**Background:** Ectopic production of the lymphoid chemokines CXCL13 and CXCL12 has been described in tertiary lymphoid structures (TLS) that harbour in the salivary glands of patients with Sjögren's Syndrome (pSS). Whilst CXCL13 expression correlates with clinical features, its potential role as a biomarker to

chemokine in the serum (pg/mL) of SLE patients compared to HC, respectively, included: sCX3CL1 (478.6±46.19; 235.4±140.8) and MCP-1 (2657±466.2; 648.5 ±69.6) (p<0.00001), MIP1β (141.0±10.71; 79.31±10.69) (p<0.0003), and TNFα (59.07±6.64; 29.31±3.15) (p<0.0041). Additionally, the disease severity and endothelial dysfunction associated biomarker VEGF increased in SLE patients (445.6.3±48.1 pg/mL) compared to HC (231.8±47.03 pg/mL) (p<0.0069). Lastly, HC monocyte subsets were stimulated with TLR7 and 8 ligands and supernatants evaluated for the analytes described above, see table 2.

**Conclusions:** Cell surface markers of activation and adhesion increased in SLE monocyte subsets compared to HC. In parallel, increased inflammatory cytokines and chemokines that attract monocytes to tissues were increased in the serum of these patients. Linking a possible source of this increase in serum analytes, HC monocyte subsets were stimulated with disease-relevant ligands and evaluated in culture. Along with increased monocyte expression of CX3CR1, preliminary data demonstrates an increase in CX3CL1 expression on endothelial progenitor cells (EPCs) and immature and mature circulating endothelial cells (iCECs and mCEC respectively) in active disease.

**FRI0292 DYSFUNCTION OF TFH, TREG AND TR1 CELLS IN APOE-/- FASLG/D C57BL/6 MICE WITH LUPUS SYMPTOMS AND ATHEROSCLEROSIS**

S. Wang, G. Yao, L. Sun. Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

**Background:** Cardiovascular disease due to atherosclerosis is currently recognised as one of the leading causes of death among patients with systemic lupus erythematosus (SLE). It is well established that dysfunction of lymphocytes contribute to the pathogenesis of SLE. Recent studies also showed infiltration of several subsets of lymphocytes in atherosclerotic lesions and their various contributions to atherosclerosis were uncovered in experimental models and patients. However, the predominant and specific subsets of lymphocytes that play critical role in the pathogenesis of SLE patients with cardiovascular complications remained to be elucidated.

**Objectives:** This study aims to define the dominant population of lymphocytes in mice with combination of lupus and atherosclerosis.

**Methods:** The mouse model of accelerated atherosclerosis in lupus (ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice) was generated from apolipoprotein E-deficient (apoE<sup>-/-</sup>) and FasI<sup>gld</sup> C57BL/6 mice. The lupus-like autoimmunity and atherosclerotic lesions was evaluated. The lymphocytes of spleen and peripheral blood were analysed by flow cytometry.

**Results:** The results of PCR and sequencing showed that the double-mutant ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice were generated. Splens from 5 month-old ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice were significantly enlarged compared with wild type mice (WT mice). ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice displayed a pattern of glomerulonephritis typically found in SLE and showed marked C3, IgG and IgM deposits in the glomeruli. Anti-dsDNA antibody and high levels of creatinine were detected in the serum of ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice. These results indicated that the ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice have typical characteristics of SLE. Oil red O staining revealed that there was significantly increased atherosclerotic lesion area at the proximal aorta in ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice compared with WT mice (figure 1 a,b). The frozen section of myocardium stained by oil red O revealed that lipid deposited in myocardial cells of ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice (figure 1 c,d). As expected, total cholesterol, LDL cholesterol and triglyceride were significantly increased, while HDL cholesterol decreased in the double-mutant mice. These results indicated that ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice had accelerated atherosclerosis.

**Conclusions:** The ApoE<sup>-/-</sup> FasI<sup>gld</sup> B6 mice simultaneously exhibit SLE and atherosclerosis characteristics. Our findings suggested that proinflammatory M1 macrophages and Th cells were increased, while the anti-inflammatory Treg and Tr1 cells were decreased and the imbalance of these cells and their releasing cytokines contributed to progression in atherosclerosis with SLE. Further studies may validate these cells as potential targets for treating SLE patients with atherosclerosis.

**FRI0293 IMBALANCE IN CIRCULATING SUBSETS OF INNATE LYMPHOID CELLS IS LINKED TO DISEASE ACTIVITY AND TYPE I INTERFERON SIGNATURE IN PRIMARY SJÖGREN'S SYNDROME**

S.L. Blokland<sup>1,2</sup>, L.L. van den Hoogen<sup>1,2</sup>, E.F. Leijten<sup>1,2</sup>, A.A. Kruijs<sup>1</sup>, T. R. Radstake<sup>1,2</sup>, J.A. van Roon<sup>1,2</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, <sup>2</sup>Laboratory of Translational Immunology, Umc Utrecht, Utrecht, Netherlands

**Background:** Recent studies indicate an important role for innate lymphoid cells (ILCs) in the pathophysiology of rheumatic diseases. In rheumatoid arthritis and spondyloarthropathies elevated numbers of subsets of ILCs have been found at the site of inflammation producing cytokines including IFN-γ and IL-22 and in addition, group 3 ILC have been suggested to be involved in formation of ectopic lymphoid structures in rheumatic diseases, Shikhaigie Nat Rev Rheumatol 2017 Wenink A and R 2017). ILC3-like cells producing IL-22 have been found in the salivary glands of pSS patients. Ciccia ARD 2012 However, circulating ILC have not yet been studied in primary Sjögren's syndrome (pSS) and systemic lupus erythematosus (SLE). Furthermore, SLE and pSS are characterised by presence of a type I interferon (IFN) signature in a large proportion of the patients. Animal studies in HIV and asthma implicate type I IFN, produced by plasmacytoid dendritic cells (pDCs), to regulate the survival of group 2 and group 3 ILCs (ILC2 and

ILC3) via increase of Fas (CD95) expression, rendering the ILC more susceptible to apoptosis, Maazi JACI 2017, Zhang JCI 2015. Duerr Nat Immunol 2016

**Objectives:** In this study, we explored for the first time the frequency and phenotype of circulating ILCs in pSS and SLE and their relation to the IFN signature.

**Methods:** Frequencies and phenotypes of ILC subsets and pDCs were assessed by flow cytometry in peripheral blood of patients with pSS (n=20), SLE (n=20) and healthy controls (n=17). Patients were stratified by the presence or absence of an IFN signature as assessed by RT-qPCR on peripheral blood mononuclear cells as previously described. Brkic ARD 2013

**Results:** ILC1 numbers were increased in peripheral blood of patients with SLE as compared to healthy controls and in pSS patients ILC1 numbers correlated with disease activity (ESSDAI score), serum IgG levels and anti-SSB auto-antibodies (all p<0.05). Numbers of ILC1, ILC2 or ILC3 did not significantly differ between patients with SLE and pSS. However, patients with a high expression of the type I IFN signature had significantly decreased numbers of ILC2 and ILC3 (p=0.04 and p=0.02, respectively). The decrease of ILC2s and ILC3s was related to increased expression of Fas (CD95) on these cells in patients with a high type I IFN signature (both p=0.01).

**Conclusions:** Both in SLE and pSS, a type I IFN signature is related to reduced numbers of circulating ILC2s and ILC3s in association with increased Fas expression on these cells possibly rendering them more susceptible to Fas/FasL-dependent apoptosis at peripheral sites.

#### FRI0294 INJURED PODOCYTES EXPRESS COMPLEMENT FACTOR H AND PROCESS IMMUNE COMPLEX DEPOSITION IN GLOMERULAR SUBENDOTHELIAL AREA

T. Zoshima<sup>1</sup>, S. Hara<sup>1</sup>, M. Nagata<sup>2</sup>, M. Kawano<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Kanazawa University Hospital, Kanazawa; <sup>2</sup>Kidney and Vascular Pathology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

**Background:** Glomerular Immune complex (IC) deposition causes glomerulonephritis in lupus nephritis. The reaction of intrinsic glomerular cells differs according to the area of IC deposition. Subepithelial IC deposits cause functional and structural changes on podocytes (glomerular visceral epithelial cells) through complement pathway activation as is well known in membranous glomerulonephritis. In this setting, podocytes can induce some complement factors including complement factor H (CFH) which serves not only to regulate the alternative pathway but also to process subepithelial IC deposition.<sup>1</sup> However, whether podocyte processing of IC deposition is limited to only the subendothelial area is obscure.

**Objectives:** To clarify the role of podocytes in IC deposition in the glomerular sub-endothelial area.

**Methods:** NEP25 mice genetically expressing human CD25 in podocytes were used. Intravenous immunotoxin for human CD25 (LMB2) provokes podocyte-specific injury (NEP25/LMB2). By shortening the period of LMB2 exposure to NEP25 mice, we mitigated the podocyte injury. We administered intraperitoneally IgG3-producing hybridoma clones, 2B11.3, which were previously established from an unmanipulated MRL/lpr mouse, to NEP25 mice (NEP25/hybridoma). Furthermore, we also injected short-term LMB2 to NEP25/hybridoma mice (NEP25/hybridoma/LMB2). We investigated IC deposits by immunofluorescence and electronic microscopic study. We measured complement regulatory factor mRNA expression including CFH, complement factor I (CFI), decay-accelerating factor (DAF), complement receptor 1-related gene/protein y (Cry), C3a receptor (C3aR) and C5a receptor (C5aR) of isolated glomeruli of each mouse by quantitative real time-PCR. In an *in vitro* study, we assessed CFH mRNA expression of immortalised mouse podocytes injured by puromycin.

**Results:** First, NEP25/LMB2 mice showed glomerular tuft collapse with epithelial cell hyperplasia, suggesting podocyte loss by light microscopy study as reported previously. mRNA expression of all complement regulatory factors but C5aR was decreased in NEP25/LMB2 mice as compared with NEP25 mice. This result suggests that podocytes produce these complement regulatory factors. On the other hand, when the podocyte injury was mitigated, CFH and C3aR mRNA expression increased, and CFI, DAF and Cry mRNA expression decreased as compared with NEP25 mice. Second, we detected IC deposition only in the glomerular sub-endothelial area without endocapillary proliferative lesion in NEP25/hybridoma mice. They showed increase of C3aR mRNA expression, and decrease of CFI and DAF mRNA expression as compared with controls. Notably, subendothelial IC deposition did not alter CFH mRNA expression. Third, NEP25/hybridoma/LMB2 (milder podocyte injury) showed decrease of IC deposits in glomeruli and increase of only CFH mRNA expression (1.7-fold) as compared to NEP25/hybridoma mice, while there was no significant change in mRNA expression of other

complement regulatory factors. Finally, puromycin-induced mild podocyte injury promoted CFH mRNA expression in cultured podocytes as compared to controls.

**Conclusions:** Mildly injured podocytes induce CFH expression, and serve to process IC deposition in the glomerular subendothelial area.

#### FRI0295 INHIBITION OF CATHEPSIN S LEADS TO SUPPRESSION OF ANTIGEN SPECIFIC T CELLS FROM PATIENTS WITH PRIMARY SJÖGREN SYNDROME

P. Hargreaves<sup>1</sup>, M. Theron<sup>2</sup>, F.A. Kolb<sup>2</sup>, M. Manchester<sup>2</sup>, B. Reis<sup>2</sup>, A. Tiaden<sup>1</sup>, D. Kyburz<sup>1</sup>, T. Manigold<sup>1</sup>. <sup>1</sup>Rheumatology, Universitätsspital Basel; <sup>2</sup>Roche Pharma Research and Early Development, F. Hoffmann-La Roche, Basel, Switzerland

**Background:** Primary Sjögren syndrome (pSS) is an autoimmune disease characterised by an infiltration of T and B cells into exocrine gland tissue and its subsequent destruction<sup>1</sup>. Antigen presenting cells, including B cells, foster T cell activation and anti-SS-A/SS-B producing plasma cells, eventually leading to disease progression and systemic complications<sup>2</sup>.

**Objectives:** Cathepsin S (CatS) is crucially involved in MHCII processing in pSS mouse models<sup>3</sup> and patients<sup>4</sup>. In this translational study we investigated the *ex vivo* effects of the CatS inhibitor RO5459072 in different bio-compartments, including specific T cells, of pSS patients and healthy controls.

**Methods:** *Ex vivo* CatS activity was assessed in different bio-compartments of 15 pSS patients and 13 healthy controls and in presence or absence of RO5459072 using commercial activity and quantification assays. In addition, antigen (5 µg/mL SS-A, 5 µg/mL SS-B, 5 µg/mL Influenza H<sub>3</sub>N<sub>2</sub>; 2 µg/mL Tetanus Toxoid and 100 ng/mL SEB) specific T cell responses were examined using 2 × 10<sup>5</sup> PBMC/well IFN-γ/IL-17 Dual ELISPOT (48 hour incubation) and 5 × 10<sup>4</sup> PBMC/well BrdU proliferation assays after (72 hour incubation) in presence or absence of RO5459072.

**Results:** pSS patients showed significantly higher CatS activity in tear fluid than healthy controls (two-tailed t-test p<0.01). RO5459072 significantly suppressed CatS activity in tears of pSS patients (two-tailed t-test p<0.01). CatS inhibition also exerted a strong and dose-dependent suppression of T cell responses towards SS-A and SS-B antigen in *ex vivo* derived pSS patient cells in Elispot and BrdU assays (table 1).

Table 1 Suppression of antigen specific T cell responses (Elispot) and suppression of cell proliferation (BrdU) in the absence or presence of RO5459072 (0–100 µM). One-tailed t-test: \*p<0.05, \*\* p<0.01, \*\*\*p<0.001, \*\*\*\* p<0.0001

**Conclusions:** CatS activity in tear fluid seems to be a relevant biomarker for pSS disease activity. RO5459072 is a potent inhibitor of CatS and the pSS associated relevant antigen specific T cell responses.

### KZR-616, A SELECTIVE INHIBITOR OF THE IMMUNOPROTEASOME, BLOCKS THE DISEASE PROGRESSION IN MULTIPLE MODELS OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

T. Muchamuel<sup>1</sup>, J.L. Anderl<sup>2</sup>, R.A. Fan<sup>2</sup>, H.W.B. Johnson<sup>3</sup>, C.J. Kirk<sup>4</sup>, E. Lowe<sup>2</sup>.  
<sup>1</sup>Pharmacology; <sup>2</sup>Biology; <sup>3</sup>Chemistry; <sup>4</sup>Research, Kezar Life Sciences, South San Francisco, USA

**Background:** The proteasome inhibitor bortezomib has been used successfully to treat patients with SLE. The immunoproteasome is a distinct class of proteasome found predominantly in immune effector cells. KZR-616 is an analogue of ONX 0914, Nature Medicine 2009) that selectively targets the LMP7 and LMP2 subunits of the immunoproteasome.

**Objectives:** To examine the therapeutic potential of KZR-616 in preclinical models of SLE and lupus nephritis (LN).

**Methods:** Cytokines were measured in human PBMCs stimulated with endotoxin and in CD4 + T cells stimulated with antibodies to CD3 and CD28. Human B-cells were stimulated with IL-21 and antibodies to CD40 and IgM to induce plasmablast differentiation. Immunoproteasome inhibition was measured in KZR-616 treated human PBMCs and in mice by measuring proteasome active site occupancy. The therapeutic effect of KZR-616 alone or in combination with mycophenylate mofetil (MMF) was evaluated in the NZB/W F1 model of SLE. T-dependent antibody responses (TDAR) were measured in mice and monkeys following 1, 4, or 13 weekly administrations.

**Results:** At a concentration resulting in inhibition of LMP7 and LMP2 by 89% and 59%, respectively, KZR-616 induced a decrease in pro-inflammatory cytokine production in human PBMCs, including TNF- $\alpha$ , GM-CSF, IL-6, and IL12/IL-23 p40. In lymphocytes, KZR-616 blocked T-cell production of IFN- $\gamma$ , TNF- $\alpha$  and GM-CSF, and the differentiation of B-cells to plasmablasts. KZR-616 administration to mice resulted in selective inhibition of LMP7 and LMP2 similar to levels *in vitro*. KZR-616 treatment in diseased mice resulted in a complete resolution of proteinuria and significant reductions in autoantibody production and renal IgG deposition. The halt in disease progression was durable as proteinuria levels did not significantly increase 8 weeks after treatment discontinuation. Histologic analysis following 12 weeks of treatment revealed a complete prevention in glomerular nephritis and sclerosis. Administration of KZR-616 in combination with MMF resulted in significantly greater disease inhibition and prolonged survival compared to either treatment alone. Levels of activated T- and B-cells and short- and long-lived plasma cells were effectively depleted in diseased animals following KZR-616 treatment. KZR-616 had no significant effect on TDAR in mice or monkeys and did not affect the number of circulating lymphocytes in monkeys.

**Conclusions:** KZR-616 is a novel and selective covalent inhibitor of the immunoproteasome that potentially blocks inflammatory cytokine production *in vitro* and disease progression in mouse models of SLE. Durable disease remission in animals was achieved at well tolerated doses without affecting normal T-cell dependent immune responses. KZR-616 is currently being developed for the treatment of LN and Phase 1 safety and pharmacokinetics results are presented elsewhere at this meeting.

### MACROPHAGE-DERIVED LCN2 CONTRIBUTES TO DEVELOPMENT OF LUPUS NEPHRITIS

W. Chen, L. Sun. *The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Renal involvement is a major concern in systemic lupus erythematosus (SLE). Many findings have indicated that plasma and urinary LCN2 is a potential marker of the presence and severity of renal involvement in SLE. However, whether LCN2 has a pathogenic or protective role in lupus nephritis (LN) is still unknown.

**Objectives:** In this study we analysed the expression of LCN2 in lupus patients and determined whether neutralisation of LCN2 with a monoclonal antibody or injection of recombinant LCN2 affects LN in mice.

**Methods:** Plasma and urine LCN2 was quantified by ELISA in SLE patients and healthy controls (HCs). The correlations between the levels of LCN2 and clinical features were analysed by Spearman's correlation test. CD14<sup>+</sup> monocytes were isolated from peripheral blood of HCs and SLE patients. We cultured human monocytes for 7 days with macrophage colony-stimulating factor (M-CSF) to generate macrophages. To investigate the production of LCN2 in lupus mice during progression of LN, plasma and urine LCN2 levels were measured by ELISA, mRNA and protein levels of LCN2 in different tissues were measured by qPCR and western blot respectively at different stages of disease. To investigate whether increased LCN2 levels contribute to the development of LN, the 16-week-old mice received weekly intraperitoneal of anti-LCN2 antibody or recombinant LCN2 for 4 weeks and analysed 1 week after the last injection. The renal pathology, proteinuria, spleen index were evaluated. The frequency of T lymphocyte subpopulation, B cells and plasma cells in spleen and lymph node was analysed by flow cytometry. Bone marrow derived macrophages (BMDMs) were isolated from tibia and femurs in mice. The expression of LCN2 in human macrophages and BMDMs were detected by qPCR.

**Results:** Plasma and urine LCN2 levels were markedly increased in SLE patients, and plasma LCN2 was positively correlated with urine LCN2. The levels of LCN2 in both plasma and urine were positively correlated with serum creatinine and 24 hour urine protein. The levels of LCN2 in the patients with LN were significantly higher than those without LN. At 10 weeks, when mice do not show any signs of systemic lupus, plasma LCN2 levels were low but increased significantly in 15- and 20-week-old mice. The increased plasma LCN2 was correlated with proteinuria and deposition of IgG in glomeruli. The mRNA level of LCN2 was increased in different tissues including liver, kidney and spleen. The same results were found in protein levels. Administration of LCN2 aggravated the disease with significantly higher renal activity scores and more IgG deposition. Neutralisation of LCN2 significantly improved renal pathology and reduced the glomerular deposition of IgG. Furthermore, anti-dsDNA antibody and proteinuria were significantly lower in the anti-LCN2 group. Flow cytometry revealed a significant decrease of T cells, B cells and Th1 cells in the anti-LCN2 group. While LCN2 significantly increased T cells, plasma cells and Th1 cells. LCN2 mRNA level in macrophages was significantly increased in SLE patients. And its expression was also increased in BMDMs with the progression of disease in lupus mice.

**Conclusions:** These findings suggested that LCN2 over-production by macrophages plays an important role in the pathogenesis of SLE and the progression of lupus nephritis. Thus, blockade of LCN2 may represent a new strategy for treatment of LN.

FRI0298

### ALTERED FREQUENCIES OF CIRCULATING INNATE LYMPHOID CELLS AND ITS SUBSETS ARE CORRELATED WITH DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Y. Jiang, Y. Zhao, Y. Liu, X. Mo. *Department of Rheumatology and Immunology, West China Hospital, Sichuan University, Chengdu, China*

**Background:** Systemic lupus erythematosus (SLE) is a chronic, multisystem autoimmune disorder with a heterogeneous clinical manifestations that results from abundant immunological abnormalities. Innate lymphoid cells (ILCs), one subset of the innate immune cells, are divided into cytotoxic ILCs (namely natural killer cells) and non-cytotoxic ILCs (namely helper-ILCs). Non-cytotoxic ILCs are composed of three groups, group 1 ILCs, group 2 ILCs and group 3 ILCs, based on depended transcription factors and producing cytokines. So far, alterations of ILCs and their subsets have been reported in some autoimmune diseases except SLE.

**Objectives:** To visualise differences in frequencies of ILCs and their subsets in the peripheral blood of patients with SLE and healthy controls in Chinese Han population.

**Methods:** Peripheral blood mononuclear cells (PBMCs) was obtained from twenty-five SLE patients and twelve healthy controls and were stained with antibodies to CD45, lineage (CD3, CD19, CD123, CD11c, CD14, CD16, CD34, CD94, and Fc $\epsilon$ R1 $\alpha$ ), CD4, CD8, CD127, CD117, CRTH2 and NKp44. Circulating total ILCs and its subsets were identified by flow cytometry. The associations between disease activity and all the detected cells were evaluated using the Pearson or Spearman correlation coefficient.

**Results:** Increased frequencies of ILC2 and ILC3 were observed in patients compared to controls, while decreased frequency of ILC1 was found in patients compared with controls ( $p=0.008$ ,  $p=0.004$ , and  $p=0.006$ , respectively). We also found the expression of T cell surface markers, CD4 or CD8, on ILCs and their subsets. The results showed that decreased frequencies of CD4<sup>+</sup>CD8<sup>+</sup> ILCs, CD4<sup>+</sup>CD8<sup>+</sup>ILC1, CD4<sup>+</sup>CD8<sup>+</sup> ILC2, CD4<sup>+</sup>CD8<sup>-</sup> ILC2, and CD4<sup>+</sup>CD8<sup>-</sup>CD336<sup>-</sup> ILC3 were found in patients compared with healthy controls ( $p=0.001$ ,  $p=0.017$ ,  $p=0.001$ ,  $p=0.004$ , and  $p=0.002$ , respectively). Furthermore, frequencies of CD4<sup>+</sup>CD8<sup>+</sup> ILCs and CD4<sup>+</sup>CD8<sup>+</sup> ILC2 were positively correlated with the SLEDAI-2000 score ( $r=-0.548$ ,  $p=0.005$  and  $r=-0.613$ ,  $p=0.001$ , respectively). Frequencies of CD4<sup>+</sup>CD8<sup>+</sup> ILCs and CD4<sup>+</sup>CD8<sup>+</sup> ILC1 were positively related with serum C3 level ( $r=0.519$ ,  $p=0.008$  and  $r=0.528$ ,  $p=0.007$ , respectively), and were positively related with serum C4 level ( $r=0.623$ ,  $p=0.001$  and  $r=0.643$ ,  $p=0.001$ , respectively).

**Conclusions:** In the present study, we demonstrated that frequencies of circulating ILCs and its subsets were altered in SLE patients and some subpopulations were negatively correlated with SLE disease activity.

#### FRI0299 MUCOSAL-ASSOCIATED INVARIANT T CELL DEFICIENCY IN SYSTEMIC LUPUS ERYTHEMATOSUS IS RELATED TO AN INTRINSIC DEFECT IN THE CA2+/CALCINEURIN/NFAT1 SIGNALLINGPATHWAY

Y.-W. Park<sup>1</sup>, Y.-N. Cho<sup>1</sup>, H.-M. Jin<sup>1</sup>, S.-J. Kee<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Laboratory Medicine, Chonnam National University Hospital, Gwangju, Korea, Republic Of

**Background:** Mucosal-associated invariant T (MAIT) cells contribute to protection against certain microorganism infections and play an important role in mucosal immunity. However, the role of MAIT cells remains enigmatic in autoimmune diseases.

**Objectives:** Here, we examined the level and function of MAIT cells in patients with rheumatic diseases.

**Methods:** Patients with systemic lupus erythematosus (SLE;  $n=54$ ), rheumatoid arthritis (RA;  $n=66$ ), Behçet's disease ( $n=9$ ), ankylosing spondylitis ( $n=21$ ), and healthy controls ( $n=136$ ) were enrolled in the study. MAIT cell, cytokine and programmed death-1 (PD-1) levels were measured by flow cytometry.

**Results:** Circulating MAIT cell levels were significantly reduced in systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) patients. In particular, this MAIT cell deficiency was more prominent in CD8<sup>+</sup> and double-negative T cell subsets, and significantly correlated with disease activity, such as SLE disease activity index (SLEDAI) and 28-joint disease activity score (DAS28). Interestingly, MAIT cell frequency was significantly correlated with natural killer T (NKT) cell frequency in SLE patients. IFN- $\gamma$  in MAIT cells was impaired in SLE patients, which was due to an intrinsic defect in the Ca<sup>2+</sup>/calcineurin/NFAT1 signalling pathway. In SLE patients, MAIT cells were poorly activated by  $\alpha$ -galactosylceramide-stimulated NKT cells, thereby showing the dysfunction between MAIT cells and NKT cells. Notably, an elevated expression of PD-1 in MAIT cells and NKT cells was associated with SLE. In RA patients, MAIT cell levels were significantly higher in synovial fluid than in peripheral blood.

**Conclusions:** Our study primarily demonstrates that MAIT cells are numerically and functionally deficient in SLE. In addition, we report a novel finding that this MAIT cell deficiency is associated with NKT cell deficiency and elevated PD-1 expression. These abnormalities possibly contribute to dysregulated mucosal immunity in SLE.

#### FRI0300 POLYMORPHISM OF 5,10-METHYLENETETRAHYDROFOLATE REDUCTASE (C677T) IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME, ITS ASSOCIATION WITH CARDIOVASCULAR LESIONS

Y. Sehedá, S. Shevchuk, I. Kuvikova, O. Galiutina. *rheumatology, Institute of invalid rehabilitation, Vinnitsya, Ukraine*

**Background:** Many studies have been conducted to determine the role of genetic polymorphism in the occurrence of cardiovascular diseases. The pathogenetic significance of MTHFR polymorphism is the subject of intensive research, especially its connexion with lesions of the cardiovascular system. The frequency of C677T polymorphism in the 5,10-MTHF gene is poorly known in patients with antiphospholipid syndrome (APS), and its relationship with vascular lesions has not been studied yet.

**Objectives:** The present study aimed to analyse the C677T mutation of the MTHFR gene and its association with endothelial dysfunction and clinical manifestations of cardiovascular lesions in APS.

**Methods:** We studied 82 patients with APS, including 34 (41.6%) with primary antiphospholipid syndrome (PAPS) and 48 (58.4%) with secondary antiphospholipid syndrome (SAPS). The analysis of the MTHFR C677T mutation was performed by PCR followed by digestion according to Frosst et al. All patients were assessed for the endothelium-dependent vasodilatation of brachial artery (EDVD), the thickness of the intima-media of the common carotid artery (IMT), the presence of atherosclerotic plaque (AP) and clinical manifestations of cardiovascular lesions

**Results:** There were 10.8% of homozygotes (677-TT), 37.8% of heterozygotes (677-CT) and 51.4% of homozygotes (677-CC) in the control group, and the frequency of T-alleles amounted to 29.7%. The incidence of T-alleles was higher among the patients with APS than in the control group and was 35.4%. The prevalence of homozygotes (677-TT), heterozygotes (677-CT) and homozygotes (677-CC) was not significantly different between the PAPS and SAPS groups (44.1%, 38.2%, 17.7% and 45.8%, 39.6%, 14.6% respectively  $p<0.05$ ). The frequency of T-alleles was higher in PAPS group than in SAPS group (36.8% against 34.4%, respectively  $p<0.05$ ). The analysis of structural and functional vascular lesions in homozygotes (677-CC), homozygotes (677-TT) and heterozygotes (677-CT) did not reveal significant differences in both mean values and the proportion of individuals with IMT thickness ( $0.86\pm 0.03$  mm,  $0.88\pm 0.05$  mm,  $0.90\pm 0.03$  and 35.3%, 38.5%, 51.7% respectively  $p<0.05$ ) with decrease of EDVD ( $7.09\pm 0.49$ ,  $6.32\pm 1.0$ ,  $6.92\pm 0.58$  and 47.0%, 53.8%, 48.3% respectively  $p<0.05$ ) and the presence of AP (26.5%, 23.1%, 48.3% respectively  $p<0.05$ ). Although there was a tendency of IMT thickness increase and EDVD decrease for T-carriers. The proportion of persons with IMT thickness ( $>0.90$  mm) and the decrease of EDVD BA ( $\leq 8.0\%$ ) among the homozygote 677-TT was 3%–6.5% higher than that of the 677-CC homozygote. The frequency of clinical manifestations of cardiovascular lesions (myocardial infarction, stroke, TIA) was in 1.2–1.8 times more often among the homozygotes 677-TT than 677-CC homozygote.

**Conclusions:** The mutation of the C677T of the MTHFR gene is not a risk factor for the development of atherosclerotic vascular damage in patients with APS, due to the lack of associative interrelationships between the decrease of EDVD, increase of IMT, clinical manifestations on the one hand, and the MTHFR polymorphism on the other

#### FRI0301 SERUM EXOSOMES INVOLVED IN THE PROGRESSION OF LUPUS NEPHRITIS

Z. Zhang, W. Xue, J. Ji, T. Fu, J. Yang, Z. Gu. *Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China*

**Background:** Systemic lupus erythematosus (SLE is a chronic autoimmune disease that systemically affects several important organs).<sup>1</sup> Lupus nephritis (LN is one of the most severe complications of SLE).<sup>2</sup> Exosomes are important mediators of biological information and play a part in the occurrence and development of various diseases including LN.<sup>3</sup>

**Objectives:** The aim of study was to find whether exosomes participate in the pathogenesis of lupus nephritis.

**Methods:** We studied 10 patients with SLE but no LN, 10 patients with LN and 10 healthy people which are in line with the SLE classification criteria of American College of Rheumatology diagnostic (ACR) in 1997 and the LN pathological classification of ISN and RPS in 2003. Exosomes were isolated from the serum by ultracentrifugation and confirmed by transmission electron microscope and western blot. The internalisation of exosomes was detected by immunofluorescence. Then exosomes were injected into MRL/lpr mouse via the tail vein and co-cultured with mesangial cells. Flow cytometry was used to detect the alteration of cell cycle. The cell proliferation was determined by CCK-8 assay. The inflammatory cytokines (TNF- $\alpha$ , IL-6) and collagen I level in medium supernatant by ELISA, signal pathway by immunoblotting. Additionally, High-throughput sequencing was used to detect the expression of miRNAs in exosomes.

**Results:** The proteinuria and the percent of kidney crescent formation index of LN group was significantly high than other three groups. Exosomes can be absorbed by mesangial cells quickly. The secretion of inflammatory cytokines and collagen I of LN group were higher than NLN and control group ( $p < 0.05$ ). PI3K/AKT pathway are involved, but there was no significant difference between NLN group and control group. High-throughput sequencing revealed 11 up-regulated miRNA in SLE relative LN, 3 up-regulated miRNA in LN relative healthy people.

**Conclusions:** LN exosomes can enhance the proliferation and secretion of mesangial cells in which PI3K/AKT pathway is activated. This tip us exosomes may involve in the pathogenesis of LN.

**Background:** The occurrence of a TMA during SLE is a rare event that complicates 1% to 4% of lupus. The full spectrum of TMA can be encountered in the course of SLE: acquired thrombotic thrombocytopenic purpura (TTP), TMA associated with glomerulonephritis (TMA GN), atypical hemolytic uremic syndrome (aHUS), microangiopathic antiphospholipid syndrome (MAPS; defined or probable catastrophic antiphospholipid syndrome) or HELLP syndrome during pregnancy.

**Objectives:** To describe the clinical phenotype of TMA in lupus, to specify the prognosis and to identify factors allowing early classification and management of the different subtypes.

**Methods:** We performed a French multicentric retrospective study from January 1987 to December 2017 in units of internal medicine, nephrology and ICU. Inclusion criteria associated SLE defined by the ACR and/or SLICC criteria and a TMA defined either by the presence of microangiopathic anaemia and peripheral thrombocytopenia, either by histological signs of TMA.

**Results:** 68 events of TMA occurred in 60 SLE patients; median age was 24 years; 56 women (F/M ratio: 14). Diagnosis of SLE was assessed at a paediatric age in 24 (35.8%) patients. Clinical manifestations of SLE were: acute cutaneous lupus (n=48, 71%), arthritis (n=36, 53%), pleuritis (n=13, 19%), pericarditis (n=25, 37%), renal involvement (n=39, 57% including 20 class IV glomerulonephritis) and auto-immune cytopenia (n=22, 32%). Triggering factors of TMA were: lupus flare (n=38), infections (n=12), pregnancy and peripartum (n=3), or therapeutic rupture (n=4). Clinical and biological features at diagnosis of each subtypes of TMA are presented in table 1. A platelet count lower than 28 000/mm<sup>3</sup> was predictive of TTP diagnosis (Se=90,5%, Sp=88,5%), likewise a creatinine plasma level greater than 100 µmol/L was predictive of TMA GN (Se=88,5%, Sp=85%). The treatment of TMA included (alone or in combination): corticosteroids in all cases, plasma exchange (n=52), cyclophosphamide (n=28), Rituximab (n=15), Eculizumab (n=2), antiplatelet agent (n=36), and/or effective anticoagulation (n=26). The median duration of follow-up was 150 months. Among TMA GN patients, the final median GFR was 58 mL/min (range: 0–120) with 5 individuals on chronic dialysis and 1 kidney transplant. Among TTP patients, one died from TMA, whereas the final median GFR of survivors (n=59) was 97 mL/min (range: 64–150), without any patient requiring dialysis.

Table 1 Comparisons of clinical and laboratory data in different subtypes of TMA in SLE

	TTP	TMA GN	MAPS	HELLP syndrome	Anti-factor II antibodies
Number of events	20	24	12	4	8
Female (n/total)	18/20	23/24	10/12	3/4	6/8
Age at diagnosis of SLE (median [IQR], years)	24.3 [21-46]	25.5 [18-41]	27 [24-46]	24 [24-36]	30
Age at diagnosis of TMA (median [IQR], years)	29 [9-51]	25.3 [14-56]	41 [29-56]	29 [24-36]	35
Number with antiphospholipid disorder (%)	12 (60)	23 (96)	11 (92)	2 (50)	8 (100)
Number with acute renal failure (%)	12 (60)	24 (100)	12 (100)	2 (50)	8 (100)
APACHE II score (median [IQR], 0-40)	12 [7-17]	13 [7-18]	16 [9-23]	13 [7-23]	14
Platelets (median [IQR], 10 <sup>9</sup> /L)	62 [20-100]*	82 [20-400]*	142 [100-200]	107 [50-150]	65
Creatinine level (median [IQR], µmol/L)	101 [51-206]*	300 [11-206]*	128 [51-200]	147 [51-242]	90
LDH (median [IQR], U/L)	630 [40-810]*	624 [41-810]*	675 [41-810]	1,13 [41-810]	1,140
Anti-ADAMTS13 activity (median [IQR], %)	200 [1-283]	202 [1-228]	200 [1-280]	200 [1-140]	24
ADAMTS13 activity (median [IQR], %)	9 [1-24]	40 [1-24]	42 [1-30]	not available	60
Survival (median [IQR], 0-220)	63 [9-137]	4 [1-24]	4 [1-24]	4 [1-17]	63
Median survival of patients, %	9 (45)	0 (0)	0 (0)	0 (0)	0
ADAMTS13 activity (median [IQR], %)	17 [14-21]	12 [14-21]	12 [14-21]	12 [14-21]	12
ADAMTS13 activity (number of patients, %)	1 (5)	1 (4)	1 (8)	1 (25)	0

Abbreviations: SLE = systemic lupus erythematosus, TMA = thrombotic microangiopathy, IIR = renal/urinary, SLE = antiphospholipid, TMA GN = thrombotic microangiopathy associated with glomerulonephritis, MAPS = microangiopathic antiphospholipid syndrome, HELLP = hemolysis, elevated liver enzymes, low platelets.

\* p < 0.05 in comparison between patient suffering from TTP or TMA GN with the rest of the cohort.

**Conclusions:** SLE-associated TMA is a heterogeneous syndrome. TTP with a decreased ADAMTS13 activity and a low platelets level (<28000/mm<sup>3</sup>) have a good renal prognosis, whereas TMA GN with a high creatinine level (>100 µmol/L)

have a poor renal prognosis. Early subtypes classification is mandatory for the clinician to provide prompt and appropriate management of this life-threatening complication.

## SLE, Sjögren's and APS – treatment

### FRI0303 EFFICACY AND SAFETY OF USTEKINUMAB IN PATIENTS WITH ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF A PHASE 2, RANDOMISED PLACEBO-CONTROLLED STUDY

R. van Vollenhoven<sup>1</sup>, B.H. Hahn<sup>2</sup>, G.C. Tsokos<sup>3</sup>, C. Wagner<sup>4</sup>, P. Lipsky<sup>5</sup>, B. Hsu<sup>4</sup>, M. Chevrier<sup>4</sup>, R. Gordon<sup>4</sup>, M. Triebel<sup>6</sup>, S. Rose<sup>4</sup>. <sup>1</sup>Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands; <sup>2</sup>University of California Los Angeles, Los Angeles; <sup>3</sup>Beth Israel Hospital, Boston; <sup>4</sup>Janssen Research and Development, LLC, Spring House; <sup>5</sup>AMPEL BioSolutions, LLC, Charlottesville, USA; <sup>6</sup>Janssen Biologics Europe, South Holland, Netherlands

**Background:** IL12 and IL23 have been linked to SLE pathogenesis.

**Objectives:** The anti-IL12/23 monoclonal antibody ustekinumab (UST) was evaluated in pts with active SLE.

**Methods:** We conducted a Ph2, PBO-controlled study in 102 pts with active SLE. Pts were randomised(3:2) to UST IV~6 mg/kg or PBO at wk0, followed by UST SC 90 mg or PBO injections q8w, both added to standard care. Primary endpoint was proportion of pts achieving SLE responder index(SRI)-4 response at wk24. Secondary endpoints were change from baseline(BL) in SLEDAI-2K, PGA and BICLA response. Additional pre-specified endpoint analyses included no BILAG worsening(defined as no new BILAG A and  $\leq 1$  new BILAG B) and BILAG flare ( $\geq 1$  new BILAG A or  $\geq 2$  new BILAG B).

**Results:** SRI-4 response occurred in 60% UST vs 31% PBO pts( $p=0.005$ ) at wk24 (table 1). UST pts had greater median change from BL in SLEDAI-2K and PGA vs PBO. No difference was observed in BICLA response at wk24; however, in the UST group vs PBO, more pts had no BILAG worsening, and the risk of a new BILAG flare was significantly lower(HR 0.11 [95% CI 0.01–0.94]; $p=0.0078$ ). UST demonstrated improvement in musculoskeletal and mucocutaneous disease features vs PBO (table 1). Through wk24, 78% UST vs 67% PBO pts had  $\geq 1$  AE; 8.3%–9.5%, respectively, had  $\geq 1$  SAE; there were no deaths. The overall safety profile was comparable between UST and PBO.

**Abstract FRI0303 – Table 1.** Efficacy Results at Wk 24.

	PBO	UST

### FRI0304 LONG-TERM AND LOW-DOSE IL-2 THERAPY MAINTAINS THE TH17/TREG BALANCE IN PERIPHERAL BLOOD OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

M. Miao<sup>1</sup>, Z. Hao<sup>1</sup>, Y. Guo<sup>1</sup>, X. Zhang<sup>1</sup>, S. Zhang<sup>1</sup>, J. Luo<sup>1</sup>, C. Zhang<sup>1</sup>, X. Zhao<sup>1</sup>, X. Liu<sup>1</sup>, X. Wu<sup>1</sup>, D. Xu<sup>1</sup>, J. Zhao<sup>2</sup>, C. Gao<sup>3</sup>, X. Li<sup>4</sup>. <sup>1</sup>The Second Hospital of Shanxi Medical University; <sup>2</sup>medical statistics department, Shanxi Medical University, Taiyuan, China; <sup>3</sup>Department of Pathology, Harvard Medical School, Boston, USA; <sup>4</sup>Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China

**Background:** Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease mainly affecting exocrine glands. To date, evidence-based guidelines for the management of pSS are lacking. Regulatory T cells (Tregs) are crucial in maintaining immune tolerance and immune homeostasis, but their role in pSS is unclear. Furthermore, low-dose Interleukin-2 (IL-2) has been shown considerable curative effect on expansion of (Tregs) in patients with GVHD. However, the effects of low-dose IL-2 on Tregs and Th17 cells in pSS are not fully elucidated.

**Objectives:** To explore the long-term effects of low dose IL-2 on Treg cells, Th17 cells and the ratio of them in peripheral blood of Chinese Han patients with primary Sjögren's syndrome.

**Methods:** A total of 190 pSS patients consented at enrollment to donate PB samples for comprehensive immune-phenotyping. In the study, BD Trucount tubes with the lyophilized pellet of a known number of internal counting beads were used for determining absolute counts of total CD4<sup>+</sup> T cells in PB and then calculating the absolute number of Th17 cells and CD4<sup>+</sup>Tregs. Eighty eight in 190 were given low-dose recombination human IL-2 (rhIL-2, 50 WIU/day for 5 days and then 50WIU/w for several months) by hypodermic injection combined with standard therapy, which includes glucocorticoid, immune-suppressants, biological agents or combination of them, while others (12 in 69) were given standard therapy only.

**Results:** (<sup>1</sup>The absolute number of Treg cells decreased significantly in peripheral blood of pSS patients compared with that of healthy control.<sup>2</sup>After short period therapy of low dose rhIL-2, Treg cells increased rapidly in one week but decreased to a lower level after one month[20.91 (9, 31.75) vs. 130.31 (65.18, 170.12) vs. 30.37(, <sup>16, 44</sup> $p<0.01$ ]. At the same time the ratio of Th17/Treg cells decreased rapidly in one week but increased to a higher level after one month[0.23 (0.19, 0.33) vs. 0.09 (0.04, 0.18) vs. 0.18 (0.14, 0.69),  $p<0.1$ ].<sup>3</sup>Long-term IL-2 could maintain the higher level of CD4<sup>+</sup>Treg cells and the balance of Th17/Treg.<sup>4</sup>Patients with balanced Th17/Treg have more obvious improvement of symptoms and more significantly decreased dose of glucocorticoid and HCQ compared with standard therapy group.

**Abstract FRI0304 – Figure 1.** The change of absolute numbers of Treg cells (A) and the ratio of Th17/Treg (B) after short-term and low-dose IL-2 therapy. (A) Absolute number (cells/ $\mu$ l) of Treg cells increased rapidly 7 days after IL-2 therapy but decreased to a lower level after 30 days. (B) Ratio of Treg cells decreased rapidly 7 days after IL-2 therapy but increased to a higher level after 30 days. Data are presented as median (Q1, Q3). Statistical analysis was performed using the Related Samples Friedman's Two-Way Analysis of Variance by Ranks. \*  $P<0.05$ , \*\*  $P<0.01$ , \*\*\*  $P<0.001$  vs. Healthy controls. Asymptotic significances (2-sided tests) are displayed. The significance level is  $p<0.05$ .

**Conclusions:** Therapy of low dose rhIL-2 could promote the proliferation of Treg cells and rebuild the balance of Th17/Treg for both short and long term. To rebuild

the balance of Th17/Treg for long-term, we should use IL-2 for a long time. Balance of Th17/Treg cells in pSS patients predicts a good prognosis.

#### FRI0305 PHASE 2 TRIAL OF INDUCTION THERAPY WITH ANTI-CD20 (RITUXIMAB) FOLLOWED BY MAINTENANCE THERAPY WITH ANTI-BAFF (BELIMUMAB) IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS

C. Aranow<sup>1</sup>, M. Dall'Era<sup>2</sup>, M. Byron<sup>3</sup>, L. Ding<sup>4</sup>, D. Smilek<sup>5</sup>, B. Diamond<sup>1</sup>, D. Wofsy<sup>2</sup> on behalf of the CALIBRATE investigators and Lupus Nephritis Trials Network. <sup>1</sup>Feinstein Institute for Medical Research, Manhasset; <sup>2</sup>University of California, San Francisco; <sup>3</sup>Rho Federal Systems, Inc, Chapel Hill; <sup>4</sup>National Institute of Allergy and Infectious Diseases, Bethesda; <sup>5</sup>Immune Tolerance Network (ITN), San Francisco, USA

**Background:** Despite case series suggesting efficacy, controlled trials of anti-CD20 in lupus nephritis (LN) did not confirm benefit. *Arthritis Rheum* 2012;64:1215 and 2013;65:2368).

**Objectives:** One possible explanation for this failure stems from the fact that B cell depletion stimulates production of B cell activating factor (BAFF) which, in turn, facilitates maturation of autoreactive B cells in lymphoid organs or during B cell repopulation. The CALIBRATE study (NCT 02260934) was designed to test this hypothesis, to determine whether addition of anti-BAFF could enhance the clinical effects of anti-CD20, and to assess safety of the combination.

**Methods:** Forty-three patients with active LN despite conventional treatment enrolled in a prospective randomised open-label trial that compared two treatment strategies. All subjects received iv rituximab (1000 mg), CTX (750 mg), and methylprednisolone (100 mg) at wks 0 and 2, followed by 40 mg/d prednisone tapered to 10 mg/d by wk 12. At wk 4, subjects received either belimumab (10 mg/kg iv at wks 4, 6, 8 and then every 4 wks) plus prednisone (n=21) or prednisone alone (n=22). Complete response (CR) was defined as: (i) urine protein:creatinine ratio (UPCR) <0.5; (ii) eGFR ≥120 or, if <120, eGFR >80% of screening; and (iii) prednisone tapered to 10 mg/d. The definition of partial response (PR) differed only in the UPCR criterion (>50% reduction).

**Results:** The clinical outcome at wk 24 was similar in both groups (table 1). The CR rate was 24% in the belimumab group (RCB) and 23% in the control group (RC). Three subjects in each group withdrew (WD) prior to wk 24 (two withdrawals in each group due either to progressive nephritis or an infusion reaction, and one in each group for reasons unrelated to SLE or its treatment). B cell depletion from blood was virtually absolute in both groups at wk 12, but the pace of recovery differed. Six subjects experienced serious adverse events between wks 0 and 24; three subjects in the RC group (pneumonia followed by LN flare; deep vein thrombosis; SLE flare); and three subjects in the RCB group (anti-CD20 infusion reaction; soft-tissue abscesses prior to anti-BAFF treatment; quadriceps tendon rupture).

Median B Cell Count Median IgG Level

CR PR NR WD Wk 0 Wk 12 Wk 24 Wk 0 Wk 24

RC Group 23%–23% 41%–14% 105 1 31 1050 1100

**RCB Group 24% 24% 38% 14% 143 1 3 984 837:**

**Conclusions:** An interim analysis of data from CALIBRATE shows: (i) anti-BAFF following anti-CD20 for LN did not improve clinical outcome at week 24; (ii) anti-BAFF delayed blood B cell reconstitution following B cell depletion; and (iii) anti-BAFF following anti-CD20 was not associated with hypogammaglobulinemia or an increase in serious infections. Further analyses at 48 weeks and beyond will address how anti-BAFF therapy affects quantitative and qualitative recovery of B cells as well as long-term clinical outcome.

#### FRI0306 DEVELOPMENT OF BAFF AND ICOSL BISPECIFIC INHIBITOR AMG 570 FOR SLE TREATMENT

H. Hsu<sup>1</sup>, M. Zhang<sup>1</sup>, K. Miner<sup>1</sup>, G. Kevin<sup>1</sup>, J. Whoriskey<sup>1</sup>, R. Jacobsen<sup>2</sup>, C. Chen<sup>2</sup>, K. Ishida<sup>3</sup>. <sup>1</sup>Inflammation; <sup>2</sup>Therapeutic Discovery; <sup>3</sup>CBSS, Amgen, Thousand Oaks, USA

**Background:** Systemic lupus erythematosus (SLE) is a heterogeneous disease lacking highly effective treatment options. Among many cell types and pathways involved in SLE pathogenesis, aberrant B cells and T cells are critical drivers in autoantibody production and tissue damage. Autoreactive T cells drive autoreactive B cell expansion and autoantibody production. Amongst key pathways that modulate the function of these cells, inducible costimulator ligand (ICOSL) is critical for T follicular helper cell (T<sub>FH</sub>) development and T memory cell homeostasis, while B cell activating factor (BAFF) is a critical B cell survival factor. We hypothesised that targeting both BAFF and ICOSL would be more efficacious than single BAFF or ICOSL inhibition in SLE and other autoimmune diseases.

**Objectives:** We tested if targeting both BAFF and ICOSL has superior efficacy than single target inhibition in the mouse arthritis and lupus models. We aimed at generating BAFF and ICOSL bispecific molecule for potential treatment of autoimmune diseases such as SLE.

**Methods:** Murine BAFF/ICOSL bispecific, combination of BAFF and ICOSL inhibitors or single inhibitor was evaluated in the sheep red blood cell (SRBC) challenge model, mouse collagen induced arthritis (CIA) model, or NZB/NZW lupus models. AMG 570 was tested for human and cyno BAFF and ICOSL binding affinities by Kinexa A. AMG 570 dual target blocking activities was evaluated in human and cyno BAFF and ICOSL mediated B cell and T cell assay, respectively. Pharmacodynamics effect of AMG 570 was evaluated in cynomolgus monkey

**Results:** Compared to treatment with single inhibitor, combination of BAFF and ICOSL inhibitors was more effective in ameliorating arthritis incidence and severity in the mouse CIA model and NZB/NZW lupus model. The murine BAFF/ICOSL bispecific molecule inhibited murine BAFF and ICOSL mediated B and T cell bioassays, and dual target inhibition in mice. In addition, treatment with murine BAFF/ICOSL bispecific was more efficacious than single BAFF and ICOSL inhibitor in reducing anti-dsDNA IgG, delaying the onset of proteinuria and improving survival in the NZB/NZW lupus model. AMG 570 was selected as the clinical candidate with high binding affinity for human BAFF and ICOSL and strong potency in the human B cell and T cell bioassays. B cell reduction was observed after AMG 570 treatment in cynomolgus monkey, consistent with the pharmacological effect of BAFF inhibition.

**Conclusions:** Inhibition of both BAFF and ICOSL is more efficacious than single target inhibition in the mouse lupus and arthritis models. By targeting both BAFF and ICOSL, AMG 570 has the potential to achieve a large treatment effect size in autoimmune diseases such as SLE and rheumatoid arthritis.

#### FRI0307 TBK1 INHIBITION DOWNREGULATES EXPRESSION OF INTERFERON TYPE I AND THE UPREGULATED EXPRESSION OF RIG-LIKE RECEPTORS AND DNA-SENSING RECEPTORS IN INTERFERON POSITIVE PRIMARY SJÖGREN'S SYNDROME PATIENTS

I. Bodewes<sup>1</sup>, E. Huijser<sup>1</sup>, C. van Helden-Meeuwse<sup>1</sup>, L. Tas<sup>1</sup>, R. Huizinga<sup>1</sup>, V. Dalm<sup>2</sup>, M. van Hagen<sup>2</sup>, N. Groot<sup>3</sup>, S. Kamphuis<sup>3</sup>, P. van Daele<sup>2</sup>, M. Versnel<sup>1</sup>. <sup>1</sup>Immunology; <sup>2</sup>Internal Medicine; <sup>3</sup>Pediatric Rheumatology, Erasmus MC, Rotterdam, Netherlands

**Background:** Type I interferon (IFN-I) upregulation is a hallmark of systemic autoimmune diseases like primary Sjögren's syndrome (pSS). Expression of IFN-I is induced by three different receptor families: Toll-like receptors (TLRs), RIG-like receptors (RLRs) and DNA-sensing receptors (DSRs). Previously we have shown increased mRNA levels of TLRs and RLRs in plasmacytoid dendritic cells (pDC) and CD14 +monocytes of IFN-I positive (IFNpos) pSS patients.<sup>1</sup> TANK-binding kinase (TBK1), is an important signalling hub downstream of RLRs and DSRs and leads to production of IFN-I and subsequent induction of interferon-stimulated genes (ISGs).

**Objectives:** Study RLRs and DSRs in pSS and explore the potential of a TBK1 inhibitor to downregulate IFN-I activation.

**Methods:** Expression of RLRs and DSRs was assessed by RQ-PCR and flowcytometry in CD14 +monocytes, BDCA4 +CD123+pDC and CD19 +B cells from IFNpos pSS patients. pDCs from IFNpos pSS patients were analysed by flowcytometry for phosphorylated-TBK1 (pTBK1). PBMCs of pSS patients were cultured with a TBK1 inhibitor, BX795, followed by analysis of IFN-I production and expression of ISGs.

**Results:** In addition to upregulated mRNA levels of RLRs IFIH1 (encoding for MDA5) and DDX58 (encoding for RIG-I), which we previously observed in pDC and monocytes of IFNpos pSS patients, gene expression of IFIH1 and DDX58 was also upregulated in B cells. Upregulation of mRNA levels of the DSRs IFI16 and ZBP1 was observed in monocytes and B cells from IFNpos patients. In pDC protein expression of MDA5, ZBP-1, IFI16 was increased in IFNpos pSS, while there were no differences in RIG-I. In monocytes protein expression of MDA5 was increased and a trend was visible for RIG-I and IFI16. B cells showed increased protein expression of MDA5 and a trend was observed for RIG-I, ZBP-1 and IFI16. These data indicate upregulation of RLRs and DSRs particularly in pDC of IFNpos pSS patients. To further look into the signalling of RLRs and DSRs, phosphorylation of TBK was studied in pDC, the main IFN-I producers, of pSS patients. Increased expression of pTBK1 was observed in pDCs from IFNpos pSS. Upon treatment with BX795, PBMCs from IFNpos pSS downregulated the production of IFN-I and mRNA expression of the ISGs MxA, IFI44, IFI44L, IFIT1 and IFIT3.

**Conclusions:** RLRs and DSRs are upregulated in IFNpos pSS. Signalling of these receptors could be blocked using a TBK1 inhibitor, which reduced IFN-I protein production and expression of ISGs in PBMCs of IFNpos pSS patients. As patented pharmacological inhibitors, amongst others a small molecule inhibitor, are available TBK1 inhibition is indicated as a potential future treatment target for IFNpos pSS.

#### CORTICOSTEROIDS COMBINED WITH DOUBLET OR SINGLE-AGENT IMMUNOSUPPRESSIVE THERAPY FOR ACTIVE PROLIFERATIVE LUPUS NEPHRITIS

B. Liu<sup>1</sup>, Y. Yu<sup>2</sup>, Y. Tang<sup>1</sup>, S. Fu<sup>1</sup>, P. Liang<sup>1</sup>, A. Xu<sup>1</sup>. <sup>1</sup>Nephrology; <sup>2</sup>Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Breast Tumor Center, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

**Background:** Current evidence exploring whether corticosteroids (C) plus doublet immunosuppressive therapy (IT) is superior to the classical combination of C with single-agent IT for active proliferative lupus nephritis (LN) is controversial.

**Objectives:** We aimed to clarify the efficacy and safety of C+doublet versus single-agent IT for active proliferative LN by a meta-analysis.

**Methods:** We searched for randomised clinical trials that evaluated the benefits and risks of C+doublet versus single-agent IT for active proliferative LN. The primary outcome was overall response rate (ORR). The second outcomes were the change from baseline in Systemic Lupus Erythematosus Disease Activity Index (SLE-DAI) score, negative conversion ratio of anti-double-stranded DNA (anti-dsDNA), and adverse events. The quality of the evidence was evaluated with the GRADE framework. The PROSPERO registry number is CRD42017068491.

**Results:** The analysis included 10 trials with 1587 unique patients. Compared with C+single agent IT, C+doublet IT was statistically significant with higher ORR (relative risk [RR], 1.22; 95% confidence interval [CI], 1.09 to 1.35;  $p < 0.0001$ ; moderate certainty). In subgroup analysis, C+doublet IT without biologics resulted into significant higher ORR than C+single agent IT (RR, 1.30; 95% CI, 1.13 to 1.50;  $p < 0.0001$ ; moderate certainty), while C+doublet IT including biologics improved ORR only for refractory severe LN (RR, 1.46; 95% CI, 1.09 to 1.96;  $p = 0.012$ ; very-low certainty). A larger change from baseline in SLE-DAI score (standardised mean difference,  $-0.49$ ; 95% CI,  $-0.68$  to  $-0.30$ ;  $p < 0.0001$ ; moderate certainty) and a higher negative conversion ratio of anti-dsDNA (RR, 1.34; 95% CI, 1.06 to 1.69;  $p = 0.014$ ; high certainty) were observed with C+doublet IT than with C+single agent IT. The rates of adverse events were similar between the two regimens (high to moderate certainty).

**Conclusions:** Compared with single-agent IT, the combination of corticosteroids with doublet IT improved clinical outcomes for active proliferative LN. C+doublet

IT including biologics may be a better regimen for refractory severe LN. There is imperative that prospective biomarker-driven trials to identify patients for whom C+doublet IT is most efficacious.

FRI0309

#### THE IMPACT OF BELIMUMAB AND RITUXIMAB ON HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I. Parodis<sup>1</sup>, A.H. Lopez Benavides<sup>1</sup>, A. Zickert<sup>1</sup>, S. Pettersson<sup>1,2</sup>, S. Möller<sup>1</sup>, E. Welin Henriksson<sup>1</sup>, A. Voss<sup>3</sup>, I. Gunnarsson<sup>1</sup>. <sup>1</sup>Department of Medicine, Rheumatology Unit; <sup>2</sup>Division of Physiotherapy, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Rheumatology Unit, Odense University Hospital, Odense, Denmark

**Background:** Accumulating evidence supports an impaired health-related quality of life (HRQoL) in patients with systemic lupus erythematosus (SLE). The impact of modern therapeutic interventions on patients' perception of HRQoL has not been explored in depth.

**Objectives:** The aim of this study was to investigate the effects of two biologic treatments – belimumab and rituximab – on SLE patients' HRQoL, fatigue and functional ability.

**Methods:** Patients with SLE from the Karolinska University Hospital treated with either belimumab (n=34) or rituximab (n=35) were included. Data were collected prospectively at treatment initiation and at months 3, 6, 12 and 24; these included the Medical Outcome Study short form-36 (SF-36) version 2, functional assessment of chronic illness therapy (FACIT)-Fatigue scale version 4, EuroQol research foundation 5-dimension (EQ-5D) health questionnaire, and Stanford health assessment questionnaire disability index (HAQ-DI).

**Results:** Substantial reductions compared to Swedish norms were observed across all SF-36 subscales at baseline (figure 1). SF-36 mental component summary scores were higher in patients who were on antimalarial agents (mean: 42.7; SD  $\pm 11.8$ ; n=29) compared to patients who were not (mean: 34.0; SD  $\pm 14.7$ ; n=32;  $p = 0.019$ ). Accordingly, patients who were on antimalarial agents performed better in SF-36 social functioning (mean: 63.7 versus 46.5;  $p = 0.022$ ) and mental health (mean: 68.7 versus 53.4;  $p = 0.023$ ) compared to patients who were not. Belimumab-treated patients reported gradual improvements in the SF-36 physical summary component (significant from month 12;  $p = 0.023$ ) and FACIT-Fatigue (significant by month 24;  $p = 0.001$ ), no changes in EQ-5D scores, and improvements in HAQ-DI by month 6 ( $p = 0.014$ ). Rituximab-treated patients reported rapid improvements in the SF-36 mental summary component and FACIT-Fatigue by month 3 ( $p = 0.031$  and  $p = 0.007$ , respectively), which declined at month 12, as well as improvements in EQ-5D at month 6 ( $p = 0.016$ ) and HAQ-DI at month 3 ( $p = 0.033$ ), which were not maintained at later time points.

**Conclusions:** HRQoL was considerably impaired in SLE patients compared to population-based norms at baseline, and was not fully compensated during follow-up. Patients' perceptions of HRQoL showed treatment-specific patterns over time, and could prove useful when evaluating the effects of biologics in SLE. Early evaluation of belimumab might underestimate improvements in HRQoL and fatigue. In severe SLE, antimalarial agents may have favourable effects on mental HRQoL aspects.

Gennimatas" General Hospital, <sup>7</sup>2nd Department of Internal Medicine, "Ippokrateion" General Hospital, <sup>8</sup>"Sismanogleio – Amalia Flemming" General Hospital, <sup>9</sup>Department of Rheumatology, "Evangelismos" General Hospital, <sup>10</sup>Department of Physiology, School of Medicine, University of Athens, Athens, <sup>11</sup>Department of Rheumatology, "Ippokrateion" General Hospital, <sup>12</sup>Private rheumatologist, Thessaloniki, Greece, <sup>13</sup>Department of Rheumatology, Hacettepe University, Ankara, Turkey

**Background:** Low disease activity is a validated target of systemic lupus erythematosus (SLE) therapy.

**Objectives:** to assess the ability of belimumab to induce low disease activity states in real-life setting.

**Methods:** Multicentre prospective observational study of SLE patients receiving belimumab due to active disease, refractory to at least one conventional immunosuppressant. Disease activity, including attainment of lupus low disease activity state (LLDAS) and remission-on-glucocorticoids (GC) (clinical SLEDAI-2K=0 with prednisone ≤5 mg/day), accrual of organ damage, flares and side effects were documented.

**Results:** Ninety-one patients were included [94.5% women, mean (SD) age 45.9 (12.5) years]. Most frequent manifestations were arthritis (76.7%), rash (72.5%), serologic activity (low C3/C4 and/or high anti-dsDNA; 54.9%), hair loss (47.2%) and mucosal ulcers (27.5%). Median (range) duration of treatment was 10.5 (3.0–42.1) months. Belimumab decreased average SLEDAI-2K, physician global assessment and daily prednisone dose over time, as early as 3 months after initiation. Complete withdrawal of GC was achieved in 17.8%, 22.5%, 31.7% and 23.3% at 3, 6, 9 and 12 months, respectively. The number of flares and severe flares was reduced by 62% and 50%, respectively, during the first year of treatment. Although reduction in clinical SLEDAI-2K was more pronounced in patients who were serologically active (from 8 to 1.5 at 12 months) compared to serologically inactive (from 6 to 4) at baseline, attainment of low disease activity states (LLDAS or remission) did not differ between groups and was reached by more than 40% of completers after 9–12 months (figure 1). Twenty patients (22.0%) discontinued treatment due to inadequate response and two due to side effects potentially related to the drug.

**Conclusions:** Belimumab is efficacious in achieving low disease activity in over 40% of active SLE patients, accompanied by complete GC discontinuation in more than 20%. Serologically active and inactive patients respond equally to the drug.

### THE EFFECT OF B CELL TARGETED THERAPIES ON AUTOANTIBODIES AND EXCESSIVE NEUTROPHIL EXTRACELLULAR TRAP FORMATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

L.S. Van Dam<sup>1</sup>, Z. Osmani<sup>1</sup>, T. Kraaij<sup>1</sup>, S.W. Kamberling<sup>1</sup>, J.A. Bakker<sup>2</sup>, H. U. Scherer<sup>3</sup>, T.J. Rabelink<sup>1</sup>, R.E. Voll<sup>4</sup>, D. Isenberg<sup>5</sup>, C. van Kooten<sup>1</sup>, Y.O. Teng<sup>1</sup>.  
<sup>1</sup>Nephrology; <sup>2</sup>Clinical chemistry; <sup>3</sup>Rheumatology, LUMC, Leiden, Netherlands; <sup>4</sup>Rheumatology, UMC, Freiburg, Germany; <sup>5</sup>Rheumatology, UCL, London, UK

**Background:** Systemic lupus erythematosus (SLE) is a severe systemic autoimmune disease characterised by immune-complexes which cause systemic inflammation and damage. Neutrophil extracellular traps (NETs) are an important source of autoantigens in SLE patients leading to the production of autoantibodies. Functionally, SLE-specific autoantibodies as immune-complexes are important triggers of excessive NET formation. As such, effective targeting of pathogenic autoantibodies in SLE is subject to several promising experimental treatment strategies. Recently, the combination of Rituximab (RTX) and Belimumab (BLM) in patients with severe SLE led to a strong decrease of autoantibodies and diminished excessive NET formation as well as improvement of clinical disease. A consortium was formed to study different experimental treatment strategies that target the humoral autoimmune system, including RTX, Bortezomib (BTZ) or combination treatment with RTX and BLM.

**Objectives:** The present study aimed to investigate the effects of B cell targeted therapies on relevant autoantibody levels and excessive NET formation in severe SLE.

**Methods:** This study involved three cohorts of anti-dsDNA positive, severe SLE patients that were eligible to experimental treatment with RTX (n=16), BTZ (n=6) or RTX +BLM (n=16). A cross-sectional cohort of 35 anti-dsDNA positive SLE patients served as a control cohort. A panel of SLE relevant autoantibodies against dsDNA, histones, nucleosomes and C1q were measured by ELISA. As a functional result of autoantibody levels, NET formation was quantified by our novel highly-sensitive NET quantification assay using 3D confocal microscopy<sup>1</sup>.

**Results:** Comparing three regimens, RTX +BLM resulted in the strongest reduction of anti-dsDNA (median ratio of baseline; 0.32 vs 0.78 vs 0.65; p=0.08), anti-histone (0.36 vs 0.51 vs 0.53; p=0.45), anti-nucleosome (0.38 vs 0.61 vs 0.58; p=0.15), and significantly the strongest reduction of anti-C1q antibodies (0.55 vs 0.91 vs 1.00; p=0.016) compared to RTX and BTZ. Excessive NET formation diminished significantly with a ratio of 0.66 [0.49–0.93] after RTX (p=0.005) and 0.25 [0.15–0.47] after RTX +BLM (p=0.0002), however it was not reduced after BTZ with 1.37 [0.90–1.61]. As such, excessive NET formation correlated with disease activity (p=0.004), except for the BTZ cohort. Importantly, regression of excessive NET formation was associated with reduction of anti-C1q antibodies. In an independent cohort of SLE patients, we confirmed that the presence of anti-C1q antibodies correlated with excessive NET formation (p=0.03). We further observed that the presence of three or more autoantibody specificities associated with excessive NET formation (p=0.02).

**Conclusions:** This study demonstrates a synergetic effect of RTX +BLM compared to RTX or BTZ on the reduction of relevant autoantibodies in SLE patients which associated with significant regression of NET formation. The reducing effects of RTX +BLM, RTX and BTZ on anti-C1q antibodies underpinned the observed, immunological effects on humoral autoimmunity.

Costedoat-Chalumeau<sup>7</sup>, J. Sellam<sup>8</sup>, J.-B. Arlet<sup>9</sup>, C. Lavigne<sup>10</sup>, O. Fain<sup>1</sup>, A. Mékinian<sup>1</sup>, on behalf of Club Rhumatismes Inflammation and SNFMI.

<sup>1</sup>Service de médecine interne, Hôpital Saint-Antoine, Paris; <sup>2</sup>Service de rhumatologie, Hôpital de Bicêtre, Kremlin-Bicêtre; <sup>3</sup>Service de biostatistiques, Hôpital Lariboisière; <sup>4</sup>Service de rhumatologie B, Hôpital Cochin, Paris; <sup>5</sup>Service de rhumatologie, CHU de Limoges, Limoges; <sup>6</sup>Service de médecine interne, CHU de Grenoble, Grenoble; <sup>7</sup>Service de médecine interne, Hôpital Cochin; <sup>8</sup>Service de rhumatologie, Hôpital Saint-Antoine; <sup>9</sup>Service de médecine interne, Hôpital Européen Georges Pompidou, Paris; <sup>10</sup>Service de médecine interne, CHU Angers, Angers, France

**Background:** Primary Sjogren's syndrome (pSS) is a chronic inflammatory disorder characterised by diminished lacrimal and salivary gland functions. Joint involvement is reported in 20% to 60% of pSS patients, and among them one third of patients present synovitis. There is a lack of data concerning therapeutic management during pSS-associated synovitis.

**Objectives:** To describe the characteristics and the outcome of pSS associated arthritis and to compare the efficacy of different therapeutic regimen.

**Methods:** We conducted a retrospective study using Club Rhumatisme and Inflammation (CRI) and French Internal Medicine Society (SNFMI) networks. All patients with a diagnosis of primary Sjogren's Syndrome (pSS) and at least one clinical and/or echographic synovitis were included. Patients with synovitis (cases) were compared to pSS patients without synovitis (controls).

**Results:** 57 patients (93% women) were included with a median age of 54 years.<sup>45-63</sup> Patients with synovitis had more frequently lymph node enlargement (12.3% vs. 1.8%, p=0.007) and a higher ESSDAI score (8<sup>6-12</sup> vs. 2,<sup>1-4</sup> p<0.0001). There was no difference concerning CRP levels, rheumatoid factor and CCP-antibodies positivity. Among 57 patients with synovitis, 101 lines of various treatments have been used during the follow-up of 40 [22.5-77] months. First line treatment consisted in steroids alone (3.5%), steroids in association (79%) with hydroxychloroquine (HCQ) (49%), methotrexate (MTX) (35%), rituximab (RTX) (5.3%) or other immunosuppressive drugs (7%). The number of complete/partial joint responses significantly increased considering the number of overall lines of treatment for MTX, HCQ and RTX: 52% for the first line, 76% for the second line and 83% for the third line (p<0.05), and data were similar considering each drug separately. There was no difference of efficacy between HCQ, MTX, and RTX concerning tender and swollen joint count, CRP level, ESSDAI score and steroids sparing effect at the end of each drug regimen. We performed a propensity score based analysis to determine whether HCQ, MTX, or RTX treatment was associated with better joint outcome. No difference could be shown for the joint response between three treatment regimen (MTX vs. HCQ, OR 1.55 [0.18-13.55], p=0.69; MTX vs. RTX, OR 5.08 [0.49-52.17], p=0.17; HCQ vs. RTX OR 3.28 [0.28-38.02], p=0.34). All 3 treatments (HCQ, MTX, and RTX) were associated with a significant reduction of ESSDAI score and a significant steroids-sparing effect.

**Conclusions:** pSS articular manifestations may include synovitis which could mimic rheumatoid arthritis but differ by the absence of structural damage. Even if the use of HCQ, MTX, and RTX seem to be effective for joint involvement, the best regimen remains to be determined.

### FRI0313 A RITUXIMAB AND BELIMUMAB COMBINATION THERAPY IN SLE PATIENTS

A.A. Mesnyankina, S.K. Soloviev, E.N. Aleksandrova, A.P. Aleksankin, A. Novikov, E.A. Aseeva, E.L. Nasonov. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Objectives:** To assess the efficacy of a rituximab and belimumab combination therapy in pts with active SLE and dynamics of CD19+ B-lymphocytes count in treated pts.

**Methods:** The study included 7 SLE pts (1M/6F) with high (SLEDAI2K<sub>≥</sub>10 - 4pts.) and moderate (SLEDAI2K<10- 2pts.) disease activity; out of them 1 patient had lupus nephritis, 1- vasculitis, and remaining 5 had predominantly mucocutaneous and articular manifestations of SLE. The dose of oral GCs at baseline did not exceed 20 mg/day, two pts were treated with prednisone 5 mg/day. The damage index at baseline was 0 in 3 pts, ≤1 in 3pts, and ≥1 - in 1 patient. Rituximab (RTM) was administered at 500-1000 mg, with subsequent adding of Belimumab (BLM) 3 months later at a standard dosing regimen 10 mg/kg once a month during 9mo. CD19+ B- lymphocytes counts were obtained before initiation RTM (0), and subsequently after 3, 6, 9, and 12mo. Depletion of CD19+ B- lymphocytes after RTM was assessed as the decrease of B-cell counts after 3mo<0,01 10<sup>9</sup>/l, where 0 10<sup>9</sup>/l was categorised as complete depletion, from 0001 to 0,01 10<sup>9</sup>/l - partial

depletion, and >0,011 10<sup>9</sup>/l - absence of depletion. The comparison group included 20 pts receiving a single 500-2000 mg dose of RTM.

**Results:** 6 pts demonstrated the decrease in clinical and laboratory SLE activity, starting from 3mo of follow-up (SLEDAI-2K 0 mo-Me 10, 9;16 3mo-Me 8, 4;86mo-Me 4, 2;6 9mo-Me 5,4;10 12mo-Me 2 2;6) with RTM+BLM combination therapy. The oral GCs dose was reduced to 7,5 5;10mg/day by 12mo, none of the patient required prednisone dose escalation during follow-up. There were no cases of severe infection. The damage index did not increase by 12mo. The combination therapy reduced the absolute counts of CD19+ B-cells. RTM therapy resulted in complete depletion in 2 pts, in partial depletion - in 3; in 1 patient the depletion was not documented. Addition of BLM resulted in slowing down of CD19 + B-cell repopulation (figure 1) among pts with complete and partial depletion (0mo-Me 0,11 × 10<sup>9</sup>/l[0,1;0,28], 12mo -Me 0,01 × 10<sup>9</sup>/l[0,0085; 0025]) vs pts receiving RTM monotherapy (0mo-Me 0,1 × 10<sup>9</sup>/l[0,06;0,2], 12mo -Me 0,03 × 10<sup>9</sup>/l[0,008; 0,08]). The decrease in CD19+ B-cell counts after RTM was also documented in the patient who didn't develop depletion initially (0mo-0,5 10<sup>9</sup>/l, 12mo-0,04 10<sup>9</sup>/l). RTM and BLM combination failure, as well as failure of standard GCs and cytostatic based therapy, was documented in one patient with cutaneous, articular and haematological SLE.

**Abstract FRI0313 - Figure 1.** Dynamics in CD19+ B-lymphocytes in pts treated RTM and RTM+BLM combination therapy

**Conclusions:** Combination therapy allows to gain control over disease activity in short time, due to the effect of RTM, while added BLM provides further prolongation of the effect achieved, minimising the risk of exacerbation. This combination may be used as a method of choice in pts with severe SLE involving vital organs, and in persistent cutaneous-articular disease and high immunological activity. Of notice is the fact, that use of RTM and BLM combination allowed to manage all pts on low and medium doses of GCs starting from RTM and BLM initiation and during the entire follow-up, thereby reducing the risk of irreversible organ damage. In these patients there were no signs of infection.

### FRI0314 RISK OF OPHTHALMOLOGIC COMPLICATIONS AS A RESULT OF HYDROXYCHLOROQUINE THERAPY

A. Khaleel. Rheumatology, Nottingham University NHS Trust, Nottingham, UK

**Background:** Hydroxychloroquine is a drug therapy licensed for patients with cutaneous and systemic lupus. A major side effect is maculopathy that can result in permanent visual loss. Often, symptoms are preceded by signs, and screening for preclinical retinopathy can decrease incidence and development of 'bullseye retinopathy'<sup>1,2</sup>. More recent high quality studies suggest cases of confirmed toxicity in 1% of patients at 5-7 years and therefore documentation of monitoring is imperative<sup>3,4</sup>.

**Objectives:** In accordance with the British Rheumatology Society guidelines 2008 an audit was carried out in March 2017 to assess whether patients on hydroxychloroquine were being monitored for maculopathy while on therapy.

**Methods:** The sample group comprised of 76 patients who were on active hydroxychloroquine treatment for SLE, chosen through randomised computer generated numbers. Electronic notes for individual patients over the last 12 months was reviewed for mention of ophthalmologic monitoring, indicating the clinician is aware and surveilling possible signs of toxicity.

**Results:** Of all patients on hydroxychloroquine (regardless of dose), 64% of patients had no mention of ophthalmologic monitoring on their documented clinic letter. Documentation of monitoring did not vary by dose, despite the increased risk of toxicity for those on 400 mg daily.

**Table to show percentage of electronic documentation of patients screened on hydroxychloroquine**

Hydroxychloroquine	documented(%)	undocumented(%)
200 mg daily	35	65
400 mg daily	44	54
200 mg/400 mg alternate days	0	100

This audit suggests that Queens Medical Centre patients are not meeting the set standard of ophthalmological review.

**Conclusions:** The BSR guidelines have highlighted that there are organisational barriers to monitoring, but acknowledges that ophthalmological risks are present with the use of continued hydroxychloroquine therapy. High risk patients with existing or early signs of visual involvement, should be selected for early assessment and more vigilant follow up. SD-OCT was found to be significantly more cost effective than standard ophthalmological examination<sup>5</sup>. It should be acknowledged that the results of the audit reflect documentation as opposed to practice. Mention of ophthalmological monitoring does not ensure that doctors are actually asking about visual problems. Guidelines have since been updated in April 2017 that recommend annual screening only after 5 years of therapy is sufficient but with a full ophthalmological screening by an ophthalmologist.

#### SAFETY, TOLERABILITY, PHARMACOKINETIC AND PHARMACODYNAMIC EFFECTS OF BIIB059, A MONOCLONAL ANTIBODY TARGETING BDCA2 FOLLOWING INTRAVENOUS (IV) AND SUBCUTANEOUS (SC) SINGLE OR MULTIPLE DOSES ADMINISTRATION IN HEALTHY VOLUNTEERS (HV) AND SUBJECTS WITH ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

C. Barbey<sup>1</sup>, H. Naik<sup>2</sup>, C. Musselli<sup>2</sup>, R. Christmann<sup>2</sup>, L. Stevenson<sup>2</sup>, D. Rabah<sup>2</sup>, P. Gulati<sup>2</sup>, N. Franchimont<sup>2</sup>. <sup>1</sup>Ophthalmology, Pain, New Indication Unit, Biogen, Zug, Switzerland; <sup>2</sup>Ophthalmology, Pain, New Indication Unit, Biogen, Cambridge, MA, USA

**Background:** BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, upon activation, inhibits the inflammatory factors production by human pDCs, including IFN- $\alpha$  a major player in the pathogenesis of SLE. This 3-Part Phase 1 study evaluated the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD) and clinical efficacy of single and multiple ascending doses (SAD-MAD) of BIIB059 in HV and SLE subjects (NCT02106897).

**Objectives:** To compare PK and PD parameters between HV and SLE following single and multiple dose administration of BIIB059

**Methods:** In the SAD Part 2, 12 subjects with active SLE were randomised 2:1 to receive a single 20 mg/kg IV dose of BIIB059 or placebo. In the MAD Part 3, HV received either 2 or 3 SC administrations of Placebo or BIIB059 20, 50 or 150 mg) Q4W or 3 SC 300 mg Q2W. Subjects with active SLE, received either 2 or 3 SC placebo or BIIB059 50 mg or 300 mg. The dose levels were selected based on emerging data from the Part 1 in HV and was not to exceed the maximum tolerated dose. Blood samples were obtained before and after each dose administration to characterise PK and PD (BDCA2 on pDC) relationship for BIIB059.

**Results:** Part 1 PK and PD results (SAD) in HV and Part 2 PD results have been previously presented<sup>1-2</sup>. In Part 2 of the study, following IV administration, mean  $t_{1/2}$  in SLE subjects was 18.1 days, with a mean CL of 0.251 L/day and a mean volume of distribution  $V_{ss}$  of 5.41 L. Following SC administration, in Part 3a, mean  $t_{1/2}$  in HV subjects ranged from 13.3 to 19.5 days, mean  $CL_{ss}/F$  ranged from 0.267 to 0.367 L/day and  $V_z/F$  ranged from 7.23 to 9.36 L. In Part 3b, mean  $t_{1/2}$  in SLE subjects ranged from 12.6 to 20.5 days with a mean  $CL_{ss}/F$  of 0.455 to 0.485 L/day and a mean  $V_z/F$  of 5.93 and 12.8 L. Exposure (AUC and  $C_{max}$ ) for BIIB059 increased with dose in both HV and SLE subjects. However exposure in SLE subjects was approximately 40% lower compared to HV which could not be attributed to body weight differences. The observed mean accumulation ratio for AUC was slightly lower in SLE subjects (2.58) compared to HV (2.66) after BIIB059 SC administration. Complete BDCA2 internalisation was achieved at all dose levels, the duration of which was dose dependent, and similar for HV and SLE subjects. Reappearance of BDCA2 on circulating pDCs occurred when serum concentrations of BIIB059 dropped to  $\sim 1$   $\mu$ g/mL. Single and multiple IV and SC doses of BIIB059 appeared to be well-tolerated in HV and SLE subjects.

**Conclusions:** BIIB059 was generally well tolerated. Exposure in SLE subjects was lower compared to HV while BDCA2 internalisation was similar. Based on the Phase 1 data, BIIB059 is currently evaluated in a Phase 2 trial (NCT02847598).

### THE PRESENCE OF ANTI-RITUXIMAB ANTIBODIES PREDICTS INFUSION-RELATED REACTIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Wincup, M. Menon, E. Smith, E.C. Jury, D.A. Isenberg, C. Maurion behalf of ABIRISK Consortium. *Rheumatology, University College London, London, UK*

**Background:** Rituximab is a genetically engineered chimeric anti-CD20 monoclonal antibody commonly used in the treatment of a variety of autoimmune rheumatic conditions. Although generally well tolerated, serious infusion related reactions can occur and are difficult to predict. It has previously been suggested that patients with systemic lupus erythematosus (SLE) who are treated with Rituximab demonstrate a higher incidence of infusion reactions and a less predictable response to the therapy when compared with other diseases.

A major limitation of biologic therapies is the development of anti-drug antibodies (ADA). To date the presence of ADAs to Rituximab have not previously been explored in detail.

**Objectives:** To assess the prevalence of ADAs to Rituximab in patients receiving treatment for SLE and how the presence of these antibodies relates to:

1. the incidence of infusion-related reactions
2. the therapeutic efficacy of the drug

**Methods:** We assessed the presence of Rituximab ADAs using a Meso Scale Discovery platform in 58 SLE patients treated with Rituximab at University College London Hospital, UK. A subgroup of 42 patients were followed up longitudinally for up to 8 years after their first dose of Rituximab. Clinical parameters including BILAG, complement C3 levels, anti-double-stranded DNA (dsDNA) antibody titres, lymphocyte count and frequency of CD19<sup>+</sup> B cells were recorded. A retrospective review of patient notes was undertaken to assess for a history of infusion related reactions. Mann-Whitney U test was used to compare variables between the ADA positive group and ADA negative group.

**Results:** A total of 58 patients were recruited of which 88% were female (51/58). Median age was 38.9 years old with a median disease duration of 84 months. ADAs to Rituximab were detected in 60% (35/58) of patients. In those with a positive ADA (n=35), 22 were later retreated with Rituximab. Infusion reactions were noted in 68% (15/22) of those undergoing retreatment in the context of a previously positive ADA. In the remaining patients who were retreated but in which no infusion reaction was seen (7/22), the average level of ADA was significantly lower than in those who did have a reaction (median in those who suffered a reaction=200 unit; median in those who were ADA positive but did not develop a reaction on retreatment=10 units; p=0.008). There were no reactions observed in patients that did not display ADAs who were subsequently retreated.

In the first six months post-Rituximab there was no statistically significant difference in BILAG, C3 levels, dsDNA titres, lymphocyte count or CD19 between the groups in which ADAs were present when compared with those in which ADAs were absent.

**Conclusions:** For the first time, ADAs to Rituximab have been described in a cohort of SLE patients who have undergone B-cell depletion therapy. High levels of circulating ADAs to Rituximab were found in patients who later developed infusion reactions on retreatment. However, there was no obvious difference in clinical outcomes between those who were ADA positive compared with those in which it was negative. Together, this suggests the presence of ADAs can predict future infusion reactions but do not adversely impact upon the efficacy of treatment.

In future, the routine screening of ADAs to Rituximab will help to reduce the risk of serious infusion reactions in patients being treated.

### REASONS FOR HOSPITALISATION AND IMMUNOSUPPRESSANT USE IN ADULT PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ADMITTED TO A TERTIARY ACADEMIC MEDICAL CENTRE

C. Anastasiou<sup>1</sup>, O. Dulai<sup>2</sup>, A. Baskaran<sup>2</sup>, J. Proudfoot<sup>2</sup>, S. Verhaegen<sup>2</sup>, K. Kalunian<sup>2</sup>. <sup>1</sup>University of California San Diego and University of California San Francisco; <sup>2</sup>University of California San Diego, San Diego, USA

**Background:** An estimated 22% to 28% of US SLE patients are hospitalised each year.<sup>1</sup> SLE and other connective tissue diseases have been ranked the sixth most likely conditions to result in 30 day readmission to the hospital.<sup>2</sup>

**Objectives:** To determine if the number of SLE patient hospital admissions, primary reasons for hospitalisation, and mortality have changed over time. We also sought to evaluate changes in immunosuppressant use in these patients.

**Methods:** A retrospective chart review was conducted on all adult patients with SLE admitted to the University of California San Diego Medical Centre in 2005 and 2013. Patients were identified by SLE billing code 710.0 of the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM).

**Results:** The number of yearly SLE patient hospitalizations decreased from 178 to 86 between the two times of observation. Infection was the most common reason for

hospitalisation accounting for 39.9% of hospitalizations in 2005 versus 31.4% of hospitalizations in 2013 (p=0.29). Lupus flare accounted for 9.6% of admissions in 2005 versus 8.1% of admissions in 2013 (p=0.722). SLE patient mean length of hospital stay decreased from 7.6 days to 6.4 days compared to all patient length of stay which decreased from 6 days to 5.75 days. Seven patients (3.9%) died during their hospitalisation in 2005 as opposed no inpatient deaths in 2013. Of the 261 admissions between 2010 and 2013, six admissions resulted in death (2.3%). Corticosteroid use decreased (79.8% to 61.6%, p=0.109), while hydroxychloroquine (27.0% to 59.3%, p<0.001), mycophenolate mofetil (5.6% to 13%, p=0.060), and leflunomide (0.6% to 9.3%, p=0.008) use increased over time.

