (p<0.05) preoperative, one-year, and two-years for mean changes in BMD and Z-Scores following surgery. Analysis of the BMD and Z-scores indicated that patients showed improvements at one-year post-surgery.

Conclusions: These results suggest that osseointegrated implants are effective at encouraging bone growth and restoring BMD levels for amputees within a short period of time post-surgery. Osseointegrated implants therefore have the potential to address stress distribution issues associated with socket prostheses and restore the normal bone loading regime in lower limb amputees.

VERTEBRAL FRACTURES ARE LIKELY TO OCCUR IN LUMBAR VERTEbra IN PATIENTS WITH OSTEOPOROSIS AND EVEN IN OSTEOPENIA

Rheumatology, THE THIRD AFFILIATED HOSPITAL OF SUN YAT-SEN UNIVERSITY, Guangzhou, China

Background: Osteoporosis is a common disease, which can lead to fracture. New diagnosis includes fracture of the vertebral bodies and hips. T-scores of bone mineral density (BMD) less than −2.5 or osteoporosis together with humeral, forearm or the pelvis facture. Vertebral assessment should be considered in some conditions.1

Objectives: Our study was to investigate the condition of osteoporosis in patients who underwent bone mineral density in our hospital and fracture status according to lateral X-ray of cervical, thoracic and lumbar vertebra. The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis.

Results: Of all the 210 patients, 60 (28.6%) were male patients. 59.5% of female patients were in post-menopause stage. Mean age was 57.60±13.17 years. 124 patients were asked to perform BMD by the rheumatologists. 20 patients did the test after they saw an endocrinologist. 40 patients did the test after they saw an orthopedist. 102 patients had T-scores less than 2.5. 61 patients had osteopenia according to BMD. 22 patients had fracture according to past history or X-ray scans’ findings. 10 patients had multiple fractures. The most frequent fractures were located in L1 (nine patients) and L2 (four patients). The other parts included L3, L5, C7, T12, T6, T8, and T9. Two patients had ankle or humeral fractures before because of injury. Vertebral fractures were identified in 5 (8.2%) of the patients with T-scores of −2.5 to −1 during this study.

Conclusions: Lateral X-ray scans of the vertebra can detect vertebral fractures in patients with osteoporosis according to BMD scores, even in patients less than 50-year-old. Osteoporosis could be underestimated without measurement of the vertebra. The most frequent vertebra fracture happens in L1.

INTRAVENTRICAL NERICRONATE IN THE TREATMENT OF BONE MARROW ODEMA SYNDROME: EFFICACY AND SAFETY OF TWO DIFFERENT TREATMENT SCHEDULES

A. Lurati,1, A. Laria,1, P. Faggioni1, M. Marrazza1, D. Mazzocchi1, A. Gilaris2, A. Tamburello1, L. Castelvovo1, K.A. Re1, A. Mazzone2.
1Rheumatology Unit, FORNAROLI HOSPITAL; 2MEDICINA INTERNA, ASST OVEST MILANESE – OSPEDALE CIVILE DI LEGNANO E CUGGIONO, LEGNANO, Milan, Italy

Background: Bone Marrow Oedema Syndrome (BMES) is a severely disabling pain syndrome without a definite treatment well established.

Objectives: The aim of this monocentric prospective trial was to test the efficacy and the safety of the amino-bisphosphonate nercidronate in patients with BMES administered in two different schedules.

Methods: one hundred seventy-three patients with BMES at various joints were consecutively assigned to I.V. infusion of 100 mg nercidronate given four times over 10 days (Group A) or alternatively to I.V. infusion of 100 mg every 21 days over 63 days (Group B). At baseline (T0) and after 90 days from the first infusion we performed a MRI (T2). We assessed a 0–100 mm pain VAS in each patient at T0, at the day of the last infusion (T1: day 10 for group A and day 63 for group B) and at T2. Primary outcome was to evaluate the MRI changes, secondary end-point was the VAS change.

Results: we observed a significant improvement in MRI with the resolution of bone marrow oedema present at T0 [p<0.01], without a significant difference between Group A and Group B. Visual analogue scale (VAS) score decreased significantly during the study in both groups [p<0.05] without a significant difference between the two treatment groups [p>0.1].

Conclusions: In patients with BMES, the infusions of nercidronate 100 mg every 21 days over 3 months or alternatively every 3 days over 10 days are associated with clinically relevant and persistent benefits without significant differences between the two treatment-schedules. These results provide conclusive evidence that the use of bisphosphonates, at appropriate doses, is the treatment of choice BMES

PATIENTS COMPLIANCE TO CHRONIC GOUT THERAPY WHEN ADMINISTERED BY DIFFERENT MEDICAL PROFESSIONALS

A. Saripovul,1 O. Teplyakova1, A. Popov1, T. Popova1, P. Palabugina1.1URALS STATE MEDICAL UNIVERSITY, 1City Clinical Hospital 40, Ekaterinburg, Russian Federation

Background: in everyday practice chronic gout patients are frequently consulted by general practitioners, surgeons, cardiologists and other specialists. In general, chronic gout patients have been reported to be quite incompliant, but it remains unclear whether low compliance depends on the specialty of the prescribing physician.1

Objectives: to compare the clinical course of gout in patients consulted by different specialists and to identify factors of low patients’ compliance in Russia.

Methods: cross-sectional study included 56 chronic gout patients aged 31 to 82 (median 54 years). Average gout symptoms duration was 6.8 years, average attacks frequency was 6.4 per year. Tolfi were present in 21.4% of patients. All subjects were divided into three groups: Group 1 consisted of treatment naive patients at primary rheumatologist visit, Group 2 and Group 3 included patients who had previously been treated. Group 2 subjects were visiting both non-rheumatologists and rheumatologists. Group 3 were managed by rheumatologists strictly according to the EULAR evidence-based recommendations.2

Results: Group 1 primary consulted rheumatologists at the age of 47.3±14.5. Group 2 patients were assessed at the age of 58.4±15.2. and Group 3 were aged 51.2±13.5. Disease symptoms duration was maximal in Group 2 (10.5±10.6 years) while 5 years in Groups 1 and Group 3. Flares frequency was the lowest in Group 3 (2.2±1.8 per year), while in Group 2 it was extremely high – (10.58±10.56 per year). The incidence of tofli and uriculathiosis was lowest in the Group 3 whereas every third treatment naive patient had tophi or/and uriculathiosis. To relieve gout arthritis vast majority of patients used NSAIDs, though at 50% strength of the recommended dose. Only 9%–14% of flares were controlled by colchicine in Groups 2 and 3. Colchicine prevention of flares was prescribed only in 45% of cases by rheumatologists. The most frequent urate-lowering therapy (ULT) was allopurinol, it was taken only by 63% of patients of the third group and 35.7% in the second group. While patients in the third group took the drug daily, the other patients did not follow the administration scheme. Serum creatinine level was the lowest (87.5±16.8 µmol/L) in Group 3, being the highest in treatment naive patients (102.7±30.0 µmol/L). Serum uric acid target level was achieved only in the compliant Group 3 patients (434 µmol/L), while Group 2 levels varied between 462–546 µmol/L, being the highest (625 µmol/L) in Group 3, being the highest in treatment naive patients (102.7±30.0 µmol/L). Serum uric acid target level was achieved only in the compliant Group 3 patients (434 µmol/L), while Group 2 levels varied between 462–546 µmol/L, being the highest (625 µmol/L) in treatment naive Group 1.

Low compliance risk factors were: age under 45, absence of comorbidity and long term multiple drugs consumption.

Conclusions: chronic gout patients’ compliance and quality of patient management can be assessed as alarming low. Rheumatologists adhering to EULAR evidence-based approach to gout management can actually achieve recommended treatment targets. Both general practitioners and other specialists are in need of consistent educational program on gout management. Younger and comorbidity-free gout patients should be encouraged to follow attending physician’s recommendations.

PILOT ASSESSMENT OF CURRENT CHRONIC GOUT TREATMENT IN RUSSIA

A.A. Popova1, O.V. Teplyakova2, T.A. Popova3, A.V. Sarapulova2, P. A. Palatbugina1, 1Hospital Therapy Dept; Outpatient Therapy Dept., URALS STATE MEDICAL UNIVERSITY, 2Rheumatology Dept., City Clinical Hospital 40, Ekaterinburg, Russian Federation

Background: In 2016 EULAR evidence based clinical guidelines on Gout treat- ment have been updated. 1

Objectives: to assess current daily practice physicians’ approach to manage- ment of chronic gout patients

Methods: a cross-sectional anonymous survey had been offered to hospital and outpatient departments physicians dealing with gout patients resulting in 97 back- feed replies yielded. This publication deals with chronic gout treatment practice.

Results: all survey participants were divided into 3 groups. Group 1 consisted of 18 rheumatologists (professional experience median 19.6 years, range 1 to 43), group 2 included 60 general practitioners (GP, professional experience 27; 4–47), group 3 included other specialists (cardiologists, surgeons etc.) who reported frequent contacts with gout patients (professional experience 16.5; 1–44). Rheuma- tologists reported to contact median 15 (range 2–40) gouty subjects per month, while group 2 reported to see 31–146 and group 3 consults 41–125 patients per month. All rheumatologists and 45 GPs reported initiation of allopurinol or febuxo- stat after gouty arthritis resolution, while 11 general practitioners did not start anti- hyperuricemic drugs in subjects with kidney and/or cardiovascular comorbidities. In Group 3 only 6 responders had experience of antihyperuricemic drugs administra- tion, but 3 of them reported allopurinol initiation during gout flare. Only 2 rheu- matologists and 2 GPs were aware of gout flare low dose colchicin prophylaxis during allopurinol dose adjustment. Administration of maximal allopurinol daily maintenance doses over 300 mg was reported only by 7 rheumatologists and 7 GPs. Other specialists did not have any personal experience of allopurinol dose adjustment. By responders’ assessment every 2–3 patient continues to experi- ence gout flares in spite of prescribed treatment

Conclusions: intensive educational intervention is urgently required to change current practice of chronic gout treatment in Russia.

ANEURYSMAL BONE CYSTS OF THE SPINE: 4 CASE REPORTS AND REVIEW OF LITERATURE

Background: Aneurysmal bone cysts (ABC) are rare, benign, highly vascular pseudotumors of unknown cause. It most often affects individuals during their sec- ond decade of life.

Objectives: Our goal was to document the clinical characteristics, diagnostic modalities and treatment results of ABCs.

Methods: We reviewed our institution’s database over a period of 15 years to identify patients diagnosed with aneurysmal bone cysts of the spine. Four patients underwent surgery in our department (2 men and 2 women). For those four patients, we tabulated the clinical characteristics, location, diagnostic modalities and treatment.

Results: The clinical manifestations were gait disturbance in 2 patients and leg- pain in the other two. The tumour occurred in the dorsal spine in 2 cases and in the lumbar spine in the other two. All patients underwent surgical resection with total removal in only 2 patients. Postoperatively, clinical signs improved in all patients. Only one case presented tumour recurrence requiring second interven- tion and instrumentation.

ABCs constitute approximately 1.5% of spinal bone tumours. They usually affect the posterior elements of the spine. MRI is the most useful modality for preopera- tive planning. It also helps to evaluate the fluidfluid level, which is characteristic for ABC on MRI. The differential diagnosis is mainly with giant cell tumours and osteoblastomas. The primary option for treatment is surgery. Instrumentation is sometimes necessary because of the increased risk of postoperative instability, especially in cervical spine surgery. The recurrence rate is 20% to 30% in case of incomplete resection.

Conclusions: ABCs are benign lesions. Surgical resection en bloc has the lowest recurrence rate. Instrumentation is sometimes necessary because of the increased risk of postoperative instability.

EFFICACY AND TOLERANCE OF SODIUM THIOSULFATE INJECTION IN CALCIFIC TENDINOPATHY OF THE ROTATOR CUFF

C. Darieurtet-J Labbé1, T. Garnaud2, A. Bertrand-Vasseur2, B. Le Goût1, 1RHEUMATOLOGY UNIT, 2RADIOLOGY UNIT, HOPITAL HOTEL DIEU/HME, NANTES CEDEX 1, France

Background: Calcific tendinitis of the rotator cuff is one of the most common causes of shoulder pain. Ultrasound guided percutaneous lavage of calcific tendinopathy (UGPL) is indicated when conservative treatments have failed. It has been shown that dense calcifications are associated with a higher risk of treat- ment failure. Sodium thiosulfate (STS) has recently been used with success in the treatment of tumoral calcinosis. We hypothesised that STS lavage could be of interest in the treatment of dense calcification of the rotator cuff.

Objectives: To evaluate the tolerance and efficacy of sodium thiosulfate lavage in the treatment of calcific tendinitis

Methods: This was a prospective phase II open label study. We included only patients with a type A calcification according to the Molé classification. Patients were treated with a US-guided single needle technic. When backflow of calcific material could be identified in the syringe, lavage of the deposit was performed using STS 25% until the backflow becomes clear followed by the injection of 1 mL (250 mg) of STS inside the calcific deposit. Finally, 1.5 mL of corticovial was injected in the subacromial bursa. All patients had follow-up visits at 1 week, 1 month and 3 months after intervention. At each time point, VAS pain at rest and during activities was recorded and US and X-ray were performed. Our primary outcome was the percentage of patients with more than 50% of decrease of the calcification size at 1 month. Based on our experience and on the literature, we expected than more than 60% of the patients should have more than 50% of decrease in their calcification for the results to be significant.

Results: A total of 17 patients were included. Mean age was 50±11 years. There were 9 female (52.9%). Baseline VAS at rest and during daily activities was a mean 40.2±25.9 and 65.5±21.6 (27–91) respectively. Calcification involved the supraspinatus in 12 cases (70.6%) and the infraspinatus in 5 cases (29.4%). Mean surface on radiography was 80.7 mm2 ±52.4 and the calcification longest axis was 18.8±7.1 mm. All patients underwent the entire procedure with no adverse event apart of a mild and transient vasovagal reaction. Calcium backflow could be obtained in 15 patients (88.2%) with a small amount of calcium in 8 cases (53.3%) and a large quantity in 7 cases (46.7%). We found that 5 patients (30%) had more than 50% decrease of their calcific deposit at 1 month and 8 (47%) patients at 3 months. VAS pain during activities and at rest decreased significantly from 65±22 and 40±2.26 at baseline to 37.8±31 and 24.1±24 at 3 month respec- tively (p=0.0004; p=0.001)

Conclusions: Overall, our study is the first to evaluate the tolerance and efficacy of sodium thiosulfate for the treatment of the calcifications of the rotator cuff. We could not demonstrate a significant effect of one STS lavage and injection in patients with dense calcification. This treatment was well tolerated with no side effect occurring during the procedure and the follow-up. New studies using larger volume and repeated injections of STS will be needed to definitely conclude on the interest of this molecule in the treatment of calcific tendinopathies.

Disclosure of Interest: None declared
ENHANCED RENAL TRANSPORTER ACTIVITIES OF OAT1 AND OAT3 BY KEISHIBUKURYOGAN (K-06) AND IN VIVO URIC ACID MODULATING EFFECT AT POTASSIUM OXONATE-INDUCED MOUSE SETTING

D.-S. Oh1, H.-J. Shin2,3, S.H. Lee1, S.-M. Oh1. 1The K-herb Research Centre, Korea Institute of Oriental Medicine, Daejeon; 2Department of Pharmacology and Pharmaco Genomics Research Centre, College of Medicine, Inje University; 3DMPK, SPIMED, Busan, Korea, Republic of Ireland

Background: Studies on renal solute carrier transporters have made the renal pathophysiology be in progress towards more mechanistic and the knowledge on renal drugs including drug-drug interaction be more evidentary. Among the evidence, uricosuric phenomenon has been known that rodent experimental model is also useful for predicting human uricosuria.

Objectives: The aim of this study was to assess the substrate uptake at the over-expression of renal transporters, OAT1, OAT3 and URAT1 at kidney proximal tubular cell lines with or without a commercial herbal medicine, Keishibukuryogan (K-06) and to further measure serum and urinary uric acid concentrations in the setting of potassium oxonate (PO)-induced icr mouse model with or without K-06.

Methods: The transporter-expressed HEK293-OAT1 and HEK293-OAT3 cells were seeded on BD poly-d-lysine microplates to uptake the [3H] estrone sulfate for 5 min in absence or presence of K-06. URAT1 was overexpressed using Xenopus oocytes being injected with in vitro-copied RNA of URAT1, and then to measure the uptake of [3H] uric acid with/without K-06. Total radioactivity was measured using a liquid scintillation counter. Serum and urinary uric acid was measured in PO icr mice after three-day intake of K-06. They were assigned by 4 per each group: 1) control group, 2) PO-induced group, 3) PO-induced with allopurinol 50 mg/kg/day intake group and 4) PO-induced with allopurinol plus K-06 300 mg/kg/day intake group.

Results: To determine the kinetic parameters of concentration-dependent uptake of overexpressed OAT1 and OAT3 transporters in HEK293 cells, the K-06 inhibitory parameters on OAT1 and OAT3 were presented with the IC50 values of 49.3 and 31.5 μM, respectively. The K-06 inhibited URAT1 with IC50 of 59.3 μM/L. The K-06 (300 mg/kg) reduced serum levels of uric acid approximately 30% compared to that of PO-control group (p<0.039) and K-06 showed the slight elevation of urinary uric acid by 12% compared to that of PO-control group with no statistical significance.

Conclusions: The present findings demonstrated that the K-06 modulated basolateral and apical renal transporters and the K-06 showed the slight increased uric acid excretion and the uric acid lowering effect in experimental mouse setting.

AB1025
MONOSODIUM URATE CRYSTAL FORMATIONS FROM TOPHI IN SYNOVIAL FLUID

E. Pascaul1, M. Andrés2,3, F. Sivera4. 1Emeritus Professor, Universidad Miguel Hernández; 2Sección de Reumatología, Hospital General Universitario De Alicante-Isabial; 3Dpt Medicina Clinica, Universidad Miguel Hernández; 4Sección De Reumatología, Hospital General Universitario de Elda, Alicante, Spain

Background: At the joints MSU crystals form primarily at the cartilage surface; on occasions also tophi form at joint margins. Most often monosodium urate (MSU) crystals in the synovial fluid (SF) are found isolated. In tophi MSU crystals often show as spherulitic formations, fanning away from a central point1 (Figure 1, 200x, polarised light). We have detected in synovial fluid formations of MSU crystals with an organisation indicative that they formed in tophi, draining later to the fluid. The formations also help to understand how crystals formed in tophi.

Methods: Our photographic archive of SF have been reviewed.

Results: Two types of formations are found. A) A spherulitic formation where the crystals fan radially as in the segment of a sphere (Figure 1, middle, 600x, polarised light). B) Paired crystals bound longitudinally to each other (Figure 2, right, 600x, phase contrast).

Abstract AB1025 – Figure 1

Conclusions: At tophi spherulitic crystal formations are usual (figure 1) in which MSU crystals raditate as in a fan. A) Pieces of these same formations, seen as the segment of a sphere, are occasionally seen in SF (Figure 2), usually containing a large number of crystals and suggesting that they have drained from a tophus. Likely to build these formations, the initial crystals served as a template on which successive crystals formed by epitaxia, – the crystal formation method of least energy requirement -, explaining the rapid growth that tophi can present. Their unimpeded migration to the joint cavity suggest that they formed freely and unconnected to any organic structure within the tophus. B) In SF containing large numbers of crystals, paired crystals – two crystals lying side by side and usually of similar length and width – are also found. Their paired position likely indicates that one served as template to the other, or that they grew together sharing a crystal net – twin crystals. In all, these MSU crystal formations appear to indicate that besides the crystals formed in the surface of joint cartilages, the content of tophi can drain into the joint fluid, also contributing to the presence of crystals in it; the
periaricular tophi frequently seen in ultrasound appear as the likely source for these formations.