**Conclusions:** Hydroxychloroquine and leflunomide use in hospitalised patients more than doubled from 2005 to 2013 with statistical significance. Rise in mycophenolate mofetil use and drop in corticosteroid use trended toward statistical significance. Number of hospitalizations, length of stay, and mortality decreased. Infection was the primary reason for inpatient hospitalisation and there was a decrease in admission for both infections and SLE flares between the time points although this did not reach statistical significance. We hypothesise that changing medication prescribing patterns may have altered the rate of damage accrual and mortality in SLE patients, and plan to perform a national study to further evaluate SLE hospitalisation data on a larger scale.

### HEALTH CARE RESOURCE UTILISATION (HCRU) AND COST ANALYSES OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AS A FUNCTION OF DISEASE SEVERITY: ANALYSIS OF REAL-WORLD CLAIMS DATA FROM A GERMAN SICKNESS FUND

E.R. Hammond<sup>1</sup>, H. Friedel<sup>2</sup>, E. Garal-Pantaler<sup>2</sup>, M. Pignot<sup>3</sup>, E. Velthuis<sup>4</sup>, X. Wang<sup>1</sup>, H. Nab<sup>5</sup>, B. Desta<sup>1</sup>, A. Schwarting<sup>6</sup>. <sup>1</sup>AstraZeneca, Gaithersburg, MD, USA; <sup>2</sup>Team Gesundheit GmbH, Essen, Germany; <sup>3</sup>Kantar Health GmbH, Munich, Germany; <sup>4</sup>Evidera PPD, Utrecht Area, Netherlands; <sup>5</sup>AstraZeneca, Cambridge, UK; <sup>6</sup>Universitätsmedizin der Johannes Gutenberg-Universität Mainz, Mainz, Germany

**Background:** SLE is a severe, chronic autoimmune disease of the connective tissue involving multiple organ systems. Understanding the economic burden of SLE in the context of disease severity is important when considering new therapeutic options.

**Objectives:** HCRU and costs associated with SLE were examined retrospectively using anonymized data from a German Sickness Fund database.

**Methods:** Real-world claims for adult (≥18 years old) patients (pts) with SLE from a German Sickness Fund database of company health insurance schemes were analysed. HCRU and costs were assessed annually for 2009–2014 for pts diagnosed with SLE in 2009 and validated using repeated SLE-related claims, co-diagnosis codes, laboratory tests, prescription treatment, and the diagnosing physician's specialty. Pts had to have data available for 2009 and ≥3 years before the index quarter in 2009. HCRU and costs for SLE cases were compared with those of controls matched (4:1) by age, sex, and baseline Charlson Comorbidity Index (CCI). Continuous outcomes were compared with a nonparametric test (e.g., Wilcoxon–Mann-Whitney) because most outcome distributions were positively skewed.

**Results:** Of the 3,290,701 persons with data available for 2009 and ≥3 years prior, 1228 had an SLE diagnosis in 2009. SLE prevalence steadily increased from 37.32/100,000 (incidence: 5.96/100,000 per year) in 2009 to 47.36/100,000 in 2014. The final sample comprised 1,160 SLE-confirmed pts (mean age: 52 years; females: 84%; baseline CCI range: 1–13). Most (85%) pts were diagnosed with SLE before 2009 SLE disease severity at baseline was classified as mild for 148, moderate for 484, and severe for 528 pts using a combination of International Classification of Diseases-10 GM and medication/procedures codes. Compared with matched controls, SLE pts, overall and those with moderate and severe disease, had significantly greater mean annual medical costs in 2009 (all SLE: € 6895 vs. € 3,692; moderate SLE: € 4867 vs. € 3,380; severe SLE: € 10,001 vs. € 4,239; p<0.0001 for each comparison) and each year thereafter. Mean costs, total number of hospital days, numbers of outpatient visits, hospital stays, and outpatient prescriptions, and other benefits were significantly greater for all

pts with SLE and for those with moderate and severe disease vs. matched controls. For example, for pts with severe SLE vs. controls, mean costs for hospital stays, outpatient prescriptions, and other benefits were € 4335 vs. € 1,414, € 2582 vs. € 1,087, and € 1068 vs. € 691, respectively, in 2009.

**Conclusions:** In Germany, the economic burden of moderate and severe SLE was greater than that of sociodemographic- and morbidity-adjusted controls between 2009 and 2014. Pts with SLE incurred greater HCRU and total annual medical costs vs. matched controls. HCRU increased with increasing SLE disease severity, with the greatest burden among pts with severe disease. New treatments could reduce HCRU and future costs.

### FRI0319 A PRACTICAL SIMPLE DOSE ESCALATION REGIMEN FOR MILD HYDROXYCHLOROQUINE-INDUCED HYPERSENSITIVITY REACTION

E. Takamasu, Y. Nasa, H. Takahashi, S. Sugii, N. Yokogawa. *rheumatology, Tokyo metropolitan tama medical center, Tokyo, Japan*

**Background:** In a recent Japanese clinical trial of hydroxychloroquine (HCQ), HCQ-induced hypersensitivity reaction occurred in 4.9% (5/103) including a case of Stevens-Johnson syndrome.<sup>1</sup> Several desensitisation methods were proposed, however the protocols were very complicated for routine practice.<sup>2</sup> Recently, a simple dose-escalation regimen of sulfamethoxazole-trimethoprim (SMX-TMP) showed better tolerability than standard dosing.<sup>3</sup>

**Objectives:** To investigate the incidence and risk factors of HCQ-induced hypersensitivity and propose a simple dose-escalation regimen for HCQ-induced hypersensitivity.

**Methods:** This is a single-centre, retrospective study. The subjects were Japanese SLE patients who started HCQ between Apr 1, 2009 and June 30, 2017 at Tokyo Metropolitan Tama Medical Centre. HCQ was prescribed with a dosage of 6.5 mg/ideal body weight (IBW) kg or less. We identified the cases of HCQ-induced hypersensitivity by reviewing electronic medical charts and pictures taken by patients or physicians. We diagnosed with HCQ-induced hypersensitivity if generalised eruption occurred within a month of starting HCQ and resolved completely after withdrawal of HCQ. We used the simple dose escalation regimen, starting from 40 mg/day with weekly increments by 40 mg, for patients with HCQ-induced hypersensitivity who did not require hospitalisation or systemic administration of glucocorticoids. We compared the clinical parameters (age, sex, dosage/actual or ideal body weight, starting dose, use of immunosuppressives, use of SMX-TMP, profile of autoantibodies) between patients with HCQ-induced hypersensitivity and those without HCQ-induced hypersensitivity. We also evaluated the success rate of our dose escalation regimen.

**Results:** Total 234 SLE patients were analysed. HCQ-induced hypersensitivity reaction were identified in 20 cases (8.5%). All cases developed mild generalised maculopapular rashes 17 (IQR 7.8–28.8) days after initiation of HCQ. No patient required hospitalisation or systemic glucocorticoid therapy. Among the clinical parameters compared, only anti-Sm antibody was associated with HCQ-induced hypersensitivity (table 1). HCQ was restarted in 10 patients using the simple dose escalation regimen. Among them 9 patients successfully continued HCQ and only one discontinued due to reappearance of mild hypersensitivity reaction.

	Patients with HCQ-induced hypersensitivity (n=20)	Patients without HCQ-induced hypersensitivity (n=214)	P value
Age, years (SD)	39 (28-46)	40 (30-52)	0.460
Female, %	85.0	93.5	0.344
Body weight (kg) (SD)	59 (45-55)	52 (47-60)	0.178
Starting dose /IBW, mg/kg (SD)	9.1 (4.0-9.6)	3.2 (4.5-5.9)	0.039
IBW (kg)	26.3 (19.2-21.8)	29.9 (18.9-23.5)	0.091
HCQ starting dose			
- 100mg, %	5.0	0.0	
- 150mg, %	0	0.0	
- 200mg, %	45.0	43.0	
- 300mg, %	65.0	31.8	
- 400mg, %	5.0	4.7	
Usage of steroids, %	95.0	89.3	0.563
Dose of steroids, mg (SD)	6.8 (5.0-12.3)	6.8 (4.0-9.0)	0.984
Usage of immunosuppressants, %	50.0	50.0	0.994
Usage of SMX-TMP, %	25.0	21.5	0.325
Lower glabellum, %	0 (0/20)	0.5 (1/21)	0.759
Kidney glabellum, %	50.0 (5/20)	5.6 (12/21)	0.432
Positive anti-dsDNA antibody, %	45.0 (9/20)	59.8 (128/214)	0.465
Positive anti-Sm antibody, %	60.0 (12/20)	34.2 (73/214)	0.022
Positive anti-RNP antibody, %	50.0 (10/20)	49.9 (107/214)	0.588
Positive anti-SSA antibody, %	40.0 (8/20)	33.5 (71/214)	0.385

**Conclusions:** HCQ-induced hypersensitivity reaction typically presents with mild generalised eruption 1–4 weeks after starting HCQ. Restarting HCQ with the simple dose escalation regimen may be a practical option for patients with mild HCQ-induced hypersensitivity reaction.

### FRI0320 ANTIMALARIALS PROTECTIVE EFFECTS IN SYSTEMIC LUPUS ERYTHEMATOSUS IN CHINA

F. Wang, W. Zhang, X. Feng, L. Sun. *Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Hydroxychloroquine (HCQ) and chloroquine (CQ), both known as antimalarial drugs, have become fundamental therapeutic elements in systemic lupus erythematosus (SLE) in these decades. However, their specific benefits on organs or in a large cohort of Chinese SLE patients haven't been elucidated.

**Objectives:** This retrospective multicenter study sought to examine the potential protective roles of antimalarials in a large retrospect multicenter study of SLE patients in China.

**Methods:** Data were collected from 1372 patients' first and following hospitalizations during 1999 to 2009. Laboratory variables, medications, disease activity, organ involvements, and survival statuses were analysed according to antimalarial usage.

**Results:** Antimalarials improved the survival of SLE patients as an independent predictor (HR 0.503, p=0.000). Using antimalarials protected patients with longer disease duration (>2 years), SLEDAI (>15) on admission, high SLEDAI (>10) on discharge, organ involvements (cardiopulmonary, gastrointestinal, renal, hematologic), anti-dsDNA positive, and no application of cyclophosphamide. In second hospitalisation, compared to non-users, SLE patients who had been treating with antimalarial drugs had lower levels of total cholesterol (TC) (4.47 (0.13) mmol/L vs 5.03 (0.21) mmol/L, p=0.027) and less chance of anaemia (46.5% vs 58.2%, p=0.033).

**Conclusions:** Using antimalarials benefits outcomes of SLE patients through multiple facets in Chinese patients.

**Disclosure of Interest:** None declared

### FRI0321 SURVIVAL RATE AND CAUSES OF WITHDRAWAL OF BELIMUMAB TREATMENT IN SLE IN A REAL LIFE SETTING

E. Morello<sup>1</sup>, F.R. Spinelli<sup>2</sup>, F. Ceccarelli<sup>2</sup>, L. Massaro<sup>2</sup>, L. Novelli<sup>2</sup>, F. Miranda<sup>2</sup>, C. Perricone<sup>2</sup>, S. Truglia<sup>2</sup>, C. Alessandri<sup>2</sup>, G. Valesini<sup>2</sup>, F. Conti<sup>2</sup>. <sup>1</sup>Dipartimento di Medicina Interna e Specialità Mediche – Reumatologia, Sapienza Università di Roma, Rome, Italy; <sup>2</sup>Dipartimento di Medicina Interna e Specialità Mediche – Reumatologia, Sapienza Università di Roma, Rome, Italy, rome, Italy

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic disease requiring long-term treatment. Even though immunosuppressive therapies improved the survival rate, a great percentage of SLE patients exhibit a persistently active disease, or disease flares. Belimumab (BLM), is currently the only biological drug

approved for the treatment of active SLE patients not responding to standard of care, without active kidney or neuropsychiatric (NP) involvement.

**Objectives:** Aim of the study was to analyse 36 months survival of BLM treatment, causes of withdrawal in a monocentric cohort of SLE patients followed-up in a daily practice setting.

**Methods:** The study was proposed to all the patients starting BLM. After the informed consent was obtained, demographic, clinical and serological data, indication to BLM and concomitant therapies were registered. At baseline and at 6,12,24,36 months of follow-up, disease activity (SLEDAI 2K), DAS28, C3 and C4 levels, anti-dsDNA status and weekly dose of glucocorticoids were recorded. Data were expressed as median-interquartile range; after 6,12,24,36 months, differences in all parameters compared to baseline were evaluated (Student t test) The treatment survival was evaluated by Kaplan-Meier analysis. P value<0.05 were considered significant.

**Results:** We enrolled 39 Caucasian individual, 38 females, 1 male, with median age of 43 (IQR 7.5) years and median disease duration 14.5 (5.5) years. Indications for starting BLM were: mucocutaneous involvement (n=11,28%), arthritis (n=25,64%), systemic symptoms (n=3,7%) and lung involvement (1 pt,2%). At baseline, all the patients were taking PDN;97% hydroxychloroquine,23% mycophenolate mofetil,23% azathioprine, 5% cyclosporine, 7% methotrexate and 2% thalidomide. Table 1 summarises trend of SLEDAI 2K, C3 and C4, DAS28 (for articular involvement), prednisone dose and percentage of patients positive for anti-dsDNA during the follow-up. Fourteen out of the 39 patients (35.8%) reached 12 months of observation and only 4 the 24 months, 3 the 36 months. Figure 1 shows the survival curve of Belimumab. In 8 patients (20%) adverse events were the cause of BLM withdrawal (severe infection in one patient, severe bradycardia in one and acute infusion reaction in another one). In 4 patients (10%) BLM was discontinued for lack of efficacy(articular and skin manifestations)after 4, 8, 12 and 23 months respectively; in 6 patients (15%) for loss of efficacy; one patient developed a severe NP flare after 2nd BLM infusion and was admitted in our hospital for depression. One patient was lost during the follow-up. Two patients withdrew BLM therapy to plan a pregnancy. We found significant reduction of PDN week levels, and improvement of C4 and aDNA levels at T6; as for disease activity, we found significant reduction of DAS28 at T6, and of SLEDAI-2k at T6 and T12.

	T0	T6	T12
N° of patients	39	25	14
PDN mg/sett	52.5 (39.5)	35 (17.5)	35 (0)
SLEDAI 2K	6 (3.5)	2 (2)	2 (0.75)
C3	79 (19.75)	84.5 (17.5)	73.5 (9.75)
C4	13.5 (12.75)	7 (10) <sup>s</sup>	10 (10.25)
aDNA(%)	100	20	5
DAS28	4.32 (0.7)	3.3 (1.33)	3 (0.65)

**Abstract FRI0321 – Figure 1.** the figure shows patients mantaining treatment with Belimumab

**Conclusions:** In our monocentric cohort of SLE patients, BLM demonstrated to be effective on disease activity and serology and led to a significant decrease of glucocorticoids dose; the main causes of BLM withdrawal were adverse events or disease flares.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6313

### FRI0322 RATIONALE FOR THE ATACEPT DOSE FOR A PHASE III STUDY IN PATIENTS WITH HIGHLY ACTIVE AND AUTO-ANTIBODY POSITIVE SLE

J. Shen<sup>1</sup>, O. Papisoulitis<sup>2</sup>, E. Samy<sup>1</sup>, P. Haselmayer<sup>3</sup>, P. Chang<sup>1</sup>, V. Ona<sup>1</sup>, A. Kao<sup>1</sup>. <sup>1</sup>EMD Serono Research and Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, USA; <sup>2</sup>Merck Institute for Pharmacometrics (an affiliate of Merck KGaA, Darmstadt, Germany), Lausanne, Switzerland; <sup>3</sup>Merck KGaA, Darmstadt, Germany

**Background:** Atacept targets the B-cell stimulating factors BlyS and APRIL, and is currently in clinical development for the treatment of patients (pts) with active, auto-antibody positive SLE.

**Objectives:** Here, we evaluated integrated nonclinical, clinical and exposure-response (E-R) data from atacept studies to determine an appropriate atacept dose for a Phase (P) III study in SLE pts with high disease activity (HDA).

**Methods:** Nonclinical efficacy and pharmacokinetic (PK)/pharmacodynamic data for atacept were obtained from two murine models: An F1 hybrid NZBWF1/J spontaneous SLE model (given mouse Fc-protein control or mouse TACI-Fc 5 mg/kg intraperitoneal [IP] three times per week) and a 4-Hydroxy-3-nitrophenyl-acetyl-Keyhole Limpet Haemocyanin (NP-KLH) vaccinated C57BL/6 model to assess immunomodulation (given control protein 10 mg/kg or atacept 1, 3 or 10 mg/kg IP every third day). Clinical PK, efficacy, safety and E-R data were obtained from a PI PK study in healthy participants (Study 022; single dose atacept: 25, 75 or 150 mg) and two PII studies in pts with autoantibody-positive SLE (APRIL-SLE [EudraCT 2007-003698-13] and ADDRESS II [EudraCT 2013-002773-21]; randomization [1:1:1] to once weekly [QW] subcutaneous [SC] injections of atacept [75 or 150 mg] or placebo [PBO]). In APRIL-SLE, the primary endpoint was the proportion of pts with BILAG A/B flare over 52 weeks. In ADDRESS II, the primary endpoint was SRI-4 response at Week 24. SRI-6 response was analysed post-hoc in pts with HDA (SLEDAI-2K $\geq$ 10) at Screening. A population PK model was established using data from the PI and PII studies. Population PK model-derived exposure vs probability of clinical response (BILAG A/B flare, SRI-4, SRI-6) was assessed, and an exploratory analysis of exposure vs safety performed.

**Results:** TACI-Fc 5 mg/kg prevented proteinuria development and glomerular damage in the F1 hybrid NZBWF1/J spontaneous SLE model. Anti-KLH IgG decreased markedly in atacept-treated NP-KLH vaccinated mice (>50% reduction vs control protein at all doses), with mean atacept serum trough concentrations ( $C_{min}$ ) of ~2.3  $\mu$ g/mL (1 mg/kg), ~5  $\mu$ g/mL (3 mg/kg) and ~8.5  $\mu$ g/mL (10 mg/kg). In post-hoc analyses of the proportion of pts with BILAG A/B flare and time to flare in APRIL-SLE, and SRI-4 and SRI-6 response in SLE pts with HDA in ADDRESS II, treatment with atacept 150 mg QW demonstrated greater clinical response vs PBO. In both studies, atacept E-R relationships based on population PK-derived exposure were observed. For maximal flare reduction, an atacept exposure of  $AUC \geq 1$  mg\*hr/mL was identified. This exposure was more achievable with 150 than 75 mg (60% vs 15% probability) and corresponded to an atacept  $C_{min}$  of 5  $\mu$ g/mL, which was similar to the  $C_{min}$  values observed in the NP-KLH vaccinated mouse model. Both atacept 150 and 75 mg had acceptable safety profiles in SLE pts, with no apparent E-R relationship observed for serious infections.

**Conclusions:** Integrated nonclinical, clinical and E-R data demonstrate an acceptable benefit-risk profile for atacept in SLE pts with HDA and support the selection of the 150 mg QW dose for a PIII study.

**FRI0323 APREMILAST THERAPY IN REFRACTORY SKIN LUPUS LESIONS**

J.L. Martín-Varillas<sup>1</sup>, J. Loricera<sup>1</sup>, S. Armesto<sup>1</sup>, E. Cuende<sup>2</sup>, V. Calvo-Río<sup>1</sup>, C. González-Vela<sup>1</sup>, B. Atienza-Mateo<sup>1</sup>, J.L. Hernández<sup>1</sup>, M.A. González-Gay<sup>1</sup>, R. Blanco<sup>1</sup>. <sup>1</sup>Rheumatology, Dermatology, Internal Medicine and Pathology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander; <sup>2</sup>Rheumatology, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain

**Background:** Skin lesions of lupus may be refractory to standard therapy. Apremilast is an orally small molecule which inhibits phosphodiesterase-4 (PDE-4) that modulates some inflammatory pathways.

**Objectives:** Our aim was to assess the efficacy of apremilast in lupus rashes refractory to conventional treatment.

**Methods:** Retrospective study on 5 lupus patients treated with apremilast at standard dose of 30 mg twice daily. The outcome was improvement of lupus rashes.

**Results:** We described 5 patients (4 women and 1 male) with a mean age of 44.2 ±8.5 years with extensive skin lesions due to lupus. Three patients had a discoid lupus and 2 patients had systemic lupus erythematosus (SLE) (one with panniculitis and the other with polycyclic ring lupus). The cutaneous lupus was confirmed in all patients by skin biopsy. Prior to apremilast all patients had received conventional treatment: topical corticosteroids (n=5), antimalarials (n=5), topical tacrolimus (n=2), oral corticosteroids (n=2), thalidomide (n=1), belimumab (n=1) and rituximab (n=1). After a mean follow-up of 6.2±2.9 months, all the patients experienced improvement of the skin lesions (in two patients was complete). In one patient it was necessary to reduce the dose of apremilast to 30 mg/day because of digestive symptoms.

**Conclusions:** Apremilast can be useful in the treatment of refractory skin lesions of lupus.

**Disclosure of Interest:** None declared

**FRI0324 IMMUNOSUPPRESSION FOR PRIMARY SJOGREN'S SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS**

L. Chu, K. Cui, J. Pope. LHSC, London, Canada

**Background:** The current focus of treatment in primary Sjogren's Syndrome (pSS) is mainly symptom management. Since pSS is an autoimmune disease with multi-system involvement, there may be a role for systemic immunosuppression and/or biologic therapy. A wide variety of immune response targets have been examined in existing randomised controlled trials including inhibiting purine synthesis, blocking TNF-alpha, and depleting B lymphocytes. There is conflicting evidence as to whether immunomodulation alters disease progression.

**Objectives:** To assess the efficacy and safety of immunosuppressive therapy on pSS from clinical trials.

**Methods:** Five electronic databases (MEDLINE, EMBASE, CENTRAL, CLINICALTRIALS.GOV, WHO ICTRP) were searched to include randomised controlled trials of systemic immunosuppressive therapies in adults with pSS published in English prior to Oct 1, 2017. Efficacy measures included ocular dryness, oral dryness, fatigue, tear production, unstimulated and stimulated salivary flow, quality of life (QOL), ESSPRI, ESSDAI, ESR/CRP; Safety measures included serious adverse events (AEs) and withdrawals due to AEs.

**Results:** The searched yielded 32 trials evaluating 19 different medications. Studies enrolled anywhere between 7 to 133 patients, with the exception of 1 study with 497 patients. Mean age was in the fifth decade, with an average duration of diagnosis up to 9.2 years.

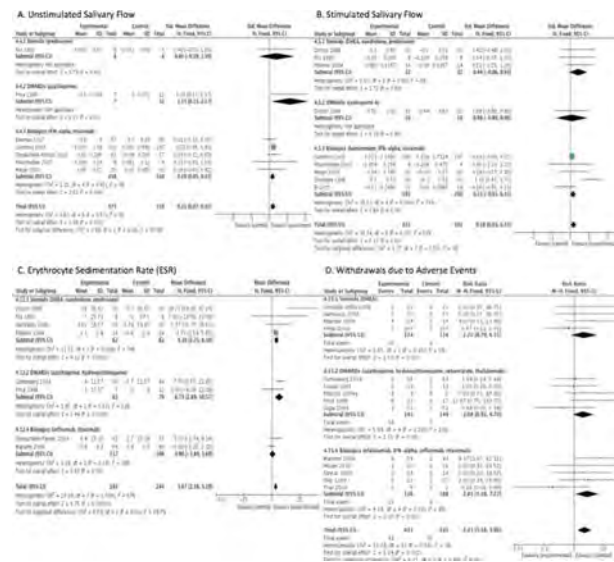

Twenty-two trials examined ocular and oral dryness, of which 2 and 3 revealed statistically significant improvements respectively (table 1). Only 1/14 trials found benefit for fatigue, none for tear production; 3/16 trials and 2/14 trials found increases in unstimulated and stimulated salivary flow respectively. Reductions in ESR were seen in 3/14 trials. Few studies examined QOL, ESSPRI, ESSDAI, and CRP. Trials often noted non-statistically significant trends toward improvement, but no particular drug or drug class consistently showed discrete benefit in subjective or objective efficacy measures possibly due to low statistical power.

**Abstract FRI0324 – Table 1. Efficacy Outcome Measures**

Outcome	# Trials Total	# Trials showing statistical improvement
Ocular dryness	22	1 of 1 Prednisone 1 of 2 Rituximab
Oral dryness	22	1 of 3 Prednisone 1 of 3 Rituximab 1 of 3 DHEA
Fatigue	14	1 of 4 Rituximab
Tear production	19	0
Unstimulated saliva production	16	2 of 3 Rituximab 1 of 3 Interferon alpha

Stimulated saliva production	14	2 of 4 Interferon alpha
Quality of life (mental component)	8	0
Quality of life (physical component)	8	0
ESSPRI	7	1 of 1 Igaruratimod
ESSDAI	6	1 of 1 Bamiercept 1 of 1 Igaruratimod
ESR	14	1 of 1 Nandrolone 1 of 1 Prednisone
		1 of 3 Hydroxychloroquine
CRP	3	1 of 1 Hydroxychloroquine

Meta-analyses of the above outcomes were performed at 6 months (figure 1). With pooled estimates, significant improvements were seen in unstimulated salivary flow (p=0.003), stimulated salivary flow (p=0.02), and ESR (p<0.001). There was a trend towards increased serious AEs in the intervention groups, and a significant increase in withdrawals from AEs (RR 2.33, 95% CI 1.38 to 3.96).

**Abstract FRI0324 – Figure 1. Meta-analyses at 6 months**

**Conclusions:** Reducing immune activity and inflammation potentially improves salivary gland function. Subjective measures may be less helpful as sicca symptoms likely have subtle progression if trials span less than 1 year. Given that most trials were small, beneficial treatment effects could be missed. Standardisation of objective, reliable, clinically meaningful outcome measures that are sensitive to change may allow for positive treatments in the future.

**Disclosure of Interest:** None declared

**FRI0325 RITUXIMAB IN PRIMARY SJÖGREN'S SYNDROME: A SYSTEMATIC REVIEW ON ITS EFFICACY**

M. Greco<sup>1</sup>, J. Del Pino Montes<sup>2</sup>, P. Díaz del Campo<sup>3</sup>, M. Fernández Castro<sup>4</sup>, F. Francisco<sup>1</sup>, J.L. Andreu<sup>5</sup>. <sup>1</sup>Rheumatology Department, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas; <sup>2</sup>Rheumatology Department, Hospital Universitario de Salamanca, Salamanca; <sup>3</sup>Unidad de Investigación de la Sociedad Española de Reumatología; <sup>4</sup>Rheumatology Department, Hospital Infanta Sofía; <sup>5</sup>Rheumatology Department, Hospital Puerta de Hierro Majadahonda, Madrid, Spain

**Background:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease that produces a limpho-plasmocitary infiltrate of the exocrine glands. Considering the primary role attributed to B-lymphocytes in pSS pathophysiology, it has been suggested that Rituximab (RTX) may have certain role in controlling the disease.

**Objectives:** To evaluate RTX efficacy in the treatment of xerostomia, xerophthalmia and systemic manifestations (including fatigue) in patients with pSS.

**Methods:** In the framework of the preparation of a recommendations document of the Spanish Society of Rheumatology on the use of biologics in pSS, a systematic search of the literature was carried out (until May 2017). Were included adults older than 18 years who met the 2002 American European Consensus Criteria, treated with RTX, with desired comparison to groups treated with other drugs or

with placebo and a follow-up time of 6 months. The quality of the studies was assessed through the levels of evidence (LOE) of SIGN scale.

**Results:** The search resulted in a total of 749 articles and only 9 of them were selected (**figure 1**). The best available evidence for each variable studied is summarised in **chart 1** ("+" significant improvement; "-" no significant improvement). The most relevant results obtained in the studies with **LOE 1+**, showed significant differences comparing RTX with labebo ( $p < 0.05$ ) in: 1) Souza 2016: Salivary flow rate at 24 w (weeks) (0.09; 95% CI 0.02 to 0.16). 2) Meijer 2010: Ocular dryness VAS score at 24 (-27.00, 95% CI -46.28 to -7.72), 36 and 48 w. Lissamine green test at 24 w (-2.00, 95% CI -3.52 to -0.48). Absolute number of B cells from 5 to 48 w (-0.23; IC 95% -0.31 to -0.15). Rheumatoid Factor at 12, 24 and 36 w. Tendomyalgia at 12 and 36 w. Vasculitis at 24 w. 3) Devauchelle-Pensec 2014: 'immunoglobulin's G (1.2 g/L; 95% CI 0.4 to 2 g/L), A, M and beta2-microglobulin (1.6 g/L; 95% CI 0.5 to 2 g/L) at 24 w. The studies with **LOE 3** also report improvement in a percentage of patients in other systemic manifestations, but without demonstrating statistical significance.

**Abstract FRI0325 – Figure 1.** Flow chart.

**Conclusions:** The studies of high methodological quality that evaluate the efficacy of RTX in pSS do not find significant improvement in the primary outcome variables, such as ESSDAI, glandular involvement and other objective parameters of dryness. However, open and retrospective studies find significant improvement in activity parameters, systemic manifestations, glandular involvement and improvement of certain objective tests of dryness.

### FRI0326 IMMUNE CELLULAR PROFILE ASSOCIATED WITH DIFFERENT TREATMENT OUTCOME IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ON CYCLOPHOSPHAMIDE

G. Gabcova<sup>1</sup>, M. Skacelova<sup>2</sup>, Z. Mikulkova<sup>1</sup>, P. Horak<sup>2</sup>, S. Zehnalova<sup>3</sup>, A. Smrzova<sup>2</sup>, F. Mrazek<sup>1</sup>, V. Smotkova Kraiczova<sup>1</sup>, M. Kudelka<sup>3</sup>, E. Kriegova<sup>1</sup>.

<sup>1</sup>Department of Immunology, Palacky University Olomouc; <sup>2</sup>Department of Internal Medicine III – Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Palacky University Olomouc, University Hospital, Olomouc; <sup>3</sup>Department of Computer Science, Faculty of Electrical Engineering and Computer Science, VSB-Technical University of Ostrava, Ostrava, Czech Republic

**Background:** Cyclophosphamide (CFA) is an effective immunosuppressive drug used for treatment of severe manifestations of systemic lupus erythematosus (SLE). The knowledge about modulatory effect of CFA on circulating immune cells and its changes associated with treatment response is limited.

**Objectives:** To determine the effect of a cumulative dose of CFA on circulating immune cells in SLE patients and to assess its association with treatment outcome.

**Methods:** Using 6-colour flow cytometry (BD FACSCanto II) we analysed T and B lymphocytes, NK cells, neutrophils, and monocytes in peripheral blood from 11 SLE female patients. SLE patients were investigated before and after cumulative 1000 mg and 3000 mg of CFA dose. Patients subgroups were assessed according to the treatment response (n=5, good responders; n=6, poor responders); SLEDAI (Systemic Lupus Erythematosus Disease Activity Index) was used to assess the disease activity. Healthy age-matched females (n=12) were included in the study. Statistics was done by GraphPad Prism and R statistical software package.

**Results:** Cumulative dose of 1000 mg of CFA resulted in decreased percentage of B lymphocytes ( $p=0.0004$ ) and CD4 +T lymphocytes ( $p=0.02$ ) and increased the percentage of total and CD8 +T lymphocytes ( $p=0.03$ ;  $p=0.0003$  respectively). After 3000 mg CFA, the percentage of B lymphocytes ( $p=0.002$ ), naïve B lymphocytes ( $p=0.005$ ), memory B lymphocytes ( $p=0.02$ ) and CD4+/CD8 +ratio ( $p=0.01$ ) decreased while the percentage of CD8 +T lymphocytes ( $p=0.0003$ ), Tregs ( $p=0.01$ ) and CD69 +NK cells ( $p=0.02$ ) increased. CFA treatment in our patients resulted in reduction of B lymphocyte percentage reaching the values of healthy controls. In good responders, decreased percentage of B lymphocytes ( $p=0.04$ ), CD4 +T lymphocytes ( $p=0.04$ ), CD4+/CD8 +ratio ( $p=0.007$ ) and increased percentage of CD8 +T lymphocytes ( $p=0.004$ ), CD69 +NK cells ( $p=0.04$ ) and non-classical monocytes ( $p=0.04$ ). In poorly responding patients percentage of CD8 +T lymphocytes ( $p=0.01$ ), activation marker HLA-DR on both CD4 +and CD8+T lymphocytes ( $p=0.01$ ;  $p=0.02$  respectively), Tregs ( $p=0.02$ ), memory B lymphocytes ( $p=0.03$ ) were increased and percentage of total B lymphocytes was decreased ( $p=0.02$ ). The analysis using advanced data mining methods for identification of treatment outcome related profiles are ongoing

**Conclusions:** Administration of CFA modulates several cell populations in SLE patients, whereas changes in B and T lymphocytes were associated with different treatment outcome. Whether the immune profile may predict the treatment response deserves further investigation.

FRI0327

**RELIABILITY OF LA AND DIAGNOSTIC PERFORMANCE OF APS/PT IN DIFFERENT CLINICAL SETTINGS OF APS: A MULTICENTER STUDY**

M. Radin<sup>1</sup>, I. Cecchi<sup>1</sup>, E. Rubini<sup>1</sup>, A.M. Scotta<sup>1</sup>, R. Rolla<sup>2</sup>, B. Montaruli<sup>3</sup>, P. Pergolini<sup>2</sup>, G. Mengozzi<sup>1</sup>, E. Muccini<sup>1</sup>, D. Roccatello<sup>1</sup>, S. Sciascia<sup>1</sup>. <sup>1</sup>Università Degli Studi Di Torino, Turin; <sup>2</sup>Università del Piemonte Orientale, Novara; <sup>3</sup>Ospedale Mauriziano, Turin, Italy

**Background:** Correct interpretation of lupus anticoagulant (LA) tests is crucial for diagnosis of antiphospholipid syndrome (APS). However, testing patients during vitamin K antagonist (VKA) or other anticoagulant remains a contentious issue and has been discouraged by official guidelines<sup>1</sup> because of interpretational problems affecting the mixing test. Similarly, the clinical significance of weak LA, especially in the context of VKA, remains uncertain and certainly needs a more thorough evaluation. Autoantibodies that recognise a phosphatidylserine/prothrombin (PS/PT) complex have been reported to be associated with APS and may have diagnostic relevance in these settings.

**Objectives:** To evaluate the reproducibility of LA testing when performed in different centres and to assess the diagnostic performance of anti-PS/PT in different clinical settings of APS.

**Methods:** aPL testing was performed in a blind fashion in 4 centres. LA was tested as per the current criteria from the ISTH Subcommittee on LA-Phospholipid-dependent antibodies.<sup>1</sup> Thirty-two patients were enrolled in this study, as follows: 13 patients with thrombotic APS treated with vitamin K antagonist; 5 patients thrombotic APS treated with DOAC; 14 patients with transitory/low aPL titer. Anti-PS/PT IgG/IgM (aPS/PT, Inova Diagnostics) were tested by ELISA. We analysed the categorical agreement and degree of linear association, for LA and aPS/PT, respectively.

**Results:** Demographic, clinical and laboratory characteristics are summarised in table 1. Categorical agreement for LA among the centres, as expressed by Cohen's kappa coefficients, ranged between 0.61 and 0.80 (as substantial agreement). The correlation among quantitative results in the aPS/PT IgG was strong (when dichotomizing for positive Vs. negative results, Cohen's kappa coefficients=0.81–1. Spearman rho 0.84). We observed 12 (37.5% of the total) cases (7/12, 58% patients on VKA) in which LA results were discordant (as defined by lack of agreement in  $\geq 2$  laboratories) or inconclusive. Conversely, in those cases, we observed a good correlation for aPS/PT IgG testing (Cohen's kappa coefficients=0.81–1, Spearman rho 0.86).

	Patients	% (32 Patients)
<b>Anagraphic</b>		
mean age (S.D.) at data collection	49,4 (14,1)	
gender (females)	20	62.5
<b>Clinical manifestations of APS</b>		
Thrombosis	25	81.3
Arterial Thrombosis	10	31.3
Venous Thrombosis	15	46.9
Obstetric APS	0	0.0
<b>aPL profile at diagnosis</b>		
LA (positive, n)	26	81.3
ACA (IgG/M)	26	81.3
anti-β2GPI (IgG/M)	21	65.6
<b>Anticoagulant Therapy</b>		
VKA (warfarin)	13	40.6
LMWH	3	9.4
DOAC	5	15.6
None	11	34.4

**Conclusions:** Despite the progress in the standardisation of aPL testing, we observed up to 37.5% of discrepant results for LA, especially in patients on VKA. Our findings showed that some discordances in the reliability of LA testing still exist. The introduction of aPS/PT antibodies in the diagnostic process of APS might represent a further diagnostic tool, especially when LA is not available or nor reliable.

**TARGETED THERAPY USING INTRADERMAL INJECTION OF ETANERCEPT FOR REMISSION INDUCTION IN DISCOID LUPUS ERYTHEMATOSUS (TARGET-DLE): FIRST RESULTS FROM A PROOF-OF-CONCEPT PHASE 2 TRIAL**

M.Y. Md Yusof<sup>1</sup>, M. Wittmann<sup>1</sup>, C. Fernandez<sup>2</sup>, D. Wilson<sup>2</sup>, S. Edward<sup>3</sup>, G. Abignano<sup>1</sup>, A. Alase<sup>1</sup>, L. Sharples<sup>2</sup>, P. Laws<sup>4</sup>, M.J. Goodfield<sup>4</sup>, E.M. Vital<sup>1</sup>, P. Emery<sup>1</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine; <sup>2</sup>Leeds Institute of Clinical Trials Research, University of Leeds; <sup>3</sup>Department of Histopathology; <sup>4</sup>Department of Dermatology, Leeds Teaching Hospitals NHS Trust, Leeds, UK

**Background:** A significant proportion of patients with discoid lupus erythematosus (DLE) are resistant to conventional therapies. Tumour necrosis factor (TNF) is pathogenic in DLE. A concern with systemic TNF-i administration is induction of pathogenic autoantibodies and flare of disease. This could be overcome using a low-dose intra-dermal injection, which may be sufficient to neutralise the TNF in lesions, **without systemic TNF effects.**

**Objectives:** To assess the efficacy and safety of a novel route of administration of a TNF-i using a low dose intra-dermal injection of etanercept (ETN) for remission induction in DLE.

**Methods:** A prospective single arm, Simon's 2-stage minimax design with Hybrid adaptation, phase II open label trial was conducted in Leeds [NCT02656082]. Key inclusion criteria were i) adults aged 18–80 y; ii)  $\geq 1$  active DLE lesion and iii) refractory to anti-malarials. One index lesion with the highest activity was treated with weekly intra-dermal injection of up to 10 mg ETN. The primary endpoint was  $\geq 6$  patients achieving the modified limited Score of Activity and Damage in DLE (ML-SADDLE) 20 response (defined as reduction  $\geq 20\%$  in total activity comprises erythema, induration and scaling from baseline) at Week 12 for a Phase 3 trial to be recommended. Secondary endpoints included change in objective outcome measures; lesional thermography and laser Doppler imaging.

**Results:** All 25 DLE patients were recruited over 18 months (18 female, mean age 47 $\pm$ 12 y, 6 had SLE, 9 had positive ANA and median (range) no. of previous systemic therapies was 5(1–16) 17 patients completed the primary efficacy assessment [Did not attend Week 12 visit=1, early withdrawals=7 (personal choice=2, AE=2, worsening of DLE=1, non-compliance=1, pregnant=1)]. The primary endpoint was met with 13/25 (52%, 95% CI 31–73) meeting the ML-SADDLE 20 in full-set analysis. The rates for ML-SADDLE 50 and 70 were 48% and 20% respectively. Key secondary endpoints were met (table 1). Fifty-one AEs (treatment-emergent=28, Grade 3/4=4) were recorded. There was no worsening of BILAG or SLEDAI in patients with SLE. Trough serum ETN levels were detected in 6/23 (26%).

**Abstract FRI0328 – Table 1.** Secondary endpoints (per protocol; n=17)

Endpoint	Pre-Treatment	Post-Treatment	p-value
Physician VAS, mean (SD) mm	53.1 (16)	23.2 (20)	<0.001
Patient VAS, mean (SD) mm	56.9 (28)	29.7 (28)	0.001
DLQI, mean (SD)	11.4 (7)	6.5 (6)	<0.001
Laser Doppler Imaging, mean (SD) perfusion unit	495.1 (224)	376.2 (223)	0.018
Infrared thermography, mean (SD), °Celsius	1.92 (1.17)	1.08 (1.05)	0.005

**Conclusions:** Intradermal injection of ETN substantially reduced clinical activity, met its primary, secondary endpoints and was tolerable in DLE patients who were refractory to anti-malarials and other systemic therapies. This drug warrants further development in multi-centre trials. Analyses of other imaging and histological biomarkers are ongoing and can help stratifying patients for response.

**FRI0329 THE NET-EFFECT OF COMBINING RITUXIMAB WITH BELIMUMAB IN SEVERE SYSTEMIC LUPUS ERYTHEMATOSUS**

O. Teng<sup>1</sup>, T. Kraaij<sup>1</sup>, S. Kamerling<sup>1</sup>, E. de Rooy<sup>1</sup>, P. van Daele<sup>2</sup>, O. Bredewold<sup>1</sup>, J. Bakker<sup>3</sup>, I. Bajema<sup>4</sup>, H. Scherer<sup>5</sup>, R. Toes<sup>5</sup>, T. Huizinga<sup>5</sup>, T. Rabelink<sup>1</sup>, C. van Kooten<sup>1</sup>. <sup>1</sup>Nephrology, Leiden University Medical Center, Leiden; <sup>2</sup>Clinical Immunology, Erasmus Medical Center, Rotterdam; <sup>3</sup>Clinical Chemistry; <sup>4</sup>Pathology; <sup>5</sup>Rheumatology, Leiden University Medical Center, Leiden, Netherlands

**Background:** In systemic lupus erythematosus (SLE) patients, excessive formation of neutrophil extracellular traps (NETs) is observed while their degradation is impaired. *In vitro*, immune complexes (ICx) trigger NET formation while NET-derived DNA is a postulated autoantigen for anti-nuclear autoantibodies (ANAs), found in SLE. Based on these self-perpetuating mechanisms in SLE, we hypothesised that interfering with ICx formation should regress NET formation and potentially ameliorate disease.

**Objectives:** Investigate the effect of Rituximab+Belimumab therapy on pathogenic autoantibodies in relation to NET formation in severe refractory SLE

**Methods:** A phase 2A, open-label, single arm proof-of-concept study was performed wherein 16 SLE patients with severe, refractory disease were treated with a combination of CD20-mediated B-cell depletion with rituximab and sustained inhibition of B-cell activating factor with belimumab. Besides safety, the study's endpoints were chosen to address the concept of autoantibodies in relation to excessive NET formation.

**Results:** We demonstrated that SLE-derived immobilised IgG, but not soluble IgG, induced excessive NET formation, confirming *ex vivo* that ICx mediate excessive NET formation in SLE. We showed that therapeutic intervention with RTX+BLM led to specific reductions in ANAs and regression of excessive NET formation. RTX+BLM appeared to be safe and achieved clinically significant responses: low lupus disease activity state was achieved in 10 patients, renal responses in 11 patients and concomitant immunosuppressive medication was tapered in 14 out of the 16 patients.

**B. Effect of RTX+BLM on excessive NET formation**

**Conclusions:** This study provides novel insights into clinical beneficence of reducing excessive NET formation in SLE by therapeutic targeting ANA production with RTX+BLM. Altogether putting forward a new treatment concept that specifically ameliorates underlying SLE pathophysiology.

**FRI0330 RITUXIMAB THERAPY IN SLE: EARLY RETREATMENT IS ASSOCIATED WITH LOWER DISEASE ACTIVITY AND A REDUCTION IN CORTICOSTEROID USE**

R.L. Batten, S. Batool, C.E. Kidd, A. Lorenzi, J. Vila, K. Walker, B. Griffiths. *Rheumatology, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle, UK*

**Background:** The recently published UK guidelines for the management of SLE recommend biologic therapy for severe or refractory disease. The British Isles Lupus Assessment Group Biologics Register (BILAG-BR) has shown rituximab (RTX) to be safe, effective and corticosteroid [CS] sparing when used to treat refractory SLE. In 2013 NHS England published an interim clinical commissioning policy statement with criteria determining when RTX can be used to treat SLE.

**Objectives:** We evaluated our centre's RTX retreatment strategy in patients with SLE and the consequent outcomes (disease activity and CS dose).

**Methods:** Records for the first 50 patients receiving RTX for refractory SLE who consented to join BILAG-BR from our centre between December 2013 and January 2016 were analysed (data cut off July 2016). Demographics, disease activity<sup>BILAG</sup> 2004/SLEDAI-2K, change in CS dose, retreatment schedules and adverse events were analysed.

**Results:** Median(IQR) age and disease duration were 42.8 (33–53) years and 9.5 (4–15.8) years respectively. Male: female ratio was 1:25. 80% were Caucasian, 6% Asian, 4% Caribbean and 10% other. All patients met SLICC/ACR classification criteria for SLE. The median(IQR) SLEDAI-2K scores and BILAG 2004 scores reduced from 6 (4–8) to 4 (0–4) ( $p < 0.00001$ ) and 20 (10–24.5) to 9 (2–15.5) ( $p < 0.001$ ) respectively at 6 months. Complete response was achieved in 62.8% patients (defined as loss of all BILAG A and B scores to  $\leq 1$ B score with no new A/B scores in other organ domains). 66% patients lost all A scores at 6 months. Median(IQR) daily CS dose reduced from 10 mg(0–20) to 5 mg(0.5–9.5) at 6 months ( $P = < 0.001$ ) and was 5 mg (0–6.63) at last reported visit (median (IQR) 13 (12–19.5) months). 16 patients did not fully respond to baseline treatment but 11 responded to retreatment. Serious infections (requiring hospital admission) occurred in 6 patients (12%).

30/50 patients received their 1<sup>st</sup> course of RTX at BILAG-BR baseline visit. 23 met criteria for active disease (at least 1A or 2Bs), 6 were taking an unacceptably high maintenance CS dose, and 1 was planning pregnancy. Median(IQR) CS dose in this group at baseline was 10 mg(1.5–20), and 5 mg(3–9) at 6 months. 70.8% demonstrated complete response at 6 months. 17 (57%) went on to have retreatment due to active disease, of which 11 (64.7%) had responded at 6 months post retreatment. Median(IQR) time to retreatment was 8 (6–12) months. 20/50 patients had received retreatment at predetermined intervals prior to their baseline BILAG-BR visit. Median(IQR) numbers of previous RTX courses were 3 (2–6). Median(IQR) CS dose was 8.75 mg(0–11.3) at baseline BILAG-BR visit and 5.5 mg(0–10) at 6 months. Median(IQR) time from baseline to retreatment was 6 (6–9.5) months. Median(IQR) sustained response was 18 (13.5–18) months.

**Conclusions:** Historically, our centre used time from 1<sup>st</sup> treatment to flare as a guide to a patient's future RTX retreatment schedule; patients were, on average, treated 2 months earlier than those treated under the current commissioning policy. Findings suggest that earlier retreatment led to sustained disease control and reduction of CS dose with no increase in adverse events. 11/16 incomplete responders responded following retreatment. Early retreatment may be associated with better outcomes for the patient and further research is needed in this area.

**Disclosure of Interest:** None declared

### FRI0331 TROUGH CONCENTRATION OF MYCOPHENOLIC ACID CORRELATES WITH RENAL FUNCTION AND SERUM ALBUMIN LEVEL IN JAPANESE PATIENTS WITH SLE

R. Hiwa<sup>1</sup>, K. Murakami<sup>2</sup>, M. Mori<sup>3</sup>, S. Nakagawa<sup>3</sup>, S. Akizuki<sup>1</sup>, N. Kuramoto<sup>1</sup>, R. Nakashima<sup>2</sup>, M. Hashimoto<sup>4</sup>, H. Yoshifuji<sup>1</sup>, M. Tanaka<sup>4</sup>, K. Ohmura<sup>2</sup>, T. Mimori<sup>2</sup>.  
<sup>1</sup>Department of Rheumatology and Clinical Immunology, Kyoto University Hospital; <sup>2</sup>Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University; <sup>3</sup>Department of Clinical Pharmacology and Therapeutics, Kyoto University Hospital; <sup>4</sup>Department for Advanced Medicine for Rheumatic Diseases, Graduate School of Medicine, Kyoto University, Kyoto, Japan

**Background:** Mycophenolate mofetil (MMF) is an immunosuppressant used for treatment of lupus nephritis. MMF is converted to mycophenolic acid (MPA) by esterases, which is the active metabolite with pharmacological activities. A fixed dose of 2–3 g/day is administered as remission induction therapy.<sup>1</sup> The usefulness of therapeutic drug monitoring (TDM) of MMF has not been elucidated. Moreover, little is known about the factor that affects the concentration of MPA in Asian patients.

**Objectives:** The aim of this study is to investigate the factor that affects the trough concentration of MPA in Japanese patients with SLE.

**Methods:** We recruited the SLE cases whose trough concentrations of MPA were measured from 2014 to 2017 at Kyoto University Hospital. When trough concentrations were measured multiple times in each patient with the same dose of MMF, median concentration was used for the analyses. Linear regression analysis was performed to identify the factor that affects the trough concentration of MPA. The association of trough concentration of MPA and adverse effects of MMF was investigated as well.

**Results:** Total of 20 cases were recruited and 43 trough concentrations were included for the analyses. The median daily dose of MMF (g) was 1.5 (range; 0.25–3.0) and the median trough concentration of MPA ( $\mu\text{g/ml}$ ) was 2.0 (range; 0.4–15.0). Linear regression analysis (table 1) revealed that trough concentration of MPA was correlated with daily dose of MMF ( $p=0.0081$ ,  $r=0.40$ , figure 1A), serum albumin level ( $p=3.3 \times 10^{-4}$ ,  $r=0.52$ , figure 1B) and creatinine clearance ( $p=1.8 \times 10^{-5}$ ,  $r=-0.60$ , figure 1C). Daily dose of prednisolone and serum C4 level were correlated with trough concentration of MPA as well, though multicollinearity was found in these two variables and serum albumin or creatinine clearance. Multivariate analysis (table 2) revealed that serum albumin and creatinine clearance were independently associated with trough concentration of MPA ( $p=6.2 \times 10^{-4}$  and  $1.6 \times 10^{-5}$ , respectively). Adverse effects of MMF, such as diarrhoea and cytopenia, were not associated with trough concentration of MPA.

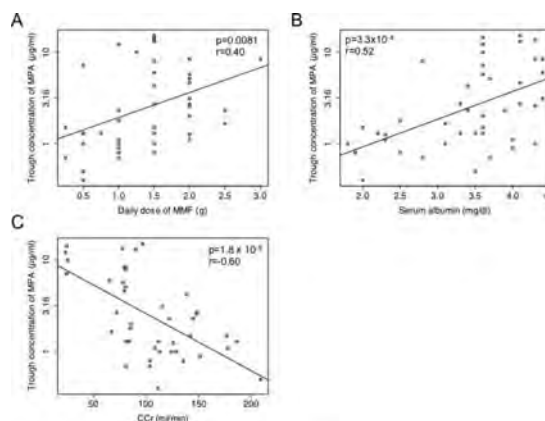

**Abstract FRI0331 – Table 1.** Linear regression analysis (Univariate analysis) of parameters influencing trough concentration of MPA

Variables*	Standardised beta coefficient	P-value	Odds ratio (95% CI)
Daily dose of MMF (g)	0.27	0.0081	1.31 (1.08–1.59)
Serum albumin (mg/dl)	0.30	$3.3 \times 10^{-4}$	1.35 (1.16–1.57)
CCr (ml/min)	-0.062	$1.8 \times 10^{-5}$	0.94 (0.91–0.96)
Age (years)	0.0039	0.52	1.00 (0.99–1.02)
BW (kg)	-0.0025	0.79	1.00 (0.98–1.02)
PSL (mg/day)	-0.015	0.0035	0.99 (0.98–0.99)
Serum C3	0.0073	0.055	1.01 (1.00–1.01)
Serum C4	0.019	0.023	1.02 (1.00–1.03)

**Abstract FRI0331 – Table 2.** Linear regression analysis (Multivariate analysis) of parameters influencing trough concentration of MPA

Variables*	Beta	P-value	Odds ratio (95% CI)
Daily dose of MMF (g)	0.14	0.068	1.15 (0.99–1.32)
Serum albumin (mg/dl)	0.23	$6.2 \times 10^{-4}$	1.26 (1.11–1.42)
CCr (ml/min)	-0.053	$1.6 \times 10^{-5}$	0.95 (0.93–0.97)

BW=body wt, PSL=prednisolone, \*Standardised beta coefficient and odds ratio of CCr was calculated with 10 as one unit.

**Conclusions:** Trough concentration of MPA was correlated with daily dose of MMF, serum albumin level and creatinine clearance.

### FRI0332 THE EXTENT OF TUBULOINTERSTITIAL INFLAMMATION PREDICTS THE PROGNOSIS OF TREATED PATIENTS WITH LUPUS NEPHRITIS

S.J. Lee<sup>1</sup>, Y.J. Kim<sup>2</sup>, S. Jae Seok<sup>1</sup>, N.R. Kim<sup>1</sup>, E.J. Nam<sup>1</sup>, Y.M. Kang<sup>1</sup>.  
<sup>1</sup>Internal Medicine, Division of Rheumatology; <sup>2</sup>pathology, Kyungpook National University Hospital, Daegu, Korea, Republic Of

**Background:** Lupus nephritis is common clinical manifestation and contributes significantly to mortality of systemic lupus erythematosus (SLE)

**Objectives:** Recently it has been reported that severity of tubulointerstitial inflammation (TII) predicts subsequent renal failure. However, it has not yet been reported what histologic features affect the survival rate in patients with lupus nephritis who had conventional treatment.

**Methods:** Seventy-six patients with lupus nephritis, who had conventional treatment and renal biopsy, were enrolled in this study. The extent of tubulointerstitial lymphocytic infiltrates was semi-quantitated (grade 1–4) using standard histochemical staining. This was then compared to other established lupus nephritis classification (ISN/RPN classification) which focuses on histologic changes of the glomerulus as well as clinical and laboratory characteristics. Follow-up data were obtained and survival analysis was carried out to determine the predictive values for subsequent mortality.

**Results:** TII was a common pathologic finding, 64% percent of biopsy samples were graded as 1, 11% as 2, 14% as 3, and 11% as 4. In 29% of biopsies (22/76), there were well circumscribed lymphocytic aggregates in tubulointerstitium and 5% of biopsies (4/76), structures like germinal centre (GC) were observed. When TII was divided into mild (grade 1–2) and severe (grade 3–4), lymphocyte aggregates and GC formation were more common in patients with severe TII (15/19, 4/19) than those with mild TII (7/57, 0/57) ( $p<0.001$  and  $p=0.004$ , respectively). Patients with severe TII or lymphocyte aggregates were significantly higher in serum creatinine, but not with double-stranded DNA (ds DNA) antibodies, serum complement 3, SLE disease activity (SLEDAI) and degree of proteinuria at the time of biopsies compared to those without. The mean follow-up time was  $62.9 \pm 47.0$  months and overall, 9 patients died as a result of disease progression ( $n=6$ ) and infection ( $n=3$ ). Patients with severe TII, lymphocyte aggregates or GC formation were at greater risk for mortality compared to those without. However, both glomerular proliferation and laboratory markers including baseline ds DNA, complement, SLEDAI and degree of proteinuria did not affect on long term mortality. After multivariate logistic analysis including SLEDAI and histologic features, only GC formation provided poor prognostic information for mortality (hazard ratio 24.5, 95% confidence interval 2.2–274.6;  $p=0.009$ ).

**Conclusions:** TII severity, especially GC formation, was independent predictor for a worse outcome in lupus nephritis patients with conventional treatment. A larger study is needed to confirm whether the presence of GC formation influences disease outcome.

**FRI0333 B-CELLS DEPLETION AS RESCUE THERAPY FOR EXTRA-CRITERIA MANIFESTATIONS OF PRIMARY ANTIPHOSPHOLIPID SYNDROME**

S. Sciascia<sup>1</sup>, M. Radin<sup>1</sup>, I. Cecchi<sup>1</sup>, E. Rubini<sup>1</sup>, D. Rossi<sup>2</sup>, M. Bazzan<sup>3</sup>, D. Roccatello<sup>1</sup>. <sup>1</sup>Department of Clinical and Biological Sciences, Università Degli Studi Di Torino; <sup>2</sup>Ospedale S. Giovanni Bosco, Turin, Italy; <sup>3</sup>UOSD Hematology and Thrombosis Unit, Ospedale S. Giovanni Bosco, Turin, Italy

**Background:** While immunosuppressive drugs may be helpful in patients with active systemic autoimmune diseases, their use in antiphospholipid syndrome (APS) is still controversial, and mainly limited to very selected cases of catastrophic APS or in severe cases refractory to standard therapy.<sup>1</sup> B-cells are likely to play a central role in the generation of the aPL-induced clinical manifestations of the disease, so they might constitute a logical therapeutic target in APS.

**Objectives:** To investigate PAPS patients with extra-criteria manifestations of APS treated with Rituximab (RTX) as a rescue therapy.

**Methods:** We retrospectively retrieved data from patients who attended the S. Giovanni Bosco Hospital, Turin, Italy, who met the following inclusion criteria: a) persistent aPL positivity and fulfilled the Sydney criteria for PAPS<sup>2</sup> b) presented with at least 1 extra-criteria manifestation; c) were treated with RTX as a rescue therapy (e.g. because they were refractory/intolerant/contraindicated to standard therapy) for the management of extra-criteria manifestations of APS.

**Results:** This retrospective study included 7 consecutive PAPS patients [median age 53 (range 38–66), female 6:1]. Table 1 resumes the characteristics of the PAPS patients included in the study. Six patients presented with severe thrombocytopenia (plts <50.000/mm<sup>3</sup>) and 1 patient presented with recurrent superficial venous thrombosis (3 events in 6 months despite ongoing anticoagulation therapy with VKA). Previous therapies included intravenous immunoglobulins (5 patients) and high doses of steroids (3 patients). One patient received RTX as rescue therapy as a steroid-sparing agent because of the high cardiovascular risk (high body mass index, uncontrolled arterial hypertension, and diabetes). We observed a full response after treatment with RTX in 6 out of 7 patients (86%, 5 with thrombocytopenia and 1 with recurrent superficial thrombosis). One patient who did not respond to the B-cell depletion therapy, and was treated with a splenectomy 1 month after RTX therapy and platelets levels normalised 3 months after the procedure. Overall, median time free from relapse was 27.5 months (range 4–97), no adverse events were reported, no patients developed infections.

**Abstract FRI0333 – Table 1.** Patients with PAPS with extra-criteria manifestations that followed a B-cells depleting protocol from the experience of our centre

	Age	aPL profile	Clinical manifestations of APS	Extra-criteria manifestations	RTX Protocol	Adverse events	Previous Immunosuppressive Therapy	Autoimmunity	Time free from relapse (months)
Patient 1 (male)	45	Triple positivity	1 episode of TVP and PE, 1 episode of retinal thrombosis	Recurrent superficial venous thrombosis	CYC 750mg/weekly for 2 weeks and RTX 375 mg/m <sup>2</sup> weekly for 4 weeks + 2 monthly infusions	None	IVIG	Warfarin, target INR 2.5-3.5	10 ongoing
Patient 2 (female)	38	Triple positivity	1 episode of stroke	Severe thrombocytopenia	RTX 375 mg/m <sup>2</sup> weekly for 4 weeks + 2 monthly infusions	None	IVIG	Warfarin, target INR 2-3	34 ongoing
Patient 3 (female)	66	Triple positivity	1 retinal haemorrhage, 1 thrombosis of distal venous sinus, 1 thrombosis of the jugular vein	Severe thrombocytopenia	RTX 1g/15 days, 2 infusions in total	None	IVIG, high doses of steroids	Warfarin 2.5-3.5, then Fondaparinux	12
Patient 4 (female)	53	LA positive	Recurrent miscarriages, Thrombosis of the Abdominal aorta	Severe thrombocytopenia	RTX 1g/15 days, 2 infusions in total	None	IVIG, high doses of steroids	Warfarin, target INR 2-3	8 ongoing
Patient 5 (female)	58	Triple positivity	1 episode of TVP and PE, 1 recurrence of TVP	Severe thrombocytopenia	RTX 375 mg/m <sup>2</sup> weekly for 4 weeks + 2 monthly infusions	None	None	Warfarin, target INR 2-3	43 ongoing
Patient 6 (female)	60	Triple positivity	1 episode of stroke	Severe thrombocytopenia	RTX 375 mg/m <sup>2</sup> weekly for 4 weeks + 2 monthly infusions	None	IVIG	Warfarin, target INR 2-3	97 ongoing
Patient 7 (female)	66	Triple positivity	1 episode of TVP	Severe thrombocytopenia	RTX 375 mg/m <sup>2</sup> weekly for 4 weeks	None	High doses of steroids	Warfarin, target INR 2-3	0

APS Antiphospholipid Syndrome, UC undifferentiated connective tissue disease, CYC cyclophosphamide, RTX rituximab, AZA azathioprine, MTX methotrexate, DVT deep vein thrombosis, PE pulmonary embolism

**Conclusions:** In selected case of patients with PAPS, RTX can represent a safe and efficacious therapeutic tool to manage the extra-criteria manifestations of the syndrome, especially when standard approaches have failed or cannot be pursued.

**FRI0334 COMPARISON OF DIFFERENT DEFINITIONS OF REMISSION IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) – A STUDY BASED ON THE BLISS-76 CLINICAL TRIAL**

S. Emamikia<sup>1</sup>, C. Gentile<sup>1</sup>, E. Arkema<sup>2</sup>, L. Arnaud<sup>3</sup>, K. Chatzidionysiou<sup>1</sup>, R. van Vollenhoven<sup>1,4</sup>. <sup>1</sup>Department of Medicine; <sup>2</sup>Clinical Epidemiology Unit, Karolinska Institute, Stockholm, Sweden; <sup>3</sup>Department of Rheumatology, Université de Strasbourg, Strasbourg, France; <sup>4</sup>Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands

**Background:** Standardisation of a definition of disease remission in SLE is one of the most important unmet needs in rheumatology and up to today there is no gold standard for the definition of remission.<sup>1</sup>

**Objectives:** An international task force consisting of 60 rheumatologists, nephrologists, dermatologists, clinical immunologists and patient representatives agreed on various definitions of remission in SLE (DORIS).<sup>2</sup> Our aim was to apply these definitions on a clinical trial.

**Methods:** This is a post-hoc analysis of a prospective randomised controlled trial (RCT) in SLE, the BLISS-76 clinical trial.<sup>3</sup> We have applied two DORIS definitions (table 1) at three time points, week (wk) 24, 52 and 76. The patient could be in remission on or off treatment. Remission on treatment allowed maintenance anti-malarials, low dose glucocorticoids (GCs) (prednisone ≤5 mg/day or equivalent), maintenance immunosuppressives and maintenance biologics. Remission off treatment allowed maintenance anti-malarials only. Additionally, we applied each definition where the remission on treatment allowed a GC dose ≤10 mg/day (not a part of the original DORIS-definitions).

**Abstract FRI0334 – Table 1.** DORIS definitions of remission in SLE

Definition	1a	1b	3a	3b
cSLEDAI=0	√	√	-	-
PhGA<0.5	√	√	√	√
Serology	Regardless	Normal	Regardless	Normal
BILAG D/E only	-	-	√	√

cSLEDAI: clinical Systemic Lupus Erythematosus Disease Activity Index; PhGA: Physician Global Assessment; BILAG: British Isles Lupus Assessment Group  
**Note:** Anti-double stranded DNA and complement (C3 and C4) is included in serology. These definitions were first tested (a) regardless of serology and then (b) normal serology (negative anti-dsDNA antibodies AND normal complement).

**Abstract FRI0334 – Table 2.** Percent of Patients who started the BLISS-76 trial (n=819) who were in remission at week 24, week 52, and week 76 using different definitions

Def1a: cSLEDAI=0, PhGA<0.5 and normal serology

Def 1b: cSLEDAI=0, PhGA<0.5 and regardless of serology

Def3a: BILAG D/E only, PhGA<0.5 and normal serology

Def 3b: BILAG D/E only, PhGA<0.5 and regardless of serology

GCs: Glucocorticoids

On treatment: maintenance anti-malarials, low dose glucocorticoids (prednisone ≤ 5 mg/day or equivalent), maintenance immunosuppressives, and maintenance biologics are allowed.  
 Off treatment: maintenance anti-malarials only is allowed.

**Results:** There were 819 patients enrolled in BLISS-76. The proportions of patients that fulfilled remission according to the above definitions are shown in table 2. The highest point prevalence (9.5%) was when definition 1a on treatment was applied at wk 76. As expected, even more patients fulfilled definition 1a when a GC dose ≤10 mg/day was allowed at wk 76 (13.8%). More patients fulfilled the

remission criteria when clinical SLEDAI was used compared to when BILAG was used. When serology (anti-DNA antibodies and complement) was taken into consideration (definitions 1b and 3b), less patients fulfilled remission. Very low numbers of patients ( $\leq 1\%$ ) fulfilled remission off treatment.

**Conclusions:** Overall, few patients fulfilled remission according to these definitions. More patients fulfilled the definitions when serology was excluded and when a higher dose of GCs was allowed.

#### FRI0335 HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR AUTOIMMUNE DISEASES – A 20 YEARS SINGLE CENTRE EXPERIENCE

T. Alexander<sup>1</sup>, L. Templin<sup>1</sup>, A. Grützkau<sup>2</sup>, H. Hirsland<sup>2</sup>, A. Thiel<sup>3</sup>, G. Burmester<sup>1</sup>, A. Radbruch<sup>2</sup>, R. Arnold<sup>4</sup>, F. Hiepe<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, Charité – University Medicine Berlin; <sup>2</sup>German Rheumatism Research Center; <sup>3</sup>Center Research Translation Education Berlin-Brandenburg Center for Regenerative Therapies; <sup>4</sup>Hematology, Oncology and Tumor Immunology, Charité – University Medicine Berlin, Berlin, Germany

**Background:** Over the past 20 years, hematopoietic stem cell transplantation (HSCT) has been emerging as a promising treatment option for severe cases of autoimmune diseases (ADs). Meanwhile, positive results have been obtained in 3 randomised clinical trials for systemic sclerosis. The goal of this therapy is to induce medication-free remissions by ablating the pathologic autoreactive memory and restoring of self-tolerance.

**Objectives:** Here, we summarise the clinical outcomes of AD patients receiving HSCT at the Charité – University Medicine.

**Methods:** In this prospective study, the outcome of 22 patients been analysed after receiving a CD34<sup>+</sup>-selected autologous HSCT after immunoablation with ATG and cyclophosphamide for different ADs (10 SLE, 4 SSc, 3 vasculitis, 2 multiple sclerosis, 1 polycondritis, 1 inflammatory polyneuropathy, 1 autoimmune haemolytic anaemia) between 1998 and 2015. Multiparametric flow cytometry was applied to characterise peripheral blood lymphocytes subsets including analysis of the TCR-Vbeta repertoire on CD4<sup>+</sup> T cells, CD31 expression as marker for thymic output of CD4<sup>+</sup> T cells, including Foxp3<sup>+</sup> Tregs. In SLE, Siglec-1 on monocytes as surrogate for interferon activity and RNA expression profiling by microarray of FACS-sorted CD14<sup>+</sup> monocytes was performed (Affymetrix). Autoantibodies were investigated with ELISA.

**Results:** With a median follow-up of 135 months, the overall survival was 76.5% and progression-free survival 67.9%, respectively. 3 deaths were regarded treatment related, 1 patient had persisting disease (haemolytic anaemia) and 4 relapses occurred in SLE at 1, 18, 36 and 80 months, respectively. Remaining patients are in stable clinical remissions despite discontinuation of immunosuppressive therapy. HSCT was associated with significant reduction or normalisation of auto-antibody levels and a profound reconfiguration of the adaptive immune system, the latter characterised by a re-emergence of naïve T cells with markers of recent thymic emigrants and renewed TCR repertoire, including Foxp3<sup>+</sup> Tregs and regeneration of naïve B cells. In SLE patients, Siglec-1 expression on monocytes completely normalised and transcriptome analysis revealed an abrogation of type I interferon signalling in responding patients.

**Conclusions:** Our data provide the "...proof-of-concept" that a chronic autoimmune system can be reset into a naïve and self-tolerant state by HSCT, potentially providing cure in AD. Although applied as salvage therapy in severely affected patients with poor outcomes, TRM gradually improved due to accumulating centre experience and better patient selection and supportive care. Based on positive results from RCT in the major indications, HSCT should be placed earlier in the

treatment algorithm, especially in systemic sclerosis with rapid progress and lung involvement.

**Disclosure of Interest:** None declared

#### FRI0336 BELIEF ABOUT MEDICINE QUESTIONNAIRE PREDICTS THERAPEUTIC ADHERENCE TO HYDROXYCHLOROQUINE DURING SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Rozban<sup>1</sup>, H. Devilliers<sup>2</sup>, M. Hié<sup>1</sup>, P. Micheline<sup>1</sup>, A. Mathian<sup>1</sup>, F. Cohen-Aubart<sup>1</sup>, H. Julien<sup>1</sup>, N. Zahr<sup>3</sup>, Z. Amoura<sup>1</sup>. <sup>1</sup>French National Referral Center for Systemic Lupus Erythematosus, Antiphospholipid Antibody Syndrome and Other Autoimmune Disorders, Service de Médecine Interne 2, Institut E3M, Assistance Publique–Hôpitaux de Paris (APHP), Groupement Hospitalier Pitié–Salpêtrière, Paris; <sup>2</sup>Médecine Interne et Maladies Systémiques – Médecine 2, CHU Dijon Bourgogne, Dijon; <sup>3</sup>Service de pharmacologie biologique, Assistance Publique–Hôpitaux de Paris (APHP), Groupement Hospitalier Pitié–Salpêtrière, Paris, France

**Background:** Therapeutic adherence is a key element of chronic disease management and one of the most difficult to assess. The Belief about Medicines Questionnaire (BMQ) evaluates patients' own beliefs related to medication. It is available in two sections: the BMQ-General and the BMQ-Specific. The BMQ-specific focuses on the representations of medication prescribed for personal use. It was set up as a screening test for poor therapeutic adherence during certain chronic diseases. Early detection of lupus patients at risk of poor therapeutic adherence could lead to preventive actions.

**Objectives:** To assess the BMQ-Specific as a predictive test of adherence to hydroxychloroquine in SLE.

**Methods:** Case-control, retrospective and monocentric study. Cases were enrolled according to the following criteria: systemic lupus erythematosus (SLE) according to the ACR classification criteria and HCQ dosage <100 ng/ml after a minimum of 2 months of treatment. The matched control was a lupus patient, enlisted within the centre the same week, with a HCQ dosage  $\geq 800$  ng/ml. Each patient answered the BMQ-Specific through a telephone interview. The BMQ-Specific comprises two 5-item factors assessing beliefs about the necessity of prescribed medication (*Specific-Necessity*) and concerns about the danger of dependence and long-term toxicity of medication (*Specific-Concerns*). Responses to each statement were scored on a five-point Likert scale (1=strongly disagree and 5=strongly agree). Scores obtained for the individual items within both scales were summed to give total scores for the Specific-Necessity and Concerns scales range from 5 to 25. A Necessity–Concerns (N-C) differential was calculated (range from –20 to +20). It expresses the cost–benefit perceived by the patient for taking the medication. Case and control characteristics were compared using usual tests. Diagnosis performance of each BMQ score and necessity-concern differential were studied by the mean of ROC curves.

**Results:** The BMQ-Specific questionnaire was submitted to 118 patients: 59 cases and 59 matched controls. The concern score was significantly higher in cases (mean 16.8 vs. 12.7,  $p < 0.0001$ ). The necessity score was significantly higher in control (mean 18.4 vs 15, respectively,  $p < 0.0004$ ). ROC curves show a better area under the curve (AUC) with the N-C differential compared to the AUC of separate scores (respectively 0,8 vs 0,7). The sensitivity and specificity are optimal for a N-C differential of 3.

**Conclusions:** During SLE, nonadherent patients are primarily concerned about the risks inherent to treatment, rather than its effectiveness. To date, we are the only study to show that specific BMQ is an efficient tool for detecting patients at risk of poor therapeutic adherence to HCQ during SLE. The necessity-concerns differential score must be preferred to the scores taken separately. Thus, targeted educational actions can be provided as soon as the patients are taken in charge, in order to improve their adherence to treatment.

**Disclosure of Interest:** None declared

#### FRI0337 FACTORS ASSOCIATED WITH POOR THERAPEUTIC ADHERENCE TO HYDROXYCHLOROQUINE DURING SYSTEMIC LUPUS

Y. Rozban<sup>1</sup>, H. Devilliers<sup>2</sup>, M. Hié<sup>1</sup>, M. Pha<sup>1</sup>, A. Mathian<sup>1</sup>, F. Cohen-Aubart<sup>1</sup>, J. Haroche<sup>1</sup>, J.-S. Hulot<sup>3</sup>, N. Zahr<sup>3</sup>, Z. Amoura<sup>1</sup>. <sup>1</sup>French National Referral Center for Systemic Lupus Erythematosus, Antiphospholipid Antibody Syndrome and Other Autoimmune Disorders, Service de Médecine Interne 2, Institut E3M, Assistance Publique–Hôpitaux de Paris (APHP), Groupement Hospitalier Pitié–Salpêtrière, Paris; <sup>2</sup>Médecine Interne et Maladies Systémiques – Médecine 2, CHU Dijon, Dijon; <sup>3</sup>Pharmacologie biologique, Hôpital universitaire Pitié–Salpêtrière, PARIS, France

**Background:** Poor adherence to medication regimens is a major cause of relapse during systemic lupus erythematosus (SLE). Hydroxychloroquine (HCQ),

the main therapy of SLE, has a long half-life. Thus, undetectable blood HCQ concentrations can be used to identify patients who do not take their treatment

**Objectives:** To identify the determinants of poor therapeutic adherence in patients with SLE.

**Methods:** Case-control, retrospective, monocentric study. The cases were enrolled in our centre from 02/11/2011 to 13/01/2015 according to the following criteria: SLE defined according to ACR classification criteria and blood concentration of HCQ <100 ng/ml after a minimum of 2 months on therapy. For each case, the matched control was a lupus patient, enlisted from our centre the same week, with an HCQ dose greater than or equal to 800 ng/ml. Case and control characteristics were compared using standard tests and a uni-multivariate logistic regression.

**Results:** One hundred and fifty patients were included, 75 cases (68 women) and 75 controls (72 women), with an average age of 35.7 years ( $\pm 11.3$  years) vs 35.6 years ( $\pm 10.6$  years). Most patients had inactive lupus (3 patients had SLEDAI  $\geq 4$ ), 27% of them had benefited from therapeutic education sessions. The average dosage of HCQ was 1110 ng/ml within the control group. In our univariate analysis, nonadherent patients lived significantly further away from the centre than adherent patients (median distance [interquartile range]: 22<sup>11-52</sup> vs 14 km [5.9-35], respectively,  $p=0.03$ ) and were more likely to be unemployed, (23 vs 8%, respectively,  $p=0.006$ ). Nonadherent patients had less often benefited from the patient's therapeutic education program (18 vs 35%, respectively,  $p=0.018$ ), were taking less treatment (3 vs 4, respectively,  $p=0.008$ ), had a significantly lower level of education (61% compared to 89% of patients with at least a bachelor's degree,  $p<0.001$ ). In our multivariate analysis, a level of education below the A levels was the strongest factor explaining poor therapeutic adherence, OR (IC 95): 4.09 (1.5-10.8).

**Conclusions:** The main drivers of therapeutic adherence during SLE are socio-economic factors. The least educated and most disadvantaged patients are most likely to display poor therapeutic adherence. Targeted preventive actions and enhanced therapeutic education should be provided to them.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.5333

### FRI0338 HYDROXYCHLOROQUINE MAY HELP TO IMPROVE THE IN VITRO FERTILIZATION-EMBRYO TRANSFER OUTCOMES IN ANA AND DS-DNA POSITIVE PATIENTS

F. Lian, J. Zhou, Y. Wang, H. Xu, X. Yang. Dept. Of Rheumatology, 1st Affiliated Hospital Of Sun Yat-Sen University, Guangzhou, China

**Background:** Assisted reproductive technology has helped a large quantity of couples having trouble in natural pregnancy. Failure of *in vitro* fertilization-embryo transfer (IVF-ET) may be attributed to ANA and ds-DNA. ANA+/anti-dsDNA was related to low-quality embryos, low clinical pregnancy, and early miscarriage rate.<sup>1</sup> Hydroxychloroquine (HCQ) is recommended preconceptionally and throughout pregnancy for patients with SLE, and was proved to benefit the patients with Antiphospholipid syndrome. For those women with positive ANA and ds-DNA, but haven't any symptoms related to lupus or any other autoimmune diseases, the treatment for improving reproductive outcomes was controversial. In the present study, we retrospectively reviewed 156 patients with positive ANA and ds-DNA who underwent IVF-ET, compared the efficacy among different therapeutic strategies and observed side effects of the medication.

**Objectives:** To assess the efficacy, safety and tolerability of HCQ as preconceptionally and throughout pregnancy therapy in the treatment of IVF-ET patients with positive ANA and ds-DNA.

**Methods:** We retrospectively reviewed 156 patients in the treatment of IVF-ET with positive ANA and ds-DNA but without any symptoms in south China from January 2010 to December 2016 who received prednisone or prednisone +HCQ as preconceptionally and throughout pregnancy therapy. Prednisone was administered at a dose of 7.5 mg/day. HCQ was administered at a dose of 0.2 twice a day. Details of the IVF-ET outcomes and side effects were collected.

**Results:** Of the 156 patients, no significance of demographic variables and reproductive related parameters such as duration of infertility, basal sex hormone, total Gn dose, E2 level on the day of HCG initiation, and number of retrieved oocytes was found among prednisone group (65 cases) and prednisone +HCQ group (91 cases). Fertilisation rate, implantation rate and clinical pregnancy rate were significantly higher in prednisone +HCQ group than in prednisone group, 75.8% vs 60.0%,  $p=0.017$ , 29.7% vs 15.4%,  $p=0.032$ , and 62.6% vs 47.7%,  $p=0.028$ , respectively. Abortion rate was lower in prednisone +HCQ group, 7.0% vs 12.9%, but not significantly. Clinical pregnancy rate was not associated the titers of ANA or ds-DNA. Low C3 was correlated with failure of implantation. None of the cases on prednisone or prednisone plus HCQ had side effects affecting the treatment course.

**Conclusions:** Combination of prednisone and HCQ may be more effective than solo treatment of prednisone for patients underwent IVF-ET with positive ANA and ds-DNA who had no clinical symptoms of autoimmune diseases.

### FRI0339 SLEDAI-2K RESPONDER INDEX-50 IS EFFECTIVE IN DEMONSTRATING PARTIAL RESPONSE IN A PHASE 2, RANDOMISED PLACEBO-CONTROLLED STUDY OF USTEKINUMAB IN PATIENTS WITH ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS

Z. Touma<sup>1</sup>, M.B. Urowitz<sup>1</sup>, D.D. Gladman<sup>1</sup>, C. Wagner<sup>2</sup>, B. Hsu<sup>2</sup>, M. Chevrier<sup>2</sup>, S. Rose<sup>2</sup>, B. Zhou<sup>2</sup>, R. Gordon<sup>2</sup>. <sup>1</sup>Krembl Research Institute, Toronto, Canada; <sup>2</sup>Janssen Research and Development, LLC, Spring House, USA

**Background:** Ustekinumab (UST), a monoclonal antibody that targets shared p40 subunit of cytokines IL-12 and IL-23, is being investigated in pts w/active systemic lupus erythematosus(SLE). While traditional SLE Disease Activity Index 2000(SLEDAI-2K)scoring assesses complete SLE response for individual disease manifestations, SLEDAI-2K Responder Index-50(S2K RI-50)can be used to evaluate SLE responses using partial improvement( $\geq 50\%$ )in each domain.

**Objectives:** To evaluate SLEDAI-2K vs S2K RI-50 response in a randomised, PBO-controlled trial of UST in pts w/active SLE.

**Methods:** We conducted a Ph2, PBO-controlled study in adults w/active disease (SLEDAI score  $\geq 6$  w/ $\geq 1$  BILAG A and /or  $\geq 2$  BILAG B scores)despite standard-of-care therapy. Pts(n=102)were randomised(3:2) to UST IV~6 mg/kg or PBO at wk0, followed by SC inj of UST 90 mg q8w or PBO beginning at wk8, both added to standard-of-care. We calculated S2K RI-50 response at wk24 using various thresholds to define response including decrease of at least 1,2,3,4,5, or6 points from baseline(BL) in S2K RI-50 score. We also compared proportion of pts w/SLEDAI-2K response vs S2K RI-50 response in pts receiving UST(n=62)vs PBO (n=40)at wk24.

**Results:** Change from BL SLEDAI-2K and S2K RI-50 scores were strongly correlated( $R=0.89$ , $p<0.0001$ )at wk24. A greater proportion of UST vs PBO pts achieved S2K RI-50 response at wk24, regardless of threshold used to define response (table 1). The greatest differences in S2K RI-50 response rates between UST vs PBO were observed for a 4-point decrease(23.1%, $p=0.010$ ), a 5-point decrease(26.8%, $p=0.010$ ), and 6-point decrease (25.5%, $p=0.016$ ) from BL. S2K RI-50 captured more responders than SLEDAI-2K at wk24, however, the difference in SLEDAI-2K 4-point response in UST vs PBO was  $\Delta 27\%$ ( $p=0.005$ ) while S2K RI-50 was  $\Delta 23\%$ ( $p=0.010$ ).

**Abstract FRI0339 – Table 1.** S2K RI-50 response rates at Wk 24 for various thresholds to define response

Decrease from Baseline	UST (%) <sup>a,b</sup>	PBO (%) <sup>a,b</sup>	Difference between UST and PBO	p-value <sup>c</sup>
1 Point Decrease	96.0	94.2	1.8	0.3664
2 Point Decrease	90.0	84.2	5.8	0.2261
3 Point Decrease	86.9	74.1	12.8	0.0772
4 Point Decrease	86.2	63.1	23.1	0.0101
5 Point Decrease	74.5	47.7	26.8	0.0102
6 Point Decrease	66.3	40.8	25.5	0.0158

Note: S2K RI-50 response is defined differently in each row using different cutoffs. S2K RI-50 uses partial response definition of  $\geq 50\%$  improvement for each individual SLEDAI-2K descriptor.

<sup>a</sup> Values for pts meeting treatment failure criteria are set to missing from point of treatment failure forward.

<sup>b</sup> Response based upon multiple imputations for missing data from Wk16 to Wk24, where Markov chain Monte Carlo method is used to make missing pattern monotone and serial logistic regression is used to impute monotone missing. The imputation model includes treatment group and baseline SLEDAI-2K covariate.

<sup>c</sup> Test for greater treatment effect in UST over PBO (alternative hypothesis) is based upon logistic regression w/treatment group, baseline SLEDAI-2K, baseline medication use for SLE and race as covariates.

**Conclusions:** S2K RI-50 is an instrument that can capture partial clinically important improvement of  $\geq 50\%$  in SLE disease manifestations. The data suggests

cutpoints for defining S2K RI-50 response in clinical trials of pts w/moderate-severe SLE disease activity.

#### FRI0340 DOSAGE OF HYDROXYCHLOROQUINE (PLAQUENIL) ONLINE SURVEY BY PATIENT ORGANISATION NVLE

Z. Osmani, W. Zacouris-Verweij, S. Otteron behalf of Lupus APS committee. *Lupus APS committee, NVLE patient association, Utrecht, Netherlands*

**Background:** Hydroxychloroquine (HCQ) has been proven effective in several immune mediated diseases. Long-term use of HCQ is very common in patients with systemic autoimmune disease. The greatest advantage of HCQ is that it may reduce the risk of flares and thereby allow glucocorticoid dose reduction. The risk/benefit ratio of HCQ is excellent but HCQ is also known for its potentially severe and fortunately rare side effect: retinal toxicity. In The Netherlands, there are no standard guidelines regarding the dosing of HCQ and ophthalmologic screening of HCQ-induced complications. The American Academy of Ophthalmology (AAO) has recently published their revised recommendations on screening and dosing of HCQ. Risk of retinal toxicity is mainly determined by the two most significant risk factors: daily dose of HCQ (mg/kg/day) and duration of HCQ therapy (years). The AAO recommends a maximum daily HCQ dosage of <5.0 mg/kg real weight, to reduce the risk of toxicity.<sup>Marmor, 2016</sup>

**Objectives:** To raise more attention for the revised recommendation of the AAO, our patient organisation started an online survey asking patients with (systemic) autoimmune diseases which dose of HCQ (mg) they take on a daily basis.

**Methods:** Patients in the Netherlands were given the opportunity to complete the online survey at the website of the NVLE (Dutch patient association for people with Lupus Erythematosus, Anti-Phospholipid Syndrome, Systemic Sclerosis and Mixed Connective Tissue Disease) from July 26th – November 18th, 2017. The promotion of the survey took place solely through Social Media with a link to the survey. A total of 24 questions had to be filled in to complete the survey. Each individual was asked to write down their real weight (kg) for calculating the daily HCQ dosage (mg/kg/day).

**Results:** A total of 705 individuals completed the online survey. The daily dosage (mg/kg/day) was available from 645 patients. The majority were females (n=645) and diagnosed with (systemic) lupus erythematosus (n=518). The average dosage of HCQ was 4.50±1.68 mg/kg/day. The daily dosage of 5 mg/kg was exceeded by 258 of the patients (40%). Eighty-one individuals (12.6%) used a daily dosage of ≥5 mg/kg for more than 10 years. The most reported HCQ-induced complications were gastrointestinal complaints (n=55), problems with vision (n=43), and nausea (n=32).

**Conclusions:** Patients (and prescribing physicians) should be informed about risk of toxicity, proper dose levels, and the importance of regular annual screening. Physicians prescribing HCQ must aim for a daily HCQ dosage of less than 5.0 mg/kg/day, especially for patients using HCQ for already more than 10 years. (Inter)national guidelines regarding the screening and dosing of HCQ should be provided by the authorities to secure patient safety and reduce the frequency of (severe) retinal complications.

#### SLE, Sjögren's and APS – clinical aspects (other than treatment)

#### FRI0341 LUPUS LOW DISEASE ACTIVITY STATE (LLDAS) VERSUS CLINICAL REMISSION AS TREATMENT TARGETS IN THE FIRST 18 MONTHS OF SYSTEMIC LUPUS ERYTHEMATOSUS MANAGEMENT

A. Floris, M. Piga, G. Cappellazzo, E. Chessa, M. Congia, A. Cauli, A. Mathieu. *Chair of Rheumatology and Rheumatology Unit, University and AOU of Cagliari, Monserrato, Italy*

**Background:** In the view of applying a treat to target (T2T) strategy in the management of systemic lupus erythematosus (SLE), a novel definition of minimal acceptable disease activity – the lupus low disease activity state (LLDAS)<sup>[1]</sup> – and clinical remission (CR)<sup>[2]</sup> were recently proposed.

**Objectives:** To compare attainability and outcomes of LLDAS and CR as treatment targets in the early stages of SLE management.

**Methods:** LLDAS and CR prevalence were analysed at 6 (T1) and 18 (T2) months after treatment initiation (T0) in a monocentric cohort of 107 (median disease duration 9.7 months) prospectively followed Caucasian SLE patients. LLDAS was defined as SLE disease activity index 2000 (SLEDAI-2K)≤4 without major organ activity and no new disease activity, physician global assessment (0–3)≤1, prednisone ≤7.5 mg/day and well-tolerated immunosuppressant dosages. CR was defined as clinical SLEDAI-2K=0 (increased anti-dsDNA and low complement were excluded) and prednisone ≤5 mg/day in patients treated with/without stable immunosuppressants and/or antimalarials. Multivariate models were built to identify factors associated with failure to achieve LLDAS and CR, as well as to investigate relationship between the latter and early damage accrual (defined as SLICC/Damage Index≥1 at T2).

**Results:** LLDAS was achieved significantly more frequently than CR both at T1 [47 (43.9%) vs. 25 (23.4%); p<0.001] and T2 [48 (44.9%) vs. 35 (32.7%); p<0.001]. Out patients achieving LLDAS, 25 (53.2%) and 35 (66.7%) concomitantly fulfilled the criteria for CR at T1 and T2, respectively. A prednisolone (PDN) dose exceeding the minimal acceptable range set in the respective definitions was the most frequent reason for failure to achieve both LLDAS and CR (in 83.0% of no-LLDAS patients at T1% and 95.1% of no-CR at T1). The disease manifestations with the highest persistence rate during follow-up were: increased anti-dsDNA (persistently present in 85.7% and 67.5% of cases at T1 and T2, respectively), low complement (73.2% and 66.3%) and renal abnormalities (46.4% and 28.6%). Renal involvement at baseline significantly associated with failure to achieve LLDAS both at T1 (OR: 7.8, 95% CI: 1.41–43.40; p=0.019) and T2 (OR: 3.87, 95% CI 1.41–10.6; p=0.008) and CR at T2 (OR 9.46, 95% CI 1.13–78.8). High PDN dosage was significantly associated with no-CR achievement both at T1 (OR 6.23, 95% CI 2.2–18.3; p=0.01) and T2 (OR 1.11, 95% CI 1.02–1.20; p=0.02). Early damage was recorded in 23 (21.5%) patients and was significantly associated, on multivariate analysis, with older age at diagnosis (OR 1.05 95% CI 1.01–1.09; p=0.016) and failure to achieve LLDAS (OR 4.82, 95% CI 1.44–16.09; p=0.11) at T1. No significant association was found between early damage and failure to achieve CR, possibly due to its low prevalence among this cohort of early SLE patients.

**Conclusions:** During the early stages of SLE, LLDAS and CR overlap definitely less frequently than reported in long-standing disease (53.2%–66.7% vs 83.9%–96.5%<sup>[2]</sup>). Although remission is recommended as the primary treatment target in SLE, LLDAS may represent a valid alternative in the first stages of disease management, being more attainable compared to CR and negatively associated to early damage.

**FRI0342 DOES UNDERSTANDING SLE MATTER TO DISEASE ACTIVITY IN SLE PATIENTS?**

A.S. Meara<sup>1</sup>, P. Hackenberger<sup>2</sup>, J. Yedimenko<sup>3</sup>, C. Rodman<sup>4</sup>, S.P. Ardoin<sup>5</sup>, E. Peters<sup>6</sup>. <sup>1</sup>Division of Immunology and Rheumatology; <sup>2</sup>College of Medicine; <sup>3</sup>Internal Medicine, The Ohio State University; <sup>4</sup>The; <sup>5</sup>Department of Medicine; <sup>6</sup>Department of Psychology, The Ohio State University, Columbus, USA

**Background:** Systemic lupus erythematosus (SLE) is a heterogeneous disease with high morbidity and mortality with complex long-term treatments. These dynamic treatments can be daunting especially to the 25%–60% of SLE patients who have cognitive and neuropsychiatric deficits. Patients lacking understanding of their own baseline health status and treatment options cannot effectively collaborate in making informed choices with their physicians.

**Objectives:** This project aimed to identify SLE patients' comprehension of their medication regimens and disease outcomes in relation to standard markers of disease activity (SLEDAI) and damage (SLICC DI).

**Methods:** Patients >18 years were recruited from The Ohio State University (OSU) Lupus Vasculitis Glomerulonephritis (LVG) clinic. An IRB-approved 25-item true/false disease questionnaire was administered to 75 SLE patients who provided informed consent. Individual question and composite scores for each patient were correlated with their SLEDAI and SLICC DI scores. To our knowledge, a disease comprehension questionnaire has never been used in lupus patients.

**Results:** 75 SLE patients completed the comprehension questionnaire. Lower comprehension was associated with greater disease activity ( $r = -0.14$ ), while no correlation was found between composite score and disease damage (SLICC DI) ( $r = -0.03$ ). Figures 1 plot the comprehension composite scores against the SLEDAI. P values were not significant, but trending to correlate with the r. Evaluation of individual questionnaire items demonstrated: approximately 80% of patients did not associate heart disease with lupus, over 25% of patients did not recognise the side effects of prednisone, and over 15% of patients did not know lupus affects bone health.

**Conclusions:** These preliminary results suggest that patients with more understanding of their SLE diagnosis, comorbidities, and treatments had less measured disease activity. The comprehension questionnaire and SLEDAI characterize patients in their present disease state, so this correlation likely reflects the evolution of patient understanding and the fluctuating nature of their disease. Alternatively, higher disease activity scores represent more severe disease, which could be associated with greater neurocognitive deficits leading to poorer scores on the comprehension questionnaire. The lack of correlation between composite score and SLICC DI is likely attributed to the discrepancy between a metric evaluating current knowledge and a long-term indicator that may derive from decisions made when patients' comprehension was different than current. These initial results are promising and may represent a cost-effective opportunity for physicians to evaluate and address their patients' comprehension gaps in an effort to improve shared decision making. However, more data are needed to test the robustness of these trends.

**FRI0343 BLOOD CONCENTRATIONS OF COMPLEMENT SPLIT PRODUCT IC3B AND SERUM C3 ASSOCIATE WITH SLE DISEASE ACTIVITY**

A.H. Kim<sup>1</sup>, V. Strand<sup>2</sup>, D. Sen<sup>1</sup>, Q. Fu<sup>3</sup>, N. Mathis<sup>1</sup>, M. Schmidt<sup>4</sup>, R. Bruchas<sup>4</sup>, N. Staten<sup>4</sup>, P. Olson<sup>4</sup>, C. Stiening<sup>4</sup>, J. Atkinson<sup>1</sup>. <sup>1</sup>Rheumatology, WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, Saint Louis; <sup>2</sup>Immunology and Rheumatology, Stanford University School of Medicine, Palo Alto; <sup>3</sup>Epidemiology and Biostatistics, Saint Louis University; <sup>4</sup>Kypha, Inc., Saint Louis, USA

**Background:** The complement system plays a central role in systemic lupus erythematosus (SLE). Since complement activation occurs during SLE flares, complement proteins are predicted to be consumed with concomitant generation of activation-derived products at a rate proportional to the degree of disease activity. However, interpretation of values may be confounded due to the unknown impact of increased acute phase production of C3 and C4, as well as in individuals with low C4 gene copy number who have persistently low serum C4.

Improved detection of complement activation would enhance clinicians' ability to more readily assess SLE disease activity and promptly identify and treat flares. We hypothesize that complement split products are more sensitive measures of complement activation and better correlate with SLE disease activity.

**Objectives:** To examine correlations between blood levels of complement split product iC3b and serum component C3 with clinically meaningful changes in disease activity in patients with SLE.

**Methods:** 159 consecutive subjects with American College of Rheumatology or Systemic Lupus International Collaborating Clinics classified SLE were enrolled into CASTLE (Complement Activation Signatures in Systemic Lupus Erythematosus), a prospective observational study. Patients with 1–7 study visits were included in this longitudinal analysis. 48 healthy volunteers were enrolled to establish the normal reference range of iC3b/C3. Serum C3 and C4 were measured by nephelometry. Blood levels of iC3b were assessed by a lateral flow assay. SLE disease activity was monitored utilizing the Systemic Lupus Erythematosus Disease Activity Index 2K Responder Index-50 instrument.

**Results:** iC3b/C3 ratio, double-stranded (ds)DNA antibodies (Abs), and supra-physiologic prednisone dose (>7.5 mg/day) each independently correlated with SLE disease activity employing multilevel multiple logistic regression analysis. Only iC3b/C3 was significantly associated with clinically meaningful improvements in disease activity among subjects receiving supraphysiologic doses of prednisone (high disease activity). iC3b/C3 outperformed C3 and C4 levels in discriminating both active versus inactive SLE disease and major flares versus no disease activity (figure 1). Finally, iC3b/C3, dsDNA Abs, ESR, and supra-physiologic prednisone dose were independently associated with lupus nephritis, while none were associated with SLE rash.

**Abstract FRI0343 – Figure 1.** ROC curves of iC3b/C3, iC3b, C3, C4, and dsDNA levels distinguishing new major flares from subjects with no SLE activity

**Conclusions:** Blood iC3b/C3 ratio correlates with SLE disease activity and clinically meaningful improvement in disease activity. Furthermore, it discriminates between active versus inactive SLE, and major flares compared to those patients without disease activity.

#### FRI0344 SERUM FREE LIGHT CHAINS AS A FLARE BIOMARKER IN SYSTEMIC LUPUS ERYTHEMATOSUS

A.B. Rodriguez Cambroñ<sup>1</sup>, J. Jimenez Jimenez<sup>2</sup>, M.A. Blazquez Cañamero<sup>3</sup>, M. J. García De Yébenes<sup>4</sup>, F. Rey Pazos<sup>5</sup>, C. Macía Villa<sup>1</sup>, M. Alcalde Villar<sup>1</sup>, F. Cabero Del Pozo<sup>1</sup>, P. Collado Ramos<sup>1</sup>, E. Alvarez Andrés<sup>1</sup>, A. Cruz Valenciano<sup>1</sup>.  
<sup>1</sup>Rheumatology; <sup>2</sup>Immunology, Hospital Universitario Severo Ochoa; <sup>3</sup>Rheumatology, Hospital Universitario Ramón y Cajal; <sup>4</sup>Musculoskeletal Health Institute (InMusc); <sup>5</sup>Rheumatology, Hospital Universitario Infanta Sofía, Madrid, Spain

**Background:** Complement levels are already known as biomarkers of flare in systemic lupus erythematosus (SLE); currently the usefulness of free light chains (FLC) in different autoimmune diseases in which the B cell has a relevant pathogenic role, as in the case of SLE, is being investigated.

**Objectives:** To explore the usefulness of FLC determination as a flare biomarker in patients with SLE and to analyse possible discriminative differences between FLC and complement C3 and C4 levels.

**Methods:** We performed an uncentric prospective longitudinal study with the following inclusion criteria: age greater than 18 years old and fulfilment of ACR or SLICC criteria for the diagnosis of SLE. Exclusion criteria were non-SLE related haematological disease, severe infection and severe kidney disease (Crea>2 mg/dl) to avoid interferences with FLC clearance. SLE flare definition was based on the SFI index. Receiver operator curves (ROC) and calculation of the area under the curve (AUC) were used to compare the discriminative ability between FLC and C3-C4 levels.

**Results:** 46 patients were enrolled. For the present communication, only baseline data were analysed. 41 (91%) patients were women. Most frequent clinical manifestations were haematological (83%) and cutaneous (72%). Laboratory findings were 98% positive ANA, 67% positive antiDNAc, 54% decreased C3% and 39% decreased C4. 6 (13%) patients presented a SLE flare and their characteristics compared to non-flare patients were lower C3 levels (70 vs 95; p=0,017) and C4 levels (10 vs 17; p=0,008) with higher concentrations of lambda light chains ( $\lambda$  LC) (27 vs 19; p=0,028). In addition, flare patients had higher IgA levels (402 vs 250; p=0,029), higher score in the global assessment of the doctor (4.3 vs 1.6; p=0,0003), longer time disease evolution (17.8 vs 14.3 years; p=0,844), higher values of SLEDAI (2.7±2 vs 1.4±1.3; p=0,083) and higher lymphopenia (982 vs 1474; p=0,068). We found no association between FLC levels and the presence of antiDNAc. The correlation of FLC with the rest of activity biomarkers (C3, C4, SLEDAI, VAS) occurred in the expected way although the magnitude of the association was moderate, with a higher correlation between C3 and  $\lambda$  LC.  $\lambda$  LC were the only FLC that showed ability to discriminate flares (AUC 0.781), with sensitivity 100%, specificity 65% and 69.6% of patients correctly classified for a cut-off point  $\geq 19.5$ . On the other hand, C3 and C4 also had a high discrimination capacity for flare (AUC 0.804 and 0.837 respectively). Comparing the three parameters, C4 achieved the highest AUC (0.837, 95% CI: 0.663–1000).

**Conclusions:** Lambda free light chains have a good discrimination capacity for SLE flares and could be useful as a SLE flare biomarker. Longitudinal studies with a larger number of patients are necessary to evaluate its usefulness as a flare predictor.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2018-eular.5374

#### FRI0345 ASSOCIATION BETWEEN CIGARETTE SMOKING AND SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) – AN UPDATED META-ANALYSIS OF CASE-CONTROL AND COHORT STUDIES

M.H.Y. Chua, I. A. T. Ng, A. Mak. *Medicine, National University of Singapore, Singapore, Singapore*

**Background:** While the association between cigarette smoking and the occurrence of SLE has been studied over the past two decades, conflicting results have rendered such association controversial. With the global increase in woman smokers and more prospective data addressing the risk of the development of SLE and cigarette smoking being available, it is timely to provide an update on the evidence of the relationship between cigarette smoking and the occurrence of SLE.

**Objectives:** To study the association between cigarette smoking and the odds, as well as the risk of SLE occurrence by meta-analyses of case-control and cohort studies.

**Methods:** We performed an extensive literature search using the relevant keywords including “systemic lupus erythematosus”; “lupus”; “smoking”; “cigarette smoking”; “environmental”; “autoimmune disease” and “connective tissue disease” in various combinations to identify case-control and cohort studies addressing the relationship between cigarette smoking and SLE published in English in computerised databases including PubMed (from 1966 to , Jan 2018 Embase (1980 to Jan 2018 and Cochrane Central Register of Control Trials (last quarter of 2017). Effect sizes were pooled as odds ratio (OR) and relative risk (RR) and the corresponding 95% CI for case-control and cohort studies, respectively. Heterogeneity was studied by  $I^2$ . If the effect sizes were associated with low heterogeneity ( $I^2 < 40$ ), the fixed effects model was used. Otherwise ( $I^2 \geq 40$ ), the random effects model was used, based on the model suggested by DerSimonian and Laird.

**Results:** Thirteen relevant studies (10 retrospective case-control and 3 cohort) were selected for these meta-analyses. Data were aggregated based on smoking statuses comprising current, past, ever and never smoking. Analyses of case-control studies revealed significant relationships between the occurrence of SLE and current smoking (OR 1.639 [1.171–2.295], p=0.004,  $I^2=85.8$ ), and ever smoking (OR 1.438 [1.037–1.995], p=0.029,  $I^2=86.3$ ). However, no significant relationship was found between the occurrence of SLE and past smoking (OR 1.208 [0.853–1.711], p=0.286  $I^2=74.7$ ). While no relationship was found between the development of SLE and current smoking (RR 1.002 [0.680–1.475], p=0.994,  $I^2=51.6$ ), and ever smoking (RR 1.163 [0.944–1.433], p=0.157,  $I^2=0$ ) when the effect sizes of cohort studies were amalgamated, a significant risk in the development of SLE was found amongst ex-smokers compared with never smokers when the prospective data were combined (RR 1.351 [1.085–1.681], p=0.007,  $I^2=28.0$ ).

**Conclusions:** Smoking is associated with the occurrence of SLE based on the aggregation of effect sizes from case-control and cohort studies. The higher risk of development of SLE in ex-smokers but not among current and ever smokers compared to never smokers based on prospective data warrants further mechanistic studies to unravel the actual immunologic impact of cigarette smoke on SLE development in different subsets of SLE patients.

#### FRI0346 NEUTROPENIA IN SYSTEMIC LUPUS: PREVALENCE, SPECIFIC FEATURES AND CLINICAL CONSEQUENCES. RESULTS FROM THE LARGE UPPER RHINE DATABASE LBBR

A. Meyer<sup>1</sup>, P.-E. Gavand<sup>1</sup>, G. Blaison<sup>2</sup>, T. Martin<sup>1</sup>, A.-S. Korganow<sup>1</sup>, A. Guffroy<sup>1</sup>, on behalf of LBBR Study Group. <sup>1</sup>Clinical Immunology, CHRU Strasbourg, Strasbourg; <sup>2</sup>Internal Medicine, CH Colmar, Colmar, France

**Background:** The prevalence, pathophysiology and underlying causes or consequences of neutropenia in systemic lupus erythematosus (SLE) are still not well defined even if neutropenia seems to be rather common in this disease.<sup>1</sup>

**Objectives:** To evaluate the prevalence of neutropenia in a large cohort of SLE patients and to identify correlation between neutropenia and other socio-demographical, clinical, serological or therapeutic factors.

To precise the influence of chronicity or severity of neutropenia in the course of SLE.

**Methods:** We used the LBBR database, a cross-sectional collection of detailed socio-demographic, clinical, serological and therapeutic data from 1,078 SLE patients (14 french or german Upper Rhine Hospitals).

Neutropenia was defined by the presence of less than 1800 circulating neutrophils  $\times 10^9/L$ . Patients with and without neutropenia were compared considering 47 variables.

The second part of the study focused on a subgroup of SLE LBBR patients for which full data were available about the duration and depth of neutropenia. Chronic neutropenia was defined by neutrophils count less than 1,500  $\times 10^9/L$  during at least 6 months and moderate and severe neutropenias were defined by neutrophils count less than 1,000  $\times 10^9/L$ .

**Results:** Among 1078 SLE patients, 223 (20.7%) were registered with neutropenia during their history. Mean age and sex ratio were comparable to the whole SLE cohort and to patients without neutropenia (mean age: 43.9 years old, sex ratio: 194 F/28 M). In multivariate analysis, neutropenia was associated with lymphopenia (OR=3.44 (2.48–4.80), p=0.0002) and thrombopenia (OR=3.59 (2.55–5.06), p=0.0002). There was no association with susceptibility to infections (OR 0.97 (0.52–1.80), p=0.6640), neither with SLEDAI score, SLE treatments or other ACR criteria.

Sixty-five patients out of 223, for which deepness and duration of neutropenia were available, were compared with patients without neutropenia. Moderate and severe neutropenias were again statistically associated with lymphopenia (OR 11.25 (2.60–48.61),  $p=0.0468$ ) and thrombopenia (OR 8.1 (3.28–19.99),  $p=0.0014$ ). There was again no association with susceptibility to infections or with treatment at sampling. In this group, using multivariate analysis, chronic neutropenia was statistically associated with lymphopenia (OR 9.48 (2.83–31.71),  $p=0.0177$ ), low C3 (OR 3.81 (1.59–9.14),  $p=0.0053$ ), anti-SSA antibodies (OR 2.40 (1.07–5.39),  $p=0.0042$ ) and Sjögren syndrome (2.56 (0.93–7.03),  $p=0.0435$ ).

**Conclusions:** The large LBBR cohort allows an approach of neutropenia prevalence and characteristics in SLE. Neutropenia concerns about 20% of SLE patients. Considering multivariate analysis, it is not directly linked to treatment and appears separated from infections occurrence, even when severe. Neutropenia in SLE is significantly associated with thrombopenia and lymphopenia, defining a subtype of SLE patients with haematological features and suggesting possible common pathophysiology.

#### FRI0347 PERFORMANCE OF POTENTIAL DEFINITIONS OF REMISSION IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) VERSUS QUALITY OF LIFE OVER 5 YEARS IN SWEDISH PATIENTS WITH RECENT-ONSET SLE

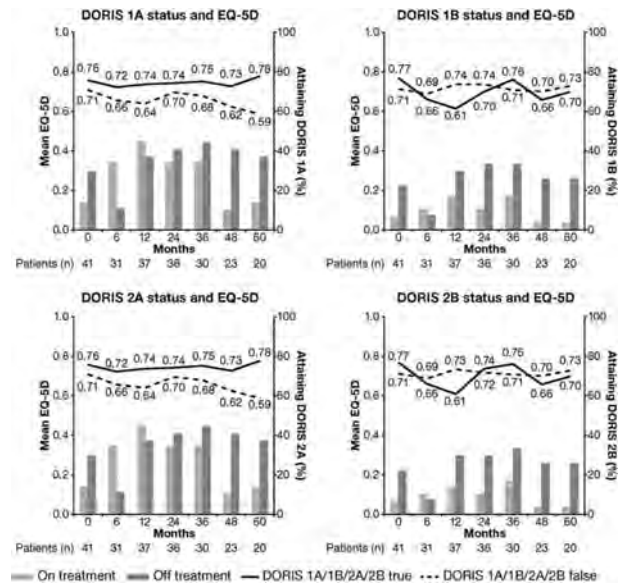

M. Björk<sup>1</sup>, R. Heijke<sup>1</sup>, M. Frodlund<sup>1</sup>, S. Ramagopalan<sup>2</sup>, E. Alemao<sup>3</sup>, C. Sjöwall<sup>1</sup>.  
<sup>1</sup>Linköping University, Linköping, Sweden; <sup>2</sup>Bristol-Myers Squibb, Uxbridge, UK; <sup>3</sup>Bristol-Myers Squibb, Princeton, USA

**Background:** Remission constitutes a desirable goal in the management and treatment of patients with systemic lupus erythematosus (SLE), but no universally accepted definition exists. Based on established disease activity measures (e.g. clinical SLE Disease Activity Index [cSLEDAI], physician's global assessment [PhGA] and British Isles Lupus Assessment Group [BILAG] index), serology (anti-double-stranded DNA antibodies and low complement) and ongoing therapy, an international task force recently suggested four preliminary definitions of remission in SLE (DORIS).<sup>1</sup> However, the definitions did not include any patient-reported outcome measures (PROMs).

**Objectives:** Using data from well-characterised Swedish patients with recent-onset SLE included in the KLURING (*Clinical Lupus Register In Northeastern Gothia*) cohort, we aimed to describe the performance of the four definitions over 5 years in relation to PROMs and quality of life (QoL) as defined by EuroQoL-5 Dimensions (EQ-5D).

**Methods:** Patients with SLE who met the 1982 ACR and/or the 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria were included and followed prospectively from the time point of SLE diagnosis. Patients were (at least) seen by a rheumatologist at Months 0 (inclusion), 6, 12, 24, 36, 48 and 60, with collection of disease activity measures, damage accrual, serology, therapy and PROMs such as fatigue, pain intensity, well-being (all visual analogue scale) and QoL (EQ-5D). Definitions of remission were: **DORIS 1A:** cSLEDAI 0, PhGA <0.5; **DORIS 1B:** cSLEDAI 0, PhGA <0.5, serology normal; **DORIS 2A:** PhGA <0.5, BILAG D/E only; **DORIS 2B:** PhGA <0.5, serology normal, BILAG D/E only. Each definition could be reached either on or off treatment (maintenance with antimalarials only was allowed).<sup>1</sup> The effect on QoL of achieving versus not achieving remission was assessed using multilevel regression modelling.

**Results:** A total of 41 patients were included in the study: median (interquartile range) age at baseline 39 years, (18–77) 33/41 (81%) female, 35/41 (85%) white and 18/41 (44%) former/current tobacco smokers. The median number of fulfilled 1982 ACR criteria was 4 (range 3–9) and 15/41 (37%) had lupus nephritis. Using DORIS 1A or 2A, patients with SLE achieving versus not achieving remission had higher QoL ( $p=0.01$ ), whether on or off treatment (figure 1). This association remained significant after adjusting for sex, tobacco smoking and treatment in multivariable analysis. Achieving remission according to DORIS 1B ( $p=0.93$ ) or 2B ( $p=0.86$ ) was not significantly decisive for QoL (figure 1).

**Abstract FRI0347 – Figure 1.** Months Since SLE Diagnosis

Bars represent % pts attaining remission (on vs off treatment) and lines represent mean EQ-5D (QoL) for pts (meeting vs not the definition of remission) at each time point since SLE onset

**Conclusions:** This pilot study demonstrates the first real-life performance of the suggested preliminary definitions of remission in SLE. Higher QoL was associated with achieving remission as defined by DORIS 1A or 2A. However, further evaluation of the accuracy of DORIS in larger longitudinal studies of recent-onset SLE is required before introduction in routine clinical practice.

#### FRI0348 MBL2 GENE POLYMORPHISMS AND ITS ASSOCIATION WITH INFECTION IN BRAZILIAN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A 10-YEAR STUDY

C.F. Saldanha<sup>1</sup>, G.K. da Silva<sup>2</sup>, N. Glesse<sup>2</sup>, J.C.T. Brenol<sup>1</sup>, J.A.B. Chies<sup>2</sup>, O. A. Monticelo<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital de Clinicas de Porto Alegre; <sup>2</sup>Genetics, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

**Background:** Systemic lupus erythematosus (SLE) is a multifactorial disease and *MBL2* genetics variants potentially affect its etiology and increase infection risk in this population. Systemic lupus erythematosus (SLE) is a multifactorial disease and *MBL2* genetics variants potentially affect its etiology and increase infection risk in this population.

**Objectives:** To evaluate the relation of *MBL2* gene polymorphisms of the coding and promoter region and their respective haplotypes on hospitalisation, number of admissions and days of admission for major infection causes in Brazilian SLE patients.

**Methods:** Three hundred and twenty-five SLE patients from a southern Brazilian outpatient SLE clinic were genotyped in 2006 for *MBL2* gene polymorphisms from coding and promoter region (rs1800450, rs1800451, rs5030737, rs11003125, and rs7096206) and followed until 2016. Clinical and laboratory data from each patient was obtained and information regarding the need for hospitalisation, the number of admissions and amount of days admitted for infection treatment were compiled and compared with *MBL2* gene polymorphisms and haplotypes. A linear regression analysis was constructed considering the variables of bivariate which demonstrated an association ( $p<0.05$ ) and variables which had a theoretical basement.

**Results:** No difference was found in polymorphism prevalence when comparing the group that was admitted for infection treatment and the group who did not. Allele C, and haplotypes LY and HY correlated with more infection hospitalizations (normal homozygosity for C: 2 (IQR 1–3), heterozygosity for C: 3 (IQR 2–6)  $p=0.038$ ; LY 2 (IQR 1–3)  $p=0.049$ ; HY 2 (IQR 1–3)  $p=0.005$ ) and haplotype HY staid fewer days in hospital for infection treatment: 18 (IQR 10–38)  $p=0.041$ . The table 1 shows the results after regression model was applied.

**Abstract FRI0348 – Table 1.** Linear regression model for days admitted for infection and total admissions for infection treatment.

Variables *	Days admitted for infection <sup>a</sup>		Total admissions for infection <sup>a</sup>	
	Coef B (IC 95%) <sup>†</sup>	p-value <sup>‡</sup>	Coef B (IC 95%) <sup>†</sup>	p-value <sup>‡</sup>

<b>SLECC</b>				
Haplotype HY regression model	1.70 (-2.5–5.9)	0.422	-0.04 (-0.29–0.19)	0.692
Haplotype LY regression model			-0.02 (-0.27–0.23)	0.889
Allele C regression model			-0.02 (-0.28–0.22)	0.831

<sup>a</sup>Were listed variables with p-value <0.05 in bivariate analyses besides age that were used to construct the multivariate model; <sup>b</sup> Variables with a p-value <0.05; <sup>c</sup> coef B (IC 95%) coefficient B and confidence interval of 95%; <sup>d</sup> Statistical significance was considered with a p-value <0.05.

**Conclusions:** The presence of the HY promoter haplotype leads to fewer in hospital care for infection treatment probably due to higher MBL plasma levels. Also, HY haplotype and older age at SLE diagnosis is related to less admissions for infection. It is important to consider that infection is a very import cause of mortality in SLE patients and not only related to aggressive immunosuppressive treatment.

## FRI0349 LOW TITER ANTI-PHOSPHOLIPID ANTIBODIES CONVEY AN INCREASED OBSTETRIC RISK

C.B. Chighizola<sup>1</sup>, F. Pregnolato<sup>2</sup>, M.G. Raimondo<sup>3</sup>, C. Comerio<sup>4</sup>, C. Sobrino Grande<sup>5</sup>, L. Trespidi<sup>4</sup>, M.O. Borghi<sup>1</sup>, M. Gerosa<sup>1</sup>, B. Acaia<sup>4</sup>, M.W. Ossola<sup>4</sup>, A. Bulfoni<sup>6</sup>, P.L. Meroni<sup>2</sup>. <sup>1</sup>Department of Clinical Sciences and Community Health, University of Milan; <sup>2</sup>Istituto Auxologico Italiano; <sup>3</sup>Istituto G. Pini; <sup>4</sup>Fondazione Cà Granda, Ospedale Maggiore Policlinico, Milan, Italy; <sup>5</sup>Hospital Universitario Ramón y Cajal, Madrid, Spain; <sup>6</sup>Humanitas S. Pio X, Milan, Italy

**Background:** Persistent positivity for anti-phospholipid antibodies (aPL) at medium-high titres is required to diagnose anti-phospholipid syndrome (APS), an

autoimmune condition characterised by thrombosis and/or pregnancy morbidity (PM). However, increasing evidence points towards the clinical relevance of low titre aPL in obstetric APS.

**Objectives:** This study investigated the association of low titre aPL with PM assessing the efficacy of low-dose aspirin (LDASA) and low-molecular weight heparin (LMWH).

**Methods:** Data on pregnancies in women with persistent aPL positivity at any titre were retrospectively collected at a single centre. An association model for repeated measures was applied to quantify the obstetric risk conveyed by low titre and criteria aPL, allowing to: i) evaluate pregnancy outcomes over time using available longitudinal data; ii) account that pregnancies of the same woman are not independent events; iii) consider that women had a different number of pregnancies; iv) estimate the role of several confounders and predictors. The association model envisaged as dependent variable pregnancy outcome as a binary outcome, defined for each pregnancy as “obstetric complication yes versus no” (pregnancy loss before 10 weeks, pregnancy loss after 10 weeks, premature birth before 34 weeks, according to updated APS classification criteria [Miyakis et al]).

**Results:** One hundred eleven women were recruited in this study: 160 pregnancies in women with low titer aPL and 178 pregnancies in women with criteria aPL. According to the association model, women with low titre aPL had a probability of PM of 63% (odds 1.72, 95% CI 1.05–2.80) in case of single positivity and of 79% (odds 3.78, 95% CI 1.96–7.30) in case of double positivity. Criteria aPL conveyed a 2.2-fold higher risk: the probability of PM was 79% in case of single positivity (odds 3.82, 95% CI 2.15–6.80), raising to 89% (8.41, 95% CI 3.99–17.73) for multiple aPL.

LDASA-treated women with single low titer aPL positivity had a 16% probability of experiencing an adverse outcome (odds 0.19, 95% CI 0.08–0.44) while LDASA did not significantly affect the probability of in patients with low titre double aPL positivity (odds 0.42, 95% CI 0.17–1.02). Similarly, LDASA significantly reduced PM among women with single, but not multiple, criteria aPL positivity (odds 0.42, 95% CI 0.19–0.94; odds 0.93, 95% CI 0.39–2.21). Among women treated with LDASA +LMWH, the probability of PM was 14% in case of single low titre aPL positivity (odds 0.17, 95% CI 0.08–0.37) and 28% in case of two low titre aPL (odds 0.38, 95% CI 0.18–0.80). Among women with aPL criteria, treatment with LDASA +LMWH reduced the probability of PM to 28% (odds 0.38, 95% CI 0.21–0.70) in case of a single positive test and, not significantly, to 45% (odds 0.84, 95% CI 0.45–1.55) in case of multiple positivities.

Parameter	Estimate	SE	z-value	OR [95%CI]	P
<b><math>\beta_0</math> Intercept</b>	0.54	0.25	2.17	1.72 [1.05–2.80]	0.030
<b>Covariates</b>					
$\beta_1$ =Criteria aPL vs low aPL	0.80	0.31	2.55	2.23 [1.20–4.13]	0.011
$\beta_2$ =Multiple vs single aPL	0.79	0.29	2.74	2.20 [1.25–3.86]	0.006
$\beta_3$ =LDASA vs no LDASA	-2.20	0.40	-5.54	0.11 [0.05–0.24]	<<0.001
$\beta_4$ =LMWH vs no LMWH	-1.85	0.77	-2.41	0.16 [0.03–0.71]	0.016
<b>Confounders</b>					
$\beta_5$ =LDASA*LMWH	1.74	0.86	2.01		0.044
$\beta_6$ =Age≥35 vs age<35	0.19	0.26	0.73		0.466
$\beta_7$ =HCQ vs no HCQ	-0.22	0.43	-0.52		0.600
$\tau$	1.07	0.04	25.88		

**Conclusions:** Low titre aPL are associated with PM; the association treatment with LDASA and LMWH is effective even among women with low titre aPL. The risk of PM and the response to treatment depend upon aPL profile, suggesting the importance of a tailored treatment.

FRI0350

### LUPUS LOW DISEASE ACTIVITY STATE (LLDAS-50) IS A SIGNIFICANT PREDICTOR FOR DAMAGE ACCRUAL AND MORTALITY: A NORWEGIAN COHORT ANALYSIS

C. Sharma<sup>1</sup>, W. Raymond<sup>2</sup>, G. Eilertsen<sup>3</sup>, J. NOSSENT<sup>1</sup>. <sup>1</sup>Rheumatology, Sir Charles Gairdner Hospital; <sup>2</sup>University of Western Australia, Perth, Australia; <sup>3</sup>Clinical medicine, Arctic University, Tromsø, Norway

**Background:** Disease activity in patients with Systemic Lupus Erythematosus (SLE) is an important contributor to organ damage and premature mortality. Current indices to capture disease activity are not well suited to reflect their contribution to long term outcome. Lupus Low Disease Activity State (LLDAS) has been developed as an alternative measure of long term disease activity.

**Objectives:** To determine whether 50% of time spent in Lupus Low Disease Activity State (LLDAS-50) impacts on mortality and damage accrual in SLE

**Methods:** A retrospective analysis of prospectively collected data was conducted on 3650 clinic visits by 207 patients in the Tromsø Lupus Cohort. Lupus Low Disease Activity State –50 (LLDAS50) score was defined as at least 50% of follow-up time with SLE Disease Activity Index (SLEDAI)  $\leq$ 4, no new disease activity, prednisone  $\leq$ 7.5 mg/day and no escalation of maintenance immunosuppressant therapy. Cox regression analysis was used to evaluate the impact of LLDAS50 in terms of mortality and damage development (either new or severe) by Systemic Lupus Erythematosus Clinical Criteria (SLICC)/American College of Rheumatology (ACR) Damage Index (SDI). New damage was defined as a rise in SDI by 1 from baseline whereas severe damage was defined as a rise of 3 points or more from baseline.

**Results:** The median age at diagnosis of the cohort was 34 years with the majority (84%) being female. The median follow-up time was 125 months. A total of 69 patients (33.5%) spent at least half of their follow up time in LDAS, thus achieving LLDAS50. After correction for age and gender, LLDAS-50 was associated with a significant reduction in risk of having any new damage (OR 0.65; 95% CI 0.44–0.96,  $p < 0.01$ ), severe damage (OR 0.46; 95% CI 0.25–0.83,  $p < 0.01$ ), and also a reduction in mortality risk (OR 0.42; 95% CI 0.21–0.82,  $p < 0.01$ ). These values were also tested for those patients who spent 30% or more time in LDAS, and were also found to be significant for death (OR 0.46, 95% CI 0.26–0.83,  $p < 0.05$ ) but not for new damage (OR 0.92, 95% CI 0.62–1.35,  $p = 0.67$ ) or severe damage (OR 0.71, 95% CI 0.42–1.19,  $p = 0.19$ ).

**Conclusions:** The significant reduction in the risk of long term damage and mortality supports the use of LLDAS50 as a therapeutic goal.

FRI0351

### CLINICAL CHARACTERISTICS AND OUTCOMES OF EARLY-ONSET AND LATE-ONSET LUPUS NEPHRITIS AND ITS RISK FACTORS

C.-B. Choi, S. Won, S.-C. Bae. *Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic Of*

**Background:** The kidney is one of the most commonly involved major organ in systemic lupus erythematosus (SLE). It may occur as an initial presentation at the onset of SLE and it can also present later in the course of the disease.

**Objectives:** To compare clinical characteristics, management, and outcomes after 12 months in patients with early-onset lupus nephritis (LN) and late-onset LN and to assess the risk factors for late-onset LN.

**Methods:** Patients with lupus nephritis enrolled in the Hanyang BAE Lupus Cohort were retrospectively assessed. Patients who developed LN within one year of the diagnosis of SLE (early-onset) were compared with those who developed LN more than a year later from the diagnosis of SLE (late-onset). Clinical characteristics including the features of SLE, management, and outcomes including renal responses and SLE disease activity were assessed.

**Results:** From 1,294 SLE patients in the Hanyang BAE Lupus Cohort, 641 (49.5%) patients had LN. Early-onset LN was observed in 469 (73.2%) and late-onset LN in 172 (26.8%). Hypertension was more frequent in early-onset LN while malar rash, discoid rash, photosensitivity, oral ulcer, arthritis, leukopenia, anti-Sm Ab, and anti-RNP Ab were more frequent in late-onset LN. Late-onset LN patients also showed lower C3 and higher activity index in renal biopsy. There was no significant difference in ISN/RPS classification and in induction therapy. SLEDAI score at onset of LN and after 12 months was similar in the two groups. Complete and partial response rates at six months and twelve months were also similar and there were no differences in progression to end-stage renal disease or death between the two groups. Multivariate analysis identified younger age at onset, malar rash, arthritis, serositis, anti-dsDNA Ab, and anti-Sm Ab as independent risk factors for late-onset LN.

**Abstract FRI0351 – Table 1.** Clinical characteristics

	Early-onset LN (n=469)	Late-onset LN (n=172)	No LN (n=653)
Age at onset, mean $\pm$ SD, years	23.84 $\pm$ 10.38	22.66 $\pm$ 8.55	26.73 $\pm$ 10.51
Female, n (%)	417 (88.91)	161 (93.60)	615 (94.18)
Time to LN, mean $\pm$ SD, years	0.06 $\pm$ 0.19	5.48 $\pm$ 4.42	
Malar rash	200 (42.64)	105 (61.05)	262 (40.12)
Discoid rash	20 (4.26)	17 (9.88)	56 (8.58)
Photosensitivity	123 (26.23)	74 (43.02)	248 (37.98)
Oral ulcer	136 (29.00)	67 (38.95)	246 (37.67)
Arthritis	243 (51.81)	131 (76.16)	449 (68.76)
Serositis	152 (32.41)	46 (26.74)	120 (18.38)
Neurologic disorder	35 (7.46)	10 (5.81)	28 (4.29)
Hematologic disorder	383 (81.66)	147 (85.47)	539 (82.54)
Immunologic disorder	421 (89.77)	164 (95.35)	550 (84.23)
ANA positivity, %	469 (100.00)	172 (100.00)	653 (100.00)
Anti-SSa, %	150 (33.56)	69 (42.59)	265 (41.41)
Anti-SSb, %	33 (7.38)	10 (6.17)	40 (6.25)
Anti-RNP, %	130 (29.08)	62 (38.27)	219 (34.27)
Antiphospholipid Ab, %	124 (26.44)	57 (33.14)	219 (33.54)
Proteinuria, g	2.55 $\pm$ 2.43	2.45 $\pm$ 2.48	
SLEDAI	6.71 $\pm$ 4.75	7.20 $\pm$ 4.80	3.98 $\pm$ 2.86

**Conclusions:** Late-onset LN patients showed more mucocutaneous symptoms, autoantibodies, and higher activity index in renal biopsy compared to early-onset. However, there were no differences in outcomes after 12 months. Younger age at onset, malar rash, arthritis, serositis, anti-dsDNA Ab, and anti-Sm Ab were risk factors for late-onset LN.

### DAMAGE ACCRUAL IN A LARGE MONOCENTRIC COHORT OF PRIMARY SJÖGREN'S SYNDROME PATIENTS: DETERMINANTS AND IMPACT ON PATIENT REPORTED OUTCOMES

C. Baldini, F. Ferro, N. Luciano, E. Calabresi, E. Elefante, M. Mosca, S. Bombardieri. *Rheumatology Unit, University of Pisa, Pisa, Italy*

**Background:** Primary Sjögren's Syndrome (pSS) is a chronic progressive disease potentially leading to irreversible organ damage. To date only a limited number of studies have analysed prevalence and factors associated with damage accrual in pSS.

**Objectives:** a) to characterise cumulative damage in pSS patients, b) to identify determinants associated with its presence and c) to evaluate the impact of damage on patient reported outcomes (PROs).

**Methods:** Data from a monocentric cohort of 466 pSS patients were analysed. Glandular and extra-glandular damage manifestations were assessed by the Sjögren's Syndrome Disease Index (SSDDI). Additional items of damage defined 'a priori' as being potentially related to treatment (i.e osteoporosis, diabetes, infections) were analysed separately. The EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) was used to measure disease activity at baseline and prospectively during the follow-up. The EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), Oral Health Impact Profile (OHIP) and Ocular Surface Disease Index (OSDI) were utilised to record PROs. Patients' comorbidities were assessed by the Charlson Comorbidity Index (CCI).

**Results:** A total of 466 pSS patients (446 F:20 M, median age (IQR): 59 years (48–69) were included in the study. The frequency of anti-Ro-SSA in the cohort was 69.5% (324/466). The median ESSDAI was 4 (IQR 1–8) at baseline and 2 (IQR 0–5) at the last evaluation, respectively. In addition to symptomatic agents, patients had been treated during the disease course with low-medium doses of glucocorticoids (GCs) (56%), hydroxychloroquine (HCQ) (62%) and DMARDs (16.6%). After a median follow-up of 5 years (IQR, 2–10), 208 patients (44.6%) had accrued some damage in either the oral damage items (33%), ocular damage items (20%) and/or systemic damage items (12%). In addition, 24/466 patients had developed a non-Hodgkin lymphoma and 2 patients a multiple myeloma. The SSDDI score ranged from 0 to 14. In the regression analysis: patients more likely to develop damage were those that were older, with a longer disease duration, higher baseline ESSDAI and who had been treated with DMARDs, whereas patients who had been ever treated with HCQ were less likely to develop disease-related damage. Similarly, treatment-related damage was independently associated with: disease duration, age of the patients, baseline ESSDAI, anti-Ro/SSA

positivity and use of GCs. Oral and ocular damage items significantly correlated with ESSPRI, OHIP and OSDI, whereas systemic damage items positively correlated with patients CCI.

**Conclusions:** This large pSS cohort confirmed that demographic and clinical characteristics as well as medication are independently associated with disease-related and treatment-related damage. In particular, this study shows a highly significant impact of baseline disease activity on the development of future damage and poor PROs in pSS patients.

**FRI0353 DEVELOPMENT AND VALIDATION OF QUESTIONNAIRES TO ASSESS HEALTHCARE UTILISATION AND ACCESS IN COHORTS OF PATIENTS WITH PRIMARY SJOÖGREN'S SYNDROME AT THE DIAGNOSIS AND DURING THE DISEASE COURSE**

C. Seghieri<sup>1</sup>, T. Grillo Ruggieri<sup>1</sup>, C. Baldini<sup>2</sup>, L. Quartuccio<sup>3</sup>, R. Prioni<sup>4</sup>, E. Bartoloni<sup>5</sup>, F. Carubbi<sup>6</sup>, M. Orlandi<sup>7</sup>, S. Gandolfo<sup>3</sup>, S. De Vita<sup>3</sup>, S. Bombardieri<sup>2</sup> on behalf of Italian Rheumatology Society-pSS study group and of the HarmonicSS – "Harmonization and integrative analysis of regional, national and international Cohorts on pSS towards improved stratification, treatment and health policy making" group. <sup>1</sup>Sant'Anna School of Advanced Studies; <sup>2</sup>University of Pisa, Pisa; <sup>3</sup>University of Udine, Udine; <sup>4</sup>University of Rome, Rome; <sup>5</sup>University of Perugia, Perugia; <sup>6</sup>University of L'Aquila, L'Aquila; <sup>7</sup>University of Florence, Florence, Italy

**Background:** The geographic variation in healthcare spending, utilisation and quality, across and within countries is well documented. Part of this geographic variation is linked to differences in population health and needs. However, some of the variation may be unwarranted and driven by factors including provider discretion, availability and distribution of resources, financing and reimbursement models.

**Objectives:** To develop and validate an instrument a) to assess the pSS patients' experience and satisfaction along their clinical pathway including both primary care services and specialists, b) to collect comparable information in Europe to establish practice profiles in the diagnosis, management and treatment of patients with primary Sjögren's Syndrome (pSS).

**Methods:** The questionnaire consists of 32 items and collects patient-reported data on: type and intensity of treatments and services received (e.g. diagnostic testing, hospitalizations, specialist visits), costs, patients' satisfaction with the care received and general information covering patients' overall health, education, ethnicity and marital status. A narrative-based medicine section is also included in the questionnaire administered to newly diagnosed patients to explore their journey to pSS diagnosis. Additionally, a short questionnaire is administered to the specialists treating the pSS patients to collect data on the organisation of their clinical centres.

**Results:** The pilot version of the questionnaire was administered to 164 pSS patients (mean (SD) age: 60 (12.2) yrs) from 6 clinical centres. The majority of the respondents had a primary or secondary school (59%). Disease activity was significantly associated with frequency of rheumatologic visits and diagnostic tests ( $p < 0.001$ ). Both the total number of specialists involved in the care other than the rheumatologist and the number of treatments received in the last 12 months before the interview varies significantly among patients and across centres ( $p < 0.001$ ). Patients with lower education have attended on average less specialists than those with a high school or university degree ( $p < 0.001$ ). Construct validity was supported by the questionnaire's ability to discriminate between groups with different levels of activity of the disease and socio-demographic characteristics.

**Conclusions:** Preliminary results confirm that the questionnaire is a valid instrument to assess and compare patterns of care for pSS patients in terms of access and utilisation of treatments and services across and within providers. Patient-reported data linked with available information from clinical records will allow to measure quality of care more comprehensively and to identify best practices and opportunities for improvement, enhance care outcomes, and increase value for patients. Further analysis will be conducted in other clinical centres within the European Horizon2020 project "HarmonicSS" to verify the generalizability and additional psychometric properties of the instrument before collecting data across and within countries

**FRI0354 URINE METABOLOMIC FINGERPRINT AS DIAGNOSTIC BIOMARKER FOR LUPUS NEPHRITIS**

D.A. Herrera Van Oostdam<sup>1</sup>, C. Abud Mendoza<sup>1</sup>, R. Flores Ramírez<sup>2</sup>, M. Rodríguez Aguilar<sup>2</sup>, M. Pierdant Pérez<sup>3</sup>, M.U. Martínez Martínez<sup>1</sup>. <sup>1</sup>Unidad Regional de Reumatología y Osteoporosis, Hospital Central "Dr. Ignacio Morones Prieto"; <sup>2</sup>Coordinación para la Innovación y Aplicación de la Ciencia y la Tecnología, Coordinación para la Innovación y Aplicación de la Ciencia y la Tecnología; <sup>3</sup>Facultad de Medicina, Universidad Autónoma de San Luis Potosí, San Luis Potosí, Mexico

**Background:** Lupus nephritis (LN) represents the main prognostic factor for worsening in systemic lupus erythematosus (LES).<sup>1</sup> The relevant classes of LN –due to the need of treatment- are the proliferative (III, IV, III/IV+V) and membranous (V).

**Objectives:** The aim of the study was to find a urinary metabolomic fingerprint to diagnose proliferative and/or membranous LN.

**Methods:** Cross-sectional study. Inclusion criteria: lupus patients with and without clinical significant lupus nephritis (classes III, IV, V and mixed classes). Urine samples were screened for metabolites using gas chromatography mass spectrometry (coupled with electronic nose). Statistical analysis: principal component analysis (PCA), and for the selection of the metabolites we used Random Forest.

**Results:** We included 29 lupus patients, 11 with LN. The median SLEDAI score in LN patients was of 13 vs. 3 in those without NL ( $p < 0.0001$ ). Class IV nephritis was present in 45%, mixed class in 36%, and class V in 18%. The median proteinuria of patients with NL was 1 g/L, (IQR 2.7).

The variance explained using the first two principal components was 80%.

With random forest we selected, 2 nonanone, as the metabolite with the best diagnostic accuracy, (sensitivity of 0.87 and specificity of 0.93) of proliferative LN. Obtaining the ratio of 2-bromopropane/2-nonanone, the diagnostic accuracy improved, with a positive likelihood ratio (LR) of 14 and a negative LR of 0.1 (AUC 90%).

Metabolic pathways involved in LN were: methane, glycolysis, pyruvate and glycerophospholipid pathways.

**Conclusions:** We identified a urinary metabolomic fingerprint that involved several metabolic pathways; 2-nonanone and the ratio of 2-bromopropane/2-nonanone had the best diagnostic accuracy in our study.

FRI0355

### PREDICTIVE ABILITY OF AVAILABLE 10 YEARS CARDIO-VASCULAR RISK ALGORITHMS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY ON 2 ITALIAN LUPUS COHORT

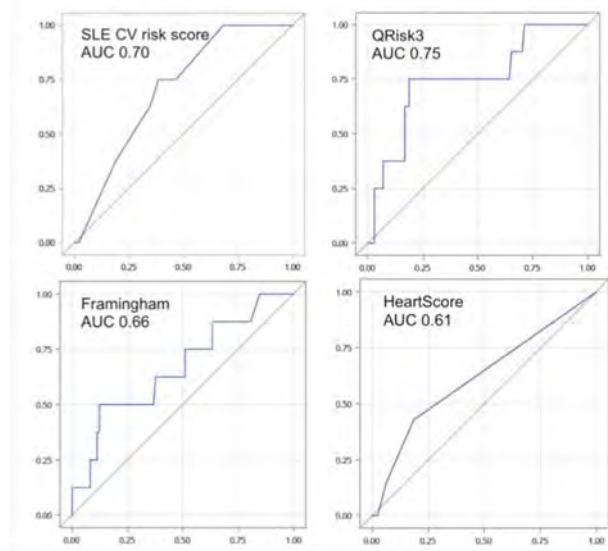

D.P.E. Margiotta<sup>1</sup>, S. Fasano<sup>2</sup>, L. Navarini<sup>1</sup>, L. Pierro<sup>2</sup>, A. Riccardi<sup>2</sup>, G. Dolcini<sup>1</sup>, G. Valentini<sup>2</sup>, A. Afeltra<sup>1</sup>. <sup>1</sup>Unit of Immuno-Rheumatology, Università Campus Bio-Medico di Roma, Rome; <sup>2</sup>Rheumatology Unit, Università degli studi della Campania Luigi Vanvitelli, Naples, Italy

**Background:** Patients with Systemic Lupus Erythematosus (SLE) present an increased incidence of Cardio-Vascular Events (CVE) compared to general population, and the difference with healthy subjects is particularly evident in young SLE women.

**Objectives:** The aim of this study is to assess the predictive ability of established 10 years CV risk models in SLE

**Methods:** A retrospective analysis of two Italian SLE prospective cohorts was performed. SLE patients without previous CVE, with age  $\geq 25$  years, a minimum continuative follow-up of 10 years and sufficient data to calculate the 10 years risk scores were enrolled. The 10 years CVE risk scores were calculated at the first observation and all CVE were prospectively recorded in the following 10 years. We calculated the following scores: the QRisk3, the Framingham CV disease 10 years score, the HeartScore (Europe Low Risk) and the SLE CV Risk Score proposed by Petri et al. Discriminatory ability for CV risk prediction was estimated by the area under the receiver operating characteristic curve. Hosmer-Lemeshov (HL) tests was used to evaluate calibration comparing the observed versus expected number of events

**Results:** Analysis was performed on 131 SLE patients (mean baseline age of 37  $\pm 11$  years). We observed 10 CVE during the 10 years follow-up from baseline (3 acute coronary syndrome, 4 stroke, 1 transitory ischaemic attack and 2 peripheral artery disease). The AUC values were 0.75 (95% CI 0.55–0.94) for QRisk3, 0.66 (0.45–0.88) for Framingham score, 0.62 (0.41–0.82) for the HeartScore and 0.7 (95% CI 0.55–0.85) for the SLE CV risk score. The p values of HL test were 0.8 for QRisk3 and SLE CV score and 0.4 for Framingham score and HeartScore, suggesting a good model fit for all the CV risk scores. Considering scores with better discriminative ability and calibration, 20% of CVE were observed with QRisk3 score lower than 3.6% and with SLE CV risk score between 6% and 8%. Discriminative ability and calibration were not improved by multiplying by 2 the Framingham score and the HeartScore.

**Conclusions:** The available CV risk scores demonstrate a moderate predictive ability of 10 years CVE in SLE. We observed a better model fit for QRisk3 and SLE CV risk score. Nevertheless, a considerable proportion of patients, with very low predicted CV risk, developed CVE during follow-up.

### ORGAN DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS IS CONSISTENTLY ASSOCIATED WITH INCREASED MORTALITY: A META-ANALYSIS

E.R. Hammond<sup>1</sup>, I.B. Murimi<sup>2</sup>, D.H. Lin<sup>2</sup>, H. Nab<sup>3</sup>, H. Kan<sup>2</sup>, O. Onasanya<sup>2</sup>, J. C. Tierce<sup>2</sup>, X. Wang<sup>1</sup>, B. Desta<sup>1</sup>, G.C. Alexander<sup>2</sup>. <sup>1</sup>AstraZeneca, Gaithersburg, MD; <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA; <sup>3</sup>AstraZeneca, Cambridge, UK

**Background:** More than half of all patients with systemic lupus erythematosus (SLE) develop organ damage over time, including damage to the kidney, skin, cardiovascular, musculoskeletal and central nervous systems. Several mechanisms have been associated with organ damage, including long-term steroid use. SLE organ damage, like comorbid disease, may contribute to increased mortality.

**Objectives:** We conducted a systematic literature review and meta-analysis of the association between organ damage in SLE and mortality.

**Methods:** A literature search (January 2000–February 2017) of PubMed, EMBASE, Cochrane Library, and Latin American and Caribbean Health Sciences Literature from four continents evaluating organ damage by the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) and mortality was conducted. Exclusion criteria included non-English language articles and study designs that did not report original, population-level measures of association. We used a random-effects meta-analysis to evaluate studies that modelled SDI as a continuous predictor of mortality and reported hazard ratios (HR) associated with a 1-unit SDI increase.

**Results:** The search yielded 10 420 articles, of which, 21 prospective cohort studies were selected. Ten studies evaluating SDI as a continuous variable and reporting HR as measure of association were pooled and meta-analysed. The pooled HR of mortality for a 1-unit increase in SDI was 1.34 (95% confidence interval [CI]: 1.21–1.44;  $p < 0.001$ ). A study of 213 patients followed for 13 years in China yielded the greatest risk of mortality for a 1-unit SDI increase (HR 3.65, [95% CI: 1.52–8.76]). When excluded from the meta-analysis, the pooled HR of mortality for a 1-unit increase in SDI was 1.32 (95% CI: 1.25–1.42;  $p < 0.001$ ). Four studies that evaluated SDI as binary variable reported HR for various SDI reference groups: SDI=0: HR 5.10 (95% CI: 1.99–13.03); SDI<1: HR 3.8 (95% CI: 1.30–16.40); SDI<3: HR 4.74 (95% CI: 1.55–14.51); and SDI<5: HR 55.12 (95% CI: 19.15–158.63). Two studies reported odds ratios (OR) as the measure of association; for a 1-unit SDI increase, the OR was 19.7 (95% CI: 5.30–72.50), and for SDI=0 as reference group, the OR was 12 (95% CI: 1.60–92.00).

**Conclusions:** Organ damage in SLE is consistently associated with increased mortality across studies from various countries, regardless of how it is modelled. Novel therapies that are potentially disease modifying and steroid sparing could reduce organ damage, improve overall outcomes, and decrease mortality in patients with SLE.

### VALIDATION OF A DISEASE-SPECIFIC HEALTH – RELATED QUALITY OF LIFE MEASURE FOR RUSSIAN ADULT PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: LUPUSQOL-RUSSIAN

E. Aseeva<sup>1</sup>, L. Vorobyova<sup>1</sup>, S. Soloviev<sup>1</sup>, G. Koilubaeva<sup>2</sup>, S. Glukhova<sup>1</sup>. <sup>1</sup>Intensive care department, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; <sup>2</sup>rheumatology department, National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov, Bishkek, Kyrgyzstan

**Background:** Improvements in the survival of patients with systemic lupus erythematosus (SLE) in Russia have to some extent paralleled that seen worldwide over the last 20 years, but have at times come at the cost of increased morbidity and reduction in health-related quality of Life (HRQoL). Recently, a specific questionnaire to evaluate HRQoL in adult SLE patients (LupusQoL) has been developed and validated in United Kingdom and in several European countries.

**Objectives:** To assess the validity of a LupusQoL-Russian in adult SLE patients **Methods:** The LupusQoL-Russian was administered to a cohort of Russian patients affected with SLE. To perform a control, QoL was evaluated also with SF-36. The Russian version of LupusQoL questionnaire was developed by the University of Central Lancashire and the East Lancashire Hospitals NHS Trust ([www.lupusqol.com](http://www.lupusqol.com)), after a linguistic validation process. Disease activity was evaluated by the SLEDAI-2K, and chronic damage by the Systemic Lupus International

Collaborating Clinics Damage Index score (SDI). Internal consistency and test-retest reliability, convergent and discriminant validity were examined.

**Results:** 328 Russian SLE patients were enrolled in the study (M/F 30/298, mean age 34.4±11.5 years, mean disease duration 106.3±97.9 months; mean SLEDAI 2K 9.6±8.0; mean SDI 0.2±0.6). The LupusQoL-Russian demonstrated substantial evidence of construct validity. Each domain showed good correlation when compared with equivalent domains of the SF-36 ( $p<0.001$  for all comparisons). LupusQoL-Russian discriminated between patients with different degrees of disease activity according to SLEDAI 2K: Lupus-QoL domains showed a trend to lower values in patients with higher disease activity (SLEDAI-2K $\geq$ 4) compared with those with lower disease activity (SLEDAI 2K<4), reaching statistically significant difference when considering the domains "Pain", "Planning", "Intimate relationship" and "Body image" ( $p=0.007$ ,  $p=0.0004$ ,  $p=0.003$  and  $p=0.007$ , respectively).

LupusQoL-Russian was significantly lower for "Physical health", "Planning" and "Fatigue" in patients with SDI $\geq$ 1 ( $p=0.002$ ,  $p=0.03$ , and  $p=0.03$ ) respectively (table 1). Test-retest reliability was good to excellent between baseline and day 3 (intra-class correlation coefficient (ICC) 0.7–0.9)

Abstract FRI0357 – Table 1. External divergent validity (N=328)

Domain	SLEDAI-2K $\leq$ 4 (n=113)	SLEDAI-2K $\geq$ 4 (n=215)	p-value	SDI $\leq$ 1 (n=142)	SDI $\geq$ 1 (n=186)	p-value
Physical health, mean $\pm$ SD	70,1 $\pm$ 22,0	64,9 $\pm$ 23,6	0,07	71,01 $\pm$ 22,5	63,3 $\pm$ 23,1	0002
Pain, mean $\pm$ SD	74,7 $\pm$ 23,6	67,5 $\pm$ 24,8	0007	72,3 $\pm$ 24,2	68,2 $\pm$ 24,8	0,1
Planning, mean $\pm$ SD	71,1 $\pm$ 27,9	60,1 $\pm$ 28,0	0,0004	67,7 $\pm$ 27,3	60,9 $\pm$ 29,0	0,03
Intimate relationship, mean $\pm$ SD	78,3 $\pm$ 28,7	69,9 $\pm$ 31,7	0003	76,06 $\pm$ 28,4	70,6 $\pm$ 32,5	0,22
Burden to others, mean $\pm$ SD	61,2 $\pm$ 26,8	54,2 $\pm$ 28,0	0,03	55,7 $\pm$ 28,4	57,4 $\pm$ 27,3	0,68
Emotional health, mean $\pm$ SD	67,3 $\pm$ 24,8	63,2 $\pm$ 24,6	0,13	66,2 $\pm$ 25,2	63,3 $\pm$ 24,3	0,24
Body image, mean $\pm$ SD	71,1 $\pm$ 24,7	62,02 $\pm$ 28,5	0007	66,6 $\pm$ 27,9	64,03 $\pm$ 27,3	0,33
Fatigue, mean $\pm$ SD	65,0 $\pm$ 24,5	65,09 $\pm$ 24,8	0,22	65,7 $\pm$ 25,3	60,35 $\pm$ 24,0	0,03

**Conclusions:** The LupusQoL-Russian is valid to assess quality of life in SLE patients

**Disclosure of Interest:** None declared

#### FRI0358 FACTORS ASSOCIATED WITH PULMONARY MANIFESTATIONS IN SJÖGREN SYNDROME

E. Judez<sup>1</sup>, C. Sanchez-Piedra<sup>2</sup>, M. Fernández Castro<sup>3</sup>, J.L. Andreu<sup>4</sup>, J. Rosas<sup>5</sup>, V. Martínez Taboada<sup>6</sup>, A. Olive<sup>7</sup> on behalf of SjogrenSer project (GEEAS-SER).

<sup>1</sup>Rheumatology, Complejo Hospitalario Universitario de Albacete, Albacete;

<sup>2</sup>Unidad de Investigación de la Ser, Ser; <sup>3</sup>Rheumatology, Hospital Infanta Sofía,

Madrid; <sup>4</sup>Rheumatology, Hospital Puerta de Hierro, Madrid; <sup>5</sup>Rheumatology,

Hospital Marina Baixa, Alicante; <sup>6</sup>Rheumatology, Hospital Marqués de Valdecilla,

Santander; <sup>7</sup>Rheumatology, Hospital Germans Trias i Pujol, Barcelona, Spain

**Background:** Primary Sjögren's Syndrome (pSS) is a systemic autoimmune disorder characterised by lymphocytic infiltration of the exocrine glands resulting in dry syndrome. Approximately one-third of patients have extraglandular systemic findings, such as respiratory symptoms (43%–75%), that are also considered to be a cause of morbidity and conditioning quality of life. The aim of the study is to estimate the prevalence of pulmonary manifestations in pSS, and to identify factors associated with its development.

**Methods:** SJOGREN-SER (Spanish Rheumatology Society Registry of pSS) is a multicenter cross-sectional study of pSS patients under active follow-up at 33 rheumatology departments through Spain. Patients fulfilled the European-American consensus criteria of 2002. Airway disease (dry cough, xerotrachea, bronchial, hyperresponsiveness and airway obstruction) and pulmonary involvement (ILD, pulmonary amyloidosis, pulmonary arterial hypertension, vasculitis and pleural involvement) were considered according to the definition contained in EULAR Sjögren's Disease Activity Index (ESSDAI), as well as Sjögren's

Syndrome Disease Damage Index. Bivariate logistic regression models and multivariate analysis were used to establish the independent effect of patient characteristics associated with pulmonary manifestations. The results were considered significant when the P value was less than 0.05.

**Results:** The SJOGREN-SER registry included 437 patients (95% women, median age at inclusion 59 years [50–68 years] and mean of ESSDAI 2 (IQR 0–4)). One hundred and seventeen patients (26.8%) had pulmonary manifestations (19.2% airway disease and 9.8% pulmonary involvement). Ten patients presented both. Sociodemographic characteristics were: mean age 59.5 years (SD: 11.46), 94.9% women and 19.6% smokers or former smokers. Patients with pulmonary manifestations had higher ESSDAI score (6 (SD 6) vs 4 (SD 5)), prolonged disease duration (10.05 years (SD: 7.15) vs 7.7 (SD 6.3)) and were ANA positive more frequently (94.9% vs 62.2%). Airway involvement preceded or occurred at the time of diagnosis in 46.4% of patients. Pulmonary involvement occurred 5 years after the diagnosis of pSS in 37.2% of them. [RS1] Twenty-nine patients (6.6%) were diagnosed with ILD. The most frequent radiological patterns were: Non-Specific Interstitial Pneumonia n=14, Usual Interstitial Pneumonia n=5, Lymphocytic Interstitial Pneumonia n=5 and Cryptogenic Organised Pneumonia n=2. Stepwise multivariate analysis was performed including the following variables: sex, age, laboratory findings, disease duration, smoking and ESSDAI. Disease duration (OR of 1.05 (95% CI, 1.006–1.083)), ESSDAI score (OR of 1.044 (95% CI, 1.006–1.083)) and positivity for ANA (OR of 3.725 (95% CI, 1.141–12.159)) were found to be associated factors with pulmonary involvement in pSS.

**Conclusions:** Prevalence of pulmonary manifestations in this cohort of pSS patients is substantial due to both airway disease and pulmonary involvement. Disease duration, activity of pSS according to ESSDAI score and ANA positivity were factors associated with the development of pulmonary manifestation.

**Disclosure of Interest:** None declared

#### FRI0359 ROUTINE CLINICAL PATHOLOGY MEASUREMENTS ARE ASSOCIATED WITH RISK OF ORGAN DAMAGE ACCRUAL IN SLE

K. Zhang<sup>1</sup>, S. Boyd<sup>2</sup>, F. Petitjean<sup>2</sup>, A. Hoi<sup>3</sup>, R. Koelmeyer<sup>3</sup>, E. Morand<sup>3</sup>, H. Nim<sup>2</sup>.

<sup>1</sup>Monash University, Melbourne, Australia; <sup>2</sup>Information Technology; <sup>3</sup>Faculty of Medicine Nursing and Health Sciences, Monash University, Melbourne, Australia

**Background:** Prevention of permanent organ damage, a major predictor of morbidity and mortality, is a key goal in the treatment of SLE. Physician-measured disease activity scores, which entail some subjectivity, are associated with damage accrual risk, but there have been few studies of objective measures as indicators of organ damage risk. Routine pathology laboratory measurements provide objective biological data, but their association with damage accrual in SLE has not been studied.

**Objectives:** To evaluate the association of objective pathology laboratory measurements with risk of organ damage accrual in SLE.

**Methods:** A dataset of SLE patients between 2007–2017 from the Australian Lupus Registry and Biobank was studied. Variables recorded prospectively included disease activity (SLEDAI-2k), drug treatment and 16 routine pathology measurements at each visit, and organ damage (SLICC-SDI) annually. Longitudinal patient data was split into annual periods, and each visit classified as being either in a "transition" or "non-transition" period based on whether SDI increased during that period. Time adjusted means (TAMs) of the variables were calculated for each period, and multivariable logistic regression analysis of the association with being in a "transition" period (adjusting for age, gender, race, previous organ damage and prednisolone dose) was performed, with Holm-Bonferroni correction. An "odds ratio plot" was generated to depict the effect on risk of organ damage accrual at each threshold of the continuous variables.

**Results:** 893 periods, comprising 5082 visits from 245 patients (85.6% female, 50.2% Caucasian), were analysed. Five out of 16 laboratory variables: estimated glomerular filtration rate (eGFR), creatinine ( $p<0.01$ ), urine protein:creatinine ratio ( $p<0.01$ ), ESR ( $p<0.001$ ), and haemoglobin ( $p<0.001$ ) were significantly associated with risk of damage increase. Moreover, the odds of damage increase were approximately proportional to the deviation of each of these variables from its respective normal range. SLEDAI-2k was also significantly associated with damage increase ( $p<0.001$ ), but the association of SLEDAI-2k with damage did not exhibit this proportionality.

**Abstract FRI0359 – Figure 1.** Ln (natural log) odds ratio for damage transition vs time-adjusted mean of laboratory variables. Red region (95% CI) lying above the  $y=0$  line indicates the risk is statically significant ( $p<0.05$ ). Regression lines (blue) suggest the risk of damage increase is approximately proportional with the distance from normal pathology measure range.

**Conclusions:** Routine pathology measures were found to be proportionally associated with organ damage risk in SLE. The potential for the use of these measures as biomarkers, for example to generate an organ damage risk calculator for SLE, warrants further research.

**Disclosure of Interest:** None declared

**Background:** The negative influence of African-American ethnicity on the prognosis of lupus nephritis (LN) is well known but – to the best of our knowledge – the impact of Maghrebian ethnicity has never been evaluated, although the disease is purported to be quite prevalent and severe in North Africa.

**Objectives:** To study the influence of Maghrebian ethnicity on the clinical and pathological presentation of LN, the renal relapse rate, the renal and overall survival and the predictive value of an early proteinuria decrease for good long-term renal outcome in this population compared to native Europeans.

**Methods:** We retrospectively reviewed the files of an inception cohort of 194 patients with proliferative LN followed in 7 lupus centres belonging to three groups: Europeans living in Belgium/France (E;  $n=111$ ), Maghrebians living in Europe, *in casu* Belgium/France (ME;  $n=43$ ) and Maghrebians living in Morocco (MM;  $n=40$ ). Baseline presentation was compared between these 3 groups but complete long-term outcome data were available only for E and ME patients.

**Results:** At presentation, clinical (gender, age, nephrotic syndrome, serum creatinine, eGFR, uP/C ratio) and pathological (ISN/RPS class) characteristics of LN did not differ between E, ME and MM patients. At one year, renal remission was met in 73%, 63% and 68% in E, ME and MM patients, respectively. Achievement of a target proteinuria below 0.7 g/day one year after treatment initiation was 76%, 63% and 68%, respectively. Nevertheless, while proteinuria measured at month 12 accurately predicted a serum creatinine value  $<1$  mg/dl at 7 years in E patients, this was not the case in the ME group, in whom serum creatinine at month 12 performed better. Renal relapses were more common in ME patients (54% than in E patients (29%) ( $p<0.01$ ). Time to renal flare and to ESRD was shorter in ME patients compared to E patients ( $p<0.0001$  and  $p<0.05$ , respectively) as shown in figure 1. At last follow-up, mean proteinuria, serum creatinine and eGFR did not differ between E and ME patients, nor did the percentage of patients who died or suffered from ESRD or permanent renal impairment.

**Conclusions:** Despite a similar disease profile at onset, the prognosis of LN is more severe in Maghrebians living in Europe compared to native Europeans, with a higher relapse rate and a shorter time to ESRD.

### FRI0361 PREGNANCY OUTCOMES AND THERAPY IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM OUR 30 YEARS' EXPERIENCE PREGNANCY CLINIC

F. Crisafulli<sup>1</sup>, M.G. Lazzaroni<sup>1</sup>, L. Andreoli<sup>1</sup>, M.C. Gerardi<sup>1</sup>, L. Antolini<sup>1</sup>, G. Parma<sup>1</sup>, C. Benigno<sup>2</sup>, A. Lojaco<sup>3</sup>, S. Zatti<sup>3</sup>, V. Cappa<sup>4</sup>, S. Calza<sup>4</sup>, F. Franceschini<sup>1</sup>, A. Tincani<sup>1</sup>. <sup>1</sup>U.O. Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia; <sup>2</sup>U.O. Rheumatology and Clinical Immunology, Federico II University Hospital and University of Napoli, Napoli; <sup>3</sup>Obstetrics and Gynecology Unit; <sup>4</sup>Biostatistics and Biomathematics Unit and Bioinformatics Unit, Spedali Civili and University of Brescia, Brescia, Italy

**Background:** The outcome of Systemic Lupus Erythematosus (SLE) pregnancies has dramatically improved thanks to pregnancy planning, multidisciplinary management and close monitoring during pregnancy. In our experience, programmed pregnancies in SLE patients had similar rates of pregnancy losses as compared to general obstetric population, but there are still open issues on some pregnancy complications that more frequently affect SLE patients.

**Objectives:** To analyse the obstetric outcome of SLE patients, according to specific therapy received during pregnancy.

**Methods:** A monocentric, retrospective study of 98 SLE patients with a total of 134 pregnancies followed prospectively by multidisciplinary team (1987–2015). Adverse Pregnancy Outcomes (APOs) were defined as one of the followings: premature miscarriage ( $<10$  th week), intrauterine fetal death ( $>10$  th week), perinatal death ( $<30$  th day of life), severe preterm birth ( $<34$  th week) and preterm birth (between 34th–36th weeks). We also evaluated the frequency of other pregnancy complications such as preterm premature rupture of membranes (pPROM) and pre-eclampsia (PE).

**Results:** Among the 134 pregnancies (including 3 twin pregnancies), flares occurred in 10 (7.5%) and APOs in 39 (29.1%) cases (table 1). pPROM complicated 9 pregnancies, all resulted in preterm deliveries, including 3 severe preterm birth; PE complicated 6 pregnancies resulting in 2 preterm birth, 1 intrauterine fetal death, 1 perinatal death and 2 term birth. The rates of APOs, pPROM and PE were compared according to receiving or not a specific therapy: hydroxychloroquine (HCQ), low dose aspirin (LDA), immunosuppressant (IS) during the overall pregnancy and corticosteroids  $>35$  mg/week (CS) during the 1st, the 2nd and the 3rd trimester. No statistical significant association was found between a specific therapy and the rate of PE. HCQ and LDA did not significantly affected the rate of APOs or pPROM while pregnancies exposed to IS showed a higher frequency of APOs (47% vs 20%,  $p.0.003$ ), in particular premature miscarriages (16% vs 2%,  $p.0.007$ ). Pregnancies exposed to CS had higher frequency of APOs (1st trimester 44% vs 28%,  $p.0.015$ ; 2nd trimester 36% vs 13%  $p.0.004$ ; 3rd trimester 34% vs 14%,  $p.0.019$ ). Considering only the 120 pregnancies resulted in live birth, those exposed to CS had higher frequency of preterm birth (1st trimester  $p.0.006$ ; 2nd trimester  $p.0.023$ ; 3rd trimester  $p.0.011$ ) (table 2). In particular, pregnancies exposed to CS in the 1st trimester had higher frequency of preterm birth on 34th–36th w ( $p.0.017$ ), while pregnancies exposed in the 3rd trimester had a higher frequency of preterm birth before 34th w ( $p.0.038$ ). Furthermore, a higher frequency of pPROM was observed in those exposed to CS (1st trimester  $p.0.001$ ; 2nd trimester  $p.0.003$ ; 3rd trimester  $p.0.001$ ).

\* 1<sup>st</sup> trimester; \*\* 2<sup>nd</sup> trimester; \*\*\* 3<sup>rd</sup> trimester

**Conclusions:** Use of IS seems to be associated with premature miscarriages; this could reflect their use in patients with a more severe disease phenotype. The exposure to CS in doses greater than 35 mg/w in the 1<sup>st</sup> trimester seems to be associated with preterm birth at 34<sup>th</sup>-36<sup>th</sup> w, while in the 3<sup>rd</sup> trimester with severe preterm birth (<34<sup>th</sup> w), that could be related to the strong association observed between CS use and pPROM.

### FRI0362 PREVALENCE, RISK FACTORS, AND IMPACT ON MORTALITY OF NEUROPSYCHIATRIC LUPUS: A LARGE PROSPECTIVE SINGLE-CENTRE STUDY

G.Y. Ahn<sup>1</sup>, D. Kim<sup>1</sup>, S. Won<sup>2</sup>, S.T. Song<sup>1</sup>, H.-J. Jeong<sup>1</sup>, I.W. Sohn<sup>1</sup>, S. Lee<sup>1</sup>, Y. B. Joo<sup>3</sup>, S.-C. Bae<sup>1</sup>. <sup>1</sup>Hanyang University Hospital for Rheumatic Diseases; <sup>2</sup>Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul; <sup>3</sup>St. Vincent's Hospital, The Catholic University of Korea, Suwon, Korea, Republic Of

**Background:** Neuropsychiatric involvement is one of the most serious involvement of SLE and generally associated with a worse prognosis. However, previous reports about the prevalence and risk factors of neuropsychiatric systemic lupus erythematosus (NPSLE) have yielded inconsistent findings. Also, there are only few studies of the prognosis of NPSLE, especially in a large prospective cohort.

**Objectives:** To identify the prevalence, risk profiles, and impact on mortality of NPSLE.

**Methods:** Patients from the Hanyang BAE lupus cohort were registered and followed from 1998 to 2015. Demographics, autoantibodies, SLEDAI-2K and SLICC/ACR damage index were collected at baseline and then annually. Patients registered within 12 months of SLE development were grouped as the inception cohort and analysed separately to elucidate the clinical features at disease onset. NP manifestations were defined using the ACR 19 case definitions and Ainiola NPSLE that did not include minor NP events<sup>1</sup>. Mortality data were derived by linking data from the Korean National Statistics Office.

**Results:** The prevalence of NPSLE by ACR 19 case definition was 38.3%, and 19.3% by Ainiola criteria. Higher SLEDAI, APLA positivity, absence of anti-dsDNA antibody at SLE diagnosis and fewer years of education increased NPSLE risk.

Patients with any NPSLE manifestation had a three-fold increased risk of mortality (HR 3.09, p=0.04), and patients with focal CNS NPSLE showed nearly an eight-fold increased risk of mortality in SLE patients (HR=7.83, p<0.01). Among the 216 patients with Ainiola NPSLE, sixty-four (29.6%) had multiple events. The two most common symptom combinations were seizure with CVA (18 patients) and seizure with psychosis (8 patients).

**Abstract FRI0362 – Table 1.** Risk factors for the development of NPSLE in the inception cohort (N=388).

	NPSLE (n=88)	Non-NPSLE (n=300)	P	Adjusted OR (95% CI)	P
<b>Demographics</b>					
Age at SLE diagnosis	28.2 ±11.6	29.3±11.3	0.42	0.99 (0.97–1.01)	0.45
Female sex	81 (92.1)	270 (90.0)	0.71	1.88 (0.71–4.96)	0.20
SLEDAI at diagnosis, NP manifestations excluded <sup>a</sup>	4.7 ±4.5	3.8±3.3	0.10	1.08 (1.01–1.16)	0.02*
SDI at diagnosis, NP manifestations excluded <sup>b</sup>	0.2 ±0.4	0.1±0.4	0.43	1.23 (0.72–2.11)	0.45
HTN	5 (5.8)	16 (5.4)	1.00	1.14 (0.38–3.37)	0.82
Education (years)	12.2 ±3.1	13.0±3.3	0.05*	0.92 (0.85–1.00)	0.04*
Anti-dsDNA antibody positivity	61 (69.3)	238 (79.3)	0.07	0.43 (0.24–0.78)	<0.01*
APLA positivity	40 (45.5)	96 (32.0)	0.03*	1.72 (1.03–2.87)	0.04*

\*Values are number (percentage) or mean ±standard deviation. a. SLEDAI was calculated using the remaining items except CVA, seizure, organic brain syndrome, psychosis, visual disturbance, cranial nerve disorder. b.SDI was calculated using the remaining items except CVA, myelopathy, seizure, psychosis, cognitive impairment, carinal neuropathy, and peripheral neuropathy.

**Abstract FRI0362 – Figure 1.** Kaplan-Meier survival curves for NPSLE and non-NPSLE patients; Inception cohort and all analysed patients.

**Conclusions:** Higher SLEDAI, APLA positivity, absence of anti-dsDNA antibody at SLE diagnosis and fewer years of education are risk factors for development of NPSLE. Presence of NPSLE, especially focal CNS NPSLE, increased the risk of mortality in SLE patients.

### FRI0363 POSITIVE REMODELLING INDEX AND LOW ATTENUATION NON-CALCIFIED CORONARY PLAQUES: MARKERS OF VULNERABLE CORONARY PLAQUES IN SYSTEMIC LUPUS?

G. Stojan<sup>1</sup>, L. Magder<sup>2</sup>, M. Petri<sup>1</sup>. <sup>1</sup>Rheumatology, Johns Hopkins University; <sup>2</sup>Epidemiology, University of Maryland, Baltimore, USA

**Background:** Accelerated atherosclerosis leading to premature coronary artery disease remains the major cause of late death in SLE. Coronary plaques with a large necrotic/lipid core and/or a thin fibrous cap are prone to rupture, leading to acute coronary events. In coronary CT angiography, plaque lipid content correlates with lower CT attenuation values when compared with fibrotic tissue.

Positive (or outward) vessel remodelling has been postulated to explain the finding of atherosclerosis that does not encroach on the arterial lumen. Positive remodelling index and presence of low attenuation noncalcified plaque (<30 Hounsfield units) are characteristic vessel changes in unstable coronary plaques.

**Objectives:** We sought to characterise noncalcified plaque lesions in patients with systemic lupus erythematosus and to identify high risk lesions.

**Methods:** A total of 66 patients who meet the American College of Rheumatology classification criteria for SLE were included in the study. Of these, 30 patients had two studies. All patients underwent coronary CT angiography. Coronary plaque area was measured by manual tracing for the difference between the area within the external elastic membrane and the area of the vessel lumen at the site of maximal luminal narrowing as observed on a cross-sectional coronary CT angiography image. Each noncalcified plaque detected within the vessel wall was evaluated with the minimum CT density and vascular remodelling index (RI). Total low density plaque volume per patient and low density/high density noncalcified plaque ratio were then compared by patient characteristics which included age, sex, ethnicity, BMI, smoking, SLEDAI, PGA, anti-dsDNA, low complement, current prednisone, current hydroxychloroquine, current NSAID use, history of cardiovascular event, hypertension, lupus anticoagulant, antidiarrhoeal, hypercholesterolemia, and methotrexate use.

**Results:** All patients had at least one plaque with a positive remodelling index (>10%), and 83.1%(n=271) of total identified plaques had a positive remodelling index. Low density noncalcified plaque volume was associated with age ( $p<0.01$ ) and body mass index ( $p<0.01$ ). African Americans had significantly more ( $p<0.05$ ) low density noncalcified plaque compared to patients of other ethnicities. The low density/high density noncalcified plaque ratio did not correlate with any patient characteristics and was on average 46% (SD=10). There were only cardiovascular events in the studied group and there were no differences in remodelling index or low density noncalcified plaque observed in this group, but the number of events was small.

**Conclusions:** Positive remodelling index and low attenuation noncalcified plaques are characteristic vessel changes seen in unstable coronary plaques. They are common in patients with lupus and are significantly more likely to be seen among African American patients, patients with a BMI>30, and the elderly (age over 60).

#### FRI0364 CLINICAL AND DIAGNOSTIC SIGNIFICANCE OF IMMUNOGLOBULIN A RHEUMATOID FACTOR IN PRIMARY SJOGREN'S SYNDROME

H.-R. Kim, K.-A. Lee, S.-H. Lee. Konkuk University Medical Center, Seoul, Korea, Republic Of

**Background:** Rheumatoid factors (RFs) are among the autoantibodies associated with Primary Sjogren's syndrome (pSS). Although measurement of non-IgM RFs is not performed routinely in clinical practice due to technical difficulties, RFs can belong to any isotype. A few studies have suggested the prognostic value of non-IgM RFs in pSS. However, few studies evaluated the clinical and diagnostic value of non-IgM RF in pSS.

**Objectives:** This present study aimed to answer the question on whether the RF isotype has a potential diagnostic value for the detection of pSS, particularly for distinguishing pSS from idiopathic sicca syndrome. In addition, we assessed whether IgA RF may serve as a prognostic factor by evaluating their association with clinical and serological characteristics.

**Methods:** RF levels were measured in 85 and 38 patients with pSS and idiopathic sicca syndrome, respectively, using the ELISA and analysed with respect to clinical and laboratory disease characteristics. ROC curves were used to determine and compare the diagnostic accuracy of IgA RF with other diagnostic tests.

**Results:** Serum levels of IgA RF were significantly higher in patients with pSS than in those with idiopathic sicca syndrome. IgA RF showed a sensitivity, specificity, positive, and negative predictive value of 90.7%, 78.9%, 89.5%, and 81.1%, respectively, for pSS diagnosis. IgA RF was associated with xerostomia; abnormal Schirmer's test; severe sialoscintigraphic grade; low unstimulated salivary flow rate (USFR); antinuclear antibody and anti Ro/SSA positivity; high IgG and IgM/G RF levels; and low C3 levels in patients with pSS. IgA RF titres had positive correlations with sialoscintigraphic grade and IgG and IgG/M RF levels and had negative correlations with USFR, Schirmer's test value, and C3 levels (figure 1).

**Conclusions:** Our findings confirmed the potential of IgA RF to distinguish pSS from idiopathic sicca syndrome. The presence of IgA RF in patients with pSS was associated with significantly worse exocrine function and active serologic profile. No association between IgA RF and extra-glandular manifestations was noted.

#### FRI0365 FACTORS ASSOCIATED WITH LEFT VENTRICULAR DIASTOLIC DYSFUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

L.-W. Baek<sup>1</sup>, K.-J. Kim<sup>2</sup>, Y.-J. Park<sup>2</sup>, W.-U. Kim<sup>3</sup>, C.-S. Cho<sup>4</sup>. <sup>1</sup>Division of Rheumatology, Yeouido St. Mary's Hospital, The Catholic University of Korea, Seoul; <sup>2</sup>St. Vincent's Hospital, The Catholic University of Korea, Suwon; <sup>3</sup>Seoul St. Mary's Hospital, The Catholic University of Korea; <sup>4</sup>Yeouido St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

**Objectives:** Myocardial damage is common and often silent in patients with systemic lupus erythematosus (SLE). In this study, we investigated the clinical parameters associated with left ventricular diastolic dysfunction in SLE patients using algorithms of 2016 American Society of Echocardiography/European Association of Cardiovascular Imaging (ASE/EACVI) recommendations.

**Methods:** Sixty consecutive SLE patients and 38 controls matched for age and sex who were free of clinical cardiovascular disease were enrolled. Left ventricular diastolic dysfunction was assessed by echocardiography using 2016 ASE/EACVI guidelines. The demographic, clinical and laboratory data were obtained from medical records.