AB1026 CLINICAL CHARACTERISTICS AND RISK FACTORS FOR GOUT ATTACK DURING THE POSTSURGICAL PERIOD

H. Jeong¹, Y.H. Eun², E.-J. Park³, H. Kim⁴, J.Y. Cha⁵, J. Lee⁶, C.H. Jeon⁷.
¹Soonchunhyang University Hospital, Bucheon, ²Samsung Medical Center, ³National Medical Center, Seoul, ⁴Bundang Jesaeng Hospital, Seongnam, Korea, Republic of Ireland

Objectives: To evaluate the clinical features and risk factors for gout attack during the postsurgical period in patients with gout.

Methods: Seventy patients who had histories of gout and had been consulted to rheumatologic clinic before surgery under general anaesthesia at a single tertiary hospital were included. Clinical characteristics of patients who developed postsurgical gout attack were compared with patients who did not develop gout attack.

Results: Among 70 patients, 31 (44.3%) patients developed gout attack during postsurgical period. Mean time of gout attack after surgery was 3.7±4.9 days. Most of attacks involved lower extremity joints (83.9%) and tended to monoarticular involvement (61.3%). Knee joint (26%) and foot (21.4%) were the most frequently involved joints of gout attack. Uric acid levels before surgery (OR 1.46, 95% CI 1.13–1.88, p=0.004) and amount of uric acid changes between before and after surgery (OR 1.21–2.18, p=0.001) were risk factors for postsurgical gout attack. Taking medications for gout during hospitalization prevents the postsurgical gout attack. Conclusions: Adequate uric acid control and taking medications for gout could prevent the postsurgical gout attack.

AB1027 THE PREDICTIVE VALUE OF CYSTATINE C FOR GOUTY NEPHROPATHY

D. Rekalov, ¹D Danuk, G. Medvedchuk. Internal diseases-3, Zaporizhzhia State Medical University, Zaporizhzhia, Ukraine

Background: The clinical importance of acute gout in hospitalised patients who have significant comorbidities and receive multiple medications is high. The aim of the study was to determine the correlation between levels of cystatin C and creatinine as the markers of nephropathy in patients with gout.

Methods: The main group was the 80 males with primary gout (average age - 53.4±8.2 years), with the disease duration from 3 up to 25 years. The second group - 20 healthy men (49.5±4.5). We determined the correlation between serum uric acid level and GFR (r=-0.4, p<0.05) which explains the increase of uric acid concentration in the serum. We determined the correlation between level of uric acid and creatinine concentration (r=-0.5, p<0.05) in the main group, but concentration between albuminuria and cystatin C was stronger (r=-0.6, p<0.05). We detected that cystatin C level had a greater accuracy for the diagnosis of albuminuria than creatinine according to the ROC-analysis. These facts show that serum concentration of cystatin C more closely connected with the renal function than creatinine.

Conclusions: 1. The increase of serum cystatin C level can be identified before the clinical manifestation of renal dysfunction while the serum creatinine remain relatively normal. 2. Serum range of cystatin C more closely correlate with elevation of urine albumin than creatinine.

AB1028 ACTH VS BETAMETHASONE FOR THE TREATMENT OF ACUTE GOUT IN HOSPITALISED PATIENTS

P. Kords1, ¹Antonopoulou2, D. Velissaris3, D. Daousis3. ¹Internal Medicine; ²Rheumatology, University of Patras Medical School, Rio, Patras, Greece

Background: The management of gout can be problematic in the hospital setting; hospitalised patients usually have significant comorbidities and receive multiple medications which leads to a high frequency of concomitances to established gout therapies. We have previously shown the ACTH is a safe and fast acting therapeutic option for acute gout in hospitalised patients in a large scale retrospective study.

Objectives: To directly compare the efficacy of ACTH vs betamethasone for the treatment of acute gout in hospitalised patients in a prospective manner.

Methods: Hospitalised patients with acute gout, fulfilling the ACR criteria, were recruited and treated with ACTH or betamethasone on an alternate 1/1 basis. Clinical efficacy was assessed at 24, 48, 72 hour and 5 days as follows: a) Intensity of pain using a Visual Analogue Scale (VAS 0–10), b) physician global assessment (0–10) and c) swelling, redness and warmth (0–3 scale). Pain VAS was also self reported by the patient at 6 and 12 hour. Concomitances representing concomitances to established gout therapies were recorded. Primary outcome of the study was the change in pain VAS at 24 and 48 hour. Secondary outcomes were changes in physician global assessment and changes in objective signs of inflammation.

Results: This is a 6 month interim analysis of an ongoing investigator initiated clinical study. Twelve patients (8 male) with a mean ±SD of 66.9±12.3 years were recruited and treated with ACTH or betamethasone on an alternate basis (6 in each treatment group). In most cases (n=11) the attack was monoarticular. The majority of patients had multiple comorbidities with the commonest being hypertension (9/12). Both treatments were effective. ACTH led to a significant decline in pain VAS at 24 hour compared to baseline (mean ±SEM: 2.33±1.21 vs 7.66 ±0.81 respectively, p=0.0002) and at 48 hour (1.40±1.14, p=0.011 compared to baseline). Betamethasone was also effective with an improvement in pain VAS at 24 hour compared to baseline (mean ±SEM: 1.83±0.98 vs 5.33±2.16 respectively, p=0.0024) and at 48 hour (0.75±0.95, p=0.02 compared to baseline). However, direct comparison between treatment arms showed that ACTH treated patients exhibited a higher change in pain VAS at 24 hour compared to betamethasone treated patients (mean ±SEM: 5.5±0.5 vs 3.5±0.61 respectively, p=0.03). At the 48 hour time point ACTH treated patients still showed a higher change in pain VAS (mean ±SEM: 6.4±0.6 vs 4.0±0.1 respectively, p=0.056). A trend favouring ACTH was already evident at the 12 hour time point; the change in pain VAS was 4±1.54 vs 3.1±1.47 for ACTH vs betamethasone, respectively, (p=0.05).

No changes in physician global assessment and objective signs of uric acid level and GFR (r=–0.4, p<0.05) which explains the increase of uric acid concentration in the serum.
inflammation was found at 24 and 48 hour between treatment groups. Treatment was well tolerated in both groups.

Conclusions: Both steroids and ACTH are effective in the treatment of gout in hospitalised patients but ACTH is faster acting. ACTH may be an attractive therapeutic choice in patients with multiple comorbidities that cannot receive standard treatment.

ALLPURINOL AND CARDIOVASCULAR OUTCOMES IN PATIENTS WITH ISCHAEMIC HEART DISEASE (ALL-HEART) STUDY: BASELINE CHARACTERISTICS OF THE RANDOMISED PATIENT POPULATION

I. Mackenzie1, I. Ford2, C. Hawkey3, A. Begg4, J. Taggar5, A. Struthers6, L. Wei6, A. Avery7, A. Walker7, S. Duce7, R. Barr7, J. Dumbleton7, T. MacDonald7, on behalf of the ALL-HEART study group.

1MEMO Research, University of Dundee, Dundee; 2The Robertson Centre for Biostatistics, University of Glasgow, Glasgow; 3University of Nottingham, Nottingham; 4Townhead Medical Practice, Montrose; 5University of Dundee, Dundee; 6University College London, London; 7University of Glasgow, Glasgow, UK

Background: Allopurinol is licensed for the prevention of gout. In recent years, several studies have suggested that allopurinol may have beneficial effects on cardiovascular parameters. The ALL-HEART study is a large outcome trial designed to investigate whether allopurinol improves cardiovascular outcomes in patients with ischaemic heart disease. It is a multicentre, controlled, prospective, randomised, open-label, blinded endpoint trial comparing the cardiovascular safety of allopurinol and febuxostat in patients with symptomatic hyperuricaemia. The trial includes patients aged over 60 years who are taking chronic allopurinol therapy at baseline and have at least one additional cardiovascular risk factor. After uptitration on allopurinol to reach EULAR urate targets, patients are randomised to febuxostat or allopurinol then followed up for events. Patient recruitment to the trial completed in late 2017 and follow-up is ongoing.

Objectives: To describe the baseline characteristics of the patients randomised into the FAST study.

Methods: The primary endpoint of the FAST study is the composite of non-fatal myocardial infarction, non-fatal stroke or cardiovascular death. The primary analysis is a non-inferiority analysis with a non-inferiority upper limit for the hazard ratio for the primary outcome of 1.3.

Results: 6142 patients from UK, Denmark and Sweden have been randomised into the FAST study. The mean age at randomisation was 71.0±6.4 (SD) years. 85.3% of participants are male. 57.3% are former smokers and 7.9% current smokers. Mean systolic blood pressure was 138±16 mmHg and mean diastolic blood pressure 75±12 mmHg. Mean body mass index was 31.1±5.2 kg/m². 10.7% of participants had a history of previous myocardial infarction, 5.0% a history of previous cerebrovascular accident and 4.8% a history of peripheral arterial disease. 22.5% had a history of diabetes mellitus and 4.6% a history of heart failure. 78.0% had a history of high blood pressure. 33.3% had a history of any cardiovascular disease (defined as history of myocardial infarction, cerebrovascular accident, transient ischaemic attack, acute coronary syndrome, coronary revascularisation, angina pectoris or heart failure). The mean baseline urate at study entry (screening) was 297±47 μmol/L. The mean allopurinol dose being taken at study entry (screening) was 225±106 mg daily. 2206 patients (35.9%) had at least one uptitration of allopurinol dose prior to randomisation.

Conclusions: This ongoing European trial will report on the cardiovascular safety of febuxostat versus allopurinol in patients with symptomatic hyperuricaemia.

EXPERIMENTAL INVESTIGATION OF THE TOXIC EFFECT OF Hyperuricemia IN RATS

K. Ichida1, M. Nagamura1, R. Tanino1, W. Yoshioka2, 1Department of Pathophysiology, Tokyo University of Pharmacy and Life Sciences; 2Department of Public Health and Environmental Medicine, The Jikei University School of Medicine, Tokyo, Japan

Background: Hyperuricemia induces gout and kidney stones and accelerates the progression of renal diseases. Hyperuricemia is a common multifactorial disorder having several environmental factors such as sex, diet, alcohol consumption, and obesity. The increasing prevalence of hyperuricemia in recent years is thought to be due to environmental factors, particularly diet. Based on the reported association between sugar-sweetened beverages and hyperuricemia in epidemiological studies, it has been hypothesised that fructose, the primary sweetener in sugar-sweetened beverages, directly increase plasma urate levels.

Objectives: The aim of this study was to investigate whether and how fructose induces an increase in plasma urate levels.
Methods: Urate in plasma and urine were measured after fructose, glucose, or water was administered to Sprague-Dawley rats at doses of 2.5 or 7.5 g/kg at a time. Intestinal closed loops were made using approximately 10 cm of ileum. Phosphate buffered saline was injected into each intestinal loop. After 4 hours, urate levels in the loops were measured.

Results: Plasma urate level was significantly increased within 15–30 min by oral administration of fructose, without an increase in urinary and intestinal urate excretion, and a decreasing tendency of urate clearance was observed. These actions were evident at a dose of 7.5 g/kg body weight. The absence of an increase in urinary and intestinal urate excretion indicated that an increase in urate production did not result in the increase in plasma urate level. In the meantime, a decrease in urate clearance was suggested to cause the increase in plasma urate level.

Conclusions: The present study demonstrated that oral intake of fructose induces an increase in plasma urate level within a short time and that a decrease in renal urate clearance could mainly work for that.

**HIGHER BODY FAT IS AN INDEPENDENT RISK FACTOR FOR METABOLIC SYNDROME IN GOUT**

Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University; Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou, China

Background: The development of gout is associated with obesity and metabolic syndrome (MS). Obesity is defined by body mass index (BMI). However, BMI has been challenging for the limitation of not distinguishing different comprising tissues of the body. Body composition (BC) has been frequently recommended to assess metabolic status and will eventually replace BMI as a more reliable measure.

Objectives: To investigate the characteristics of BC in gout patients and their significance with disease characteristics.

Methods: BC was assessed in 180 consecutive gout patients and 1,860 control subjects (white-collar employees in Zjiangjing Innopark of Shanghai) by bioelectrical impedance analysis. Overfat was defined by body fat percentage (BF%) as ≥25% for men and ≥35% for women. Demographic and clinical data as well as comorbid diseases were collected simultaneously. For the significant differences of the body fat in gout patients, BC was assessed in 180 consecutive gout patients and 1,860 control subjects, gout patients were characterised by higher BMI (25.4±3.5 kg/m² vs. 24.3±3.3 kg/m²), fat mass (19.3±6.9 kg vs. 16.5±6.2 kg), trunk fat mass (10.2±5.4 kg vs. 8.4±3.4 kg), BF (26.2±6.6% vs. 22.7±6.2%), proportion of male fat (55.6% vs. 13.3%), hyper-low density lipoproteinemia (55.6% vs. 17.8%) and fatty liver (72.4% vs. 43.2%).

Results: Among 180 gout patients recruited, the mean age was 42.5±15.5 years, mean serum uric acid (sUA) was 9.0±2.4 mg/dl and 17.2% of patients presented tophi. The mean BMI was 25.4±3.5 kg/m² with 44.4% overweight and 35% for women. Demographic and clinical data as well as comorbid diseases were collected simultaneously. For the significant differences of the body fat in gout patients, BC was assessed in 180 consecutive gout patients and 1,860 control subjects, gout patients were characterised by higher BMI (25.4±3.5 kg/m² vs. 24.3±3.3 kg/m²), fat mass (19.3±6.9 kg vs. 16.5±6.2 kg), trunk fat mass (10.2±5.4 kg vs. 8.4±3.4 kg), BF (26.2±6.6% vs. 22.7±6.2%), proportion of male fat (55.6% vs. 13.3%), hyper-low density lipoproteinemia (55.6% vs. 17.8%) and fatty liver (72.4% vs. 43.2%).

Conclusions: Our results indicated higher body fat in gout patients which is an independent risk factor for MS.

**COMORBIDITIES AND METABOLISM INDEXES IN PATIENTS WITH HUA COMPARE WITH NORMAL URIC ACID: A DATA FROM 33319 PATIENTS BETWEEN 2014 AND 2015**

J. Xu, H. Zhu, Y. Su, Dept of Rheumatology and Immunology, Peking University People’s Hospital, Beijing, China

Objectives: To investigate and compare the differences in Comorbidities and metabolism indexes between patients with high and normal uric acid.

Methods: All the outpatients were enrolled in this cross-sectional study from September 2014 to September 2015 in Peking university people’s hospital. The patients were divided into high uric acid (HUA) and normal uric acid according to the international definition of HUA. The distribution characteristics of UA level and prevalence of comorbidities and metabolism indexes, including, hyperlipemia, hypertension, hyperglycemia, diabetes mellitus, coronary artery disease, heart failure, renal disease, were significantly increased in HUA patients than those with normal uric acid, such as hypertension, hyperlipidaemia, diabetes mellitus (DM), diabetic nephropathy (DN), chronic renal failure. And male patients with HUA had higher prevalence of gout than females (10.76% VS 6.52%, p=0.001).

Results: Among 33 319 outpatients, with an average age of 56.4, 44.4% were men and 19.2% had higher uric acid level than women (368±131.3 umol/ vs 300±95.5 umol/L, p<0.001). In all patients, 25.6% had HUA and the sex ratio was about 1:1, while 50–59 age were most common in men and women with 60–69 age were the most. Both the levels of uric acid in males and females had a significant relationship with the metabolism indexes above-mentioned. However, the levels of uric acid in females had a positive correlation with age and blood glucose, the levels of uric acid in males were negative correlated with age and bloodglucose. And the uric acid levels in females displayed a higher relationship with coronary artery disease and eGFR. The prevalences of common chronic metabolic disorders, were significantly increased in HUA patients than those with normal uric acid, such as hypertension, hypertensive renal disease, hyperlipopdenia, diabetes mellitus (DM), diabetic nephropathy (DN), chronic renal failure. And male patients with HUA had higher prevalence of gout than females (10.76% VS 6.52%, p=0.001).

Conclusions: The prevalence of HUA in females was showing a increasing trend and the uric acid level in females had more influence in blood glucose and renal function than males.

THE URATE-LOWERING EFFECT OF FEBUXOSTAT 80 MG AND 40 MG (80 MG FILM-COATED TABLETS SPLIT IN HALF) IN GOUT PATIENTS IN DAILY CLINICAL PRACTICE

M. Flendrie1, B. van den Bermt2, V. Huiskses2, M. Hoelnagels1, F. van den Hoogen1.

1Rheumatology; 2Pharmacy, Sint Maartenskliniek, Nijmegen, Netherlands

Background: In Europe, the urate-lowering drug febuxostat for gout is registered in two strengths, 80 mg and 120 mg, but not 40 mg. Starting 40 mg can sometimes be considered desirable, for instance for safety reasons. Splitting an 80 mg film-coated tablet in half is an option, but is off-label and might violate coating function and influence effectiveness and safety.

Objectives: To investigate the urate-lowering effect and safety of starting febuxostat at 40 mg once daily (80 mg film-coated tablet split in half) in gout patients compared to 80 mg once daily.

Methods: Single-centre retrospective study on all gout patients starting febuxostat 80 mg or 40 mg (80 mg film-coated tablets split in half). Patients characteristics were collected, as well as starting dose and starting date of febuxostat, follow-up time, adverse events (AEs), stop date and reason, serum urate (sU) and creatinin (sCreat) over time and relevant comorbidity.

Patient characteristics were compared by Chi-square or T-test. Mean sU, percentage change from baseline and percentage of patients reaching targets (sU <0.36 or 0.30 mmol/L) were tested using the appropriate t-test.

Results: 36 gout patients started febuxostat between April 1st 2012 and July 1st 2017. Twenty-three started on 80 mg and 13 on 40 mg once daily. Patient characteristics are shown in table 1. Table 2 shows mean sU at baseline and after start, percentage change in sU and percentage of patients reaching targets. Median follow-up time was 1.6 years (range 0 – 6.7); 1.4 y (0 – 6.7) resp. 1.9 (0.4 – 5.5) for 80 mg resp. 40 mg group. Figure 3 shows mean sU per group in the first year.

Conclusions: Both daily dosages febuxostat of 80 mg and 40 mg film-coated tablets split in half result in significant decline in sU levels within 12 weeks. A starting dose of 80 mg febuxostat appears more effective in reducing sU levels. Selection bias may be a problem.

ULTRA-LOW DOSE ANTI-INTERLEUKIN IN CHRONIC GOUT: A SAFE AND SUCCESSFUL COMBINATION THERAPY WITH LOW DOSE COLCHICINE AND URATE LOWERING AGENTS

M. Capasso1, F. Gallicchio, M. Mattucci Cetinio. AOUC Careggi, Reumatologia, Firenze, Italy

Background: Gout is the most common inflammatory arthritis in humans; is caused by deposition of monosodium urate (MSU) crystals within and around joints. Left untreated, a more chronic course may develop, characterised by persistent inflammation and visible MSU deposits (tophi), bone erosion, irreversible joint damage, and significant disability. Management is based on two strategies: treating pain and inflammation with NSAIDs, steroids and colchicine and preventing flares and urate deposition with urate-lowering therapy. For many patients, standard treatments are ineffective or contraindicated, mainly due to comorbidities. The main mechanism of crystal-induced inflammation is interleukin 1b (IL-1b), which strengthens the relevance of targeting IL-1b in patients with crystal-induced arthritis. Selective blockade of IL-1b has shown to drastically reduce pain, inflammation and risk of flares. Three biologic therapies inhibits IL-1b and have been studied for difficult to treat acute gouty arthritis flares: anakinra, rilonacept and canakinumab.