**Results:** Diastolic dysfunction was more common in SLE patients compared with controls (38.3% versus 13.2%,  $p=0.011$ ), while LV ejection fraction was not different between groups. When patients were divided into 2 groups according to the presence of diastolic dysfunction, patients with diastolic dysfunction had higher prevalence of hypertension ( $p<0.001$ ), dyslipidemia ( $p=0.031$ ) and chronic kidney disease ( $p=0.045$ ), but there was no difference between groups with regard to other organ involvement or autoantibody profile. Importantly, patients with diastolic dysfunction showed significantly higher SLICC/ACR damage index ( $p=0.001$ ) and C-reactive protein levels ( $p=0.005$ ). In multivariate regression analysis, hypertension (OR=16.6, 95% CI=3.466-79.479,  $p<0.001$ ), higher SLICC/ACR damage index (OR=1.68, 95% CI=1.039-2.720,  $p=0.034$ ), and CRP level (OR=1.12, 95% CI=1.004-1.254,  $p=0.042$ ) was independently associated with diastolic dysfunction in SLE patients.

**Conclusions:** Diastolic dysfunction is more common in SLE patients, and overall inflammatory burden reflected by SLICC/ACR damage index as well as conventional cardiovascular risk factors are associated with development of diastolic dysfunction in SLE patients.

**Disclosure of Interest:** None declared

**Objectives:** To investigate the primary respiratory manifestations (PRM) in SLE. **Methods:** All patients in the RELESSER cohort were retrospectively investigated for the presence of PRM. **Results:** At least one PRM was present in 11.3% (365/3215) of cases. The most common was pleurisy, occurring in 21.1% of patients, followed by ALP in 3.6%, PE in 2.9%, PPH 4%, DILD in 2%, DAH in 0.8%, and SLS in 0.8%. The variables associated with the presence of PPM are shown in the following table 1:

	Odds Ratio	95% Confidence Interval	P
Age	1,03	1,02–1,04	0,000
SLEDAI score	1,03	1,00–1,07	0,02
Raynaud phenomenon	1,41	1,09–1,84	0,01
Severe nephritis	1,56	1,18–2,06	0,002
Secondary APS	2,2	1,63–2,97	0,000
Anti-RNP positivity	1,32	1,00–1,75	0,054
Cardiac disease	2,81	1,90–4,16	0,000
Vasculitis	1,81	1,25–2,62	0,002
Hematologic abnormalities	1,31	1,00–1,71	0,048
Neuropsychiatric manifestations	1,49	1,11–2,02	0,009
Gastrointestinal involvement	2,05	1,14–3,67	0,016

After adjusting for known confounders in the multivariable model, PPM remained a risk factor for diminished survival (HR: 3.13).

**Conclusions:** PPM independently contributed to a decreased survival in SLE

**Disclosure of Interest:** None declared

### ASSOCIATION OF VITALITY AND SUBSEQUENT PHYSICAL FUNCTIONING IN SYSTEMIC LUPUS ERYTHEMATOSUS: ANALYSIS OF DATA FROM THE GERMAN LULA COHORT 2002 – 2013

J. Mucke<sup>1</sup>, G. Chehab<sup>1</sup>, R. Fischer-Betz<sup>1</sup>, J. Richter<sup>1</sup>, B. Winkler-Rohlfing<sup>2</sup>, M. Schneider<sup>1</sup>, R. Brinks<sup>1</sup>. <sup>1</sup>Polyclinic of Rheumatology and Hiller-Research Centre of Rheumatology, Heinrich-Heine-University Duesseldorf, Düsseldorf; <sup>2</sup>German Lupus Self-Help Community, Wuppertal, Germany

**Background:** Fatigue, defined as loss of vitality, is a major burden in patients with systemic lupus erythematosus (SLE). It is well-known from cross-sectional studies that fatigue is associated with physical functioning (PF) whereas the effect of fatigue on subsequent PF has not yet been further looked on.

**Methods:** Data from the German *Lupus-Langzeitstudie* (LuLa) cohort was used to explore the effect of self-reported vitality on PF. The ongoing LuLa study comprises patients from the German SLE self-help group. The current analysis uses data from 2002 to 2013. We looked for associations between the PF score (outcome) and the vitality score of the SF-12 questionnaire in one to four years preceding the outcome. Statistical analysis was accomplished by a linear mixed regression model (LMM) adjusting for the potential confounders age, sex, disease duration and disease activity as surveyed by the Systemic Lupus Activity Questionnaire score (SLAQ).

**Results:** 1511 patients (93.3% women) provided data with a total of 7841 person-years of observation. Median age at study entry was 46 (interquartile range: 37 to 57). The table 1 shows the regression coefficients of the vitality score (and 95% confidence intervals, CI) estimated by the LMM without and with adjusting for age, sex, disease duration and SLAQ.

Exposure: Vitality scale score	Crude estimates		Adjusted estimates	
	Estimate with 95% CI	p-value	Estimate with 95% CI	p-value
1 year ahead	0.08 (0.05–0.10)	<0.001	0.07 (0.05–0.09)	<0.001
2 years ahead	0.09 (0.07–0.11)	<0.001	0.07 (0.05–0.09)	<0.001
3 years ahead	0.05 (0.03–0.08)	<0.001	0.05 (0.03–0.07)	<0.001
4 years ahead	0.03 (0.001–0.06)	0.038	0.04 (0.01–0.07)	0.002

**Conclusions:** We found evidence that self-reported vitality in patients with SLE is associated with PF in the subsequent years. The data indicate a "window of opportunity" for treating fatigue symptoms of up to four years for maintenance of PF.

### COMPARISON OF CLINICAL AND LABORATORY PROFILES IN 3575 SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH AND WITHOUT SJÖGREN'S SYNDROME: DATA FROM A NATIONWIDE PATIENT REGISTRY (RELESSER)

J.G. Ovalles-Bonilla<sup>1</sup>, F.J. López-Longo<sup>1</sup>, I. Rúa-Figueroa<sup>2</sup>, M. Galindo<sup>3</sup>, J. Calvo-Alen<sup>4</sup>, R.D. González<sup>1</sup>, B. Serrano<sup>1</sup>, I. Janta<sup>5</sup>, C. González<sup>5</sup>, I. Monteagudo<sup>5</sup>, J. C. Nieto<sup>5</sup>, J. Martínez<sup>5</sup>, C.N. Saenz<sup>5</sup>, J.M. Pego-Reigosa<sup>6</sup>, on behalf of RELESSER. <sup>1</sup>Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid; <sup>2</sup>Rheumatology Division, Hospital Doctor Negrin, Las Palmas GC; <sup>3</sup>Servicio de Reumatología, Hospital 12 de Octubre, Madrid; <sup>4</sup>Rheumatology, Txagorritxu Hospital, Araba, Vitoria; <sup>5</sup>Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid; <sup>6</sup>Rheumatology Section, Hospital de Meixoeiro, Pontevedra, Vigo, Spain

**Background:** The clinical coexistence of Systemic Lupus Erythematosus (SLE) and Sjögren's Syndrome (SS) was recognised in 1959. The prevalence of SS among patients with SLE varies considerably among the published studies (10%–30%). There is still controversy as to whether or not SLE patients with overlapping SS have a distinct and significantly milder lupus.

**Objectives:** To address the clinical and serologic features of SLE and differences from SLE that occurs in overlap with SS.

**Methods:** A retrospective cohort of 3575 unselected SLE patients from 45 Rheumatology Units across Spain was evaluated for the presence of overlapping SS

using the American-European consensus criteria. Cumulative clinical data were collected at the moment of the last assessment. Clinical and laboratory parameters in SLE patients with SS (SLEwSS) were compared with those in SLE patients without SS (SLEwoSS).

**Results:** SS was identified in 516 SLE patients (14.4%). Compared with the SLEwoSS group, patients with SLEwSS were significantly older, had a higher frequency of mucocutaneous manifestations, Raynaud's phenomenon, peripheral neuropathy, anti-Ro/SSA, anti-La/SSB, neoplasia, and older age at death, but had a significantly lower frequency of renal involvement, thrombocytopenia, anti-DNA, anti- $\beta$ 2-GPI IgM and complement consumption. Both groups displayed a clinically similar presentation of lymphadenopathy, systemic vasculitis, serositis, damage accrual, mortality, musculoskeletal and CNS manifestations.

FEATURES	SLEwSS N=516	SLEwoSS N=3059	P
Age, years $\pm$ SD	54.2 $\pm$ 14.9	45.6 $\pm$ 14.5	<0.001
Age at SLE onset, years $\pm$ SD	38.6 $\pm$ 15	32.1 $\pm$ 14	<0.001
Female	97.5	89.1	<0.001
Lymphadenopathy	11.8	10.0	0.233
Photosensitivity	65.0	57.2	0.002

Fibromyalgia	13.9	5.1	<0.001
Pleurisy	22.7	22.4	0.893
Pulmonary fibrosis	2.3	1.9	0.563
Renal manifestations	18.3	32.7	<0.001
Seizures	6.3	6.6	0.805
Peripheral neuropathy	5.4	2.9	0.004
Hemolytic anemia	7.1	8.6	0.272
Leucopenia	55.6	53.5	0.428
Thrombocytopenia	15.5	20.8	0.007
Anti-Ro/SSA	69.2	34.4	<0.001
Anti-La/SSB	48.1	14.4	<0.001
Anti-Sm	19.8	21.2	0.495
Anti-RNP	23.2	25.2	0.317
Anti-DNA	55.9	65.1	<0.001
Anti- $\beta$ 2-GPI IgM	8.6	14.5	0.006
Antiphospholipid syndrome	13.0	14.0	0.520
Hypocomplementemia	62.3	69.0	0.012
SLICC-ACR DI	1.19 $\pm$ 1.8	1.03 $\pm$ 1.7	0.062
Neoplasia	7.8	5.5	0.042
Exitus	7.2	6.0	0.324
Age at death, years $\pm$ SD	67.3 $\pm$ 14.4	54.2 $\pm$ 18.0	<0.001

SLEwSS: Systemic lupus erythematosus with Sjögren's syndrome. SLEwoSS: Systemic lupus erythematosus without Sjögren's syndrome. SLICC-ACR DI: Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index. Except where indicated otherwise, values are the percentage.

**Conclusions:** SLEwSS appears to constitute a subgroup of SLE patients with distinct clinical and serologic features, in whom SS is expressed as an overlapping entity. A particular cluster of clinical variables, namely, mucocutaneous manifestations, Raynaud's phenomenon, peripheral neuropathy, renal involvement and thrombocytopenia, was found to be important overall for discriminating SLE patients with or without SS. SLEwSS patients constitute a subgroup of patients with SLE characterised by milder lupus: older age at death, similar rates of mortality and SLICC-ACR damage index, less renal and immunological manifestations.

### FRI0369 PREGNANCY OUTCOMES IN WOMEN WITH ANTIPHOSPHOLIPID ANTIBODIES: INTERIM RESULTS FROM A SINGLE CENTRE COHORT STUDY

K. Schreiber<sup>1,2</sup>, M. Frishman<sup>1</sup>, M.J. Cuadrado<sup>3</sup>, K. Breen<sup>1</sup>, S. Robinson<sup>1</sup>, B. J. Hunt<sup>1</sup>. <sup>1</sup>Department of Thrombosis and Haemophilia, Guy's and St Thomas' Hospital, London, UK; <sup>2</sup>Copenhagen Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; <sup>3</sup>Department of Rheumatology, Guy's and St Thomas' NHS Foundation Trust, London, UK

**Background:** Persisting antiphospholipid antibodies (aPL) are associated with adverse obstetric events including recurrent miscarriage, late fetal loss or early

delivery due to pre-eclampsia or placental insufficiency (obstetric APS) and also thrombosis. We are a tertiary referral centre for those with aPL, and have a management protocol for women with aPL during pregnancy and the puerperium with the aim of preventing obstetric complications and maternal thrombosis.

**Objectives:** To report the fetal and maternal outcomes from a single centre cohort of 511 pregnancies in 372 women over a period of eight years.

**Methods:** This is an ongoing retrospective observational study registered as an audit. Data was collected from clinic lists attending the pregnancy clinic at the Thrombosis centre of St. Thomas' Hospital in London, UK between Jan 2010 to December 2017. Women persistently positive for aPL were included if pregnancy outcome data was available.

**Results:** 511 pregnancies in 372 women were included in the study (table 1). The overall live birth rate was 78.9%. Pregnancy outcomes are outlined in table 2.

#### Abstract FRI0369 – Table 1. Demographics

Age in years, median (range)	35 (18–50)
Ethnicity (white:black:asian:other:not specified)	(186 (50%):17(5%):35(9%):94(25%):40 (11%))

#### Antiphospholipid antibody profile at diagnosis

Lupus anticoagulant, n (%) (dAPTT:DRVVT:TSVT)	261 (70%) (183:144:27)
Anticardiolipin IgG and IgM, n (%)	119 (40%) and 144 (39%)
$\beta$ 2-glycoprotein-I IgG and IgM, n (%)	16 (4%) and 27 (7%)

#### APS history

Obstetric APS (any), n (%)	125 (34%)
Obstetric APS (1 st trimester loss), n (%)	74 (20%)
Obstetric APS (2nd trimester loss), n (%)	35 (9%)
Fetal death (>24 weeks), n (%)	19 (5%)
Intrauterine growth restriction, n (%)	30 (8%)
Pre-eclampsia, n (%)	19 (5%)
Thrombotic APS (any), n (%)	106 (29%)

#### Autoimmune profile

ANA:ENA:dsDNA, n (%)	141 (39%):94 (26%):19 (5%):56 (15%)

#### Abstract FRI0369 – Table 2. Pregnancy outcomes

Pregnancy outcomes	Total pregnancies, n=511
<b>Treatment during pregnancy</b>	
Aspirin, 75 mg daily, n (%)	502 (98%)
Low molecular weight heparin, n (%)	381 (75%)
Aspirin + Heparin	267 (52%)
Aspirin + Heparin + HCG	86 (17%)
Hydroxychloroquine, n (%)	158 (31%)
Azathioprine, n (%)	52 (10%)
Antithrombotics, n (%)	17 (3%)
Steroids, n (%)	113 (22%)
Steroids dose in mg, mean (SD, range)	105 (-/5.4, 1-40)
B12 supplements, n (%)	13 (3%)
VCA prior to pregnancy, n (%)	37 (7%)
IV treatment, n (%)	69 (13%)
<b>Pregnancy outcomes (n=511)</b>	
Live births, n (%)	404 (79%)
Twin pregnancies	13 (3%)
Gestational age at delivery/weeks, mean (SD, range)	39 (-/3, 25-44)
Birthweight <2500g	55 (10%)
Birthweight <1500g	7 (1%)
Birthweight in grams, mean (SD, range)	3320 (-/315, 575-6300)
Pregnancy loss, <10 weeks, n (%)	70 (14%)
Pregnancy loss, >10 weeks, n (%)	27 (5%)
Preterm delivery < 34 weeks gestation	13 (2.5%)
Preterm delivery < 37 weeks gestation	52 (10%)
Intrauterine death (>24 weeks), n (%)	7 (1%)
Pre-eclampsia	23 (4%)
Thrombosis during pregnancy, n (%)	9 (1%)
Cesarean section, n (%)	188 (37%)

Key: HCG, hydroxychloroquine

**Conclusions:** These results from the largest single centre cohort reported show that using our management protocol, nearly 80% of women with aPL had a successful pregnancy outcome.

**Disclosure of Interest:** None declared

**FRI0370** **CLINICAL FEATURES AND OUTCOMES OF LUPUS NEPHRITIS WITH PODOCYTE INJURY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

K. Suzuki, Y. Kaneko, R. Anan, H. Takei, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** Lupus podocytopathy is a recently recognised, new class of lupus nephritis (LN) characterised by diffuse foot process effacement (FPE) without capillary wall immune deposits and glomerular proliferation. However, the frequency, clinical features and treatment response to glucocorticoid and additional immunosuppressive agents of podocyte injury has not been well investigated.

**Objectives:** To clarify clinical characteristics of podocyte injury and its association with therapeutic response in patients with LN.

**Methods:** Consecutive patients with LN with available electronic microscopic findings in our institute were included. Patients were divided into 2 groups according to the presence or absence of FPE (FPE positive group and FPE negative group), and patient characteristics and laboratory data and pathological classification were compared.

**Results:** Twenty-seven patients with LN with electronic microscopic findings were enrolled. The mean age was 43.7 years old, and 22 (81.5%) were female. The ISN/RPS classification of lupus nephritis were 2 of unclassified, 1 class II, 3 class III, 3 class IV, 9 class V, 6 class III+V, and 3 class IV+V. Two cases were identified as lupus podocytopathy and their renal tissues showed focal segmental glomerulosclerosis pattern. Eighteen patients (67%) were identified to have FPE (FPE positive group) and the remaining 9 patients (33%) did not show FPE in their renal tissues (FPE negative group). The mean age was comparable (42.1 vs 41.2 y/o,  $p=0.84$ ). The mean estimated glomerular filtration rate (eGFR) at LN diagnosis was 77.5 and 70.9 ml/min/1.73 m<sup>2</sup> ( $p=0.39$ ), and the mean urine protein was 1.35 and 2.41 g/day ( $p=0.11$ ). During the mean observation period of 50.1 months, 19 patients (70%) achieved complete response (CR, urinary protein/urine creatinine ratio <0.5 mg/gcr or proteinuria by dipstick test  $\leq \pm$ ). While the dose of prednisolone at treatment initiation and subsequent immunosuppressive therapy was similar in both groups (prednisolone dose, 34.8 vs 39.2 mg/day,  $p=0.57$ ), the rate of CR achievement was significantly higher in the FPE positive group (15 cases, 83%) than the FPE negative group (four cases, 44%,  $p=0.04$ ). The duration to CR achievement was also significantly shorter in the FPE positive group (median, 8 vs 2 months,  $p=0.05$ ).

**Conclusions:** This study showed that podocyte damage was common in LN and pathological types and FPE was associated with renal prognosis in LN. We should be more aware of findings of electronic microscopic in patients with LN.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.5266

**FRI0371** **CLINICAL CHARACTERISTICS AND OUTCOME OF ISOLATED LUPUS NEPHRITIS**

K. Bugdayli<sup>1</sup>, V.R. Chowdhary<sup>1</sup>, C.S. Crowson<sup>1,2</sup>, L. Zand<sup>3</sup>, M.P. Alexander<sup>4</sup>, L. D. Cornell<sup>5</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Health Sciences Research; <sup>3</sup>Nephrology and Hypertension; <sup>4</sup>Anatomic Pathology; <sup>5</sup>Anatomic Pathology, Mayo Clinic, Rochester, USA

**Background:** Lupus nephritis (LN) is a serious manifestation of systemic lupus erythematosus (SLE) associated with significant mortality and morbidity. At least 50% of patients will develop renal involvement at some point in their disease course. Rarely, patients may present with LN alone and have no extra-renal clinical manifestations of lupus. The clinical course, response to treatment and subsequent development of extra-renal manifestations of lupus is not well known in this subset.

**Objectives:** To study the treatment response and development of extra-renal manifestations of lupus in patients who present with isolated lupus nephritis.

**Methods:** Subjects were identified by searching a pathologic renal biopsy database for patients with immune complex glomerulonephritis and lupus nephritis (n=1015). Clinical records were reviewed for exclusion of infectious and secondary causes (e.g. IgA nephropathy, C1q nephropathy, C3 glomerulonephropathy, post-infectious glomerulonephritis etc.). Cases with isolated LN were defined per 2012 SLICC criteria as having biopsy proven LN with positive antinuclear antibody (ANA) and/or anti-dsDNA antibodies and who did not have any extra-renal clinical manifestations at onset. Demographics, biopsy information, clinical and laboratory features at onset, and during follow-up and treatment was recorded on a standardised data collection form. Complete and partial renal response were defined per the Dutch Working Party criteria.<sup>1</sup>

**Results:** Thirty four patients with isolated LN were identified. The median age at presentation was 41 years and majority were female (71%) Caucasians (77%). Median follow up was 5.4 years. At presentation, mean serum creatinine was 1.7 mg/dl (range 0.7–5.4), and mean proteinuria was 6.8 g/24 hours (range 0.1–62.9). Antinuclear antibodies were positive in 71%, positive dsDNA in 36%. Mean C3 and C4 levels were 78.2 mg/dl (range 26.5–133.0) and 11.0 mg/dl (range 3.0–40.0), respectively. Antibodies to extractable nuclear antigens were checked in 12

patients and positive for anti-SSA,<sup>5</sup> anti-SSB,<sup>2</sup> anti-Sm,<sup>2</sup> anti-RNP;<sup>3</sup> Anticardiolipin were positive in 7/13 and lupus anticoagulant in 4/4. Renal biopsies showed changes of Class III nephritis in 10 patients (29%), Class IV in 13 (38%) and class V in 7 (21%). Induction treatment included Corticosteroids (94%), mycophenolate mofetil (76%), cyclophosphamide (18%) and tacrolimus (3%). Maintenance treatment included corticosteroids (73%), MMF (79%), azathioprine (8%), rituximab (5%), cyclophosphamide (5%), calcineurin inhibitor (2%), chlorambucil (2%). At the last follow up CR was seen in 14 (42%) and partial response in 5 (15%). End-stage renal disease developed in 6 (18%) and 3 patients received renal transplant. Extra-renal manifestations of lupus developed in 8 patients (24%) and included acute cutaneous,<sup>2</sup> chronic cutaneous,<sup>3</sup> arthritis<sup>1</sup> and serositis.<sup>4</sup>

**Conclusions:** Majority of patients with isolated lupus nephritis respond well to treatment. The development of extra-renal manifestations of lupus after treatment is a rare occurrence.

**FRI0372** **COMPARISON OF CLINICAL FEATURES BETWEEN YOUNG AND ELDERLY ONSET IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME**

M. Kojima<sup>1</sup>, Y. Kaneko<sup>1</sup>, M. Tsukamoto<sup>2</sup>, T. Takeuchi<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, National Hospital Organization, Tokyo, Japan

**Background:** Primary Sjogren's syndrome (pSS) generally develops in middle-aged women. Currently, elderly-onset pSS has been increasing, however, differences in clinical and serological features between young-onset and elderly-onset pSS is unclear.

**Objectives:** The aim of this study was to compare clinical and serological features between young-onset and elderly-onset patients with pSS.

**Methods:** All patients with pSS diagnosed with 2016 ACR/EULAR classification criteria in our department from 1995 to 2017 were included. Patients were divided into 2 groups according to the age of diagnosis at 65 years old; young-onset and elderly-onset. The symptoms and laboratory findings were compared.

**Results:** Six hundred twelve pSS patients were reviewed. Five hundred seventy (93%) were female. Four hundred twenty six (70%) were young-onset and the remaining 186 (30%) were elderly-onset. The mean age at pSS diagnosis was 47.8 and 72.4 years old, the ratio of women:men is around 12:1 and 20:1. The observation period from the diagnosis to the last visit was 3.46 and 5.50 years, respectively. At diagnosis, the positivity of anti-SS-A antibody (86.8 vs 73.7%,  $p<0.001$ ), anti-SS-B antibody (48.3 vs 30.7%,  $p<0.001$ ), and rheumatoid factor (49.6 vs 35.2%,  $p<0.01$ ) were significantly higher in the young-onset patients than the elderly-onset patients. Also, the level of platelet cell count (23.0 vs 20.8\*10<sup>4</sup>/μl,  $p<0.001$ ), IgG (1996 vs 1745 mg/dl,  $p<0.001$ ) and IgM (154 vs 131 mg/dl,  $p<0.001$ ) were significantly higher in the young-onset patients. On the other hand, that of white blood cell count (4814 vs 5301/μl,  $p<0.001$ ), neutrophil count (2822 vs 3201/μl,  $p<0.001$ ), lymphocyte count (1512 vs 1632/μl,  $p<0.01$ ), C3 (87.2 vs 93.2 mg/dl,  $p<0.001$ ), C4 (22.1 vs 24.7 mg/dl,  $p<0.001$ ), and CH50 (48.2 vs 51.1/ml,  $p<0.001$ ) were significantly lower in the young-onset patients. While the young-onset patients had higher rate of liver dysfunction (3.99 vs 0.54%,  $p<0.05$ ), and arthritis (6.81 vs 2.69%,  $p<0.05$ ), the elderly-onset patients were more frequently complicated with pulmonary disease (4.2 vs 11.8%,  $p<0.001$ ). The C3 levels in the elderly-onset patients with pulmonary disease were conversely lower than the young-onset patients with pulmonary disease. The incidence of lymphoma was not different between two groups.

**Conclusions:** Although elderly onset pSS patients have milder symptoms and immune-disturbances than young-onset ones, pulmonary disease was more frequently affected in the elderly-onset patients with a decrease in complement levels, suggesting there may be difference in the pathogenesis in pSS according to onset ages and organ involvement.

**Background:** Rheumatic Diseases (RD) frequently affect women during reproductive age, therefore counselling on family planning is crucial for their quality of life. Children's outcome is a major topic, but no large studies are available.

**Objectives:** To assess the long-term health conditions of children born to women with RD in a large multicentre cohort.

**Methods:** 24 Rheumatology Centres distributed the questionnaire (65 multiple-choice and 12 open-answer questions) to consecutive patients (18–55 years) in September 2015. Data were analysed dividing children upon maternal diagnosis: Chronic Arthritis (CA) and Connective Tissue Diseases (CTD).

**Results:** Data were collected for 320 children (166 males, 52%) born to 184 mothers (63 CA and 121 CTD). At the time of interview, children had a mean age of 17.1±9.6 years. Preterm delivery (<37 w) was observed in 72 cases (22.5%), including 13 (4%)<34 w. Data on autoimmune/inflammatory disease (AIID) and/or neurodevelopmental disorders (ND)/learning disabilities (LD) is reported in table 1. 12 children (3.7%) had a diagnosis of AIID, mostly coeliac disease (8/12, 67%) and 11 children (3.4%) of a ND and/or LD by a Paediatric Neuropsychiatrist. To rule out the possible effects of *in utero* exposure to maternal autoantibodies and/or anti-rheumatic drugs in the pathogenesis of ND, these data were retrieved for 280 children (88%) and a comparison was performed between 11 affected and 269 non-affected children (table 2).

**Abstract FRI0373 – Table 1.** DM: diabetes mellitus; LD: learning disorder; ADHD: attention deficit hyperactivity disorder

**Conclusions:** In this long-term follow-up of children born to mothers with RD in this large, multicenter study of randomly interviewed women each AIID did not display a significantly increased frequency as compared to the literature; only coeliac showed a mild increased frequency. Children with LD had a tendency to cluster in the group of mothers with CTD, especially after maternal diagnosis (4/63, 6.3%), with a higher frequency as compared to general paediatric population. No significant relationships between ND/LD and prematurity, intrauterine drug exposure or maternal autoantibodies were identified.

### MILDER CLINICAL PRESENTATION OF LUPUS NEPHRITIS AND IMPROVED RENAL SURVIVAL DURING THE LAST 50 YEARS: A MULTICENTRIC STUDY

M. Gatto<sup>1</sup>, G. Moroni<sup>2</sup>, F. Raffiotta<sup>2</sup>, P.G. Vercelloni<sup>3</sup>, S. Quaglini<sup>4</sup>, L. Sacchi<sup>4</sup>, D. Gainfreda<sup>5</sup>, A. Vaglio<sup>5</sup>, R.A. Sinico<sup>3</sup>, A. Doria<sup>1</sup>. <sup>1</sup>Rheumatology, University of Padova, Padova; <sup>2</sup>Nephrology unit, Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico; <sup>3</sup>Nephrology unit, University Milano Bicocca, Milano; <sup>4</sup>Electrical, Computer and Biomedical Engineering, University of Pavia, Pavia; <sup>5</sup>Nephrology unit, University Hospital Parma, Parma, Italy

**Background:** Lupus nephritis (LN) presentation changed over time following earlier diagnosis and treatment.

**Objectives:** To evaluate changes in LN clinical and histological presentation in the last 5 decades.

**Methods:** This is a retrospective multicentric study on prospectively collected data in four Italian hospital centres. Patients diagnosed between 1970 and 2016 were recruited provided they had a biopsy-proven LN that was retrospectively reclassified according to the ISN/RPS classification criteria. Follow-up was subdivided into three periods (P) based on the year of LN diagnosis: P1:1970–1895; P2:1986–2000; P3:2001–2016. Predictors of patient and renal survival were investigated by univariate and multivariate analysis; survival curves were compared by log-rank test. Clinical pictures at presentation included isolated urinary abnormalities, nephrotic syndrome, nephritic syndrome, rapidly progressive renal failure. Outcome at last observation was defined as complete renal remission or

partial renal remission, or poor renal outcome, including chronic kidney disease (CKD) or end stage renal disease (ESRD).

**Results:** 499 patients were included (85.6% females) with a median follow-up of 10.6 years (IQR 4–18). We observed an increase in both age at diagnosis of LN (P1 28.4±10.4; P2 29±11.5; P3 34.4±13.3 years) and disease duration before LN diagnosis (P1 1.3±1.3; P2 2.6±4.5; P3 4.6±6.3 years) from 1970 to 2016 ( $p<0.001$  for both). At clinical presentation, renal insufficiency and acute nephritic syndrome became less common (P1 14.2%; P2 3.9%; P3 3.4% and P1 29%, P2 20.3%; P3 12.4%, respectively,  $p<0.0001$ ) while isolated urinary abnormalities became significantly more prevalent from P1 to P3 (P1 26.4%; P2 38%; P3 48.9%;  $p<0.0001$ ). Outcome was available in 95.8% of patients. Frequency of partial and complete renal remission progressively increased (P1 6.9%; P2 28%; P3 32% and P1 49.6%; P2 48%; P3 58.5%;  $p<0.001$  and  $p=0.01$ , respectively) while CKD, ESRD and death decreased (P1 7.9%; P2 8.5%; P3 4.5%; P1 24.8% P2 9%; P3 1.3%; P1 19.8%; P2 5.9%; P3 3.6%, respectively.  $p<0.001$  for all). Survival without ESRD at 10 and at 20 years was 87% and 80% in P1, 94% and 90% in P2 and 99% in P3 ( $p=0.0019$ ). Induction therapy with immunosuppressants was more frequently performed over time (P1 71%; P2 82%; P3 94.6%,  $p<0.0001$ ) and use of MMF significantly increased both as induction and maintenance treatment (P1 0, P2 2.7%; P3 33.8% and P1 1%; P2 15%; P3 54.8%, respectively,  $p<0.0001$ ). At multivariate analysis, logarithm of serum creatinine (RR:2.72), male gender (RR:3.34), activity index (RR:1.1), chronicity index (RR:1.29), arterial hypertension (RR:5.95), and lack of maintenance immunosuppressive therapy (RR:3.04) predicted ESRD. No significant changes in histological classes or active lesions at the time of renal biopsy were observed, while chronicity index significantly decreased from P1 to P3 ( $p=0.023$ ).

**Conclusions:** The clinical presentation of LN apparently became less severe in the last decades, likely due to earlier diagnosis and proper treatment, leading to an improved renal survival.

#### DELAYED LUPUS NEPHRITIS IN THE COURSE OF SYSTEMIC LUPUS ERYTHEMATOSUS PREDICTS A POORER RENAL RESPONSE TO INDUCTION THERAPY, RENAL FLARES, AND WORSE LONG-TERM RENAL OUTCOMES: A MULTICENTER, RETROSPECTIVE COHORT STUDY

M. Nakano<sup>1,2</sup>, K. Kubo<sup>1</sup>, Y. Shiota<sup>3</sup>, Y. Iwasaki<sup>1</sup>, N. Tanaka<sup>2</sup>, Y. Takahashi<sup>2</sup>, S. Tateishi<sup>1</sup>, H. Yamashita<sup>2</sup>, M. Miyazaki<sup>3</sup>, H. Sato<sup>3</sup>, T. Igarashi<sup>2</sup>, H. Kanda<sup>1</sup>, H. Kaneko<sup>2</sup>, T. Ishii<sup>3</sup>, K. Fujio<sup>1</sup>, A. Mimori<sup>2</sup>. <sup>1</sup>The University of Tokyo Hospital, <sup>2</sup>National Center for Global Health and Medicine, Tokyo; <sup>3</sup>Tohoku University Hospital, Sendai, Japan

**Background:** Some prognostic factors for lupus nephritis (LN) have been mentioned such as nephrotic syndrome, class 4 and chronicity on histology. In a previous single-centre study, we reported a potentially poorer renal response to induction therapy in LN that developed later after SLE onset (delayed, D-LN) compared with LN manifesting at SLE onset (early, E-LN) <sup>1</sup>. However, our study was limited by a small sample size and lack of long-term observation.

**Objectives:** This multicenter study aimed to validate whether D-LN was a useful predictor of a poor response to induction therapy with more detailed clinical and pathological parameters. Furthermore, we investigated whether D-LN was also a predictor of flares and long-term renal outcomes in addition to the established prognostic factors.

**Methods:** We retrospectively examined 215 biopsy-proven LN patients (136 E-LN, 79 D-LN) who attended 3 hospitals above between 1997 and 2014 and who were observed for 3–20 (median: 10.8) years from LN onset. We compared baseline clinical, pathological features and treatment options at LN onset between E-LN and D-LN. Then we compared the cumulative complete response (CR) rates, renal/extra-renal relapse rates, and the rates of renal insufficiency between the two groups. Renal insufficiency was defined as follows: <sup>1</sup> serum creatinine (SCr) doubling or ESRD for severe insufficiency, and <sup>2</sup> SCr increasing by 1.5 times and also >1.0 (female) or >1.2 mg/dl (male) for mild insufficiency. Moreover, we evaluated predictors of the response, flares and long-term renal outcomes with multivariate analysis.

**Results:** Anti-Sm/RNP antibodies and mixed proliferative and membranous nephritis (class 3+5 or 4+5) were significantly more prevalent in D-LN than E-LN (48.1 vs. 32.4%, 68.8 vs. 40.4%, 40.5 vs. 18.4%, respectively). Log-rank test showed that significantly lower cumulative CR rates over 3 years (65.8 vs. 83.1% at 12 months, 83.5 vs. 92.6% at 36 months,  $p<0.01$ ) and significantly higher relapse rates (both renal and extra-renal) over 20 years in D-LN than E-LN. Mild renal insufficiency was significantly more likely to occur in D-LN over 20 years (21.5 vs. 12.5%,  $p=0.04$ ). We performed multivariate Cox regression analysis for the response, flare, and renal outcomes including significant variables on univariate analysis. As independent predictors of CR, D-LN, nephrotic syndrome and chronicity index were identified. As those of renal flares, D-LN was detected.

Although D-LN was not associated with severe renal insufficiency, D-LN was identified as an independent predictor of mild renal insufficiency as well as some other factors (table 1).

Univariate analysis	Hazard ratio	P-value	Multivariate analysis	Hazard ratio	P-value
<b>Predictors of CR</b>

Anti-Sm antibodies	2.49(1.34-4.65)	0.004	Anti-Sm antibodies	2.31(1.23-4.34)	0.009
<b>Predictors of severe renal insufficiency</b>					
D-LN	2.31(0.89-5.99)	0.085			
Anti-RNP antibodies	9.41(2.14-41.3)	0.003	Anti-RNP antibodies	10.1(2.27-44.6)	0.002
Chronicity index	1.42(1.03-1.97)	0.032			
Non-CR at 6months after induction therapy	4.38(1.54-12.4)	<0.001	Non-CR at 6months after induction therapy	3.21(1.06-9.75)	0.039
<b>Predictors of mild renal insufficiency</b>					
D-LN	2.00(1.02-3.92)	0.044	D-LN	2.12(1.03-4.34)	0.041
Male	2.14(1.02-4.48)	0.044	Male	2.87(1.31-6.27)	0.008
Serum creatinine	1.97(1.45-2.67)	<0.001	Serum creatinine	1.97(1.30-2.99)	0.002
Nephrotic syndrome	2.48(1.26-4.88)	0.009			
Activity index	1.14(1.04-1.24)	0.003			
Chronicity index	1.77(1.42-2.19)	<0.001	Chronicity index	1.61(1.25-2.09)	<0.001
Non-CR at 6months after induction therapy	5.24(2.50-11.0)	<0.001	Non-CR at 6months after induction therapy	3.29(1.46-7.41)	0.004

**Conclusions:** D-LN might be a novel predictor of a poorer treatment response, renal flares and long-term renal outcomes independent of the established prognostic factors. The distinct differences in the autoantibody profiles between E-LN and D-LN groups suggest that D-LN patients might reflect a refractory SLE subset with a specific immunological profile.

**Background:** Preventing organ damage is a major challenge in Systemic Lupus Erythematosus (SLE).

**Objectives:** To evaluate factors associated with development of damage in a prospectively followed cohort of early diagnosed SLE patients.

**Methods:** The Early Lupus Project<sup>1</sup> encompasses 9 Italian centres recruiting, from the 1st January 2012, an inception cohort of consecutive patients diagnosed with SLE within 12 months from appearance of four or more 1997 ACR classification criteria. At study entry and then every 6 months a large panel of data was recorded.

Here, we report on factors associated with the development of damage assessed by the SLICC/ACR Damage Index (SDI). Using univariate analysis, we assessed the contribution of covariates collected at baseline (demographic, comorbidities, serological, clinical by BILAG2004 domains, disease activity by ECLAM, HRQoL by visual analogic scale) in the development of damage (SDI from 0 to  $\geq 1$ ). Forward-Backward Cox-regression models were fitted with covariates with  $p<0.05$  to identify factors independently associated with increased risk of damage development.

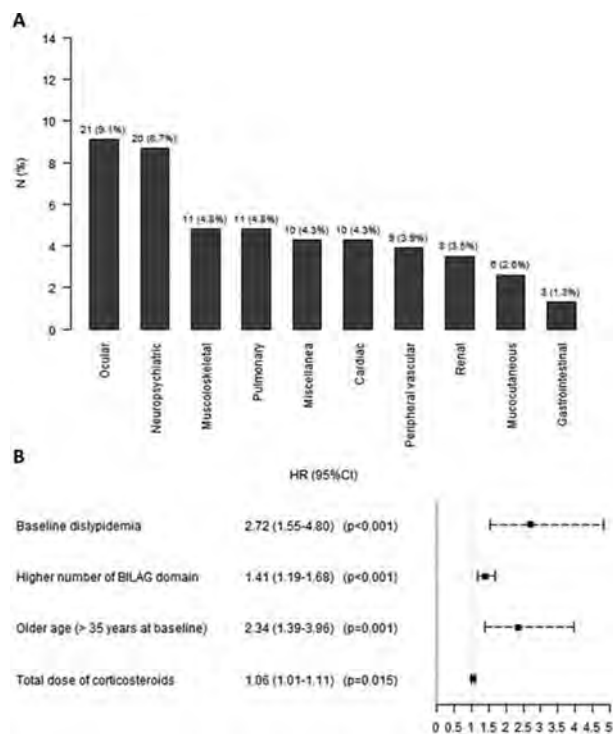

**Results:** Overall, 279 patients were enrolled in the Early Lupus Project inception cohort up to the 31st of December 2017; 230 patients (89.6% Caucasians, 13.4% males) were eligible for this study having SDI=0 at enrolment and at least 6

months of follow-up. Mean ( $\pm$ SD) age at recognition of 4 ACR criteria was 36.5 ( $\pm$ 14.4) years, median disease duration at recruitment was 1.1 months (interquartile range 0.0–4.8) and median follow-up duration was 27.4 months (interquartile range 7.2–48.0).

At last follow-up visit 84 patients (36.5%) had an SDI score  $\geq 1$  (median=0; interquartile range 0–1); see figure 1A for overall SDI domains involved.

Baseline dyslipidemia ( $p < 0.001$ ; HR 2.7 95% CI 1.5–4.8), higher number of BILAG domain involved ( $p < 0.001$ ; HR 1.4 95% CI 1.2–1.7) and older age ( $> 35$  year) at baseline ( $p = 0.001$ ; HR 2.3 95% CI 1.4–4.0) together with total dose of corticosteroids ( $p = 0.015$ ; HR 1.06 per gram of prednisone equivalent; 95% CI 1.01–1.11) during follow-up were the factors independently associated with increased risk of developing damage in this cohort (figure 1B). Their effect was confirmed after stratification for antimalarials (yes/no) and immunosuppressants (yes/no) use.

**Conclusions:** The early development of organ damage in this SLE patients cohort was associated with modifiable risk factors as baseline dyslipidemia and higher corticosteroid dose. Addressing them since the very early stages of the disease, and treating disease activity to target remission or minimal disease activity, may reduce damage and improve patients outcome.

**FRI0377 THE RELATIONSHIP BETWEEN REMISSION AND HEALTH RELATED QUALITY OF LIFE IN A COHORT OF SLE PATIENTS**

M.W.P. Tsang-A-Sjoe, I.E.M. Bultink, M. Heslinga, L.H. van Tuyl, R.F. van Vollenhoven, A.E. Voskuyl. *Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands*

**Background:** a treat-to-target approach for SLE was suggested by an international board of experts to further improve outcome in SLE. Remission was specifically identified as a suitable target. The Definition of Remission in SLE (DORIS) task force recently achieved international consensus on criteria for remission.

**Objectives:** to investigate the relationship between remission and health-related quality of life (HRQoL) in patients with systemic lupus erythematosus (SLE) in a longitudinal observational cohort.

**Methods:** retrospective analysis of prospectively obtained data. HRQoL was assessed using the physical and mental component score (PCS and MCS, respectively) of the Short Form 36 (SF-36) questionnaire. DORIS remission categories (no remission/remission on therapy/remission off therapy) were applied. Determinants of PCS and MCS were identified with simple linear regression analyses. Association between remission and HRQoL was assessed using Generalised Estimating Equation (GEE) models.

**Results:** Data from 154 patients with 2 years of follow-up were analysed. At baseline 70/154 (45.5%) of patients were in either form of remission. Patients in remission had higher SF-36 scores in all subdomains compared to patients not in remission (figure 1). PCS was positively associated with remission and having employment and negatively associated with erythrocyte sedimentation rate, patient global assessment, SLICC damage index, prednisone use, immunosuppressant use, and body mass index. MCS was positively associated with Caucasian ethnicity and negatively associated with patient global assessment. In GEE analysis, a gradual and significant increase of PCS was observed from patients not in remission (mean PCS 36.0) to remission on therapy (41.8) to remission off therapy (44.8) (table 1). No significant difference in MCS was found between remission states.

**Abstract FRI0377 – Table 1.** GEE analysis of the association between PCS or MCS and remission in patients with SLE

**A. PCS:**

	Mean PCS ( $\pm$ SD)	Unadjusted		Adjusted*	
		B (95% CI)	p-value	B (95% CI)	p-value
No remission	36.0 (10.9)	Ref.		Ref.	
Remission on therapy	41.8 (10.0)	6.3 (3.2–9.3)	$< 0.001$	6.2 (3.3–9.0)	$< 0.001$
Remission off therapy	44.8 (10.4)	8.2 (5.3–11.2)	$< 0.001$	8.3 (5.4–11.1)	$< 0.001$

\*Adjusted for age and SDI

**B. MCS:**

	Mean MCS ( $\pm$ SD)	Unadjusted		Adjusted**	
		B (95% CI)	p-value	B (95% CI)	p-value
No remission	46.1 (10.6)	Ref.		Ref.	
Remission on therapy	49.3 (10.5)	2.9 (0.1–5.7)	0.041	2.3 (–0.5–5.1)	0.112
Remission off therapy	46.8 (10.1)	0.8 (–1.7–3.4)	0.52	0.4 (–2.1–3.0)	0.739

\*\*Adjusted ethnicity

**Abstract FRI0377 – Figure 1.** Mean SF-36 subdomain scores in 154 patients at baseline, categorised between SLE patients in remission (n=60) or not in remission (n=94). Patients in remission at baseline have higher mean scores in all SF-36 subdomains compared to patients not in remission.

**Conclusions:** we show a strong and persistent association between remission and PCS, but not MCS. These results support the relevance (construct validity) of

the DORIS remission definitions and the further development of a treat-to-target approach in SLE.

### FRI0378 ANTIPHOSPHOLIPID SYNDROME IN PATIENTS WITH ACUTE MYOCARDIAL INFARCTION

M. Jordhani, J. Seiti, V. Duraj, D. Ruci. *Internal Medicine, Uhc Tirana, Tirana, Albania*

**Background:** Antiphospholipid syndrome (APS) is a known cause of thrombotic disorders, including Acute Myocardial Infarction (AMI). Although the incidence of APS in AMI patients it's not known, it can be an important cause of myocardial infarction especially in young patients.

**Objectives:** The aim of this study is to evaluate the relationship between antiphospholipid syndrome and acute myocardial infarction in patients presented at cardiac emergency and cardiac reanimation at UHC Mother Teresa, Tirana, Albania

**Methods:** This is an observational study which included all patients from 23 to 45 years old presented as Acute Myocardial Infarction at our hospital from 10 december 2016–10 december 2017. In this period, there were diagnosed with AMI 61 patients fulfilling the inclusion criteria of the study: 37 males and 24 females. Besides the usual laboratory tests, all patients included in the study were completed with the titration of APS autoantibodies (Anti-cardiolipin, Lupus anticoagulant,  $\beta$ 2 glycoprotein 1 antibodies). If positive, according to diagnosis guidelines, the tests were repeated after 12 weeks.

**Results:** Of 61 patients with AMI, 17 patients were positive for Antiphospholipid Syndrome at the first test and after 12 weeks, APS was confirmed in 15 patients (24.6%): 10 females (67%) and 5 males (33%). Three of the patients diagnosed with APS underwent to a second Percutaneous transluminal coronary angioplasty due to rapid occlusion of stents placed in concomitant stenotic coronary arteries.

**Conclusions:** From this study it was found that Antiphospholipid syndrome in relatively young patients hospitalised for Acute myocardial infarction is a concomitant-causing disorder in a quarter of the patients included in our study. This implies that in young patients it should be kept in mind that APS could be the reason of the problem.

### FRI0379 INFLAMMATORY JOINT INVOLVEMENT IS ASSOCIATED WITH SEVERE DRY EYE IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

M. Fernandez Castro<sup>1</sup>, C. Sanchez-Piedra<sup>2</sup>, J.L. Andreu<sup>3</sup>, V. Martínez Taboada<sup>4</sup>, A. Olive<sup>5</sup>, J. Rosas<sup>6</sup> on behalf of SJOGRENER project (GEEAS-SER).  
<sup>1</sup>Rheumatology, Hospital Infanta Sofía, Madrid; <sup>2</sup>Research Unit of the Spanish Society of Rheumatology; <sup>3</sup>Rheumatology, Hospital Puerta de Hierro Majadahonda, Madrid; <sup>4</sup>Rheumatology, Hospital Marqués de Valdecilla, Santander; <sup>5</sup>Rheumatology, Hospital Germans Trias i Pujol, Barcelona; <sup>6</sup>Rheumatology, Hospital Marina Baixa, Alicante, Spain

**Background:** Primary Sjögren's syndrome (pSS) is characterised by lymphocytic infiltration of exocrine glands and other organs, resulting in dry eye, dry mouth and extraglandular systemic involvement such as pain, myalgia or polyarthralgia, among others.

**Objectives:** The aim of the present study is to explore the association of severe or very severe dry eye with extraocular involvement in patients with pSS.

**Methods:** SJOGRE-SER registry is a multicenter cross-sectional study of pSS patients fulfilling European/American consensus criteria 2002 from 33 Spanish rheumatology departments. Data were collected by reviewing clinical records and interviewing patients. For the construction of our main variable, "severe/very severe dry eye" (S/VSDE), we used those variables present in our cohort that represented a degree 3–4 of severity (S/VSDE) according to the dry eye TFOS DEWS I classification 2007 (Tear Film and Ocular Surface Society Dry Eye Work-Shop): Schirmer score ( $\leq 5$  mm/5 min) and/or corneal ulcers and/or use of autologous sera and/or contact lenses and/or Stenon conduit bypass and/or palpebral cleft reduction. First, bivariate logistic regression models were used to identify the effect of each independent variable on S/VSDE. Secondly, multivariate analysis using regression model was used to establish the independent effect of patient characteristics associated with the dependent variable.

**Results:** Four hundred and thirty-seven patients were included in SJOGRE-SER registry (female gender 95%; median age 58 (50.02–67.98) years). Mean time of evolution of the disease in the cohort was 8.3 years. ESSDAI mean score was 2 (0–4, P25-P75) in the full registry. Ninety-four per cent of the patients in SJOGRE-SER cohort complained of daily, persistent, troublesome dry eyes, 92% had sensation of sand in the eyes and 16% developed corneal ulcer. In the

full cohort Schirmer's test was performed in 402 patients and was pathological ( $\leq 5$  mm/5 min) in 371 patients (92%). The use of autologous sera was 14%, contact lenses 2%, Stenon conduit bypass 0.23% and palpebral cleft reduction 0.23%. Three hundred and seventy-eight patients (86.5%) presented S/VSDE; 95% were women, and the median age was years. Mean time of evolution of the disease was 8.51 and ESSDAI mean score was 5. Inflammatory articular involvement was significantly more frequent in patients with S/VSDE (82.5%) than in those without S/VSDE (69.5%) ( $p=0.028$ ). Inflammatory joint affection was associated with S/VSDE in the multivariate analysis, OR 2.079 (95% CI, 1.096–3.941). These results were adjusted by sex, age, time of evolution of the disease and ESSDAI score.

**Conclusions:** Severe or very severe ocular involvement is associated with the presence of inflammatory joint involvement in patients with pSS. These results suggest that a directed anamnesis including systemic comorbidities, such as the presence of inflammatory joint affection and dry mouth, in patients with severe dry eye, would be useful to suspect an pSS.

### FRI0380 ASSESSMENT OF SUBMANDIBULAR GLAND QUALITATIVE CHANGES USING SHEAR WAVE ELASTOGRAPHY IN PATIENTS WITH SJÖGREN'S SYNDROME

N. Hashimoto<sup>1</sup>, S. Uchiyama<sup>2</sup>, M. Kitano<sup>3</sup>, T. Nakazawa<sup>4</sup>, T. Iwasaki<sup>5</sup>, T. Hashimoto<sup>1</sup>. <sup>1</sup>Hashimoto Rheumatology Clinic; <sup>2</sup>Temabashi General Clinic, Kansai Medical University, Osaka; <sup>3</sup>Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya; <sup>4</sup>Department of Rheumatology, Osaka Saiseikai Nakatsu Hospital, Osaka; <sup>5</sup>Department of Pharmacy, Hyogo University of Health Sciences, Kobe, Japan

**Background:** We have reported that the submandibular gland ultrasonography (SGUS) is a useful noninvasive and inexpensive procedure for the evaluation of the structural changes of salivary gland (SG) in Sjögren's syndrome (SS), International Symposium on SS 2002, EULAR 2009, EULAR 2012, EULAR 2015. However, our previously study demonstrated that although SGUS findings were useful for the diagnosis of SS with low salivary flow they were not for early-stage SS with normal salivary flow. EULAR 2016. Recently, ultrasound elastography has been reported to be a new tool to evaluate tissue stiffness and diagnose tumour.

**Objectives:** The aim of this study was to examine the usefulness of SGUS using US staging and PD grading score in combination with shear wave elastography (SWE) in patients with SS.

**Methods:** Fifty-eight patients who fulfilled the American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria for SS were studied. SS patients were divided into three groups according to salivary flow using gum test (VL/SS: $<5$  mL/10 min. (n=21), L/SS: 5–10 mL/10 min. (n=27) and N/SS: $\geq 10$  mL/10 min. (n=10)). All patients were examined SGUS by a single investigator who was blinded to device (TUS-A300; Canon Medical Systems, Tokyo, Japan) with a linear transducer (7.5–10MHz). The examination consisted of conventional B-mode US (US staging score), pulsed wave Doppler US (PD grading score) and SWE with quantitative assessment. US staging scores were assessed by glandular size, inhomogeneity and contrast of diaphragm muscle (stage 0 to 3). PD grading scores were graded by pulsed wave pattern in pulsed wave Doppler US at the internal SG facial arteries (grade 0 to 2). With the region-of-interest (ROI) placed over the stiffest areas of the lesion on SWE, the quantitative mean of the elasticity values were measured by shear wave velocity (Vs: m/s) and elasticity (E: kPa) for each lesion.

**Results:** The US staging scores of SS patients were 0.0% in stage 0; 17.2% in stage 1; 8.6% in stage 2; 74.1% in stage 3. The PD grading scores of SS patients were 20.7% in grade 0, 17.2% in grade 1, 62.1% in grade 2. The US staging and grading scores were significantly lower in N/SS patients (1.40 $\pm$ 0.70, 0.10 $\pm$ 0.32) than in L/SS (2.74 $\pm$ 0.66,  $p<0.001$ , 1.59 $\pm$ 0.69,  $p<0.001$ ) and in VL/SS (2.91 $\pm$ 0.30,  $p<0.001$ , 1.81 $\pm$ 0.40,  $p<0.001$ ) patients. The elasticity value measure by Vs and E were significantly higher in N/SS patients than in VL/SS patients (Vs: 1.90 vs 1.56 m/s,  $p<0.05$ , E: 11.2 vs 7.57 kPa,  $p<0.05$ ). The Vs and E were significantly decreased as US staging score (stage 1 vs 3: 1.91 vs 1.62 m/s,  $p<0.05$ , 11.3 vs 8.21 kPa,  $p<0.05$ ) and PD grading score (grade 0 vs 2: 1.90 vs 1.61 m/s,  $p<0.05$ , 11.1 vs 8.13 kPa,  $p<0.05$ ) increased.

**Conclusions:** The present study demonstrated that the tissue elasticity was increased due to inflammation and high viscosity in the SG at the early stage, but was decreased due to structural changes in the SG at the advanced stage of the

disease. The SWE may be a useful tool for elucidation of early stage pathological changes of the SG when salivary gland functions are not impaired in SS.

### FRI0381 ARE THE ANTIPHOSPHOLIPID ANTIBODIES A "NEW" INDEPENDENT RISK FACTOR FOR ACCELERATED ATHEROSCLEROSIS

*N. Stoilov<sup>1</sup>, V. Boyadzieva<sup>1</sup>, R. Rashkov<sup>1</sup>, S. Stefanov<sup>2</sup>. <sup>1</sup>Clinic of Rheumatology, Umbal "Sv. Ivan Rilski"; <sup>2</sup>Clinic of Rheumatology, SBALDB, Sofia, Bulgaria*

**Background:** The physiological function of phospholipids and their protein co-factors, which are aPL target, are well known. Beta 2 glycoprotein 1 is an important transport molecule that binds negatively charged particles to free circulation, including various lipoproteins, such as LDL. In this context,  $\beta$ 2GPI plays the role of protein co-factor of low density lipoprotein and is a key factor affecting serum levels of free LDL and total cholesterol, respectively. Its physiological function is suppressed by antibodies against it.

**Objectives:** We investigated the incidence of atherosclerosis in patients with antiphospholipid syndrome compared with systemic lupus erythematosus without aPL and healthy controls at pre-treatment sites.

**Methods:** We examined 219 people divided in three groups – APS (136), SLE, <sup>42</sup> healthy controls.<sup>41</sup>

We performed an ultrasound examination of the carotid arteries, measuring intima-media thickness as well and evaluate the vessel wall for atherosclerotic plaques.

We performed calcium score on the coronary arteries, aorta and aortic valve as well.

**Results:** Between our groups we do not find statistically significant difference for BMI.

Comparative analysis for LDL-cholesterol showed higher APS median values (3.13 mmol/L) compared to other groups. Using the Kruskal-Wallis test, we have a statistically significant result for a direct correlation with the antiphospholipid syndrome ( $p=0.001$ ). Patients with APS shows higher levels for LDL.

With the Kruskal-Wallis analysis, we found a statistically significant difference in IMT between the study groups for left ( $p=0.005$ ) and right ( $p=0.014$ ) carotid arteries.

With Mann-Whitney analysis, we do not detect statistically significant differences in IMT values between patients with primary antiphospholipid syndrome and those with secondary.

We investigated the frequency distribution of atherosclerotic plaques in individuals in the groups. In the right carotid artery, plaque was found in 18 (31.6%) patients with APS, 3 (7.3%) cases were recorded in healthy controls, and in the SLE group there were no reported cases. We establish a statistically significant correlation of carotid plaques in APS patients ( $p\leq 0.001$ ).

In our study group of patients with APS is characterised by the highest incidence of positive CaScore, and its maximum values are significantly higher than the other two groups. The maximum Agatston score for patients with antiphospholipid syndrome is 908 HU, with SLE being 2.1 HU, with healthy controls – 233HU.

We investigate the levels of anti-ox LDL antibodies and we found that there is a correlation between the levels of aPL and anti-oxLDL.

**Conclusions:** The conclusion from our study is that the aPL could be considered for independent risk factor for accelerated atherosclerosis. The aPL are responsible for dyslipidemia in some cases blocking the transport molecules like  $\beta$ 2GPI.

### FRI0382 A STUDY OF MCP1 AND LIPOCALIN AS URINARY BIOMARKERS IN LUPUS NEPHRITIS

*R. Ramamoorthy, T.N. Tamilselvam, B. Kumar. Institute of Rheumatology, Madras Medical College, Chennai, India*

**Background:** Currently, major efforts have been undertaken to identify biomarkers that can predict impending lupus renal flare, development of chronic kidney disease or reflect renal histology at the time of the flare.

**Objectives:** This study aims to assess the correlation of urinary biomarkers MCP1 and NGAL with the disease activity in lupus nephritis.

**Methods:** This was a prospective study conducted in a tertiary care centre. 60 patients with SLE were recruited. They were divided into 3 groups, one with Active Lupus Nephritis ( $n=22$ ), another with Inactive Lupus Nephritis ( $n=20$ ) and a third formed of SLE patients with no renal involvement ( $n=18$ ). For comparison another group of age and sex matched controls was taken ( $n=20$ ). Disease activity was correlated with disease activity indices, baseline characteristics and biopsy. Urinary MCP1 and NGAL were measured. Statistical analysis using SPSS11.5 was

done to find the correlation between levels of urinary biomarkers and disease activity.

**Results:** In patients with active LN, both UMCP1/Cr and UNGAL/Cr were significantly elevated (92.78, 76.11 pg/ml,  $p<0.001$ ). In both control group and SLE without renal involvement the values of UMCP1/Cr and UNGAL/Cr were normal (24.44, 22.22 pg/ml in control and 24.3, 22.80 pg/ml in SLE without renal involvement). In patients with inactive LN the values of UMCP1/Cr and UNGAL/Cr were observed to be significantly higher than control (44.18, 38.45 pg/ml,  $p<0.005$ ) and lower than those of active LN. Values of UMCP1/Cr and UNGAL/Cr were found to be in close correlation with mean rSLEDAI scores of active LN<sup>10</sup> and inactive LN (3.6).

**Conclusions:** Levels of urinary biomarkers UMCP1 and UNGAL were significantly elevated in active lupus nephritis and found to have excellent correlation with disease activity index and rSLEDAI scores.

### FRI0383 CHANGES IN WHITE MATTER MICROSTRUCTURE CORRELATE WITH SF-36 MENTAL COMPONENT SUBSCORE IN INFLAMMATORY NPSLE

*R.C. Monahan<sup>1</sup>, L. Beaat- van de Voorde<sup>1</sup>, C. Magro-Checa<sup>1</sup>, T. Huizinga<sup>1</sup>, H. Middelkoop<sup>2</sup>, M. van Buchem<sup>3</sup>, I. Ronen<sup>3</sup>, A. Kaptein<sup>4</sup>, G. Steup-Beekman<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Neurology; <sup>3</sup>Radiology; <sup>4</sup>Psychiatry, Leiden University Medical Center, Leiden, Netherlands*

**Background:** The diagnosis and treatment of neuropsychiatric systemic lupus erythematosus (NPSLE) is challenging due to the lack of a diagnostic gold standard and controlled trials. Immunosuppressive therapy is prescribed for immune-mediated NPSLE manifestations, despite little evidence supporting its effectiveness. There is increasing evidence for the value of magnetization transfer imaging (MTI) in NPSLE. Recent research has demonstrated that white matter (WM) magnetic transfer ratio histogram peak height (MTR-HPH), a derived-MTI index, is a valuable radiological biomarker for the diagnosis and follow-up in inflammatory NPSLE.<sup>1</sup> It remains unknown whether the changes in WM MTR-HPH also correlate with the change in health-related quality of life (QoL) in these patients.

**Objectives:** To analyse the correlation between change in WM MTR-HPH and change in QoL in different subsets of NPSLE (inflammatory, ischaemic, non-NPSLE).

**Methods:** Patients that visited the Leiden University Medical Centre (LUMC) NPSLE clinic between 2007 and 2015 were included in this study. The attribution process of NP events to SLE and one of its underlying pathogenic mechanisms (ischaemic or inflammatory) was established by multidisciplinary consensus. All patients underwent MRI examination at two different time points and filled in the Short-Form 36 (SF-36). Summary scores were deducted from the SF-36, leading to a Physical Component subscore (PCS) and a Mental Component subscore (MCS) for QoL. Spearman rank correlation coefficient (SR) was used to correlate WM MTR-HPH and the overall difference in change between visits in MCS and PCS. Data was analysed per patient and per event.

**Results:** A total of 15 patients (mean age 39.5 $\pm$ 14.1 years, 93% female) were included. Thirty-one NPSLE events were present, of which 68% were inflammatory, 13% ischaemic and 19% non-NPSLE events. Average time between visits was 2.9 $\pm$ 1.5 years. The per patient analysis showed statistical significant correlation between WM MTR-HPH and MCS change (SR=0.62;  $p=0.01$ ) and no effect on PCS change (SR=0.09;  $p=0.76$ ). The per event analysis showed a significant correlation between change in WM MTR-HPH and MCS in inflammatory events (SR=0.56;  $p=0.01$ ), but not in ischaemic ( $p=0.20$ ) or non-NPSLE events ( $p=0.65$ ). No correlation was observed between change in WM MTR-HPH and PCS in any of the subsets ( $p=0.21$ ,  $p=0.40$  and  $p=0.91$  respectively).

**Conclusions:** We are the first to demonstrate a correlation between a radiological biomarker and change in the mental component of QoL in inflammatory NPSLE patients. Our study supplies evidence for the use of immunosuppressive therapy in inflammatory NPSLE and supports the use of this radiological biomarker as an outcome measure for future trials in NPSLE.

**FRI0384** PRIMARY SJÖGREN'S SYNDROME STRATIFIED BASED ON THE SEVERITY OF PATIENT-REPORTED FATIGUE

S. Gandolfo, E. Doriguzzi Breatta, C. Fabro, S. Zandonella Callegher, L. Quartuccio, S. De Vita. *Clinic of Rheumatology, University Hospital of Udine, Udine, Italy*

**Background:** fatigue is one of the most common symptoms reported by patients affected by primary Sjögren's syndrome (pSS), and a major contributor to impaired quality of life.

**Objectives:** to analyse the clinical, serological and histological features of pSS patients stratified according to the severity of their self-reported fatigue.

**Methods:** among pSS patients undergoing clinical evaluation in our Sjögren's Clinic in a six-months period (January-June 2017), 86 consecutive unselected patients, fulfilling the latest ACR/EULAR pSS classification criteria, accepted to report their degree of fatigue on a 10 cm VAS (range 0–100) and to complete the ESSPRI questionnaire. Four subgroups of fatigue severity were defined, as previously published<sup>1</sup>: no fatigue (VAS=0); low fatigue (VAS=1–24); moderate fatigue (VAS=25–74); high fatigue (VAS=75–100). For each subgroup demographic, serological, histological features and ESSDAI score were collected, as well as the prevalence of pSS-related lymphoma, fibromyalgia (FM), autoimmune thyroiditis, and anaemia.

**Results:** fatigue was reported by the 87.2% (n=75) of pSS patients, distributed in subgroups as following: 25.3% (n=19) with low fatigue, 58.7% (n=44) with moderate fatigue and 16% (n=12) with high fatigue. Lymphoma was significantly (p=0.0133) more frequent in the pSS subgroup with high fatigue (33.4%, by considering active lymphoma cases; 50%, by considering also the cases with lymphoma in remission). FM patients were a minority (4.7% ; n=4), and never complained of high fatigue, all of them reporting moderate fatigue. A significant correlation was finally found between fatigue severity and ESSPRI (p<0.0001), but not with ESSDAI (p=0.31). No significant age or sex difference was observed between subgroups. Also autoimmune thyroiditis, anaemia, anti-SSA and/or anti-SSB positivity, rheumatoid factor positivity, and cryoglobulinemia showed no significant difference between subgroups.

**Conclusions:** when fatigue is better stratified in pSS, it appears that it is usually moderate or severe, rather than mild. Furthermore, it is unrelated to FM. Overall, fatigue appears as a consequence of pSS itself. Of note, severe fatigue was related in this study with the most important complication influencing patient survival in pSS, i.e., lymphoma. Further studies are needed to disclose the pathogenetic events leading to fatigue in pSS, and investigation of lymphoma in pSS might be also helpful to this end.

**FRI0385** CLINICAL CHARACTERISTIC FEATURES OF BRAINSTEM ENCEPHALITIS IN NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

S. Hirohata<sup>1</sup>, Y. Matsueda<sup>1</sup>, Y. Arinuma<sup>1</sup>, H. Kikuchi<sup>2</sup>. <sup>1</sup>KITASATO UNIVERSITY SCHOOL OF MEDICINE, Kanagawa; <sup>2</sup>Teikyo University School of Medicine, Tokyo, Japan

**Background:** Neuropsychiatric manifestation in systemic lupus erythematosus (NPSLE) is one of the most serious complications of the disease. The American College of Rheumatology (ACR) developed standardised nomenclature and case definitions for neuropsychiatric involvement in SLE (NPSLE) in 1999. Although myelopathy is included in the ACR nomenclature, no space is provided for the brainstem encephalitis. Moreover, it is still unclear whether the brainstem encephalitis is an independent clinical entity in NPSLE.

**Objectives:** The present study was designed in order to disclose the clinical characteristic features of the brainstem encephalitis in NPSLE.

**Methods:** We prospectively collected the patients who presented brainstem lesions from 2005 to 2015. The diagnosis of the brainstem encephalitis was made by the elevation of cerebrospinal fluid (CSF) IL-6, Magnetic Resonance Imaging and response to steroid. Serum autoantibodies, including anti-ribosomal P protein antibodies (anti-P), anti-NMDA receptor NR2 antibodies (anti-NR2), anti-Sm antibodies and anti-aquaporin 4 antibodies (anti-AQP4) and anti-cardiolipin antibodies (anti-CL), were measured by ELISA.

**Results:** Seven patients presented the brainstem encephalitis during the period of 10 years. All the patients showed the elevation of CSF IL-6 (8.3–2716 pg/ml, median 377 pg/ml), whereas CSF cell count was elevated in 6 patients. The most common clinical symptoms were headache (4 patients), vertigo (3patients) and consciousness disturbance (3 patients). All the patients showed high intensity lesions in FLAIR images on MRI. Notably, 5 of the 7 patients also showed the high intensities periventricular regions, including cerebral aqueduct and the 4th ventricle (figure 1). Anti-NR2 and anti-P were positive in 7 patients and 6 patients, respectively. By contrast, anti-CL, anti-Sm and anti-AQP4 were positive in 4 patients, 3 patients and 1 patient, respectively. Six patients recovered after steroid therapy, while 1 patient died due to severe brainstem damages at the onset.

**Cerebral aqueduct**

**The 4th ventricle**

**Conclusions:** These results indicate that the brainstem encephalitis is an independent clinical entity in NPSLE, characterised by reversible high intensity lesions, especially in periventricular areas. Moreover, the data demonstrate that anti-AQP4-related neuromyelitis optica disorder is a minor population within the brainstem encephalitis. By contrast, it is suggested that anti-NR2 and anti-P might play an important role in the pathogenesis of the brainstem encephalitis.

**FRI0386** WORK DISABILITY AND QUALITY OF LIFE AMONG MULTI-ETHNIC MALAYSIAN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS

S.S. Shaharir, F. Abu Bakar, M.S. Mohamed Said, R. Mohd. *Internal Medicine, National University of Malaysia Medical Centre, Bandar Tun Razak, Malaysia*

**Background:** Patients with Systemic Lupus Erythematosus (SLE) are at risk of work disability due to the substantial impact of the disease towards their physical and mental health.

**Objectives:** To study the prevalence of work disability (WD) and unemployment rate among SLE patients, and their associations with the quality of life (QOL) in National University of Malaysia Medical Centre (UKMMC)

**Methods:** This was a cross-sectional study which recruited consecutive SLE patients who attended the Nephrology and Rheumatology clinic at Universiti Kebangsaan Malaysia Medical Centre (UKMMC) from March 2017 to July 2017. Information on their current and past employment history were obtained from a customised questionnaire and WD was defined as unemployment or an inability to do paid work due to illness at the time of study or at any time after the diagnosis of SLE being made. The disease characteristics, disease activity and damage were determined from the medical records. The quality of life was measured using SF-36 questionnaires. Statistical analyses were subsequently performed to determine the factors associated with WD. This study was approved by the UKMMC ethics research committee (FF FF-2017–109).

**Results:** A total of 197 patients were recruited, and their median age was 37 (32 to 47) years with median disease duration of 12 (8 to 17) years. Majority of them were Malays (n=116, 58.9%), followed by Chinese (n=69, 35%), Indians (n=8,

4.1%) and others (n=4, 2.0%). The prevalence of work disability was 35%(n=69) and the onset of WD was 4 (IQR:1 to 9) years after SLE diagnosis. WD was associated with older age, lower education level, more frequent disease flare, longer disease duration, higher SLICC ACR Damage Index, active disease (SLEDAI 2K and BILAG 2004 and had major organ involvement (lupus nephritis, haematological and neuropsychiatric), all p<0.05. Patients who received plasmapheresis, intravenous methylprednisolone, intravenous immunoglobulin, Mycophenolate Mofetil and calcineurin inhibitors were also associated with WD. Patients with work disability also had significantly impaired QOL with lower SF 36 scores. On multivariate logistic regression analysis, the independent predictors of WD were lower education level, being married and involvement of lupus nephritis, haematological and neuropsychiatric lupus (NPSLE).

**Conclusions:** More than one third of SLE patients had experienced work disability. Lower education level, being married and major organ involvement were the independent predictors for work disability. A larger prospective study is warranted to further delineate the risk factors.

#### FRI0387 FACTORS ASSOCIATED WITH OSTEOPOROSIS AND FRACTURE IN PATIENTS WITH SJÖGREN PRIMARY SYNDROME

T. Salman Monte<sup>1</sup>, V. Torrente-Segarra<sup>2</sup>, C. Sanchez-Piedra<sup>3</sup>, M. Fernández Castro<sup>4</sup>, J.L. Andreu<sup>5</sup>, A. Olivé<sup>6</sup>, J. Rosas<sup>7</sup>, V. Martínez Taboada<sup>8</sup> on behalf of SJOGRENSER project (GEEAS-SER). <sup>1</sup>Rheumatology, Parc de Salut Mar/IMM. Barcelona; <sup>2</sup>Rheumatology, H.de L'Hospitalet, Barcelona; <sup>3</sup>Unidad de Investigación de la SER. Madrid; <sup>4</sup>Rheumatology, H. Infanta Sofía. Madrid; <sup>5</sup>Rheumatology, H. Puerta de Hierro, Madrid; <sup>6</sup>Rheumatology, H. Germans Trias i Pujol, Barcelona; <sup>7</sup>Rheumatology, H. Marina Baixa, Alicante; <sup>8</sup>Rheumatology, H. Marqués de Valdecilla, Santander, Spain

**Background:** Primary Sjögren's syndrome (SSp) is a systemic autoimmune disease characterised by exocrine gland affectation and multisystem involvement. In addition to the systemic inflammatory affectation, patients with pSS have additional risk factors to develop osteoporosis (OP) and its major complication, osteoporotic fracture.

**Objectives:** The aim of the study is to determine the sociodemographic and clinical factors of pSS associated with the presence of OP and osteoporotic fracture in patients with pSS from the SJOGRENSER registry.

**Methods:** SJOGRENSER is a descriptive, cross-sectional and multicenter study of patients with pSS classified according to European-American consensus criteria. Patients attended in consultations of 33 Spanish rheumatology services were randomly included. Both the medical history and the medical interview were used to obtain the data. Epidemiological, clinical, serological and complications were collected. The continuous and categorical variables were analysed by means, medians and frequencies, with their respective deviations and interquartile ranges (p25-p75). Bivariate and multivariate analyses were carried out using a binomial logistic regression to study the factors associated with osteoporosis and osteoporotic fracture in pSS.

**Results:** In the SJOGRENSER registry, 437 patients were included (95% women, with a median age of 58.63 (50.02–67.98) years). The prevalence of OP in the cohort was 18.54% (81 patients). The prevalence of OP in men (n=21) was 19%, 2 men in the age group of 51–64 years and 2 in the group of >64 years. Three hundred of the women in the registry were menopausal (76.4%); a total of 67/300 women with menopause had OP (15%). A total of 37 osteoporotic fractures (8.5%) were recorded in the cohort. Factors associated with OP in women with SSp in the bivariate analysis were: age (60.5% in the group of >64 years, 28% in the group of 51–64 years and 2.6% in the group ≤50 years, p<0.001), the time course of the disease (11.35 (SD 7.95) vs 7.8 (SD 6.14), p<0.001), the age of menopause (47(SD 7.29) vs 48.11 (SD 5.67), p=0.020), the ESSDAI (6 (DS 7) vs 4 (DS 5), p=0.020), and presence of anti-La (77.6% vs 64.7, p=0.030). In the multivariate analysis, there was an association between OP and age in the 51–64 age group, OR 9.993 (95% CI, 2.301–43.399, p=0.002), age >64 years, OR 20.610 (CI 95% 4.679–90.774, p<0.001) and time course of the disease, OR 1.046 (95% CI 1.008–1.085, p=0.017). Similarly, an association was found between the fracture and age in the 51–64 age group, OR 5.068 (95% CI, 1.117–22.995, p=0.035), age >64 years, OR 7.674 (95% CI 1.675–35.151, p<0.009), the time course of the

disease, OR 1.049 (95% CI 1.003–1.097, p<0.036) and the ESSDAI score, OR 1.080 (95% CI, 1.029–1.134, p=0.002).

**Conclusions:** Patients with pSS have a considerable prevalence of osteoporosis and osteoporotic fracture. Age and time of evolution were factors associated with the development of OP, and similarly, age, time of evolution of the disease and ESSDAI were factors associated with the development of fracture in patients with pSS.

#### FRI0388 RISK OF PREVENTABLE ADMISSIONS AMONG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS PRIOR AND SUBSEQUENT DIAGNOSIS

T.-T. Chung<sup>1</sup>, C.-F. Kuo<sup>1,2</sup>, J.-S. Chen<sup>1</sup>, M.-J. Chiou<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China; <sup>2</sup>Division of Rheumatology, Orthopaedics and Dermatology, University of Nottingham, Nottingham, UK

**Background:** Preventable hospitalizations for specific conditions are considered preventable because appropriate outpatient care should potentially avoid hospitalisation for these conditions. Although not all of the hospitalizations can be prevented, to identify the rate of preventable hospitalizations among patients with systemic lupus erythematosus (SLE) can help us to understand the excess potential preventable hospitalizations and to provide an action to the SLE patients.

**Objectives:** To investigate the risk of preventable hospitalisation in patients with SLE before and after initial diagnosis of the disease.

**Methods:** We identified 4483 adult patients with incident SLE between 2005 and 2009 using the Taiwan National Health Insurance Database. Each SLE patients were matched to five controls without SLE during the same study period, by age and sex. The index date was the first date of SLE diagnosis and their matched controls. We estimated the incidence and incidence rate ratios (IRRs) of preventable hospitalisation by conditional Poisson regression, adjusted for age, sex, Elixhauser Comorbidity Index, number of outpatient visits and hospitalizations 1-y prior to index date, residence urbanisation, income levels, occupation and the number of physicians at the patients' residence.

**Results:** The overall incidence of preventable hospitalisation was 1.88 (95% CI, 1.74 to 2.03) per 1000 person-months among SLE patients and 0.53 (95% CI, 0.49 to 0.56) per 1000 person-months among controls, giving an adjusted IRR of 3.57 (95% CI, 3.25 to 3.93). The IRRs especially higher in heart failure, bacterial pneumonia and urinary tract infection and the respective estimates were 2.85 (95% CI, 2.14 to 3.80), 4.67 (95% CI, 4.03 to 5.42) and 3.84 (95% CI, 3.35 to 4.41).

**Conclusions:** Risk of preventable hospitalisation is higher in patients with SLE.

**Disclosure of Interest:** None declared

#### FRI0389 BIOMARKERS AS DISEASE ACTIVITY INDICANTS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

V. Zivkovic<sup>1</sup>, T. Cvetkovic<sup>2</sup>, B. Mitic<sup>3</sup>, B. Stamenkovic<sup>1</sup>, S. Stojanovic<sup>1</sup>, M. Stojanovic<sup>4</sup>, B. Radovanovic Dinic<sup>5</sup>. <sup>1</sup>Institute for Treatment and Rehabilitation "Niska Banja"; <sup>2</sup>Clinic of Nephrology, Clinical centre; <sup>3</sup>Clinic of Nephrology, Clinical Centre; <sup>4</sup>Faculty of Medicine University of Nis; <sup>5</sup>Clinic of Gastroenterology and Hepatology, Clinical Centre, Nis, Serbia

**Background:** In recent years, the search has been going on for the biomarkers potentially useful in the follow-up of patients with systemic lupus erythematosus (SLE).

**Objectives:** The aim of our study was to establish the importance of various immunological and biological parameters as disease activity indicants in SLE.

**Methods:** The study involved 85 SLE patients in whom disease activity assessment was performed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). In addition to standard anti-dsDNA antibodies and C3 complement component, anti-nucleosome and anti-C1q antibodies and monocyte chemoattractant protein-1 (MCP-1) were determined in the serum and urine. The antibodies were determined using the ELISA test, while serum and urine MCP1 was determined using the sandwich enzyme immunoassay in accordance with the instructions by the manufacturer, R and D Systems, Inc. Minneapolis (USA).

**Results:** The studied group consisted of 78 women and 7 men, with the mean age of 45.27±9.71 years and average disease duration of 10.37±7.99 years. Univariate linear regression analysis showed that all of the examined parameters with the exception of C3 complement demonstrated a statistically significant impact on the SLEDAI values (for anti-dsDNA p=0.033, anti-nucleosome p=0.002, anti-C1q antibodies p=0.005, serum MCP1 p=0.006, urinary MCP1

$p < 0.001$ ). The SLEDAI value rose with increasing values of all the parameters except C3 complement. Using the standard multiple regression analysis, the impact of anti-dsDNA, anti-nukleosome, anti-C1q antibodies, complement C3, and serum and urinary MCP1 on SLEDAI was evaluated. The studied model was able to explain 26.60% of disease activity index variance (corrected  $r^2 = 0.246$ ,  $F = 4.755$ ,  $p < 0.001$ ). As the statistically significant risk factors, serum MCP1 (Beta=0.257,  $p = 0.040$ ) and urinary MCP1 (Beta=0.326,  $p = 0.008$ ) could be singled out. Serum MCP1 increased SLEDAI values and explains their variance with 4.80%. The impact of urinary MCP1 was stronger. SLEDAI values increased with elevated urinary MCP1. This parameter was able to explain 8.10% of SLEDAI variance.

**Conclusions:** The study showed that anti-dsDNA, anti-nukleosome and anti-C1q antibodies were associated with SLE disease activity, but the association was strongest with serum and urinary MCP1.

#### FRI0390 IMPAIRED OVARIAN RESERVE IN PATIENTS AFFECTED BY SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE-CONTROL STUDY

V.A. Pacucci<sup>1</sup>, F. Ceccarelli<sup>1</sup>, V. D'Ambrosio<sup>2</sup>, T. Colasanti<sup>1</sup>, C. Aliberti<sup>2</sup>, F. R. Spinelli<sup>1</sup>, C. Perricone<sup>1</sup>, S. Truglia<sup>1</sup>, F. Miranda<sup>1</sup>, C. Alessandri<sup>1</sup>, G. Perrone<sup>2</sup>, A. Giancotti<sup>2</sup>, G. Valesini<sup>1</sup>, F. Conti<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Scienze Ginecologiche Ostetriche e Scienze Urologiche, Policlinico Umberto I Sapienza University of Rome, Rome, Italy

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease showing a strong predilection for reproductive age women (female/male ratio 9:1). This is in part due to the effects exerted by sexual hormones on immune system. The term ovarian reserve has been used traditionally to describe the number and quality of oocytes in women. This is assessed by detection of FSH, AMH and Estradiol (E2) and by ultrasonographic (US) evaluation of antral follicular bilateral count (AFC), as recommended by the Society of Reproductive Medicine. The evaluation of AFC should be conducted in the early follicular phase of the menstrual cycle. An AFC lower than 3–4 follicles is highly specific (73%–97%) of poor ovarian function. Data from the literature about ovarian reserve in SLE showed contrasting results.

**Objectives:** We aimed at assessing ovarian reserve in a SLE cohort, by US determination of AFC and by analysing serum levels of AMH, FSH, E2.

**Methods:** In this case control study, we enrolled consecutive SLE patients in reproductive age (<45 years), fulfilled the 1997 ACR revised criteria, not treated by gonadotoxic chemotherapy agents. Moreover, we enrolled age-matched healthy women (HS). Clinical and laboratory data were collected in a standardised, computerised and electronically filled form, including demographics, past medical history with date of diagnosis, autoantibody profile, comorbidities, previous and concomitant treatments. We assessed the disease activity and chronic damage by using SLEDAI-2K and SDI, respectively. In order to assess AFC, patients and HS underwent to transvaginal US evaluation by a single operator (Samsung Elite USS-WS8EL4U/WR) between the 2nd and 7th day of the menstrual cycle. At the same day of the US assessment, we obtained sample of peripheral venous blood from patients and HS to evaluate FSH, AMH and E2 dosages (ELISA kit CLOUD-CLONE Corp., My Biosource, USA).

**Results:** Nineteen SLE patients (median age 35 years, IQR 6.0; mean disease duration  $\pm$ SD 12.2 $\pm$ 7.7 months) and 8 HS were evaluated. A mean  $\pm$ SD SLEDAI-2K of 2.5 $\pm$ 1.5 was registered; 3 patients had a chronic damage (SDI=1). FSH values were significantly higher in SLE patients compared with HS [SLE: median (IQR) 35;<sup>6</sup> HS: median (IQR) 3 (1.5);  $p = 0.01$ ]. Concerning the AFC, we found significantly lower values in SLE patients than in HS [SLE: median (IQR) 13;<sup>11</sup> HS: median (IQR) 22.5 (10.5);  $p = 0.03$ ]. The Spearman analysis demonstrated a negative correlation between AFC and BMI ( $r = -0.5$ ,  $p = 0.02$ ), FSH ( $r = -0.5$ ,  $p = 0.04$ ) and age ( $r = -0.5$ ,  $p = 0.02$ ) (figure 1).

**Abstract FRI0390 – Figure 1**

**AFC:** antral follicular bilateral count; **BMI:** body mass index; **FSH:** follicle-stimulating hormone

**Conclusions:** The preservation of fertility is a crucial point in SLE patients and the evaluation of ovarian reserve should be included in the patients' management in order to assess ovarian function. Moving from these premises, in the present study we demonstrated an impaired ovarian reserve in SLE patients in terms of AFC values and a negative correlation with hormonal and some demographic features.

#### FRI0391 THE RELATIONSHIP BETWEEN OESTROGEN RECEPTORS AND HYPERURICEMIA IN YOUNG FEMALE SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

H.-J. Liu<sup>1,2</sup>, L. Dai<sup>3</sup>, X.-Y. Cai<sup>4</sup>, J.-D. Ma<sup>3</sup>, Y.-Q. Mo<sup>3</sup>. <sup>1</sup>Department of Rheumatology, PanYu central Hospital, <sup>2</sup>Department of Rheumatology, Jinan University, <sup>3</sup>Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, <sup>4</sup>Department of Rheumatology, The Second Affiliated Hospital, South China University of Technology, Guangzhou, China

**Background:** We have found that the incidence of hyperuricemia of young female systemic lupus erythematosus (SLE) patients was higher than that of healthy young women<sup>[1]</sup>. Why the high level of oestrogen didn't show protection in uric acid (UA) level of fertile female SLE patients? There few reports yet.

**Objectives:** To investigate the relationship between UA level and the levels of oestrogen, oestrogen receptors, antibodies to oestrogen receptors.

**Methods:** This was a cross-sectional study of 62 fertile female SLE patients that were divided into two groups including a high UA group (n=27) and a normal UA group (n=35). Serum UA levels, kidney index, SLE disease indicators and levels of oestrogen, oestrogen receptors, antibodies to oestrogen receptors were determined. Multiple linear regression analysis was applied to analyse the associations of UA levels with clinical features and levels of oestrogen, oestrogen receptors and antibodies to oestrogen receptors.

**Results:** 1. The mean ages of the two groups were (28.62 $\pm$ 7.89) years and (28.82 $\pm$ 8.28) years respectively, with no significantly different ( $t = 0.096$ ,  $p = 0.924$ ). There was no SLE patients manifested renal failure (CRE level higher than 120  $\mu$ mol/l). All the SLE patients were at the onset of disease.

2. The mean UA levels of the high UA group and the normal UA group were (531.74 $\pm$ 134.05)  $\mu$ mol/L and (238.86 $\pm$ 61.32)  $\mu$ mol/L respectively, with significant difference ( $t = -11.48$ ,  $p < 0.001$ ).

3. In the high UA group, the levels of CRE, LDL, cystatin, urine protein and were dramatically higher than those were found in the normal UA group ( $t = -3.617$ ,  $-3.319$ ,  $-2.782$ ,  $-2.979$ , and  $p = 0.001$ ,  $0.002$ ,  $0.007$ ,  $0.004$ , respectively), and oestrogen receptor  $\beta$  level were significantly lower than that of the normal group ( $t = 2.138$ ,  $p = 0.037$ ). The positive rate of urine blood of the high UA group were significantly higher than that of the normal UA subgroup ( $\chi^2 = 6.213$ ,  $p = 0.012$ ).

4. Multiple linear regression analysis revealed there were significant relationships between UA level and CRE, oestrogen receptor  $\beta$ , and urine protein, urine blood.

**Abstract FRI0391 – Table 1.** Independently-Associated Clinical Biomarkers with Serological UA levels in fertile SLE female patients

Variable	Unstandardized Coefficients	Standardised Coefficients	t	P	95% CI
	B	SEM			
CRE	1.145	0.462 0.263	2.478	0.016	0.223–2.068
oestrogen receptor $\beta$ urine protein	-2.758	0.933 0.239	2.299	0.033	3.132–44.38
UBLD	2.906	1.042 0.286	2.788	0.019	0.825–4.986
Constant	56.426	28.058 0.216	2.011	0.048	0.422–112.43
	177.283	42.179	4.203	0.001	93.09–216.47

**Conclusions:** Hyperuricemia in young female SLE patients indicated the renal damage, and low level of oestrogen receptor  $\beta$  may contribute to hyperuricemia.

### FRI0392 THE RELATIONSHIP BETWEEN SALIVARY FLOW RATES, ORAL HEALTH ASSESSMENT AND ULTRASONOGRAPHIC SCORING OF THE MAJOR SALIVARY GLANDS IN SJOGREN SYNDROME

Y. Yalçinkaya<sup>1</sup>, G. Mumcu<sup>2</sup>, Z. Erturk<sup>1</sup>, A.U. Unal<sup>1</sup>, P. Atagunduz<sup>1</sup>, H. Direskeneli<sup>1</sup>, N. Inanc<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine; <sup>2</sup>University of Health Sciences, Istanbul, Turkey

**Background:** Salivary flow rates (SFR) and oral health were known to be frequently impaired in Sjogren's syndrome (SjS) due to chronic inflammation and destruction of the salivary glands. Ultrasonography (USG) of major salivary glands (SG-USG) is a non-invasive widely used tool to evaluate salivary glands in SjS.

**Objectives:** The aim of the study was to assess the relationships between SFRs, oral health and USG changes of major salivary glands in patients with primary SjS.

**Methods:** Fifty-nine SjS patients (F/M:57/2) with the mean age of 52.2±11.5 years. The duration of follow-up period of 9.±7.1 years fulfilling ACR-EULAR classification criteria (2002) were included. Major salivary glands (bilateral parotis and submandibular glands) were scored according to two different scoring systems which are Hocevar A.(0–48) and Milic VD. (0–12). Oral health was assessed by indices. Measurements of whole unstimulated and stimulated SFRs were carried out in patients between 9 a.m. and 10 a.m in the morning. Oral health related quality of life (OHRQoL) as a patient reported outcome measure was evaluated by using Oral health impact profile (OHIP-14). High scores indicated poor OHRQoL status. Pathologic findings in oral health (GM) and USG images (NI) were evaluated by two authors as double-blind.

**Results:** Unstimulated SFR (0.2±0.2 ml/min) was correlated with stimulated SFR (1.1±0.7 ml/min) in the whole group ( $r=0.8$   $p=0.000$ ). Moderate correlations were seen between unstimulated and stimulated whole SFRs and scores of hypoechoic areas in bilateral parotid and submandibular glands ( $p<0.05$ ). Scores of Hocevar, Milic and OHIP-14 were found to be poor in patients with unstimulated SFR  $\leq 0.1$  ml/minute compared to those of others ( $p<0.05$ ) (table 1). In addition, the number of extracted teeth (8,6±7,5) was correlated with the number of carious teeth ( $r=-0.3$ ,  $p=0.036$ ).

**Abstract FRI0392 – Table 1.** Salivary Flow Rates, OHIP-14 and SG-USG Scores of SjS Patients

	Salivary Flow Rates (SFR)		P
	$\leq 0.1$ ml/minute (n=17)	$>0.1$ ml/minute (n=39)	
Hocevar-total score	24,8±8,9	16,4±5,8	P=0,003
Milic-total score	7,4±2,2	4,9±2,3	P=0,001
OHIP-14 score	36,4±15,2	15,1±8,3	P=0,001

**Conclusions:** Unstimulated and stimulated SFRs were found correlated with the structural changes of major salivary glands. Tooth loss and poor OHRQoL were shown in patients due to reduced salivary outputs. USG images of salivary glands

could give insight to physicians about oral health and OHRQoL as outcome measure in patients with SjS.

### FRI0393 MATERNAL AND FETAL OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS

I.Y. Yii<sup>1</sup>, L. Yang<sup>2</sup>, H.K. Tan<sup>2</sup>, L.K. Tan<sup>2</sup>, J. Thumboo<sup>1</sup>, Y.J. Poh<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Obstetrics and gynaecology, Singapore General Hospital, Singapore, Singapore

**Background:** Systemic Lupus Erythematosus (SLE) is associated with an increased risk of adverse pregnancy outcomes.

**Objectives:** We aim to evaluate the maternal and fetal outcomes in SLE pregnancies in a single tertiary referral centre.

**Methods:** We retrospectively analysed 75 pregnancies in 45 patients with SLE over a 16 year period from 2000 to 2016. All patients fulfilled the 1997 American College of Rheumatology (ACR) criteria or the Systemic Lupus International Collaborating Clinics (SLICC) criteria for diagnosis of SLE.

**Results:** In our multi-ethnic cohort, there were 65% Chinese, 23% Malays and 7% Indians. The mean age was 32 years old and majority (55%) were nulliparous. The mean SLE disease duration was 5.9 years. Baseline SLE manifestations were predominantly haematological (73%), arthritis (71%) and renal (57%). There were 33 pregnancies (44%) with anti-Ro (SS-A) antibody positivity. There were 9 pregnancies (12%) with SLE and antiphospholipid syndrome. In our cohort, the majority of the patients were on prednisolone (76%). Half of the patients (48%) were on hydroxychloroquine or chloroquine and 27% were on azathioprine. In the subgroup of patients with SLE and antiphospholipid syndrome, 67% (6/9 pregnancies) were treated with therapeutic clexane and 33% (3 pregnancies) with the combination of prophylactic clexane and aspirin. The mean SELENA-SLEDAI score at the booking visit was 4.0.

In our cohort, the live birth rate was 75%. More than half of the deliveries were via Caesarean section (57%). There were maternal and fetal complications in 61% of the pregnancies. Pregnancy losses occurred in 16 pregnancies with the majority (87%) being early pregnancy losses that occurred prior to 13 weeks gestation. There were 13 pregnancies (17%) with intrauterine growth restriction and 18 pregnancies (24%) with preterm delivery. In the subgroup of the preterm births, 2 were extremely preterm birth (<28 weeks gestation) and 2 were very preterm birth (28 weeks to <32 weeks gestation). There were no cases of congenital heart block or neonatal lupus. There was one neonatal death.

SLE flares occurred in 25 pregnancies (33%). The most common organ involvement were haematological (44%), renal (40%), mucocutaneous (28%) and arthritis (16%) Pre-eclampsia occurred in 2 pregnancies (2%). There were 3 cases of a first presentation of lupus nephritis in pregnancy. In the subgroup of SLE pregnancies with antiphospholipid syndrome, there were higher SLE flare rates (44%) and more adverse pregnancy outcomes with 3 pregnancies (33%) that resulted in miscarriages, 2 pregnancies (22%) with preterm delivery and one pregnancy (11%) complicated by pre-eclampsia (table 1). There were 7% of pregnancies with a post-partum SLE flare.

**Abstract FRI0393 – Table 1.** Comparison of maternal and fetal outcomes between SLE pregnancies and SLE with antiphospholipid (APS) pregnancies

Adverse pregnancy outcomes	SLE pregnancies (n=75)	SLE with APS pregnancies (n=9)
SLE flares, n(%)	25 (33.33%)	4 (44.44%)
Pre-eclampsia, n(%)	2 (2.67%)	1 (11.1%)
Miscarriages, n(%)	15 (20%)	3 (33.33%)
Early pregnancy loss (<13/40), n(%)	14 (18.67%)	3 (33.33%)
Late pregnancy loss ( $\geq 13/40$ ), n(%)	1 (1.33%)	0
Preterm delivery, n(%)	18 (24%)	2 (22.22%)
Neonatal death, n(%)	1 (1.33%)	1 (11.1%)

**Conclusions:** In our multi-ethnic cohort, more than half of the patients experienced an adverse pregnancy outcome. SLE flares in pregnancy occurred in a third of the cohort with the most common organ manifestation being haematological and renal flares. SLE pregnancies with antiphospholipid syndrome appeared to be associated with a higher risk of SLE flares and adverse pregnancy outcomes.

**FRI0394 THE ROLE OF D-DIMER TEST AS A SCREENING TOOL FOR VENOUS THROMBOEMBOLISM IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AS COMPARED TO MATCHED CONTROL SUBJECTS**

Y.J. Oh, E.H. Park, J.W. Park, Y.W. Song, E.B. Lee. *Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

**Background:** d-dimer test is widely used as a screening tool for venous thromboembolisms (VTE). Meanwhile, d-dimer can increase in various conditions including severe infection, and inflammation. However, it has been rarely reported whether d-dimer test is useful for screening of VTE in systemic lupus erythematosus (SLE) patients.

**Objectives:** We evaluated the role of d-dimer test as a screening tool for VTE in patients with SLE, compared to age-, and sex-matched non-autoimmune disease subjects.

**Methods:** In this retrospective cohort study, a total of 283 SLE patients and 1132 age-, and sex-matched control subjects (those who had no rheumatic diseases) who underwent d-dimer test as a screening test for VTE were enrolled at Seoul National University Hospital between January 2000 and July 2017. VTE was defined to be present when a thromboembolism was proven in imaging studies which included computed tomography, lung perfusion scan or duplex ultrasonography. Predictive value of d-dimer test for VTE was compared between SLE patients and control subjects by calculating area under the curves (AUC) in receiver operating characteristics (ROC) curves of d-dimer test. Finally, the usefulness of d-dimer test was evaluated in different subsets of SLE patients by analysing ROC curves.

**Results:** The mean (SD) age of the 283 SLE patients was 36.8 (13.5) years and that of 1132 control subjects was 38.2 (12.8) years. The mean (SD) plasma level of d-dimer was 2262.1 (3794.5) ng/ml in SLE patients, while it was 1087.5 (5063.1) ng/ml in the control group ( $p < 0.001$ ). The incidence of VTE was significantly higher in SLE patients than the controls (12.7% vs. 5.8%,  $p < 0.001$ ). When the cut-off value of d-dimer test was set to 500 ng/ml, the AUC for VTE was only 0.614 in SLE patients, while it was 0.891 in the control group, suggesting that d-dimer test may not be useful as a screening tool for VTE in SLE patients. When the SLE patients were divided according to the presence of antiphospholipid antibodies (APS Abs), the AUC value for VTE was 0.788 in patients who didn't have APS Abs but it was only 0.556 in patients who had APS Abs.

**Abstract FRI0394 – Figure 1.** ROC curves in control and SLE group (cut-off value of d-dimer = 500 ng/ml)

**Conclusions:** d-dimer test cannot predict VTE in SLE patients as accurately as in general population. In SLE patients, d-dimer's diagnostic capability for VTE is even lower in the presence of APS Abs.

**FRI0395 SLE DISEASE ACTIVITY INDEX GLUCOCORTICOID INDEX (SLEDAI-2KG) IDENTIFIES MORE RESPONDERS THAN SLEDAI-2K**

Z. Touma<sup>1</sup>, D. Gladman<sup>1</sup>, J. Su<sup>2</sup>, N.M. Anderson<sup>2</sup>, M.B. Urowitz<sup>1</sup>. <sup>1</sup>Internal Medicine, Division Of Rheumatology, UNIVERSITY OF TORONTO, <sup>2</sup>Internal Medicine, Division Of Rheumatology, Krembil Research Institute, University Health Network, Toronto, Canada

**Background:** Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K) is one of the most commonly used disease activity indices in clinical practice and research but this index doesn't account for severity within each descriptor. Moreover, in clinical trials, the use of standard of care (SoC), which includes glucocorticoid (GC) often confounds trial results.

We developed and validated a novel lupus disease activity index, SLEDAI-2K GC (SLEDAI-2KG), that describes disease activity while accounting for GC dose. SLEDAI-2KG has the same descriptors as SLEDAI-2K in addition to a new descriptor "GC" with different weight scores based on the dose of GC. Furthermore, SLEDAI-2KG has a low administration burden and a simple scoring system similar to SLEDAI-2K.

**Objectives:** We aimed to compare the performance of SLEDAI-2K and SGI in identifying responders in response to SoC.

**Methods:** Patients have been followed prospectively according to a standard protocol between January 2011 and January 2014, at a single lupus centre, with active disease (SLEDAI-2K ≥ 6), on prednisone ≥ 10 mg/day, and with follow up visits within 5–24 months were studied. Treatment was determined based on the judgment of the treating rheumatologist.

Response to SoC therapy, at first follow up visit, was assessed by SLEDAI-2K and SLEDAI-2KG. Responders were defined based on the decrease in SLEDAI-2K and SGI score by ≥ 4. The performance of SLEDAI-2K and SGI was also compared using different cut-off points; 5, 6 and 7. Descriptive analysis was used.

**Results:** 111 patients met the inclusion criteria of the study and were further analysed. Patients' characteristics are represented in table 1.

SLEDAI-2KG identified more responders at 6 months (94% vs. 84%) and at 12 months (92% vs. 76%) compared to SLEDAI-2K by cut off of 4. SLEDAI-2KG also identified more responders with cut off points 5, 6 and 7 (table 2).

**Abstract FRI0395 – Table 1.** Patient Characteristics

Variables	Total (n=111)
Sex (female)	98 (88.3%)
Age at baseline (mean±SD)	35.75±11.51
SLE duration at baseline (mean±SD)	9.02±7.74
Ethnicity	13 (11.7%)
Asian	23 (20.7%)
Black	51 (45.9%)
Caucasian	24 (21.6%)
Others	
Months from baseline to 1 st follow-up (mean±SD)	7.68±2.95
SLEDAI-2K at baseline (mean±SD)	12.39±6.03
Prednisone dose at baseline (mg/day) (mean±SD)	22.94±14.19
SLEDAI-2KG at baseline (mean±SD)	17.48±6.78
SLEDAI-2K at 1 st follow-up	8.08±6.04
Prednisone dose at 1 st follow-up (mg/day) (mean±SD)	15.23±10.94
SLEDAI-2KG at 1 st follow-up	12.67±6.98

**Abstract FRI0395 – Table 2.** Responders by SLEDAI-2K and SLEDAI2KG in 111 patients

Indices	Percentage of responders at 6 months			Percentage of responders at 12 months		
	≥4	≥5	≥6	≥4	≥5	≥6
SLEDAI-2K	84%	68%	68%	59%	76%	57%
SLEDAI-2KG	94%	88%	83%	79%	92%	80%
Additional Responders	10%	20%	15%	20%	16%	23%

**Conclusions:** The novel index, SLEDAI-2KG, is superior to SLEDAI-2K in identifying responders at 6 and 12 months accounting for steroid dose and thus adjusting for severity within each descriptor of SLEDAI-2K. SLEDAI-2KG has the ability to enhance analyses in clinical trials to differentiate between responders on minimal and moderate/large doses of GC.

## Systemic sclerosis, myositis and related syndromes – etiology, pathogenesis and animal models

### FRI0396 THE ATM KINASE AND PTEN, DRIVE MYOFIBROBLASTS DIFFERENTIATION BY ACTIVATING THE TGFB AUTOCRINE LOOP

S. Xu<sup>1</sup>, I. Papaioannou<sup>1</sup>, M. Ponticos<sup>1</sup>, C. Denton<sup>1</sup>, A. Wells<sup>2</sup>, E. Renzoni<sup>2</sup>, D. Abraham<sup>1</sup>. <sup>1</sup>Centre for Rheumatology and Connective Tissue Diseases, UCL Medical School (Royal Free Campus), London, UK; <sup>2</sup>Interstitial Lung Disease Unit, NHLI, Royal Brompton Hospital/Imperial College, London, UK

**Background:** Pulmonary fibrosis is a major cause of mortality in scleroderma (SSc) and Idiopathic Pulmonary Fibrosis (IPF). Fibrosis is driven by inappropriate myofibroblast differentiation and persistence. Understanding this process, is vital for developing an effective treatment. Angiotensin II, is implicated in fibroblast activation in the heart and kidney, through interactions with growth factors (e.g. EGF and TGFβ).

**Objectives:** We examined the role of Angiotensin II in myofibroblast activation in the lung.

**Methods:** Lung fibroblasts were isolated from SSc, IPF, or control patient lungs (6 each). Fibroblasts were also cultured from PTEN null and wild-type mice. Protein expression after angiotensin II treatment (AngII) was investigated by western blotting. Myofibroblast differentiation and function was assayed through the contraction of 3D collagen gels and scratch migration assays. The signalling pathways involved were dissected using specific inhibitors: PI3-kinase/AKT (wortmannin, LY294002), TGFβ (1d11 neutralising antibody, SB431542 ALK5 inhibitor) Ataxia-Telangiectasia Mutated (ATM – Ku55933), AngII (Losartan).

**Results:** SSc and IPF lung fibroblasts showed increased AKT phosphorylation and suppressed PTEN expression (p<0.05). Their phenotype was more myofibroblast-like, with higher αSMA expression (p<0.05), increased collagen gel contraction (control; 207±14 vs SSc; 93±15 vs IPF 91±21, p<0.05), and enhanced migratory capacity (p<0.05). PTEN-null fibroblasts showed a similar phenotype. AngII treatment activated AKT, suppressed PTEN and induced myofibroblast differentiation in normal lung fibroblasts. In both AngII-treated and PTEN lung fibroblasts AKT activation required the ATM kinase. Inhibition of AKT either with PI3K or ATM inhibitor abrogated these effects. The increased expression of Myofibroblast-related genes after AngII treatment, was also blocked by inhibition of TGFβ with a neutralising antibody or an ALK5 inhibitor. AKT phosphorylation on the other hand was only partially blocked by TGFβ inhibition.

**Conclusions:** Our data demonstrate for the first time that AngII signals via the ATM kinase, which together with PTEN suppression are essential for the activation of AKT by AngII. AngII promotes myofibroblast differentiation, by stimulating the fibroblast TGFβ autocrine loop through AKT. Our data shows that activation of AKT through ATM and PTEN, may serve as the molecular link between pulmonary hypertension and lung fibrosis in fibrotic diseases.

### FRI0397 PECULIAR EXPRESSION OF AUTOPHAGY BIOMARKERS IN NECROTIZING AUTOIMMUNE MYOPATHY MUSCLE

M. Giannini<sup>1</sup>, F. Girolamo<sup>2</sup>, A. Amati<sup>2</sup>, A. Lia<sup>2</sup>, L. Serlenga<sup>3</sup>, D. D'Abbicco<sup>4</sup>, M. Tampoia<sup>5</sup>, F. Iannone<sup>1</sup>. <sup>1</sup>Rheumatology Unit, University of Bari; <sup>2</sup>D.S.M.B.N.O. S. Neurology, Bari; <sup>3</sup>Ospedale L. Bonomo, Andria, BT; <sup>4</sup>Marinaccio General Surgery, Bari; <sup>5</sup>University Clinical Pathology Laboratory, Bari, Italy

**Background:** Immune mediated necrotizing myopathy (IMNM) is a recently recognised pathology within the spectrum of idiopathic inflammatory myopathies (IIMs). Specific autoantibodies and the response to immunosuppressants aid to make the diagnosis and suggest immune-mediated pathogenesis, although histopathological features are not specific for IMNM. Autophagy and ubiquitin-proteasome system are two interacting systems by which dysfunctional cellular components are degraded in the cell. Their dysregulation, in sporadic Inclusion

Body Myositis (sIBM), seems to be responsible for the protein aggregates. The autophagy dysfunction in IMNM was not widely investigated.

**Objectives:** To investigate autophagy marker expression, macrophages localization and accumulation of misfolded proteins in non-necrotic fibres of IMNM muscle in comparison with Dermatomyositis (DM), Polymyositis (PM) and sIBM.

**Methods:** Among 52 IIMs diagnosed from January 2015 to June 2017, we reviewed muscle biopsies and stored sera. Six subjects were included in the IMNM group, characterised by many necrotic muscle fibres, regenerating muscle fibres and no significant inflammation despite of numerous but scattered macrophages removing necrotic muscle fibres. Two patients had anti-signal recognition particle (SRP) autoantibodies, two patients anti-3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR), the others tested negative for specific autoantibodies. All IMNM patients had a positive response to immunosuppressants. Muscle sections were immunolabelled with the following antigens: ubiquitin, autophagy markers LC3b, p62 (a receptor of autophagy), TDP-43 (a marker of ubiquitinated proteic inclusions), SMI31 and SMI310 (Phosphorylated Neurofilaments), CD31 (endothelial cell marker), C5b-9 (membrane attack complex), CD4 (T-helper lymphocytes), CD8 (T-suppressor lymphocytes), CD68 (macrophages), CD20 (B-lymphocytes), CD56 (NK lymphocytes and regenerating muscle fibres), MHC I, MHC II. Quantitative results were compared among IMNM (n=6), DM (n=4), sIBM (n=4), PM (n=5) and healthy controls (n=4).

**Results:** In IMNM, inflammation was mild compared with DM, PM, sIBM, and consisted in sporadic endomysial and/or perivascular cells CD68+. Skeletal muscle fibres (SMFs) containing LC3b+puncta were significantly higher in IMNM and IBMs than in DM or PM. In all IMNM, the greater proportion of LC3b+puncta was localised in CD56+fibres (figure 1), instead, sIBM showed a high number of LC3b+puncta in vacuolated SMFs with low expression of CD56+SMFs. As expected, P62 and SMI31 aggregates were significantly higher in sIBM than in the other IIMs, even if, also in IMNM, there were moderate p62 accumulations and a little proportion of SMFs stained by SMI31. Finally, in IMNM there was the highest number of ubiquitin+SMFs.

**Conclusions:** These findings suggest an involvement of cellular clearance systems in the pathophysiology of IMNM similarly to sIBM. Nevertheless, LC3b+puncta in regenerating fibres can be considered a peculiar biomarker in IMNM. Further studies of larger cohort of patients are needed to better define IMNM.

### FRI0398 SL-401, A NOVEL TARGETED THERAPY DIRECTED TO THE INTERLEUKIN-3 RECEPTOR (CD123), KILLS PLASMACYTOID DENDRITIC CELLS FROM SYSTEMIC SCLEROSIS PATIENTS

M.-D. Ah Kioon<sup>1</sup>, R. Lindsay<sup>2</sup>, J. Chen<sup>2</sup>, J. Gordon<sup>3</sup>, R. Spiera<sup>3</sup>, F. Barrat<sup>1</sup>, C. Brooks<sup>2</sup>. <sup>1</sup>Autoimmunity and Inflammation Program, Hospital for Special Surgery Research Institute; <sup>2</sup>RandD, Stemline Therapeutics; <sup>3</sup>Scleroderma and Vasculitis Center, Hospital for Special Surgery, New York, USA

**Background:** SL-401 is a novel biologic targeted therapy directed to the interleukin-3 receptor (CD123). SL-401 is comprised of human IL-3 recombinantly fused to a truncated diphtheria toxin (DT) payload engineered such that IL-3 replaces the native DT receptor-binding domain. In this way, the IL-3 domain of SL-401 directs the cytotoxic DT payload to cells expressing CD123. Upon internalisation, SL-401 irreversibly inhibits protein synthesis and induces apoptosis of the target cell.

Plasmacytoid dendritic cells (pDCs) are immune cells that express CD123, secrete IFN- $\alpha$ , and play a role in inflammation and disease pathogenesis observed in systemic sclerosis (SSc) patients<sup>1,2</sup>. Therefore, depletion of pDCs or attenuation of pDC function may represent a novel approach to treating SSc patients.

**Objectives:** To assess the ability of SL-401 to deplete pDCs from healthy volunteers (HV) and SSc patients *ex vivo*.

**Methods:** Patients fulfilled the 2013 ACR/EULAR classification criteria for SSc<sup>3</sup>. PBMCs from either SSc patients or healthy volunteers (HV) were prepared using Ficoll-Paque density gradient from fresh blood. pDCs were isolated from PBMCs as previously described<sup>4</sup> and used to further enrich additional PBMCs. pDC-enriched PBMCs (3%–6% pDCs) were cultured at  $2 \times 10^5$  cells per well in the presence or absence of CpG-274 (0.5 mM) to activate pDCs and then incubated with SL-401 (0.01–100 ng/ml, 0.17 pM–1.7 nM) at 37°C, 5% CO<sub>2</sub>, and 95% humidity. After 24 hours of culture, pDC survival was assessed by flow cytometry (CD14<sup>+</sup>, CD3<sup>+</sup> B220<sup>+</sup> CD123<sup>+</sup>), and supernatants were collected for cytokine quantification by a multiplexed Luminex assay.

**Results:** CD123 expression levels on pDCs from HV and SSc donors were comparable, suggesting that targeting of pDCs in SSc can be modelled in HV. SL-401 was cytotoxic towards pDCs from both HV (n=5) and SSc donors (n=3) to a similar extent. The ED<sub>50</sub> of SL-401 against pDCs from HV and SSc was 4.3 and 3.3 ng/ml (74.5 and 57.2 pM), respectively (figure 1). No effect was observed on B or T cells across the SL-401 dose range tested. SL-401-mediated pDC depletion was further accompanied by a significant reduction in CpG-induced IFN- $\alpha$  secretion.

**Conclusions:** SL-401 is a novel CD123-targeted therapy capable of killing pDCs from both HVs and SSc patients. These data present a potentially novel approach of targeting pDCs in the treatment of SSc and warrant further investigation. A clinical trial is planned.

#### RNAI-BASED IDENTIFICATION OF NOVEL DRUG TARGETS TO REDUCE ENDOTHELIAL TO MESENCHYMAL TRANSITION (ENDOMT) IN HUMAN DERMAL MICROVASCULAR ENDOTHELIAL CELLS: A TARGET DISCOVERY APPROACH FOR SCLERODERMA

C. Corallo<sup>1</sup>, J. Benschop<sup>1</sup>, M. Grimbergen<sup>1</sup>, J. Crawford<sup>1</sup>, J. Meuldijk<sup>1</sup>, R. A. Janssen<sup>1</sup>, N.E. Vandeghinste<sup>2</sup>, N. Giordano<sup>3</sup>, M.A. Tessari<sup>1</sup>. <sup>1</sup>Galapagos BV, Leiden, Netherlands; <sup>2</sup>Galapagos NV, Mechelen, Belgium; <sup>3</sup>Scleroderma Unit, Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy

**Background:** Systemic sclerosis (SSc) is an autoimmune connective tissue disease characterised by early vascular abnormalities and subsequent fibroblast activation and differentiation into myofibroblasts, leading to fibrosis.<sup>1,2</sup> Recently, endothelial to mesenchymal transition (EndoMT), a complex biological process in which endothelial cells lose their specific markers and acquire a mesenchymal or myofibroblastic phenotype, was reported in SSc.<sup>3</sup>

**Objectives:** We developed a high-content screening assay with the aim to identify novel proteins which, upon inhibition, will reduce EndoMT in SSc.

**Methods:** Human dermal microvascular endothelial cells (HMVECs) were seeded in 384 well plates and transfected with a RNAi-based library targeting 866 genes. Cells were then triggered with either disease-related cytokines, such as transforming growth factor beta (TGF- $\beta$ ), or with serum from very early diagnosed, limited cutaneous and diffuse cutaneous SSc patients. Serum derived from healthy donors was used as a control. After 72 hours of triggering, changes in expression level of endothelial and mesenchymal markers were quantified by immunocytochemistry and high content imaging.

**Results:** We developed a high-throughput EndoMT assay that allows for monitoring of changes in endothelial and mesenchymal markers upon triggering with disease-related cytokines and serum derived from SSc patients. We used this assay to screen an RNAi-based library in HMVECs and identify more than 100 targets able to reduce EndoMT triggered by either TGF- $\beta$  or SSc patient serum. Identified hits subsequently will be extensively validated in secondary biological assays, and the validated targets will represent excellent candidate drug targets.

**Conclusions:** This program constitutes a critical path of experiments that will enable the selection of only those targets which meet pre-determined target acceptance criteria. We have chosen to identify targets in a human primary cell system and employ patient's serum as trigger of EndoMT to be able to closely investigate the cellular processes promoting EndoMT in SSc pathogenesis. By using this high-throughput screening platform, we aim to find disease-modifying targets that will be used as an entry point for small molecule drug discovery.

FRI0400

#### THE AP1 TRANSCRIPTION FACTOR CJUN AMPLIFIES HEDGEHOG-INDUCED FIBROBLAST ACTIVATION AND TISSUE FIBROSIS

C. Bergmann, B. Merlevede, C. Beyer, L. Hallenberger, A. Brandt, C. Dees, S. Pötter, A. Bozec, G. Schett, J. Distler. *Internal Medicine III-Rheumatology, University Clinic Erlangen-nuremberg, Erlangen, Germany*

**Background:** The pathologic activation of fibroblasts is a key feature of fibrotic disorders such as Systemic Sclerosis (SSc). Deregulation of TGF $\beta$ - and Hedgehog signalling has been shown to be critical for the persistent, uncontrolled activation of fibroblasts in SSc.<sup>1–3</sup> However, the consequences of the concomitant upregulation of multiple profibrotic pathways are unknown and cross-talk between individual pathways in fibrotic diseases is currently poorly characterised. Mutual activation and amplification of profibrotic signals might be central for the persistent activation of fibroblasts.

**Objectives:** The aim of this study is to characterise the crosstalk between AP1- and hedgehog signalling in fibrotic tissue disease in SSc.

**Methods:** Co-localization of cJUN and GLI2 in fibrotic skin was analysed by confocal microscopy and interaction was shown by Co-IP. cJUN/AP1 signalling and GLI2 signalling were inhibited *in vitro* and *in vivo* using the pharmacological inhibitors T5224 and GANT61. Hedgehog signalling was activated in mice by fibroblast-specific overexpression of constitutively active Smoothened (Smo<sup>ACT</sup> mice).

**Results:** Expression profiling of all AP1 family members revealed most pronounced differences for cJUN in Smo<sup>ACT</sup> mice. The expression of cJUN colocalized with the hedgehog transcription factor GLI2. Overexpression and colocalization of cJUN and GLI2 were also observed in fibroblasts in the skin of SSc patients. The number of GLI2- and cJUN double-positive fibroblasts was strongly increased in involved SSc skin compared to healthy controls and was particularly high in samples of SSc patients with diffuse and progressive disease. Based on the upregulation of both cJUN and GLI2 and their colocalization, we hypothesised that cJUN and GLI2 might interact with each other to amplify fibroblast activation and tissue fibrosis. Stimulation of resting fibroblasts with TGFβ induces both cJUN and GLI2 mRNA and protein in a time-dependent manner. cJUN and GLI2 are also induced upon stimulation with Sonic hedgehog (SHH), demonstrating that TGFβ and SHH are both capable to activate cJUN and GLI2-dependent transcription. This crosstalk occurs by direct interaction of cJUN and GLI2, which amplifies the transactivation potential of both transcription factors. Co-immunoprecipitation demonstrated that stimulation of fibroblasts with TGFβ or SHH induces direct interaction of cJUN and GLI2. Overexpression of cJUN and Gli2 resulted in activation in both AP1 and Hedgehog target genes. The central role of the crosstalk between cJUN and GLI2 for tissue fibrosis was further highlighted by the finding that hedgehog-induced fibrosis was strongly reduced by AP1 inhibition. Smo<sup>ACT</sup> mice developed extensive skin fibrosis. Treatment with a cJUN/AP1 inhibitor T5224, however, strongly ameliorated hedgehog-induced fibrosis in Smo<sup>ACT</sup> mice.

**Conclusions:** We demonstrate in the present study that the concomitant activation of AP1- and hedgehog signalling amplifies signalling through both cascades to promote excessive fibroblast activation and tissue fibrosis. This finding may open venues for combined inhibition of AP1- and hedgehog signalling for the treatment of fibrosis.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.7374

siRNA-mediated knockdown of *SHP2* and upon pharmacological inhibition of SHP2. We show that SHP2 can dephosphorylate JAK2 at the inhibitory Y570 site to promote TGFβ-dependent activation of JAK2 and its downstream mediator STAT3. In contrast, pharmacologic inhibition of SHP2, overexpression of a catalytically inactive SHP2 mutant or knockout of *SHP2* inhibits dephosphorylation of pJAK2<sup>Y570</sup> preventing phosphorylation of JAK2 at the activation site Y1007/Y1008 and subsequent activation of STAT3 in TGFβ-stimulated fibroblasts and in experimental fibrosis. Fibroblasts overexpressing SHP2 are more susceptible to the profibrotic effects of TGFβ, whereas the stimulatory effects of TGFβ on myofibroblast differentiation and collagen release are reduced in *Shp2* knockout fibroblasts. In addition, fibroblast-specific inactivation of *Shp2* *in vivo* protected from experimental fibrosis induced by overexpression of a constitutively active TGFβ receptor type I, by bleomycin injection and ameliorated fibrosis in TSK1 mice.

**Conclusions:** The present study describes for the first time a role of SHP2 in the pathogenesis of SSc. SHP2 is required for the activation of JAK2 and STAT3 by TGFβ. Inactivation of SHP2 prevents fibroblast activation and tissue fibrosis, providing evidence that SHP2 may be a potential target for the treatment of fibrosis.

#### FRI0402 MICRORNA-125B REGULATES APOPTOSIS IN SYSTEMIC SCLEROSIS

A. Kozlova<sup>1</sup>, E. Pachera<sup>1</sup>, B. Maurer<sup>1</sup>, A. Jüngel<sup>1</sup>, J.H. Distler<sup>2</sup>, G. Kania<sup>1</sup>, O. Distler<sup>1</sup>. <sup>1</sup>Center of Experimental Rheumatology, Department of Rheumatology, University Hospital, Zurich, Switzerland; <sup>2</sup>Department of Internal Medicine 3, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany

**Background:** The role of apoptosis in systemic sclerosis (SSc) is an emerging topic. MicroRNAs (miRs) are a class of small noncoding RNAs that regulate many important biological processes including apoptosis.

**Objectives:** To analyse the differential expression, regulation and pathophysiological role of miR-125b in systemic sclerosis.

**Methods:** MiR-125b expression was assessed by qPCR on RNA derived from cultured fibroblasts, whole skin biopsies and paraffin embedded dermis and epidermis from healthy controls (HC) and SSc patients. Fibroblasts were stimulated with pro-inflammatory and/or pro-fibrotic cytokines and with different epigenetic stimuli. Knockdown with anti-miR-125b (or scrambled controls) in HC fibroblasts was performed to identify downstream effects. RNA from healthy fibroblasts (n=4) after knockdown was proceeded to RNAseq using Illumina HiSeq2000. Bioinformatics analysis included differential gene expression and pathway analysis. Sequencing data were validated using qPCR (on HC and SSc fibroblasts). Apoptosis was assessed by Caspase-Glo 3/7 assay, Western Blot of cleaved caspase 3 and Annexin V live assay on cultured fibroblasts.

**Results:** MiR-125b was downregulated in SSc skin biopsies (n=10, median 47%, Q<sub>1</sub>,35%, 69%; p<0.01) in comparison with HC skin (n=10). To localise its expression in the skin, we separately analysed miR-125b expression in dermis and epidermis of paraffin embedded skin where it was downregulated in both compartments (n=3 each). The expression of miR-125b in primary dermal fibroblasts was also downregulated (median 53%, Q<sub>1</sub>,36%, 58%; n=10, p<0.01) compared to HC fibroblasts (n=10).

MiR-125b expression was not affected by major cytokines operative in SSc such as TGFβ or PDGF. However, TSA (histone deacetylase pan-inhibitor) downregulated miR-125b expression in a time- and dose-dependent manner (n=5, median 23%, Q<sub>1</sub>,319%, 48%; p<0.01).

RNAseq identified >3500 differentially expressed genes with p<0.05. More than half of the differentially expressed genes with at least 15% change were predicted targets of miR-125b by TargetScan and MiRWalk, indicating successful functional

#### FRI0401 THE TYROSINE PHOSPHATASE SHP2 CONTROLS TGFβ-INDUCED STAT3 SIGNALLING TO REGULATE FIBROBLAST ACTIVATION AND FIBROSIS

A. Zehender<sup>1</sup>, J. Huang<sup>2</sup>, A.-H. Györfi<sup>1</sup>, A.-E. Matei<sup>1</sup>, C. Dees<sup>1</sup>, C. Beyer<sup>3</sup>, K. Gelse<sup>4</sup>, A. Ramming<sup>1</sup>, C. Bergmann<sup>1</sup>, W. Birchmeier<sup>5</sup>, O. Distler<sup>6</sup>, G. Schett<sup>1</sup>, J. Distler<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Internal Medicine (Med3), Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen; <sup>2</sup>Clinical Chemistry and Laboratory Medicine, University Medical Center Hamburg-Eppendorf, Hamburg; <sup>3</sup>Department of Internal Medicine 1; <sup>4</sup>Unfallchirurgische Abteilung, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen; <sup>5</sup>Max-Delbrück-Centrum für Molekulare Medizin, Max-Delbrück-Centrum für Molekulare Medizin, Berlin, Germany; <sup>6</sup>Rheumaklinik, University Hospital Zurich, Zurich, Switzerland

**Background:** SHP2, encoded by the PTPN11 gene, is a ubiquitously expressed non-receptor tyrosine phosphatase (PTP). Altered expression and activity levels of SHP2 have also been implicated into the pathogenesis of autoimmune diseases.

**Objectives:** In our study, we aim to characterise the role of SHP2 as a possible novel molecular checkpoint of transforming growth factor-β (TGFβ)-induced JAK2/STAT3 signalling in fibrotic diseases.

**Methods:** Mice carrying *Shp2*<sup>fl/fl</sup>*xCol1a2-CreER* were generated to specifically knockout *Shp2* in fibroblasts. SHP2 was inhibited using NSC-87877 inhibitor. The role of *Shp2* was investigated in three different mouse models: Bleomycin- and TBRI<sup>CA</sup> induced dermal fibrosis as well as TSK1 genetic model of skin fibrosis. The construct pCMV3-Flag-JAK2 was used for overexpression and for *in vitro* mutagenesis of human JAK2. Co-immunoprecipitation was performed to confirm the interaction between SHP2 and JAK2. STAT3 activation was analysed by reporter assay. Protein and mRNA expression levels were analysed by Western Blot and qPCR.

**Results:** Our data characterise SHP2 as an important regulator of TGFβ signalling in fibroblasts. Although SHP2 expression is decreased in systemic sclerosis (SSc), the moderate downregulation of SHP2 expression is not sufficient to counterbalance the hyper-activation of TGFβ signalling in SSc. However, *Shp2*-deficient murine fibroblasts are less responsive to TGFβ. An impaired response to the profibrotic effects of TGFβ was also observed in human SSc fibroblasts with

inhibition of miR-125b. Gene ontology revealed apoptosis regulation as the main activated pathway. Apoptotic genes included BAK1, BMF and BBC3, which are part of the BCL2 apoptosis pathway and predicted targets of miR-125b. Consistent with the sequencing results, qPCR confirmed that miR-125b knockdown upregulated these genes 24, 48 and 72 hours after transfection (n=12, p<0.01 for each). BAK1 showed the strongest induction, that was also confirmed on the protein level by Western blot. Accordingly, miR-125b knockdown resulted in an increased apoptosis (at least 1.5-fold, n=10, p<0.01) compared to scrambled controls, measured by Caspase-Glo 3/7 assay 24, 48 or 72 hours post-transfection. Consistently, miR-125b overexpression decreased apoptosis (by at least 50%, n=10, p<0.01) at these time points. Cleaved caspase 3 was upregulated in anti-miR-125b transfected cells (median 2.3 fold, Q<sub>1,3</sub> 1.6, 4; n=10, p<0.01) confirmed by Western Blot. Annexin V live assay showed prevailing of apoptosis after miR-125b downregulation.

**Conclusions:** MiR-125b is downregulated in SSc skin and primary SSc dermal fibroblasts. MiR-125b downregulation increases apoptosis in dermal fibroblasts that might be a compensatory strategy against excessive fibrosis that could be used for therapeutic purposes.

#### FRI0403 MITOCHONDRIAL DYSFUNCTION AND OXIDATIVE STRESS IN MYOSITIS: A CENTRAL PATHOGENIC PATHWAY FROM MOUSE TO MAN

O. Boyer<sup>1</sup>, A. Meyer<sup>2</sup>, C. Boitard<sup>3</sup>, C. Abad<sup>1</sup>. <sup>1</sup>Inserm U1234, Normandy University, Rouen; <sup>2</sup>EA3072, Strasbourg University Hospital, Strasbourg; <sup>3</sup>Inserm U1016, Cochin Institute, Paris, France

**Background:** Myositides are severe diseases leading to a bedridden state and possibly death. The lack of animal model with spontaneously-occurring autoimmune myositis has hampered pathophysiological and therapeutic research. Auto-immune-prone NOD mice represent an invaluable model of type 1 diabetes (T1D). Inducible T cell co-stimulator (ICOS) is involved in germinal centre reaction and induction of helper T cell responses. We developed a unique model of myositis by invalidating the ICOS pathway in NOD mice<sup>1</sup>. Muscle holoproteome analysis in diseased mice together with observations of mitochondrial dysfunction in patients with dermatomyositis<sup>2</sup> suggest a main role of oxidative stress in disease pathogenesis.

**Objectives:** To determine the pathogenic role of oxidative stress and evaluate the effect of antioxidant therapy on *Icos*<sup>-/-</sup> NOD myositis.

**Methods:** Disease course was studied in *Icos*<sup>-/-</sup> NOD mice by grip strength, locomotor analysis and MRI. Muscle pathology was evaluated after conventional stainings, or by immuno-enzymology or immuno-histochemistry. Muscle-infiltrating cells were characterised by flow cytometry. New autoantibodies were identified in mice by serum proteomic analysis and sought for in myositis patients by ALBIA. Mouse muscle proteomic and transcriptomic analyses were performed by LC-MS/MS (Orbitrap) and RT-PCR, respectively. Muscle free radical production was assessed by EPR. Mice were treated by prednisolone (10 mg/kg/day) or N-acetylcysteine (2 g/L) in drinking water.

**Results:** *Icos*<sup>-/-</sup> NOD mice did not develop diabetes. Instead, myositis spontaneously occurred with decreased grip strength, impaired cadence, reduced print area and death around 40 wks. Pathological muscle analysis revealed necrotic myofibers and important inflammatory infiltrates (CD4<sup>+</sup> T cells, macrophages). Muscle lesions yielded MRI T2 hypersignals that regressed under steroids. CD4<sup>+</sup> T cells transferred disease to NOD.*scid* recipients. Serum proteomic analysis revealed a new autoantibody directed against a mitochondrial antigen. It was found present in ~1% individuals from a ~700 myositis patient cohort. Oxidative stress was manifest in *Icos*<sup>-/-</sup> NOD muscle by augmented free radical production, H<sub>2</sub>O<sub>2</sub> production-related atrophy, altered O<sub>2</sub> consumption and dysregulation of several mitochondrial genes and proteins. N-acetylcysteine partially prevented myositis or ameliorated established disease.

**Conclusions:** This work establishes *Icos*<sup>-/-</sup> NOD mice as a unique paradigm of myositis. A new autoantibody was discovered. Oxidative stress is present in diseased muscle. Antioxidant therapy is effective in a preventive or curative fashion. Together with our previous data in dermatomyositis patients<sup>2</sup>, this work indicates the central role of mitochondrial dysfunction and oxidative stress in myositis pathogenesis and opens new perspectives for therapy.

#### FRI0404 CHARACTERISATION OF A MONOCYTES/MACROPHAGES CELL SUBSET CO-EXPRESSING BOTH M1 AND M2 PHENOTYPE MARKERS IN SYSTEMIC SCLEROSIS PATIENTS

S. Soldano<sup>1</sup>, A.C. Trombetta<sup>1</sup>, B. Ruaro<sup>1</sup>, V. Tomatis<sup>1</sup>, R. Brizzolara<sup>1</sup>, P. Montagna<sup>1</sup>, S. Paolino<sup>1</sup>, C. Pizzorni<sup>1</sup>, V. Smith<sup>2</sup>, P. Contini<sup>3</sup>, A. Sulli<sup>1</sup>, M. Cutolo<sup>1</sup>. <sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, IRCCS Polyclinic San Martino Hospital, Genoa, Italy; <sup>2</sup>Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; <sup>3</sup>Clinical Immunology, Department of Internal Medicine, University of Genoa, IRCCS Polyclinic San Martino Hospital, Genoa, Italy

**Background:** In the pathogenesis of systemic sclerosis (SSc), the immune cell activation is an important event that includes alteration in the macrophage polarisation.<sup>1</sup>

Macrophages may polarise into classically activated (M1), which are characterised by the expression of specific markers such as Toll-like receptors (TLR2 and 4) and costimulatory molecules (CD80 and CD86), or alternatively activated (M2), which are characterised by the expression of specific phenotype markers such as mannose receptor-1 (CD206) and macrophage scavenger receptors (CD204 and CD163). M2 are present in the circulation and in the skin infiltrate of SSc patients (pts), where they seem to contribute to fibrosis.<sup>2-4</sup>

**Objectives:** To characterise circulating M2 monocytes/macrophages from SSc pts and healthy subjects (HSs) by their co-expression of CD204, CD163 and CD206, as well as cells expressing both M1 and M2 phenotype markers.

**Methods:** Fifty-eight SSc pts (54 females/4 males, mean age 63±13 years), fulfilling the new EULAR/ACR criteria for SSc, and 27 age-matched HSs were consecutively enrolled after Informed Consent was obtained. Peripheral blood was collected and the antibodies CD14-APC-Vio770 and CD45-VioGreen were used to identify the monocyte/macrophage lineage; CD204-VioBright-FITC, CD163-PE-Vio770 and CD206-PeerCP-Vio700 were used to characterise the M2 phenotype, whereas CD80-APC, CD86-VioBlue, TLR4-PE and TLR2-PE-Vio615 were used to characterise the M1 phenotype (Miltenij Biotech). Flow Cytometry analysis was performed using Navios Flow Cytometer and the related Navios analysis software (Beckman Coulter).

**Results:** In the CD14<sup>+</sup>cell subset (monocytes), the CD14<sup>+</sup>CD163<sup>+</sup>CD206<sup>+</sup>CD204<sup>+</sup>cell percentage was significantly increased in SSc pts compared to HSs (p=0.02). Inside the CD14<sup>+</sup>CD163<sup>+</sup>CD206<sup>+</sup>CD204<sup>+</sup> monocytes/macrophages a subset of cells co-expressing also TLR4, CD80 and CD86 was detected. This mixed population (M2/M1) of cells was significantly increased in SSc pts compared to HSs (p=0.003).

At the same time, circulating monocytes/macrophages showing a full M2 phenotype and characterised as CD204<sup>+</sup>CD163<sup>+</sup>CD206<sup>+</sup>cells were investigated independently of the expression of CD14, and they also resulted significantly increased in SSc pts compared to HSs (p<0.0001).

In the CD204<sup>+</sup>CD163<sup>+</sup>CD206<sup>+</sup>cell subset (M2), the percentage of cells expressing also TLR4, CD80 and CD86 (M1) was significantly increased in SSc pts compared to HSs (p<0.0001).

**Conclusions:** These results describe for the first time a subset of circulating cells belonging to the monocyte/macrophage lineage with a mixed phenotype, which are characterised by the expression of both M1 and M2 surface markers. These

cells were observed to be increased in the peripheral blood of SSc pts compared to HSs, suggesting their possible role in the pathogenesis of the disease.

### FRI0405 A NOVEL ANIMAL MODEL FOR SYSTEMIC SCLEROSIS INDUCED BY IMMUNISATION OF ANGIOTENSIN II RECEPTOR 1

X. Yue<sup>1</sup>, F. Petersen<sup>1</sup>, X. Wang<sup>1</sup>, H. Heidecke<sup>2</sup>, G. Riemekasten<sup>3</sup>, X. Yu<sup>1</sup>.

<sup>1</sup>Research center borstel, Borstel; <sup>2</sup>Celltrend GmbH, Luckenwalde; <sup>3</sup>Department of Rheumatology, University hospital Lübeck, Lübeck, Germany

**Background:** Systemic sclerosis (SSc) is a complex connective tissue disease which is characterised by autoimmunity, vasculopathy and fibrosis<sup>1</sup>. Our recent study showed that the progression of SSc was strongly associated with the autoantibodies against angiotensin II receptor I (AT1R), suggesting a role of autoimmunity to AT1R in the pathogenesis of the disease<sup>2</sup>

**Objectives:** In this study, we aimed to investigate the role of AT1R in the pathogenesis of SSc in mice.

**Methods:** C57BL/6J mice were immunised with membrane extract (ME) of CHO cell overexpressing human AT1R or with ME of CHO cells as control. Serum, lung and skin samples were collected and assessed 63 days after immunisation for autoantibody production, inflammation and fibrosis, which are hallmarks for SSc.

**Results:** Immunisation with hAT1R induced the production of autoantibodies against the receptor in mice, and autoantibody deposition was found in the lung. Histologically, mice immunised with hAT1R showed a SSc-like disease, including perivascular infiltrates and fibrosis in the skin as well as pulmonary inflammation. The inflammation in the skin and the lung were characterised by infiltration of T- and B-cells. Furthermore, transfer of immune cells from hAT1R-immunised mice into C57BL/6J mice induced inflammation in the lung.

**Conclusions:** This study demonstrates that immunisation with hAT1R can induce a SSc-like disease, thus showing a pathogenic role of autoimmunity to AT1R and providing a novel mouse model for the diseases. Furthermore, this study also introduces a new immunisation strategy to generate functional autoantibodies against receptors on the cell membrane.

### FRI0406 INCREASED FREQUENCY OF CIRCULATING CD163+ NON-CLASSICAL MONOCYTES IN SCLERODERMA AND ENHANCED DUAL POLARISATION TOWARDS M1 AND M2-LIKE PHENOTYPES IN MONOCYTE-DERIVED MACROPHAGES

A. Tam<sup>1</sup>, L. Reinke-Breen<sup>2</sup>, G. Trujillo<sup>2</sup>, S. Xu<sup>1</sup>, C. P. Denton<sup>1</sup>, D. J. Abraham<sup>1</sup>, G. Jarai<sup>2</sup>, V. H. Ong<sup>1</sup>. <sup>1</sup>Centre for Rheumatology and Connective Tissue Disease, UCL, London, United Kingdom, <sup>2</sup>Discovery Biology, Fibrotic Diseases, Bristol-Myers Squibb, Pennington, United States

**Background:** Scleroderma (SSc) is an autoimmune connective tissue disease involving complex interactions between various cell types leading to organ-based tissue fibrosis. Emergence of the monocytes (Mo)/macrophages (M $\phi$ ) lineage(s) as key contributors to inflammation, vascular dysfunction and scarring in scleroderma<sup>1,2</sup> have led to increased scrutiny of their phenotype and function.

**Objectives:** To determine the circulating Mo subpopulations and phenotypes of M $\phi$  in SSc.

**Methods:** PBMC were collected from healthy (HC) and SSc donors, and analysed by flow cytometry using Mo phenotypic antibodies or purified and cultured *in vitro*. For flow cytometry immunophenotyping, Mo were gated on

CD3<sup>+</sup>CD19<sup>-</sup>CD56<sup>+</sup>HLA-DR<sup>+</sup> populations, and subsets defined by CD14, CD16, CD163 and CD206 expression. For M $\phi$  cultures, Mo were negatively selected from PBMCs, cultured for 7 days, and treated with IFN- $\gamma$  (5 ng/ml) or IL-4 (20 ng/ml) for 24 hours. Cytokine levels in the conditioned media were evaluated by MSD analyses and normalised to total protein levels.

**Results:** The frequency of circulating CD163<sup>+</sup> non-classical Mo (CD14<sup>lo</sup>CD16<sup>hi</sup>) was 2-fold higher in SSc patients than in HC (unpaired t-test, p=0.026). No difference was found in the frequency of CD206<sup>+</sup> monocyte subsets between HC and SSc. *In vitro*, unstimulated SSc M $\phi$  (M0) secreted higher levels of classically-activated pro-inflammatory (M1) and alternatively-activated pro-regenerative (M2) cytokines. Compared to HC cells, SSc M $\phi$  were more readily polarised towards an M1 phenotype or an M2 phenotype, when cultured in the presence of IFN- $\gamma$  or IL-4, respectively. Th17 markers and MMPs were significantly increased in SSc M $\phi$  (table 2).

**Abstract FRI0406 – Table 1.** Demographics.

n	Mo (flow cytometry)		M $\phi$ supernatant (cytokine assay)	
	HC n=9	SSc n=10	HC n=13	SSc n=27
Age (years)	56.7±14.3	50.7±5.7	60.6±16.7	52.1±13.0
Female : Male	7:2	8:2	6:7	26:5
SSc subtype	-	dcSSc <sup>(10)</sup>	-	dcSSc <sup>(27)</sup>
Disease duration	-	≤5 years <sup>(10)</sup>	-	≤5 years <sup>(15)</sup> >5 year <sup>(12)</sup>

**Abstract FRI0406 – Table 2.** Cytokines significantly increased in SSc vs control. Unpaired t-tests, \*p<0.05, \*\*P<0.01.

Cell Population	M1 Markers	M2 Markers	Th17 Cytokines and MMP's
M0	CCL-3, CCL-4, IL-6, IL-18, IL-12, IL-15, TNF- $\alpha$	CCL-1, CCL-17, CCL-20, CCL-24, IL-1R $\alpha$ , YKL-40	IL-21, IL-22, IL-31, MMP1, MMP3
M0 + IFN- $\gamma$	CCL-3, CCL-4, CCL-11, CXCL8, IL-1 $\beta$ , IL-6, IL-18, TNF- $\alpha$	CCL-1, CCL-22, CCL-24, CCL-26, IL-1R $\alpha$ , YKL-40	IL-21
M0 + IL-4	CCL-3, CCL-4, IL-12, IL-18, TNF- $\alpha$	CCL-17, CCL-22, CCL-24, IL-1R $\alpha$ , YKL-40	IL-21, MMP3

**Conclusions:** Studies exploring Mo have revealed distinct populations with selective biological functions. Our observation of an increased number of CD163<sup>+</sup> non-classical Mo in SSc suggests that this subpopulation may play a key role in inflammatory-driven fibrosis and act as an important source of pro-fibrotic cytokines. This data is consistent with previous reports of elevated serum levels of CD163 and increased CD163 secretion by SSc PBMCs<sup>3</sup>. SSc M $\phi$  showed a pronounced and enhanced dual M1 and M2 polarisation basally compared to HC, indicating cells were 'primed' to undergo phenotypic polarisation. Our studies support the notion that M $\phi$  cytokine secretion generates a pro-fibrotic milieu in scleroderma tissues, playing a prominent role in dysregulated tissue repair in fibrosis.

### FRI0407 DIPEPTIDYL-PEPTIDASE-4 (DPP4) IS A POTENTIAL NEW MOLECULAR TARGET FOR TREATMENT OF FIBROSIS

A.M. Soare, H. Györfy, A. Matei, C. Dees, Y. Zhang, T. Wohlfahrt, C.-W. Chen, A. Ramming, G. Schett, J. Distler. *Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Universitätsklinikum Erlangen, Erlangen, Germany*

**Background:** Dipeptidyl-peptidase-4 (DPP4) plays a role in tissue scarring and its inhibition leads to reduced scar formation. Its function in tissue fibrosis, however, is unknown.

**Objectives:** The aim of the study was to investigate the expression of DPP4 in fibrotic tissue of systemic sclerosis (SSc) patients, to characterise DPP4 positive cells, to study the mechanism of action of DPP4 in fibroblasts and to evaluate the antifibrotic effect of pharmacological and genetically inhibition of DPP4 in different preclinical models of SSc.

**Methods:** Expression of DPP4 in human and murine skin was analysed. Mouse fibroblasts were isolated and DPP4 positive cells properties were assessed.

Pulmonary fibrosis was induced by bleomycin in DPP4 knockout (KO) mice and wildtype littermates. Fibrosis of the lungs was additionally evaluated by computer tomography scans (CT). Two oral DPP4 inhibitors were tested in two concentrations in bleomycin-induced skin fibrosis and in scleroderma-like chronic graft-versus-host disease (scl-cGVHD) model. Antiinflammatory effects of DPP4 inhibition were assessed by CD45 staining of fibrotic and non-fibrotic mouse tissue upon DPP4 inhibition. Moreover, chimeric mice were generated by transplanting bone marrow from DPP4-KO mice in WT-littermates (DPP4→WT) and vice versa (WT→DPP4) and fibrosis was by intratracheal injections of bleomycin.

**Results:** DPP4 positive fibroblasts were increased in fibrotic skin of SSc patients and also in murine models of fibrosis. DPP4 expression is induced by TGF- $\beta$  in an Erk-dependent manner. DPP4-positive fibroblasts strongly express stress fibres after TGF- $\beta$  stimulation and released increased amounts of collagen. Mechanistically, inhibition of DPP4 selectively interferes with the TGF- $\beta$  induced activation of ERK signalling, but does not inhibit TGF- $\beta$  induced SMAD signalling, or other non-canonical TGF- $\beta$  pathways involving Fra2, c-Jun, p38, Akt or STAT3. Furthermore, pharmacological inhibition of DPP4 reduced the release of collagen and the expression of myofibroblast markers. DPP4-KO mice are less sensitive to bleomycin-induced pulmonary fibrosis as shown by milder changes on CT, reduced Ashcroft scores and reduced hydroxyproline content. DPP4-KO mice also show reduced skin fibrosis upon bleomycin challenge. Moreover, treatment with DPP4 inhibitors demonstrated potent antifibrotic effects in bleomycin-induced skin fibrosis and experimental scl-cGVHD mouse model. Treatment with DPP4 inhibitors also reduced leukocyte infiltrations into the skin. The extent of pulmonary fibrosis of DPP4→WT was comparable to that of WT→WT control mice. Fibrosis was strongly ameliorated in WT→DPP4 mice and results were comparable to that of DPP4→DPP4 mice, characterising resident cells such as fibroblasts as major target cells for the antifibrotic effects of DPP4 inhibitors.

**Conclusions:** DPP4 characterises an activated subpopulation of fibroblasts in SSc. Moreover, inhibitors of DPP4 show a significant anti-fibrotic effect in several mouse models of SSc in well tolerated doses. These results may have direct translational implications as DPP4 inhibitors are already in clinical use for diabetes.

#### FRI0408 INVARIANT NATURAL KILLER T CELLS IN SYSTEMIC SCLEROSIS

A.-C. Pecher, F. Kettmann, J. Henes, S. Duerr-Stoerzer, C. Schneidawind, L. Kanz, D. Schneidawind. *universitätsklinikum tübingen, Tübingen, Germany*

**Background:** Systemic sclerosis (SSc) is a rare and heterogeneous immune-mediated disease. Its complex pathogenesis remains incompletely understood. Invariant natural killer T (iNKT) cells have been discussed in several autoimmune diseases<sup>1</sup>. They recognise selected endogenous as well as synthetic glycolipids like  $\alpha$ -galactosylceramide by their TCR with high affinity and when activated, they typically release high amounts of pro- and/or anti-inflammatory cytokines<sup>2</sup>.

**Objectives:** To evaluate numbers and function of invariant natural killer T cells in patients with systemic sclerosis and analyse their correlation with disease parameters.

**Methods:** Human iNKT cells from 91 patients with SSc and 23 healthy controls were analysed by flow cytometric analysis. Their proliferative capacity and cytokine production was investigated following activation with CD1d ligand  $\alpha$ -GalCer.

**Results:** We observed an absolute and relative decrease of iNKT cells in patients with SSc (0.036 iNKT cells/ $10^6$  lymphocytes) compared with healthy controls (0.159 iNKT cells/ $10^6$  lymphocytes,  $p < 0.001$ ). We could also demonstrate that iNKT cells from patients with SSc showed a significantly decreased expansion capacity upon stimulation with  $\alpha$ -GalCer. Interestingly, there was no difference concerning the subtype of SSc, disease severity or whether patients received immunosuppressive drugs.

**Conclusions:** iNKT cells are deficient and functionally impaired in patients with SSc. Therefore, adoptive transfer strategies using culture-expanded iNKT cells or administration of glycosphingolipids such as  $\alpha$ -GalCer could be a novel approach to treat SSc patients.

#### FRI0409 MYOSITIS SPECIFIC ANTI-HISTIDYL TRNA SYNTHETASE (HISRS) AUTOANTIBODIES DISPLAY HIGH REACTIVITY AGAINST HISRS CONFORMATIONAL EPITOPES AND ASSOCIATE WITH LUNG AND JOINT INVOLVEMENT

C. Cerqueira, N. Renard, A. Notarnicola, E. Wigren, P.-J. Jakobsson, S. Gräslund, I.E. Lundberg. *Department of Medicine, Rheumatology Unit, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden*

**Background:** Autoimmune myositis (rheumatic muscle inflammation) associated with interstitial lung disease (ILD) and arthritis is strongly correlated with the presence of anti-histidyl tRNA synthetase (HisRS) autoantibodies.<sup>1</sup>

**Objectives:** The aims of this study were to investigate: 1) myositis IgG reactivity against HisRS conformational epitopes; and 2) association between clinical manifestations and anti-HisRS reactivity profiles.

**Methods:** Serum IgG was isolated using a protein G affinity column (from 25 anti-HisRS negative (-) and 19 anti-HisRS positive (+) myositis sera and 24 age/gender matched healthy controls, HC). Autoantibody reactivity was tested by in house ELISA developed against HisRS full-length protein and three HisRS conformational epitopes (WHEP domain – localised in the N-terminal; HisRS without WHEP (HisRS\_WHEP); and ABD – anticodon-binding domain located in the C-terminal). Correlations between diagnosis, clinical manifestations and anti-HisRS IgG reactivity were evaluated.

**Results:** HisRS(+) myositis IgG displayed stronger reactivity against full-length HisRS and HisRS\_WHEP (median 372 ng/mL and 334 ng/mL, respectively), compared to WHEP and ABD (6.38 and 6.48 ng/mL). The strongest anti-full-length HisRS reactivity (>371 ng/mL) was detected in patients presenting ILD (10/10 of patients), arthritis (6/10) and polymyositis diagnosis (PM 9/10), in comparison to patients with low anti-HisRS reactivity (<23 ng/mL, ILD – 5/6; arthritis – 3/6; PM – 5/6) or no anti-HisRS reactivity (ILD – 10/28; Arthritis – 8/28; PM – 15/28). On the contrary, myositis patients displaying no anti-HisRS reactivity were largely diagnosed with DM (11/28), skin rash (11/28) and dysphagia (6/28) when compared to patients with the highest anti-full-length HisRS reactivity (1 out of 10 patients was diagnosed with DM, skin rash or dysphagia). Similar associations were observed between the degree of anti-HisRS\_WHEP, anti-WHEP or anti-ABD reactivities and manifestations of ILD, arthritis, skin rash or dysphagia, and DM or PM diagnosis. No anti-HisRS reactivity was detected in the HC group.

**Abstract FRI0409 – Figure 1.** Anti-full-length HisRS IgG reactivity in myositis patients diagnosed with either polymyositis (PM) or dermatomyositis (DM), and presenting manifestations of interstitial lung disease (ILD), arthritis, skin rash and dysphagia. Numbers represent the patients included in the analysis.

**Conclusions:** This study provides evidences for a possible underlying role of anti-HisRS autoantibodies in the pathogenesis of myositis with interstitial lung disease and joint involvement.

**FRI0410 TGF $\beta$  PROMOTES FIBROSIS BY MYST1-DEPENDENT EPIGENETIC REGULATION OF AUTOPHAGY**

A. Zehender<sup>1</sup>, N.-Y. Lin<sup>2</sup>, A. Stefanica<sup>1</sup>, C.-W. Chen<sup>1</sup>, A. Soare<sup>1</sup>, T. Wohlfahrt<sup>1</sup>, S. Rauber<sup>1</sup>, C. Bergmann<sup>1</sup>, A. Ramming<sup>1</sup>, O. Distler<sup>3</sup>, J. Distler<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Internal Medicine (Med3), Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany; <sup>2</sup>College of medicine, National Taiwan University (NTU), Taipei, Taiwan, Province of China; <sup>3</sup>Rheumaklinik, University Hospital Zurich, Zurich, Switzerland

**Background:** Autophagy is catabolic process allowing cells to degrade unnecessary or dysfunctional cellular organelles. Aberrant activation of autophagy has been also implicated into the pathogenesis of fibrotic diseases. Several stimuli present in fibrosis such as pro-fibrotic cytokines are known to activate autophagy. **Objectives:** The objective of this work is characterise the regulation of autophagy by TGF $\beta$  and analyse whether targeting of autophagy in fibroblasts may prevent their aberrant activation in fibrotic diseases.

**Methods:** To selectively disable autophagy in fibroblasts we generate *Atg7<sup>fl/fl</sup> × Col1a2;CreER* mice. The role of the autophagy was investigated in the model of bleomycin- and T $\beta$ R1act-induced dermal and pulmonary fibrosis. Overexpression of *Myst1* was achieved by adenovirus encoding for *Myst1*. Collagen release and protein expression were measure by Western blot. Target genes were analysed by RT-PCR. Co-immunoprecipitation and reporter assay were performed to study physical and functional interactions between MYST1 and SMAD3. To monitor the autophagic flux *in vitro* and *in vivo* we generate an adenovirus encoding for tandem fluorescent-tagged LC3 (mRFP-EGFP-LC3), defined as reliable autophagy maker.

**Results:** We provide evidence that transforming growth factor- $\beta$  (TGF $\beta$ ) activates autophagy by an epigenetic mechanism to amplify its profibrotic effects. TGF $\beta$  induces autophagy in fibrotic diseases by SMAD3-dependent downregulation of the H4K16-histoneacetyltransferase MYST1, which controls the expression of core components of the autophagy machinery such as ATG7 and BECLIN1. Activation of autophagy in fibroblasts promotes collagen release and is both, sufficient and required, to induce tissue fibrosis. Forced expression of MYST1 abrogates the stimulatory effects of TGF $\beta$  on autophagy and re-establishes the epigenetic control of autophagy in fibrotic conditions. Interference with the aberrant activation of autophagy inhibits TGF $\beta$ -induced fibroblast activation and ameliorates experimental dermal and pulmonary fibrosis. These findings link uncontrolled TGF $\beta$  signalling to aberrant autophagy and altered epigenetics in fibrotic diseases and may open new avenues for therapeutic intervention in fibrotic diseases.

**Conclusions:** We demonstrate that the epigenetic control of autophagy is disturbed by a TGF $\beta$ -dependent downregulation of MYST1. The increased activation of autophagy induces fibroblast-to-myofibroblast transition and promotes fibrotic tissue remodelling. Re-expression of MYST1 prevents aberrant autophagy, limits the profibrotic effects of TGF $\beta$  and ameliorates experimental fibrosis. Restoration of the epigenetic control of autophagy might thus be a novel approach to ameliorate fibrotic tissue remodelling.

**FRI0411 DUAL PRO-INFLAMMATORY AND ANTI-FIBROTIC ROLE OF IL-17A IN SYSTEMIC SCLEROSIS SKIN**

A.M. Dufour<sup>1,2</sup>, M. Alvarez<sup>1,2</sup>, S. Lemeille<sup>1</sup>, M.-E. Truchetet<sup>3</sup>, N.C. Brembilla<sup>1,4</sup>, C. Chizzolini<sup>1,2</sup>. <sup>1</sup>Department of Pathology and Immunology, School of Medicine; <sup>2</sup>Immunology and Allergy Department, University Hospital, Geneva, Switzerland; <sup>3</sup>Rheumatology Department, Bordeaux University Hospital, Bordeaux, France; <sup>4</sup>Dermatology Department, University Hospital and School of Medicine, Geneva, Switzerland

**Background:** Increased levels of IL-17A have been reported in systemic sclerosis (SSc) which role in fibrogenesis is still debated.<sup>1</sup> Furthermore, epithelial cells

are preferential targets of IL-17A and recent findings suggest that keratinocytes may participate in dysregulated extracellular matrix homeostasis.<sup>2</sup>

**Objectives:** Our aim was to investigate the interactions between epidermis and dermis in the presence of IL-17A, taking into perspective the fibrotic process.

**Methods:** Primary human keratinocytes were primed with IL-17A and/or TGF- $\beta$  and conditioned-media were used to stimulate healthy donors (HD) and SSc fibroblasts. Alternatively, organotypic cultures of HD full human skin were challenged with these cytokines. Responses were assessed by quantifying inflammatory mediators and type I collagen (Col-I) levels. The factors produced by keratinocytes were identified by a proteomic approach and their contribution was evaluated by neutralisation assays. Changes in gene expression in full human skin after treatment with IL-17A and/or TGF- $\beta$  were analysed by RNA sequencing (RNA-seq).

**Results:** Unstimulated HD- and SSc-derived keratinocyte-conditioned media (KCM) promoted collagen production by fibroblasts to a similar extent and in a dose-dependent manner. Cytokine array analysis and neutralising assays showed that TGF- $\beta$  was, at least in part, responsible for the pro-fibrotic effect of KCM. Priming of keratinocytes with IL-17A directly decreased Col-I production and significantly reduced Col-I induced by TGF- $\beta$  both in SSc and HD fibroblasts. In full human skin, IL-17A promoted pro-inflammatory responses by inducing 2- to 4-fold increase of IL-8, IL-6, MCP-1 and MMP-1 levels, while showing direct anti-fibrotic effects, as well as decreasing by 2-fold collagen production triggered by TGF- $\beta$  (p=0.02). RNA-seq revealed that TGF- $\beta$  induced the expression of many collagen genes, while this was not the case for IL-17A. However, IL-17A promoted a pro-inflammatory signature in the skin and strongly downregulated expression of serpin family members, known to be involved in fibrogenesis.

**Conclusions:** Keratinocytes profoundly influence dermal fibroblast responses, which are further modulated in the presence of IL-17A. These data support a role for keratinocytes in the pathogenesis of SSc. IL-17A acts as a potent anti-fibrotic factor in the model of keratinocyte – fibroblast interactions, as well as in the full human skin, promoting pro-inflammatory and anti-fibrotic responses.

**FRI0412 B CELL DEPLETION AMELIORATES TISSUE FIBROSIS THROUGH REGULATING MACROPHAGE DIFFERENTIATION IN A BLEOMYCIN-INDUCED SYSTEMIC SCLEROSIS MODEL MOUSE**

H. Numajiri, A. Yosizaki, T. Fukasawa, S. Ebata, Y. Asano, S. Sato. *Department of Dermatology, The University of Tokyo Graduate School of Medicine, Hongo, Bunkyo-ku, Tokyo, Japan*

**Background:** B cells play a critical role in pathogenesis of autoimmune diseases through various functions such as cytokine production and induction of other immune cell activation. Recent studies have shown the efficacy of B cell depletion therapy with rituximab, a human CD20 chimeric monoclonal antibody, in systemic sclerosis (SSc) patients. However, it still remains unclear why B cell depletion can be effective for SSc.

**Objectives:** The purpose of this study is to assess the role of B cell depletion in SSc. We evaluated the skin and lung fibrosis of bleomycin (BLM)-induced SSc model mice treated with B cell depletion. Furthermore, we investigated effects of B cell depletion on T cells and macrophages.

**Methods:** To generate BLM-induced SSc model mice, 200  $\mu$ g of BLM was injected subcutaneously to C57BL/6 mice every other day for 4 weeks. Anti-mouse CD20 monoclonal antibodies, which can deplete mouse B cells, were also injected every 2 weeks from either one week before (the pre-depletion group) or 2 weeks after (the post-depletion group) BLM treatment. After 4 weeks of BLM treatment, skin and lung fibrosis was assessed histopathologically. To examine the effect of B cell depletion on T cells and macrophages, purified B cells were cultured with T cells or macrophages and then T cell cytokine production and macrophage phenotype were analysed.

**Results:** Skin and lung fibrosis increased in BLM-induced SSc mice. In the coculture experiments, B cells from BLM-induced SSc mice promoted differentiation of T cells producing fibrogenic cytokines such as interleukin-4 compared with control B cells, while they inhibited regulatory T cell (Treg) differentiation. Skin and lung fibrosis was inhibited in both pre- and post-depletion groups with the inhibition greater in the pre-depletion group than in the post-depletion group. Despite the finding that greater fibrosis remained in the post-depletion group than in the pre-depletion group, the post-depletion group showed significantly higher frequencies

of Treg compared with the pre-depletion group. Furthermore, the post-depletion group also exhibited lower fibrogenic cytokine-producing T cell frequencies, suggesting that the change in T cell cytokine production could not account for the more strongly reduced fibrosis observed in the pre-depletion group. Therefore, we examined other immune cell response to B cell depletion. Recent studies have revealed that macrophages are divided into two subtypes: M1 and M2 and that M2 macrophages show fibrogenic effects in SSc. This study showed that macrophages cultured with B cells from BLM-induced SSc mice exhibited enhanced M2 differentiation compared with control B cells. Remarkably, frequencies of M2 macrophage with fibrogenic capacity significantly decreased in the pre-depletion group compared with the post-depletion group, which could account for the more strongly inhibited tissue fibrosis in the pre-depletion group.

**Conclusions:** Our results indicate that therapeutic effects of B cell depletion on tissue fibrosis exert through regulating macrophage differentiation rather than T cell cytokine production in SSc, first demonstrating that interaction between B cells and macrophages in development of fibrosis in SSc.

### FRI0413 ARYL HYDROCARBON RECEPTOR EXPRESSION IS ASSOCIATED WITH LUNG INVOLVEMENT IN SYSTEMIC SCLEROSIS

H. Takeji<sup>1</sup>, H. Yasuoka<sup>1</sup>, K. Yoshimoto<sup>1,2</sup>, K. Yamaoka<sup>1</sup>, T. Takeuchi<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; <sup>2</sup>Clinical and Translational Research Center, Keio University Hospital, Tokyo, Japan

**Background:** Systemic sclerosis (SSc) is characterised by autoantibody production, microvascular injury and systemic excessive fibrosis<sup>1</sup>. Genetic and environmental factors are thought to be important for the trigger of development of the disease, however, direct connexion between these factors and pathogenesis of SSc is not yet elucidated<sup>2,3</sup>. Recent reports showed that environmental toxic pollutants, such as dioxins, play a significant role in the disturbance of immune system and the trigger of autoimmunity through binding aryl hydrocarbon receptor (AhR)<sup>4,5</sup>. However, little is known about the association between AhR and pathogenesis of SSc yet.

**Objectives:** To elucidate the association between AhR and the clinical characteristics of SSc.

**Methods:** Twenty-one patients with SSc who fulfilled 2013 ACR/EULAR classification criteria and 10 healthy controls (HC) were analysed. Peripheral blood mononuclear cells (PBMCs) were isolated from heparinized whole blood by using gradient centrifugation and total RNA was prepared from PBMCs. Expression of AhR mRNA was detected by quantitative polymerase chain reaction and standardised by mRNA level of 18S ribosomal RNA in each sample. Level of AhR mRNA in the cells was compared between SSc and HC and also between SSc patients with and without various clinical features.

**Results:** The proportion of diffuse cutaneous subset (dcSSc) was 33%. Mean disease duration was 9±9 years. The positive proportion of anticentromere antibodies, anti-topoisomerase I antibodies, anti-U1 ribonucleoprotein antibody, anti-RNA polymerase III antibody and antinuclear antibody positive without SSc-specific antibodies among 21 patients were 33.3%, 33.3%, 4.8%, 9.5% and 9.5%, respectively. Antinuclear antibody was negative in 2 (9.5%) patients. AhR mRNA expression level was tended to be higher in SSc compared to HC (1.7±1.1 versus 1.2±0.6, p=0.1). Notably, the expression level of AhR mRNA in dc SSc was tended to be higher than that of limited cutaneous SSc (p=0.15), whereas no significant difference was detected between with or without SSc related autoantibodies, vasculopathy such as pulmonary arterial hypertension or digital tip ulcer. Importantly, the expression level of AhR mRNA was significantly higher in patients with interstitial lung disease (ILD) (n=14) than those without (n=7) (2.0±1.1 versus 1.0±0.4, p<0.05). Furthermore, AhR mRNA expression level was significantly and negatively correlated with DLCO% predicted (r=-0.57, p<0.05).

**Conclusions:** Expression level of AhR mRNA was higher in patients with SSc, especially in SSc patients with ILD. In addition, AhR expression level was correlated with a parameter of pulmonary function test, DLCO% predicted. These results collectively suggest that AhR possibly plays an important role in the disease process of ILD in SSc.

### FRI0414 EVALUATION OF A NOVEL MULTI-ANALYTE ASSAY FOR THE DETECTION OF AUTOANTIBODIES IN THE DIAGNOSIS OF SYSTEMIC SCLEROSIS

P.L. Meroni<sup>1</sup>, T. Schioppo<sup>2</sup>, F. Ingegnoli<sup>2,3</sup>, M.O. Borghi<sup>1,3</sup>, J.L. Milo<sup>4</sup>, C. Bentow<sup>4</sup>, A. Seaman<sup>4</sup>, G. Valentini<sup>5</sup>, S. Vettori<sup>5</sup>, P. Di Benedetto<sup>6</sup>, V. Liakouli<sup>6</sup>, R. Giacomelli<sup>6</sup>, M. Mahler<sup>4</sup>. <sup>1</sup>Immunorheumatology Research Laboratory, Irccs Istituto Auxologico Italiano; <sup>2</sup>Division of Rheumatology, Asst Pini-CTO; <sup>3</sup>Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milan, Italy; <sup>4</sup>Research and Development, Inova Diagnostics, San Diego, USA; <sup>5</sup>Department of Clinical and Experimental Medicine, Rheumatology Section, Second University of Naples, Naples; <sup>6</sup>Department of Rheumatology, University of L'Aquila, School of Medicine, L'Aquila, Italy

**Background:** Systemic sclerosis (SSc) is a chronic autoimmune disease characterised by vascular changes and progressive fibrosis of skin and various internal organs. In SSc a variety of autoantibodies have been detected which are useful for the diagnosis and management of the disease. Some of these autoantibodies are well-established tools strongly associated with SSc (e.g. anti-centromere, anti-topoisomerase I, anti-RNA polymerase III). Other autoantibodies are less frequent and/or less-specific for SSc even if potentially useful to better assess disease subsets and prognosis.

**Objectives:** Our goal was to assess the frequency of SSc-related autoantibodies detected using a novel technology as well as to study the associations between these antibodies and clinical features in an Italian SSc cross sectional cohort.

**Methods:** Serum samples from 218 consecutive patients with SSc collected at three Italian sites were tested for a variety of autoantibodies (see table 1) using a novel fully automated system utilising bead-based immunoassays (research use only, Inova Diagnostics, San Diego, CA). The Italian cohort included: women 200 (92%), limited cutaneous SSc (lc-SSc) 166 (76%), patients with history of digital ulcers 91 (42%), calcinosis 46 (21%), lung fibrosis 84 (39%), heart involvement 38 (17.4%), pulmonary arterial hypertension 20 (9%), and esophageal involvement 138 (63.3%).

**Results:** The prevalence of antibodies is summarised in the table 1 below. Of note, anti-BICD2, anti-CENP-B, and anti-nucleosome antibodies were significantly associated with lc-SSc subtype (p=0.0237, p<0.0001, p=0.0096, respectively), while anti-Ro60, anti-SSB, anti-ScI-70, and anti-DFS70 antibodies were significantly associated with the diffuse cutaneous SSc (dc-SSc) subtype (p=0.0102, p<0.0001, p<0.0001, and p=0.0032, respectively). When analysing all antibodies with multivariate analysis, SSc patients showed significant clustering based on antibody profile and clinical phenotype.

**Conclusions:** Autoantibodies identified via the novel system in this SSc cohort were found in the expected frequencies and also correlated to clinical features of the patients. The multiparameter approach combined with cluster analysis holds promise for a molecular and more precise stratification of SSc subsets.

**FRI0415 HUMAN SKELETAL MUSCLE XENOGRAFTS TO MODEL SPORADIC INCLUSION BODY MYOSITIS**

K. Britson<sup>1</sup>, K. Russell<sup>2</sup>, K. Wagner<sup>3</sup>, L.W. Ostrow<sup>4</sup>, T.E. Lloyd<sup>5</sup>. <sup>1</sup>Graduate Program in Cellular and Molecular Medicine, Johns Hopkins University School of Medicine, Baltimore; <sup>2</sup>Thomas Jefferson University, Philadelphia; <sup>3</sup>Kennedy Krieger Institute; <sup>4</sup>Department of Neurology and Pathology; <sup>5</sup>Departments of Neurology and Neuroscience, Johns Hopkins University School of Medicine, Baltimore, USA

**Background:** Sporadic inclusion body myositis (IBM) is the most common acquired muscle disease in adults over the age of 50, yet the underlying cause of the disease is unknown, and there are no disease-modifying therapies<sup>1</sup>. The robust endomysial inflammation in addition to an increased association of IBM with specific HLA haplotypes and other autoimmune diseases suggests that IBM is primarily an autoimmune disease<sup>2</sup>. However, an association with ageing, a lack of response to immunotherapy, and presence of pathological features such as ubiquitinated protein aggregates seen in neurodegenerative diseases suggest the immune response may be secondary to myodegeneration. Thus, the relationship between inflammation, inclusions, and myodegeneration in IBM is poorly understood.

**Objectives:** Fundamental obstacles to therapeutic development for IBM include the limited understanding of disease pathogenesis as well as a lack of animal models. It is our objective to address these deficiencies by developing a novel mouse xenograft model of IBM.

**Methods:** In this xenograft model, human muscle biopsy specimens are transplanted into immunodeficient mice. The human myofibers cut during the biopsy procedure degenerate, but new muscle fibres regenerate from the patient's satellite cells. This newly regenerated muscle is revascularized and innervated by the mouse host<sup>2</sup>. Xenografts are collected at various post-operative timepoints ranging from three to eleven months and cryosectioned to carry out histochemical and immunohistochemical analysis.

**Results:** Our preliminary data show that IBM xenografts develop pathologic features of the human disease.

At 4 months, collections of xenografts from a patient with healthy muscle, a dermatomyositis patient, and an IBM patient display successful regeneration. Regeneration appears less robust in IBM xenografts and is inversely associated with number of human CD3+ cells and sarcoplasmic MHC-I upregulation. A proportion of the CD8+ T cells within the IBM xenografts are proliferative at 4 months, and this is significantly reduced at 6 months (Fisher exact test,  $p < 0.0001$ ). In addition, at 8.5 months, the IBM xenograft shows rare fibres containing p62 positive puncta.

**Conclusions:** This xenograft model will allow us to investigate the interactions between human muscle and immune system in a mouse host. We are using this model for mechanistic studies and preclinical therapeutic testing in IBM.

**FRI0416 XIAP AS NOVEL INTEGRATOR OF TGF BETA SIGNALLING AND CANONICAL WNT SIGNALLING IN TISSUE FIBROSIS**

C. Bergmann<sup>1</sup>, L. Hallenberger<sup>1</sup>, B. Merlevede<sup>1</sup>, A. Brandt<sup>1</sup>, C. Dees<sup>1</sup>, C.-W. Chen<sup>1</sup>, M. Stock<sup>1</sup>, C. Beyer<sup>1</sup>, O. Distler<sup>2</sup>, G. Schett<sup>1</sup>, J. Distler<sup>1</sup>. <sup>1</sup>Internal Medicine III-Rheumatology, University Clinic Erlangen-nuremberg, Erlangen, Germany; <sup>2</sup>Department for Rheumatology, Universitätsspital, Zürich, Switzerland

**Background:** Aberrant activation of profibrotic pathways is a key feature of systemic sclerosis (SSc). Extensive evidence characterises TGF $\beta$ - and canonical WNT-signalling as key drivers of fibroblast activation. The crosstalk between those pathways, however, remains largely unknown. A better understanding of the interplay of different profibrotic pathways may be the key to the development of effective targeted therapies. XIAP (X-linked inhibitor of apoptosis protein) is an ubiquitously expressed member of the IAP protein family with important functions in tissue turnover. XIAP was recently described to be implicated in canonical Wnt signalling and TGF $\beta$  signalling.

**Objectives:** The aim of this study is to characterise the role of XIAP in fibrotic disease.

**Methods:** XIAP-expression was analysed by qPCR, IF and Western blot. XIAP was targeted pharmacologically with Embelin. The activation of the canonical Wnt pathway was assessed by analyses of Wnt target genes and by TOPflash/FOP-flash luciferase reporter assay. *In vivo*, XIAP inhibition was analysed in two different models of fibrosis.

**Results:** The expression of XIAP is increased in the skin of SSc patients compared to matched healthy individuals with a particularly prominent expression in fibroblasts. The overexpression of XIAP is more pronounced in SSc patients with diffuse and active skin fibrosis compared to SSc patients with limited and inactive disease. The overexpression of XIAP is also reflected in several experimental fibrosis models: the model of sclerodermatous graft versus host disease, the model of bleomycin induced skin fibrosis and in Wnt10b transgenic mice. Stimulation with either recombinant Wnt1 or TGF $\beta$  cytokine induces the expression of XIAP in cultured fibroblasts. Inhibition of XIAP reduced the Wnt1- and TGF $\beta$  induced activation of fibroblasts with reduced collagen release and expression of myofibroblast markers. In addition, XIAP inhibition reverted the activated fibroblast phenotype in SSc fibroblasts with reduced expression of stress fibres and  $\alpha$ SMA. The antifibrotic effects of XIAP inhibition occurred in non-toxic doses. Mechanistically, XIAP inhibition reduced the activation of canonical Wnt signalling as demonstrated by TOPflash reporter assays and by the analysis of canonical Wnt target genes. XIAP inhibition also reduced the expression of canonical Wnt target genes in Wnt10b transgenic mice. To analyse the effects of XIAP inhibition *in vivo*, two mouse models were used: the model of bleomycin-induced dermal fibrosis and Wnt10b-transgenic mice. In both models, the pharmacological inhibition of XIAP exerted anti-fibrotic effects with reduced dermal thickening, reduced myofibroblast counts and reduced hydroxyproline contents.

**Conclusions:** XIAP is upregulated in SSc fibroblasts in a TGF $\beta$ -dependent manner and promotes fibroblast activation by fostering canonical WNT signalling. Our data suggest that XIAP mediates an amplification loop between TGF $\beta$  and canonical Wnt signalling. Inhibition of XIAP may thus be a novel approach to target aberrant canonical WNT signalling in fibrotic diseases.