Objectives: Evaluate the efficacy of low dose anti-IL1 inhibitors administer by sublingual route in gout arthritis with remitting course that cannot be completely controlled with standard therapy regimens

Methods: Inclusion criteria was diagnosis of chronic gouty arthritis with remitting course (acute flares in patients with chronic gout and no inter-critical period), high CRP levels and need of chronic assumptions of NSAIDs or steroids, with flare at suspension. 20 patients fulfilled the criteria (exclusion criteria: intolerance to the study drug, poor compliance to therapies or diet, hyperuricemia, end stage renal disease) The study consist of two consecutive parts. An observational part were patients are treated for 6 months with 0.5–1 mg/daily of colchicine and 300 mg/daily of allopurinol. They performed visits at baseline, 3 and 6 months and we collected data about blood tests, VAS score, number of flares, compliance to therapy and adverse events. An experimental part were we added GUNA anti-IL1 (an infinitesimal dilution of anakinra that has has a concentration of 10 fg/mL) 20 drops administrated SL. Again patients performed visits at baseline (which coincides with the last visit of the observational phase), 3 and 6 months and we collected the same kind of data.

Results: At 6 months after introduction of GUNA anti-IL1 all patients, except 1, experienced no flares of disease, levels of CRP became negative and VAS pain scale was significantly reduce (CRP level p<0.0001; VAS p<0.0001). NSAIDs and steroid consumption was significantly reduced. No adverse events happened

Conclusions: Ultra-low dose of anti-IL1 agents added to standard therapy is an effective and safe way to achieve disease remission

FEATURES OF KIDNEY FUNCTION AND URODYNAMICS AT PATIENTS WITH CHRONIC GOUT BASED ON COMPLEX RENAL SCINTIGRAPHY DATA

M. Gromova1, O. Klyakal1, V. Tsurko1, A. Kashkadayeva1, S. Averinova2, S. Shiryaev1, 1PIROGOV RUSSIAN NATIONAL RESEARCH MEDICAL UNIVERSITY (NRNMRU), Moscow, Russian Federation

Background: One of the frequent manifestations of gout is the gout nephropathy. For assessment of the urinary system functional reserves and the risk of renal failure routine analyses of urine in combination with a sonography are often not enough. Modern technology of the systemic examination of nephrological status based on complex renal scintigraphy (SENS-CRS) was developed in the laboratory of radiosotope diagnosis in ‘N.N. Blokhin National Medical Research Center’ and realised as an automated workplace. SENS-CRS technology is designed for assessment of the urinary system functional reserves and the risk of renal failure at all macrostructural levels, and allows lowest radiation doses (0.6 mSv for one patient).

Objectives: To define features of kidney function and urodynamics at patients with chronic gout based on the complex renal scintigraphy (CRS) data.

Methods: 59 medical records of patients with gout (2007–2011) were analysed retrospectively. Most of the patients (95%) were men, average age was 54.4±9.5 years. Duration of the disease was 8–11 years. All patients had chronic gouty arthritis, 28% of patients had tophuses. The CRS tests was carried out on a two-detector gamma camera with simultaneous 2 projections recording. 1,440mCi-Tc-tech-nephore was used, a Russian radiopharmaceutical (RP) from the group of bispine (CPPD) as a frame hemodynamic and a parenchymal therapeutic product concentrating mainly in the nephrons via filtration, with partial (10%–15%) involvement of secretion. Working protocol consisted of a base 21 min (1 min angiophase) study with administration of RP and a delayed 21 min study without administration of RP, but after taking 200–300 ml of water and/or an antispasmodic or diuretic drug to identify persistent urodynamic dysfunction. The interpretation of CRS data is based on a concentrational-hydrodynamic model of urinary excretion and SENS-CRS software. The Statistica 10.0 software was used too.

Results: According to CRS tests patients with gout had, on average, the level of blood cleansing from RP reduced slightly with a trend to a moderate level, and buffer retention of RP labelled blood in extrarenal structures increased. The signs of a relative hemostasis were found against the background of fast excretion accelerated by taking hypotensive drugs. Quantitative analysis of CRS data allows to estimate sustainability of relative urine delays in the pyelocutaneous system (PCS), in 70% of patients residual urostasis in the renal parenchyma and groups of calyx remained relatively stable, and the urostasis signs in the renal pelvis were disappearing. This result means that there could be a latent increased residence time of substances such as uric acid as well as nephotoxic drugs in the kidney parenchyma. This requires control of correct drugs dosage and when prescribing repeated therapy courses.

Conclusions: The SENS-CRS technology provides the quantitative assessment of kidney blood cleansing from RP and concentrational function of parenchyma as well as unique quantitative indicators of urodynamic delays in all parts of urinary tract. This kind of functional diagnostics allows to monitor parenchyma and urinary tract condition promptly and with lowest radiation doses, apply therapeutic measures to prevent more severe kidney dysfunction and refer patients to a specialist consultation.

PHARMACOKINETICS, PHARMACODYNAMICS AND SAFETY OF NC-2500, A NOVEL XANTHINE OXIDASE INHIBITOR, IN HEALTHY JAPANESE MALE SUBJECTS

M. Hirao1, S. Kobayashi2, E. Miyama2, T. Ohta1, M. Yamamoto2, T. Yamakawa1, 1Discovery Research Laboratories, Nippon Chemiphar Co., Ltd., Misato, Saitama Prefecture, 2Development Planning Department, Nippon Chemiphar Co., Ltd., Tokyo, Japan

Background: Gout flare due to rapid urate reduction after initiating urate-lowering therapy (ULT) is one of the major issues in the therapy, which impairs patients quality of life and adherence. For the prevention of it, the guidelines in the ACR, the EULAR and Japan recommend initiating ULT with a low starting dose followed by adequate titrations, however it is rare in clinical settings. NC-2500 is a novel orally active xanthine oxidoreductase (XOR) inhibitor in development for the treatment of gout/hyperuricemia. Preclinical studies showed that multiple doses increase the plasma concentration and enhance the urate-lowering effect of NC-2500, suggesting that NC-2500 may decrease the risk of gout flare when initiating the treatment.

Objectives: The aim of this study was to evaluate the pharmacokinetics, pharmacodynamics and safety of NC-2500 in healthy Japanese male subjects.

Methods: A Phase 1, randomised, single-blind, placebo-controlled, single and multiple ascending dose study was conducted. Each cohort consisted of 8 subjects, with 6 receiving NC-2500 and 2 receiving placebo orally. A total of 5 cohorts were studied in the single-dose study (10 mg to 160 mg, fasted conditions) and 4 cohorts were studied in the multiple-dose study (10 mg to 80 mg, fed conditions). The levels of NC-2500 and urate in plasma/serum and urine were assayed at pre-determined time points. Safety and tolerability were assessed by physical examination, vital signs, electrocardiography, clinical laboratory tests and adverse events (AEs).

Results: Following single oral doses of NC-2500, maximum plasma concentration (Cmax) and area under the plasma concentration-time curve (AUC) increased approximately in a dose-proportional manner except that the increase in the Cmax at 160 mg was less than dose proportional. The time to reach the Cmax (Tmax, median) was at 2.0–3.5 hours post dose and food intake delayed the Tmax by 1 hour. In the presence of food, NC-2500 absorption appeared to decrease slightly or not be affected. Plasma NC-2500 concentration increased...
with multiple doses and the Cmax and AUC on Day 7 at 80 mg were 1.4–1.5 times higher than those on Day 1. NC-2500 was hardly excreted into the urine. Effects of NC-2500 on serum urate (sUA) levels were approximately dose-dependent. The sUA level in the single 160 mg dose cohort decreased by 1.03 mg/dL. Moreover, in the subjects receiving multiple doses of 80 mg, the sUA level decreased gradually over the 7 days with a decrease from baseline of 1.93 mg/dL. The incidence of AEs was similar between NC-2500 and placebo treatments and all AEs were mild in severity.

Conclusions: From the results, NC-2500 is expected to have potential to resolve the issues of current ULT by its unique urate-lowering property to decrease acute flare, with no or minimal titrations. As for safety, NC-2500 was considered safe and well-tolerated. Furthermore, NC-2500 was hardly excreted through the kidneys, which can be a favourable profile for patients with renal impairment, frequently observed in gout.

**Diet may play essential role for the success of the urate lowering therapy in gout**

N.B. Kalkan, M.E. Tercan, Family Medicine; Rheumatology, University of Health Sciences, Kartal Dr. Lutfi Kirdar Training and Research Hospital, Istanbul, Turkey

**Background:** Chronic deposition of monosodium urate crystals, in case of hyperuricemia, is the main cause of the gout. Furthermore, lowering uric acid to the targeted levels is the main therapeutic objective in chronic gout treatment. Uric acid lowering treatment (ULT) has three main aims: Practicing lifestyle modifications, pharmacologic ULT and targeting co-morbid illnesses. Thus, patients’ medical and therapeutic properties may have a role in successful ULT.

**Objectives:** We evaluated the demographic and therapeutic properties; co-illnesses and disease features of the patients that would relate with the success of ULT. Then, we compared these parameters between the gout patients with successful ULT and inadequate ULT.

**Methods:** 66 gout patients on pharmacologic ULT were enrolled to the study. Non-adherence to pharmacologic ULT was accepted an exclusion criteria. Demographic and therapeutic features; co-illnesses and disease features of the patients were obtained during the study. Then, we compared these parameters between the patients with successful ULT and inadequate ULT.

**Results:** Adherence to diet was found different between groups (OR, 7.00; CL% 95 2.27–21.56). All other features including maximum allopurinol dosage were similar. Only one patient from successful ULT group and none of the patients in inadequate group had an drinking habit.

**CONCLUSIONS:** Diet may play essential role for the success of the urate lowering therapy in gout.

**Disclosure of Interest:** None

**doi:** 10.1136/annrheumdis-2018-eular.2078

**Is gout a chronic inflammatory disease of a low level of activity?**

M.M. Basaric, N. Damjanov, M. Perovic-Radak. Institute of rheumatology, Belgrade, Serbia

**Objectives:** To determine the presence of physical, laboratory and ultrasound (US) signs of inflammation on the affected joints, but also on the joints that in the clinical sense never showed an inflammatory reaction in the intercritical gout period.

**Methods:** This prospective study included 43 patients (pts.) with diagnosis primary gout (20 with and 23 without acute gout attacks). The research included: demography; medical history; laboratory analyses; sedimentation of erythrocytes (ESR), C reactive protein (CRP), and serology; physical: detect tender and swollen joint; and US examination detect synovial fluid and hypertrophy, Power Doppler (PD) signal and “double contour” sign on the wrist, first metatarsal joint (MTP1), tibial (TT) joint and knee.

**Results:** A physical examination showed presence of 78% tender and 43% swollen joints in the group pts. with acute gout attack, but also 23% pts. had painful and 10% swollen joints in the group without acute gout attack (p<0.001). In the group with acute gout attacks the mean ESR was 32.80 mm/L, value CRP was 8.20 mg/L and leukocytes (Le) (9.09 × 10^9/L). So we found that there was no statistical difference (p>0.5) in the laboratory parameters (ESR, CRP and Le) between the groups. There was also no statistically significant difference in the findings of US signs of “double contour” (p=0.5), synovial fluid and hypertrophy (p=0.05), per group, but the presence of PD signal statistics was more often observed in a group of patients in an acute gout attack (p=0.05), table 1.

**CONCLUSIONS:** We found that diet was the only factor that relate with success of ULT while patients were on pharmacologic ULT. So, clinicians should emphasise the importance of all part of ULT including diet with informing patients about the nature of disease and benefits of ULT during visits.

Abstract AB1041

OCCURRENCE OF MAJOR CARDIOVASCULAR EVENTS IN PATIENTS WITH GOUT TREATED WITH FEBUXOSTAT

N. Quilis, 1 M. Andres, 2,3, 4, S. de Reumatologia, Hospital Universitario del Vinalopó, Elche, 5 Dpt Medicina Clinica, Universidad Miguel Hernández, 4 Seccion De Reumatologia, Hospital General Universitario De Alicante-ISAIBAL, Alicante, Spain

Background: Controversy persists regarding the use of febuxostat (FBX) in patients with gout and the development of cardiovascular (CV) events. In both APEX 2 and FACT 7 trials a higher risk was identified in those on FBX arm compared to those on allopurinol, but this was later not confirmed in CONFIRM 8 trials and the extension phases. Recently, the FDA has published a warning on the risk of CV death in relation to FBX, based on preliminary data of a safety study enrolling 6000 participants. 8

Objectives: To assess the occurrence of CV events in patients with gout after being prescribed with FBX in clinical practice.

Methods: Retrospective review of patients with crystal-proven gout enrolled in an inception cohort since January 2014. Epidemiological (age, gender), clinical (CV risk factors, CV disease background), and laboratory variables (serum urate, creatinine, CRP, LDL-C) were collected. The presence/absence of CV events was assessed using a visual analogue scale (VAS) for evaluating pain. We measured the VAS results in two groups, one with CV events and the other without them. The VAS results were split in three groups: low, moderate and high. Among the patients on dialysis, 46.1% declared a low VAS, 36.5% moderate and 17.3% a high VAS, while in the control group the distribution according to VAS was 46% in the low, 34% in the moderate and 20% in the high lot.

Results: In the cohort, 43 patients were treated with FBX, but three were excluded (two early stopped FBX because of rash, and one was lost of follow-up), so finally 40 patients were analysed. Their median age was 76 years (p25-p75 70–79), being 24 of them men (60%), CV risk factors were prevalent, especially hypertension (87.5%), and 20 of them (50%) had established CV disease. Median time since first gout attack was 1.5 years (p25–75 0.0–9.5) and 14 patients (35%) were tophaceous. After initiating FBX, 7 cases (17.5%, 95% CI 5%–30%) of CV events were identified: three of CHF (7.5%), two of CHD (5.0%) and one stroke (2.5%), with no PAP events. Five CV-related deaths (12.5%) were noted. The occurrence of CV events significantly associated with an older age and background of established CV disease (table 1).

Conclusions: In our cohort, about one on six patients treated with FBX suffered from a CV event, some being fatal. The development associated with older age and CV disease background, so it merits a cautious use in this setting, although whether these CV events are directly related to FBX needs further clarification.

PATHOLOGIC MUSCULOSKELETAL ULTRASOUND FINDINGS IN PATIENTS WITH CHRONIC KIDNEY DISEASE ON DIALYSIS- A PILOT CONTROLLED STUDY

R.D. Declercq, 1 M. Bojinca, 1 C.A. Capusa, 2 A. Zugrava, 2 V.C. Bojinca. 1 Internal Medicine and Rheumatology, St. Maria Clinical Hospital, 2 Internal Medicine and Rheumatology, Dr I. Cantacuzino Clinical Hospital; 3Nephrology, Carol Davila Clinical Hospital, Bucharest, Romania

Background: There are numerous studies about the musculoskeletal abnormalities associated with dialysis, but most of them target osteoporosis and the bone metabolism. While this is, in fact, of great importance, we consider that the abarticular abnormalities should also be taken into account: Because of the pain they cause and the quality of life impairment in patients already affected in this domain, suffering from depression or at its’ edge.

Objectives: We aimed to detect the dialysis associated soft tissue abnormalities, using musculoskeletal ultrasound (MSUS) scanning of patients diagnosed with late-stage chronic kidney disease (CKD) on dialysis. In order to achieve this, we compared the data obtained from this group, to a control group of pre-dialysis late-stage CKD.

Methods: Over the last 8 months, we ran a prospective study including 108 patients. The study group included 52 patients with stage G5 (GFR <15 ml/min/1.73 m 2), on dialysis – hemodialysis (HD)/hemodialysis (PD), while the control group included 50 patients with stage G5 (GFR <15 ml/min/1.73 m 2), pre-dialysis). Each patient had 68 joints scanned with a Samsung HM70A machine, by the same ultrasonographist, in order to avoid the inter-observer variability. Also, each patient completed a visual analogue scale (VAS) for evaluating pain.

Results: The findings included median nerve entrapment (71.1% in the study group, 6% in the control group), tendon calcifications (61.5% in the study group, 20.4% in the control group). There were no particular abnormalities found only in the control group, but the percentages of the common findings were significantly higher.

The VAS results were split in three groups: low, moderate and high. Among the patients on dialysis, 46.1% declared a low VAS, 36.5% moderate and 17.3% a high VAS, while in the control group the distribution according to VAS was 46% in the low lot, 34% in the moderate and 20% in the high lot.

Conclusions: We detected soft tissue abnormalities in an important percentage of patients on dialysis, but the results were disproportionate to the algo-functional symptoms. We found a higher percentage of low VAS then we were expecting. Considering the results, we plan to continue our study, aiming to create a rehabilitation programme adapted to the needs of the dialysed patient.

THE CLINICAL PROFILE OF GOUT SIGNIFICANTLY DIFFERS BETWEEN MALE AND FEMALE

R. te Karper1, C. van Durme2, M. Janssens3, A. Boonen2, T. Jansen2.
1Rheumatology, Maastricht University Medical Center, Maastricht; 2Rheumatology, VieCuri Medical Center, Venlo, Netherlands

Background: Gout, the most common type of inflammatory arthritis, is considered as a predominant male disease. Notwithstanding, there is an increased risk of gout in female after the menopause.

Objectives: Our objective was to assess differences in the clinical features between female and male patients.

Methods: Data of newly diagnosed gout patients attending the rheumatology outpatient clinics of one secondary and one tertiary i.e. university centre in the south of the Netherlands were used. We compared baseline characteristics of males and females regarding demographics, BMI, presence of tophi, medication use (diuretics, prophylaxis of gout and uric acid lowering drugs), serum and urine concentration of uric acid and creatinine, and comorbidities.

Results: Of 116 patients with gout were enrolled and categorised by two groups, 1R rheumatology, Maastricht University Medical Center, Maastricht, Netherlands, 2R Rheumatology, VieCuri Medical Center, Venlo, Netherlands

Conclusions: The clinical profile of gout in females significantly differs compared with males: significantly older, more advanced decrease in renal function and higher prevalence of hypertension in the females. As Dutch guidelines recommend starting with a diuretic for the treatment of hypertension in patients aged 70 +, this may have a role in explaining the higher numbers of females using diuretics. The start of diuretics has previously been associated with hyperuricemia and increases the risk of gout in the female population. Although diuretic use has proven to be a safe and effective first-line treatment for hypertension, our results suggest that diuretic use in combination with a decreased renal function is associated with an increased risk at developing gout in females, and possibly needs reconsideration. Furthermore, despite the fact that the FEUs was similar distributively between genders did seem to have a lower urinary uric acid excretion. However, the number of patients with tophi and nephrolithiasis is the first harbinger of kidney damage. However, predictors of GN have not been established for today.

Disclosure of Interest: None declared

MICROPROTEINURIA AS A MARKER OF SUBCLINICAL GOUTY NEPHROPATHY

S. Smirnov, M. Franchuk, R. Komorovsky. Internal Medicine No.2, I. Horbachevsky Ternopil State Medical University, Ternopil, Ukraine

Background: The prevalence of kidney damage in patients with gout ranges from 30% to 70%. Currently the concept of “gouty nephropathy” (GN) comprises all renal pathologies due to gout. There is no clear opinion whether hyperuricemia is a marker of renal dysfunction or risk factor. It is important to identify the early stages of GN as its course is subclinical for a long period of time. Microproteinuria is the first harbinger of kidney damage. However, predictors of GN have not been established for today.

Objectives: To establish predictors of GN.

Methods: A total of 103 patients with chronic gouty arthritis were examined in rheumatology department of Ternopil University Hospital. All patients had no history of any kidney disease. ELISA method was used to determine microproteins in urine. Subsequently, patients were divided into 2 groups: I (n=58) – patients with subclinical gouty nephropathy, abnormal microproteins level (56.3%), II (n=45) – control group, patients without kidney damage, normal microproteins level (43.7%). Statistical analysis was performed with STATISTICA software.

Results: Patients with subclinical gouty nephropathy had a higher prevalence of arterial hypertension and metabolic syndrome. The prevalence of osteoarthritis, diabetes mellitus and dyslipidemia was the same in both groups. Also, group I patients showed longer duration of the disease, greater radiologic changes, arterial hypertension and metabolic syndrome. The prevalence of osteoarthritis, diabetes mellitus and dyslipidemia was the same in both groups. Also, group I patients showed longer duration of the disease, greater radiologic changes, arterial hypertension and metabolic syndrome.

Conclusions: Formation of GN is asymptomatic, causing delays in early diagnosis, but can be suspended timely. Gouty nephropathy develops in 56.3% of patients with chronic gout arthritis, and manifests by microproteinuria in the early subclinical stages. Duration of the disease, obesity, presence of tophi, arterial hypertension, hyperuricemia, increased triglycerides and low-density lipoproteins levels were found to be predictors of gouty nephropathy.

**AB1047 CERVICAL POTT’S DISEASE: 5 CASE REPORTS AND REVIEW OF LITERATURE**

**Background:** Spinal tuberculosis (Pott’s disease) is the most common as well as one of the most dangerous forms of skeletal tuberculosis and accounts for 50% of all cases of skeletal tuberculosis. Pott’s disease is still common in developing countries. Although the thoracolumbar junction seems to be the most common site of the spinal column involvement, cervical localization is scarce and accounts for 2% to 5% of spinal tuberculosis. Furthermore, the incidence of neurologic complications in spinal tuberculosis varies from 10% to 43%.

**Objectives:** The purpose of this study was to perform an updated review and present our experience with 5 cases of tuberculosis of cervical spine, including clinical characteristics, diagnostic modalities and management of spinal tuberculosis.

**Methods:** A review of 5 cases of cervical Pott’s disease collected at the Department of Neurosurgery of National Institute of Neurology of Tunis over a period of 2 years, between 2011 and 2012 and an updated literature review.

**Results:** The average age of our patients was 35 years old with extremes ranging from 16 to 63 years old. There is a slight male predominance. The diagnostic delay is on average 6 months. The clinical manifestations were dominated by cervical pain (4 cases) and progressive spinal cord compression syndrome (3 cases). The biological inflammatory syndrome is found in only one patient. The intra-dermal reaction to tuberculin is positive in 4 patients. X-ray of the cervical spine, CT scan and magnetic resonance imaging were performed in all patients. All patients underwent a surgical resection. The medical treatment was administered to all our patients. The evolution was favourable, clinically and biologically, under anti-tubercular treatment.

**Conclusions:** Tuberculous spondylodiscitis remains a major global public health problem in endemic countries that affects mostly young adults in their most productive years. Thoracolumbar junction seems to be the most common site of the spinal column involvement in spinal tuberculosis (95%) and cervical spine is concerned in only 5% of cases. The delayed diagnosis, between 3 and 20 months, explains the frequency of neurologic deficits which are found in proportions of 20% to 40%. For the diagnosis of spinal tuberculosis, magnetic resonance imaging is more sensitive using radiologic technique than x-ray and more specific than computed tomography. Antitubercular treatment remains the cornerstone of treatment. Surgery may be required in selected cases. With early diagnosis and early treatment, prognosis is generally good.

**AB1048 EVOLUTION OF INFECTIOUS SACROILIITIS ACCORDING TO THE GERM**

H. Ben Abid1,2,3, S. Rekk3, S. Bousaid6, H. Ajjani2, H. Sahli2, I. Cheour2, M. Elleuch4,5,6,7,8,9, H. Kchir1, D. Kaffel2, H. Dabbabi1, D. Issaoui1, H. Sahli3, W. Hamdi2,3, H. Kchir1,2, D. Kaffel2, H. Dabbabi1, D. Issaoui1, H. Sahli3, W. Hamdi2,3

**Background:** Infectious sacroiliitis is a rare rather rheumatological emergency that has a misleading semiology because of the deep condition of the joint, the germ responsible plays an important role in this semiology and in its evolution.

**Methods:** This is a retrospective study of 42 patients who have been hospitalised in the LA Rabta for Infectious Sacroiliits from 1999 to 2017. The epidemiological data (age/sex) were recorded as well as the clinical radiological and biological data (symptoms, inflammatory assessment, x-rays, CT scan and/or IRM biopsy).

**Results:** Forty-two patients were included in this study. The average age was 36.7 years old, sex distribution is 19 women 23 men. Bacillar sprouts are responsible in 48.15% of cases: Staphylococcus aureus 28.7% escherichia coli 17.07% and 2.38% streptococcus, the progression was favourable in 87.4% of the cases under appropriate antibiotic therapy for the rest: 23.8% deaths, 2.38% state of septic shock. 7.84% mortality inherent to the treatment: tuberculosis is responsible for 37.2% of infectious sacroiliits with a favourable evolution in 77.6%, a complication related to treatment is noted in 17.64%, a subcutaneous abscess 2.34%, multifocal bone tuberculosis 2.38% Brucellosis sacroiliits is diagnosed in 14.65% of cases, the evolution is favourable in 7.51%, in 4.76% a rapid progression towards anklyosis was noted despite appropriate antibiotic therapy, 2.38% a progression towards brucellosis chronic.

**Conclusions:** Common germs are most responsible during infectious sacroiliitis and seem to have the best prognosis, tuberculosis is responsible for various complications and its treatment is at high risk of iatrogenic which limits the therapeutic choice of the clinician. Chronicity is the most feared development during Brucella sacroiliits as antibiotic therapy is no longer effective.

**AB1049 RHEUMATOLOGICAL MANIFESTATIONS DURING CHRONIC HEPATITIS C**

H. Kchir1,2, D. Kaffel2, H. Dabbabi1, D. Issaoui1, H. Sahli2, W. Hamdi2, M. Elleuch4,5, M.M. Kchir1, R. Debbeche6, N. Maamoun1, C. Gastroenterology, La Rabta Hospital, Tunis; 2. Rheumatology, Kassab, Manouba; 3. Rheumatology, La Rabta Hospital, 4. Gastroenterology, Charles Nicolle Hospital, Tunis, Tunisia

**Background:** Chronic hepatitis C (CHC) is assimilated to a systemic disease because of his multiple extrahepatic manifestations notably rheumatological.

**Objectives:** The aim of this study was to determine the prevalence and the characteristics of rheumatological manifestations (RM) associated with CHC.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3198
AB1050

REACTIVE ARTHRITIS DUE TO PARVOVIRUS B19 MAY BE OVERLOOKED IN ADULT RHEUMATOLOGY

K. Hutton1, K. M. Carlsen2. 1Department of Dermatology, Bispebjerg University Hospital, Copenhagen; 2Copenhagen Centre for Arthritis Research, Rigshospitalet Hillerød, Hillerød, Denmark

Background: In 1991 parvovirus B19 analyses, for the 5th disease of childhood, were established in Denmark, revealing the first epidemic. Prior to this, erythema infectiosum, “slapped cheek appearance” and reactive arthritis were only clinical diagnoses. A project in the PhD thesis Human Parvovirus B19 Erythrovirus – Methods established for Virological and Diagnostic Aspects 2006 APMS 120;114;1–121, revealed that 35.4% of 3,628 pregnant women were susceptible to parvovirus B19 infection.

Objectives: To present manifestations of parvovirus B19 in a susceptible adult population

Methods: During the years 2011, 2014 and 2017 the following patients were admitted. Case 1: A 61-year-old woman with rash and thrombocytopenic purpura in April 2011. Routine blood tests, RF, anti-CCP, tuberculosis, ANA and anti-ds DNA, serological tests for viral and autoimmune hepatitis were performed. Also ECG and finally, parvovirus B19 IgM and IgG, PCR for Parvovirus B19 was performed, June 2011. Case 2: A 52-year-old woman with rash, swollen joints and pericarditis in May 2011. Case 3: A 45-year-old woman with swollen joints, March 2011. Case 4: A 45-year-old woman with swollen joints and rash, November 2014. Case 5: A 68-year-old man admitted to the Department of Dermatology and diagnosed with Sweet’s Syndrome, severe anaemia and swollen joints, September 2014. Case 6: A 62-year-old woman transferred due to parvovirus B19 positive IgM and IgG antibodies with reactive arthritis and itching skin rash, June 2017. All six patients were tested as mentioned above in Case 1.

Results: In all 6 patients, routine tests were normal. HBV, STD, ANA, anti-ductilus, TB, RF and anti-CCP were negative. Parvovirus B19 DNA by PCR, IgM and IgG antibodies were positive except for the last patient, who did not have PCR but a punch biopsy of her maculo-papular rash performed. Ultrasound revealed oedema and synovitis in the patients.

The 1st patient contracted parvovirus B19 from her 4-year-old grandchild, the 2nd during work in a daycare. They both had self-limiting infections and pericarditis resolved without treatment. The 3rd patient was also infected from daycare and her persistent synovitis, required DURADARs and biologic treatment. The 4th patient was treated with DMARDs for one year. The 5th patient had severe anaemia for ½ year, almost overlooked due to Sweet’s syndrome but his anaemia (due to replication of the parvovirus in erythroblasts) was finally diagnosed. The patient continues treatment for Sweet’s Syndrome at the Department of Dermatology. The 6th patient slowly recovered from her skin rash and reactive arthritis.

Conclusions: The 5th disease of childhood was almost overlooked in 6 patients probably due to their ages. Therefore, clinicians must be aware of the need for parvovirus B19 analyses in seronegative RA patients. Parvovirus B19 occurs as epidemics approximately every 3rd year as an occupational risk, jeopardising patients’ female family members who may be pregnant and develop foetal hydrops and anaemia necessitating intrauterine blood transfusion at a Foetal Medical Centre.

BRUCELLOSIS IN RHEUMATOLOGY: A STUDY OF 27 CASES IN TUNISIA

K. Saadaoui, H. Sahli, S. Rekki, H. Ajmani, M. Mariem, T. Aissaoui, S. Boussaid, E. Cheour, M. Elleuch, on behalf of CHU LARABTA, Rheumatology, CHU LA RABTA, Tunis, Tunisia

Background: Brucellosis is an endemic zoonosis in the Mediterranean basin. The osteo-articular localization, although rare, remains redoubtable.

Objectives: The aim of our work is to study the characteristics of osteo-articular brucellosis in Tunisia.

Methods: This is a descriptive retrospective study including 27 cases of osteo-articular brucellosis, collected in a rheumatology department over a period of 12 years (2006–2017)

Results: The Sex Ratio Female/male was 1.07 with an average age of 50.9 years. In the 27 patients, the brucellosis diagnosis was made by PCR and serological tests. In 6 cases (22.2%), the WBC average was 9.49×10^9/L. In 2 cases (7.4%), the CRP was elevated in 26 patients with an average of 59.6 mg/L. Laboratory examination found high erythrocyte sedimentation rate in 23 patients with an average of 9.49 mm/h. CRP was elevated in 26 patients with an average of 59.6 mg/L. WBC was elevated in 23 patients (85.2%) and sarcoidosis in 4 patients (14.8%). Spinal or cervical pain was found in all patients. Fever was present in 22 patients. Swell in 11 patients, loss of weight or appetite were respectively found in 16 and 12 patients. Eleven patient reported fatigue. Further examination, the spondylosis was multi-focal in 2 cases. Spinal disc biopsy was performed in only 4 cases, neither anapathological nor bacteriological examination was conclusive. The treatment was based on the cyclople and rifampic combination for an average duration of 4.5 months. The evolution was favourable in the majority of the cases with a relapse in only 2 cases. The most frequent location is spinal and whose adequate treatment allows a favourable evolution.

Conclusions: Osteoarticular brucellosis is a focal form of brucellosis, the most frequent location is spinal and whose adequate treatment allows a favourable evolution.

COMPARISON OF SEVERAL BIOMARKERS (MMP-2, MMP-9 AND ITS INHIBITOR TIMP-1, CTX-II, CALPROTECTIN AND COMP) IN THE SYNOVIAL FLUID AND SERUM OF PATIENTS WITH AND WITHOUT SEPTIC ARTHRITIS

M. Couderc1,2, C. Peyrød2, B. Pereira2, E. Miot-Noirault2, S. Mathieu1, M. Soubré1, J.-J. Dubost1, 1Rheumatologie, CLERMON FERRAND UNIVERSITARY HOSPITAL; 2most, UMR 1240/INSERM/UCA; 3biostatistic unit, CLERMON FERRAND UNIVERSITARY HOSPITAL, Clermont-Ferrand, France

Background: Diagnosing septic arthritis (SA) is an emergency, and for a diagnosis to be made a microorganism must be found in the synovial fluid or blood culture. Besides direct bacteriological examination, which is positive in only 25% to 50% of cases, no laboratory examination can differentiate SA from other forms of arthritis.

Objectives: To assessed the performances of several serum and synovial biomarkers (matrix metalloproteinase [MMP]-2, MMP-9, the metalloproteinase inhibitor [TIMP]-1, cartilage oligomeric matrix protein [COMP], C-terminal telopeptide of type II collagen [CTX-II], and calprotectin [CALP]) for discriminating between septic and non-SA in a population of patients with suspected SA.

Methods: Using the ELISA technique, a number of potential biomarkers (MMP-2, MMP-9, TIMP-1, COMP, CTX-II, and CALP) were measured in the synovial fluid and serum of 39 patients with suspected SA (of whom 21 had SA and 18 non-SA). The levels of the various markers were compared on univariate and then multivariate analysis using logistic regression.
Results: The two groups were similar in terms of age, gender, history of diabetes and type of joint affected. SA patients had higher whole blood white cell counts (p<0.03) but similar C-reactive protein levels. Synovial fluid was more frequently turbid in septic cases than in non-septic ones. Serum TIMP-1 (p=0.003), synovial MPP-9 (p=0.002), serum (p=0.03) and synovial CTX-II (p=0.004), and serum (p=0.04) and synovial CALP (p=0.03) were significantly higher in the septic group than in the non-septic group. The AUCs for diagnosing SA of synovial MPP-9, serum TIMP-1, synovial CTX-II, and serum and synovial CALP were, respectively, 0.94, 0.79, 0.81, 0.7 and 0.72. A combination of serum TIMP-1 and synovial CTX-II led to 75% sensitivity and 94% specificity for diagnosing SA (AUC 0.89) and correctly classified patients in 86% of cases. Serum TIMP-1 and synovial CTX-II did not correlate with each other (r=0.1) and did not correlate with C-reactive protein (r=0.4 and r=0.25, respectively) or synovial white blood count (r=−0.04 and r=0.27, respectively).

Conclusions: The combination of two laboratory measurements, serum TIMP-1 and synovial CTX-II, may make it possible to differentiate SA from other forms of arthritis in 86% of cases. These results need to be confirmed in larger samples of patients.

AB1054

FACTORS ASSOCIATED WITH TUBERCULOSIS IN RHEUMATOID ARTHRITIS

Background: Rheumatoid arthritis (RA) is associated with infections that are favored by the disease itself or by its treatments. Tuberculosis (TB) is a severe infection that can occur in patients with RA, especially with the use of anti-TNF.

Objectives: We aimed to estimate the incidence of TB in RA patients and identify factors associated with TB during RA.

Methods: This is a retrospective study of RA patients according to ACR/EULAR criteria 2010 collected in rheumatology department during the period from April 2010 to April 2015. Diagnosis of latent or patent TB was made as part of the pretreatment screening (biotherapy) or if signs of infection occurred.

Results: During the study period, 150 RA patients (124 women and 26 men) were enrolled. The mean age was 57.09 years. Mean disease duration was 7.52 years. The incidence of TB in RA patients was 0.01 (95% CI: 0.005, 0.016). The most frequent type of TB was pulmonary TB (0.87%), lumbar spine TB (0.53%), and chest TB (0.27%).

Conclusions: Our study showed that RA patients were exposed to a higher risk of TB, especially when using anti-TNF therapy with increased incidence of extra pulmonary TB. Understanding the associated factors with TB may lead to establish a continuous monitoring in order to improve the quality of care.

ADVERSE EFFECTS AND THEIR CONSEQUENCES IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHROPATHIES IN TREATMENT WITH BIOLOGICAL THERAPY

N. Martinez-Lopez De Castro 1,2, A. Martin-Vila 1, M. Alvarez-Payero 1, M. Samartin-Ucha 1, G. Piñeiro-Corrales 1, J.M. Pego-Reigosa 1, 1Pharmacy, 2Institute of biomedica investigation of South Galicia, University Hospital of Vigo, Vigo, Spain

Background: The introduction of biological therapies (BT) for the treatment of chronic inflammatory arthropathies (CIA) has improved the prognosis of these diseases and the quality of life of patients. However, the safety of these drugs in the long term continues to be an aspect of interest.

Objectives: The aim of this study is to review the safety of BT in patients with CIA and the consequences of these adverse effects for patients and the health system under daily clinical practice conditions.

Methods: A descriptive, observational and retrospective study was performed. All patients with CIA: rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) who started BT (abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, tocilizumab and ustekinumab) from January 2009 to January 2017 in the Rheumatology Department of the Sanitary Area of Vigo (Spain) were included. Demographic variables (age, sex), variables related to CIA and its comorbidities: clinical and analytical data (CRP, ESR, haemoglobin, Das and BASDAI) and years of disease evolution and variables about BT: concomitant treatment (glucocorticoids, methotrexate and leflunomide), persistence and number of lines were collected. Variables about the adverse effects (AEs) of BT: type and clinical consequence, requirement for additional visits to the Rheumatology clinic, visits to the Emergency Department or need for hospital admission was also collected.

Results: Three hundred sixty-two patients and 478 BT lines (250 lines in patients with RA, 119 with AS and 109 with PsA) were analysed (mean ±SD of BT lines: 1.7±1.1 per patient). In 301 (63.0%) BT lines, some AEs occurred. In total, 683 AEs were detected (0.57 AEs per patient and year of treatment). The most frequent types of AEs were: bacterial infection (0.39 events per year of BT), viral infections (0.04 events per year of BT), fungal infections (0.04 events per year of BT), reactions related to the administration of BT (0.03 events per year of BT) and cardiovascular alterations (0.02 events per year of BT). Certolizumab and abatacept were the drugs that were more associated with bacterial infections: 0.82 and 0.69 per year of BT, respectively. Infliximab was the BT that was less associated with bacterial infections: 0.24 per year of BT. There were 7 deaths in probable or confirmed TB with a period of 17 years [2000-2016] performed. Diagnosis was made on clinical presentation, laboratory findings, radiographic evidence and Brucellar seroagglutination tests. Three patients underwent CT scans and a spinal MRI was carried out for 24 patients. All of them received antibiotic treatment based on a combination of Rifampicin and Doxycycline of varying duration.

Conclusions: Our study showed that RA patients were exposed to a higher risk of TB, especially when using anti-TNF therapy with increased incidence of extra pulmonary TB. Understanding the associated factors with TB may lead to establish a continuous monitoring in order to improve the quality of care.

Disclosure of Interest: None declared

neurological examination showed no abnormalities. Spinal MRI showed paravertebral abscess in 56.5% of cases. Seventeen patients (73.9%) had epiduritis and 9 patients (39.9%) had spinal cord compression on the MRI. An abnormal signal of the spinal cord was observed in 2 cases (8.7%). All patients received a combination of Rifampicin and Doxycycline. The mean duration of the antimicrobial treatment was 8 months. There was no statistically significant association between the occurrence of abscesses, epiduritis, spinal cord compression, abnormal signal of the spinal cord on the MRI and the duration of treatment (p=0.935, p=0.925, p=0.379, p=0.889 respectively).