**FRI0417 CD86 EXPRESSION ON CULTURED SKIN FIBROBLASTS FROM SYSTEMIC SCLEROSIS PATIENTS: IN VITRO EFFECTS OF CTLA4-IG**

M. Cutolo<sup>1</sup>, P. Montagna<sup>1</sup>, S. Soldano<sup>1</sup>, A.C. Trombetta<sup>1</sup>, P. Contini<sup>2</sup>, B. Ruaro<sup>1</sup>, A. Sulli<sup>1</sup>, S. Scabini<sup>3</sup>, E. Stratta<sup>3</sup>, R. Brizzolara<sup>1</sup>. <sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, IRCCS Policlinic San Martino, Genoa; <sup>2</sup>Division of Clinical Immunology, Department of Internal Medicine, University of Genoa, IRCCS Policlinic San Martino, Genoa; <sup>3</sup>Oncology Surgery, Department of Surgery, IRCCS Policlinic San Martino, Genoa, Italy

**Background:** Skin fibroblasts (SFs) are involved in the excessive production of extracellular matrix (ECM) proteins which characterises fibrosis in systemic sclerosis (SSc).<sup>1</sup> Myofibroblasts which are characterised by a higher expression of pro-fibrotic molecules (a-SMA: alpha-smooth muscle actin; S100A4: fibroblast-specific protein-1) as well as by the over-production of ECM proteins (FN: fibronectin; collagens type I and III), may originate from the activation and differentiation of resident fibroblasts after multiple profibrotic stimuli.<sup>2</sup>

CTLA4-Ig interacts with the cell surface costimulatory molecule CD86 and can downregulate the target cell activation.<sup>3</sup>

**Objectives:** To evaluate CD86 expression and the *in vitro* effects of CTLA4-Ig on skin fibroblasts (SFs).

**Methods:** Skin biopsies were obtained from 8 "limited" cutaneous SSc patients (treated only with vasodilators, mainly cyclic prostanoids) and 4 healthy subjects (HSs), after EC and patient informed consent. After 8 days (T8) of culture, SFs obtained from biopsies were treated for 24 and 48 hours, in the absence or in the presence of CTLA4-Ig (10, 50, 100 and 500 micrograms/ml). Evaluation of CD86 expression was performed by quantitative real-time polymerase chain reaction (qRT-PCR). In addition, also human macrophages obtained from PBMCs of SSc patients, were cultured. The statistical analysis was carried out by the non-parametric Mann-Whitney U test.

**Results:** Cultured SSc fibroblasts showed a very low gene expression level of CD86, compared to cultured macrophages of SSc patients, taken as positive control for CD86 expression (99% less). Therefore, cultured SSc fibroblasts treated for 24 hours and for 48 hours with CTLA4-Ig (10, 50, 100 and 500 micrograms/ml) did not show any significant modulation in the gene expression levels of CD86, compared to untreated fibroblasts (CNT). Interestingly, cultured HSs fibroblasts treated with CTLA4-Ig for 24 hours and for 48 hours showed a significant decrease in the gene expression of CD86, limited to the highest dose (500 micrograms/ml), compared to CNT (0.16% and 0.64% less, respectively) ( $p < 0.05$ ).

**Conclusions:** In the present short-term study (24 and 48 hours), no significant effects at qRT-PCR resulted after CTLA4-Ig treatment of cultured SSc SFs. The result might arise from a limited expression of CD86, as consequence of a retained advanced differentiation of the the SSc fibroblasts. On the contrary, a significant reduction of CD86 expression on HSs fibroblasts treated with CTLA4-Ig was observed.

### FRI0418 IN VITRO EFFECTS OF CTLA4-IG TREATMENT ON CULTURED FIBROCYTES FROM SYSTEMIC SCLEROSIS PATIENTS

M. Cutolo<sup>1</sup>, P. Montagna<sup>1</sup>, S. Soldano<sup>1</sup>, A.C. Trombetta<sup>1</sup>, B. Ruaro<sup>1</sup>, P. Contini<sup>2</sup>, A. Sulli<sup>3</sup>, S. Scabini<sup>3</sup>, E. Stratta<sup>3</sup>, R. Brizzolara<sup>1</sup>. <sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, IRCCS Policlinic San Martino, Genoa; <sup>2</sup>Division of Clinical Immunology, Department of Internal Medicine, University of Genoa, IRCCS Policlinic San Martino; <sup>3</sup>Oncologic Surgery, Department of Surgery, IRCCS Policlinic San Martino, Genoa, Italy

**Background:** Circulating fibrocytes (CFs) are progenitor cells derived from bone marrow, expressing markers of both hematopoietic cells (CD45, MHC class II) and stromal cells (collagen I and III), together with the chemokine receptors, which regulate their migration into inflammatory lesions (CXCR4, CCR2, CCR7).<sup>1</sup> CFs can migrate into SSc-affected tissues and can differentiate into fibroblasts/myofibroblasts.<sup>2</sup> CFs express the CD86 (B7.2) costimulatory molecule and the adhesion molecules CD11a, CD54, ICAM-1, and CD58. The fusion molecule CTLA4-Ig interacts with CD86 and can downregulate the target cell.<sup>3</sup>

**Objectives:** To study the *in vitro* effects of CTLA4-Ig on cultured CFs.

**Methods:** CFs were obtained from the peripheral blood samples of 8 “limited” cutaneous SSc patients (treated only with vasodilators, mainly cyclic prostanoids) and from 4 healthy subjects (HSs). CFs were characterised by fluorescence-activated cell sorter analysis (FACS), at basal time (T0) and after 8 culture days (T8), for CD45, collagen type I (COL I), CXCR4, CD14, CD86, and HLA-DRII expression. T8-cultured CFs were treated for 3 hours in the absence or in the presence of CTLA4-Ig (10, 50, 100 and 500 micrograms/ml). Quantitative real-time polymerase chain reaction (qRT-PCR) for CD86, COL I, IL1b, TGFb, αSMA, S100A4, CXCR2, CXCR4, CD11a were performed. The statistical analysis was carried out by the nonparametric Mann-Whitney U test. Skin samples for fibroblast (SFs) cultures were obtained from the same patients after EC and patient informed consent.

**Results:** At qRT-PCR, T8-SSc fibrocytes, in the absence of CTLA4-Ig treatments, showed higher CD86 expression levels compared to HSs fibrocytes. Similarly also αSMA, S100A4, TGFb and COL I gene expression resulted higher in SSc fibrocytes compared to HSs. After CTLA4-Ig treatments, only in SSc fibrocytes, the αSMA and COL I gene expression resulted significantly decreased (p<0.01, p<0.05), whereas the gene expression for S100A4 resulted significantly increased (p<0.01), compared to untreated fibrocytes. Interestingly, in skin fibroblasts from the same SSc patients, the CD86 gene expression was found to be very low, compared to CFs.

**Conclusions:** Circulating fibrocytes from patients affected by limited cutaneous SSc seem to be responsive and downregulated after *in vitro* CTLA4-Ig treatments, suggesting a possible antifibrotic effect on progenitor cells before their final homing and differentiation in active myofibroblasts. Fibroblasts from the same patient do not show the same expression of target molecules and reactivity to CTLA4-Ig.

Sanges<sup>1,2,3</sup>, E. Hachulla<sup>1,2,3</sup>, G. Lefevre<sup>1,2,3</sup>, M. Labelette<sup>1,4</sup>, S. Dubucquoi<sup>1,4</sup>, D. Launay<sup>1,2,3</sup>. <sup>1</sup>Univ. Lille, INSERM U995 LIRIC – Lille Inflammation Research International Center; <sup>2</sup>Centre National de Référence Maladies Systémiques et Auto-immunes Rares (Sclérodémie Systémique); <sup>3</sup>CHU Lille, Département de Médecine Interne et Immunologie Clinique; <sup>4</sup>CHU Lille, Institut Immunologie, Lille, France

**Background:** Systemic sclerosis (SSc) is an autoimmune disease characterised by an extensive multi-organs fibrosis. Immunosuppressants are effective in some extent but their incomplete efficacy is hampered by a higher infection risk. Intravenous immunoglobulins (IVIg) have a good safety profile, exhibit immunomodulatory and antifibrotic properties and hence could be a relevant treatment for SSc.

**Objectives:** The purpose of this study was to investigate the effects of IVIg in an experimental model of SSc.

**Methods:** SSc was induced in 6 weeks old Balb/c mice by subcutaneous injections of HOCl five days a week during six weeks (n=20), whereas control mice received subcutaneous injections of PBS (n=20). Human IVIg was administered intravenously by single retro-orbital injection at a dose of 2 g/kg the first day of HOCl administration (n=20). A control group received an injection of 2% Maltose (n=20). Skin thickness was assessed during the protocol until the sacrifice (day 42). Skin tissues were collected in 4% PFA and processed for histological analysis. Dermal thickness was measured by performing a May-Grünwald-Giemsa staining of 4 μm skin sections; collagen deposition was assessed by performing a Picrosirius red-staining and quantified by using a colour deconvolution method. In addition, immunostaining of skin sections was performed in order to evaluate the α-smooth muscle actin (α-SMA) expression. Frozen skin tissues were analysed to also assess the mRNA expression of main inflammatory and pro-fibrotic genes (by quantitative reverse transcription polymerase chain reaction). Collagen deposition was also evaluated by measuring the content of hydroxyproline in 10 mg of frozen tissue.

**Results:** Mice exposed to HOCl developed a diffuse cutaneous SSc with higher dermal thickness compared to the PBS group. IVIg significantly reduced dermal thickness and collagen deposition in HOCl-receiving mice. The amount of α-SMA positive cells evaluated by immunofluorescence was reduced in the HOCl treated mice receiving IVIg. mRNA expression profile of various markers of fibrosis (fibronectin, TGFβ) or inflammation (TNFα, IL-1β, IL-6) were also significantly decreased in the skin of HOCl mice treated with IVIg compared to HOCl-treated mice receiving 2% maltose.

**Conclusions:** These results demonstrate the efficacy of IVIg in preventing experimental fibrosis in a HOCl murine model of SSc.

**Disclosure of Interest:** None declared

### FRI0420 ALTERED TRANSCRIPTOME OF CIRCULATING CD14+ MONOCYTES IN SYSTEMIC SCLEROSIS

M. Rudnik<sup>1</sup>, M. Stellato<sup>1</sup>, P. Blyszczuk<sup>1,2</sup>, O. Distler<sup>1</sup>, G. Kania<sup>1</sup>. <sup>1</sup>Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; <sup>2</sup>Department of Clinical Immunology, Jagiellonian University Medical College, Krakow, Poland

**Background:** Previous studies indicated monocyte-derived cells as important players in the development of multiple organ fibrosis. Although changes in monocyte's phenotypes as well as an increased infiltration into fibrotic organs were reported in systemic sclerosis (SSc), the detailed role of these cells in multi-organ fibrogenesis remains unclear.

**Objectives:** We aimed to characterise a contribution of circulating CD14<sup>+</sup> monocytes in the disease course in limited cutaneous (lc) and diffuse cutaneous (dc) SSc.

**Methods:** CD14<sup>+</sup> monocytes were isolated from peripheral blood of lcSSc (n=5, age=54.4±6.7), dcSSc patients (n=5, age=51.8±7.2) and age- and sex-matched healthy controls (HC) (n=5, age=50.8±9.7). Total RNA was isolated and polyA libraries were prepared using TruSeq Stranded mRNA kit. Next Generation Sequencing was performed using Illumina HiSeq 4000 platform. Differentially expressed genes were computed using DESeq2 algorithm. Principal Component Analysis (PCA) was accomplished as well as pathway analysis using Metacore software. mRNA levels of top targets were confirmed by qPCR.

**Results:** We detected 1440 differentially expressed genes between dcSSc vs HC and 225 between lcSSc and HC respectively ( $p < 0.01$ ;  $\log_2$  ratio  $\geq 0.5$ , figure 1). Among those, in dcSSc 1076 were upregulated (e.g. MMP9, IL1R2, FLT3, MIF, TLR9) and 364 were downregulated (e.g. TGFBR1, CD44, CD244, HLA-DRA, HLA-G). In lcSSc 160 transcripts were upregulated (e.g. CCL2, WNT5B, MMP17) and 65 were downregulated (e.g. KLF11, IRAK2). We identified 123 commonly deregulated genes between SSc subgroups (e.g. CCL3, CD14, IL27, MMP17). Principal component analysis showed close clustering within SSc subgroups and clear separation from healthy controls. Pathway analysis revealed alterations in several biological processes important in fibrogenesis including antigen presentation, MIF-induced immune responses, TGF- $\beta$ , NOTCH and WNT signalling pathways. qPCR analysis further confirmed differences in gene expression on mRNA level (n HC=8, n SSc=25,  $p < 0.05$ ).

**Abstract FRI0420 – Figure 1.** Volcano plots representing differentially expressed genes in lcSSc vs HC (A) and dcSSc vs HC (B). Red dots stand for significantly deregulated transcripts ( $p < 0.01$ ;  $\log_2$  ratio  $\geq 0.5$ ).

**Conclusions:** To our knowledge, this is the first global transcriptome analysis of peripheral blood CD14<sup>+</sup> monocytes in SSc. Our results suggest an initial activation of monocytes in peripheral blood, which might be further translated into novel cellular biomarker of the disease and potentially used for distinguishing between responders and non-responders to a novel treatment in future clinical trials.

#### FRI0421 TOLL LIKE RECEPTOR-7/8 ACTIVATION EXACERBATES MURINE EXPERIMENTAL AUTOIMMUNE MYOSITIS

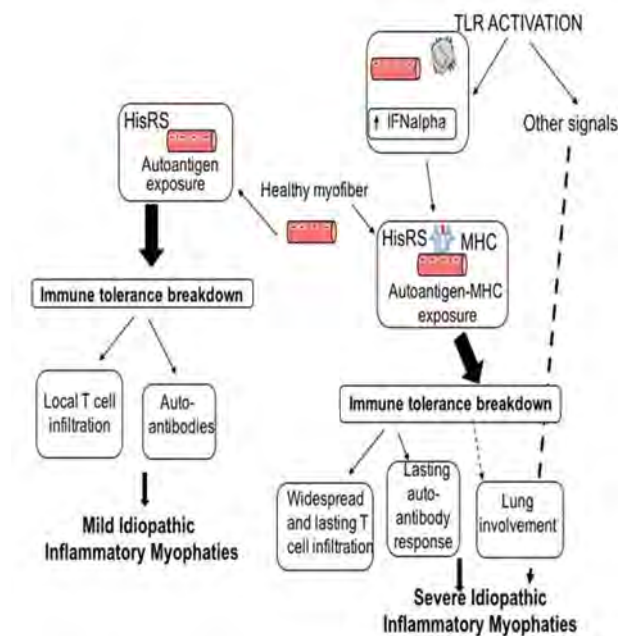

R. De Lorenzo<sup>1</sup>, C. Sciorati<sup>1</sup>, A. Monno<sup>1</sup>, M.G. Doglio<sup>1</sup>, E. Rigamonti<sup>1</sup>, D. Ascherman<sup>2</sup>, A. Manfredi<sup>1</sup>, P. Rovere-Querini<sup>1</sup>. <sup>1</sup>San Raffaele Scientific Institute, Milan, Italy; <sup>2</sup>University of Miami, Miami, USA

**Background:** Type I interferon (IFN)-regulated proteins are upregulated in muscle and skin tissues of patients with idiopathic inflammatory myopathies (IIM).<sup>1</sup> Type I IFN induction might rely upon the activation of toll-like receptors (TLRs).<sup>2</sup> Specifically, TLR-7/8 is indeed upregulated in infiltrating leukocytes and muscle tissue of IIM patients.<sup>3</sup>

**Objectives:** To investigate whether the activation of TLR-7/8 and type I IFN influences the natural history of the IIM.

**Methods:** Experimental autoimmune myositis (EAM) was induced by injection of the amino-terminal portion of the murine Histidyl t-RNA synthetase (HisRS). Disease activity was compared in the presence or absence of the TLR-7/8 agonist R848 in wild-type mice and in mice that failed to express the IFN $\alpha$ R receptor (IFN $\alpha$ R null).

**Results:** EAM induced by a single intramuscular immunisation with HisRS spontaneously abated after 7–8 weeks. In contrast, the levels of anti-HisRS autoantibodies, endomysial/perimysial leukocyte infiltration and myofiber regeneration persisted until the end of the follow-up period (22 weeks after immunisation) in mice immunised with HisRS in the presence of R848. Myofiber MHC class I molecules were detectable in HisRS +R848 immunised mice only. Muscle MHC expression occurred in parallel with leukocyte infiltration. Type I IFN was necessary for the prolonged autoantibody response to occur and for the spreading of the autoimmune response, as demonstrated using IFN $\alpha$ R null mice.

**Abstract FRI0421 – Figure 1.** Role of TLR7/8 activation in HisRS-induced myositis

**Conclusions:** TLR7/8 activation is needed to induce and maintain a systemic autoimmune response against the skeletal muscle. This EAM model reproduces many characteristics of human IIM and may represent a tool for pre-clinical studies.

#### FRI0422 ROLE OF THE PROLYL 3-HYDROXYLASE LEPREL1 IN FIBROSIS

H. Lopez<sup>1,2</sup>, B. Abdi Ahmed<sup>1</sup>, D. Abraham<sup>1</sup>, L. Bozec<sup>3</sup>, C. Denton<sup>1</sup>, A. Strange<sup>3</sup>, G. Martin<sup>4</sup>, R. Stratton<sup>1</sup>. <sup>1</sup>Centre for Rheumatology and Connective Tissue Diseases, UCL, London, UK; <sup>2</sup>Murigenics, Valejo CA, USA; <sup>3</sup>Eastman Centre for Postgraduate Research, UCL, London, UK; <sup>4</sup>Riptide Bioscience, San Francisco CA, USA

**Background:** Three prolyl 3-hydroxylase enzymes, *LEPRE1*, *LEPREL1* and *LEPREL2*, are known to modify prolines in certain sequences in the C-terminal helical region of the polypeptide chains of procollagens converting them to 3-hydroxyproline residues. This modification appears to facilitate correct alignment of the chains in forming the triple helical domains of the procollagen molecules prior to secretion. Increased deposition of triple helical collagen and other extracellular matrix (ECM) proteins by activated fibroblasts underlies pathological fibrosis in systemic sclerosis (SSc), and may be dependent on prolyl 3-hydroxylase activity as a rate-limiting step.

**Objectives:** The objectives of this study were: 1) to screen candidate genes with large first introns containing regulatory elements for association with systemic sclerosis (SSc) through copy number variation (CNV), 2) to study the lead candidate gene *LEPREL1* further, as a fibrosis-related factor in genetically modified mice subject to bleomycin induced skin fibrosis, 3) to determine the levels of

LEPREL1 protein in SSc and control fibroblasts and measure possible induction by profibrotic factors, and 4) measure the effect of *LEPREL1* gene editing on triple helical collagen secretion by SSc disease fibroblasts.

**Methods:** DNA samples from SSc patients and controls were assayed by qPCR for CNVs within regulatory regions of 40 candidate genes. The lead candidate, *LEPREL1* was studied further through tagging SNP analysis, of rs7612998, rs1447936, s1018343, s696065, in 564 SSc and 627 controls. In wild type (WT), GPVI  $-/-$  single knockout (SKO) or *LEPREL1* $-/-$  GPVI  $-/-$  double knockout (DKO) mice skin fibrosis was initiated by daily subcutaneous bleomycin for 14 days (*LEPREL1* $-/-$  embryonically lethal due to placental thrombosis). Skin fibrotic lesions sampled on day 21 were analysed by histology and picrosirius red stain. SSc and control skin fibroblasts grown from forearm skin biopsies, were cultured at passage 3–5, with or without the pro-fibrotic TGF $\beta$ , or with or without estradiol in cells grown in oestrogen depleted conditions (no phenol red). *LEPREL1* was assayed by Western blot. CRISPR/Cas9 was used to edit the *LEPREL1* gene in SSc skin fibroblasts.

**Results:** Initial screening of candidate genes revealed a weak statistical association between a first intron CNV nsv514192 and SSc susceptibility in males ( $p < 0.028$ ). However SNP analysis demonstrated that a haplotype, identified as CTA across the 4 SNPs, was associated with increased risk of SSc development (OR 3.45,  $p < 0.0023$ ). This allele opens a FOXA1 site in the first intron and was seen predominantly in females. In cultured dermal fibroblasts *LEPREL1* protein levels were raised in SSc samples and induced to SSc levels in control fibroblasts by culture with TGF $\beta$ . Estradiol also induced *LEPREL1* and collagen I protein. In genetically modified *LEPREL1* knockout mice, resistance to bleomycin skin fibrosis was seen (figure 1). Silencing of *LEPREL1* in SSc fibroblasts by CRISPR/Cas9 preferentially reduced triple helical collagen I secretion.

**Conclusions:** The prolyl 3-hydroxylase *LEPREL1* is confirmed as a fibrosis-related gene associated with SSc susceptibility. Small molecule inhibitors of this endoplasmic reticulum enzyme may limit the overproduction of collagen as a therapy for fibrosis.

**Disclosure of Interest:** None declared

#### FRI0423 EFFECTS OF SELEXIPAG IN CULTURED SCLERODERMA SKIN FIBROBLASTS

M. Cutolo<sup>1</sup>, B. Ruaro<sup>1</sup>, P. Montagna<sup>1</sup>, R. Brizzolara<sup>1</sup>, A.C. Trombetta<sup>1</sup>, S. Scabini<sup>2</sup>, P.P. Tavilla<sup>3</sup>, A. Parodi<sup>3</sup>, C. Corallo<sup>4</sup>, N. Giordano<sup>4</sup>, S. Paolino<sup>1</sup>, C. Pizzorni<sup>1</sup>, A. Sulli<sup>1</sup>, V. Smith<sup>5</sup>, S. Soldano<sup>1</sup>. <sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Polyclinic San Martino Hospital; <sup>2</sup>Oncologic Surgery, Department of Surgery, Polyclinic San Martino Hospital; <sup>3</sup>Department of Health Science, Unit of Dermatology, University of Genoa, Genoa; <sup>4</sup>Department of Medicine, Surgery and Neurosciences, Scleroderma Unit, University of Siena, Siena, Italy; <sup>5</sup>Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

**Background:** In systemic sclerosis (SSc), the transition of fibroblasts into profibrotic myofibroblasts contributes to fibrosis through their over-production of extracellular matrix (ECM) proteins, primarily type I collagen (COL-1) and fibronectin (FN), a process which is mediated by the activation of fibrogenic intracellular signalling transduction molecules, including Erk1/2 and Akt kinases.<sup>1,2</sup> Selexipag and its active metabolite (ACT-333679) are prostacyclin receptor agonists which leads to vasodilation in the pulmonary circulation and mainly used in the treatment of pulmonary arterial hypertension.

**Objectives:** To investigate the possible effects of selexipag and ACT-333679 in downregulating the profibrotic activity of cultured SSc fibroblasts/myofibroblasts and the fibrogenic signalling molecules involved in the process.

**Methods:** After obtaining Ethics Committee (EC) approval and informed consent, fibroblasts isolated from skin biopsies of 6 SSc patients (mean age 63±13 years) were cultured until the 3rd culture passage and then either maintained in normal growth medium (untreated cells) or independently treated with different

concentrations of selexipag (from 30 µM to 0.3 µM) or ACT-333679 (from 10 µM to 0.1 µM) for 48 hours. Protein and gene expressions of  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA), fibroblast specific protein-1 (S100A4), COL-1, and FN were investigated by Western blotting and qRT-PCR.

Erk1/2 and Akt phosphorylation was investigated in untreated and ACT-333679 treated cells at 15 and 30 min as well as at 48 hours by Western blotting.

**Results:** Selexipag and ACT-333679 significantly reduced the protein synthesis and the gene expression of  $\alpha$ -SMA, S100A4, and COL-1 in cultured SSc fibroblasts/myofibroblasts compared to untreated cells, primarily at the concentrations of 3 µM and 0.3 µM for selexipag and 1 µM and 0.1 µM for ACT-333679 ( $p < 0.05$ ). Differently, FN was significantly downregulated at protein level ( $p < 0.05$  vs. untreated cells).

Of note, ACT-333679 significantly reduced the phosphorylation of Erk1/2 and Akt kinases already after 30 min of treatment in cultured SSc fibroblasts/myofibroblasts, and this effect was further maintained at 48 hours from treatment ( $p < 0.05$  vs. untreated cells, for all tested concentrations).

**Conclusions:** For the first time selexipag and mainly its active metabolite ACT-333679 were found to interfere with the profibrotic activity of cultured SSc fibroblasts/myofibroblasts, possibly through the downregulation of fibrogenic Erk1/2 and Akt intracellular signalling molecules.

#### FRI0424 COMPARATIVE ANALYSIS OF CLINICALLY AFFECTED AND UNAFFECTED SKIN BIOPSIES FROM SCLERODERMA PATIENTS BASED ON RNA-SEQUENCING

Z. Makowska<sup>1</sup>, A. Buttgereit<sup>1</sup>, S. Babaei<sup>1</sup>, N. Limaye<sup>2</sup>, C. Galant<sup>2</sup>, F. Houssiau<sup>2</sup>, B. Weiss<sup>1</sup>, R. Lesche<sup>1</sup>, F. McDonald<sup>1</sup>, B. Lauwerys<sup>2</sup>. <sup>1</sup>Bayer AG, Berlin, Germany; <sup>2</sup>Université Catholique de Louvain, Brussels, Belgium

**Background:** Systemic sclerosis (SSc) is a complex chronic autoimmune disease characterised by vasculopathy, inflammation and fibrosis across different organ systems. The origin and pathogenesis of the disease are not well understood and symptoms may vary among affected individuals, complicating the diagnosis and therapy.

**Objectives:** We aimed at characterising gene expression profiles in biopsies from affected and unaffected skin of SSc patients.

**Methods:** RNA isolated from affected and unaffected skin biopsies of 23 SSc patients was analysed using polyA-selected RNA sequencing. Paired differential expression analysis was performed with DESeq2, and Molecular Signatures Database gene set collections were used for functional annotation.

**Results:** Paired analysis of SSc gene expression profiles identified over 900 genes differentially regulated between the affected and unaffected skin biopsy samples (adjusted p value < 0.05). Macroscopically unaffected skin samples showed clear gene expression differences from the affected skin samples, even though the histological examination showed that pathological changes were already present in most of the samples classified as unaffected. Clustering of differentially expressed genes and subsequent functional characterisation of the resulting gene modules revealed sets of co-expressed genes involved in inflammatory response, extracellular matrix interaction, metabolic function and epithelial differentiation, and highlighted the importance of a number of transcription drivers, such as serum response factor (SRF) or interferon regulatory factor 7 (IRF7). Several genes from the HOX family of transcription factors were found to be among the most significantly differentially expressed genes, pointing to an important role of wound healing and regeneration processes in SSc skin lesions. Additionally, we found significant association between expression of several proteasome subunits and the inflammation score obtained by histological assessment of the skin biopsies.

**Conclusions:** RNA sequencing analysis in paired skin biopsy samples revealed coordinated changes in the gene expression between SSc lesions and macroscopically unaffected skin, providing insights into the SSc skin pathogenesis at the molecular level.

FRIDAY, 15 JUNE 2018

## Scleroderma, myositis and related syndromes

### FRI0425 ASSOCIATION BETWEEN TISSUE OXYGEN DELIVERY AND DIGITAL ULCERS IN SYSTEMIC SCLEROSIS

A. Sari<sup>1</sup>, Y.Z. Sener<sup>2</sup>, M. Oksul<sup>2</sup>, B. Armagan<sup>1</sup>, A. Erden<sup>1</sup>, L. Kiliç<sup>1</sup>, A. Akdogan<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Cardiology, Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background:** Digital ulcers (DUs) are common manifestations of vascular disease in systemic sclerosis (SSc) patients.

**Objectives:** To investigate the association between the amount of oxygen delivered to peripheral tissues and the development of DUs in SSc patients.

**Methods:** One hundred and eleven SSc patients (103 female) were recruited consecutively to the study. Thirty age and sex matched controls were also enrolled. Transthoracic echocardiography (TTE) was performed for each patient to estimate cardiac output (CO). Arterial oxygen saturation (SaO<sub>2</sub>) with pulse oximeter in room temperature and serum haemoglobin concentration (Hb) were measured at the time of TTE. The amount of oxygen delivered to tissues (D0<sub>2</sub>) in 1 min was estimated using the equation  $D0_2 = CO \cdot (SaO_2 \cdot 1.39 \cdot Hb)$  and adjusted for body weight. Demographic, clinical and laboratory data were retrieved from hospital records. DUs were described as ulcerations on the skin distal to proximal interphalangeal joints (PIF) of the digits. Patients were divided into 2 groups according to presence of DUs within 1 year of study enrollment (Group1=with DU, Group2=without DU). Chi-square and Mann-Whitney U tests were used for comparing categorical and continuous variables between the groups, respectively.

**Results:** Mean age was 52.6 (11.8) years in SSc patients and 51.3 (13.0) in controls. Median disease duration was 138.0 (1.8–415.2) months. Diffuse disease was present in 30.6% of patients. There were no differences in terms of Hb level, left ventricular ejection fraction (LVEF) and calculated D0<sub>2</sub> between SSc patients and controls. Mean CO was higher in healthy controls (6.1 vs. 5.1,  $p=0.004$ ). Interestingly, mean S0<sub>2</sub> measurements was lower in control group (96.8 vs. 98.0,  $p=0.005$ ). Comparison of demographics, disease characteristics, tissue oxygen delivery and relevant variables were summarised in table 1. When patients with active DUs were compared with patients without active DUs; no difference was found in Hb, S0<sub>2</sub>, CO and D0<sub>2</sub> between groups.

**Abstract FRI0425 – Table 1.** Comparison of demographics, disease characteristics and D0<sub>2</sub> parameters between patients with and without DUs

	Group 1 (n=64)	Group 2 (n=47)	p
Age, years (SD)	52.3(12.0)	49.9(14.4)	0.34
Disease duration, months (SD)	141.0(96.8)	177.3(97.4)	0.06
Female, n (%)	58(90.6)	44(93.6)	0.56
Diffuse disease, n (%)	11(17.2)	23(48.9)	<0.01
ILD, n (%)	32(50.0)	35(74.5)	0.01
PAH, n (%)	3(4.7)	1(2.1)	0.63
Ever smoked, n (%)	16(25.0)	13(27.6)	0.82
HT, n (%)	15(23.4)	6(12.7)	0.22
DM, n (%)	12(18.7)	3(6.3)	0.09
Cardiac involvement, n (%)	1(1.5)	1(2.1)	1.0
Hb, g/dL	12.8(1.4)	12.2(1.4)	0.04
S0 <sub>2</sub> , % (SD)	97.8(2.5)	98.3(1.1)	0.13
CO, ml/min (SD)	5.1(1.5)	5.1(1.6)	0.91
D0 <sub>2</sub> , ml/min/kg (SD)	13.6(4.5)	14.3(4.6)	0.89

**Conclusions:** Although the haemoglobin concentration was higher in the non ulcer group, there was no difference in the amount of delivered oxygen between patients with and without DUs. These findings imply that vasculopathy and/or peripheral artery disease plays a major role in the development of ulcers.

**Disclosure of Interest:** None declared

FRI0426

### RESPONSE OF THE REACTIVE SPECIES INTERACTOME TO HYPOTHERMIA INDUCED RAYNAUD'S ATTACK IN PRIMARY RAYNAUD AND SYSTEMIC SCLEROSIS

A. Eman Abdulle<sup>1</sup>, A.M. van Roon<sup>1</sup>, A.J. Smit<sup>1</sup>, A. Pasch<sup>2</sup>, M. van Meurs<sup>3</sup>, H. Bootsma<sup>4</sup>, B.O. Fernandez<sup>5</sup>, M. Feelisch<sup>5</sup>, H. van Goor<sup>6</sup>, D.J. Mulder<sup>1</sup>.  
<sup>1</sup>Dept. of Internal medicine, div Vascular medicine, University of Groningen – University Medical Centre Groningen., Groningen, Netherlands; <sup>2</sup>Dept. of Clinical Research, University of Bern and Calcison, Bern, Switzerland; <sup>3</sup>Dept. of Critical Care; <sup>4</sup>Dept. of Rheumatology and Clinical Immunology, University of Groningen – University Medical Centre Groningen., Groningen, Netherlands; <sup>5</sup>Dept. of Clinical and Experimental Sciences, University of Southampton – Southampton, Southampton, UK; <sup>6</sup>Dept. of Pathology and Medical Biology, Section Pathology, University of Groningen – University Medical Centre Groningen., Groningen, Netherlands

**Background:** Although the exact etiology of systemic sclerosis (SSc) remains unknown, a current hypothesis is that reactive species (including reactive oxygen species (ROS), reactive nitrogen species (RNS and reactive sulfur species (RSS)) play an important role in the pathogenesis. In addition, the chemical interactions between these molecules, also known as the reactive species interactome, may lead to the formation of more harmful free radicals, thus leading to more damage. We have previously shown a rapid free thiol increase in SSc patients during a cooling and recovery experiment, however the implications of RNS and RSS in this process remain uncharacterized.

**Objectives:** The aim of the current study was to explore nitric oxide and sulfate response, as a measure of the unified reactive species interactome, during hypothermia induced Raynaud's attack in systemic sclerosis (SSc), primary Raynaud's phenomenon (PRP) and healthy controls (HC).

**Methods:** Healthy controls (n=10), PRP patients (n=10) and SSc patients (n=10), all aged ≥ 18 years, were included. All SSc patients fulfilled the ACR/EULAR 2013 criteria. Fingertip photoelectric plethysmography was performed during a standardised cooling and recovery experiment. Patient characteristics were obtained and blood was drawn at four predetermined time points (T<sub>0</sub>, T<sub>1</sub>, T<sub>2</sub> and T<sub>3</sub>). In addition to the previously mentioned free thiols, the following markers were also measured: nitros(yl)ated species, nitrite, nitrate, sulfate and the vascular leakage related molecules angiotensin-1 and angiotensin-2).

**Results:** Our results revealed a significantly longer median duration of hypoperfusion and longer recovery time in SSc patients compared to PRP patients and HC. This coincided with stable levels of angiotensin-1/angiotensin-2 throughout the experiment. In regards to the thiol modification related molecules, (nitrate, nitrite and RXNO) an increased median level of nitrate (T<sub>2</sub>: median 29.6 μmol, range 21.99–41.70 μmol,  $p=0.041$ ) was found in SSc patients. Correspondingly, the same trend was observed for the median plasma concentrations of sulfate ( $p>0.05$  at all time points).

**Conclusions:** We have previously shown an increase of free thiols in all patients during the reperfusion phase. This finding sheds new light on the possibility that processes related to oxidative thiol modification, are rapidly reversible. The current findings revealed also a trend in increased levels of nitrate and sulfate in SSc patients. Therefore, it is plausible that these markers of the redox system interact with one another through the same pathway, underlining the complexity of the redox interactome and suggesting potential novel approaches for therapeutic intervention.

**Abstract FRI0428 – Table 2.** Associations between mean number of capillaries at baseline and disease activity (ESSG score 2003) at FU (linear regression)

Predictors	B (95% CI)	p
m_nr/pat rater 2	-0.45 (-0.834,-0.07)	0.02
m_nr/3rd dom rater 2	-0.33(-0.62,-0.03)	0.03
m_nr/4th non-dom rater 2	-0.27 (-0.57,0.02)	0.07

**Conclusions:** The mean number of capillaries had a good association with the history of DUs and predicted disease activity at 6 months follow-up. The m\_nr/pat performed better in our analysis than the m\_nr/3rd dom and m\_nr/4th non-dom, however these could be used alternatively in clinical practice as they are less time consuming.

#### FRI0429 DISTINCT CLINICAL AND IMMUNOLOGICAL PICTURE OF MCTD PATIENTS WITH SKIN INVOLVEMENT

A. Felis-Giemza<sup>1</sup>, E. Kontny<sup>2</sup>, J. Nalecz-Janik<sup>1</sup>, K. Walkiewicz-Pielaszek<sup>1</sup>, Z. Czuszyńska<sup>3</sup>, Z. Zdrojewski<sup>3</sup>, A. Paradowska-Gorycka<sup>4</sup>, M. Olesińska<sup>1</sup>.

<sup>1</sup>Connective Tissue Disease Department; <sup>2</sup>Department of Patophysiology and Immunology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw Poland, Warsaw; <sup>3</sup>Clinic of Internal Medicine, Connective tissue Disease and Geriatrics, Medical University of Gdansk, Gdańsk; <sup>4</sup>Department of Biochemistry and Molecular Biology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw Poland, Warsaw, Poland

**Background:** Mixed connective tissue disease (MCTD) is characterised by the co-existence of systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), systemic sclerosis (SSc) and polymyositis/dermatomyositis (PM/DM) symptoms. The majority of patients have skin symptoms typical of at least one of the diseases making up the clinical picture MCTD. MCTD is characterised by an auto-reactive antibody response to RNP antigen and resultant formation of anti-U1RNP antibodies. Current knowledge on cytokine biology and their documented role in the pathogenesis of SLE, SSc and PM/DM suggests that also in MCTD some of them may affect clinical course, activity and/or degree of organ damage.

**Objectives:** To compare clinical and immunological characteristics of MCTD patients with/without skin involvement.

To identify clinical and immunological parameters increasing the risk for a specific (SLE- or SS-like) type of skin lesions and protecting against them.

**Methods:** 79 MCTD patients based Kasukawa' MCTD diagnostic criteria were included. The patients were divided into groups based on the presence of skin lesions typical for a given MCTD component: SLE- SSc- and DM-specific.

**Results:** Skin lesions were found in the majority of the MCTD patients (81%). The SLE-, SSc- and DM-specific skin symptoms were found in 54%, 61% and 5% of the patients, respectively. The group of patients with skin symptoms typical of DM was too small to distinguish it separately (4/79). The measures of disease activity (mean AI=10.6 vs 5.5; p=0.006) and MCTD-related damage (DI=4.1 vs 2.1; p=0.009) in patients with skin involvement were twice as high as in individuals with the intact skin. Furthermore, patients with skin involvement had higher mean serum concentrations of TNF- $\alpha$  (46.4 vs 2.3 pg/ml; p=0.013), and lower levels of IFN- $\gamma$  (43.2 vs 120.8 pg/ml; p<0.001) than patients without any skin symptoms.

The following clinical and immunological parameters were shown to be independently associated with specific types of skin involvement in MCTD patients on multivariate logistic regression analysis:

Independent risk factors for:

- SLE-like skin changes: increased ESR (OR=8.9, 4.47 and 2.6, respectively), higher AI scores and swelling of the hands,
- SSc-like skin changes: higher DI scores (OR=1.522), and presence of anti-Ro60 antibodies (OR=15.903)

Independent protective factors for:

- SLE-like MCTD: chronic progressive course of the disease (OR=0.248) and higher serum concentration of IFN- $\gamma$  (OR=0.988)
- SSc-like MCTD: acute onset of the disease (OR=0.155).

**Conclusions:** The course of MCTD in patients with skin involvement is more severe with specific panel of cytokine levels (increased TNF- $\alpha$  and decreased IFN- $\gamma$  serum concentrations) is characteristic, as compared to patients with the intact skin.

In patients with SLE-like skin lesions MCTD is more often multiphasic, its clinical activity and levels of inflammatory markers are higher while serum concentration of IFN- $\gamma$  is diminished. Patients with SSc-like skin lesions more often have chronic MCTD, associated with more severe organ damage and elevated serum levels of TNF- $\alpha$ .

#### FRI0430 EFFECT OF ORAL NUTRITIONAL INTERVENTION ON NUTRITIONAL STATUS IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Wojteczek<sup>1</sup>, M. Ziętkiewicz<sup>1</sup>, S. Małgorzewicz<sup>2</sup>, Z. Zdrojewski<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Connective Tissue Diseases and Geriatrics; <sup>2</sup>Department of Clinical Nutrition, Medical University Of Gdańsk, Gdańsk, Poland

**Background:** Patients with systemic sclerosis (SSc) are at risk of malnutrition, which ranges from 18% to 56% of cases.<sup>1,2</sup> The high impact of nutritional status on clinical outcome has been shown for many diseases. The optimal nutritional treatment can lead to improvement or preservation of the current nutritional status and increases probability of long-term survival.<sup>3</sup>

**Objectives:** The aim of the study was to determine whether nutritional support has an impact on improvement of nutritional status in SSc patients.

**Methods:** The study included 61 patients with SSc and 49 healthy adults. Nutritional status was determined with subjective global assessment (SGA), body mass index (BMI), bioelectrical impedance analysis (BIA) and anthropometric measurements. Nutrition-related laboratory tests were measured. Appetite was assessed by simplified nutritional appetite questionnaire (SNAQ).

**Results:** Impaired nutritional status was confirmed in 16 patients with SSc (26,2%). Those patients had significantly lower SGA, BMI (p=0,0019), hand grip strength (p=0,0019), appetite (p=0,019) and BIA parameters such as lean tissue mass (p=0,013), intracellular water (p=0,0006), adipose tissue mass (p=0,04). In laboratory tests levels of haemoglobin, albumin and HDL cholesterol were significantly lower, while erythrocyte sedimentation rate (ESR) was higher (p=0,0025). Thirteen patients had dietary intervention (high-energy, high-protein, oral, liquid nutritional supplements) for 12 weeks. SGA (p=0,017) and hand grip strength (p=0,006) improved after nutritional treatment. BMI, appetite, BIA parameters, lipid profile and ESR after 12 weeks remained stable.

**Conclusions:** Assessment of nutritional status in SSc patients should be performed regularly, because inclusion of oral nutritional intervention may improve SGA and hand grip strength.

#### FRI0431 DYSREGULATION OF LYMPHANGIOGENETIC FACTORS IN SYSTEMIC SCLEROSIS PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION

A.-M. Hoffmann-Vold<sup>1</sup>, H. Didriksen<sup>1</sup>, H. Fretheim<sup>1</sup>, E. Gude<sup>1</sup>, V. Palchevskiy<sup>2</sup>, T. Garen<sup>1</sup>, Ø. Midtvedt<sup>1</sup>, A. Andreassen<sup>1</sup>, J. Belperio<sup>2</sup>, Ø. Molberg<sup>1</sup>. <sup>1</sup>Oslo University Hospital, Oslo, Norway; <sup>2</sup>UCLA, La, USA

**Background:** Pulmonary arterial hypertension (PAH) continues to be a major complication in systemic sclerosis (SSc); indicating an unmet need for rational therapeutic targets. Recently, we found that chemokine CCL21 was upregulated in SSc and associated with PAH. CCL21 appears to be a key regulator of the expression and secretion of vascular endothelial growth factor-C (VEGF-C); a critical growth factor for lymphatic vessels. This is interesting as SSc is marked by lymphatic vessel abnormalities; and high blood levels of Angiotensin-2, which is a known regulator of VEGF-C. Moreover, it was recently shown that VEGFR3, the cognate receptor for VEGF-C, is down-regulated in pulmonary arterial endothelial cells from human idiopathic PAH subjects with BMPR2 gene defects. Based on these observations, we reasoned that the observed upregulation of CCL21 in SSc-PAH could be linked to VEGF-C and Ang-2 dysregulation.

**Objectives:** Assess serum concentrations of CCL21, the VEGF family and Ang-2 in right heart catheterization (RHC) verified SSc-PAH patients and compare these to patients with borderline PAH, no PH and to healthy controls.

**Methods:** Sera from the prospective Oslo University Hospital SSc cohort (n=372) and healthy controls (n=100) were analysed for VEGF-A,C,D, CCL21 and Ang2 using Luminex kits from Millipore. Patients with an incident RHC (n=167) were included in the present study. PAH was defined as precapillary PH (mean

pulmonary arterial pressure, mPAP  $\geq 25$  mmHg) in the absence of significant interstitial lung disease (ILD), based on high resolution computed tomography and lung function tests. Borderline PAH was defined as mPAP of 20–24 mmHg in the absence of significant ILD. Patients with pulmonary hypertension (PH) due to other causes were excluded. Descriptive statistics and logistic regression analyses were performed and tested by the goodness-of-fit test with area under the curve (AUC).

**Results:** Mean age at onset was  $54 \pm 14.1$ , at RHC  $61 \pm 10.9$  years. The time from sera to RHC was  $0.9 \pm 3.1$  years. In total, 73.7% (123) patients had limited cutaneous SSc, 46.7%<sup>48</sup> were positive for anti-centromere antibody and 80.2% (134) were females. Of these, 123 (73.7%) patients were included in the study, 28 patients with PAH, 45 borderline PAH and 50 patients with no PH. Mean VEGF-A, C, D, CCL21 and Ang2 levels are shown in figure 1A. VEGF-A was significantly higher in SSc patients compared to healthy controls ( $p=0.001$ ), no significant differences between PAH and no PH patients were found. VEGF-D was decreased in SSc-PAH but not significantly. CCL21 and Ang2 levels were increased in patients with PAH, whereas in VEGF-C was significantly decreased in patients with PAH (figure 1 B-D). In univariable logistic regression analyses, VEGF-C (OR 0.99, 95% CI 0.997–0.998,  $p=0.001$ , AUC=0.79), CCL21 (OR 1, 95% CI 1–1.003,  $p=0.050$ , AUC=0.69) and Ang2 (OR 1, 95% CI 1–1.0001,  $p=0.49$ , AUC=0.67) were associated with PAH compared to no PH patients. Due to few event numbers, no multivariable analyses were performed.

Abstract FRI0431 – Figure 1. Serum levels of A) all; B) CCL21; C) VEGF-C and D) Ang2

**Conclusions:** The present study is the first to demonstrate dysregulation of lymphangiogenic factor expression of multiple targets in sera of SSc-PAH patients.

**Disclosure of Interest:** None declared

**FRI0432 SINGLE-PORT THORACOSCOPIC SYMPATHICOTOMY FOR TREATMENT RESISTANT RAYNAUD'S PHENOMENON. FIRST REPORT OF A NOVEL MINIMALLY-INVASIVE ENDOSCOPIC TECHNIQUE**

A. Van Rooij<sup>1</sup>, M. Kuijpers<sup>2</sup>, A. Eman Abdulle<sup>1</sup>, S. Van de Zande<sup>1</sup>, M. Mariani<sup>2</sup>, R. Bos<sup>3</sup>, T. Klinkenberg<sup>2</sup>, H. Bootsma<sup>4</sup>, A. Smit<sup>1</sup>, D.J. Mulder<sup>1</sup>. <sup>1</sup>Dept. Internal Medicine, div. Vascular Medicine; <sup>2</sup>Dept. Thoracic surgery, University of Groningen, University Medical Center Groningen, Groningen; <sup>3</sup>Dept. Rheumatology, Medisch Centrum Leeuwarden, Leeuwarden; <sup>4</sup>Dept. Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands

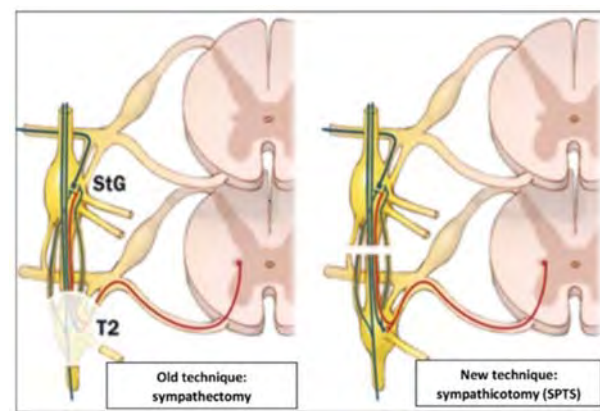

**Background:** Raynaud's phenomenon of the hands is a great burden in daily life and reduces quality of life in patients with or without an underlying connective tissue disease. Although vasodilatory treatment may be effective in some patients, complaints may be resistant to treatment, for which additional treatment options are very limited. In earlier years, thoracic sympathectomy by anterior or axillary thoracotomy has been shown effective, but with a great surgical burden and limited durability. In the 90 s, endoscopic procedures were introduced. However, these techniques needed multiple endoscopic ports and still performed a relatively

mutilating sympathectomy of the sympathetic ganglia. In our centre, the single-port thoracoscopic sympathectomy (SPTS) was developed, which is a new minimally-invasive endoscopic technique with a limited surgical burden.

**Objectives:** The aim of the current pilot study was to evaluate feasibility and efficacy of SPTS in patients with treatment resistant Raynaud's.

**Methods:** This new technique entails only a single-port endoscopic procedure, during which a sympathectomy (figure 1) of the nerve is performed, thus sparing the ganglia. Hospital stay is limited to one day. The procedure has been developed for treatment of hyperhidrosis and performed in our hospital in over 550 patients without major adverse events with a success rate of 98%. In the current study, we aim to include 10 patients with treatment resistant Raynaud's, defined as unsatisfactory effect or contraindications of oral vasodilatory agents and iv prostaglandin analogues. Sympathectomy was performed on the left hand first and the effects were compared with the contralateral hand after 3 and 12 months. Major exclusion criteria were severe lung involvement or proximal vascular stenosis. The primary end point was Raynaud's Condition Score (RCS) and Quality of life (SF-36). Among others, cooling fingertip plethysmography (PPG) and laser doppler imaging (LDI) were used as secondary end points for objective assessment of hand perfusion.

**Results:** This is an interim report, and 4 patients have been included so far (age 20,29,32,56 years), male/female 3/1, 3 primary, 1 secondary), without a history of digital ulcers. No adverse events have been observed, apart from some hyperaemia in the first post-operative week. RCS significantly in each patient. Additionally, a clear improvement in hand perfusion following cooling was observed with PPG and LDI, as compared to the contralateral site. All 4 patients were satisfied and agreed to have their contralateral site operated on also. Patients will be followed in the outpatient clinic to assess long term efficacy.

**Conclusions:** Single-port thoracoscopic sympathectomy is a novel minimally-invasive technique which appears to be safe and feasible in patients with treatment resistant Raynaud's phenomenon. However, this study is ongoing and long-term efficacy needs to be established.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6991

**FRI0433 ASSESSING MORTALITY MODELS IN SYSTEMIC SCLEROSIS RELATED INTERSTITIAL LUNG DISEASE**

R.L. Mango<sup>1</sup>, E.L. Matteson<sup>1</sup>, C.S. Crowson<sup>1</sup>, J.H. Ryu<sup>2</sup>, A. Makol<sup>1</sup>. <sup>1</sup>Division of Rheumatology; <sup>2</sup>Division of Pulmonary and Critical Care, Mayo Clinic, Rochester, USA

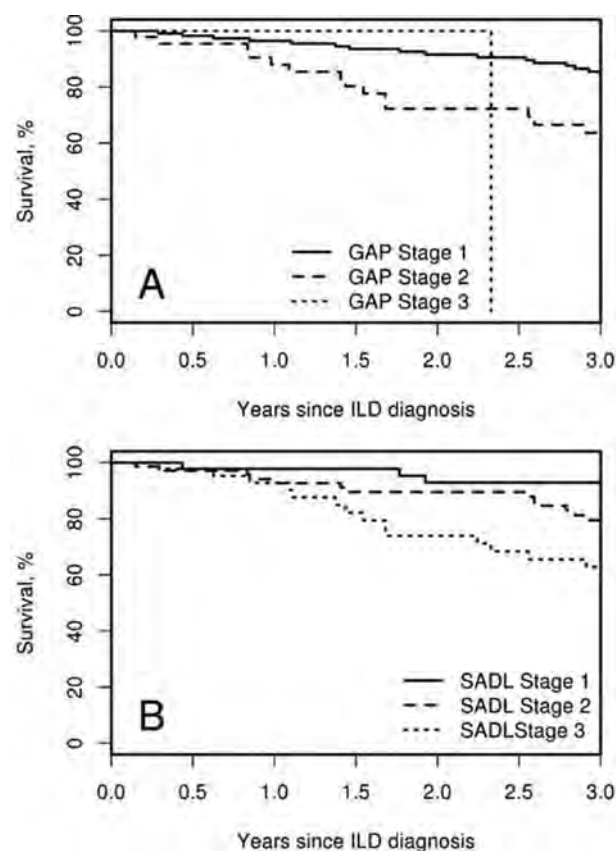

**Background:** Interstitial lung disease (ILD) is a major cause of morbidity and mortality in systemic sclerosis (SSc). However, the severity of lung involvement can vary widely, and current evidence-based treatment options have modest benefit. Prognosis assessment is particularly important for initial management decisions at the time SSc-ILD is diagnosed. There are now multiple mortality models available for use in SSc-ILD which utilise patient's baseline parameters

**Objectives:** The Gender, Age, and Lung Physiology (GAP) model,<sup>1</sup> interstitial lung diseases –GAP (ILD-GAP) model,<sup>2</sup> and the Smoking history, Age, and Diffusion capacity of the Lung (SADL) model<sup>3</sup> were compared using a systemic sclerosis-ILD (SSc-ILD) cohort to evaluate which best determined prognosis.

**Methods:** The models were applied to a cohort of patients with SSc (meeting the 2013 ACR/EULAR classification criteria) seen at a tertiary care centre within 1 year of ILD diagnosis from 2000–2013. Demographics, clinical characteristics,

and mortality were recorded. The performance of the models was assessed using standardised mortality ratios (SMR) of observed vs. predicted outcomes for calibration, and concordance (c)-statistics for discrimination.

**Results:** The cohort included 179 patients with SSc-ILD. Mean age at ILD diagnosis was 57.8 years. There was a female predominance (73%). The mean length of follow up after ILD diagnosis was 4.3 years (SD 4.0). Based on high resolution chest CT (or biopsy when available), 147 (83%) were characterised as nonspecific interstitial pneumonia (NSIP), 31 (17%) as usual interstitial pneumonia (UIP), 1 as unclassifiable ILD. A history of smoking was noted in 49%, and this was not associated with ILD pattern (former/current 46% in NSIP vs. 61% in UIP,  $p=0.11$ ). Pulmonary hypertension (PHTN) was noted in 66 (49%) at baseline, and this did not differ between ILD subtypes. 84% had limited cutaneous SSc, 9% had diffuse cutaneous, and 7% SSc sine scleroderma. SSc specific serologies (i.e., SCL-70, centromere, and/or RNA Pol III) were positive in 73 (43%) patients, somewhat more common in NSIP than UIP (47% vs 26%;  $p=0.034$ ). During a median of 3.2 years of follow-up, 65 patients died. SSc-ILD patients with UIP had a higher mortality than those with NSIP (hazard ratio: 2.27; 95% CI: 1.03–4.97). Other risk factors for progression included baseline DLCO ( $p<0.001$ ), FVC ( $p<0.001$ ) and PHTN ( $p=0.012$ ). All 3 models had comparable discrimination ( $c=0.72$ ,  $0.72$ , and  $0.70$ , respectively). Figure 1 shows the differential mortality based on the GAP and SADL staging systems. (Note the staging in the GAP and ILD-GAP models are identical.) Regarding calibration, the ILD-GAP model underestimated mortality (SMR: 1.5; 95% CI: 1.05–2.14). Calibration was acceptable for SADL (SMR: 0.77; 95% CI: 0.54–1.10) and GAP (SMR: 0.90; 95% CI: 0.63–1.29). The SADL model overestimated mortality in Stage III ILD.

**Conclusions:** The ILD-GAP model underestimated mortality, and the SADL model overestimated mortality in certain subgroups. However, the GAP model performed well in this cohort, providing the best prognostic information for SSc-ILD.

## FRI0434 PATIENTS WITH INFLAMMATORY MYOPATHIES ADMITTED IN ICU ARE CHARACTERISED BY RECENT ONSET AND UNTREATED ACTIVE DISEASE AS WELL AS OLDER AGE AND HIGH COMORBIDITIES

B. Michard, T. Artzner, F. Severac, M. Schenck, J.-E. Herbrecht, R. Janssen-Langenstein, O. Collange, G. Freys, J. Pottecher, J. Sibilia, T. Martin, F. Meziani, F. Schneider, A. Meyer. *CHU Strasbourg, Strasbourg, France*

**Background:** Inflammatory myopathies (IM) are life-threatening but treatable diseases. The risk factors for admission in Intensive care unit (ICU), the management and the outcome of patients with IM admitted to ICU has not yet been assessed.

**Objectives:** To assess the clinical features, risk factors and outcome of patients with IM admitted in ICU.

**Methods:** A single centre cohort of 509 patients with IM was screened for admission in ICU from 1992 to 2017. Patients admitted for trauma or for complications from elective surgery were excluded. Control patients with IM who had not been hospitalised in ICU were randomly selected from the cohort.

**Results:** Thirty-two ICU admissions were recorded in 27 IM patients during the study period ( $<0.05\%$  of admissions over this 25 year period). Three IM patients were admitted more than once.

Characteristics and prognosis of patients in ICU

Patients hospitalised in ICU had a mean age of  $63\text{ y.} \pm 15$  with SAPS II score of  $58 \pm 24$  and LODS score of  $9 \pm 5$  corresponding to an intermediate severity at admission in ICU. The delay between IM diagnosis and first ICU admission was  $27 \pm 43$  months. It is noteworthy that 12 patients (44%) were admitted in the ICU within the first month of IM diagnosis, among whom 4 (15%) were diagnosed with IM during ICU stay. Sixteen patients (60%) were not treated at the time of their first ICU admission. In 56% of the ICU stays, patients had active disease at admission. Patients were most frequently admitted for respiratory failure (88%) but cardiac (47%), renal (47%), neurologic (47%), haematological (22%) and hepatic (15%) failures were also recorded. Infections were present in 72% of the ICU stays, with septic shock in 44%. Nine patients (33%) died in ICU and 3 others (11%) within 90 days of the last ICU discharge (vs. 15% during a  $7.5 \pm 5$  years period of follow-up in the control group,  $p<0.0001$ ).

**Risk factors of ICU admission:** The case control analysis identified 6 risk factors significantly associated with hospitalisation in the ICU, 3 of which were independently associated with hospitalisation in multivariate analysis. ICU patients had a higher age at first clinical signs of illness ( $62 \pm 13$  years old vs.  $53 \pm 13$  years old,  $p<0.05$ ), they had a higher rate of chronic kidney failure (26% vs. 0%,  $p<0.05$ ) and higher incidence of arterial or venous thrombosis history (37% vs. 0%,  $p<0.05$ ). Other risk factors that were only identified in univariate analysis included lower BMI ( $22.6 \pm 4.5$  vs.  $25.4 \pm 6.3$ ), a history of interstitial lung disease (48% vs. 30%) and a higher Charlson comorbidity index ( $4.6 \pm 2.6$  vs.  $3.3 \pm 2$ ).

The type of myositis was not significantly associated with admission in ICU, although no patient admitted in ICU had sIBM. It is noteworthy that cumulative number of immunomodulatory treatments in patients at the time of hospitalisation in ICU was lower than in the control group ( $0.5 \pm 0.7$  vs.  $1.9 \pm 0.8$   $p<0.001$ ).

**Conclusions:** IM patients admitted in ICU frequently have recent onset and untreated active IM with respiratory failure. Admission to ICU is associated with older age and a higher number of comorbidities. Mortality of IM patients in ICU is high.

### CLINICOPATHOLOGICAL CORRELATION IN INFLAMMATORY MYOSITIS: ANALYSIS OF THE REMICAM COHORT (REGISTRY OF INFLAMMATORY MYOSITIS FROM MADRID, SPAIN)

B.E. Joven<sup>1</sup>, F. Lozano<sup>1</sup>, L. Nuño<sup>2</sup>, F.J. López-Longo<sup>3</sup>, O. Toldos<sup>1</sup>, E. Rabadán<sup>1</sup>, A. Hernández<sup>1</sup>, J. Martínez-Barrios<sup>3</sup>, C. Larena<sup>4</sup>, M. Blazquez<sup>4</sup>, C. Barbadillo<sup>5</sup>, I. Llorente<sup>6</sup>, A. Pérez<sup>7</sup>, T. Cobo<sup>8</sup>, R. Almodovar<sup>9</sup>, L. Lojo<sup>10</sup>, R. Calvo<sup>1</sup>, M.J. García de Yébenes<sup>11</sup>, P.E. Carreira<sup>1</sup>, on behalf of REMICAM group. <sup>1</sup>H 12 Octubre; <sup>2</sup>H La Paz; <sup>3</sup>H Gregorio Marañón; <sup>4</sup>H Ramón y Cajal; <sup>5</sup>H. Puerta de Hierro; <sup>6</sup>H. La Princesa; <sup>7</sup>H Príncipe de Asturias; <sup>8</sup>H Infanta Sofía; <sup>9</sup>H Fundación Alcorcón; <sup>10</sup>H Infanta Leonor; <sup>11</sup>Instituto musculoesquelético, Madrid, Spain

**Background:** Associations between muscle pathology and clinical features in inflammatory myositis (IM) are not well defined

**Objectives:** to describe the pathological findings in REMICAM<sup>1</sup> muscle biopsies, and analyse their associations with clinical features

**Methods:** All patients with available biopsy were included. According to the score proposed by ENMC workshop<sup>2</sup>, from muscle biopsy reports was extracted: inflammatory cells and location (endomysial, perimysial, perivascular), rimmed vacuola, fibre atrophy, necrosis, regeneration, and HLA expression. Descriptive analysis and association studies between histology and clinical features were performed (t and chi square tests, univariate logistic regression with OR)

**Results:** From 479 patients, 244 (51%) had available biopsy. Most frequent findings were: inflammatory infiltrates (75%): endomysial (44%), perimysial (49%) perivascular (26%); fibre atrophy (54%), perifascicular (27%); necrosis (55%) and regeneration (47%). HLA expression was + in 60/75 cases (80%). Endomysial infiltrate was associated with PM (OR 0.4; p<0.0001), cardiac involvement (OR 2.2; p=0.014), less arthritis (OR 0.5; p=0.01) and older age (51 vs 42 y; p<0.01); perimysial infiltrate and perifascicular atrophy with DM (OR 3.8; p<0.0001) and younger age (40 vs 48 y; p<0.05); necrosis with cardiac involvement (OR 2.1; p=0.035), neoplasia (OR 2.5; p=0.02) and no connective tissue disease (OR 0.4; p=0.01); and HLA with PM (OR 0.1; p=0.003)

**Conclusions:** most frequent histologic findings in IM muscle are inflammatory infiltrates, necrosis, HLA expression and perifascicular atrophy. Endomysial infiltration and HLA are characteristic of PM, and perimysial infiltration/perifascicular atrophy of DM. Endomysial infiltrates are associated with cardiac involvement. Necrosis is more frequent in neoplasia and less in connective tissue diseases, and is associated with cardiac involvement and older age. Our data suggest that muscle biopsy might help to identify those IM patients at higher risk of severe complications, as neoplasia or cardiac involvement

### COMPARISON OF THE 2017 EULAR/ACR CRITERIA WITH BOHAN AND PETER CRITERIA FOR THE CLASSIFICATION OF ADULT AND JUVENILE IDIOPATHIC INFLAMMATORY MYOPATHIES

B. Pinto<sup>1</sup>, R. Janardana<sup>1</sup>, R. Nadig<sup>2</sup>, A. Mahadevan<sup>3</sup>, A. Bhatt<sup>3</sup>, J.M. Raj<sup>4</sup>, V. Shobha<sup>5</sup>. <sup>1</sup>Clinical Immunology and Rheumatology, St John's National Academy of Health Sciences; <sup>2</sup>Neurology, St. John's National Academy of Health Sciences; <sup>3</sup>Neuropathology, NIMHANS; <sup>4</sup>Biostatistics; <sup>5</sup>Clinical Immunology and Rheumatology, St. John's National Academy of Health Sciences, Bengaluru, India

**Background:** The 2017 EULAR/ACR classification criteria provide a validated scoring system for the classification of both adult and juvenile idiopathic inflammatory myopathies (IIM) with reasonable sensitivity and specificity.

**Objectives:** To assess the performance of the 2017 EULAR/ACR criteria<sup>1</sup> in retrospective cohort of IIM and compare with Bohan and Peter criteria.<sup>2,3</sup>

**Methods:** We conducted a retrospective study of all patients clinically diagnosed to have IIM in a tertiary care centre in the last ten years. Performance of both the criteria in the cohort was assessed and compared with clinical diagnosis.

**Results:** One hundred and seven patients were included in the study. Nine patients had juvenile onset. Clinical features are summarised in table 1. 80.4% of the patients were classified as probable/definite myositis using the Bohan and Peter criteria. 81.3% of the patients were classified as having probable/definite inflammatory myositis using the new criteria (score  $\geq 5.5$  without biopsy or  $\geq 6.7$  with biopsy). However the agreement between the two classification criteria was weak in our cohort (kappa=0.43). Complete details of muscle biopsy were available in 44 patients. In this subgroup 95.5% were classified by and Bohan and Peter and 84.1% by EULAR/ACR criteria. Both criterias performed poorly in patients without biopsy data and in polymyositis subset (table 2).

**Abstract FRI0436 – Table 1.** Clinical features of patients with idiopathic inflammatory myositis

Age (at diagnosis)	38.73 years	Proximal Muscle weakness	104 (97.2%)
Sex (Female:male)	3.12:1	Dysphagia	33 (30.8%)
Raynauds	22 (20.6%)	ILD	10 (9.3%)
Arthralgia/arthritis	71 (66.4%)	Anti Jo1 positivity (n=91)	3 (2.8%)
ANA positivity	59 (55.1%)	Elevated muscle enzymes	94 (87.9%)
Clinical Diagnosis	52 (48.9%)	Cutaneous involvement (s/o DM)	65 (60.7%)
Dermatomyositis	2 (1.9%)	Heliotrope	35 (32.7%)
Amyopathic DM	20 (18.7%)	Gottron's papules	21 (19.6%)
Polymyositis	22 (20.6%)	Gottron's Sign	8 (7.5%)
Myositis Overlap Syndrome	8 (7.5%)	Other rashes	18 (16.8%)
Juvenile Dermatomyositis	1 (0.9%)		
Juvenile onset myositis	2 (1.9%)		
overlap			
Cancer associated myositis			

**Abstract FRI0436 – Table 2.** Classification using Bohan and Peter and 2017 EULAR/ACR criteria

	Bohan and Peter	EULAR/ACR
Total IIM (n=107)	86 (80.4%)	87 (81.3%)
With Biopsies (n=44)	42 (95.5%)	37 (84.1%)
Without Biopsies (n=63)	44 (69.8%)	50 (79.4%)
DM (n=67)	62 (92.5%)	61 (91.0%)
PM (n=40)	24 (60%)	26 (65%)

**Conclusions:** The new EULAR/ACR criteria did not perform better than Bohan and Peter criteria in our cohort. The new criteria are more time consuming and seem to be of limited utility in daily clinical practice.

FRI0437

### IS EXTENDED AUTO ANTIBODY PROFILING ASSOCIATED WITH THE PREVALENCE OF DISEASE COMPLICATIONS?

B. Kersten<sup>1</sup>, R. Smeets<sup>2</sup>, F. van den Hoogen<sup>1</sup>, R. van der Molen<sup>3</sup>, W. Alkema<sup>4</sup>, E. van den Ende<sup>1</sup>, M. Vonk<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Laboratory Medicine; <sup>3</sup>Laboratory of Medical Immunology; <sup>4</sup>Centre of Molecular and Biomolecular Informatics, Radboud University Medical Center, Nijmegen, Netherlands

**Background:** Auto antibodies play a prominent role in both classification and disease prognosis of systemic sclerosis (SSc). In several cohorts the association between auto antibodies and prognostic factors has been described. In recent years, new methods of antibody profiling have become available, and have shown an important prognostic role for anti-RNAPolymerase 3 antibodies (anti-RNAP3). However, it is uncertain whether other auto antibodies have associations with complications as well.

**Objectives:** The aim of this study is to determine prevalence of auto antibodies in a well characterised cohort of SSc and to evaluate the associations with complications.

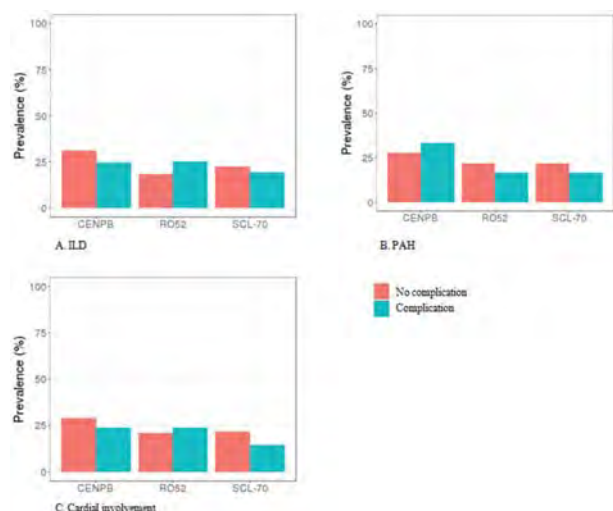

**Methods:** A total of 319 patients from the Nijmegen SSc Cohort were consecutively included in this study. All patients fulfilled the ACR/EULAR 2013 classification criteria for SSc. Patients were subclassified as limited cutaneous SSc (LcSSc), diffuse cutaneous SSc (DcSSc) or SSc overlap syndrome according to Leroy and Medsger. Blood samples were collected at regular outpatient clinic visits and analysed using LIA. (SSc and ENA immunoblot, Euroimmun, Lubeck, Germany). Clinical data was collected prospectively.

**Results:** The Nijmegen cohort comprises mainly of Caucasians. The percentage of male patients and diffuse patients is higher compared to other cohorts<sup>1</sup> (table 1). There is a relative anticentromere antibody (ACA) dominance in our cohort and ACA antibodies are more common in patients with pulmonary arterial hypertension (PAH), which is consistent with previous studies.<sup>1</sup> However, in our cohort we

found a relatively high prevalence of anti-RO52 antibodies in patients with complications (figure 1).

Clinical/laboratory feature/ total	No.	%
Male gender	100	31%
LcSSc	182	57%
DcSSc	102	32%
Overlap	35	11%
PAH	36	11%
ILD	134	42%
Cardiac involvement	21	7%
Renal crisis	3	0.9%
ACA	90	28%
ATA	63	21%
Anti-RNAP3	14	4.4%
Anti-SSA/Ro52	30	9.4%
RP-11	22	6.9%
RNP-SM	22	6.9%
RP-155	21	6.5%
M2-3E	21	6.5%
M2	21	6.5%
PM-75	19	5.9%
PM-100	19	5.9%

**Abstract FRI0437 – Table 1.** Demographic and clinical characteristics

**Abstract FRI0437 – Figure 1.** Prevalence of auto antibodies in SSc with and without complications. Antibodies < 10% prevalent not shown. ILD interstitial lung disease; PAH pulmonary arterial hypertension.

**Conclusions:** The distribution of the main auto-antibodies is comparable to other Caucasian cohorts.<sup>1</sup> Because the prevalence of anti-RNAP3 is relatively low, it is of limited value in our population. In contrast, the prevalence of anti-Ro52 was high in patients with the three major disease complications, but this antibody was also present in a number of patients who did not (yet) have these complications. Previous studies have shown ambiguous results concerning the relevance of this autoantibody.<sup>2</sup> Furthermore, RNP/SM and RNP-70 may be associated with cardiac involvement. To evaluate the prognostic value of anti-Ro52, RNP/SM and RNP-70 in SSc, a large prospective cohort study is necessary.

FRI0438

#### HOSPITALISATION MORTALITY AND ASSOCIATED RISK FACTORS IN PATIENTS WITH POLYMYOSITIS AND DERMATOMYOSITIS: A RETROSPECTIVE CASE-CONTROL STUDY

C. Wu, Q. Wang, L. HE, E. Yang, X. ZENG. *Rheumatology, Peking Union Medical College Hospital, Beijing, China*

**Background:** Polymyositis and dermatomyositis (PM/DM) are systemic autoimmune diseases with multiple organ involvements that manifest as muscular and cutaneous disorders, interstitial lung disease (ILD) and malignancies. However, information concerning the outcomes and associated factors for PM/DM patients who are hospitalised is limited.

**Objectives:** We retrospectively reviewed the medical records of 982 PM/DM patients admitted to our centre from 2008 to 2014 and performed a case-control analysis to identify possible related risk factors for death among PM/DM patients in China.

**Methods:** We retrospectively reviewed the medical charts of PM/DM patients admitted to a Chinese tertiary referral hospital (Peking Union Medical College Hospital, PUMCH) from 2008 to 2014. The deceased group included 63 patients who had “deceased discharge” status or were confirmed to have died within two weeks of hospital discharge. The demographic data, clinical manifestations, and direct causes of death were analysed retrospectively. Medical records for 126 age- and sex-matched PM/DM patients were selected as controls from 982 inpatients successively admitted to the same centre during the same period. In addition to the comparison of clinical manifestations between the two groups, binary logistic regression was conducted to explore the risk factors related to PM/DM mortality.

**Results:** Over the past 6 years at PUMCH, the in-hospital mortality rate of PM/DM patients was 4.58%. The male gender and the elder patients had a high risk of death ( $p=0.031$  and  $p=0.001$  respectively). The three most frequent causes of death for PM/DM patients were pulmonary infection (35%), ILD exacerbation (21%) or both conditions (25%). Pulmonary infection ( $p<0.001$ , OR=5.63, 95% CI, 2.37–13.36), pneumomediastinum ( $p=0.041$ , OR=11.02, 95% CI, 1.10–110.54), Gottron’s papules ( $p=0.010$ , OR=3.24, 95% CI, 1.32–7.97), and elevated erythrocyte sedimentation rate (ESR) ( $p=0.005$ , OR=9.9, 95% CI 2.0–49.0) were independent risk factors for in-hospital mortality of PM/DM patients.

**Conclusions:** PM/DM patients continue to display high in-hospital mortality. Pulmonary infection is the strongest predictor of poor prognosis in PM/DM patients, followed by pneumomediastinum, Gottron’s papules, and elevated ESR.

#### THE PROMISING ROLE OF LUNG MRI IN DETECTING SYSTEMIC SCLEROSIS (SSC)-RELATED INTERSTITIAL LUNG DISEASE (ILD)

L. Gargani<sup>1</sup>, C. Brun<sup>2</sup>, D. De Marchi<sup>3</sup>, C. Romei<sup>4</sup>, S. Guiducci<sup>2</sup>, S. Bellando-Randone<sup>2</sup>, G.D. Aquaro<sup>3</sup>, A. Pepe<sup>3</sup>, F. Falaschi<sup>4</sup>, A. Pingitore<sup>1</sup>, M. Matucci-Cerinic<sup>2</sup>. <sup>1</sup>Institute of Clinical Physiology, National Research Council, Pisa; <sup>2</sup>Dept of Experimental and Clinical Medicine, Division of Rheumatology, University of Firenze, Firenze; <sup>3</sup>Department of Magnetic Resonance, Fondazione Toscana G. Monasterio; <sup>4</sup>2nd Radiology Unit, University Hospital of Pisa, Pisa, Italy

**Background:** Interstitial lung disease (ILD) is very frequent and highly disabling in patients with systemic sclerosis (SSc). Magnetic resonance imaging (MRI) is not routinely used for the evaluation of the lung, since MRI generally provides a less detailed view of the pulmonary parenchyma, as well as poorer spatial resolution, compared to the non-invasive gold-standard of high resolution computed tomography (HRCT). Thus, its usefulness in the evaluation of interstitial lung disease (ILD) is limited at present.

**Objectives:** To evaluate MRI signals in different pathological and non-pathological lung areas, and to establish their clinical and instrumental correlations.

**Methods:** Thirty-two SSc patients underwent a cardiac MRI with dedicated lung scanning and chest HRCT on the same day. One-hundred-thirty-five regions of interest (ROIs) were identified, and STIR and T1 sequences were acquired [before (T0) and after 5 (T5), 10 (T10) and 15 (T15) minutes from gadolinium injection]. The ROIs were classified according to HRCT as normal, dependent areas (probably related to blood pooling in supine position) and pathological areas (ground glass ±reticulation on HRCT). Mean STIR and T1 times were also calculated for each patient, and correlated with FVC, DLco, B-lines on lung ultrasound and HRCT semi-quantitative scoring (Scleroderma Lung Study score). Patients were followed-up and lung worsening was defined on the basis of clinical judgement and at least >15% DLco decline.

**Results:** Mean STIR and mean T1 times were significantly different between normal, dependent and pathologic areas ( $p < 0.001$  between groups). Patients' mean STIR showed a significant correlation with DLco ( $R = -0.56$ ,  $p < 0.01$ ), HRCT Scleroderma Lung Study score ( $R = 0.52$ ,  $p < 0.01$ ) and B-lines on lung ultrasound ( $R = 0.63$ ,  $p < 0.01$ ). The mean STIR of the 10 patients who developed a worsening pulmonary involvement had significantly different MRI signal intensity in comparison to the 25 patients without worsening pulmonary involvement ( $125 \pm 46$  vs  $66 \pm 37$  msec,  $p < 0.01$ ).

**Conclusions:** Our data highlight the usefulness of lung MRI in SSc patients to differentiate normal, dependent and pathologic areas, without need for contrast medium administration, and with good correspondence to other functional and imaging parameters. STIR values may have prognostic implications to predict lung worsening. Lung MRI, although still very preliminary, is a promising imaging tool that in the future may integrate HRCT in SSc-related ILD.

#### FRI0440 RENAL INVOLVEMENT IN MIXED CONNECTIVE TISSUE DISEASE: A SINGLE CENTRE EXPERIENCE

E. Martín Nares<sup>1</sup>, S.E. Ramírez Andrade<sup>2</sup>, N.O. Uribe Uribe<sup>3</sup>, T.S. Rodríguez Reyna<sup>1</sup>. <sup>1</sup>Immunology and Rheumatology Department, <sup>2</sup>Nephrology Department, <sup>3</sup>Pathology Department, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

**Background:** Kidney injury in mixed connective tissue disease (MCTD) is an uncommon manifestation. Prevalence has been reported to be <4% in some cohorts. The frequency of renal involvement in Hispanic patients with MCTD is not known.

**Objectives:** We aimed to describe the prevalence, clinical characteristics and outcomes of renal involvement in Mexican patients with MCTD.

**Methods:** We conducted a retrospective single-centre study. We included patients with a diagnosis of MCTD according to the Alarcón-Segovia criteria who regularly attended to a referral centre in Mexico City (2003–2017) and we identified those with renal involvement defined as proteinuria >500 mg/d with or without active sediment, creatinine elevation 50% above baseline or development of glomerular filtration rate (GFR) <60 ml/min, with no other known cause. We collected demographics, clinical manifestations, follow-up time, treatment, outcomes and damage (SLICC/ACR-DI), renal function, serological and histological variables.

**Results:** One hundred and thirty one patients with MCTD were followed at our centre. We identified 14 patients with renal involvement with a prevalence of 10.7%. Among those patients, 13 were women (92.8%); mean age at onset of renal involvement was  $44 \pm 8$  years. Most frequent manifestations were Raynaud's phenomenon in 13 (92.8%) patients, arthritis in 12 (85.7%), puffy hands in 12 (85.7%), sclerodactyly in 8 (77.1%), sicca syndrome in 8 (77.1%) and myositis in 7 (50%). Median time elapsed from MCTD diagnosis to renal involvement was 83 (2–365) months. In 3 patients, renal involvement was present at MCTD onset. Seven (50%) patients had other signs of MCTD activity at the time of renal involvement onset. Four (28.5%) patients presented with sub-nephrotic proteinuria, 3 (21.4%) with nephrotic range proteinuria and kidney injury, 2 (14.3%) with sub-nephrotic proteinuria and kidney injury, 2 (14.3%) with nephrotic range proteinuria, 1 only with nephrotic range proteinuria and 1 (7.1%) with end-stage renal disease. Microscopic hematuria was present in 9 (64.3%) patients and leukocyturia in 6 (42.8%). Renal biopsy was performed in 8 (57%) patients; pathological diagnoses were: crescentic and necrotizing glomerulonephritis (GN) (2 patients; one of these patients developed positive ANCA antibodies), GN ISN/RPS 2003 class III+V, 1 GN ISN/RPS 2003 class III+V with thrombotic microangiopathy, 1 GN ISN/RPS 2003 class IV+V and vasculopathy, 1 membranous GN, 1 minimal mesangial GN<sup>1</sup> and chronic tubulointerstitial nephritis with vasculopathy. 1 Ten (71.4%) patients achieved either total or partial remission at a median follow up of 82 (1–367) months. Only one patient required dialysis. At last follow up the median SLICC/ACR-DI was 1.5 (0–4) points. Two patients died.

**Conclusions:** In our cohort of MCTD patients, prevalence of renal involvement was low, although higher than the one reported in other populations. Clinical presentation and pathological diagnoses were diverse. Renal biopsy was helpful, since glomerulonephritis, vasculopathy and overlap with ANCA associated

vasculitis were found in several patients; these options should be considered in the differential diagnoses of MCTD patients with renal involvement.

#### FRI0441 IDIOPATHIC INFLAMMATORY MYOPATHIES: CLINICAL CHARACTERISTICS, SURVIVAL AND POOR PROGNOSTIC FACTORS OF 110 PATIENTS FROM TURKEY

E. Oguz, M. Erdugan, B.A. Esen, A. Gul, L. Ocal, M. Inanc. Department of Internal Medicine, Division of Rheumatology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

**Objectives:** In this study, we aimed to assess clinical features, poor prognostic factors and survival analysis of patients with Idiopathic inflammatory myopathy (IIM).

**Methods:** Records of 110 patients with IIM that had at least 6 months of follow-up, fulfilling Bohan and Peter's criteria were analysed for this study. Survival analysis was done by using Kaplan Meier method and multiple "Cox" regression analysis was applied to calculate the effect of multiple factors.

**Results:** Sixty-eight percent of 110 patients was female, the mean age of the patients was 46 years, and the average follow up time was 77.5 months. Diagnosis of these patients was dermatomyositis (DM) in 68%, polymyositis (PM) in 26%, autoimmune necrotizing autoimmune myopathy (NOM), inclusion body myositis (IBM) 6%. The percentage of periungual erythema, arthritis, dysphagia, respiratory muscle involvement and interstitial lung disease (ILD) 56, 22, 24, 32, 11 and 30. Malignancy was identified in 26% of patients. The percentages of malignancies diagnosed at the time of diagnosis, before the diagnosis and during the follow-up were 3.6, 11.8 and 8.2. The most frequent malignancy was breast cancer. Others are carcinoma of gastrointestinal tract, lung, and genitourinary tract. ANA was present in 36% and 12% of patients was positive for anti-Jo-1 antibody. The average daily dose of prednisolone was 7.5 mg, the average usage time was 35.5 months. Causes of death were aspiration pneumonia-sepsis (50%) and malignancy (25%). Significant associations with mortality was found between systemic symptoms, periungual erythema, respiratory muscle involvement, dysphagia, presence of malignancy. Mortality was higher in ANA negative patients ( $p < 0.001$ ), Five and 10 year survival in these patients were 83% and 75%. Five year survival rate in patients with respiratory muscle involvement was 38% and 68% in those with dysphagia. The presence of systemic symptoms, and malignancies were identified as risk factors for mortality in multivariable analysis.

**Conclusions:** ILD and malignancies are frequent in our IIM cohort. Malignancies are mostly detected at diagnosis. The mortality rate was high and the most common cause was infection. 10 year survival rate was 79%. Malignancy, respiratory muscle involvement, dysphagia, negative ANA have a detrimental effect survival in IIM patients.

#### FRI0442 LONG-TERM TREATMENT WITH RITUXIMAB IN INTERSTITIAL LUNG DISEASE RELATED TO SYSTEMIC SCLEROSIS: OUR CLINICAL EXPERIENCE

E. Lumetti<sup>1</sup>, A. Spinella<sup>1</sup>, A. Ariani<sup>2</sup>, E. Cocchiara<sup>1</sup>, M. Colaci<sup>3</sup>, M. Silva<sup>4</sup>, N. Sverzellati<sup>4</sup>, C. Ferri<sup>1</sup>, C. Salvarani<sup>1</sup>, D. Giuggioli<sup>1</sup>. <sup>1</sup>Scleroderma Unit, Chair of Rheumatology, University of Modena and RE, Modena; <sup>2</sup>Department of Medicine, Internal Medicine and Rheumatology Unit, Azienda Ospedaliero-Universitaria di Parma, Parma; <sup>3</sup>Internal Medicine Unit, Cannizzaro Hospital, University of Catania, Catania; <sup>4</sup>Department of Clinical Sciences, Section of Radiology, University of Parma, Parma, Italy

**Background:** Systemic sclerosis (SSc) is an immune-mediated disorder characterised by abnormal fibrosis and diffuse microangiopathy with skin and internal organ involvement. Interstitial lung disease (ILD) represents one of the most challenging complication of SSc, difficult to manage and correlate with a poor prognosis. Chest Computed Tomography (CT) is the gold standard for detection and evaluation of SSc-ILD by means of semi-quantitative scoring of extent of lung involvement. Some preliminary data suggest that rituximab (RTX) may be usefully employed in the treatment of SSc patients.

**Objectives:** To investigate the role and effect of RTX on ILD in our SSc patients' series.

**Methods:** We retrospectively evaluated a series of 18 SSc patients (M/F 6/12, mean age  $54.6 \pm 17.6$  SD years, mean disease duration  $11.4 \pm 6.5$  SD years, L/D cutaneous subsets 6/12) who received one or more cycles of RTX (4 weekly infusions of 375 mg/m<sup>2</sup>) every 6 months for a total of 1–6 cycles. Lung involvement was studied by means of pulmonary function tests (PFTs) (18/18) and inspiratory

chest CT (10/18) before and after treatment. In particular, we considered PFTs performed 6 months before RTX, at time 0, one year after the first RTX cycle, and at the end of follow-up (13.7±7.3 years). ILD extent score was assessed by the semi-quantitative method proposed by Goh et al (2008).<sup>1</sup>

**Results:** Forced vital capacity (FVC%) significantly reduced during the year before RTX treatment [from 95.2±17.4 to 84.8±16.4; p=0.0017], as well as the diffusing capacity for carbon monoxide (DLCO%) [from 58.1±14.3 to 47.6±12.9; p=0.0002]. Conversely, FVC% and DLCO% stabilised one year after the first RTX cycle (80.8±23 and 47.8±15.7, respectively), and at the end of the follow-up (84.3±24.6 and 54.8±12.3, respectively; p=0.0001). In our cohort, only 7/10 patients had ILD detectable on CT before treatment. At the end of the follow-up we observed that ILD extended in 6/7 cases one patient remained stable, the three subjects without ILD did not developed pulmonary fibrosis.

**Conclusions:** According to PFTs results, our study showed that RTX could stabilise the progression of lung function tests in SSc patients. However, the semi-quantitative visual score identified radiological pulmonary worsening in many patient with stabilised PFTs. Therefore, the correlations between functional and radiological outcomes are so weak that many Authors suggested they should be considered together in SSc-ILD assessment.