Conclusions: MRI of the spine frequently revealed signs of severity in brucellar spondylodiscitis patients, although without clinical expression. Despite their severity these signs did not result in a longer period of antibiotic therapy

Disclosure of Interest: None declared

AB1056

DIAGNOSIS VALUE OF PERCUTANEOUS SPINAL NEEDLE BIOPSY IN BRUCELLAR SPONDYLODISCITIS

O. Saidane, I. Oueslati, I. Mahmoud, A. Ben Tekaya, R. Tekaya, L. Abdelloulou. Rheumatology department, Charles Nicole hospital, Tunis, Tunisia

Background: Spondylodiscitis is a serious condition with a large variety of infectious etiology. Vertebral biopsy is needed to perform the microbiologic diagnosis when no causative organism is identified. CT-guided percutaneous spinal biopsy (CTSB) may reduce the risk of contamination and complications.

Objectives: The aim of this study is to determine the contribution of CTSB to the diagnosis of Brucellar spondylodiscitis.

Methods: We conducted a retrospective study on 27 patients admitted for Brucellar spondylodiscitis over a 17 years period [2000 to 2016]. The etiological diagnosis was based on Brucella agglutination test which was positive for all patients. Twelve patients had a CTSB with cytobacteriological and histological tests.

Results: Twenty-seven patients (17 men and 10 women) with a mean age of 54 years were included. Twenty-six patients (96.3%) reported a spinal pain. This pain involved the lumbar spine (59.3%), the dorsal spine (18.5%) and less frequently the cervical spine (11.1%). Eight patients reported lumbosciatica (29.6%). An etiological doubt subsisted in 12 cases and a CTSB was performed. Culture results were negative for 11 biopsy samples and one culture was positive to Staphylococcus aureus. In a case of a co-infection. The results of the histological examination showed chronic non-specific inflammation in 92.3% of cases. An infectious etiology was suspected histologically in 53.8% of cases and particularly of a pyogenic germ (78.3%). The biopsy was not contributive in one case.

Conclusions: Our results suggest that CT-guided spinal biopsy is not useful to diagnose Brucellar spondylodiscitis. However, the absence of tuberculosis granuloma and caseous necrosis helped ruling out the tubercular origin

AB1057

BRUCELLAR SPONDYLODISCITIS: THE IMAGING FINDINGS

O. Saidane, I. Oueslati, R. Tekaya, A. Ben Tekaya, I. Mahmoud, L. Abdelloulou. Rheumatology department, Charles Nicole hospital, Tunis, Tunisia

Background: Brucellar spondylodiscitis is an important complication of brucellosis that can cause neurologic involvement and spinal deformities if not appropriately treated. Imaging examination is a major key in diagnosis

Objectives: The aim of this study was to report the imaging findings in brucellar spondylodiscitis

Methods: We performed a retrospective study including 27 patients with Brucellar spondylodiscitis over a period of 17 years from 2000 to 2016. Diagnosis was made on clinical presentation, laboratory findings, radiographic evidence and Brucella agglutination tests. All patients underwent X-rays of the involved spine levels. Spinal computed tomography (CT) was carried out in 13 cases and spinal MRI in 24 cases.

Results: Seventeen men and 10 women aged from 33 to 75 years were included. Plain radiographs showed a disc space narrowing for 26 patients (96.3%) and an irregularity of the vertebral end plate in 16 cases (59.3%). A paravertebral abscess formation was detected in 3 patients. No obvious abnormalities were found in one case. CT scans of most patients revealed signs of spondylodiscitis (92.3%). This examination showed an erosion of the vertebral end plates (69.2%), intervertebral disc space narrowing (61.5%) and bone destruction (38.5%). The severity signs detected on the CTs were the soft tissue thickening (46.2%), abscesses formations (7.4%), epiduritis (30.8%) and one patient had a spinal cord compression. The 24 MRIIs realised exhibited a signal abnormality of the vertebral body (95.7%) and the intervertebral disc (47.8%) in addition to disc space narrowing (73.9%) with erosions of the vertebral end plates (56.0%). The contrast enhanced T1-weighted images showed marked enhancement of affected vertebrae and disc (73.3%). Thirteen patients had abscesses formations (56.5%), 17 had epiduritis (73.3%) and 9 patients (31.9%) presented a spinal cord compression on MRI. Brucellar spondylodiscitis involved one spinal level in 23 cases whereas multilevel involvement was found in the 4 others.

Conclusions: Plain radiographs and spinal CT scans lack sensitivity in diagnosing brucellar spondylodiscitis and spinal MRI remains the referential imaging modality to recognise early bone infection, allowing complete lesion topography and identifying the complications.

AB1058

IS HEPATITIS B SURFACE ANTIGEN (HB S AG) ENOUGH ALONE AS A SCREENING TEST FOR HBV INFECTION IN RHEUMATIC DISEASE PATIENTS BEFORE STARTING IMMUNOSUPPRESSIVE THERAPIES?

A. Abd El Noor1, M. Watany2, S. Abi-Eisalam2, W. Elkhalaawy3, S. Soliman4, R. Badaw4.1 Internal Medicine and Rheumatology; 2Clinical Pathology; 3Tropical Medicine, Faculty of Medicine, Tanta University, Tanta; 4Public Health and Community Medicine, Faculty of Medicine, Menofia University, Menofia, Egypt

Background: Prevalence of hepatitis B virus in patients with rheumatic diseases has been reported differently among studies. The loss of immune control in these patients may result in the reactivation of HBV replication within hepatocytes. Considering the lifelong use of multiple anti-rheumatic drugs, screening for HBV is recommended before starting immunosuppressive or immunomodulatory therapy.

Objectives: The aim of this study was to select the best and simplest test for screening of HBV in rheumatism patients in Egypt.

Methods: This cross sectional study was carried out on 102 patients with different rheumatic diseases. Screening to all patients by hepatitis B surface antigen (HBsAg), hepatitis C virus (HCV) and human immune deficiency virus antibodies (HIV) were done. HBV core antibodies and real time PCR to detect HBV DNA were done.

Results: The mean age of the patients was 37.18 ±12.37. 39% of them were males and 61% were females. We found that HBsAg was positive in two patients (2%) and negative in 100 patients (98%). HBcAb was positive in 24 patients (23.5%) and negative in 78 patients. However PCR for hepatitis B DNA was positive in 2 patients (2%) only who were positive for both HBsAg and HBC Ab. HBsAg had 100% Sensitivity, 100% Specificity, 100% PPV, 100% NPV and 99.0% accuracy. While anti-Hbc had 100% Sensitivity, 78% Specificity, 8% PPV, 100% NPV and 78% accuracy in screening of HBV.

Abstract AB1058 – Figure 1. Receiver operating characteristic (ROC) plot for “HBs Ag in relation to PCR in diagnosing HBV” on the left side & “HB c Ab in relation to PCR” on the right side.
Conclusions: We can conclude that screening for hepatitis B virus is essential for all patients with rheumatic diseases before starting therapies either steroids, immunosuppressive therapies or biologics. For financial issues especially in developing countries screening by HBsAg may be enough as an initial test especially if non biological therapies are used as it is superior to anti HBC for screening for HBV infection.

References:

Methods: A 54 y.o. male patient E. was admitted to the Rheumatological department with complaints of joint swelling, low back pain, weight loss, diarhhea, headache and low grade fever. Peripheral joint arthritis appeared about 4 years ago with progressive worsening of general condition and development of additional complaints during the past year. From 2013 to 2017 the patient received in-hospital and outpatient treatment because of active seronegative polyarthritis without sufficient effect. On admission: clinical examination and joint ultrasound (US) investigation revealed the signs of polyarthritis. Neurological evaluation showed organic psychiatric disorder with signs of pseudodementia, bradykinesia without focal neurological deficits.

Because of both incomplete responsiveness to DMARD-therapy and suspicion of chronic infection or malignant neoplasms, abdominal US and transthoracic echo-cardiography, gastroscopy, colonoscopy, immunofixation, bone marrow biopsy, chest X-ray and bone scintigraphy, tests for viral hepatitis (B,C), HIV, Lues and QFT-Tb were performed, however without objective evidence of the cause. PET-CT was performed as well, but showed no signs of malignancy or infection. MRI revealed bilateral brain atrophy, low-grade bilateral sacroiliitis and degenerative changes of the cervical spine.

For differential diagnosis PCR stool investigation for TW was performed and was positive. Upon the suspicion of WD duodenoscopy with duodenal biopsy were done. Histological examination showed PAS-positive macrophages, typical for WD. Immunohistochemical analysis also supported the diagnosis. PCR investigation of liquor and synovial fluid from ankle joint for TW were also positive. Antibiotic treatment using a 2 week course of parenteral Ceftriaxon 2 g/day was initiated. On the third day of the treatment the patient developed immune reconstitution inflammatory syndrome with febrile temperature and increased inflammatory markers. The symptoms regressed after additional prednisolon 20 mg/day prescription. Because of organic brain syndrome, administration of Co-trimoxazole was recommended. Under the antibacterial therapy the patient had rapid positive response. PCR stool test in October 2017 didn’t detect TW.

Conclusions: This presentation reemphasizes the importance of excluding a rare infection as a cause of atypical inflammatory arthropathy. In patients with seronegative rheumatoid arthritis or axial and peripheral spondyloarthritides, who don’t adequately response to immunosuppression, Whipple disease should be taken into account.

AB1059
CONTRIBUTION OF CT-GUIDED DISCOVERTEBRAL BIOPSY DURING INFECTIOUS SPONDYLODISCITIS

S. Latiaou1, S. Belghali1, H. Zaghouani2, S. Sridi2, K. Baccouche1, S. Majdoub2

Background: Infectious spondylodiscitis is an infection involving the vertebral endplates and the intervertebral discs. The diagnosis is based on a combination of clinical symptoms, biological and radiological findings. Identifying the causative germ is sometimes difficult and a CT-guided discovertebral biopsy (DVB) might be of help, with varying success rates.

Objectives: The aim of this study was to assess the contribution of CT-guided DVB in the diagnosis of infectious spondylodiscitis in a rheumatological environment in Tunisia.

Methods: A retrospective study including patients diagnosed with infectious spondylodiscitis in the rheumatology department of Farhat Hached hospital, Sousse, Tunisia, between 1998 and 2017. Only patients who underwent a DVB for etiologic diagnosis of infectious spondylodiscitis were included in this study.

Results: Thirty five patients, with 12 (34.3%) women, were included. The mean age was 57.3±19.14 years [15–83 years], All patients presented with back pain for 83.06±73.32 days [10–330 days], seven (20%) patients had fever and six (17.1%) patients had abnormal neurological signs on examination. The mean WBC, CRP and ESR levels were respectively 8170.83±3476.94 elements/mm3, 50.2±59.22 mg/L and 86.85±50.74 mm/h. The affected levels were the lumbar in 23 (65.7%) cases and dorsal spine in 9 (25.7%) cases. Three patients (8.6%) had both dorsal and lumbar spondylodiscitis.

First DVB was contributive in 11 (31.4%) cases, isolated germs were staphylococcus aureus in 4 (36.4%) cases, tuberculosis in 3 (27.3%) cases, and brucellosis, coagulase negative staphylococcus, enterobacter cloacae, streptococcus oralis in one case each. Only one patient underwent a second DVB attempt, which was contributive, isolating a staphylococcus aureus. The rest of patients were treated based on local bacteriological findings (2 cases of brucellosis, 2 cases associated with Escherichia coli urinary infection and 1 case with pulmonary tuberculosis), or presumption arguments (6 cases treated as pyogenic infection and 12 cases as tuberculosis).

Conclusions: DVB remains essential for the positive diagnosis of infectious spondylodiscitis. Nevertheless, its bacteriological insufficient contribution should not delay therapeutic management based on presumption arguments.

WHIPPLE DISEASE WITH INITIAL PRESENTATION AS NON-EROSSIVE SERONEGATIVE POLYARTHRITIS: A CASE REPORT FROM A SINGLE CENTRE

V. Korendovych1, J. Schoenhenn1, T. Duerdott1, F. Schumann2, D. Blendea2, D. Spiridon1, H. Abdellatif1, M. Sarholz1, H. Marion1, D. Department of Rheumatology, St. Marien-Hospital Vreden, Academic Educational Hospital of the University Duisburg-Essen, Vreden; 2Rheumatology, Praxis Center Reken, Reken, Germany

Background: Whipple disease (WD) is a rare disease caused by the bacterium Tropheryma whipplei (TW), which manifestations may range from joint and GI tract involvement to severe neurological complications.

Objectives: To present a clinical case of WD with non-erosive seronegative polyarthritis, sacroiliitis, abdominal and CNS involvement, and immune reconstitution inflammatory syndrome after antibiotic therapy.

Methods: Case report. Prospective follow-up of the patient E. with WD, who was diagnosed HLA-B27-negative nonerosive seronegative rheumatoid arthritis in 2013. The disease was partially responsive to glucocorticoids with temporary effect to different DMARDs (MTX, lefunomid, etanercept, abatacept, tocilizumab either as monotherapy or in combination).

Results: A 54 y.o. male patient E. was admitted to the Rheumatological department with complaints of joint swelling, low back pain, weight loss, diarrhea, headache and low grade fever. Peripheral joint arthritis appeared about 4 years ago with progressive worsening of general condition and development of additional complaints during the past year. From 2013 to 2017 the patient received in-hospital and outpatient treatment because of active seronegative polyarthritis without sufficient effect. On admission: clinical examination and joint ultrasound (US) investigation revealed the signs of polyarthritis. Neurological evaluation showed organic psychiatric disorder with signs of pseudodementia, bradykinesia without focal neurological deficits.

MULTIFOCAL SPONDYLODISCITIS IN IMMUNOCOMPETENT PATIENTS

W. Handi, S. Bouden, H. Riahi, K. Maatallah, M.D. Kaffel, M. Bouaziz, M. Iadem, M. M. Khiri. Institut Kassab, Tunis, Tunisia

Background: The prevalence of infective spondylodiscitis (SPD) has decreased recently with the development of effective means of prevention. Multifocal forms are more common in immunocompromised persons, but may be seen in immunocompetent ones. They are severe, and fortunately remain rare.

Objectives: The aim of our study was to report the clinical, biological, radiological and therapeutic features of multifocal SPD in immunocompetent patients.

Methods: A retrospective study was performed including patients hospitalised in the departement of rheumatology between January 2007 and December 2017. Clinical, data, laboratory findings and radiologic features were evaluated.

Results: Six patients were included. Their mean age was 53 years.34–81 No comorbidities were found in all patients. The interval between the beginning of the symptomatology and the diagnosis was 3 to 6 months. Fever was noticed in 4 cases. All the patients had inflammatory spinal pain. Two patients had neurologic deficieny: one spinal compression and one root compression. The localization of the infection was lumbar and thoracic in 3 cases, cervical in 1 case and lumbar in 2 cases. MRI showed epiduritis in 3 cases and paravertebral abscess in 1 case. The infectious agent was identified by blood cultures in 1 case (Staphylococcus Aureus), by disco vertebral biopsy in 3 cases (tuberculosis) and by bruccella seology in 2 cases. All patients underwent antibiotic therapy and immobilisation with a good outcome, only one patient needed surgery aiming to decompress the spinal cord. Investigation for immunodeficiency was negative in all patients.

Conclusions: Multifocal SPD in immunocompetent patients remains rare. Its etiology is dominated by tuberculosis. The most frequent localizations are lumbar and thoracic spine.

RISK FACTORS FOR MORTALITY AFTER TUBERCULOUS ARTHRITIS

Y.-C. Chen, Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China

Background: Tuberculosis arthritis is an emerging international problem despite advances in the methods of diagnosis and treatment; it is still prevalent in developing countries and on the increase in developed ones.

Objectives: Patients with tuberculosis (TB) arthritis increase mortality This study investigated to search for the risk factors of mortality in TB arthritis.

Methods: We retrospectively reviewed patients with TB arthritis who admit to Kaohsiung Chang Gung Memorial Hospital January 2001 to December 2015. The long-term outcomes of the patients were analysed.

Results: A total of 281 patients (124 females and 17 males; mean age: 64.86 ±14.51 years) were enrolled. At the end of the study, 229 patients were alive and 52 had died. The mean follow up period were 8.31±4.52 years. The patients who were old age (p=0.004, HR=1.038, 95% CI 1.012–1.065), liver disease (p=0.036, HR=2.571, 95% CI 1.062–6.224) and underlying cancer (p=0.001, HR=3.640, 95% CI 1.725–7.679) had a significantly higher mortality rate than others.

Fibromyalgia

AB1063 SWALLOWING DIFFICULTY IN FIBROMYALGIA: REAL OR MYTH?

E. Umay, E. Gurcay, O. Karahmet, A. Hasturk, D. Dulgerolu Erdogdu, University of Health Sciences Ankara Yildirim Beyazit Education and Research Hospital, Ankara, Turkey

Background: Fibromyalgia Syndrome (FMS) is a chronic disease that the most common disease in medical practice. This syndrome is including some general symptoms such as chronic pain, fatigue, tenderness and sleep disturbance, that can be seen in many disorders. Other than these, there are symptoms such as dysphagia, which are reported less frequently but have serious consequences such as aspiration. Studies in literature have been reported that this may not be a real swallowing difficulty and may be a symptom of somatization or may be due to adverse events such as drug side effects.

Objectives: This study was aimed to reveal the presence of dysphagia with objective diagnostic tests in FMS patients.

Methods: This study was conducted on 165 subjects. Patients (n=83) with FMS regardless of whether the complaint is difficulty swallowing as well as had ages between 18–65 were included in the study. Healthy volunteers (n=82) consisting of medical staff and relatives of patients and sex, age and body mass index-matched with patients were included as control group.

Demographic and disease characteristics were recorded. Fibromyalgia Impact Questionnaire (FIQ) was used to assess severity of disease, functional disability and specific quality of life of patients. Also, the general quality of life of patients was evaluated with Short Form-36 (SF-36). All subjects were evaluated with clinical screen test (10-item eating assessment tool EAT-10) flexible fiberoptic endoscopic evaluation of swallowing (FEES) and electrophysiologic evaluation (EE) as well as ultrasonography (US).

The patients were divided into two groups according to the presence of complaints of difficulty in swallowing, which was taken with eat-10 as group 1 (with dysphagia) and group 2 (with normal swallowing). Patients who healthy volunteers (group 3) were compared in terms of swallowing evaluation methods.

Results: Twenty-one (25.3%) of the 83 patients were defined with dysphagia (group 1) as well as 62 (74.7%) patients with normal swallowing (group 2) according to the eat-10 scale. The groups were similar in terms of demographic characteristics (p=0.05).

The mean disease severity of the all patients was between moderate and severe levels as well as there was a mild impact on quality of life. Disease severity and quality of life by using FIQ and SF-36 were significantly worse in patients with dysphagia (group 1) compared with normal swallowing patients (group 2) (p<0.05). None of the subjects had dysphagia with endoscopic evaluation. All subjects could drink 20 ml of water which normal dysphagia limit. Swallowing intervals in patients groups were significantly prolonged compared to healthy volunteers (p<0.05). There was no significant difference between the patient groups in swallowing intervals (p>0.05). Ultrasonographic measurement results in healthy subjects were higher than patient groups (p<0.05). But ultrasonographic values of patients groups were similar (p<0.05).

Conclusions: Swallowing functions and structures are affected in patients with FMS, even though there are no symptoms of swallowing difficulty. Hence, while the main symptoms such as pain, fatigue and sleep disturbance are being questioned, a detailed evaluation including swallowing should be performed.

Disclosure of Interest: None declared

EXPLORING CEREBROSPINAL FLUID PROTEOME IN FIBROMYALGIA

E. Ossipova1, P. Emami Khoonsari2, J. Lengqvist1, E. Kosek3, D. Kadetoff3, J. Jakobsson1, K. Kultima2, J. Lamp1, Medicine, Karolinska Institutet, Stockholm; 2Medical Sciences, Upssala University, Upssala; 3Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden

Background: Fibromyalgia (FM) is a heterogeneous disease of unknown etiology characterised by chronic widespread pain that affects up to 4% of population. Overlapping and heterogeneous symptoms of various chronic pain conditions complicate their diagnosis, emphasising the need for more specific biomarkers to improve the diagnosis and understand the disease mechanisms. Cerebrospinal fluid (CSF) flows in the ventricles within the brain and diffuses over the brain and spinal cord. Due to direct contact of CSF with CNS, content of CSF reflects biochemical changes in CNS making it an excellent source for biomarker discovery.

Objectives: In current study we aim to explore CSF proteome of FM patients utilising quantitative proteomics method based on stable isotope labelling of CSF peptides combined with multivariate data analysis (MVDA) in order to monitor the dynamics of the proteome while comparing to the CSF proteomes in patients with rheumatoid arthritis (RA) and other neurological diseases (OND) and define the potential biomarker candidates in FM. We also investigate, which protein products have been found in human CSF with respect to known "pain" genes, human CSF proteome explored if these proteins represent any clear subgrouping of "pain proteins".

Methods: CSF samples from patients with FM, RA and control OND group were collected by lumbar puncture and equal aliquots were subsequently reduced, alkylated and digested by trypsin. Obtained peptides were labelled by stable isotopes and mixed prior sample fractionation. The degree of sample complexity was reduced by off-line peptide separation using HPLC instrumentation. Obtained 80 peptide fractions were combined into 10 fractions across the gradient area. Fractions were analysed by LC-MS/MS, proteins in acquired data were identified and quantified, and data was analysed using MVDA.

Results: Out of the 1422 proteins identified, 855 proteins were included in the quantitative data analysis. Comparing FM, RA and OND groups to each other using univariate testing we found 53 statistical significant proteins (q-value <0.05). Six out of these have been reported as "pain proteins" (Complement C4-A, Prostaglandin-H2 d-isomerase, Apolipoprotein D, Granulins, Pro-cathepsin H, and BMP and activin membrane-bound inhibitor homolog).

Conclusions: We have employed quantitative proteomics methods combined with extensive bioinformatics data analysis to investigate differences in proteome profiles in CSF obtained from patients with FM, and identified six differentially expressed pain proteins of various functions in CSF of FM patients. The involvement of these proteins in the disease pathogenesis as well as used of the identified proteins as potential biomarkers should be investigated.

**PRELIMINARY FINDINGS OF A 2-MONTHS DIABETES MELLITUS TYPE 2 RISK ASSESSMENT IN FIBROMYALGIA WOMEN**

M. Di Carlo, G. Beci, F. Salaffi. Rheumatological Clinic, Università Politecnica delle Marche, Jesi, Italy

**Background:** Acupuncture is frequently used in the treatment of different chronic pain conditions. In Fibromyalgia (FM) the evidences are somehow controversial, and the correct positioning of such kind of therapy has not yet precisely defined.

**Objectives:** To assess the response to a single course of acupuncture in patients with FM non-responsive to the usual pharmacological treatment.

**Methods:** Consecutive FM patients with unsatisfactory response or intolerance to the pharmacologic treatment (duloxetine and/or pregabalin) were involved in this study. Unsatisfactory response was defined by the presence of a revised Fibromyalgia Impact Questionnaire (FIQ-R) total score ⩾40 and of a Patient Health Questionnaire 15 (PHQ15) ⩾5 after 3 months of stable pharmacological treatment. Acupuncture treatment consisted in 8 weekly sessions. The acupuncture formula, according to the Traditional Chinese Medicine indications, included the following points: LV3 + LI4 (to move Qi), ST36 + CV6+CV12 (to tonify Qi and Blood), GV20 (to raise Qi), and Ex-HN-3 (Yintang) (to calm the Shen), with acupuncture needle 0.25 × 25 mm with guide tube (Huanqiu). For each session needles were retained for 30 min. At baseline (before the first session) and at the end of the treatment course (after the eighth session) were collected the number of tender points (TP) and patient-reported outcomes (PROs). Differences between baseline and end of the acupuncture treatment were evaluated through the Wilcoxon test, results expressed in median values with 95% confidence interval (CI).

**Results:** Thirty-four subjects were enrolled in the study. Thirty-two patients (29 women, 3 men, mean age 49 years, range 18–72 years) completed the acupuncture treatment. In two patients (one woman and one man) the acupuncture therapy was stopped at the second session for poor tolerance to the needles. Eleven patients were in pharmacological therapy with pregabalin, nine with duloxetine, while 12 resulted intolerant both to pregabalin and duloxetine. From baseline, after the 2 months of acupuncture treatment, different parameters showed a significant improvement. Particularly, it has been observed a significant reduction in the TP number (17 [95% CI 16–18] vs 10 [95% CI 8–12]; p=0.0001), in the somatic symptoms assessed with the PHQ15 (13.5 [10.0–17.0] vs 7.0 [6.0–10.0]; p=0.0001), but also in the FIQ-R total score (61.5 [39.8–70.3] vs 30.2 [26.6–65.0]; p=0.0029), in the Fibromyalgia Activity Score (FAS) (6.7 [4.8–7.7] vs 4.6 [CI 3.2–6.1]; p=0.0017), and in the Self-Assessment Pain Scale (SAPS) (4.5 [3.8–5.6] vs 3.2 [2.9–4.2]; p=0.0192). Interestingly, acupuncture revealed a good effect even in the neurotic-like features of pain, measured by the painDETECT questionnaire (19.0 [15.0–26.0] vs 14.5 [10.9–17.0]).

**Conclusions:** A 2 months acupuncture treatment provides an important global improvement in the health status in FM patients refractory/intolerant to the pharmacologic treatment. The strongest ameliorations are represented by the reduction in the TP number and in the somatic symptoms.

**PRELIMINARY FINDINGS OF A 2-MONTHS DIABETES MELLITUS TYPE 2 RISK ASSESSMENT IN FIBROMYALGIA WOMEN**

O.V. Dzekan1, M. Stanislavchuk2. 1 Rheumatology, Vinnytsya Regional Clinical Hospital; 2 Internal Medicine, National Pirogov Memorial Medical University, Vinnytsya, Ukraine

**Background:** Fibromyalgia (FM) female are less physically active than sedentary healthy women. Low physical activity (PA) is among the leading causes of the major noncommunicable diseases, including diabetes mellitus type 2 (DM2). An increased prevalence rate of DM in FM2 patients was revealed. Risk of the development of DM2 in FM is unknown.

**Objectives:** The purpose of this study was to assess the risk of DM2 development in FM women.

**Methods:** The study involved 67 FM women (ACR 1990 and 2010 criteria) aged 42.6 ±7.8 (MS±SD) years without diabetes and 51 healthy controls (HCs) (all women) aged 44.8±7.3 years. All participants were asked to complete a modified version of the Finnish Diabetes Risk Score (FINDRISC), which evaluates age, body mass index, waist circumference, current antihypertensive medication, frequency of fruit and vegetable consumption, physical activity, personal history of high blood glucose, and family history of DM2. Fasting plasma glucose (FPG), oral glucose tolerance test (OGTT) and/or glycated haemoglobin (HbA1C) were collected from all subjects to detect their glucometabolic state. Prediabetes was diagnosed by the presence of impaired FPG (⩾100 mg/dl <126 mg/dl), impaired OGTT (⩾140 mg/dl to <200 mg/dl) and/or impaired HbA1c (5.7% to ⩾6.4%).

**Results:** According to the FINDRISC questionnaire low risk of DM2 in the next 10 years was found in 14.92% of FM women, intermediate risk—in 22.39%, moderate risk—in 29.85%, high risk—in 23.88%, a very high risk—in 8.96% of patients. In the group of HCs low risk of DM2 was found in 19.61% of women, intermediate risk—in 39.22%, moderate risk—in 21.57%, high risk—in 15.68%, a very high risk—in 3.92% of subjects. Therefore, in most of FM female (53.73%) risk of DM2 was detected as moderate-to-high, while in the majority of HCs (60.79%) it was detected as intermediate-to moderate. Prediabetes was diagnosed in 11.94% of FM female compared to 5.83% among healthy women.

**Conclusions:** FM women are found to have increased risk of DM2 development compared to healthy women.

PAIN, FATIGUE AND FUNCTIONAL IMPAIRMENT IN CHRONIC WIDESPREAD PAIN, SLEEP PROBLEMS AND FM: A PRELIMINARY STUDY OF 21 PAINFUL KNEE OA PATIENTS

Objectives: The purpose of this study was to evaluate the prevalence of fibromyalgia (FM) in patients with painful knee OA.

Methods: The study involved 92 patients (63 females and 29 males) with painful knee OA\textsuperscript{1-3} according to Kellgren-Lawrence scale grading.\textsuperscript{4} FM was diagnosed in these subgroups if both the \textsuperscript{1}ACh 1990\textsuperscript{1} and \textsuperscript{2}ACh 1990\textsuperscript{1} criteria were met.\textsuperscript{5-6}

Results: FM was diagnosed in 21 painful knee OA patients (22.83%). Among female patients FM was confirmed in 19 from 63 subjects (30.16%) compared to 2 from 29 male patients (6.90%). No relationship was found between the radiologic stage of the knee OA and FM prevalence in the investigated subjects.

Conclusions: FM prevalence is relatively high in painful knee OA patients, mostly females. Further studies investigating possible FM impact on pain modulation, functional disability and quality of life in painful knee OA are needed.

AB1068 PAIN, FATIGUE AND FUNCTIONAL IMPAIRMENT IN FIBROMYALGIA PATIENTS MAY BE REDUCED BY ADDING A CYCLE OF HYPERBARIC OXYGEN THERAPY (HBOT) TREATMENT

P. Sarzi-Puttini\textsuperscript{1,2}, R. Casale\textsuperscript{3}, A. Batticciotto\textsuperscript{1}, R. Talotta\textsuperscript{1}, M. Gerardi\textsuperscript{1}, I.F. Masala\textsuperscript{4}, F. Salaffi\textsuperscript{5}, F. Atzeni\textsuperscript{5}.

Background: Fibromyalgia Syndrome (FM) is a persistent and debilitating disorder estimated to impair the quality of life of 2%–4% of the population. FM is an important representative example of central nervous system sensitisation and is associated with abnormal brain activity. The syndrome is still elusive and refractory. Hyperbaric oxygen therapy (HBOT) may rectify abnormal brain function underlying the symptoms of FM patients. Increasing oxygen concentration by HBOT may change the brain metabolism and gial function to rectify the FM-associated brain abnormal activity.\textsuperscript{1}

Objectives: To evaluate the effect of HBOT on clinical symptoms in FM resistant to the usual pharmacological treatment.

Methods: Thirty female patients, aged 21–67 years and diagnosed with FM at least 2 years earlier, and resistant to any pharmacological treatment were assigned to be added on with HBOT. The treated group patients were evaluated at baseline and after 10 and 20 HBOT sessions. Evaluations consisted of physical examination, including tender point count, extensive evaluation of quality of life. Study endpoints included assessments of pain (VAS), the FACIT Fatigue Scale which is a short, 13-item, that measures an individual's level of fatigue during their usual daily activities over the past week. A validated Italian version of the Fibromyalgia Impact Questionnaire (FIQ-R) was used to evaluate the level of functional impairment as well as the FAS index which is a short and easy to complete self-administered index combining a set of questions relating to non-articular pain, fatigue and the quality of sleep that provides a single composite measure of disease activity ranging from 0 to 10. The HBOT protocol comprised 20 sessions, 3 days/week, 90 min, 100% oxygen at 2.5 ATA.

Results: The effect of the hyperbaric oxygen therapy on the clinical symptoms are summarised in table 1. HBOT treatments of treated group led to statistically significant improvements in the mean scores of pain and fatigue (FACIT) after 10 and 20 HBOT sessions (mean change of pain after 20 sessions –1.76±2.5, p<0.001) (mean change of fatigue after 20 sessions 5.93±2.10, p<0.001) The FIQ-R score significantly improved following HBOT in the treated group (mean change after 20 sessions –12.89±17.04, p<0.001). The FAS score showed a positive trend after 10 sessions and a significant improvement after 20 sessions (mean change –2.02±3.14, p=0.006).

Conclusions: These preliminary data show that HBOT may determine a significant clinical improvement in patients affected by FM and resistant to the common pharmacological treatment. However, further studies of large numbers of patients are required in order to confirm this preliminary finding and modify treatment strategies accordingly.

AB1069 CHRONIC WIDESPREAD PAIN, SLEEP PROBLEMS AND PRESSURE PAIN THRESHOLDS IN A POPULATION SAMPLE

S. Bergman\textsuperscript{1,2,3}, E. Haglund\textsuperscript{4,5}, K. All\textsuperscript{6}, C. Olsson\textsuperscript{7}, A. Bremander\textsuperscript{3,4,5}

\textsuperscript{1}Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund; \textsuperscript{2}Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg; \textsuperscript{3}Rando centre Spenshult; \textsuperscript{4}School of Business, Technology and Science, Halmstad University, Halmstad; \textsuperscript{5}Unit of occupational medicine, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Chronic musculoskeletal pain is common in the general population and 11% report chronic widespread pain (CWP). A sensitisation of the nociceptive system has been proposed to be one possible mechanism behind CWP, a prerequisite for fibromyalgia (FM). A reduced pressure pain threshold (PPT) has been reported in subjects with FM, but also as an effect of bad sleep.

Objectives: The aim was to study pain thresholds in people with CWP in comparison with those having no chronic pain (NCP) or chronic regional pain (CRP), but also in relation to self-reported sleep problems.

Methods: From a 21 year follow-up of the Swedish population based Epipain cohort (n 1321), 146 subjects, with and without a report of chronic pain, were invited to a clinical assessment including measurement of PPT. Subjects were classified as having NCP, CRP or CWP, according to the definition of CWP in the ACR 1990 criteria for FM, as a pain matrix, including >18 body regions. Sleep problems (initiating sleep, frequent awakenings, not feeling rested, early awakening) were reported by Uppsala Sleep Inventory (four items scored from 1–5, best to worst). PPTs were measured in kPa at eight different anatomical sites representing upper, lower, left and right side of the body using the AlgoMed Pressure PPT device (Medoc Ltd Advanced Medical Systems, Israel). A mean was calculated from all eight points to create a global pressure pain threshold (PPTg), where a lower PPTg indicated a higher sensitivity to pain. ANCOVA regression analysis was performed to study associations between PPTg and reports of chronic pain and sleep problems, controlled for age and gender.

Results: Out of 146 subjects, 89 (61%) were women. Mean age was 64.6 (SD 12.7) years. This sub-population from the Epipain cohort reported a high prevalence of CWP without significant difference between men and women (33.9% vs 44.9%; p=0.041). Women had lower PPTg than men (345.0 kPa vs. 563.9 kPa; p<0.001). Subjects classified as CWP had lower PPTg than those classified as NCP (362.0 kPa vs. 479.9 kPa; p<0.003). A report of CRP did not affect PPTg in

AB1070 VARIATIONS IN THE LENGTH OF MUSCULOSKELETAL TEMPORARY WORK DISABILITIES IN PATIENTS INCLUDED IN AN EARLY INTERVENTION PROGRAM

A. Lois Ilojesias, C. Bejerano, F.J. de Toro Santos. Hospital Universitario A Coruña, A Coruña, Spain

Background: Musculoskeletal disorders cause in Spain 23% of temporary work disability (TD) and they are the first cause of permanent work disability (PD). A study of early intervention (early assessment and immediate treatment by a rheumatologist) reduced TD days (39%) and evolution to PD (50%)1. Using the ‘Fit for Work’ European coalition led by AbbVie, the program is implemented nationwide.

Objectives: The aim of this study is to analyse the variation in the number of days of sick leave in the patients included in an early intervention program comparing to usual care. Methods: Observational cross-sectional study of a hospital cohort of outpatients referred during 18 consecutive months. The patients were referred for the first time to the Rheumatology Early Intervention consultation program because of temporary work disabilities due to musculoskeletal disorders. All of them received medical treatment; and underwent joints ultrasound, joint injections and learned exercises when needed. Patients whose disabilities were due to trauma or surgery were not included in the study.

Results: We evaluated 270 patients with a mean age of 48.9 years. 64% were women. The most frequently reported diseases were lumbar/sciatic pain (28.5%), shoulder pain (20%), neck pain (8%), knee pain (5.6%) and other arthralgias and tendinopathies (20%). All patients received medical treatment, 38.5% underwent ultrasound examination and 19.2% received joint injections. The pathologies with longest lengths of TD after the first visit to the rheumatologist were lumbar/sciatic pain (mean 40.6 days), neck pain (mean 33 days) and shoulder pain (mean 23.8 days). If we compare this data with the existent control group from San Carlos Hospital (Madrid), we can see a decrease of the days in sick leave of 29.5% in lumbar/sciatic pain (from 57.6 to 40.6 days), 11.7% in neck pain (from 37.4 to 33 days) and 36.3% in shoulder pain (from 37.4 to 23.8 days).

Conclusions: Early intervention by rheumatologists in patients with temporary work disability due to musculoskeletal disorders reduces the length of sick leaves. A quick diagnosis and assessment by specialists can improve the patient outcomes saving costs to health system.

AB1071 WHAT FACTORS AFFECT THE EFFECTIVENESS OF NSAIDS FOR ACUTE LOW BACK PAIN?

A. Karatsev, E. Pogozheva, A. Lila. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Nonsteroidal anti-inflammatory drugs (NSAID) are the main instruments for acute LBP (LOW BACK PAIN) treatment. However, up to now, factors that influence the effectiveness of NSAIDs have not been determined fully.

Objectives: To assess effects of some clinical and anamnestic factors on NSAIDs effectiveness in acute LBP.

Methods: The study group comprised 2078 patients (46±13.4 years, women 56.6%) with acute LBP treated in real clinical practice. 34.8% had first episode of LBP, 65.2% had second episode (an average of 2.6±1.4 episodes a year). Numerical rating scale (NRS) of 0–10 points estimated the level of pain. Initially, the pain level was 6.6±1.65. 57.0% of patients had severe pain (> 7 NRS). Pain remained at rest in 32.0%, at night in 19.0%, stiffness was noted in 60.7%, radiating leg pain in 28.2%, sciatica at 9.6%. NSAIDs used 70.2% of patients in the history of LBP. 28.0% rated their effectiveness as good, 54.6% as moderate and 17.4% as low. Meloxicam 15 mg once daily was prescribed for a period of up to 2 weeks for all the patients. 86.1% of patients received meloxicam intramuscular injection (i/m) for 2 days, then per os, 13.9% only per os. 52.3% received muscle relaxants, 17.4% – B vitamins, per os or i/m. 21.6% of patients received PPI for the prevention of gastrointestinal complications. The study evaluated the frequency of LBP complete relief with NSAIDs for up to 2 weeks.

Results: The complete pain relief was in 75.2% of patients, the average NSAID use duration before pain ceased was 8.6±5.5 days. 83.7% of patients rated the early treatment as “good” or “excellent.” Adverse reactions were noted only in 4.6% of patients, there were no serious complications. Female sex and the use of B vitamins did not influence the outcome of the treatment: odds ratio (OR, 95% confidential interval) 0.967 (0.795–1.177), p=0.763 and 0.917 (0.804–1.1201), p=0.452. Age <65 years, the first episode of LBP and a good effect of NSAIDs in a history were associated with the best result of treatment: OR 2.053 (1.592–2.642), p=0.000; 1.415 (1.09–1.836), p=0.009; 1.937 (1.513–2.481), p=0.000. Severe pain (> 7 NRS), pain at rest and at night, radiating leg pain and especially sciatica were associated with worse results: OR 0.599 (0.487–0.737), p=0.000; 0.481 (0.393–0.588), p=0.000; 0.559 (0.441–0.709), p=0.000; 0.511 (0.413–0.631), p=0.000; 0.348 (0.256–0.466), p=0.000. The combination of NSAIDs and muscle relaxants, in comparison with the monotherapy of NSAIDs, was associated with a lower incidence of pain: OR 0.827 (0.594–0.889), p=0.02.