#### FRI0443 DIGITAL ARTERY VOLUME INDEX: THE FIRST OBJECTIVE, AUTOMATED, NON-INVASIVE IMAGING DIAGNOSTIC OF MACROVASCULAR INVOLVEMENT IN SSC

G. Lettieri<sup>1</sup>, G. Agnanno<sup>1</sup>, G. Bagnato<sup>1</sup>, S. Eng<sup>1</sup>, J.P. Ridgeway<sup>1</sup>, J.N. Kaftan<sup>2</sup>, M. Hinton<sup>2</sup>, O. Kubassova<sup>2</sup>, M.H. Buch<sup>1</sup>, P. Emery<sup>1</sup>, P. O'Connor<sup>1</sup>, F. Del Galdo<sup>1</sup>.  
<sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds; <sup>2</sup>IAG, Image Analysis Group, London, UK

**Background:** Macrovascular involvement in Systemic Sclerosis (SSc) is caused by proliferation of vascular smooth muscle cells within the intima of arteries (neointimal proliferation). The resulting decrease in arterial volume is responsible for the severity of Raynaud's and for the onset of severe clinical manifestations such as Renal Crisis and Pulmonary Artery Hypertension.

Several RCTs have demonstrated the efficacy of Endothelin Receptor Antagonists (ERAs) in targeting neointimal proliferation, which makes them to date, the only disease modifying agent available in SSc. Nevertheless, the lack of validated early diagnostics means the intention to treat with ERAs remains limited to the diagnosis of end stage clinical manifestations of neointimal proliferation, such as presence of Digital Ulcer (DU) and PAH.

**Objectives:** Here we aimed to determine the proof of concept validity of automated Digital Artery Volume Index (DAVIX) measured by non-contrast Time of Flight (TOF) MRI as an objective diagnostic tool to be used as surrogate outcome measure of neointimal proliferation in SSc.

**Methods:** 10 Healthy Volunteers (HV) and 8 SSc patients were enrolled. Six patients underwent longitudinal assessments at least 12 months apart. MRI scans were performed on a 3T Magnetom Verio (Siemens) and consisted of a VIBE 3D T1 scan and a 2D TOF sequence of 8 min. DAVIX was calculated as the percentage of the ratio of digital artery and the respective finger volumes. The vessels and fingers were manually outlined by an expert radiologist and used as a 'gold standard' (DAVIX-1) and compared to a 2nd independent radiologist assessment (DAVIX-2). An automated segmentation algorithm was developed using threshold based segmentation and region growing (DAVIX-A) and validated against gold standard. Intraclass correlation coefficient (ICC) and absolute agreement were calculated to estimate reliability. Bland-Altman bias and 95% limits of agreement (LoA) were calculated as well.

**Results:** SSc patients and HV had comparable age (44±8 vs 45±8) and gender (F:M=5:2 vs 4:2). 4 fingers were affected by DUs at baseline and two fingers were affected by new DU at follow up. Mean(±SD) DAVIX in HV was 1.21 (±0.39) with no significant difference among individual fingers. Mean DAVIX in SSc patients was 0.37 (±0.18) and 0.32 (±0.39) at baseline and follow-up, respectively (p<0.0001 vs HV for both). The fingers with DU had an average DAVIX of 0.24 (±0.08) vs 0.40 (±0.18) of the fingers without DU (p=0.02). DAVIX changed over time in both directions. In the fingers affected by new DU, DAVIX dropped by 56% (0.161 vs 0.072) and 86% (1.149 vs 0.132), respectively. ICC among two independent readings was 0.90 (95% LoA -0.139, 0.118) with overall r<sup>2</sup>=0.74 (p<0.0001). Automated segmentation showed superior correlation to gold standard with r<sup>2</sup>=0.80 (p<0.0001).

**Conclusions:** This proof of concept study demonstrated validity and sensitivity to change of DAVIX for the automated volumetric assessment of digital arteries, which reflected clinical worsening in patients with new DU. Larger, longitudinal studies are planned to assess DAVIX' predictive value for the onset of DU and its potential use as early diagnostic of neointimal proliferation in SSc.

#### FRI0444 PERIOSTIN IN SYSTEMIC SCLEROSIS: SERUM LEVELS AND SKIN EXPRESSION OF A NOVEL POSSIBLE BIOMARKER

G. De Luca<sup>1</sup>, C. Campochiaro<sup>1</sup>, S. Franchini<sup>1</sup>, S. Burastero<sup>2</sup>, S. Sartorelli<sup>1</sup>, A. Giachi<sup>1</sup>, G. Cavalli<sup>1</sup>, C. Dogliani<sup>3</sup>, L. Dagna<sup>1</sup>. <sup>1</sup>Unit of Rheumatology, Immunology, Allergy and Rare Diseases (UnIRAR); <sup>2</sup>Cellular and molecular allergy; <sup>3</sup>Unit of Pathology, San Raffaele Scientific Institute, Milan, Italy

**Background:** Periostin(PN), a matricellular protein, serves as a regulator of wound healing and fibrosis. PN<sup>-/-</sup> mice develop lower degrees of fibrosis when exposed to bleomycin(BLM), suggesting a possible role in the pathogenesis of Systemic Sclerosis(SSc)<sup>1</sup>. PN serum levels are increased in SSc and seem to be associated with skin disease severity<sup>2</sup>.

**Objectives:** To evaluate the role of serum PN as a biomarker of SSc severity, and to determine PN tissue expression in SSc patients.

**Methods:** PN serum levels were assessed by ELISA in 48 patients: 3 primary Raynaud's, 12 early SSc, 11 SSc without organ involvement, 22 SSc with organ involvement. All SSc patients met 2013 ACR/EULAR criteria. PN serum levels were evaluated in 28 sex-/age-matched healthy-controls(HCs). Data regarding disease subtypes and organ involvement were correlated. PN skin expression was determined by immunohistochemistry on paired involved and uninvolved skin biopsy samples in 10 patients(4 lcSSc and 6 dcSSc) in combination with a-SMA, CD68, CD3, CD4, CD8, CD163, CD20 and CD131.

**Results:** PN serum levels were higher in SSc patients compared to HCs(32.7±8.0 vs 27.7±7.3 ng/ml, p<0.001). Its levels were comparable among different groups. No differences in PN serum levels were detected when comparing disease subtypes, disease duration, presence and extent of organ involvement, autoantibodies profile and current or previous treatment. Higher PN levels were found in SSc patients with active pattern at nailfold videocapillaroscopy and a history of digital ulcers(p<0.02). PN serum levels did not correlate with skin or lung disease extent. Skin samples from involved SSc skin showed high PN expression in the upper dermis and in the fibrotic area of the lower dermis(more evident in dcSSc), suggesting a role in skin fibrosis. In all SSc involved skin, PN was expressed in areas where ongoing fibroproliferation and macrophage/T lymphocytic infiltration occurred, indirectly suggesting a pathogenic role in inflammation driven-fibrosis. Interestingly, an identical PN immunohistochemical expression was evident in uninvolved dcSSc skin, but not in lcSSc skin.

**Conclusions:** In our cohort PN serum levels are elevated in SSc patients but they do not correlate with disease features. Its postulated role as a severity biomarker needs to be further elucidated. The different immunohistochemical expression of PN in uninvolved skin from dcSSc and lcSSc patients suggests a possible pathogenic role in the progressive inflammation-driven fibrosis that characterise diffuse cutaneous involvement.

#### FRI0445 A RANDOMISED CONTROLLED TRIAL TO COMPARE THE EFFICACY OF ORAL MYCOPHENOLATE MOFETIL WITH PLACEBO IN PATIENTS WITH SYSTEMIC SCLEROSIS RELATED EARLY INTERSTITIAL LUNG DISEASE

G. Naidu<sup>1</sup>, S. Sharma<sup>1</sup>, V. Dhir<sup>1</sup>, S. Dhooira<sup>2</sup>, A. Sinha<sup>3</sup>, A. Mb<sup>1</sup>, S. Jain<sup>1</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Pulmonary Medicine; <sup>3</sup>Radiodiagnosis, PGIMER, Chandigarh, India

**Background:** Previous studies showed benefit of immunosuppressants in moderate to severe ILD in systemic sclerosis (SSc).<sup>1,2</sup> Initiation of immunosuppression early in the course of SSc-ILD might help in halting disease process and improve long term morbidity and mortality.

**Objectives:** Aim of the study was to determine efficacy and safety of mycophenolate mofetil (MMF) in treating early and mild SSc-ILD (ILD on HRCT, FVC ≥70%

predicted). Primary outcome was to compare the change in FVC after 6 months of therapy with MMF or placebo. Secondary outcomes were change in SF-36v2, Mahler dyspnoea index (MDI) and adverse events profile of MMF and placebo.

**Methods:** This was a double-blind, randomised, placebo-controlled trial conducted at a tertiary care centre in north India. SSc-ILD patients with FVC  $\geq 70\%$  and aged  $>18$  years were randomised to receive either MMF (up to 2 g/day) or placebo for 6 months. FVC, DLCO, MRSS, SF36v2, MDI and 6 min walk distance (6MWD) were noted at baseline and 6 months. Outcome was categorised into improved/stabilised (any increase in FVC or fall in FVC  $<10\%$  from baseline) and worsened (fall in FVC  $\geq 10\%$  from baseline). Trial was approved by the institute ethics committee and was registered at ClinicalTrials.gov (NCT02896205).

**Results:** Forty-one subjects were included in the study (20 MMF and 21 placebo). Mean age was  $40.3 \pm 10.1$  years and 95.1% were females. Median duration of illness was 5 years (IQR: 3–9). Mean baseline FVC was  $81.71\% \pm 9.35\%$ , DLCO was  $50.36\% \pm 14.24\%$ , MDI was  $7.68 \pm 2.72$ , 6MWD was  $423.61 \pm 61.64$  m, MRSS was  $17.07 \pm 8.36$ . Fifteen subjects in MMF arm and 19 in placebo arm completed 6 months study duration. Mean change in FVC was  $-1.79 \pm 7.32\%$  in MMF arm and  $1.34\% \pm 4.47\%$  in placebo arm. Mean absolute difference in FVC change from baseline to 6 months between the two arms was 3.13% (95% CI,  $-1.02$  to  $7.28$ ;  $p=0.131$ ). In mITT analysis, 15 subjects improved/stabilised and 5 subjects worsened in MMF arm compared to 19 and 2 subjects respectively in placebo arm. SF36v2 scores showed significant improvement in both the groups. No significant difference was noted between the two groups in mean change in focal score of MDI (3.33 vs 2.79;  $p=0.638$ ), DLCO (2.46% vs 2.31%;  $p=0.412$ ), 6MWD (2.8 m vs 12.11 m;  $p=0.522$ ) and FVC among subjects with Scl-70 positivity ( $-2.19\%$  vs  $1.51\%$ ;  $p=0.184$ ). The MRSS decreased by a mean of 4.73 points in MMF arm compared to 1.53 points in placebo arm ( $p=0.042$ ). MMF was well tolerated and rates of diarrhoea and infections were similar to that with placebo. Three subjects on MMF and 1 on placebo discontinued drugs.

**Conclusions:** In this small study, MMF for 6 months was not effective in stabilising the lung disease in early and mild SSc-ILD but was effective in controlling skin disease and was well tolerated.

#### FRI0446 INITIAL PREDICTORS FOR MORTALITY IN PATIENTS WITH CANCER-ASSOCIATED MYOSITIS: A MULTICENTER RETROSPECTIVE COHORT IN JAPAN

H. Kadota<sup>1</sup>, T. Gono<sup>1,2</sup>, Y. Yamaguchi<sup>3</sup>, E. Watanabe<sup>2</sup>, Y. Okazaki<sup>1</sup>, Y. Nakajima<sup>1</sup>, S. Kobayashi<sup>1</sup>, Y. Shirai<sup>1</sup>, M. Takeno<sup>1</sup>, C. Terai<sup>2</sup>, M. Kuwana<sup>1</sup>. <sup>1</sup>Department of Allergy and Rheumatology, Nippon Medical School, Tokyo; <sup>2</sup>Department of Rheumatology, Saitama Medical Center, Jichi Medical University, Saitama; <sup>3</sup>Department of Environmental Immuno-Dermatology, Yokohama City University Graduate School of Medicine, Yokohama, Japan

**Background:** Concomitant malignancy is one of the prognostic factors in patients with myositis,<sup>1</sup> but clinical parameters for mortality still remain unknown in patients with cancer-associated myositis (CAM).

**Objectives:** Initial predictors for mortality were examined using a multicenter cohort of CAM patients.

**Methods:** This retrospective study enrolled 67 consecutive patients diagnosed as having CAM in 3 referral hospitals between 1995 and 2017. Clinical data at diagnosis of myositis as well as treatment regimens and outcomes of myositis and malignancy were collected by review of medical charts. Myositis-specific autoantibodies (MSAs) were comprehensively detected using RNA immunoprecipitation (IP), enzyme-linked immunosorbent assay, and IP-immunoblotting. We initially conducted a univariate analysis to select variables that were different between survivors and dead cases. In multivariate analysis, the Cox proportional hazard model with backward selection method ( $p > 0.20$ ) was employed to identify factors independently associated with mortality. Explanatory variables were chosen

based on the following three models. The Model 1 included age at diagnosis of myositis, gender and candidate variables ( $p < 0.1$ ) selected by the univariate analysis. The Model 2 included age, gender, prognostic factors previously reported in myositis, such as dermatomyositis, dysphasia, interstitial lung disease (ILD), anti-ARS, and anti-MDA5, and malignancy type and staging, as explanatory variables. In the Model 3, age, gender, disease duration before diagnosis of myositis, period between diagnosis of myositis and tumour, myositis classification, MSAs, dysphasia, ILD, myositis disease activity after treatment, and malignancy type and staging were used as explanatory variables. Cumulative survivals calculated using the Kaplan-Meier method were compared between the patients with and without risk factors.

**Results:** The median age at diagnosis of myositis was 63 years, and 62% were female. MSAs were detected in 47 patients: anti-TIF1- $\gamma$  in 27, anti-ARS in 6, anti-MDA5 in 5, anti-Mi-2 in 3, anti-NXP2 in 3, anti-SAE in 2, and anti-SRP in 1. During the median observation period of 2 years, 19 (28%) of 67 CAM patients were dead due to tumour in 16, ILD in 1, and an unknown cause in 2. The univariate analysis identified significant poor prognostic factors ( $p < 0.1$ ) as follows: male ( $p=0.04$ ), elder age at diagnosis of myositis ( $p=0.08$ ), longer period between diagnosis of myositis and tumour ( $p=0.07$ ), absence of breast cancer ( $p=0.001$ ), malignancy stage III/IV ( $p=0.006$ ). In multivariate analysis, male (HR 8.1, 95% CI 2.6–25.2;  $p < 0.001$ ) and malignancy stage III/IV (HR 12.1, 95% CI 3.3–44.9;  $p < 0.001$ ) were identified as independent risk factors for mortality in the Model 1, and identical variables were identified in the Models 2 and 3. Cumulative survival rates of patients with 0, 1, or 2 risk factors were 100%, 93%, and 69% at 1 year, and 100%, 82%, and 0% at 3 years, respectively. Cumulative survival rates were statistically different between the groups stratified by the number of risk factors (figure 1).

**Abstract FRI0446 – Figure 1.** Cumulative survival rates of patients with CAM with 0, 1, or 2 or risk factors.

**Conclusions:** Male and progression of malignancy at diagnosis of myositis were identified as predictors of survivals in CAM patients.

### WORLDWIDE EXPERT AGREEMENT ON UPDATED EULAR/EUSTAR RECOMMENDATIONS FOR THE TREATMENT OF SYSTEMIC SCLEROSIS

J. De Vries-Bouwstra<sup>1</sup>, Y. Allanore<sup>2</sup>, M. Matucci-Cerinic<sup>3</sup>, A. Balbir-Gurman<sup>4</sup>.  
<sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden, Netherlands;  
<sup>2</sup>Rheumatology, Cochin Hospital, Paris, France; <sup>3</sup>Experimental and Clinical Medicine, University of Florence, Florence, Italy; <sup>4</sup>B. Shine Rheumatology Unit, Rappaport Faculty of Medicine- Rambam Health Care Campus, Haifa, Israel

**Background:** In 2017, updated EULAR/EUSTAR recommendations for treatment of Systemic sclerosis (SSc) were published.<sup>1</sup> Implementation in clinical practice of these recommendations might be dependent on agreement and local drug availability.

**Objectives:** To evaluate worldwide agreement of the updated recommendations for treatment of SSc among SSc experts. To determine factors that might influence agreement.

**Methods:** An online survey was set out (June – September 2017), containing the 17 EULAR/EUSTAR updated recommendations. Levels of agreement were determined for each item on a 10-point scale (0=not at all; 10=completely agree). Local drug availability was assessed (yes/no). An e-mail containing a web link to the survey was sent out to international SSc-networks (EUSTAR, Scleroderma Clinical Trials Consortium, Australian Scleroderma Interest Groups, International Systemic Sclerosis Inception Cohort) and to 54 additional SSc-experts representing South-America and Asia. Levels of agreement were compared between subgroups stratified for EUSTAR membership, geographical area, drug availability, and years of experience.

**Results:** In total 269 responders participated, of whom n=209 completed each single item. The majority are rheumatologists (n=200, 83%), currently working in Europe (n=185; 71%); 65% (n=156) are EUSTAR member, and have >10 years of experience in the SSc field (n=150; 63%). Other geographical areas are also represented (Africa n=2, 1%; Asia n=18,7%; Australia n=13,5%; North-America n=27,10%; South-America n=17,6%). Mean level of agreement was high (8.0; standard deviation [SD, 2.5], with top-3 highest mean agreement for ACE-inhibitors for scleroderma renal crisis (9.2 [2.1]), blood pressure control in case of corticosteroids (9.0 [2.2]) and treatment with protonpump inhibitors to prevent reflux complications (9.0 [2.2]). Top 3 of lowest mean agreement included fluoxetine for Raynauds phenomenon (RP) (4.6 [2.8]), hematopoietic stem cell transplantation (HSCT) for severe SSc (7.1 [2.9]) and methotrexate for skin involvement in early diffuse SSc (7.4 [2.8]). When comparing Europe to other regions agreement differed significantly (p<0.05) for the following recommendations: iloprost for RP, iloprost and bosentan for digital ulcers, methotrexate for early diffuse SSc, cyclophosphamide for SSc-related lung disease, and HSCT for severe SSc. Comparison of agreement between responders stratified for EUSTAR membership (yes/no), years of clinical experience (<or>10 years) and local availability of the drug/treatment option (yes/no) showed that in case of iloprost, bosentan and HSCT availability of drug/treatment option contributed to differences in agreement. Neither EUSTAR membership nor years of experience could explain these differences.

**Conclusions:** In general, worldwide agreement on recently updated recommendations for treatment of SSc is high. Differences in agreement are partially explained by geographical area and local drug availability. Future evaluations should focus on implementation of published recommendations and take drug availability into account to further improve guideline-development.

### MDA5 ANTIBODY POSITIVE CLINICAL AMYOPATHIC DERMATOMYOSITIS (CADM): A SINGLE TERTIARY CENTRE CASE SERIES OF 13 PATIENTS

K. Huang, K. Shojania, J. Yeung, A. Avina-Zubieta. *Rheumatology, University of British Columbia, Vancouver, Canada*

**Background:** Positive anti-melanoma differentiation-associated gene 5 (MDA5) antibody has been reported in 50%–73% of patients with clinical amyopathic dermatomyositis (CADM)<sup>1</sup>. About half of MDA5 +CADM patients die of rapid

progressive interstitial lung disease (RP-ILD), defined as worsening dyspnea within 1 month that required high-flow oxygen therapy or ventilator support in previously stable patients.

**Objectives:** This descriptive study aims to systematically characterise the clinical features, treatment and outcome of 13 cases of MDA5 +CADM patients at a single referral centre.

**Methods:** Myositis antibody testing became available at Vancouver Coastal Health, Canada since 2014. We retrospectively reviewed clinical presentations, laboratories, imaging studies, treatment and outcome of patients with MDA5 antibody. The data is presented descriptively.

**Results:** Total 13 cases (4 male and 9 female) of MDA5 +CADM were identified (2014–2017). Mean age was 49.9±11.5. Ten were Asian descent (8 Chinese, 1 Philippine, and 1 Indo-Mauritian) and 3 Caucasians. All 13 patients had typical DM rash (heliotope, Gottron's, mechanic's hands, periungual erythema). Cutaneous ulcers over the extensor surfaces of joints were seen in 7/13 and palmar papules in 4/13, both of which were characteristic for MDA5 +CADM. Only 3/13 patients had CK elevation with little muscle weakness; all others had normal CK and no detectable weakness.

ILD was present in all 13 patients. 7/13 (53.8%) patients had RP-ILD and 4/13 (30.7%) died within 3 months of onset of worsening dyspnea, despite steroid, cyclophosphamide, Rituximab, cyclosporine and IVIG; 3 survived after receiving lung transplant. 6/13 (46.2%) patients had stable ILD and are still alive. 5/7 patients with RP-ILD (71.4%) had coexisting Ro52 antibody whereas only 1/6 patients with stable ILD (16.7%) had Ro52. Of the 6 patients with stable ILD, one had worsening cutaneous ulceration and ILD that required IV cyclophosphamide; one had refractory dermatitis and recurrent pneumomediastinum eventually stabilised on rituximab; one responded to tacrolimus with improving respiratory symptoms; one had panniculitis refractory to IVIg, hydroxychloroquine, azathioprine and tofacitinib, and ultimately responded to IV cyclophosphamide; one had mild ILD but severe cutaneous disease who eventually agreed to rituximab, and the last patient went with traditional Chinese medicine and lost follow up. None had underlying malignancy.

**Conclusions:** In this case series of 13 patients with MDA5 +CADM, 54% were Chinese, a finding similar to previous reported higher incidence in Asians. It is important to recognise the characteristic cutaneous and pulmonary features of this entity early on as mortality is high. Refractory panniculitis can be found in MDA5 +CADM. All patients had ILD with 54% RP-ILD and 31% mortality within 3 months. Coexisting Ro52 may be predictive of worse prognosis. Early intensive immunosuppression is instrumental for refractory cutaneous manifestation and/or progressive ILD. As lung transplantation became more available, three patients with RP-ILD in this series received lung transplant successfully and they were maintained on mycophenolate and tacrolimus after transplant.

**Background:** Among the subtypes of idiopathic inflammatory myopathy (IIM), it has been recognised that primary polymyositis (PM) and primary dermatomyositis

(DM) have a worse prognosis than overlap syndrome (OM). However, the benign course of OM has not been confirmed in other studies. The identification of specific characteristics that could allow a correct classification may be important for its prognosis.

**Objectives:** To analyse clinical characteristics and survival of patients diagnosed with OM, and to compare if there are differences with other IIM subgroups in a multicentric cohort.

**Methods:** Retrospective, multicentric longitudinal observational study of a cohort of patients followed between January 1980 and December 2014, with a diagnosis of IIM. The patients were divided into 2 groups: OM and primary idiopathic inflammatory myositis (PIIM), which included PM and DM. Patients classified as OM had to meet IIM criteria and criteria for rheumatoid arthritis (RA), systemic sclerosis (SSc), systemic lupus erythematosus (SLE), mixed connective tissue disease (MCTD) or primary Sjögren's syndrome (SS).

**Results:** The present study included a total of 348 patients (98 OM, 250 PIIM). The connective tissue diseases associated with OM were: MCTD in 32 (32.7%), SSc in 29 (29.6%), SLE in 21 (21.4%), RA in 8 (8.2%) and SS in 8 (8.2%). Patients with OM showed remarkable differences compared to PIIM. In general, OM exhibited more extramuscular involvement and more complications, with more serious infections (41% vs. 24%,  $p < 0.001$ ) and higher mortality (31% vs. 20%,  $p = 0.043$ ). In the multivariate study of mortality prognostic factors, the overlap syndrome contributed significantly to a higher mortality (OR 5.56 (95%CI 2.32–13.23);  $p < 0.0001$ ).

**Conclusions:** In the REMICAM registry of 348 inflammatory myopathies, 98 cases of myositis with overlap syndrome have been included, presenting with more extramuscular complications, more severe infections and higher mortality than other myopathies. It would be important to identify these patients at the onset of the disease, in order to closely monitor for development of possible complications.

#### ASSOCIATIONS OF ALTERATIONS OF PERIPHERAL REGULATORY T AND TH17 ABSOLUTE CELL NUMBERS WITH CLINICAL FEATURES IN PATIENTS WITH SYSTEMIC SCLEROSIS

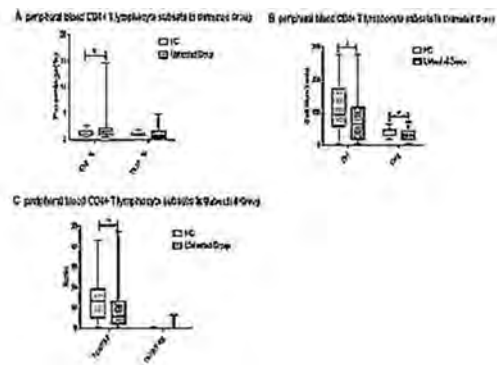

L. Shang<sup>1</sup>, J. Luo<sup>1</sup>, J. Yuan<sup>1</sup>, Q. Li<sup>1</sup>, X. Liu<sup>1</sup>, C. Gao<sup>2</sup>, X. Li<sup>1</sup>, H. Gao<sup>1</sup>.

<sup>1</sup>Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; <sup>2</sup>Pathology, Brigham and Women's Hospital, Boston, USA

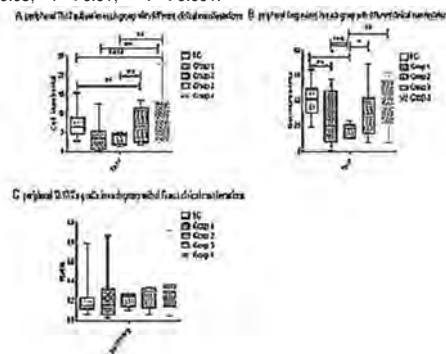

**Background:** Systemic sclerosis (SSc) is a chronic inflammatory disease with complex pathogenesis. The role of regulatory T cells (Tregs) in the development of SSc has started being studied during the last decade with new aspects being disclosed continuously. Although there is a general agreement in the medical literature regarding the decreased functional capacity of circulating Tregs in SSc, the alteration of absolute number of Treg and Th17 cells as well as their associations with clinical characteristics of SSc are still unclear.

**Objectives:** The aim of the present study was to explore the relationship between absolute reduction of peripheral CD4 + regulatory T and Th17 cell subset and clinical characteristics in SSc patients.

**Methods:** The peripheral CD4 + T subsets from 54 patients with SSc and 30 healthy control subjects were analysed. The patients were divided into the untreated group (n=29) and treated group (n=25). The patients were also divided into group 1 (n=9) for the prominent pulmonary lesions, group 2 (n=5) for prominent esophageal involvement, group 3 (n=8) for both lung lesions and esophageal involvement, and group 4 (n=10) who had fingers swelling, sclerosis, ulceration prominent. Directly using the results from flow cytometry combined with internal standard beads, absolute number of peripheral Th17 and Treg cells from the subjects in each group were calculated.

**Abstract FRI0450 – Figure 1.** Comparison of the levels of CD4+T lymphocyte subgroups among different groups. (A) The percentage of Th2 cells were significantly increased in untreated group compared with healthy controls. (B) The number of CD4+CD25+FOXP3+Treg cells decreased in patients with prominent pulmonary lesions. (C) The ratio of Th1/Th2 cells was not found to be significantly decreased in each group. \* $P < 0.05$ ; \*\* $P < 0.01$ ; \*\*\* $P < 0.001$ .

**Abstract FRI0450 – Figure 2.** Comparison of absolute number of Treg and Th17 cells in each group with different clinical manifestations. (A) The number of Th17 cells were significantly increased in group 4 compared with group 1 and group 2. (B) The number of CD4+CD25+FOXP3+Treg cells decreased in patients with SSc. (C) The ratio of Th17/Treg cells was no statistically significant different in each group. \* $P < 0.1$ ; \*\* $P < 0.01$ ; \*\*\* $P < 0.01$ .

**Results:** Although there were some changes among CD4 + T cell subsets in peripheral blood from these SSc patients, the major alteration was the reductions of Treg cell absolute number. Compared with the normal controls, the number of CD4+CD25+FOXP3+Treg cells were significantly decreased in untreated group ( $p = 0.029$ ), in group 1 ( $p = 0.014$ ) and in group 2 ( $p = 0.073$ ) as compared with healthy controls. Interestingly, Tregs in group 2 were significantly lower than those in group 1 ( $p = 0.006$ ), in group 3 ( $p = 0.098$ ) and in group 4 ( $p = 0.034$ ). In addition, the number of Th17 cells were significantly higher in group 3 ( $p = 0.003$ ) and 4 ( $p < 0.001$ ) when compared with the normal controls, as well as in group 4 was significantly higher than that in group 1 ( $p = 0.044$ ), in group 2 ( $p = 0.016$ ), moreover, the number of Th17 cells in group 3 was significantly higher than that in group 2 ( $p = 0.017$ ).

**Conclusions:** The absolute number of peripheral CD4 + CD25+FOXP3+Treg cells decreased in untreated patients, indicating that this reduction arising from the disease itself. Our findings suggest that the severity of clinical manifestations in patients with SSc is related to the absolute decrease of peripheral Treg cells. Although there was no statistically significant different, absolute number of the Treg cells trended to decrease in patients who had more severe clinical manifestations. With the involvement of vital organs, the absolute number of Treg cells decreased more significantly. Moreover, in patients with relatively mild clinical manifestations, the increase in the absolute number of Th17 cells is even more obvious, suggesting that Th17 also plays an important role in early and intermediate stages.

### CONTINUOUS PRESENCE OF IGM ANTI-TOPOISOMERASE I ANTIBODIES INDICATES AN ONGOING IMMUNE RESPONSE IN SYSTEMIC SCLEROSIS

M. Boonstra<sup>1</sup>, J.A. Bakker<sup>2</sup>, A. Grummels<sup>2</sup>, M.K. Ninaber<sup>3</sup>, N. Ajmone Marsan<sup>4</sup>, H. U. Scherer<sup>1</sup>, R.E. Toes<sup>1</sup>, T.W. Huizinga<sup>5</sup>, J.K. de Vries-Bouwstra<sup>1</sup>. <sup>1</sup>department of Rheumatology; <sup>2</sup>department of Clinical Chemistry and Laboratory Medicine; <sup>3</sup>department of Pulmonology; <sup>4</sup>department of Cardiology, Leiden University Medical Center; <sup>5</sup>department of Rheumatology, Leiden University Medical Center, Rheumatology, Leiden, Netherlands

**Background:** Small case-series of anti-topoisomerase I antibodies (ATA) in Systemic Sclerosis (SSc) show a highly varying immune response over time. IgA and IgG levels were shown to correlate with skin scores. One small study showed that increasing IgG levels can precede increasing skin scores. Thus far, detailed analysis of ATA characteristics with disease features in larger cohorts have not been performed.

**Objectives:** By taking advantage of our well described SSc cohort with annual follow-up data, we aimed to evaluate whether clinical heterogeneity within ATA +patients can be explained by ATA characteristics.

**Methods:** ATA IgG, IgM and IgA levels were assessed in consecutive serum samples of baseline ATA-IgG +patients from the Leiden SSc cohort. Disease progression during the first year of follow-up was defined as increase of modified Rodnan Skin Score (mRSS) with  $\geq 5$  points, progression of pulmonary involvement ( $<10\%$  of predicted forced vital capacity [FVC] or diffusion capacity of the lung [DLCO]), development of digital ulcers, renal crisis, pulmonary arterial hypertension and/or mortality. Here, we present data on the association between the presence of ATA-IgM and disease progression.

**Results:** In total 344 samples of 102 ATA +patients were measured. Baseline and follow-up samples were available from 70 patients. Median follow-up was 3.7 years (range 0.9–7.4 years). At baseline 42/70 patients were positive for ATA IgM and 69/70 patients for ATA IgA (table 1). Strikingly, while clinical characteristics did not differ, mean ATA-IgM at baseline was higher in disease progressors (table 2). The possible relevance of an ATA-IgM response for disease progression was confirmed by the observation that of those patients positive for ATA-IgM both at baseline and at FU, 59% of cases showed disease progression, as compared to 15% of patients negative for ATA IgM at both time points ( $p=0.02$ ).

**Abstract FRI0451 – Table 1.** Changes in presence and levels of ATA isotypes in paired serum samples

	ATA isotype status at baseline/ follow-up				median ATA level (aU/mL[IQR])		p
	+/+	±	-/-	-/+	baseline	follow-up	
IgG	66	4	-	-	454 (193–876)	283 (79–647)	<0.01
IgM	29	13	25	3	627 (271–2081)	348 (167–1315)	0.06
IgA	65	4	1	0	2832 (812–8069)	2210 (645–7593)	0.01

**Abstract FRI0451 – Table 2.** Baseline characteristics of SSc patients with and without disease progression during the first year of follow-up

	progressors (n=25)	non-progressors (n=36)	p
female, n(%)	18 (72)	28 (78)	0.61
age, mean[yr.]±SD	55±16	50±15	0.15
time since onset first non-Raynaud symptom, median [yr.] (IQR)	4 (1–8)	3 (1–12)	0.75
mRSS, median (IQR)	4 (3–8)	5 (2–13)	0.94
DLCO, mean [% of predicted]±SD	69 (56–81)	63 (49–75)	0.17
ATA IgG level, median [aU/mL](IQR)	636 (301–1127)	312 (111–900)	0.09
ATA IgM level, median [aU/mL](IQR)	933 (533–3122)	447 (215–1293)	0.03
ATA IgA level, median [aU/mL](IQR)	5217 (2003–14187)	2202 (513–6240)	0.07

**Conclusions:** The presence of ATA-IgM at baseline and at follow-up and its association with disease course suggests that the ATA response in SSc patients is an ongoing process that possibly explains the heterogenic disease course of ATA +patients over time.

**Background:** Antisynthetase syndrome (ASSD) is an autoimmune disease characterised by the clinical triad arthritis, myositis, and interstitial lung disease (ILD). Despite Raynaud's phenomenon (RP) is another typical feature of ASSD, nailfold videocapillaroscopy (NVC) assessment of these patients has been only sporadically described, without the elucidating data for clinicians.

**Objectives:** To describe NVC features of ASSD patients and to investigate possible correlations with clinical and serological features of the disease.

**Methods:** We retrospectively analysed NVC images of 190 ASSD patients (females/males 3.76, mean age 49.7±12.8 years, mean disease duration 51.2±71.4 months, 133 anti-Jo-1 and 57 non-anti-Jo-1 positive patients). For each patient, we examined number of capillaries, giant capillaries, micro-haemorrhages, avascular areas, ramified capillaries, and the presence of scleroderma (SSc) patterns. Finally, we correlated NVC features with clinical and serological findings of ASSD patients.

**Results:** NVC abnormalities were observed in 62.1% of ASSD patients compared with 29.3% of a group of 75 patients with primary Raynaud's phenomenon ( $p<0.001$ ). A SSc-like pattern was detected in 67 (35.3%) patients and it was associated with anti-Jo-1 antibodies ( $p=0.002$ ) and also with a longer disease duration ( $p=0.004$ ). Interestingly, there was no significant correlation between the presence of SSc-like pattern and RP, and only 47% of patients with SSc-like pattern had RP.

**Conclusions:** NVC abnormalities are commonly observed in ASSD, independently to the occurrence of RP. The presence of a SSc-like pattern should let to identify a more defined ASSD subtype and prospective studies could confirm the association with clinical and serological features of ASSD.

**Disclosure of Interest:** None declared

### HOSPITALISATION AND SURVIVAL ANALYSIS IN SYSTEMIC SCLEROSIS PATIENTS WITH CONCOMITANT OR ISOLATED PULMONARY HYPERTENSION AND INTERSTITIAL LUNG DISEASE IN THE MULTIETHNIC SCLERODERMA COHORT SINGAPORE

M. Noviani<sup>1</sup>, E.S. Seyed<sup>2</sup>, S.M.Y. Kua<sup>1</sup>, G.Y.L. Chan<sup>3</sup>, G.G. Teng<sup>4</sup>, W.G. Law<sup>3</sup>, A. Santosa<sup>4</sup>, A. Lim<sup>4</sup>, J.L. Tan<sup>5</sup>, E.L.W. Tay<sup>6</sup>, J.W.L. Yip<sup>6</sup>, S.C. Ng<sup>1</sup>, A.H.L. Low<sup>1</sup>.

<sup>1</sup>Department of Rheumatology and Immunology, Singapore General Hospital; <sup>2</sup>Center for Quantitative Medicine, Duke-NUS Medical School; <sup>3</sup>Department of Rheumatology, Allergy and Immunology, Tan Tock Seng Hospital; <sup>4</sup>Department of Rheumatology, National University Health System; <sup>5</sup>Department of Cardiology, National Heart Center Singapore; <sup>6</sup>Department of Cardiology, National University Heart Center, Singapore, Singapore

**Background:** Concomitant pulmonary hypertension and interstitial lung disease in systemic sclerosis (SSc-PH-ILD) represents a distinct subpopulation of SSc with poorer prognosis in Western studies. In Asian patients, characterisation of SSc-PH-ILD is still lacking.

**Objectives:** To analyse hospital admissions, survival and prognostic markers among SSc patients with PH, ILD or concomitant PH-ILD in the Scleroderma Cohort Singapore.

**Methods:** In this study involving 3 tertiary Rheumatology institutions Jan 2008 to , Oct 2016 SSc patients with significant pulmonary involvement were included. ILD was based on high resolution computed tomography and predicted FVC <70%. PH was based on either echocardiographic systolic pulmonary arterial pressure (sPAP)  $\geq$ 50 mmHg, or right heart catheterization (RHC) findings of mean PAP  $\geq$ 25 mmHg. Hospitalisation rates and survival of SSc patients with PH, ILD or PH-ILD were compared. Risk factors of poor outcomes were identified by multivariate stepwise Cox regression analysis.

**Results:** Among 490 patients, 92 had ILD, 50 PH and 43 PH-ILD (table 1). Of 93 patients with PH or PH-ILD, 56 were based on echocardiography and 37 on RHC. The 5 year survival was 79%, 87% and 90% in PH, PH-ILD and ILD subgroup, respectively (figure 1). In multivariable analysis, PH was significantly associated with 2.8-fold increased risk of death. Male gender, malabsorption, digital ulcerations and renal crisis were also significantly associated with mortality (table 2). No significant difference in hospital admissions/year among different subgroups. Increased hospital admissions were associated with renal crisis, right heart failure and use of PH medications.

**Abstract FRI0453 – Table 1.** Clinical characteristics

	PH (n=50)	ILD (n=92)	PH-ILD (n=43)	No PH/ILD (n=305)

**Abstract FRI0453 – Table 2.** Survival analysis

	Hazard Ratio (95% CI)	P Value
Male gender	2.85 (1.53–5.33)	0.0010
Malabsorption	2.89 (1.67–5.01)	0.0002
Renal crisis	2.00 (1.00–3.99)	0.0490
Digital ulcerations	2.06 (1.21–3.50)	0.0076

**Abstract FRI0453 – Figure 1.** Adjusted survival curve comparing survival of SSc patients with PH, ILD, and concomitant PH-ILD. X-axis shows years of survival from diagnosis of PH or ILD.

**Conclusions:** Compared to those with ILD or PH-ILD, SSc-PH patients had increased mortality, but not hospitalisation rates. This could be due to small sample size or short follow up duration. We identified risk factors associated with worse outcomes in SSc patients with significant pulmonary involvement.

### ARTERIAL STIFFNESS OF THE FOREARM IS ASSOCIATED WITH NAIL-FOLD CAPILLARY COUNT IN SSC: A NOVEL MARKER OF EARLY VASCULOPATHY?

M.M. Habing<sup>1</sup>, A. Eman Abdulle<sup>1</sup>, A.M. van Roon<sup>1</sup>, A.M. van Roon<sup>1</sup>, H. van Goo<sup>2</sup>, H. Bootsma<sup>3</sup>, A.J. Smit<sup>1</sup>, D.J. Mulder<sup>1</sup>. <sup>1</sup>Dept. of Internal medicine, div. Vascular Medicine; <sup>2</sup>Dept. of Pathology and Medical Biology, Section Pathology; <sup>3</sup>Dept. of Rheumatology and Clinical Immunology, University of Groningen – University Medical Centre Groningen., Groningen, Netherlands

**Background:** Microvascular disease, characterised by rarefaction of capillaries, is the hallmark of systemic sclerosis. Remarkably, obliteration of the ulnar and radial artery is regularly observed, implicating involvement of the larger forearm arteries. Pulse wave velocity (PWV) is a widely accepted non-invasive measure for arterial stiffness and may serve as an early biomarker of forearm artery involvement, before the occurrence of irreversible arterial obliteration.

**Objectives:** The aim of the current study was to investigate arterial stiffness of the aorta and of the upper extremities in SSc patients compared to healthy controls and to correlate these findings with nail-fold capillary count, skin involvement, and extent of disease.

**Methods:** In total, 19 SSc patients (median age 51 years, 68% female) and 19 age and gender matched healthy controls (median age 53 years, 68% female) were included. Patients characteristics were obtained and blood was drawn. Measurements of arterial stiffness were carried out by using the SphygmoCor System (AtCor Medical, Sydney, Australia) and pressure waveforms were measured at four sites, i.e. carotid, femoral, brachial, and radial. Aortic PWV was defined as carotid-femoral (cf) PWV. Upper extremity PWV was measured as carotid-brachial (cb) and carotid-radial (cr) PWV, and the ratio between cbPWV/crPWV was used as an indication of the relative change in PWV in the forearm. Capillary count was defined as the mean capillary count per 3 mm of 8 fingers. Skin involvement was assessed by the modified rodnan skin score. The number of ACR/EULAR 2013 criteria points was used as a surrogate for extent of disease.

**Results:** Upper extremity PWV measures were significantly higher compared to aortic PWV in patients and in controls (SSc:  $p < 0.001$ ; HC:  $p = 0.03$ ), but did not significantly differ between both groups (table 1). CbPWV/crPWV ratio correlated strongly with capillary count ( $r = -0.55$ ,  $p = 0.022$ , figure 1) in SSc patients with a borderline significant trend in regards to its relation with the extent of disease ( $r = 0.48$ ,  $p = 0.053$ ) and skin involvement ( $r = 0.41$ ,  $p = 0.10$ ).

### Correlation between cbPWW/crPWW and Capillary count

**Conclusions:** Our findings demonstrate that arterial stiffness of the forearm has a relationship with nailfold capillary count and tends to be associated with the extent of disease in patients with SSc. These preliminary data may suggest that vascular damage may concomitantly occur in both capillaries as well as larger arteries of the forearm, which may potentially serve as a novel tool for assessing of early vascular involvement in SSc.

#### FRI0455 INCREASING INCIDENCE OF ADULT IDIOPATHIC INFLAMMATORY MYOPATHIES: A TEN-YEAR UK EPIDEMIOLOGICAL STUDY

M.J.S. Parker<sup>1,2</sup>, A. Oldroyd<sup>3</sup>, M.E. Roberts<sup>4</sup>, R.G. Cooper<sup>5</sup>, H. Chinoy<sup>3</sup>, on behalf of UKMYONET. <sup>1</sup>Rheumatology Department, Royal Prince Alfred Hospital, Sydney, Australia; <sup>2</sup>Rheumatology Department, Salford Royal NHS Foundation Trust, Salford; <sup>3</sup>Centre for Musculoskeletal Research, University of Manchester, Manchester; <sup>4</sup>Greater Manchester Neurosciences Centre, Salford Royal NHS Foundation Trust, Salford; <sup>5</sup>MRC-ARUK Centre for Integrated Research into Musculoskeletal Ageing, University of Liverpool, Liverpool, UK

**Background:** Studying the epidemiology of rare conditions such as the idiopathic inflammatory myopathies (IIM) can assist in the identification of risk factors, disease associations and temporal trends. Interrogation of differing geographically and genetically diverse populations can help to construct a more complete picture of underlying disease patterns. A number of UK centres have contributed to national and international IIM research collaborations, but to date there has been no published report detailing the incidence or prevalence of adult IIM in the UK, or to establish the relative proportion of the varying clinical subtypes. Moreover, previous international studies have focussed on specific IIM subtypes, such as inclusion body myositis (IBM) or immune-mediated necrotising myopathy (IMNM), are historic, were undertaken before recent developments in our understanding of the range of IIM subtypes, and utilised widely varying methodologies and case acquisition strategies.

The recently published combined European League Against Rheumatism and American College of Rheumatology (EULAR/ACR) classification criteria for adult and juvenile IIM represent potential progress in identifying IIM, as well as various disease subtypes<sup>1</sup>. We present here the first epidemiological study to utilise these new criteria as part of disease verification.

**Objectives:** Identify and characterise all incident adult cases of IIM between Jan 1 st 2007 and Dec 31 st 2016 in the City of Salford, UK.

**Methods:** Adults first diagnosed with IIM within the study period were identified by: i) a Salford Royal NHS Foundation Trust (SRFT) inpatient episode IIM-specific ICD-10 coding search; ii) all new patient appointments to SRFT neuromuscular outpatient clinics; iii) all Salford residents enrolled within the UKMYONET study. All patients with 'definite' IIM by the 2017 EULAR/ACR classification criteria were included, as were 'probable' cases if expert opinion agreed. Cases were excluded if <18 years at disease onset, if they did not meet 'probable' criteria, or when 'probable' but expert opinion concluded a non-IIM diagnosis.

**Results:** The case ascertainment procedures identified 1156 cases which, after review and application of exclusion criteria, resulted in 32 incident cases during

the study period. 23/32 were female with a mean age of 58.1 years. The mean incidence of adult IIM was 17.6/1,000,000 person years (py), higher for females than for males (25.2 versus 10.0/1,000,000py respectively). A significant incidence increase over time was apparent (13.6 versus 21.4/1,000,000py;  $p=0.032$ ). Using EULAR/ACR classification criteria, the largest IIM subtype (21/32) was polymyositis, followed by dermatomyositis (8/32), inclusion body myositis (2/32) and amyopathic dermatomyositis (1/32). Expert opinion subtype differed from EULAR/ACR Classification criteria in 19/32 cases.

**Conclusions:** The incidence of adult IIM in Salford is 17.6/1,000,000py, higher in females and is increasing over time. Disagreement exists between EULAR/ACR-derived and expert opinion-derived IIM subtype assignments.

#### FRI0456 PREDICTORS FOR DISEASE WORSENING DEFINED BY ORGAN FAILURE IN DIFFUSE SYSTEMIC SCLEROSIS: A EUROPEAN SCLERODERMA TRIALS AND RESEARCH (EUSTAR) ANALYSIS

M.O. Becker<sup>1</sup>, N. Graf<sup>2</sup>, R. Sauter<sup>3</sup>, Y. Allano<sup>4</sup>, J. Curram<sup>5</sup>, C. Denton<sup>6</sup>, D. Khanna<sup>7</sup>, M. Matucci-Cerinic<sup>8</sup>, J. Pena<sup>9</sup>, J.E. Pope<sup>10</sup>, O. Distler<sup>1</sup>. <sup>1</sup>Department of Rheumatology and the Centre of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland; <sup>2</sup>Graf Biostatistics, Winterthur, Switzerland; <sup>3</sup>Big Data Institute, Li Ka Shing Centre for Health Information and Discovery, Nuffield Department of Medicine, University of Oxford, Oxford, UK; <sup>4</sup>Paris Descartes University, Sorbonne Paris Cité, Rheumatology A Department, Cochin Hospital, Paris, France; <sup>5</sup>Bayer Plc, Reading, UK; <sup>6</sup>UCL Division of Medicine, Royal Free Campus, London, UK; <sup>7</sup>Division of Rheumatology, Department of Internal Medicine, University of Michigan Scleroderma Program, University of Michigan, Ann Arbor, MI, USA; <sup>8</sup>Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; <sup>9</sup>Bayer US LLC, Whippany, NJ, USA; <sup>10</sup>Department of Medicine, Division of Rheumatology, University of Western Ontario, St. Joseph's Health Care, London, ON, Canada

**Background:** Mortality and worsening of organ function are desirable endpoints for clinical trials in systemic sclerosis (SSc). However, these events are relatively rare, making clinical trial design challenging.

**Objectives:** To identify factors in a population of patients with diffuse SSc from the European Scleroderma Trials and Research (EUSTAR) group database that predict these endpoints and hence allow enrichment of those patients.

**Methods:** Inclusion criteria were a diagnosis of diffuse SSc and follow-up after 9–15 (12±3) months. This timeframe was chosen to reflect typical clinical trial design. Disease worsening/organ progression was fulfilled if any of the following events occurred: new renal crisis, decrease in forced vital capacity (FVC) ≥10%, new left ventricular ejection fraction (LVEF) <45% or decrease in LVEF by >10% for patients with baseline LVEF <45%, new pulmonary (arterial) hypertension, or

death. These parameters had been defined by expert nominal group technique. Methodologically, two main limitations had to be addressed:<sup>1</sup> the problem of missing data and<sup>2</sup> the low number of events, which prohibits the simultaneous exploration of a large set of predictors in a regression model. We addressed these issues by (a) imputing multiple predictors based on different algorithms (multiple imputation), and (b) using least absolute shrinkage and selection operator (LASSO) regression for 42 clinical parameters.

**Results:** Of 1451 patients who met the inclusion criteria, 706 had complete data available on all parameters for disease worsening. Of 706 patients originally evaluated, 228 (32.3%) had disease progression, most of which was either a decrease in FVC (103 patients, 14.6%) or death (92 patients, 13.0%) within the observation period (12±3 months). Of the 42 clinical parameters introduced into the model as outcome predictors, 8 remained in the final regression model, which was chosen by the Bayesian information criterion (table 1). Bootstrap with 10 000 repetitions successfully validated the model.

**Abstract FRI0456 – Table 1.** Predictive factors in the final LASSO regression model

Factor	p-value	Odds ratio	95% confidence interval
(Intercept)	<0.0001	0.06	0.03–0.14
Age (per 1 year)	0.001	1.02	1.01–1.04
Active digital ulcers	0.026	1.64	1.06–2.54
C-reactive protein elevation	0.002	1.80	1.23–2.63
Significant dyspnoea	0.491	1.20	0.72–2.00
Lung fibrosis	0.0004	2.21	1.43–3.41
Muscle weakness	0.015	1.64	1.10–2.45
Pericardial effusion	0.098	1.65	0.91–2.97
Proteinuria	0.064	1.75	0.97–3.16

**Conclusions:** The use of the predictive factors presented here could enable cohort enrichment with patients at risk for overall disease worsening in clinical trials.

FRI0457

#### RELATIONSHIP BETWEEN DIGITAL ULCERS AND SEVERITY OF LUNG FUNCTION TEST IN SYSTEMIC SCLEROSIS OVER A FIVE-YEAR PERIOD

*O.B. Ovsyannikova, O. Koneva, L. Ananieva. Department Of Vascular Pathology, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, Москва, Russian Federation*

**Background:** Systemic sclerosis-related interstitial lung disease (SSc-ILD) is the leading cause of death in SSc. Predictors of the outcomes of ILD in SSc are under investigation.

**Objectives:** to assess association of the digital ulcers with dynamics of forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLco) in patients with SSc-ILD.

**Methods:** It was a longitudinal study involving 83 pts with SSc-ILD (mean age was 46,2±13,4; 69% have limited subset of the disease; 95% were female). The mean duration of follow up was 58,9±12,0 months. At the end of the study a number of pts with digital ulcers (DUs) was 29 (35%). Additionally 77 pts. with SSc-ILD were investigated with HRCT and were divided into 3 groups; The 1 st group (16 pts) with improvement; 2nd group (39 pts) without any changes and 3rd group (22 pts) with worsening of fibrosis.

**Results:** After 5 years of follow up FVC increased significantly in all pts without DUs (n=54) from 88,5%±19 to 96%±23 (p<0,05); in group 1 – from 92%±20.5 to 106%±19 (p<0,05); in group 2 from 87%±18 to 94%±23.5 (p<0,05) and only in group 3 FVC was stable (88±22 and 87±24.5) (p>0,05). The mean value of FVC in all pts with DUs didn't change (88%±14 and 86%±16, p>0,05) with tendency to decreasing in group 3 (from 83%±12,5 to 74%±13 (p>0,05).

After 5 years of follow up DLco declined significantly in all pts with or without DUs, however in the 1 st group decline of DLco wasn't significant. The decreasing of DLCO was more prominent in group 3 than in group 2. Therefore, in group 2 in patient without DU (n=24) – from 65%±16 to 60%±11 (p<0,05) and in patients with DU (n=14) DLCO changed from 61%±15 to 57%±14 (p<0,05). In 3rd group in patients without DU (n=13) DLCO decreased from 55%±15 to 48%±15 (p<0,05) and in patients with DU (n=9)- from 50%±20 to 44,5%±15 (p<0,05).

**Conclusions:** In patients without DUs significant increasing of FVC during 5 years long follow up was observed. The worsening of fibrosis on HRCT in pts with DUs was associated with the lowest value of FVC and DLco at the entry and at the end of the study.

FRI0458

#### THE ONSET, CLINICAL COURSE AND OUTCOMES OF SSC- OVERLAP WITH PM/DM OR RA (SSC-PM/DM AND SSC-RA)

*O. Desinova, M. Starovoytova, L. Ananieva. VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Systemic sclerosis (SSc) concurrent with other connective tissue diseases (poly/dermatomyositis, rheumatoid arthritis and oths) seem to be still underexplored clinical forms of SSc.

**Objectives:** To study specific features of the onset, clinical course and outcomes of systemic scleroderma- poly/dermatomyositis (SSc-PM/DM) and SSc-RA overlap syndromes.

**Methods:** Totally 115 patients were examined, 75 – with SSc-PM/DM and 40 with SSc-RA, among them 98 women and 17 men aged 17–74 years (mean age 44 ±14,5) and disease duration from 6 months to 35 years (median 8[2–8]).

**Results:** In 18% of overlapping SSc pts the disease manifested with isolated Raynaud's syndrome (RS) at the onset, in 61% – RS came in combination with cutaneous and/or joint and muscle pathology, and in remaining 7% and 2% overlapping SSc manifested with the isolated articular syndrome or muscular involvement (proximal weakness), respectively. During the first 3 years SSc generalisation with emerging signs of PM/DM occurred in 61% of patients, erosive arthritis manifested in 51%; and in 20% of pts arthritis was detected later. Limited skin involvement predominated, while diffuse skin lesions were present in 23% of SSc-PM/DM cases, 1/3 of them showed signs of DM. All pts with overlapping SSc syndrome received a glucocorticoids (GCs)-based combination therapy (SSc-PM/DM 30–60 mg/day, SSc-RA –10–20 mg/day), with NSAIDs and vascular drugs, 74% were administered cytotoxic agents, more often methotrexate (48%) and 7% – antifibrotic drugs. Two types of overlapping SSc evolution patterns were identified: type I is favourable (stabilisation and slow progression without significant disease activity, and preserved work capacity); type II is unfavourable (continuing activity, rapid progression, disability and deaths). Favourable overlapping

SSc pattern prevailed (79%) in this study group, while unfavourable (21%) mainly consisted of SSc-PM/DM cases. Favourable overlapping SSc evolution was observed in patients with the onset before the age of 40 y, while unfavourable course was documented in pts with the late SSc onset at >40 y, with prevailing SSc-PM/DM. Fatal outcomes in 10% of cases mostly belong to SSc-PM/DM pts (8%). The specific features of overlapping SSc evolution included augmentation of SSc-characteristic symptoms – both, peripheral – teleangiectasias, calcification, osteolysis and digital trophic lesions, mainly in SSc-PM/DM pts, and visceral – involving heart, lungs, and oesophagus, which determined the unfavourable prognosis. RA manifestations (articular syndrome) in overlapping SSc pts tended to decrease, while signs of PM tended to resolve.

**Conclusions:** Timely detection of overlapping SSc pathological symptoms with administration of adequate therapy and dynamic monitoring of patients will improve the prognosis and outcomes of the disease.

#### MICROVASCULATURE CHANGES AND ANGIOGENIC FACTORS IN SYSTEMIC SCLEROSIS – A SINGLE CENTRE STUDY

R. Bečvář<sup>1</sup>, H. Hulejová<sup>2</sup>, I. Pütová<sup>2</sup>, M. Tomčík<sup>2</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Institute of Rheumatology, Praha 2, Czech Republic

**Background:** In systemic sclerosis (SSc) low capillary density in acral parts leads to a reduced blood flow, to tissue ischemia. Tissue hypoxia usually initiates the formation of new blood vessels from the pre-existing microvasculature. Despite the reduced blood flow and partial oxygen pressure levels, there is no evidence for a sufficient angiogenesis in the skin of patients with SSc. Nailfold capillaroscopy is a safe, noninvasive routine way for the microvascular investigation. At the same time different cytokines and angiogenic factors are produced.

**Objectives:** The aim of this study was to assess whether blood levels of angiogenic biomarkers are associated with microvasculature changes in SSc patients.

**Methods:** Microvasculature changes were assessed using nailfold videocapillaroscopy (NVC) which was performed by two independent examiners. The obtained images were analysed anonymously by two investigators blinded for the clinical and serum status of SSc patients and classified as early, active and late pattern.<sup>1</sup> Serum or plasma levels of soluble vascular adhesion molecule-1 (sVCAM-1) and soluble intercellular adhesion molecule-1 (sICAM-1) were measured by ELISA, big endothelin-1 (BET-1) concentrations using competitive enzyme-immunoassay and von Willebrand factor antigen (vWFAg) concentrations using ELISA kit were measured. As potential disease activity markers soluble receptor of interleukin-2 (sIL-2r) and interleukin-6 (IL-6) serum levels using commercial kits were assayed. For statistical evaluation Pearson's correlation coefficient and univariate analysis were used.

**Results:** Total 40 patients (38 females) were investigated: 30 individuals with limited form, 5 with diffuse, 3 patients with scleroderma sine scleroderma, 1 with overlap syndrome and 1 with undifferentiated connective tissue disease. The mean age ±standard deviation (SD) of the whole cohort was 51±22 years and the mean disease duration ±SD was 10±7 years. 3 patients (7.5%) had early NVC pattern, 12 patients (30%) had active, 10 (58%) late pattern, and 15 (37.5%) had nonspecific changes or normal picture.

The patients with late NVC pattern exhibited higher vWFAg levels than patients with active pattern (p<0.01). BET-1 and sICAM-1 serum levels were higher in the active pattern compared with late patterns (p<0.01 and p<0.05, respectively). When correlating these potential biomarkers with SSc-related clinical characteristics we found only these associations: vWFAg levels with heart arrhythmias and modified Rodnan skin score (p<0.01, p<0.05, respectively).

**Conclusions:** vWFAg and ET-1 increase in the late NVC pattern can be considered as an attempt to support deficient vasculogenesis. Further studies are needed to determine the role of other potential biomarkers of endothelial injury and repair in SSc.

#### THE COMPARISON BETWEEN PATIENTS WITH SYSTEMIC SCLEROSIS, POSITIVE FOR FOR ANTIBODIES TO RIBONUCLEOPROTEIN AND CLASSICAL SUBTYPES OF SYSTEMIC SCLEROSIS

R. Shayakhmetova<sup>1</sup>, L. Ananieva<sup>1</sup>, O. Koneva<sup>2</sup>, M. Starovoitova<sup>2</sup>, O. Desinova<sup>2</sup>, O. Ovsyannikova<sup>2</sup>, L. Garzanova<sup>2</sup>. <sup>1</sup>V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; <sup>2</sup>Kashirskoe Shosse 34A, V.a. nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Different clinical subtypes of systemic sclerosis (SSc) vary in frequency and severity of symptoms, progression of internal organ involvement and outcomes. The frequency of antibodies to ribonucleoprotein (RNP) in SSc varies from 5% to 30% according to reports of different studies and can be connected with separate clinical subtype of SSc.

**Purpose:** to characterise the main clinical features of patients with SSc positive for antibodies to RNP and to compare them with ACA and Scl-70 positive subtypes of SSc.

**Objectives:** to characterise the main clinical features of patients with SSc positive for antibodies to RNP and to compare them with ACA and Scl-70 positive subtypes of SSc.

**Methods:** The study included 330 patients (289 women and 41 men, mean age 50±13 years) meeting the criteria of the SSc (ACR/<sup>EULAR</sup> 2013) observed between 2011 and 2017. The level of anti-nuclear antibodies was determined by ELISA. The normal level of antibodies to RNP (U1-RNP-70) was 0–25 U/ml. The level greater than 3 times the upper limit of normal considered as highly positive.

**Results:** In study group of 330 patients 49 (15%) had antibodies to ACA, 154 (46%) – to Scl-70, 67 (20%) – to RNP antibodies. Also 4 patients simultaneously had antibodies to Scl-70 and RNP, 4 patients – to ACA and RNP, 1 patient to ACA, Scl-70 and RNP. Among RNP +group 85% of patients were highly positive and 15% – low-positive.

The vast majority of patients were female (91%), mean age 44,2±15 years. RNP +group was similar to ACA +group by predominance of a limited form of the disease which was 67,3% and 97% correspondingly. At the same time RNP +group was similar to Scl-70 +group by frequent involvement of internal organs – intestinal lung disease 67,3 and 69% correspondingly, involvement of cardiovascular system – 21% and 34%, esophagitis 61% and 44,5%.

RNP +group had scleredema frequently – 40%, in comparison with ACA+ (10%, p<0,005) and Scl-70+ (6,5%, p<0,005), involvement of joints (arthralgia/arthritis) – 65% in comparison with ACA+ (24%, p<0,005) and Scl-70+ (24%, p<0,005), muscle weakness/pain – 43%, in comparison with ACA+ (0,2%, p<0,005) and Scl-70+ (10,4%, p<0,005). All 3 groups did not differ significantly by the presence of Raynauds syndrome, telangiectasia and vascular manifestations (fingertip pitting scars or digital tip ulcers).

Furthermore patients with SSc highly positive for antibodies to RNP, met the criteria of mixed connective tissue diseases<sup>Kasukawa et al., 1987</sup> in 71%.

**Conclusions:** Our cohort of patients with SSc have high frequency of highly positive level of antibodies to RNP – 17%. Combination of specific SSc anti-nuclear antibodies (ACA, Scl-70) and antibodies to RNP was uncommon (2,7%) and predominantly in low-positive for antibodies to RNP patients.

The distinctive features of RNP +group in contrast to the "classical" subtypes of SSc were more mild skin involvement (puffy fingers) and more severe muscle and joints involvement.

Despite the limited form of the disease and mild skin involvement, RNP +group is more similar to Scl-70 +group by frequent involvement of internal organs.

We propose that well known relation between skin involvement in diffuse form of SSc with Scl-70 +and organ damage is not so evident in RNP +group of SSc.

FRI0461

#### EFFICACY AND SAFETY OF ANTIFIBROTIC AGENTS IN IDIOPATHIC PULMONARY FIBROSIS

L. Nuñez-García<sup>1</sup>, C. Valenzuela<sup>1</sup>, T. Alonso<sup>1</sup>, E.F. Vicente<sup>2</sup>, J. Ancochea<sup>1</sup>, S. Castañeda<sup>2</sup>. <sup>1</sup>Pneumology; <sup>2</sup>Rheumatology, Hospital Princesa, Madrid, Spain

**Background:** Antifibrotic (AF) agents are a family of drugs that improve the survival and quality of life of patients with idiopathic pulmonary fibrosis (IPF). Given that pulmonary fibrosis is also a common manifestation of many autoimmune diseases, we think of interest to know the efficacy and safety data of these agents in real life, which will likely soon reach the therapeutic arsenal of the rheumatologist.

**Objectives:** To analyse the efficacy and safety of treatment with AF pirfenidone (Pi) and nintedanib (Ni) at one year in patients with mild-moderate IPF treated in our hospital according to clinical practice.

**Methods:** Retrospective observational study in which all patients diagnosed with mild-moderate IPF who started treatment with Pi and/or Ni between January 2012 and May 2017 in our Hospital were included. The response was evaluated according to the results obtained in the Respiratory Function Tests: forced vital capacity (FVC) and carbon monoxide diffusion test (DLCO), which were carried out every 3

months during the first year of treatment. Some of the patients received both drugs in different evolutionary periods of their disease. The study was approved by the Clinical Research Ethics Committee (CREC) of our hospital.

**Results:** Of the 42 patients included, 29 received Pi, 69% men and 31% women, with a mean age of 71 years (78% ex-smokers). Baseline FVC was 2140 ml (74.4% of the predicted value) and DLCO was 40.8% with respect to the expected value. The absolute loss in FVC after 52 weeks of follow-up was 200 ml. 48.3% required treatment with glucocorticoids (GC) at some point, either due to exacerbations of the disease or as concomitant treatment. 65.5% presented some adverse reaction to Pi, being gastrointestinal discomfort (GI) the most frequently observed, although mainly of self-limiting course, with the definitive suspension of the drug being necessary in 6 cases. As for the patients treated with Ni, 70.6% were men and 29.4% women, 82% ex-smokers, with an average age of 72 years. Baseline CVF value was 2480 ml (83.8% of the predicted value) and DLCO value was 54.7%. The decrease in FVC in absolute terms was 70 ml. Similarly, 4 patients required the use of GC at some point in the study. With regard to adverse reactions, 76.5% presented some type of adverse event, GI discomfort being the most frequent, followed by increased transaminases and mild diarrhoea. The great majority were of limited duration, requiring the definitive suspension of the drug in 5 patients. Five patients treated with Pi died due to exacerbations of their disease.

**Conclusions:** This project supports, with data from usual clinical practice, the beneficial effect of the AF drugs available for the treatment of mild-moderate IPF. Both drugs have been shown to slow down the natural evolution of the disease, reducing the loss of FVC, a variable directly related to mortality. This therapy has acceptable safety margins. However, there are still no references regarding its administration in incipient and advanced stages of the disease nor on their combined use with each other or with immunomodulators for the control of immune mediated diseases.

**Acknowledgements:** To the nurses and all members of the Pneumology Service for their collaboration in the follow-up of the patients included in this study.

#### FRI0462 SERUM KL-6 IS A STRONG PREDICTOR FOR RELAPSE OF MYOSITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

S. Takanashi, N. Nishina, M. Nakazawa, Y. Kaneko, T. Takeuchi. *Rheumatology, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan*

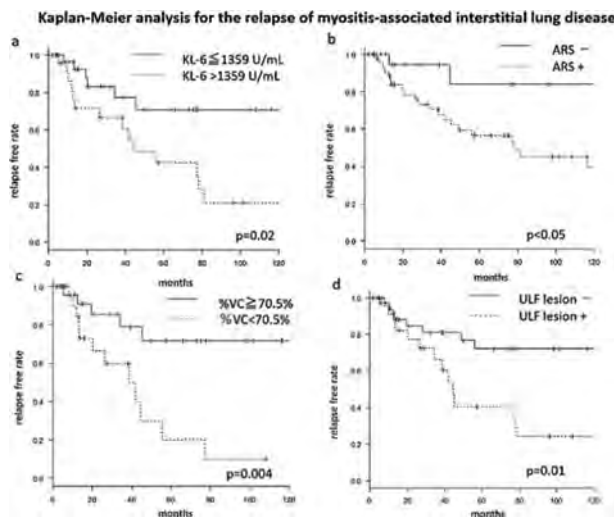

**Background:** Polymyositis (PM), dermatomyositis (DM) and clinically amyopathic DM (CADM) are autoimmune myositis which can be associated with interstitial lung disease (ILD).<sup>1,2</sup> The relapse rate of ILD is high, reported as approximately 20%–55%.<sup>3,4</sup> Since relapses result in decreased pulmonary function, it is important to identify the predictive factors for the relapse.

**Objectives:** The aim of this study was to elucidate the predictive factors for the relapse of ILD associated with myositis (PM/DM/CADM).

**Methods:** We conducted an observational retrospective study. Patients with myositis-associated ILD who have ever visited our institution between 2002–2017 and achieved remission once were enrolled. Patients who died before remission were excluded. We collected their clinical information from medical records. We compared patient characteristics between relapse group and non-relapse group by Fisher's exact test or Mann-Whitney U test at first. Relapse was defined as exacerbation of radiological findings of which doctor-in-charge decided to intensify therapy for ILD. We performed Kaplan-Meier analysis to compare the relapse-free survival for the characteristics that had significant differences between two groups. To perform Kaplan-Meier analysis, continuous variables were converted to dichotomous variables for analysis by setting cut-off values determined by receiver-operating characteristics (ROC). Then, using each characteristic which showed significant difference in Kaplan-Meier analysis, we conducted Cox's proportional hazard analysis for multivariate analysis. For relapse group, we examined the changes of serum KL-6 levels from the initial treatment of myositis-associated ILD to the relapse of ILD. We calculated the average of serum KL-6 levels of 3 months and 6 months before relapse, respectively, then compared them with KL-6 levels at the time of relapse.

**Results:** Seventy-two patients with myositis-associated ILD at our institution were enrolled. Among 72 patients, 24 experienced relapse (relapse group) and 48 did not experience relapse (non-relapse group). Median observational period was 31.5 months and 39.0 months, respectively. Median levels of serum KL-6, the rate of patients who had upper lung field (ULF) lesion by CT, and anti-ARS antibody prevalence were significantly higher in relapse group than in non-relapse group (1870 vs 935 U/mL,  $p=0.003$ ; 62 vs 27%,  $p=0.01$ ; 88 vs 60%,  $p=0.03$ , respectively). Median levels of %VC was significantly lower in relapse group than in non-relapse group (65.7 vs 81.2%,  $p=0.02$ ). By ROC analysis, the cut-off levels of serum KL-6 and %VC were determined as 1359 U/mL and 70.5%, respectively. Kaplan-Meier analysis showed serum KL-6 >1359 U/mL ( $p=0.02$ ), anti-ARS

antibody ( $p<0.05$ ), %VC <70.5 ( $p=0.004$ ), and ULF lesions ( $p=0.01$ ) were significantly related to the relapse (figure 1). Multivariate analysis revealed only serum KL-6 >1359 U/mL was an independent risk factor for relapse (hazard ratio: 4.9 (95%CI 1.0–24.0),  $p<0.05$ ) among the 4 characteristics. At the time of the relapse, serum KL-6 levels were increased 37% from the 3 months average and 51% from the 6 months average.

**Conclusions:** Serum KL-6 was a strong predictor for relapse of myositis-associated ILD.

#### FRI0463 A NEW COMPUTED TOMOGRAPHY INDEX FOR QUANTIFICATION OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS IS ASSOCIATED WITH LUNG FUNCTION PARAMETERS IN THE SHORT TERM FOLLOW-UP

S. Vettor<sup>1</sup>, M. Bocchino<sup>2</sup>, D. Bruzzese<sup>3</sup>, M. D'Alto<sup>4</sup>, P. Argiento<sup>4</sup>, V. Giacco<sup>1</sup>, E. Romeo<sup>4</sup>, A. Capaccio<sup>2</sup>, G. Rea<sup>5</sup>, T. Valente<sup>5</sup>, A. Sanduzzi-Zamparelli<sup>2</sup>, G. Valentini<sup>1</sup>. <sup>1</sup>Biochemistry, Biophysics, and General Pathology, University of Campania Luigi Vanvitelli; <sup>2</sup>Pneumology Unit; <sup>3</sup>Biostatistics, University of Naples Federico II; <sup>4</sup>Cardiology Unit, University of Campania Luigi Vanvitelli; <sup>5</sup>Radiology Unit, Monaldi Hospital, Naples, Italy

**Background:** New computer-assisted methods for the objective quantification of interstitial lung disease (ILD) at computed tomography (CT), based on the evaluation of mean lung attenuation (MLA), skewness and kurtosis have been recently investigated in Systemic Sclerosis (SSc). We developed a computerised integrated index (CII) based on a weighted evaluation of MLA, skewness and kurtosis and investigated its reliability for the quantitative assessment of SSc-ILD and its associations with lung function parameters in a cross-sectional study.

**Objectives:** To identify the CII cut off value with the highest sensitivity and specificity for CT-detected ILD and to investigate its impact on lung function parameters over-time of baseline assessed CII.

**Methods:** SSc patients meeting the new ACR/EULAR classification criteria, who had undergone a volumetric lung CT study from July 1 st 2014 to June 30th 2015, had been evaluated at baseline for ILD quantification by Goh et al. method and the previously referred dedicated software and had their CII calculated, were enrolled in a prospective study including complete clinical, serological, and functional assessment at baseline and at 1 year follow-up (FU).

**Results:** Thirty-nine out of 83 (47%) SSc patients (79 females, 4 males; mean age 56.4±11.3 years; median disease duration 12 years;<sup>2-54</sup> 18 diffuse cutaneous and 65 limited cutaneous SSc) had evidence of ILD as assessed by volumetric CT of the lungs at baseline. CII in patients with ILD was significantly lower than in those without ILD (-0.4929±0.9933 versus 0.4145±0.8059 HU;  $p<0.0001$ ). ROC analysis revealed that the best discriminating CII value for ILD was 0.1966:

sensitivity 0.81 (95% C.I. 0.68 to 0.92); specificity 0.66 (95% C.I. 0.52 to 0.80). Out of the 44 ILD negative patients, 22 (50%) presented a CII value lower than the cut-off, and 13 of them (59%) were found to have a diffusing lung capacity for CO (DLCO)<80% of predicted. At 1 year FU, the CII was significantly correlated with total lung capacity -TLC ( $r=0.45$ ,  $p=0.004$ ) and DLCO ( $r=0.29$ ,  $p=0.045$ ). Out of the 22 patients with a CII <0.1966 but no ILD at visual evaluation, 11 (50%) developed a FVC decline at 1 year, and 8 (36.7%) a DLCO decline.

**Conclusions:** Here we confirm that quantitative computer-assisted CT of the lungs could be a reliable method for SSc-ILD evaluation and found that it could also be useful in predicting the evolution of lung function in the short-term FU.

#### CLINICAL MANIFESTATIONS OF PERSISTENT ANTIPHOSPHOLIPID ANTIBODIES IN SYSTEMIC SCLEROSIS PATIENTS

S. Myriam<sup>1,2,3</sup>, V. Sobanski<sup>1,2,4</sup>, A. Lemaire<sup>1,2</sup>, J. Giovannelli<sup>4</sup>, E. Hachulla<sup>1,2,4</sup>, B. Lopez<sup>4,5</sup>, M. Lambert<sup>1,2,4</sup>, P.-Y. Hatron<sup>1,2</sup>, S. Dubucquoi<sup>4,5</sup>, D. Launay<sup>1,2,4</sup>

<sup>1</sup>Département de Médecine Interne et Immunologie Clinique; <sup>2</sup>Centre national de référence maladies systémiques et auto-immunes rares (sclérodémie systémique), CHU Lille; <sup>3</sup>Univ Lille; <sup>4</sup>Lille Inflammation Research International Center (LIRIC), Univ. Lille, U995; <sup>5</sup>Département d'Immunologie centre de biologie pathologie, CHU Lille, Lille, France

**Background:** Antiphospholipid antibodies (aPL) can be detected in systemic sclerosis (SSc) patients. While their clinical signification is well known in the primary antiphospholipid syndrome (APS), their frequency and clinical association remain debated matter of issue. In a previous study, we reported the prevalence and their clinical association of a single aPL testing a French cohort of SSc patients. Yet, the persistence of aPL during follow-up of patients has never been assessed.

**Objectives:** This study aimed to assess i. the persistence of aPL at least 12 weeks after the first dosage and ii. the clinical associations.

**Methods:** At least 12 weeks apart after the first test, 213 SSc patients were consecutively tested for lupus anticoagulant (LA), anticardiolipin (aCL) and anti-β2glycoproteine 1 (anti-β2Gp1) antibodies. aCL and anti-β2Gp1 were measured using commercial ELISA assays (Orgentec, Trappes, France), positivity was defined as  $\geq 10$  UGPL/mL (aCL) or  $\geq 10$  UA/mL (anti-β2Gp1). Clinical associations were studied using binomial logistic regressions.

**Results:** The mean time between two tests was  $13.2 \pm 6.3$  months. One or more type of aPL was persistent in 7 patients (3%). Patients with persistent aPL developed more frequently venous thrombosis (VT) [4/7 (57%) versus 23/205 (11%),  $p=0.006$ ]. Arterial or/and venous thrombosis were more common in patients with persistent aPL than other patients [4/7 (57%) versus 33/205 (16%),  $p<0.001$ ]. Persistent aPL was also associated with miscarriages [4/6 (67%) versus 33/155 (21%),  $p=0.023$ ].

Association between aPL positivity persistence and clinical manifestations

	aPL positivity	aPL negativity	p
Arterial or venous thrombosis	4 (57.1%)	33 (16.1%)	<0.001
Venous thrombosis	4 (57.1%)	23 (11.2%)	0.006
Arterial thrombosis	1 (14.3%)	14 (6.8%)	0.406
Miscarriage	4 (66.7%)	32 (20.6%)	0.023
Digital ulceration	0 (0%)	40 (19.8%)	0.351
PAH	1 (14.3%)	13 (6.7%)	0.402

**Conclusions:** The prevalence of persistent aPL in our cohort was 3%. VT and miscarriages were associated with persistent aPL.

#### QUANTITATIVE ASSESSMENT OF INTERSTITIAL LUNG DISEASE IN IDIOPATHIC INFLAMMATORY MYOPATHIES: VISUAL SCORE AND COMPUTERISED PROCESSING ANALYSIS OF HIGH RESOLUTION COMPUTERISED TOMOGRAPHY

S. Barsotti<sup>1,2</sup>, C. Romei<sup>3</sup>, E. Cioffi<sup>2</sup>, E. Perrone<sup>3</sup>, C. Giovannetti<sup>2</sup>, M. Mosca<sup>2</sup>, F. Falaschi<sup>3</sup>, R. Neri<sup>2</sup>. <sup>1</sup>Department of medical biotechnologies, University of Siena, Siena; <sup>2</sup>Rheumatology Unit, University of Pisa; <sup>3</sup>Radiology Unit, Pisa University Hospital, Pisa, Italy

**Background:** High resolution computed tomography (HRCT) is an essential technique for the characterisation of interstitial lung disease (ILD) in patients with idiopathic inflammatory myopathies (IIM). Although several visual scores are available for a semiquantitative evaluation of ILD, an automatic quantitative analysis of lung involvement may represent a valuable improvement to reproducibly determine the extent of the disease.

**Objectives:** To compare the semiquantitative visual score to a volumetric texture and local volumetric histogram feature-based analysis software (CALLIPER) to quantify the lung involvement in IIM patients.

**Methods:** 21 consecutive IIM patients (Bohan and Peter criteria) who underwent a HRCT between November 2016 and November 2017 were prospectively enrolled. Twelve were affected by polymyositis and 9 by dermatomyositis. We collected smoking habits data and myositis specific autoantibodies positivity, respiratory symptoms according to MRC dyspnea scale and two patients reported outcome questionnaires: Leicester cough questionnaire (LCQ) and St. George's Respiratory questionnaire (SGRQ). Patients underwent a non-contrast, supine, volumetric CT ( $\leq 2$  mm slice thickness) that was evaluated by an expert radiologist according to Warrick's score (WS) and also quantified by CALLIPER (Mayo Biomedical Imaging Resource – USA). CALLIPER analysis of the extent of interstitial lung abnormalities (ground glass, lung reticulation, honeycombing) was performed and a total score, expressed as percentage of lung involved (ILD%), was obtained. Analysis of the vascular involvement were performed as percent of pulmonary vessel volume (VESS%).

**Results:** Between the 21 patients, five (23.8%) were smokers. Four patients were positive for anti-synthetase autoantibodies -ASS (3 Jo-1, 1 PL-7), 1 SRP, 1 Mi2. Dyspnea was present in 19 patients (90%): 9 grade 1, 7 grade 2, 3 grade 3 according to MRC scale. There were strict correlations between WS and ILD ( $r=0.802$   $p<0.001$ ) and VESS% ( $r=0.746$   $p<0.001$ ). LCQ score was negative correlated to WS ( $r=-0.728$   $p=0.007$ ) but the correlations were stricter with ILD score ( $r=-0.868$   $p<0.001$ ) and VESS% ( $r=-0.801$   $p<0.002$ ). SGRQ did not correlate both to WS and CALLIPER parameters. Patients with ASS have higher ILD and VESS% compared to seronegative patients (respectively  $p=0.003$  and  $p=0.006$ ).

**Conclusions:** CALLIPER represents an innovative technique to quantify the lung involvement in IIM patients: the main advantage of CALLIPER is the reproducibility that avoids the inter and intra-reader bias. Although more data are needed in larger cohorts, the use of CALLIPER may open new routes for the evaluation of ILD in IIM patients, both in medical practice and in randomised controlled trials.

#### ARTICULAR AFFECTATION IN SYSTEMIC SCLEROSIS: CORRELATION OF ULTRASOUND FINDINGS WITH CLINICAL, BIOLOGICAL AND RADIOGRAPHICAL FINDINGS

C. De la Puente, J. Quiñones, S. Zegarra. *University Hospital Ramón y Cajal, Madrid, Spain*

**Objectives:** To evaluate the prevalence of subclinical synovitis in systemic sclerosis (SS), as well as the correlation of sonographic findings in hands with radiographs and with clinical-analytical parameters. In addition, the correlation with scales of functionality will be determined.

**Methods:** Cross-sectional observational-analytical study that included 40 patients with ES and 23 patients with rheumatoid arthritis (RA) as a control group during the period 10/2015–03/2016. Clinical, analytical, immunological, ultrasound and the radiological characteristics of both groups and their respective statistical correlations were compiled.

**Results:** The mean age of the group with SS was  $53.3 \pm 14.1$  years; 87.5% were women and 75% of the cases were cutaneously limited. The average time of evolution of the disease was 6.8 years from the diagnosis. Regarding the clinical joint involvement in the carpus and hands, frank arthritis was present in 16 cases (40%), with an average of DAN: 3.77 and TAN: 1.57; with an average of EVA global pain: 30/100 and elevated CRP in 42.5% of cases. The prevalence of subclinical synovitis with ultrasound expression of synovial effusion  $\pm$ synovial hypertrophy in the SS group was at carpal level (77%), FCM (60%), PFI 32.5% and DFI (15%). The statistical linear correlation between findings of carpal erosions at the ultrasound level versus the radiological data was positive only in the involvement at the joint level FCM and FID. In the group with SS, the HAQ questionnaire

had an average of 0.95 (mild disability) versus 0.77 in the RA group, and the average hand function score or Cochin index: 20.6 (moderate disability) against 17.5 of the RA group. There was no statistically significant correlation ( $\chi^2$ ) between the elevated CRP values and these 2 questionnaires in the SS group. The radiological findings of calcinosis and acroosteolysis in the group with SS were double the cases of the group with RA (7 versus 3, and 14 versus 7 respectively).

**Conclusions:** Subclinical joint involvement in systemic sclerosis had a high prevalence, similar in rheumatoid arthritis, with ultrasound being a fundamental test when evaluating subclinical inflammatory activity. It also presents an important correlation with the findings found in radiographs in the same locations.

#### THE RELATIONSHIP BETWEEN <sup>99m</sup>Tc-PERTECHNETATE HAND PERFUSION SCINTIGRAPHY AND NAIFOLID CAPILLOSOPY IN SYSTEMIC SCLEROSIS PATIENTS: A PILOT STUDY

S.R. Pavlov-Dolijanovic<sup>1</sup>, N. Petrovic<sup>2</sup>, N. Vujasinovic Stupar<sup>1</sup>, N. Damjanov<sup>1</sup>, G. Radunovic<sup>1</sup>, V. Zugic<sup>3</sup>, D. Babic<sup>4</sup>, D. Sobic-Saranovic<sup>2</sup>, V. Artiko<sup>2</sup>. <sup>1</sup>School of Medicine, University of Belgrade, Institute of Rheumatology, Belgrade, Serbia; <sup>2</sup>School of Medicine University of Belgrade, Center for Nuclear Medicine, Clinical Center of Serbia, Belgrade, Serbia; <sup>3</sup>School of Medicine, University of Belgrade, Clinic for Pulmology, Clinical Center of Serbia, Belgrade; <sup>4</sup>School of Medicine University of Belgrade, Institute for Medical Statistics and Informatics, Belgrade, Serbia, Belgrade, Serbia

**Background:** The aim of this study was to assess possible relationship between the altered blood perfusion at hands analysed by <sup>99m</sup>Tc-pertechnetate hand perfusion scintigraphy (<sup>99m</sup>TcPHPS) and, morphological microvascular abnormalities detected by nailfold capillaroscopy (NC) in SSc patients.

**Methods:** The study group consisted of 25 patients with SSc (14 with diffuse SSc, and 11 with limited SSc) and 28 control subjects (18 patients with primary RP, and 10 healthy individuals). NC and <sup>99m</sup>TcPHPS was performed in all the groups examined. The capillaroscopic pattern was classified as normal or scleroderma ("early", "active", or "late") pattern. Gamma-camera dynamic first-pass study during the first 60 s and a static scintigraphy after 5 min were recorded following a bolus injection of <sup>99m</sup>Tc-pertechnetate via a cubital vein. Regions of interest were drawn on the summed images around the fingers and the palmar region. The fingers-to-palm ratios were then calculated.

**Results:** SSc patients showed a significantly lower blood flow (BF) and blood pool (BP), ( $0.43 \pm 0.21$  vs  $0.36 \pm 0.07$ , respectively), than PRP patients ( $0.45 \pm 0.18$  vs  $0.42 \pm 0.06$ , respectively) and healthy subjects ( $0.58 \pm 0.19$  vs  $0.44 \pm 0.06$ , respectively), (p-value 0.039 vs 0.004, respectively). A gradual decrease of BF and BP was found in SSc patients with progressive severity of NVC patterns of microangiopathy ["early" ( $0.49 \pm 0.03$  vs  $0.39 \pm 0.04$ , respectively), "active" ( $0.43 \pm 0.11$  vs  $0.38 \pm 0.06$ , respectively) or "late" ( $0.40 \pm 0.28$  vs  $0.36 \pm 0.08$ , respectively), (p-value 0.462 vs 0.728 respectively), but these differences were not statistically significant. Patients with diffuse SSc showed lower BF, and higher BP ( $0.42 \pm 0.26$  vs  $0.37 \pm 0.07$ , respectively) than those with limited SSc, ( $0.44 \pm 0.14$  vs  $0.35 \pm 0.064$ , respectively), but this differences is not statistical significantly (p=0.76 vs p=0.53, respectively). There was no significant correlation between BF and BP values and type of SSc (limited or diffuse) ( $r = -0.06$ , p=0.77;  $r = 0.13$ , p=0.54, respectively) as well as three microangiopathy patterns ( $r = -0.253$ , p=0.22;  $r = -0.13$ , p=0.54, respectively).

**Conclusions:** NC represents the best method to analyse microvascular damage in rheumatic diseases, especially SSc. <sup>99m</sup>TcPHPS improves the evaluation of vascular damage in SSc patients. There is no direct relationship between these two methods, but one method complements another in the study of vascular damage in SSc patients.