Conclusions: Meloxicam 15 mg/day dosage is effective and safe for treating acute LBP. The sex of patients does not affect the outcome of treatment. Age <65 years, first episode of LBP and a good “response” to NSAIDs in history are associated with better treatment outcomes. Severe pain, the pain at rest and pain at night, radiating leg pain and sciatica are associated with the worst result. The combination of NSAIDs with muscle relaxants and B vitamins did not improve the outcome of the treatment.

AB1072 THE MEDIAN NERVE CROSS-SECTIONAL AREA MAY BE A PARAMETER OF FOLLOW-UP AFTER TREATMENT IN PATIENTS WITH CARPAL TUNNEL SYNDROME?

B. Mansiz-Kaplan1, I. Yagci2, G. Akuzu2. 1Department of Physical Medicine and Rehabilitation, University of Health Sciences, Ankara Training and Research Hospital, Department of Physical Medicine and Rehabilitation, Ankara, Turkey; 2Department of Physical Medicine and Rehabilitation, Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey

Objectives: Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy in general population. Diagnosis of CTS depends on clinical symptoms, physical examination and electrophysiological findings. In recent years, diagnostic value of median nerve ultrasonography has increased particularly for the CTS. To aim of this study compare the electrophysiological and ultrasonographic findings at CTS patients who treated with splinting at night during three months.

Methods: The patients, who were diagnosed with mild or moderate CTS, received a fabricated night orthotic which held the wrist in a neutral position during three months. All patients were evaluated clinically, electrophysiologically, and ultrasonographically before treatment and at 3 months by blind physicians. Pain was evaluated using Visual Analogue Scale (VAS) Boston Carpal Tunnel Questionnaire was used to evaluate symptom severity and functional capacity. In electrophysiologic evaluation median nerve conduction studies was recorded. Median nerve cross-sectional areas (M-CSA) were measured by ultrasonography at the level of radio-ulnar joint, pisiform bone, and hook of hamate. After treatment, 68
patients were divided into two groups according to whether there was a ≥50 reduction in VAS.

Results: The study was completed with 68 patients and 114 hands. While in group 1, in which VAS reduction was less than 50%, there were 38 hands; in group 2, in which VAS reduction was more than 50%, there were 76 hands. There were no differences in the level of severity, nerve conduction studies parameters, M-CSA at the level of the inter-union joint between groups. Improvement of functional capacity and decrease of M-CSA at the level of pisiform bone and hook of hamate were significantly better in group 2 (p<0.05).

Conclusions: After conservative treatment, while M-CSA was consistent with clinical findings, this consistency has not been observed with nerve conduction studies. M-CSA may be used to follow-up after receiving conservative treatment in patients with CTS.

AB1074 IN DEGENERATIVE SPINE DISEASE REGULAR SHORT COURSES OF NSAIDS USE ARE ASSOCIATED WITH GREATER KIDNEY INJURY, COMPARED WITH CONTINUOUS NSAIDS INTAKE AND WITH ABSENCE OF NSAIDS TREATMENT

I.Z. Gavdukova1, D. Bichurina2, A. Rebrov3, 1Therapy and Rheumatology, Northwestern State Medical University n.a.I Mechniv, St Petersburg; 2Bolshaya Kazachlia,12; 3Saratov State Medical University na VfRazumovsky, Saratov, Russian Federation

Background: Nephrotoxicity in short-term or continuous NSAIDs administration is well-known problem of anti-inflammatory treatment. However, data about kidney injury in case of repeated short-term courses of NSAIDs treatment are limited. Objectives: of the present study was to evaluate the kidney functions in patients with degenerative spine disease (DSD), taking NSAIDs in repeated short courses, compared with kidney function of patients with constant NSAIDs intake and to the healthy individuals.

Methods: The study included 137 patients, taking NSAIDs for DSD. 97 patients used NSAIDs in repeated short-term courses (3–5 courses per year, 7–14 days each course). 40 patients had continuous NSAIDs intake (5 and more days per week during the 1 year before the study). In the control group were involved healthy persons, did not treated with NSAIDs during the last year (n=40). Controls were sex- and age-matched with the DSD patients. Glomerular filtration rate (GFR) was calculated using CKD-EPI calculator. Albumin, a1-microglobulin and creatinine levels of urea were measured; albumin/creatinine and a1-microglobulincreatinine ratios were calculated.

Results: Kidney function in DSD patients with constant NSAIDs intake and in healthy controls are presented in table 1.

AB1073 THE EFFECTS OF LYMPHEDEMA SEVERITY ON DYNAMIC SCAPULAR CONTROL

E. Baran, T.I. Yildiz, C. Orhan, E. Uzelpasaci, S. Özgül, I. Düzgün, T. Akbayrak, Department of Physical Therapy and Rehabilitation, Hacettepe University Faculty of Health Sciences, Ankara, Turkey

Background: Women with mastectomy are reported to have altered dynamic scapular control compared to the asymptomatic healthy individuals. However, the effects of breast cancer related lymphedema (LE) on scapular control has not been fully understood yet.1, 2

Objectives: The aim of this study was to determine the impact of LE severity on scapular kinematics in breast cancer patients with moderate LE, severe LE and without LE.

Methods: 67 women who have undergone radical or modified radical mastectomy as part of the breast cancer treatment were included in the study. The aim of this study was approved by the local ethics committee of the university and all participants provided written informed consent. Individual’s demographic and medical characteristics were recorded. By volumetric measurement, women were divided into 3 groups. Between the affected and non-affected extremities; the non-LE group (mean ages; group 1: 45.54±5.88, group 2: 52.05±6.63, group 3: 56.37±8.24 years) had 0 and 200cc difference, the moderate LE group (group 2, n=22) had 0 and 200cc difference, and the severe LE group (group 3, n=27) had a difference of 500cc or more. 3-D analysis of the scapula was performed during the bilateral upper extremity elevation in the scapular plane with the 3D Motion Monitor-Electromagnetic System. Scapular kinematics in the scapular plane were recorded at 30°, 60° and 90° (during elevation and lowering phases) of the arm elevation in the affected side. Each measurement was repeated 3 times and the mean of 3 repetitions were recorded. Patient characteristics and scapular kinematics were analysed by Kruskal Wallis test and two-way repeated measures of ANOVA test, respectively.

Results: There was no significant difference between groups in terms of age (mean ages; group 1: 45.54±5.88, group 2: 52.05±6.63, group 3: 56.37±8.24 years) (p>0.08). Regarding the Body Mass Index (BMI) (group 1: 25.57±2.92, group 2: 25.95±2.35, group 3: 28.93±1.02 kg/m²), it was found that group 3 had higher BMI score than group 1 and 2 (p<0.001). The duration of LE (group 2: 22.38±3.21, group 3: 34.29±3.18 months) was higher in group 3 than the group 2 (p=0.004). There were significant interactions for scapular upward rotation between groups (F[8.1, 137.51] = 3.09, p=0.015). It was observed that group 1 had higher scapular upward rotation at 60° and 30° of the lowering phase of the arm elevation trials than group 3 (F[3, 0.012] = 1.02, p=0.4) among groups during the arm elevation in scapular plane.

Conclusions: The results of this study revealed that scapular upward rotation could be reduced by LE severity. LE severity might also be associated with BMI and LE duration. Further studies comparing LE patients with healthy individuals are needed to better understand the effects of LE severity on scapular kinematics.

AB1075 RELATIONSHIP OF SERUM CHOLECALCIFEROL (VITAMIN D3) LEVEL WITH MUSCULOSKELETAL SYMPTOMS

M A Razzaque1, G. Dewani2, R.S. Biswas3, M.N. Karim2, I. Sultan4, on behalf of research only. 1pharmacology, 2medicine, Rangamati Medical College, 3medicine, Chittagong mo a shishu medical college, 4medicine, cmc, chittagong, Bangladesh

Background: Patients suffering from generalised aches and pains, not adequately responding to treatment are usually considered as fibromyalgia, depression, chronic fatigue syndrome etc. But those patients need further
evaluation and low vitamin D is often the underlying cause. Both clinical and subclinical low level vitamin D is common. **1**

**Methods:** This prospective cross-sectional descriptive study was conducted during July 2017 to December 2017 in Chittagong, Bangladesh. Patients with common musculoskeletal complaints were enrolled. Each patient was screened to exclude common possibilities. Serum cholecalciferol was measured for each patient. Race, occupation, skin complexion, body mass index, sunlight exposure, covering of body with clothing’s and use of sunscreen were taken under consideration in final analysis. Visual analogue scale (VAS; 1–10) was used to quantify all complaints. Correlation of serum cholecalciferol with VAS score of individual complaints was analysed.

**Results:** A total of 110 patients (79 Female and 31 Male) were enrolled after screening 165. All of them were Bangladeshis of multi-ethnic Asian origin. Mean age was 46.5±12.8 years. Their skin complexion were pale white to white skin 45.5%, light brown 30%, moderate brown 11.8% and dark brown 12.7%. Most had (90.9%; n=100) inadequate sunlight exposure and 77.2% (n=61) women used Burkah (full covered dress). Mean vitamin D3 level was 25.2±7.3 ng/ml. Vitamin D deficiency was (mean 17.3±2.8 ng/ml) observed in 30 (27.3%), insufficiency (mean 25.1±2.7 ng/ml) in 62 (56.4%) and normal level (mean 34.8±4.4 ng/ml) in 18 (16.4%). After classifying Vitamin D level in relation to symptoms it was found that majority of patients (81.2% to 90.3%; depending on complaints) had insufficient or deficient cholecalciferol level (table 1).

**Abstract AB1076 – Table 1: Serum cholecalciferol status in different musculoskeletal complaints**

<tr>
<td>Bone pain (n=73; 66.4%)</td>
<td>8</td>
<td>10.9</td>
<td>43</td>
</tr>
</tbody>
</table>

Significant negative correlation was found between the serum cholecalciferol level and VAS for difficulty in getting up from squatting position (r=−0.253, p=0.008) and positive correlation was found for muscle cramps (r=0.220, p=0.021). Correlations with remaining symptoms were not statistically significant.

**Conclusions:** Vitamin D status directly and indirectly influences musculoskeletal health. Hypovitaminosis D should consider in every patient with muscle cramp.

**AB1076 COMPLEX REGIONAL PAIN SYNDROME TYPE 1: WHICH TREATMENT?**

M. Sohi1, S. Saleh2, A. Haj Salah1, W. Kesomint1, Z. Ben Salah1, 2, 3

**Rehabilitation department, University Hospital Tafar Star, Mahdia; 2Rehabilitation department, University Hospital Fattoura Bourgiba, Monastir, Tunisia**

**Background:** The treatment of Complex Regional Pain Syndrome Type 1 (CRPS-I) is multidisciplinary. 1 It aims to minimise symptoms, pain, preserve functional ability and professional activity. Unfortunately, therapeutic possibilities are still very limited and there is no Gold standard.

**Objectives:** The purpose of our work is to evaluate the efficiency of four therapeutic modalities in the management of CRPS-I.

**Methods:** Retrospective study of 60 patients (21 men and 39 women) treated for CRPS-I. Four groups were identified according to therapeutic modalities used: rehabilitation alone (16 patients), Calcitonin associated with rehabilitation (15 patients), Bisphosphonates (BP) (Sodium Risedronate, 1 tablet per week, over an average duration of 1 month) associated with rehabilitation (20 patients) and Calcitonin in combination with BP and rehabilitation (9 patients).

**Results:** The mean age of the patients was 51±16.5 years. The average time of treatment was 2 months and the average duration of follow-ups was 7 months. Traumatic origin was found in 88.3% of cases. Distal radius fractures (DRF) were the most incriminated (40% of cases). The evolution was judged on pain reduction, vasomotor signs and on functional improvement.

For all etiologies combined, no statistically significant difference was found between the different groups (p=0.462).

For patients with a DRF, a favourable outcome was noted in the BP group associated with rehabilitation in 85.7% of cases while it was only 42.9% for rehabilitation alone (16 patients).

**Conclusions:** Our study concludes that the different therapeutic modalities evaluated for the treatment of CRPS-I had an efficiency close to each other with a superiority of BP. Oral Sodium Risedronate could therefore be proposed as a treatment for CRPS-I without marketing authorisation (MA).

**AB1077 INVESTIGATION OF FRAILTY, MOBILITY AND DAILY LIFE ACTIVITY IN ELDERLY**

U.K. Sahin, A. Demircioglu, N. Kirdi. Physical Therapy and Rehabilitation, Hacettepe University, ANKARA, Turkey

**Background:** There are many factors that affect negatively mobility and daily life activity of older people. Frailty is one of these, frailty is a state of decline in physiologic reserve capacity and resiliency due to impairment in multiple physiological systems, thereby causing vulnerability to death and adverse health outcomes.

**Objectives:** The aim of this study was to analyse gender differences in frailty, mobility and daily life activity score.

**Methods:** The study included 173 women, 124 men total 197 persons aged 65 years and older. The demographic information including age, height and weight, the individuals marital status, educational state, chronic diseases were taken. Elder Mobility Scale (EMS), Edmonton Frail Scale (EFS) and KATZ were used to evaluate mobility, frailty and daily life activities level, respectively. Individuals were divided into groups according to their gender.

**Results:** There was significant difference between women and men in EMS (p=0.001), EFS (p=0.001) and KATZ scores (0.048). Frailty score were lower, mobility and daily life activity were divided into groups according to their gender.

**Conclusions:** It was seen that female gender affected mobility, frailty and daily life activity. It is important that Strategies for preventing or delaying the predisposing factor of frailty need to address gender differences and determinants among women.

AB1078

APPLICABILITY OF THE CASPAR CRITERIA OF PSORIASIC ARTHRITIS IN A COHORT OF CHILDREN PATIENTS FOLLOWING IN A PAEDIATRIC RHEUMATOLOGY UNIT OF A TERTIARY HOSPITAL

A. Adrovic1, K. Barut2, O. Kasapcopur2, S. Saltik1.

Background: The ILAR consensus establishes classification criteria, dividing the JIA into 7 subcategories, with juvenile psoriatic arthritis (APsJ) being one of them. In the adult population, the CASPAR classification criteria are usually used to classify a patient with psoriatic arthritis. However, the two classifications have some differences that sometimes produce confusion.

Objectives: To assess the applicability of the CASPAR classification criteria in a series of patients previously diagnosed in paediatric age of JPs or undifferentiated arthritis by exclusion criteria to be male ≥6 years old and HLA B27 positive, comparing these with the ILAR classification criteria, through the study of clinical features.

Methods: Retrospective cross-sectional observational study. Clinical, epidemiological, sociodemographic and analytical variables were collected from 30 patients previously diagnosed with JPs (<16 years) or undifferentiated arthritis by exclusion criteria age ≥6 years old in HLA B27-carrying male. It was assessed whether the patients met the ILAR classification criteria as well as the CASPAR classification criteria, which, unlike the previous ones, did not exclude HLA B27 positive patients, considered the family history of the 2nd degree and added a test to radiographic.

Results: The mean age at diagnosis was 11.2±4.6 years; 15 of them being women and 15 men. 15 (51.6%) patients presented cutaneous psoriasis at some point during the follow-up, in 5 patients onset psoriasis began after arthritis while 7 (23.3%) patients were diagnosed with arthritis than cutaneous psoriasis; in 3/15 patients the diagnosis was simultaneous during the medical visit. 9 (30%) patients presented a family history of 1st degree cutaneous psoriasis and 7/15 of them had a family history of 2nd grade psoriasis. Of the total number of patients, 10 of them would not meet the ILAR classification criteria, 8 because they presented as exclusion criteria being male, HLA-B27 positive and ≥6 years of age, among which, 7/8 would fulfill CASPAR criteria, and 2 other patients who were not classified according to ILAR criteria, did meet the CASPAR classification criteria, given the presence in these criteria of negative FR, family history of the 2nd degree and typical radiological alterations, which are not present in the ILAR criteria. 1 (1/30) patient did not meet CASPAR criteria, and belonged to the group of patients excluded from the ILAR criteria for being male ≥6 years HLA-B27 +. If we did not take into account the negative FR of the CASPAR criteria, 14 patients would not meet these criteria and if we eliminated the 2nd grade AF, 5 patients would not be classified (among them 2 who meet CASPAR and do not ILAR).

Conclusions: In our series of patients despite the fact that the presence of current skin psoriasis contributes 2 points in the CASPAR criteria, only 1 patient would not meet the CASPAR criteria, since the majority of patients present other clinical or analytical manifestations, such as the presence of negative rheumatologic factor or 2nd degree family history. Patients who do not meet criteria for PsA by CASPAR criteria, considered the family history of the 2nd degree and added a test to radiographic.

TRANSITION CARE OF PATIENTS WITH CHILGHOD ONSET CHRONIC RHEUMATIC DISEASE IN A TERTIARY MEDICAL CENTRE IN TURKEY

A. Adrovic1, E. Pehlivan1, O. Kuf1, S. Sahin1, K. Barut1, S. Ugray2, H. Ozdogan2, O. Kasapcopur1, 1Pediatric Rheumatology, 2Rheumatology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey.

Background: Transition care is a purposeful, planned movement of adolescence and young adults with chronic condition from childhood- to adult-oriented health care systems. Well-organised, systematic transitional health care is of high importance for the continuous and optimal health care of adolescents and young adults with chronic rheumatic disease. Further studies with higher number of patients would reveal the relevance of described transitional care model.

Objectives: To assess the applicability of the CASPAR classification criteria in a cohort of children patients with chronic rheumatic disease. Further studies with higher number of patients would reveal the relevance of described transitional care model.

Methods: Retrospective cross-sectional observational study. Clinical, epidemiological, sociodemographic and analytical variables were collected from 30 patients previously diagnosed with JPs (<16 years) or undifferentiated arthritis by exclusion criteria age ≥6 years old and HLA B27 positive, comparing these with the ILAR classification criteria, through the study of clinical features.

Results: The mean age at diagnosis was 11.2±4.6 years; 15 of them being women and 15 men. 15 (51.6%) patients presented cutaneous psoriasis at some point during the follow-up, in 5 patients onset psoriasis began after arthritis while 7 (23.3%) patients were diagnosed with arthritis than cutaneous psoriasis; in 3/15 patients the diagnosis was simultaneous during the medical visit. 9 (30%) patients presented a family history of 1st degree cutaneous psoriasis and 7/15 of them had a family history of 2nd grade psoriasis. NEUROLOGICAL EVALUATION OF CHILDHOOD-ONSET CRYOPYRIN-ASSOCIATED PERIODIC SYNDROMES-A PRELIMINARY REPORT

H. Klic1, S. Sahin2, C. Duman1, A. Adrovic3, K. Barut2, O. Kasapcopur4, S. Sahik1.

1Pediatric Neurology; 2Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey.

Background: The cryopyrin-associated periodic syndrome (CAPS) is a treatable autoinflammatory disease that encompasses familial cold autoinflammatory syndrome (FCAS), Muckle–Wells syndrome (MWS), and chronic infantile, neurologic, cutaneous, and articular syndrome (CINCA), which are quite different in severity. Early diagnosis of CAPS and prompt initiation of IL-1 blockers have significant effect on the neurologic prognosis of CAPS. Although neurologic complications of CINCA are well-known, there are scarce date regarding neurologic features of milder phenotypes.

Objectives: We aimed to review the neurologic features in detail and summarise the other CAPS-related manifestations in 9 children.

Methods: All children with CAPS that has been followed-up from paediatric rheumatology outpatient clinic, were enrolled to the study. In addition to the neurologic examination, magnetic resonance imaging (MRI) of brain, electroencephalography, eye examination, hearing test and neuropsychiatric tests were done. Demographic, clinical features, genetic analysis and laboratory tests were noted from patient records and hospital database.

Results: The median age of the subjects was 6 years (range 2–14 years), with a female-to-male ratio 4/5. Most frequently noted neurologic clinical manifestations during the disease course were papillodema (3/9) and epilepsy (3/9), followed by neurodevelopmental delay (2/9), aseptic meningitis (2/9), upper motor neuron...
findings (2/9), ocular symptoms/signs (2/9), sensorineural hearing loss (1/9), optic atrophy (1/9) (table 1). MRI of the brain was absent in two patients.

Conclusions: Increased understanding and awareness of this rare but treatable syndrome among neurologists is essential, since the disease could manifest with neurologic manifestations such as seizure, papillodema, sensorineural deafness and aseptic meningitis. If remains untreated and recognised, this autoinflammatory syndrome could lead to significant morbidity and mortality. Hence, early treatment with anti-interleukin-1 therapy provides complete resolution of symptoms and aseptic meningitis. If remains untreated and recognised, this autoinflammatory syndrome could lead to significant morbidity and mortality. Hence, early treatment with anti-interleukin-1 therapy provides complete resolution of symptoms and aseptic meningitis.

AB1081  FIRST TRANSITION CLINIC OF ADOLESCENTS WITH RHEUMATIC DISEASES IN MEXICO, A PILOT STUDY

N.E. Rubio-Pérez1; A.C. Arana-Guzmán2; F. García-Rodríguez3; A.V. Villareal-Treviño4; J.M. Torres-Made5; J.A. López-Rangel6; O. Salas-Fraire6; P. Ancín-Rodríguez7; M.E. Corral-Trujillo8; D.A. Galarza-Delgado9. 1Servicio de Reumatología Pediátrica, Departamento de Pediatría; 2Servicio de Reumatología, Departamento de Medicina Interna, Hospital Universitario “Dr. José Eleuterio González”; Universidad Autónoma de Nuevo León; 3Servicio de Reumatología Pediátrica, Departamento de Pediatría, Hospital Universitario “Dr. José Eleuterio González”; Universidad Autónoma Nuevo León; 4Departamento de Psiquiatría, Servicio de Medicina del Deporte y Rehabilitación, Departamento de Nutrición, Hospital Universitario “Dr. José Eleuterio González”; Universidad Autónoma de Nuevo León, Monterrey; 5Servicio de Psicología Clínica, Hospital Universitario “Dr. José Eleuterio González”; Universidad Autónoma de Nuevo León, Monterrey, Mexico

Background: The adolescence is a critical period when different processes are made, as identity, cognitive changes, enhance of autonomy, etc. Besides that, an adolescent with rheumatic disease has to front facing the disease acceptance. Already, different Transition Programs are made around the world. In Mexico does not exist this important project yet.

Objectives: Provide and uninterruped, multi-disciplinary and coordinated, properly developed health system with a comprehensive and psychosocial background.

Methods: We included rheumatologist, rehabilitation specialists, psychiatrist, nutritionist, clinical psychologist, nurse and social services. Got Transition Questionnaire (GOT) in Spanish version was used to evaluated patients and parents to evaluated the knowledge in transition process. We implemented the beginning of the clinic last July. We included patients with established rheumatic diseases, older than 16 years old. We use descriptive statistics wit measures of central tendency or frequencies depending on variable characteristics. We use Spearman’s correlation test to evaluated concordance of answers in GOT between parents and patients.

Results: We made a systematic evaluation program of all patients. Nineteen patients had already seen the clinic, most of them are female, the rest of clinical variables are shown in Table 1. Even though we found a positive Spearman’s coefficient (rho), and significant difference in answers related with “Perception of capability of adult-centred health care”, “Health knowledge”, and “Use of health-care services knowledge”, GOT results demonstrate weak of correlation between answers from patients and their parents. Correlation plots from GOT results are shown in figure 1.

Abstract AB1081 – Figure 1. GOT Transition correlations between parents and patients.
CHARACTERISATION OF A GROUP OF PATIENTS WITH IGG4-RELATED DISEASE: SINGLE CENTRE EXPERIENCE

A. Kozlova1, V. Burlakov2, D. Abramov2, A. Labertov2, G. Sagyayan2, A. Shcherbina2
1Immunology, National Medical Research Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev Moscow, Russia
2Immunology, National Medical Research Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev Moscow, Russia

Background: Immunoglobulin G4-related disease (IgG4-RD) is a chronic systemic inflammatory condition with an unclear pathophysiology and IgG4-positive plasma cell infiltration of various organs and parts of the body. If untreated, the disease can lead to fibrosis and irreversible organ damage. IgG4-RD mostly has been described in adults, hence it is generally unknown among paediatricians.

Objectives: We conducted a retrospective analysis of clinical features and response to therapy of five patients (one female, four males, median age 13.6 years) with IgG4-related disease, treated in our Centre.

Methods: The diagnosis was confirmed by detection of lymphoplasmacytoid infiltration with >30% of cells expressing IgG4 in all, and elevated IgG4 serum concentration in 4 cases.

Results: Three patients had localised lesions (orbit, hip muscle, peripancreatic tissue, respectively), two – multi-organ disease with polylymphadenopathy, pulmonary, renal and hepatic foci, dacryoadenitis with oedema of the eyelids. Autoimmune thymocytopenia (70 × 10³/l), neutropenia (0.79 × 10³/l) were present in one patient. Rituximab therapy was successful in 2 cases (one patient received monotherapy with rituximab, another one – Rituximab and Sirolimus). Two other patients received JAK inhibitor therapy (ruxolitinib) with good effect. No side effects were noted. One patient underwent surgery – the infiltration in the abdominal cavity was removed with positive effect without specific therapy.

Conclusions: IgG4-RD symptoms can be diverse and sometimes atypical, so dealing with this pathology requires physician’s awareness. Rituximab was effective in patients with multi-organ manifestations, and JAK inhibitor (Ruxolitinib) was effective in patients with mono-focal disease. Steroids are routinely used in IgG4-RD as a first line of treatment with significant side effects. We propose that alternative drugs could be used in IgG4-RD, especially in paediatric patients to achieve fast remission with significant morbidity.

CLINICAL AND DENSITOMETRIC CHARACTERISTICS IN PAEDIATRIC POPULATION WITH RISK FACTORS TO DEVELOP LOW BONE MASS/OSTEOPOROSIS

B. Magallares López1, J. Betancourt1, G. Fraga1, E. Quesada-Masachs2, M. López – Corbeto2, M. Torrent1, A. Marin1, S. Herrera1, E. Carreras1, J. Casademont1, H. Corominas1, J. Maluf1, Santa Creu i Sant Pau Hospital, Barcelona, Spain

Background: Low Bone Mass (LBM)/Paediatric Osteoporosis (Ped OP) is a disorder of unknown prevalence, partly due to the lack of diagnosis, associated with the absence of clinical manifestations of the disease until patients develop complications such as fractures, deformities or pain.

Objectives: To describe the clinical and densitometric characteristics of the paediatric population with risk factors to develop LBM/Ped OP

Abstract AB1083 – Table 1

Methods: We collected prospectively demographic and clinical data of patients aged 2 to 20 years, referred for bone health assessment due to the presence of a risk factors for LBM/Ped OP, including: inflammatory diseases, immunosuppressants and/or corticosteroids, malabsorptive diseases and chronic systemic disorders. We evaluated daily calcium intake and Bone Densitometry (DXA) was performed. We did also a vertebral morphometry.

Results: Data were collected from 90 patients, with an average age of 9.9 years, 53% female, 82% Caucasian. The age distribution and calcium intake by age can be seen in table 1.

There was a significant decrease in the compliance of the RDA with calcium with increasing age (p=0.01). No differences were found in the average daily calcium intake between the different diagnostic groups.

The most frequent diagnoses were: Malabsorption:44.4%, JIA:20%, Nephropathies:17.8%, Haematological diseases:7.8% and Vasculitis: 4.4%.

18% of the sample had had a fracture (Fx), 44% of them had more than one, being the adolescents the group of greater prevalence. 3 cases met the criteria for fragility Fx (vertebral Fx).

20% of the patients were on systemic corticosteroids, with an average dose of 5.9 mg of prednisone (or equivalent)/day, and another 20% had previously received them. The total cumulative average corticosteroid dose in both groups was: 7 grams of prednisone, with an average exposure of 37 months. 29 patients (32%) received immunosuppressive treatment, of which 29% were methotrexate (alone or in combination with biological DMARD).

Only 7% had supplements with Calcium and 14% with Vitamin D.

100% had a normal calcium, 82% a normal phosphate (rest slightly increased) and 11% were deficient in Vitamin D.

13% of the sample had a LBM for their age assessed by DXA. The densitometric results can be seen in Table 2.

Conclusions: Calcium intake in children and young with at least 1 risk factor for LBM/Ped OP is lower than recommended, especially in the groups with the highest requirements.

Up to 13% of this population have a BMO for their age and a 33% meets Ped OP criteria.

Larger studies are needed to help us to identify paediatric patients who are candidates for bone health screening.

PRELIMINARY RESULTS OF THE USE OF SERUM CALPROTECTIN (MPRS/MPR14) IN CLINICAL PRACTICE IN PAEDIATRIC RHEUMATOLOGY

B. Magallares López1, L. Martinez-Martinez2, M.G. Hernandez Latuente2, E. Molto Lacosta2 Y. Alvaro Gargallo2, H.S. Park1, I. Castelli1, M. Millán Arcinguez2, C. Diaz-Tosio1, P. Moya1, A. Laz1, J. Casademont1, H. Corominas1, E. Carreras2, C. Juarez2, Rheumatology; Immunology; Internal Medicine; Pediatrics, Santa Creu i Sant Pau Hospital, Barcelona, Spain

Background: Serum Calprotectin is a new biomarker of clinical activity in Rheumatology, especially in Juvenile Idiopathic Arthritis (JIA)

Objectives: To assess the use of serum Calprotectin in paediatric patients with inflammatory/Rheumatic diseases in clinical practice

Methods: We retrospectively collected Demographic and Clinical data from patients of our Paediatric Rheumatology Clinic, in which serum Calprotectin levels were determined.

The determination of serum Calprotectin was carried out using the ELISA technique.

Diagnostic and Inflammatory activity data were also collected: RCP, ESR and Clinical Assessment of the patients

Results: We present 26 patients, 61% females, with an average age of 11 (3–23 years)

The diagnoses were as follows: 16 JIA (57% of the total), of which 8 were of the Oligoarticular type, 3 were Polyarticular, 3 were Arthritis related to Enthesitis, 1 was Psoriatic and 1 Systemic. Other diagnoses were: Behçet1, Autoinflammatory Diseases: 4 (2 ADA2 Deficit, 1 Familial Mediterranean Fever, 1 PFAPA) and 7 patients had suspected rheumatological/inflammatory diseases in study

17 patients were considered clinically inactive, 6 with inflammatory activity and 3 doubtful at the time of blood test. The mean values of Calprotectin, RCP and ESR can be seen in Table 1.
Calprotectin was statistically correlated with Clinical Activity (p=0.018), however, neither ESR (p=0.539) nor RCP (p=0.059) did, although in RCP there was a clinical trend (ANOVA).

Calprotectin, RCP and ESR were negative in 91%, 80% and 76% respectively of inactive patients; and positive in 43%, 100% and 33% of the Active ones.

The analysis of the ROC curves in our sample showed that the value that allows to discriminate between active and non-active disease with a Sensitivity of 80% and a Specificity of 69% is 2.07 μg/mL.

Serum Calprotectin was 2 points higher in the group of patients with Autoinflammatory diseases than in the group of JIA, with a mean of 4.91 compared to 2.90 (p=0.002). However, since it is a retrospective study, we must bear in mind that this can be influenced by the reasons for the test request, being in the group of Autoinflammatory Disease the suspicion of active disease, and in the AJU simply monitoring or assessment of treatment optimisation.

It should be noted that the patients in diagnostic process that did not present any rheumatological disease (final diagnoses of: arthralgias in 3 cases and glocermenolonephritis not associated to rheumatological/autoimmune disease in 1), serum Calprotectine did not exceed in any case the 1.15 μg/mL.

Conclusions: Serum Calprotectin is emerging as a useful marker, not only in the field of JIA, but also in other diagnostic groups such as Autoinflammatory Diseases. Prospective and larger studies are needed to determine its role

AB1086

A 6-MONTH, MULTICENTER, OPEN-LABEL, EXPLORATORY STUDY OF FIXED DOSE NAPROXEN/ESOMEPRAZOLE IN ADOLESCENT PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA)

D.J. Lovell1, J.A. Dare2, J. Ball1, M. Francis-Sedlak3, B.D. Lamoreux4, R.J. Holt4,5
1 Cincinnati Children’s Hospital Medical Center, Cincinnati, 2Arkansas Children’s Hospital, Little Rock, 3Horizon Pharma USA, Inc., Lake Forest, 4University of Illinois-Chicago, College of Pharmacy, Chicago, USA

Background: JIA is an inflammatory arthritis of unknown etiology, which lasts for greater than 6 weeks with onset before 16 years of age.1, 2 Per the ACR guidelines, JIA is the most common chronic rheumatic disease in children.3 NSAIDs have been the mainstay of initial management with naproxen being commonly used, but they can cause serious side effects such as gastritis. Herein, we report the results of a clinical trial in JIA patients receiving one of 3 fixed doses of naproxen/esomeprazole magnesium (nap/eso) given BID (table 1).

Objectives: To evaluate the signs/symptoms of JIA, safety and tolerability of nap/eso in adolescents age 12 to 16 years.

Methods: Forty-six children and adolescents with JIA by ILAR criteria, mean age of 13.6 years, from 18 US sites were prospectively enrolled over 2 years and treated for up to 6 months. Mean number of active joints at baseline was 3.1. Doses were based on baseline weight (table 1). Disease activity was assessed with the ACR Pediatric-30, -50, -70, -90 Response and the Childhood Health Assessment Questionnaire (CHAQ) discomfort and functional scores at months 1, 3, and 6 as change from baseline. Occurrence and causality were assessed for treatment emergent AEs (TEAEs) and discontinuations were monitored monthly.

Results: Forty-six patients received at least 1 dose of study drug and 36 completed the trial. The% of patients achieving ACR Paediatric response increased over time (figure 1). CHAQ discomfort improved at each assessment and functional scores improved at all assessments for Arising, Walking, and Activities with several improved for Dressing and Grooming, Eating, Hygiene, and Grip. There was no indication of a dose-related efficacy effect. Thirty-seven (80.4%) had at least 1 TEAE. Frequent TEAEs (<5%) were upper respiratory tract infection, upper abdominal pain, sinusitis, diarrhea, headache, nausea, and ligament sprain. Eleven (23.9%) had at least 1 TEAE considered to be related to study drug. Most frequent study drug-related TEAE (<5%) was upper abdominal pain.

Four (8.7%) discontinued due to a TEAE.

**AB1087** PROLONGED RESPONSE WITH TUMOUR NECROSIS FACTOR ALFA INHIBITION IN A 5 YEAR OLD BOY WITH SEVERE MANIFESTATIONS OF IL-36 RECEPTOR ANTAGONIST DEFICIENCY (DITRA)

D. Clemente1, J.C. López Robledillo2, A. Torrejón, A. Hernández2, E. Villalobos3

1Pediatric Hematology, Immunology, 2Pediatric Dermatology, 3Pediatrics, Hospital Niño Jesús, Madrid, Spain

**Background:** Deficiency of the interleukin (IL)–36 receptor antagonist (DITRA) is an autosomal recessive autoinflammatory syndrome caused by mutations in the IL36RN gene. Clinical manifestations of DITRA include recurrent episodes of generalised skin postulation, fever, systemic inflammation and leukocytosis. An uniformly effective treatment for DITRA has not yet been identified.

**Objectives:** We present a case of a 5 year old patient with DITRA with prolonged response with tumour necrosis factor alfa inhibition with adalimumab.

**Methods:** A five-year-old came to our dermatology clinic after worsening of a pre-existing plaque psoriasis, with an erythematous scaly dermatitis that grew *E. Coli, S. Maltophila* and *S. epidermidis*. Skin biopsy showed acanthosis and papillomatosis with perivascular polymorphous inflammatory cells. Genetic analyses showed a homozygous mutation in the IL36RN gene (pSer113Leu). No mutations were detected in IL1RN and CARD 14 genes.

**Results:** Treatment was initiated with intravenous methylprednisolone 2 mg/kg/day and subcutaneous anakinra 2 mg/kg/day. Cefotaxime and co-trimoxazole were added until blood cultures were negative. Although skin lesions improved during the following days and patient was finally discharged, symptoms reappeared when decreasing the steroid dose. Three months later adalimumab and methotrexate were started, allowing the patient to end treatment with corticoids without evidence of activity of the disease.

**AB1088** CAPILLARY HEMOSIDERIN DEPOSITS OR EXTRAVASATIONS: A SUBTYPE OF HAEMORRHAGETHAT ACQUIRES SEPARATE ATTENTION IN QUANTITATIVE ANALYSIS OF NAILFOLD CAPILLAROSCOPY IN CHILDHOOD-ONSET SLE

D. Schonenberg-Meinema1, M. van den Berg2, A. Nasser-Sheikh-Rashid1, M. Boumans2, M. Cuto3, T. Kuijpers1, V. Smith*, on behalf of EULAR study group on microcirculation in rheumatic diseases. 1Pediatric Hematology, Immunology, Rheumatology and Infectious diseases, Emma Childrens Hospital, Academic Medical Center (AMC); 2Department of Clinical Immunology and Rheumatology, Academic Medical Center (AMC), Amsterdam, Netherlands; 3Research Laboratory and Academic Unit of Clinical Rheumatology, University of Genova, Genova, Italy; 4Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

**Background:** Quality of images in nailfold capillaroscopy has improved in the last years by introduction of videocapillaroscopy. Microangiopathy, as observed in capillaroscopy of SLE-patients,1,2,3 can now be described by more detailed quantitative analysis. Recently, in a small cohort (n=22) of childhood-onset SLE (cSLE), we described capillary bleedings by two different subtypes: large haemorrhages and small point-shaped haemorrhages with a total count of resp. 0.2/1.5 per...
INVESTIGATION OF THE EFFICACY AND SAFETY OF SECUKINUMAB TREATMENT IN JUVENILE IDIOPATHIC ARTHRITIS SUBTYPES OF JUVENILE PSORIATIC AND ENTHESIS-RELATED ARTHRITIS: DESIGN OF A RANDOMISED, DOUBLE-BLIND, PLACEBO CONTROLLED, MULTICENTER STUDY

D. Foell, J.A. Veit, E. Islas, K. Abrams*, on behalf of CAIN457F2304 Study Group. *Klinik für Pädiatrische Rheumatologie und Immunologie, Universitätsklinikum Münster, Westfälische Wilhelms-Universität, Münster, †Clinical Research Immunology and Dermatology, Novartis Pharma GmbH, Nürnberg, Germany, ‡Novartis Pharma AG, Basel, Switzerland. *Novartis Pharmaceuticals Corporation, New Jersey, USA

Background: Secukinumab (AIN457), a fully human anti-interleukin-17A monoclonal antibody, has demonstrated a significant clinically meaningful efficacy on signs and symptoms, structure and function in adults with ankylosing spondylitis (AS)† and psoriatic arthritis (PsA)‡, both approved indications. These data support the proposed study in children with enthesis-related arthritis (ERA) and juvenile psoriatic arthritis (JPsA).

Objectives: This phase 3 study will investigate the efficacy and safety of secukinumab in children ≥2 to<18 years with active JPsA or ERA. The primary objective is to demonstrate that the time to flare in a double-blind placebo control treatment withdrawal part of the trial is longer with secukinumab than placebo.