#### ABNORMAL OESOPHAGEAL MOTILITY DURING A SOLID TEST MEAL IN SYSTEMIC SCLEROSIS – DETECTION IN VERY EARLY DISEASE AND ASSOCIATION WITH DISEASE PROGRESSION

S. Bütikofer<sup>1</sup>, S. Jordan<sup>2</sup>, M. Sauter<sup>1</sup>, M. Hollenstein<sup>1</sup>, H. Heinrich<sup>1</sup>, N. Freitas-Queiroz<sup>3</sup>, T. Kuntzen<sup>1</sup>, P. Valli<sup>1</sup>, D. Ang<sup>4</sup>, M. Oberacher<sup>5</sup>, B. Maurer<sup>2</sup>, W. Schwitzer<sup>1</sup>, M. Fox<sup>1</sup>, O. Distler<sup>2</sup>, B. Misselwitz<sup>1</sup>. <sup>1</sup>Department of Gastroenterology, <sup>2</sup>Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; <sup>3</sup>Department of Gastroenterology, University of Sao Paulo, School of Medicine, Sao Paulo, Brazil; <sup>4</sup>Department of Gastroenterology, Changi General Hospital, Singapore, Singapore; <sup>5</sup>Department of Medicine, Spital Limmattal, Schlieren, Switzerland

**Background:** Ineffective oesophageal motility (IEM) is frequent in patients with systemic sclerosis (SSc). High-resolution oesophageal manometry (HRM) is the reference standard test for oesophageal motility and addition of a test meal increases diagnostic sensitivity and specificity.

**Objectives:** This study assessed whether using a test meal instead of standard water swallow in HRM increases sensitivity and can detect clinically relevant, abnormal motility in already very early SSc and whether this finding is associated with subsequent disease progression.

**Methods:** This prospective, longitudinal cohort study recruited 68 consecutive SSc patients (group #1: 32 established disease (ACR/EULAR 2013 and ACR 1980 criteria fulfilled); group #2: 24 early disease (only ACR/EULAR 2013 fulfilled); group #3: 12 very early disease (clinical expert diagnosis of SSc, no classification criteria fulfilled) and 72 healthy controls. HRM evaluated oesophageal motility for water swallows and a solid test meal using validated methods.

**Results:** SSc patients had less frequent effective oesophageal contractions during the test meal compared to healthy controls. Notably, this was detected even in very early disease (0.15, 1.0, 2.1/min for group #1, #2 and #3, vs. 2.5/min in health, p<0.001; p<0.001 and p<0.009, respectively). No other significant abnormality on HRM was found in patients with very early disease (group 1). Ineffective motility at HRM was associated with a higher modified Rodnan skin score at baseline. Moreover, at mean 18<sup>10-31</sup> months follow-up, the presence of ineffective motility at baseline was associated with progression of skin disease for the overall SSc cohort (p<0.010). In a secondary analysis, below-average lower oesophageal sphincter pressure was associated with progression of skin disease and organ disease, in particular interstitial lung disease (p<0.009).

Key HRM findings in SSc patients and healthy volunteers.

**A** Percentage of effective swallows in the test meal **B** Number effective swallows per min in the test meal. **C** Number pharyngeal swallows per min in the test meal. **D** Vigour of peristalsis (DCI) in standard HRM. Median (red bar) and IQR (error bars) are indicated. Please, note the significant decrease in effective swallows per minute which in patients with very-early disease, which is only observed for the test meal. Statistical analysis: Mann-Whitney U test. \* p<0.05. \*\* p<0.01. \*\*\* p<0.001.

**Conclusions:** Ineffective motility during a test meal is present already in patients with very early SSc. In cross-sectional analysis, findings on HRM studies at baseline are associated with disease severity and prospectively with progression of

skin disease during follow-up. Thus, performance of HRM already in very early disease stages can support individual risk-stratification of SSc patients.

#### ACUTE AND CHRONIC EFFECTS OF TWO DIFFERENT INTRAVENOUS ILOPROST REGIMENS IN SYSTEMIC SCLEROSIS: A SINGLE CENTRE PRAGMATIC NON-RANDOMISED TRIAL

T. Schioppo<sup>1</sup>, A. Orenti<sup>2,3</sup>, P. Boracchi<sup>2,3</sup>, O. De Lucia<sup>1</sup>, A. Murgio<sup>1</sup>, F. Ingegnoli<sup>1,2</sup>.  
<sup>1</sup>Division of Rheumatology, ASST Pini-CTO; <sup>2</sup>Dept of Clinical Sciences and Community Health, Università degli Studi di Milano; <sup>3</sup>Lab of Medical Statistics, Epidemiology and Biometry GA Maccacaro, Milano, Italy

**Background:** In systemic sclerosis (SSc) vascular involvement plays a pivotal role in the pathogenesis and clinical manifestations.<sup>1</sup> Intravenous (IV) iloprost (ILO), a prostacyclin analogue, is administered in SSc, according to EULAR recommendations, to improve Raynaud's phenomenon (RP) and to achieve digital ulcers (DU) healing and prevention,<sup>2</sup> even though no further indications about the regimen are specified.

**Objectives:** The aim of this study was to evaluate acute and chronic effects of IV ILO administered with two different regimens as assessed by power Doppler ultrasound (PDUS) and nailfold videocapillaroscopy (NVC) and in a group of patients not treated with ILO.

**Methods:** This was a single centre pragmatic non-randomised trial on 96 patients with SSc divided in 3 groups: no ILO (group A), ILO once monthly (group B) and ILO for 5 consecutive days every 3 month (group C). At each evaluation patients underwent PDUS and NVC. Group A patients were examined at baseline and after 3 months. Group B every month before and after IV ILO monthly therapy for 3 months. Group C before and after the 1 and 5 days of therapy at baseline and after 3 months. PDUS parameters included resistivity index (RI), finger pulp blood flow (FPBF) and periungual vascularisation. The sum of capillaries apex width in one millimetre was assessed through NVC. Results were analysed considering the average outdoor temperature at the place of residence.

**Results:** An acute IV ILO effect was observed for FPBF in group B and C ( $p < 0.001$  and  $0.005$  respectively). An acute effect was observed for RI and periungual vascularisation only in group B. A progressive increase was observed for the other parameters without being statistically different. On the contrary IV ILO effects were not observed any longer before the following infusion. Moreover, some parameters (FPBF in group B and RI in group C) showed a statistically higher increase as low as the outdoor temperature was.

**Conclusions:** IV ILO therapy was able to cause an acute effect with respect to PDUS parameters, especially in group B. The acute effect was not any longer maintained until the following infusion. Future studies are needed to assess time for re-treating.

#### A PHASE 2 STUDY OF SAFETY AND EFFICACY OF LENABASUM (JBT-101), A CANNABINOID RECEPTOR TYPE 2 AGONIST, IN REFRACTORY SKIN-PREDOMINANT DERMATOMYOSITIS

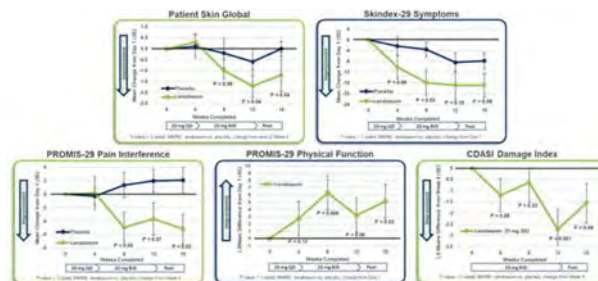

V.P. Werth<sup>1,2</sup>, E. Hejazi<sup>1,2</sup>, S.M. Pena<sup>1,2</sup>, J.S. Haber<sup>1,2</sup>, J. Okawa<sup>1,2</sup>, R. Feng<sup>1,2</sup>, K. Gabre<sup>2</sup>, J.S. Concha<sup>1,2</sup>, C. Cornwall<sup>3</sup>, N. Dgetluck<sup>3</sup>, S. Constantine<sup>3</sup>, B. White<sup>3</sup>.  
<sup>1</sup>Philadelphia Veteran Affairs Medical Center; <sup>2</sup>University of Pennsylvania, Philadelphia; <sup>3</sup>Corbus Pharmaceuticals, Inc., Norwood, USA

**Background:** Effective treatment options are limited for refractory skin disease in dermatomyositis (DM). Lenabasum is a non-immunosuppressive, synthetic, oral preferential CB2 agonist that triggers resolution of innate immune responses and reduces cytokine production by PBMC from DM patients.

**Objectives:** The purpose of this study was to test safety and efficacy of lenabasum (aka JBT-101, anabasum) in DM subjects with refractory, moderate-to-severely active skin disease.

**Methods:** A double-blind, randomised placebo-controlled 16 week Phase 2 trial (JBT101-DM-001; NCT02466243) enrolled adults with documented DM and a Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) activity score  $\geq 14$ , minimal active muscle involvement and failure or intolerance to hydroxychloroquine and stable DM medications including immunosuppressants. Subjects received 2 escalating dose levels of lenabasum (20 mg QD X 4 weeks, then 20 mg BID X 8 weeks) or PBO X 12 weeks. Subjects were followed off study drug X 4 weeks. Safety and efficacy outcomes were assessed from Day 1 through end of study at Week 16. The primary efficacy objective was to assess efficacy of lenabasum using CDASI activity score.

**Results:** 11 adults each received lenabasum and PBO (n=22). Demographic and disease characteristics were similar in both cohorts. Both cohorts had mean CDASI activity scores in the severe range<sup>33–35</sup> despite immunosuppressants (19/22 subjects). Lenabasum subjects had clinically meaningful improvement in CDASI activity scores with mean reduction  $\geq 5$  points at all visits after 4 weeks. Improvement had statistical significance at end of study (figure 1,  $p=0.02$ , 2-sided MMRM) that first became apparent after 4 weeks. Lenabasum provided greater improvement than placebo in CDASI damage index, patient-reported global skin disease and overall disease assessments, skin symptoms including photosensitivity and itch, fatigue, sleep, pain interference with activities, pain, and physical function (examples in figure 1). Improvements in secondary efficacy outcomes reached statistical significance ( $p \leq 0.1$ , 1-sided MMRM) at multiple visits after week 4 (figure 1). There were no serious, severe or unexpected adverse events (AEs) related to lenabasum. Tolerability of lenabasum was excellent with no study drop-outs. Subjects in the lenabasum cohort had numerically more mild AEs than placebo subjects (29 vs. 19) and fewer moderate AEs (4 vs. 7). AEs in  $\geq 3$  subjects in any cohort were diarrhoea, dizziness (lightheadedness), fatigue and dry mouth.

**Abstract FRI0470 – Figure 1.** Effects of Lenabasum on Efficacy Outcomes in Refractory, Skin-Predominant DM

**Conclusions:** Lenabasum demonstrated consistent evidence of clinical benefit across multiple efficacy outcomes and had acceptable safety and tolerability in this Phase 2 trial in refractory skin disease in DM. Further evaluation of lenabasum in the treatment of DM is warranted.

**FRI0471** PREDICTION OF PROGRESSION OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS: THE SPAR MODEL

W. Wu<sup>1,2</sup>, S. Jordan<sup>1</sup>, M.O. Becker<sup>1</sup>, R. Dobrota<sup>1</sup>, B. Maurer<sup>1</sup>, H. Fretheim<sup>3</sup>, S. Ye<sup>2</sup>, E. Siegert<sup>4</sup>, Y. Allanore<sup>5</sup>, A.M. Hoffmann-Vold<sup>3</sup>, O. Distler<sup>1</sup>. <sup>1</sup>Rheumatology, University Hospital Zurich, Zurich, Switzerland; <sup>2</sup>Rheumatology, South Campus, Ren Ji Hospital, School of Medicine, Shanghai JiaoTong University, Shanghai, China; <sup>3</sup>Rheumatology, Oslo University Hospital, Oslo, Norway; <sup>4</sup>Rheumatology and Clinical Immunology, Charité-University Medicine Berlin, Berlin, Germany; <sup>5</sup>Rheumatology, Paris Descartes University, Cochin Hospital, Paris, France

**Background:** The natural disease course of interstitial lung disease associated with systemic sclerosis (SSc-ILD) is highly heterogeneous. Currently, no data are available to distinguish a progressive disease course from a stable course when mild interstitial lung disease (ILD) is diagnosed in patients with systemic sclerosis (SSc).

**Objectives:** This study aimed to identify predictive clinical characteristics and establish a prediction model for the progression of mild ILD at 1 year follow-up in SSc patients.

**Methods:** Patients with SSc from two independent prospective cohorts were included in this observational study. All patients fulfilled the ACR<sup>EULAR</sup> 2013 criteria, had mild ILD at baseline diagnosed by HRCT (ILD extent <20% lung involvement on HRCT), available baseline and follow-up pulmonary function tests, at least one annual follow-up visit, and no concomitant pulmonary hypertension or airflow obstruction. ILD progression was defined as a relative decrease in FVC % $\geq$ 15%, or FVC% $\geq$ 10% combined with DLCO% $\geq$ 15% at 1 year follow-up. Candidate predictors for multivariate logistic regression were selected by expert opinion based on previous studies and clinical significance. Multiple imputation was used to address missing data. A prediction model for ILD progression was established in the derivation cohort and validated in the multinational validation cohort.

**Results:** A total of 25/98 and 25/117 SSc patients showed ILD progression in the derivation cohort and the validation cohort, respectively. Lower SpO<sub>2</sub> after six-minute walk test (6MWT) and arthritis ever were identified as independent predictors for ILD progression in the derivation, validation and pooled cohorts (figure 1). The optimal cut-off value for SpO<sub>2</sub> after 6MWT for ILD progression was determined as 94% by ROC curve analysis. In a simplified model, the presence of both SpO<sub>2</sub> after 6MWT $\leq$ 94% and Arthritis ever were set to 1, giving a SPAR score ranging from 0 to 2. The derived SPAR model increased the prediction rate for ILD progression from 7.4% (scoring 0) to 91.7% (scoring 2) with an AUC [95% CI] of 0.83 [0.73 to 0.93] in the derivation cohort, and a similar AUC [95% CI] of 0.82 [0.70 to 0.94] in the validation cohort.

**Abstract FRI0471 – Figure 1.** Multivariate logistic regression models in the derivation cohort, the validation cohort and the pooled cohort (both original and multiply imputed datasets, adjusted for age, gender, Anti-Sci-70 positive, ACA positive in the pooled cohort)

**Conclusions:** The evidence-based SPAR prediction model developed in our study might be helpful for the risk stratification of patients with mild SSc-ILD in clinical practice and cohort enrichment for future clinical trial design.

**FRI0472** TOWARDS A MULTIDIMENSIONAL PATIENT REPORTED OUTCOME MEASURES ASSESSMENT: DEVELOPMENT AND VALIDATION OF A QUESTIONNAIRE FOR PATIENTS WITH SYSTEMIC SCLEROSIS/ SCLERODERMA

Y. El Miedany<sup>1,2</sup>, M. El Gaafary<sup>3</sup>, N. El Arousy<sup>2</sup>, S. Youssef<sup>2</sup>, Y. Atef<sup>4</sup>, D. Palmer<sup>5</sup>. <sup>1</sup>Rheumatology, Darent Valley Hospital, Dartford, UK; <sup>2</sup>Rheumatology and Rehabilitation; <sup>3</sup>Community and Public Health, School of Medicine Ain Shams University, Cairo; <sup>4</sup>Rheumatology and Rehabilitation, School of Medicine Assiut University, Assiut, Egypt; <sup>5</sup>Rheumatology, North Middlesex University Hospital, London, UK

**Background:** Systemic sclerosis is a chronic multisystem autoimmune disorder associated with high morbidity and mortality rates. A multidisciplinary approach is necessary due to the complexity of the disease and its associated multi-organ affection. It is important to understand and monitor the impact of systemic sclerosis on the patients, provide them with high quality of care and to endorse the ownership of their disease process as early as possible to prepare them for the management this life-long illness.

**Objectives:** To assess the validity, reliability of a specific multidimensional patient self-reported questionnaire that can assess construct outcome measures of patients with systemic sclerosis/scleroderma.

**Methods:** The questionnaire was developed by integrating information obtained from patients suffering from systemic sclerosis as well as scleroderma based on the Rasch model. The questionnaire includes assessment of functional disability, quality of life, 0–10 numeric visual analogue scale (VAS) to rate the severity of the musculoskeletal pain, difficulty in breathing, gastrointestinal symptoms (e.g. swallowing difficulty/reflux/bloating/Faecal soilage/diarrhoea/constipation), Raynaud's phenomenon, fingers ulcers as well as the global assessment of the disease impact on the patient's life. In addition, the questionnaire includes 2 mannequins, one for self-reported body pains and the other one for self-reported skin tightness. Also there is a review of the possible comorbidities for the patient to tick in front of whatever he/she developed in the past month; as well as patient motivation. The questionnaire was completed by 52 consecutive patients with systemic sclerosis<sup>31</sup> and scleroderma.<sup>21</sup>

**Results:** The multidimensional PROMs questionnaire was reliable as demonstrated by a high-standardised alpha (0.894–0.993). The questionnaire items correlated significantly ( $p<0.01$ ) with clinical parameters of disease activity. Patient reported tender spots and skin tightness correlated significantly with the physician's as well as Rodnan skin scores (correlation coefficient 0.848 and 0.821 respectively). Changes in functional disability, quality of life and motivation scores showed significant variation ( $p<0.01$ ) with diseases activity status. The PROMs questionnaire showed also a high degree of comprehensibility (9.3).

**Conclusions:** The developed PROMs questionnaire is a reliable and valid instrument for assessment of patients suffering from systemic sclerosis/scleroderma. Being short, rapid and comprehensive, this adds more to its applicability. The data support the value of completion of the simple 2 pages patient questionnaire, which provides a quantitative written documented record by the patient, at each visit to the rheumatologist.

antibody (ANCA) positivity. On the other hand, it is also reported that 7%–13% of patients with SSc revealed myeloperoxidase-ANCA (MPO-ANCA) positivity without vasculitis manifestation in 1990s, but their clinical characteristics were unclear. It is also unknown whether ANCA positivity leads to AAV or not in patients with SSc. It is important for physicians to clarify the characteristics of SSc patients with ANCA positivity, and answer the question whether they will shift ANCA-associated vasculitis (AAV).

**Objectives:** To assess the prevalence of ANCA positive patients with SSc, and clarify the characteristics of these patients.

**Methods:** We enrolled the 333 consecutive patients with SSc who visited our clinic during October 2014 to September 2015, all of who were checked MPO-ANCA using fluorescent-enzyme immune-assay. Clinical manifestation and laboratorial data were obtained from medical chart. The data were assessed by chi-square analysis and Welch's t test.

**Results:** Two patients were diagnosed AAV before October 2014. Eight patients (2.4%) revealed MPO-ANCA positivity without vasculitis manifestation. All of MPO-ANCA positive patients were female, and mean age and disease duration were 61.1 years old and 17.2 years, respectively, and there's no statistically significant differences comparing MPO-ANCA negative patients. As a result of evaluating clinical manifestations, we found that patients with MPO-ANCA positivity more frequently had interstitial lung disease than patients without MPO-ANCA positivity (87.5% vs. 36.7%,  $p < 0.01$ ). The clinical characteristics of 8 patients were shown in table 1. Only one patient out of 8 patients with MPO-ANCA positivity newly diagnosed AAV during mean of 33 months follow-up period.

**Conclusions:** The prevalence of MPO-ANCA positivity in SSc patients were lower than previous reports. MPO-ANCA positivity may be related to interstitial lung disease in SSc. MPO-ANCA positive patient may occasionally reveal AAV in the future, and careful observation are needed.

### CLASSIFICATION OF SKIN INVOLVEMENT IN LEVAMISOLE-ADULTERATED COCAINE INDUCED VASCULOPATHY

C.H. Muñoz-Vahos<sup>1,2,3</sup>, S. Herrera-Urbe<sup>4</sup>, Á. Arbeláez-Cortés<sup>5</sup>, D. Jaramillo-Arroyave<sup>1,2</sup>, L.A. González-Naranjo<sup>6</sup>, G. Vásquez-Duque<sup>2</sup>, M. Restrepo-Escobar<sup>2</sup>, L.A. Correa-Londoño<sup>6</sup>, J. Hernández-Zapata<sup>2</sup>, A.L. Vanegas-García<sup>2,3</sup>. <sup>1</sup>IPS Universitaria Clínica León XIII; <sup>2</sup>Grupo de Reumatología, Departamento de Medicina Interna Universidad de Antioquia; <sup>3</sup>Hospital Universitario San Vicente Fundación; <sup>4</sup>Hospital General de Medellín, Medellín; <sup>5</sup>Centro Médico Imbanaco de Cali, Cali; <sup>6</sup>Sección de Dermatología, Departamento de Medicina Interna, Universidad de Antioquia, Medellín, Colombia

**Background:** Up to 88% of cocaine is tainted with levamisole, an anthelmintic withdrawn from the market due to toxicity. Since 2010 levamisole-adulterated cocaine induced vasculopathy (LACIV) patients, characterised by retiform purpura, ear necrosis, multisystemic compromise and positivity for multiple autoantibodies, have been reported. Knowing the pattern and the severity of skin involvement is essential in the approach of these patients.

**Objectives:** To describe the cutaneous manifestations of patients with LACIV and to propose a classification of skin involvement.

**Methods:** We describe the skin compromise of 30 patients with LACIV evaluated between December 2010 and May 2017. Based on this series and the review of the literature, we propose a classification according to the distribution and severity of the lesions.

**Results:** All patients were mestizo, median age of 31 (IQR 27–38), male:female ratio 5:1, time from symptoms to diagnosis 12 months (IQR 6–24). The most frequent clinical manifestations were skin lesions: ear necrosis (73%) and retiform purpura (83%) affecting the extensor part of the limbs, buttocks, face, and abdomen; sparing the scalp, palms and soles. Retiform purpura was classified in four grades according to distribution and severity (image). Skin biopsies revealed leukocytoclastic vasculitis (24%), pseudo-vasculitis (19%), thrombotic vasculopathy with leukocytoclastic vasculitis (19%), thrombotic vasculopathy with pseudo-vasculitis (19%), and pyoderma gangrenosum with vasculopathy (5%).

**Image: LACIV retiform purpura classification. A. Grade 1:** livedo reticularis or racemosa with incipient purpura (individual lesions  $\leq 1$  cm). **B. Grade 2:** More extended purpuric lesions which sometimes coalesce (individual lesions  $> 1$  cm). **C. Grade 3:** Purpuric lesions with haemorrhagic blisters. **D. Grade 4:** Deep purpuric lesions with associated ulceration.

**Conclusions:** Given the higher consumption of cocaine and its contamination with levamisole, the report of LACIV patients is increasing. A classification of the skin involvement in LACIV is proposed, according to the frequency of affection and the stratification of purpuric lesions in four degrees of severity. Cutaneous involvement is one of the pillars for the diagnosis and properly treatment, therefore a detailed description of distribution and characteristics of the lesions are fundamental for these patients care.

**FRI0475 LUNG DAMAGE IN PATIENTS WITH MICROSCOPIC POLYANGIITIS**

E. Shchegoleva<sup>1</sup>, A. Zykova<sup>2</sup>, N. Bulanov<sup>1</sup>, A. Meshkov<sup>1</sup>, P. Novikov<sup>1</sup>, S. Moiseev<sup>1</sup>. <sup>1</sup>Department of internal diseases, Sechenov First Moscow State Medical University, <sup>2</sup>Department of internal diseases, Lomonosov Moscow State University, Moscow, Russian Federation

**Objectives:** We evaluated the frequency of clinical and CT features of lung damage in patients with microscopic polyangiitis (MPA).

**Methods:** We enrolled 97 patients with MPA, that was diagnosed according to CHCC2012. The median age at disease onset was 50.7±16.6 (M±SEM) years, the median duration of follow-up was 47.6±47.5 (M±SEM) months. 64 (66.0%) patients were ANCA-MPO-positive, 24 patients (24.7%) were ANCA-PR-3-positive, and 9 (9.3%) patients had undifferentiated ANCA. Diffuse alveolar haemorrhage (DAH) was diagnosed by the presence of dyspnea, hemoptysis, anaemia and pulmonary infiltrates on chest CT.

**Results:** Lung damage was diagnosed in 77 (79.4%) patients. 43 (55.8%) patients had pulmonary damage at the disease onset, while 34 (44.2%) patients developed signs of lung involvement within 8.0±4.1 (M±SEM) months. At baseline, the median pulmonary BVAS was 4.<sup>2, 6</sup> The interstitial changes occurred in more than half of cases at the onset of the disease. The most frequent CT-patterns included pulmonary infiltrates (n=49) and ground-glass opacity (n=39) (table 1). DAH developed in 30 (30.9%) patients, among them 15 (15.5%) had DAH at the onset of the disease.

The pulmonary fibrosis was the most common CT-pattern at the end of follow-up (52 patients). Notably, interstitial damages at the onset of disease were associated with the development of fibrotic changes (OR=4.7, 95% CI 1.7–12.9) and bronchiectasis (OR=9.8, 95% CI 1.2–78.3) at the end of follow-up. The median of pulmonary VDI was 1 (0;4) at the end of the follow up.

PR-3-positive group had higher occurrence of consolidations at the end of the follow-up as compared to patients with anti-MPO-antibodies (53.8% versus 16.0%, p=0.023).

Abnormality	N (%) of cases	
	At baseline (n=77)	At the end of follow-up (n=47)
Interstitial damage	68 (70.1%)	18 (18.6%)
Infiltrates	49 (50.5%)	0 (0%)
Ground-glass opacity	39 (40.2%)	16 (16.5%)
Consolidation	5 (5.2%)	8 (8.2%)
Bronchial wall thickening	10 (10.3%)	18 (18.6%)
Bronchiectasis	4 (4.1%)	18 (18.6%)
Bronchiolitis	3 (3.1%)	5 (5.2%)
Pleural lesions	11 (11.3%)	5 (5.2%)
Pleural effusion	12 (12.4%)	0 (0%)
Pleural thickening	3 (3.1%)	5 (5.2%)
Pulmonary fibrosis	14 (14.1%)	52 (53.6%)
Honeycombing	0 (0.0%)	4 (4.1%)
Atelectasis	3 (3.1%)	8 (8.2%)
Emphysema	0 (0.0%)	13 (13.4%)
Pulmonary hypertension	0 (0.0%)	7 (7.2%)

The pulmonary fibrosis was the most common CT-pattern at the end of follow-up (52 patients). Notably, interstitial damages at the onset of disease were associated with the development of fibrotic changes (OR=4.7, 95% CI 1.7–12.9) and bronchiectasis (OR=9.8, 95% CI 1.2–78.3) at the end of follow-up. The median of pulmonary VDI was 1 (0;4) at the end of the follow up.

PR-3-positive group had higher occurrence of consolidations at the end of the follow-up as compared to patients with anti-MPO-antibodies (53.8% versus 16.0%, p=0.023).

**Conclusions:** In patients with MPA, the CT signs of interstitial damage were usually reversible. However, they predicted a higher incidence of lung fibrosis and bronchiectasis at the end of follow-up. DAH occurred in one third of patients with MPA.

**Disclosure of Interest:** None declared

**FRI0476 THE MYRIAD OF NEPHRITIS IN LEVAMISOLE-ADULTERATED COCAINE VASCULOPATHY**

C.H. Muñoz<sup>1,2,3</sup>, S. Herrera-Urbe<sup>4</sup>, Á. Arbeláez-Cortés<sup>5</sup>, D. Jaramillo-Aroyave<sup>2,3</sup>, L.A. González-Naranjo<sup>2</sup>, G. Vásquez-Duque<sup>2</sup>, M. Restrepo-Escobar<sup>2</sup>, J. Hernández-Zapata<sup>2</sup>, L.F. Arias-Restrepo<sup>6</sup>, A.L. Vanegas-García<sup>1</sup>. <sup>1</sup>Hospital Universitario San Vicente Fundación; <sup>2</sup>Grupo de Reumatología, Departamento de Medicina Interna Universidad de Antioquia; <sup>3</sup>IPS Universitaria Clínica León XIII; <sup>4</sup>Hospital General de Medellín, Medellín; <sup>5</sup>Centro Médico Imbanaco de Cali, Cali; <sup>6</sup>Departamento de Patología, Universidad de Antioquia, Medellín, Colombia

**Background:** Up to 88% of cocaine is tainted with levamisole, an anthelmintic withdrawn from the market due to toxicity. Since 2010 levamisole-adulterated

cocaine vasculopathy (LACIV) patients, characterised by retiform purpura, ear necrosis, multisystemic compromise and positivity for multiple autoantibodies, have been reported. Renal involvement is the most serious and heterogeneous manifestation.

**Objectives:** To describe the renal involvement of patients with LACIV.

**Methods:** We describe the renal manifestations of 30 patients with LACIV evaluated from December 2010 to May 2017.

**Results:** All patients were mestizo, median age of 31 (IQR 27–38), male:female ratio 5:1, time from symptoms to diagnosis 12 months (IQR 6–24). Nephritis found in 57%, creatinine elevation in 40%, median 1.85 mg/dl (IQR 1.2–4.0), 70% had proteinuria, median 3184 mg/day (IQR 552–5100), 58% in nephrotic-range; 88% had hematuria and 41% pyuria and cilindruria. Biopsy was performed in 7 patients (41%), showing immune complex mediated extracapillary glomerulonephritis (29%), membranous glomerulonephritis (29%), pauci-immune proliferative glomerulonephritis (14%), focal and segmental glomerulosclerosis (14%) and C3 mediated extracapillary glomerulonephritis (14%) (image). Three patients (10%) developed end-stage kidney disease.

**Image:** **A. Membranous glomerulonephritis:** HE: glomerular thickened capillary walls, mild mesangial cellularity increase. **B. GMS:** capillary wall thickening and spikes (arrow). **C. DIF:** strong and diffuse IgG deposits on capillary walls. **D. Immune complex mediated Extracapillary Focal Necrotizing Glomerulonephritis:** HE: endocapillary proliferation, epithelial crescent (arrow). **E. GMS:** capillary wall rupture next to the crescent (arrow). **F. DIF:** Mesangial strong and diffuse IgG deposits. **G. C3 mediated extracapillary glomerulonephritis:** HE: glomerular capillary narrowing, epithelial crescent (arrow). **H. GMS:** normal capillary networks, epithelial crescent (arrow). **I. DIF:** C3 strong and diffuse positivity. **J. Pauci-immune proliferative glomerulonephritis:** PAS: epithelial crescents (arrows and asterisk). **K. Trichrome:** epithelial crescent (arrow). **L. DIF for C3:** weak deposits on capillary tuft. Non-immune complexes. **M. Focal and segmental glomerulosclerosis:** HE: segmental sclerosing lesions (arrow). **N. PAS:** segmental sclerosing lesions (asterisks). **O. DIF for IgM:** nonspecific positivity on a sclerotic segment.

**Conclusions:** Although skin manifestations are the most characteristic and prevalent features in LIVEN, renal involvement is frequent, clinically and histologically heterogeneous, and potentially serious. The great heterogeneity on the histopathological findings suggests the participation of different physio-pathological mechanisms, establishing renal biopsy as necessary to identify the type of nephropathy and thus, optimal guidance of therapy.

**FRI0477 IMMUNOGENICITY OF INFLIXIMAB AMONG PATIENTS WITH BEHÇET'S SYNDROME: A CONTROLLED STUDY**

S.N. Esatoglu<sup>1</sup>, F.N. Akkoc<sup>1</sup>, Y. Ozguler<sup>1</sup>, F. Ozbakir<sup>2</sup>, O.K. Nohut<sup>2</sup>, D. Cevirgen<sup>1</sup>, V. Hamuryudan<sup>1</sup>, I. Hatemi<sup>3</sup>, A.F. Celik<sup>3</sup>, H. Yazici<sup>1</sup>, G. Hatemi<sup>1</sup>. <sup>1</sup>Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology; <sup>2</sup>Istanbul University, Cerrahpasa Medical School, Central Research Laboratory; <sup>3</sup>Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Gastroenterology, Istanbul, Turkey

**Background:** Immunogenicity of anti-TNFs has been recognised as an important problem that may cause loss of efficacy and adverse events such as infusion reactions. Anti-TNFs are being increasingly used among patients with Behçet's syndrome (BS).

**Objectives:** We aimed to investigate the prevalence of anti-drug antibodies against infliximab (IFX) in patients with BS together with controls.

**Methods:** We collected serum samples from 66 consecutive BS patients (51 M, 15 F and mean age 37±9 years) who were treated with IFX. IFX was used for eye involvement in 43, vascular involvement in 12, nervous system involvement in 8 and arthritis in 2 patients. Additionally, 53 ankylosing spondylitis (AS), 25 Crohn's disease (CD) and 27 rheumatoid arthritis (RA) patients, and 31 healthy subjects were included as controls. We included patients who had received at least 4 cycles of IFX. Samples were collected just before an infusion, stored at -80°C until analysis, and serum IFX trough levels and anti-IFX antibodies were measured by ELISA at the same time. We used a cut-off value of 1 µg/mL for serum IFX trough level, extrapolating from RA studies. After serum sampling, we continued to follow up patients.

**Results:** Anti-IFX antibodies were detected in 4 (6%) BS, 5 (18.5%) RA, 3 (12%) CD, and 1 (2%) AS patient, and in none of the healthy subjects. The mean number of IFX cycles was 19±14 in BS, 21±13 in RA, 19±21 in CD, and 33±18 in AS patients. Allergic reactions had occurred in 9 (14%) BS, 6 (22%) RA, 5 (20%) CD, and 4 (7.5%) AS patients. 3/6 RA patients and 3/5 CD patients who had experienced an allergic reaction had anti-IFX antibodies whereas none of BS and AS patients did.

The median serum IFX trough level was significantly lower in patients with anti-IFX antibodies compared to those without antibodies (2.32 (IQR: 0.6–3.6) vs 3.35 (IQR: 1.63–5.6; p=0.019). The serum IFX trough level was lower than the cut off value in 6/13 patients with anti-IFX antibodies and in 25/158 without anti-IFX antibodies (46% vs 16%; p=0.015).

We were able to get samples before at least 2 consecutive infusions in 27 BS patients and the presence of anti-IFX antibodies was consistent across the samples in all of these patients. We were able to get samples before the infusion and at week 2 in 5 BS patients. Serum IFX level was below 1 µg/mL before IFX and above 1 µg/mL at week 2 in all of these 5 patients.

During a median follow up of 1.5 years, 2/4 BS patients with anti-IFX antibodies had flares. Among the 62 patients without anti-IFX antibodies, 49 are still on IFX and IFX was stopped due to remission in 12 and due to infusion reaction in one patient. Overall, 5 infusion reactions occurred during the follow up (4 without anti-IFX antibodies and 1 with anti-IFX antibodies; 6.5% vs 25%).

**Conclusions:** Immunogenicity does not seem to be an important problem in BS patients treated with IFX. The frequency of anti-IFX antibodies was lower than RA and CD patients. This might be related to concomitant immunosuppressive and corticosteroid use among BS patients. The presence of anti-IFX antibodies may not be associated with efficacy loss in BS. However, longer follow-up is needed to make that statement as BS has a relapsing-remitting course.

**FRI0478 OCCURRENCE OF GENUINE VASCULITIS IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS**

P. Novikov, E. Zagvozdina, V. Kazarina, N. Bulanov, S. Moiseev, E.M. Tareev  
*Clinic of nephrology, internal and occupational diseases, Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Background:** Many patients with eosinophilic granulomatosis with polyangiitis (EGPA) lack a "vasculitic" phenotype and/or are ANCA negative. Recently, the Groupe d'Etudes et de Recherche sur les Maladies Orphelines Pulmonaires developed a revised nomenclature for EGPA and proposed to differentiate it from hypereosinophilic asthma with systemic (nonvasculitic) manifestations (HASM).

**Objectives:** To evaluate the occurrence of genuine polyangiitis and HASM in a cohort of patients with EGPA.

**Methods:** We retrospectively studied the medical records of patients with EGPA that fulfilled the classification criteria of the American College of Rheumatology. Patients with genuine vasculitis were identified by at least one of the following criteria: <sup>1</sup> definite vasculitis feature as defined: biopsy-proven necrotizing vasculitis of any organ, biopsy-proven necrotizing glomerulonephritis or crescentic glomerulonephritis, alveolar haemorrhage, palpable purpura, myocardial infarction due to proven coronary arteritis; <sup>2</sup> strong surrogate of vasculitis as defined: haematuria associated with red casts or ≥10% dysmorphic erythrocytes, or haematuria and 2 +proteinuria on urinalysis related to the systemic disease; and any organ manifestation other than ENT or bronchopulmonary manifestation associated with leukocytoclastic capillaritis and/or eosinophilic infiltration of the arterial wall; <sup>3</sup> mononeuritis multiplex; <sup>4</sup> ANCA with at least one extra-thoracic non-ENT manifestation of disease.

**Results:** We followed 68 patients with EGPA for a mean ±SD of 6.3±6.5 years (587.7 patient-years). There were 19 males and 49 females. Their mean ±SD age was 49.5±13.8 years. In 18 patients (26.5%) with EGPA diagnosis was revised in favour of HASM using the new criteria (table 1). Notably, 19 of 50 patients (38%) with genuine polyangiitis were ANCA-negative but have histological evidence or clinical signs (rapidly progressive glomerulonephritis in 1, mononeuritis multiplex 7, palpable purpura in 5) of definite vasculitis. The majority of patients in both groups were females of similar age at disease onset. The occurrence of constitutional symptoms, except myalgia, nasal involvement, cardiovascular and pulmonary manifestations did not differ between patients with genuine polyangiitis and HASM. However, patients with EGPA usually required more intensive immunosuppressive treatment, including cyclophosphamide, while monotherapy with moderate to high dose corticosteroids was adequate for the majority of patients with HASM.

Table 1 Clinical and demographic characteristics of patients with genuine EGPA and HASM

	All, n=68	HASM, n=18	EGPA, n=50	p
Age at diagnosis, years	49.5 (36; 56)	50 (35; 55)	49.0 (37; 57)	0.91
Females, n (%)	49 (72.1)	17 (94.4)	32 (64.0)	0.014

### FRI0479 PRIMARY CENTRAL NERVOUS SYSTEM VASCULITIS WITH TUMOR-LIKE PRESENTATION

C. Salvarani<sup>1</sup>, R.D. Brown<sup>2</sup>, T.J. Christianson<sup>2</sup>, C. Giannini<sup>2</sup>, J. Huston III<sup>2</sup>, G. G. Hunder<sup>2</sup>. <sup>1</sup>Azienda USL-IRCCS di Reggio Emilia e Università di Modena e Reggio Emilia, Reggio Emilia, Italy; <sup>2</sup>Mayo Clinic, Rochester, USA

**Background:** Primary central nervous system vasculitis (PCNSV) rarely presents as a tumor-like mass lesion (ML).

**Objectives:** The aim of this study was to determine the frequency of ML in a large cohort of patients with PCNSV and compare the presenting clinical, laboratory, and imaging features in those with ML to those without.

**Methods:** We retrospectively studied a cohort of 191 consecutive patients with PCNSV who were seen at the Mayo Clinic, Rochester, MN over a 35 year period. The diagnosis of PCNSV was based on brain/spinal cord biopsy or cerebral angiography. We compared PCNSV patients with tumor-like presentation to those without.

**Results:** 13/191 (6.8%) patients had tumor-like presentation. In all 13 patients PCNSV diagnosis was established by cerebral biopsy (stereotactic in 10, open-wedge in 3). 4 patients had cerebral angiography, and vasculitis was suggested in one patient. A granulomatous inflammatory histologic pattern was found in 11 biopsies, accompanied by vascular deposits of  $\beta$ -amyloid peptide in 7. In the other 2 biopsies a lymphocytic vasculitis was observed. The 13 patients with tumor-like presentation were compared with the 178 patients without. The patients with ML were more frequently males (77% vs 44%,  $p=0.04$ ), were less likely to present with transient ischaemic attacks (TIA) (0 vs 27.5%,  $p=0.023$ ) and more likely to present with seizures (46% vs 17%,  $p=0.022$ ) at presentation. No significant differences in the CSF findings and ESR levels (normal in 100% and 82% of the patients, respectively) at diagnosis were observed in the two groups. Intracerebral gadolinium-enhancing lesions were more frequently observed in patients with ML (46% vs 21%,  $p=0.07$ ), while meningeal gadolinium-enhancing lesions were equally observed (31% vs 20%,  $p=0.48$ ). The frequencies of PCNSV recurrence (38% vs 29%), patients not requiring therapy at last follow-up (15% vs 25%), response to therapy (100% vs 74%), and poor outcomes (modified Rankin disability score  $\geq 4$ ) at last followup (8% vs 26%) were not significantly different in the two groups. No differences in survival were observed between the 2 groups ( $p=0.57$ ). Considering all 191 patients, univariate Cox proportional hazards modelling showed an increased mortality rate in those with increasing age (hazard ratio, HR, 1.4), cerebral infarction on initial MRI (HR 2.95), and angiographic large vessel involvement (HR 3.2), while mortality rate was lower in those with gadolinium-enhancing lesions on MRI (HR=0.3).

**Conclusions:** Tumor-like presentation represents a subset of PCNSV characterised by vascular deposits of  $\beta$ -amyloid at biopsy, seizures at presentation, and gadolinium-enhancing cerebral lesions on MRI. As in PCNSV without ML, treatment response and prognosis was favourable in most patients.

**Disclosure of Interest:** None declared

### FRI0480 TOCILIZUMAB MONO-THERAPY FOR POLYMYALGIA RHEUMATICA ~ RESULTS OF 104-WEEK TREATMENT OF A PROSPECTIVE, SINGLE-CENTRE, OPEN TRIAL

K. Amano, K. Chino, Y. Okada, A. Shibata, S. Saito, T. Kurasawa, A. Okuyama, H. Takei, R. Sakai, T. Kondo. *Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan*

**Background:** Polymyalgia rheumatic (PMR) is a chronic inflammatory rheumatic disease in the elderly people. Glucocorticoid (GC) is still definitely a mainstay for the treatment of PMR, but long-term GC therapy is a major risk factor of osteoporotic fractures, diabetes, hyperlipidemia, cardio-cerebral vascular events, glaucoma, etc. So GC-free treatment strategies for PMR are awaited for some PMR patients with these comorbidities. IL-6 is involved in the pathogenesis of PMR and several case reports have already shown the efficacy of tocilizumab (TCZ), anti-IL-6 receptor antibody, in PMR patients<sup>1,2</sup> and there is a report of TCZ mono-therapy as the first-line therapy in PMR<sup>3</sup>.

**Objectives:** To assess the efficacy and safety of TCZ mono-therapy for PMR

**Methods:** Thirteen PMR patients (male 3, female 10) who had been diagnosed by 2012 ACR/EULAR classification criteria from Jan 2013 to Feb 2015 were enrolled in our single-centre, prospective study (IRB application No. 638, UMIN No. 000008812) after obtaining the written informed consent. TCZ (8 mg/kg) was administered biweekly for the first 8 weeks (5 infusions) and every 4 weeks thereafter for 40 weeks (total 15 infusions). ESR, CRP, patient's global health assessed by visual analogue scale (VAS), PMR activity score<sup>4</sup> were evaluated every 4 week prospectively. Primary endpoint was remission rate at week 52. Remission was defined as PMR activity score less than 1.5<sup>4</sup>. Patients were followed up for another one year without any treatment and flare rate was assessed at week 104.

**Results:** Baseline patients' characteristics revealed various kinds of comorbidities in 11 patients; hypertension in 7, hyperlipidemia in 5, diabetes mellitus in 3,

osteoporotic vertebral fractures in 2, history of angina pectoris in 1, history of brain infarction in 1, history of hematemesis due to NSAID ulcer in 1 and glaucoma in one patient. Nine patients could complete this 104 week trial and all 9 patients could achieve remission at week 52 and 8 of 9 patients fulfilled remission criteria at week 104. Two patients discontinued TCZ because of no response at week 6 (No.1) and week 16 (No. 8) respectively. One patient (No.2), who were in clinical remission of PMR, dropped out from this study due to pemphigoid at week 50 and received GC therapy. Patient No. 12 abandoned TCZ at week 12 because of lung infiltrates although she was treated successfully with TCZ mono-therapy, and she had been in remission without any treatment until week 104. The other 3 patients could obtain remission with GC therapy at week 52. There were no serious adverse events during 104 week treatment period.

**Conclusions:** TCZ mono-therapy was effective in most (9 out of 13) PMR patients although response was not so rapid as compared to GC. TCZ mono-therapy may be a good alternative therapy instead of GC for elderly patients with various comorbidities.

### FRI0481 GIANT CELL ARTERITIS AND INFLAMMATORY BOWEL DISEASE – IS THERE A CONNEXION? RESULTS FROM A POPULATION-BASED STUDY

Y. Yavne<sup>1</sup>, S. Tiosano<sup>2</sup>, A. Watad<sup>2</sup>, D. Comaneshter<sup>3</sup>, A.D. Cohen<sup>3</sup>, H. Amital<sup>2</sup>. <sup>1</sup>Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv; <sup>2</sup>Department of Medicine 'B', Zabudowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer; <sup>3</sup>Chief Physician's Office, Clalit Health Services, Tel Aviv, Israel

**Background:** Giant cell arteritis (GCA) is an autoimmune disorder which primarily affects large vessels, whilst inflammatory bowel disease (IBD), which includes Crohn's disease (CD) and ulcerative colitis (UC), mainly targets the gut. Co-existence of the two maladies has been reported sporadically in the literature<sup>1–3</sup>.

**Objectives:** The purpose of this study was to assess the authenticity of such an association in a large, cross-sectional study.

**Methods:** Utilising data derived from the Clalit Health Services' registry, the largest health maintenance organisation in Israel, we compared the proportion of CD and UC in GCA patients with age- and gender-matched controls. Univariate analysis was performed using Chi-square and student *t*-test and a multivariate analysis was performed using a logistic regression model.

**Results:** The study included 5,657 GCA patients and 28 298 age- and gender-matched controls. GCA patients had a significantly increased proportion of both CD and UC in comparison with controls (0.81% vs. 0.12% and 0.69% vs. 0.2%,  $p$ -value<0.001, respectively). The strength of the association between GCA and IBD was negatively correlated with the patients' age; thus the association was most robust amongst younger patients aged 18–44 (OR=13.2, figure 1). The association between GCA and IBD remained significant when evaluated independently of confounding factors (OR=2.367,  $p$ -value<0.001, table 1).

**Abstract FRI0481 – Table 1.** Multivariate logistic regression of covariates associated with IBD

Characteristic	OR	CI	P
Age	0.99	0.98–1	0.49
Gender	1.25	0.87–	0.22
(Female)		1.84	
BMI	0.95	0.92–	0.007
		0.98	
SES:			
Medium vs. Low	1.42	0.94–2.1	0.1
High vs. Low	1.74	1.13–2.69	0.012
GCA	2.36	1.71–3.27	<0.001

IBD: Inflammatory bowel disease; BMI: Body Mass Index, kg/m<sup>2</sup>; SES: Socioeconomic status; GCA: Giant Cell Arteritis

Abstract FRI0481 – Figure 1. Interactions between GCA, IBD and covariates

**Conclusions:** The probability that GCA patients may also suffer from IBD is increased in comparison with age- and gender-matched controls. Our findings indicate that this association is most prominent in younger patients (<70). Screening for IBD amongst GCA patients in this age group may be warranted.

#### FRI0482 CAUSES OF DEATH IN CONNECTIVE TISSUE DISEASE (CTD'S) AND VASCULITIDES; DATA FROM THE NORWEGIAN CONNECTIVE TISSUE DISEASES AND VASCULITIS REGISTRY (NOSVAR)

T. Garen, K. Lerang, H. Andersson, Ø. Midtvedt, K. Kilian, S. Reister, R. Gunnarsson, B. Gudbrandsson, Ø. Molberg, Ø. Palm. *Department of Rheumatology, Oslo University Hospital, Rikshospitalet, Oslo, Norway*

**Background:** Mortality as an outcome of disease's severity and causes of death can give extended insight into the nature of each specific diagnose and highlight distinct needs for monitoring. In connective tissue diseases (CTD) and systemic vasculitides, mortality and causes of death have been studied within most single diseases, but with heterogeneity of the studies and widely varying results. Studies applying similar methods across the diagnoses are lacking. Consequently, it is difficult to compare causes of death between the different diagnoses.<sup>1</sup>

**Objectives:** To identify the causes of death within different CTDs and systemic vasculitides.

**Methods:** We performed a prospective, observational, controlled study between 1999 and 2017 of adult patients (at least 18 years of age) with diagnosis of CTD or vasculitides. All patients were included in the Norwegian connective tissue disease and vasculitis Registry (NOSVAR). In total, 2140 patients were diagnosed and followed up until death or study end by April 31th 2017. To avoid bias by selection, we included only incident cases, excluding patients with diagnoses set prior to 1999. Moreover, cases with a disease course not consistent with the initial diagnoses were excluded. Causes of death were identified by linking NOSVAR to the Norwegian Causes of Death Registry and by reviewing hospital charts. We divided the causes of death into the main groups of cardiovascular diseases (CVD), neoplasms, chronic respiratory disease (CRD), infections and other (gastrointestinal, renal insufficiency and trauma). To compare causes of death to the general population we used data from WHO Mortality Database, Causes of death.<sup>2</sup>

**Results:** During a mean (SD) follow-up time of 9.2 years (4.7), 279 patients (13%) deceased. The major causes of death were, in descending order of frequency; CVD (27%), neoplasms (25%), CRD (16%), infections (11%), gastrointestinal manifestations (4%), renal insufficiency (2%). Data from the general population, adjusted for age and gender, showed that deaths by CVD, CRD and infections were more prevalent among the patients.<sup>2</sup> The leading causes of death are shown in figure 1. In Takayasu arteritis and ISSc, CVD was the most frequent cause of death; (56%) and (41%), respectively. More than half of the patients (53%) with antisynthetase syndrome died of CRD. Those with dermatomyositis died most frequently of neoplasms (50%).

**Conclusions:** Compared to general population, patients with CTD and vasculitis died more often of CVD, CRD and infections. CVD as a cause of death was most prevalent in patients with Takayasu arteritis, giant cell arteritis and systemic sclerosis, while neoplasm was the major cause of death in dermatomyositis. In antisynthetase syndrome, both CRD was the major causes of death. The study gives the clinician valuable information on how to monitoring the different CTDs and vasculitidis regarding serious outcome.

#### FRI0483 SULFASALAZINE AS A POTENTIAL TREATMENT FOR IGA-VASCULITIS (HENOCH-SCHÖNLEIN PURPURA) IN ADULTS

S. Giliayev, A. Semenovykh . *I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Background:** Primary IgA-vasculitis and inflammatory bowel diseases (IBD) share many clinical, endoscopic, and radiological signs. It may suggest a common pathogenetic background for both pathological conditions. While sulfasalazine (SASP) is one of the well-known potential agents able to improve symptoms in IBD, the usefulness of SASP in treatment of the primary IgA-vasculitis remains unclear.

**Objectives:** Retrospective study to assess a therapeutic value of the SASP in primary IgA-vasculitis.

**Methods:** Totally 78 adult patients with primary IgA-vasculitis were enrolled in this study. Diagnosis was made on the basis of EULAR/PRES criteria<sup>1</sup> after thorough screening to exclude a secondary nature of the disease, including colonoscopy. Purpura/petechia was present in all patients being mandatory diagnostic criterion. Arthritis/arthralgia was seen in 48 patients (61,5%). There were no patients with abdominal syndrome just before enrollment, although 46 (59%) patients had transient abdominal pains in the history. Mild to moderate signs of renal involvement (hematuria and/or proteinuria) was seen in 35 (45%) patients without renal impairment. There were 20 (25%) drug-naïve patients, 40 (51%) patients after unsuccessful immunosuppressive treatment and 18 (23%) patients failed to respond to anticoagulants or antiplatelet agents. Initially SASP was prescribed in a daily dose 1 g followed with gradual titrating up to the 2 g/day depending on tolerability and clinical response. Most patients (96%) have been taking SASP longer than 6 month and about a half of the patients (56%) – longer than year. The longest treatment was 5 years.

**Results:** Complete clinical remission of the skin rash was achieved in 48 patients (58,9%). In 27 patients (35%), there was partial improvement of the skin eruptions, characterised with less quantity of the skin purpura or longer periods free of

symptoms (see table 1). Four patients failed to improve at all. Persistent remission of the arthritis/arthralgia was found in 41 patients (85%). One patient did not improve. Complete resolution of the urinary abnormalities were registered in 14 patients (40%), improvement – in 17 cases (48.5%), further deterioration in 4 patients (11.5%).

There were side effects in 13 patients (16%). In 4 (5.1%) cases there were headache and nausea, respectively. In 2 (2.5%) cases treatment was accompanied with skin itching and urticarial rash. Most severe complication presented with reversible cytolysis, characterised with increase of AST and ALT up to the 2–5 normal limits in 3 cases (2.5%).

**Abstract FRI0483 – Table 1.** Clinical response to SASP treatment in primary IgA-vasculitis (n=78)

Clinical features	Complete remission		Partial remission		No response		Worsening	
	n	%	n	%	n	%	n	%
Skin purpura (n=78)	46	58.9	27	35	4	5.1	-	-
arthritis or arthralgia (n=48)	41	85	6	13	1	1.2	-	-
hematuria and/or proteinuria (n=35)	14	40	17	48.5	-	-	4	11.5

**Conclusions:** To our knowledge, this is the first experience of SASP in treatment of primary IgA-vasculitis not reported before. Preliminary results look promising and worthy of further evaluation.

#### FRI0484 OVERALL SURVIVAL AND MORTALITY RISK FACTORS IN TAKAYASU'S ARTERITIS: A MULTICENTER STUDY OF 318 PATIENTS

A. Mirouse<sup>1</sup>, C. Comarmond<sup>1</sup>, L. Biard<sup>2</sup>, M. Lambert<sup>3</sup>, A. Mékinian<sup>4</sup>, J.-E. Kahn<sup>5</sup>, E. Hachulla<sup>3</sup>, E. Messas<sup>6</sup>, M. Resche-Rigon<sup>2</sup>, P. Caubco, 1D. Saadoun<sup>1</sup> on behalf of French Takayasu network. <sup>1</sup>Service de médecine interne et immunologie clinique, Groupe hospitalier Pitié-Salpêtrière; <sup>2</sup>SBIM, Hôpital Saint-Louis, Paris; <sup>3</sup>Service de médecine interne, CHRU Lille, Lille; <sup>4</sup>Service de médecine interne, Hôpital Saint-Antoine, Paris; <sup>5</sup>Service de médecine interne, Hôpital Foch, Suresnes; <sup>6</sup>Service de médecine vasculaire, Hôpital Européen Georges Pompidou, Paris, France

**Background:** Takayasu arteritis (TA) is a rare large vessel vasculitis of unknown origin. Main epidemiological data come from Asia. TA significantly increases morbidity and mortality and there is an unmet need to identify patients with higher complications and mortality risks.

**Objectives:** To report the long term mortality in Takayasu arteritis (TA) and to identify risk factors associated with mortality.

**Methods:** We analysed epidemiological data according to gender and ethnic origins, the causes of death, and the factors associated with mortality in a cohort of 318 patients [median age at diagnosis was 36<sup>25–47</sup> years and 276 (86%) patients were women] fulfilling American College of Rheumatology and Ishikawa criteria of TA. Overall survival and factors associated with death and vascular complications were identified. A prognostic score for death and vascular complications was elaborated based on a multivariate model.

**Results:** In a cohort of 318 patients, men tended to be more frequently smokers (42% vs. 26%, p=0.07), had more frequently cardiac insufficiency (14% vs. 9%, p=0.034), but less frequently aneurysmal lesion (51% vs. 76%, p=0.005). Ethnic origins were Caucasian/White (n=87, 37%), North-Africa (n=73, 31%), Black (n=56, 18%), and other (n=17, 5%). White patients were more frequently smokers and diagnosis was more frequently made after 35 years. Black patients had less frequently a supra-aortic vessels involvement and more frequently a vessel wall thickening at diagnosis (78% vs. 62%, p=0.033).

Among 318 TA patients, 16 (5%) died after a median follow-up of 6.1 years. The mean (±SD) age at death was 38<sup>25–47</sup> years with 88% of women. Main causes of death included mesenteric ischemia (n=4, 25%), aortic aneurysm rupture (n=4, 25%), sudden death (n=3, 19%), septic shock (n=3, 19%), pulmonary embolism (n=1, 6%), and cardiogenic shock (n=1, 6%). One, five, and ten years' overall survival were 98.9% [97.8–100], 98.1% [96.4–99.8], and 96.1% [93.4–98.9%], respectively. Factors associated with mortality were ethnic origin (White 9.5% vs. North Africa 7.1% vs. Black 0%, p=0.049), and tobacco smokers (10.8% vs. 4.2%, p=0.002).

We define high risk patients for death and vascular complications according to the presence of two of the following factors (i.e a progressive clinical course, thoracic aorta involvement and/or retinopathy) elaborated based on the multivariate model. The probability of death and complication free survival at five years was 78.4% (69.4–88.6) and 51.5% (38.3–69.2) (p=0.001) in the low risk and high risk group, respectively.

**Conclusions:** The overall mortality in our Takayasu cohort was 5% after a median follow-up of 6.1 years. Caucasian and tobacco smokers were associated with mortality in TA. We developed a simple and useful prognosis score to identify patients at risk for vascular complication and death.

#### FRI0485 PHENOTYPE OF ANCA ASSOCIATED VASCULITIS ASSOCIATES WITH MAJOR CARDIOVASCULAR EVENTS: A RETROSPECTIVE OBSERVATIONAL STUDY FROM THE LEEDS VASCULITIS COHORT

A. Giollo<sup>1,2,3</sup>, E.M.A. Hensor<sup>1,2</sup>, J. Andrews<sup>2</sup>, M.H. Buch<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>2</sup>NIHR Leeds Biomedical Research Centre, Leeds, UK; <sup>3</sup>Rheumatology Unit, Department of Medicine, University of Verona, Verona, Italy

**Background:** Patients with ANCA-associated vasculitides (AAV) are at increased risk of cardiovascular (CV) disease than the general population. The factors associated with CV involvement in AAV are poorly understood.

**Objectives:** To explore whether patient and disease-related characteristics associated with CV disease from a single-centre AAV cohort.

**Methods:** Medical records from 145 patients with AAV were reviewed and patients' diagnoses reclassified according to a validated algorithm.<sup>1</sup> CV events (CVE) were defined as myocardial infarction, cerebrovascular accident, thromboembolic event, heart failure, or death/hospitalisation due to CV cause. Time to first CVE was calculated; patients without CVE were censored at most recent clinical follow-up. Data on CV risk factors (hypertension, hyperlipidaemia, diabetes mellitus, chronic kidney disease stage III or higher) were collected. Putative predictors included age, sex, diagnosis (GPA, MPA, EGPA, unclassifiable AAV – UAAV), ANCA (absent, PR3, MPO), number of BVAS items, prior CV disease and number of CV risk factors. Cox proportional hazards regression was used to assess the relationship between CVE and predictors. In this exploratory analysis we used p<0.10 to indicate potential associations.

**Results:** 122 patients who had been followed up for between 6 months and 23 years were included in the analysis. 11/122 patients (10%) had prior history of CV disease. 17 patients (14%) experienced a CVE within median (IQR) 5.8 (1.4, 7.6) years of diagnosis. Univariable analyses indicated older age at diagnosis, MPA and prior CVD were associated with increased risk of CVE, and that those with UAAV were at decreased risk compared to GPA. With the exception of previous CVD an adjusted model confirmed the same associations (table 1).

Variable	No CVE n=105	CVE n=17	Unadjusted HR (90% CI)	Adjusted HR (90% CI)	P value
Age: mean (SD)	49 (17)	57 (13)	1.04 (1.01–1.07)	1.03 (1.00–1.06)	0.049
Female:% (n)	55% (58)	41% <sup>7</sup>	0.76 (0.34–1.67)	0.69 (0.28–1.64)	0.488
Diagnosis:% (n)					
GPA	54% (57)	65% <sup>7</sup>	Ref.	Ref.	0.370
MPA	13% <sup>14</sup>	6% <sup>1</sup>	0.71 (0.12–2.44)	0.38 (0.05–2.21)	0.031
EGPA	10% <sup>10</sup>	29% <sup>5</sup>	3.37 (1.34–7.76)	4.81 (1.46–15.36)	0.071
UAAV	23% <sup>24</sup>	- (0)	0.15 (0.00–0.91)	0.09 (0.00–0.83)	
ANCA:% (n)					
Absent	25% <sup>26</sup>	12% <sup>2</sup>	Ref.	Ref.	0.259
PR3	45% <sup>47</sup>	65% <sup>11</sup>	1.65 (0.58–6.25)	0.33 (0.08–1.79)	0.207
MPO	30% <sup>32</sup>	24% <sup>4</sup>	1.62 (0.46–6.77)	0.27 (0.05–1.52)	
BVAS items: median (IQR)	4 (3–5)	4 (4–5)	1.26 (0.96–1.65)	1.35 (0.95–1.92)	0.156
Prior CVD:% (n)	10% <sup>11</sup>	18% <sup>3</sup>	1.28 (1.17–9.23)	2.58 (0.72–8.03)	0.211
CV risk factors: median (IQR)	1 (0–2)	1 (0–2)	0.92 (0.59–1.39)	0.64 (0.36–1.04)	0.135

**Conclusions:** This exploratory analysis suggests that, among AAV, MPA may have a higher CV risk, whereas UAAV may be associated with a decreased risk. Along with ANCA status, AAV phenotype may inform future CV risk reduction interventions in AAV.

### FRI0486 POTENTIAL PREDICTORS OF VISCERAL INVOLVEMENT IN ADULT IGA VASCULITIS

A. Hocevar<sup>1</sup>, Ž. Rotar<sup>1</sup>, V. Jurčić<sup>2</sup>, M. Tomšič<sup>1</sup>. <sup>1</sup>Dpt. of Rheumatology, University Medical Center Ljubljana; <sup>2</sup>Institute of Pathology, Faculty of Medicine, University of Ljubljana, LJUBLJANA, Slovenia

**Background:** Predictors of severity of visceral involvement in acute adult IgA vasculitis (IgAV) are poorly recognised.

**Objectives:** The aim of our study was to evaluate the role of smoking and extension of skin lesions on the visceral manifestations of acute adult IgA vasculitis.

**Methods:** We analysed medical records of adult, histologically proven IgAV cases, diagnosed at our secondary/tertiary rheumatology centre between 1 January 2010 and 31 December 2017. Purpura was defined as generalised when skin lesions extended above the waistline. Gastrointestinal (GI) disease was considered severe in case of bloody diarrhoea, ileus or bowel perforation. Renal disease was defined as severe when nephritic syndrome with acute renal failure or nephrotic syndrome developed.

**Results:** During the study period we identified 230 incident IgAV cases (57.8% males, median (IQR) age 64.8 (45.6–77.3) years). Ninety-eight (42.6%) patients were smokers (56 past and 42 current). Skin, joint, GI, renal and involvement were present in 230 (generalised purpura in 114 (49.6%), necrotizing in 108 (47.0%), 93 (40.4%), 70 (30.4%; severe in 17) and 102 (44.3%; severe in 27) patients, respectively. Smoking was associated with renal disease (RR 1.3 (95% CI 1.0–1.8)) and its severity (RR 3.2 (95%CI 1.5–7.0)), but not with GI involvement or its severity. Generalised purpura was associated with GI involvement (RR 2.9 (95%CI 1.8–4.7) and its severity (RR 3.3 (95%CI 1.1–9.8)), as well as with renal involvement (RR 1.4 (95%CI 1.0–1.9)). Data of combined influence of smoking and purpura extension on visceral involvement are presented in table 1. The risk of severe renal involvement in IgAV was the highest in ever-smoker with generalised purpura (RR 8.1 (95%CI 1.9–34.7) in comparison to IgAV non-smoker with localised purpura).

Table 1 The influence of smoking and purpura extension on visceral involvement in IgAV

Visceral involvement	Nonsmokers with localized purpura	Ever-smokers with localized purpura	Nonsmokers with generalized purpura	Ever-smokers with generalized purpura
Number of cases	69	47	63	51
GI (%)	13.0	19.1	47.6	43.1
Severe GI (%)	2.9	4.3	11.1	11.8
Renal (%)	30.4	46.8	47.6	56.9
Severe renal (%)	2.9	14.9	9.5	23.5

Legend: GI gastrointestinal; severe GI involvement: bloody diarrhea or ileus or bowel perforation; severe renal involvement: nephritic syndrome with acute renal failure or nephrotic syndrome;

**Conclusions:** Smoking and generalised purpura were associated with visceral involvement in adult IgAV.

### FRI0487 SERUM INTERLEUKIN-6 LEVELS IN ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

A. Berti<sup>1,2,3</sup>, R. Warner<sup>4</sup>, K. Johnson<sup>4</sup>, D. Corne<sup>1</sup>, D. Schroeder<sup>1</sup>, B. Kabat<sup>1</sup>, C. A. Langford<sup>5</sup>, G.S. Hoffman<sup>6</sup>, C.G. Kallenberg<sup>6</sup>, P. Seo<sup>7</sup>, R. Spiera<sup>8</sup>, W. E. St. Clair<sup>9</sup>, F. Fervenza<sup>10</sup>, J. Stone<sup>10</sup>, P. Monach<sup>11</sup>, U. Specks<sup>1</sup>, P.A. Merkel<sup>12</sup>, on behalf of the RAVE-ITN Research Group. <sup>1</sup>Mayo Clinic, Rochester, USA; <sup>2</sup>San Raffaele Scientific Institute, Milan; <sup>3</sup>Santa Chiara Hospital, Trento, Italy; <sup>4</sup>University of Michigan Medical School, Ann Arbor; <sup>5</sup>Cleveland Clinic, Cleveland, USA; <sup>6</sup>University Medical Center Groningen, Groningen, Netherlands; <sup>7</sup>Johns Hopkins University, Baltimore; <sup>8</sup>Hospital for Special Surgery, New York; <sup>9</sup>Duke University, Durham; <sup>10</sup>Massachusetts General Hospital; <sup>11</sup>Boston University, Boston; <sup>12</sup>University of Pennsylvania, Philadelphia, USA

**Background:** The deregulated overproduction of interleukin (IL)–6 has been implicated in several inflammatory and antibody-mediated autoimmune diseases.

**Objectives:** To investigate serum IL-6 levels (sIL-6) during active disease, remission, and relapse in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), and to explore the association of changes in sIL-6 with repopulation of blood B cells and disease relapse.

**Methods:** sIL-6 levels (explanatory variable) were measured longitudinally over 18 months in 78 patients with AAV enrolled in a prospective, double-blinded, randomised, control trial comparing treatment with rituximab (RTX) (n=45) or cyclophosphamide (CYC)/azathioprine (AZA) (n=33). Outcome variables included baseline clinical features, ANCA type and titers, disease activity (status of active disease versus complete remission (CR)), time to B cell repopulation, relapse and severe relapse.

**Results:** Baseline sIL6 levels were detectable (>0.49 pg/ml) in 81% of patients. At baseline, sIL-6 positively correlated with proteinase (PR3)-ANCA levels ( $r_s=0.36$ ,  $p<0.01$ ), but not with myeloperoxidase (MPO)-ANCA levels ( $r_s=-0.17$ ,  $p=0.47$ ). Higher baseline sIL-6 levels were associated with the presence of fever, pulmonary nodules/cavities, PR3-ANCA, and absence of renal involvement ( $p<0.05$  for all comparisons).

The median sIL-6 level was higher at baseline and promptly declined with induction therapy at following time-points (baseline, median [25%>75% IQR], 2.66 [0.76–20.98]; month 6th, 0.49 [0.49–1.16];  $p<0.01$ ) in a similar fashion in both treatment arms.

An increase in sIL-6 during clinical remission was a predictor for subsequent severe relapse in RTX-treated patients (Hazard Ratio (HR) 7.24,  $p=0.01$ ), but not in CYC/AZA-treated patients (HR 0.62,  $p=0.50$ ).

In RTX-treated B cell depleted patients (CD19 +B cell/microliter<10), the rise of sIL-6 levels did not precede B cell reappearance, regardless of whether a cut-off of  $\geq 10$  CD19+B cell/microliter (HR=0.97;  $p=0.97$ ) or of  $\geq 69$  CD19+B cell/microliter (HR=1.50;  $p=0.41$ ) was considered. Eighty percent of the patients who subsequently had a severe relapse in the RTX arm had B cell redetection before or at the time of the IL-6 increase, with a mean time between the redetection of B cells and sIL-6 increase of 55 days (25%>75%IQR: 0–184.25; range 0–210 days).

**Conclusions:** At baseline, sIL-6 correlates with PR3-ANCA titers and associates with the presence of fever and pulmonary nodules/cavities. A rise in sIL-6 levels after complete remission is associated with subsequent severe relapse only in RTX-treated patients. The observed discrepancies between treatments deserve confirmation and further study.

### FRI0488 INSUFFICIENT IMMUNOSUPPRESSIVE USE IS THE LEADING CAUSE OF VASCULAR RELAPSES IN BEHCET'S DISEASE

A. Aksoy<sup>1</sup>, F. Alibaz Öner<sup>2</sup>, T. Ergun<sup>3</sup>, R.H. Direskeneli<sup>2</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine; <sup>2</sup>Department of Internal Medicine, Division of Rheumatology; <sup>3</sup>Department of Dermatology, Marmara University, School of Medicine, Istanbul, Turkey

**Background:** Vascular involvement is observed in up to 40% in Behcet Disease (BD) patients, as an important cause of mortality and morbidity, especially for males (Kural-Syahi E et al,1984).

**Objectives:** Purpose of this study is to describe clinical-demographic properties, treatments and prognosis of vascular BD patients in a tertiary rheumatology clinic.  
**Methods:** BD patients fulfilling ISG 1990 criteria are recruited from the multi-disciplinary Behcet's Clinic in Marmara University, Istanbul for this retrospective study. All data is collected from patient files (ISG for BD, 1990).

**Results:** Mean age of BD patients (M/F:102/22) was 29.3±7.3 years at diagnosis and 32.4±9.5 years old during first vascular event. Median follow up was 47<sup>17-71</sup> months. Mean age of female patients was significantly older during first vascular event (table 1). 73.2% of vascular involvement was venous, mostly deep vein thrombosis (table 2). 32% (n=40) of patients presented first with a vascular event and diagnosed as BD. Twenty (16%) patients were diagnosed with a median of 12<sup>1-120</sup> months after the first vascular event. 15 (6.5%) patients were using immunosuppressive (IS- mainly azatiopirin) drugs either for resistant mucocutaneous symptoms or major other organ involvement during the first vascular event.

Vascular relaps rate was 40.7% and it was similar between sexes (F: 33.3% vs M: 42.2%,  $p=0.6$ ). After the first vascular event, 96 (85.7%) patients had been treated with ISs and 58.9% used anticoagulants. Median IS and anticoagulant usage duration was 25.5 (5–48) and 2 (0–12) months respectively. Relaps rate was higher in patients who had stopped ISs (87.5% vs 32.3%). IS treatment duration

was shorter at relapsing patients (44 vs 64 months,  $p=0.001$ ). Smoking rate was higher at male patients but no association was observed with vascular relapses.

**Abstract FRI0488 – Table 1.** Clinic and demographic features of Behçet's Disease patients

		Female (n=22)	Male (n=102)	p
Mean age at first vascular event		37±12.6	31.5±8.5	0.019
Mean age at BD diagnosis		30.5±9.5	29.1±7.5	0.467
Smoking	Yes	4 (%33.3)	32 (%68.1)	0.018
	No	8 (%66.7)	15 (%31.9)	
Pteryg	Positive	12 (%66.7)	54 (%62.8)	0.99
	Negative	6 (%33.3)	32 (%37.2)	
Number of vascular events	1	14 (%63.6)	55 (%54.5)	
	2	6 (%27.3)	39 (%38.5)	
	3 or more	2 (%9.1)	7 (%7)	

**Abstract FRI0488 – Table 2.** Type and characteristics of vascular involvement

Venous n=134 (%73.2)	Ekxtremities	106 (% 79.1)	Arteries n=44 (%23.5)	Pulmoner Trombus	36 (% 81.8)
	Cerebral	16 (% 12)		Aneurysme (2 coronary, 2 pulmoner, 2 aorta)	6 (% 13.6)
	Others (SVC, IVC, renal, retinal)	12 (8.9)		PAT+PAA	2 (% 4.6)

IVC: inferior vena cava, PAA: pulmoner arter aneurysmei, PAT: pulmoner arter trombus, SVC: superior vena cava

**Conclusions:** Our results show that female BD patients have a vascular event at a later age compared to males, but the course of vascular disease is not influenced with gender. Early termination of immunosuppressive treatments seems to be the most important cause of vascular relapses

**Disclosure of Interest:** None declared

<sup>17</sup>Internal Medicine; <sup>18</sup>Anatomic Pathology, Hospital universitario Marqués de Valdecilla, Santander, Spain

**Background:** Behçet's disease (BD) is characterised by recurrent oral and/or genital ulcers accompanied by ocular, cutaneous, articular, gastrointestinal, and/or neurologic manifestations. Oral and/or genital aphthous ulcers are often refractory to conventional treatment. Apremilast is an orally-active small molecule which inhibits phosphodiesterase-4 (PDE-4) that modulates some inflammatory pathways.

**Objectives:** Our aim was to assess the efficacy of apremilast in BD patients with oral and/or genital ulcers refractory to conventional treatment.

**Methods:** Retrospective national multicenter open-label study on 19 BD patients treated with apremilast at standard dose of 30 mg twice daily. The main outcome was achievement of oral ulcers remission.

**Results:** We included 19 patients (14 women and 5 men) with a mean age of 43.6 ±14.8 years. Before apremilast, all patients had also received several systemic conventional drugs: oral corticosteroids (n=18), colchicine (n=19), NSAIDs (n=10), methotrexate (n=10), azathioprine (n=10), cyclosporine (n=6), infliximab (n=3), adalimumab (n=5), dapsone (n=3), etanercept (n=1), mycophenolate mofetil (n=1), tocilizumab (n=1). The main clinical symptoms for starting apremilast were oral aphthous ulcers (n=19) and genital ulcers (n=14). Other manifestations present at apremilast onset were arthralgia/arthritis (n=6), folliculitis/pseudofolliculitis (n=6), asthenia (n=5), furunculosis (n=1), erythema nodosum (n=1), erythematous and scaly skin lesions (n=1), psoriasis (n=1), deep venous thrombosis (n=2) and ileitis (n=1). Table 1 shows the evolution of the patients. After a median follow-up of 6 [interquartile range, 5–10] months, most of the patients experienced clinical improvement. In this period of time, 11 patients developed any side-effect: dyspepsia (n=5), nausea (n=4), diarrhoea (n=4), abdominal pain (n=4), headache (n=3), loss of appetite (n=3), weight loss (n=1) and halitosis (n=1). Three patients had to reduce the dose to 30 mg/day. Apremilast was discontinued in 4 patients: because of not obtaining the expected improvement (n=2), due to desire of pregnancy (n=1) and due to development of neurological involvement (n=1).

**Abstract FRI0489 – Table 1**

	Basal n=19	Week 1-2 n=19	Week 4 n=19	Month 3 n=18	Month 6 n=11
Resolution of main symptom, oral and/or genital ulcers (n, %)					
Complete	7/19 (36.8)	12/19 (63.1)	13/19 (68.4)	13/18 (72.2)	7/11 (63.6)
Partial	8/19 (42.1)	4/19 (21.1)	4/19 (21.1)	3/18 (16.7)	3/11 (27.3)
Resolution of other symptoms (n, %)					
Complete	3/19 (15.8)	6/19 (31.6)	8/19 (42.1)	8/17 (47.1)	5/11 (45.5)
Partial	3/19 (15.8)	2/19 (10.5)	4/19 (21.1)	4/17 (23.5)	3/11 (27.3)
Dose of prednisone (mg/day), median [IQR]	7.5 [3-13.0]	3.5 [0-7]	2.2 [0-5]	3 [0-5]	2.5 [0-4.9]

**Conclusions:** Apremilast leads to a rapid and maintained improvement in many patients with refractory mucocutaneous ulcers of BD. Even in patients refractory to several systemic drugs including biologic therapy. However, the development of adverse digestive effects is frequent.

**Disclosure of Interest:** None declared

### FRI0490 MORTALITY AND EARLY SEVERE INFECTION IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

D. Waki, K. Nishimura, K. Kadoba, H. Mukoyama, R. Saito, T. Yokota. Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Okayama, Japan, Kurashiki, Okayama, Japan

**Background:** The introduction of treatment regimens comprising of cyclophosphamide or rituximab combined with corticosteroids has brought about dramatic improvements in the prognosis of ANCA-associated vasculitis.<sup>1</sup> Severe infectious events, especially in the early phase of treatment, associated with risk of death have been reported in the past several studies.<sup>2,3</sup>

**Objectives:** We retrospectively investigated the association between mortality and early severe infection in patients with antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV), and we also attempted to identify the potential predictors for early severe infection.

**Methods:** We recruited 182 consecutive hospitalised patients newly diagnosed with AAV at our hospital, from January 2000 to June 2017, in this retrospective cohort study. All cause mortality, relapse, and severe infections within six months after starting treatment (early severe infection) were analysed.

**Results:** The mean age was 70 years at diagnosis, and the classification according to the Chapel Hill Conference definition were microscopic polyangiitis (MPA) in 82 patients (45.1%), granulomatosis with polyangiitis (GPA) in 36 patients (19.8%), eosinophilic granulomatosis with polyangiitis (EGPA) in 24 patients (13.2%), and renal-limited vasculitis in 32 patients (17.6%).<sup>4</sup> Median follow up was 158 weeks (range 0–182 w). Using Cox regression analysis, elderly onset (age ≥75 years) AAV ( $p=0.027$ ) and early severe infection ( $p<0.001$ ) were independent predictors of all cause mortality (table 1).

Early severe infection tended to increase among patients who received immunosuppressive therapy of a corticosteroid combined with cyclophosphamide or rituximab (conventional treatment), and this trend was significant in non-severe (BVAS <20) AAV patients ( $p=0.030$ ) (table 2). Treatment response rate ( $p=0.058$ )

and relapse rate ( $p=0.137$ ) were not significant between the different treatment groups.

**Abstract FRI0490 – Table 1.** Risk factors affecting survival according to Cox regression analysis

Risk factor	Hazard ratio	95% CI	P value
Age $\geq 75$ years old	2.35	(1.1–5.03)	0.027
BVAS $\geq 20$	2.08	(0.99–4.32)	0.05
Creatinine $\geq 1.5$ mg/dl	1.18	(0.58–2.38)	0.654
Early severe infection	3.23	(1.63–6.48)	<0.001

\*Birmingham Vasculitis Activity Score (BVAS) Version.3

**Abstract FRI0490 – Table 2.** Risk factors affecting early severe infection in non-severe AAV patients

Risk factor	Hazard ratio	95% CI	P value
Age $\geq 75$ years old	2.1	(0.85–5.32)	0.105
Conventional treatment	3.0	(1.11–7.89)	0.030
Lung involvement	1.0	(0.43–2.48)	0.936
Creatinine $\geq 1.5$ mg/dl	1.0	(0.41–2.33)	0.963

**Conclusions:** Early severe infection is an independent predictor of death in patients with AAV, and conventional treatment has a potential risk of death due to severe infection. This study supports the current EULAR recommendation that several treatment strategies are recommended according to the disease severity of vasculitis.<sup>5</sup> AAV patients who receive conventional treatment should be carefully monitored to reduce the occurrence of severe infection, especially in early phase of treatment.

#### SMOKING AS A RISK FACTOR FOR GIANT CELL ARTERITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

D. Brennan<sup>1</sup>, P. Ungprasert<sup>2</sup>, K.J. Warrington<sup>2</sup>, M.J. Koster<sup>2</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Rheumatology, Mayo Clinic, Rochester, USA

**Background:** Tobacco smoking is a well-established risk factor for the development of several autoimmune diseases such as rheumatoid arthritis and systemic lupus erythematosus. A similar association between smoking and giant cell arteritis (GCA) has been suspected but remains unclear due to limited study size and conflicting epidemiologic data.

**Objectives:** To conduct a systematic review and meta-analysis to further investigate the association between smoking and the development of GCA.

**Methods:** Two investigators (D.B. and M.K.) independently searched published studies indexed in MEDLINE and EMBASE from inception to February 2017 using the terms “giant cell arteritis,” “temporal arteritis,” “cranial arteritis,” and “Horton disease.” Recent conference abstracts available online were also reviewed. The following inclusion criteria were used: 1) original observational study comparing patients with GCA to healthy controls; 2) inclusion of smoking history; 3) provision of absolute numbers and/or statistical comparisons with 95% confidence intervals. Study eligibility was independently determined by the two investigators, with disagreements reviewed by a third investigator (P.U.) and resolved by consensus. RevMan 5.3 software was used for the data analysis. Point estimates and standard errors were extracted from individual studies and were combined by the generic inverse variance method of DerSimonian and Laird. Given the high likelihood of between-study variance, we used a random-effect model rather than a fixed-effect model. Statistical heterogeneity was assessed using the Cochran’s Q test.

**Results:** The initial search yielded 3312 articles. Of these, thirteen studies (8 prospective and, 5 retrospective case-control studies) with unique cohorts were identified and included in the primary analysis (ever vs. never smoking history). Patients in the GCA cohort were more likely to have a history of smoking with an odds ratio of 1.19 (95% CI, 1.01–1.39) [figure 1A]. Considerable heterogeneity

was present ( $I^2=85\%$ ). Five of these studies included information on current smoking status. One additional study, which only reported current smoking status, was also included. The GCA cohort showed an association with current tobacco use with an odds ratio of 1.18 (95% CI, 1.01–1.38) [figure 1B].

**Conclusions:** Our study demonstrated a statistically significant increased risk of GCA among smokers compared to non-smokers.

**Disclosure of Interest:** None declared

#### CLINICAL CHARACTERISTICS OF PARENCHYMAL NEURO-BEHCHET'S DISEASE: A RETROSPECTIVE ANALYSIS

D. Yan<sup>1,2</sup>, J. Liu<sup>1</sup>, D. Wu<sup>1</sup>, L. Peng<sup>1</sup>, Z. Liu<sup>3</sup>, W. Zheng<sup>1</sup>. <sup>1</sup>Peking Union Medical College Hospital, Beijing; <sup>2</sup>The Second Affiliated Hospital of Soochow University, Soochow; <sup>3</sup>The Second Affiliated Hospital of Soochow University, Soochow, China

**Background:** Neurological involvement is one of the most serious complications in Behcet's disease (BD).

**Objectives:** To investigate the clinical characteristics of parenchymal neuro-Behcet's Disease (pNBD).

**Methods:** We retrospectively reviewed all the medical records of BD patients who were admitted to our institute between 2000 and 2016. The diagnosis of NBD was based on the 2014 International Consensus criteria for NBD.<sup>1</sup> Eighty-four BD patients without neurological involvement were randomly matched by sex and age as control.

**Results:** 42 patients (25 male and 17 female) with pNBD accounted for 4.2% of the 1009 hospitalised BD patients during that period. The mean age at BD onset and at neurological onset was (30.1±11.1 years old and (35.3±12.1 years old, respectively). The majority of patients developed neurological symptoms after other initial systemic symptoms of BD in a median period of 2 months (range from 0–49). Neurological onset was concomitant with the onset of BD in 6 cases (14.3%). The most frequent location was brainstem (23/42, 54.8%). Spinal cord involvement was presented in five cases, in which four with cervical cord involved. 13 cases suffered from multiple lesions. Pyramidal (21/42, 50.0%) and headache (14/42, 33.3%) were the most common manifestations of pNBD. Lumbar puncture was performed in 40 patients, in which 80% (32/40) of patients had normal pressure and 55% (22/40) had elevated protein levels ((0.51±0.24) g/L). Compared with the controls, the prevalence of ocular involvement (uveitis, retinal vasculitis, scleritis) was significantly higher in pNBD (35.7%) (p=0.041, OR=2.36, 95% CI=1.03–5.44) (table 1). Cranial MRI in 32 patients showed the lesions were mainly in the midline structures, including brainstem (22/42, 52.4%), periventricular (13/42, 31.0%), centrum semiovale (8/42, 19.0%). Typically, the lesions were in hypersignal in T2. All pNBD patients received corticosteroids ( $\geq 1$  mg/kg/d) and 23 patients (54.8%) received the pulse dose (1 g/d). Cyclophosphamide was the most commonly used immunosuppressant (39/42) and 10 cases took more than one immunosuppressants (including methotrexate and azathioprine). Biological agents were administered in six refractory pNBD patients, including Infliximab in 4 cases, Tocilizumab in 1 case, and Interferon- $\alpha 2a$  in 1 case. Intrathecally injection of dexamethasone 10 mg and methotrexate 10 mg was given to 28 patients. With a median follow-up of 28 months (4 to 156 months), 22 patients (52.4%) achieved clinical improvements, while 10 patients (23.8%) relapsed and 4 patients died (the mortality was 9.5%). Six patients lost to follow up.

**Table 1.** Clinical Comparison of pNBD and BD without neurological involvement<sup>a</sup>

Parameters	pNBD (n=42)	Controls <sup>b</sup> (n=84)	P Value	OR(95%CI)
Age (years, mean±SD)	36.3±11.6	35.2±10.9	0.601	1.01 (0.98-1.04)
Gender (F/M)	25/17	30/34	1.000	—
<b>Clinical Features of BD</b>				
Oral Ulceration	42 (100%)	84 (100%)	1.000	—
Genital Ulceration	27 (64.3%)	61 (72.6%)	0.337	0.68 (0.31-1.50)
Skin Lesions	19 (45.2%)	40 (47.6%)	0.801	0.91 (0.43-1.91)
Gastrointestinal lesions	3 (7.1%)	17 (20.2%)	0.058	0.30 (0.09-1.10)
Ocular involvement <sup>c</sup>	15 (35.7%)	16 (19.0%)	0.041*	2.36 (1.03-5.44)
Vascular involvement	6 (14.3%)	10 (11.9%)	0.705	1.23 (0.42-3.66)
<b>Laboratory tests</b>				
ESR(mm/h, median and range)	15(0-85)	11(1-80)	0.072	1.01(0.99-1.03)
CRP (mg/L, median and range)	3.0(0.14-124)	5.3(0.13-104)	0.995	1.00 (0.98-1.02)

OR= Odds Ratio, CI=Confidential Interval.

<sup>a</sup>Values are the number (percentage) unless otherwise indicated.<sup>b</sup>Eighty-four age- and gender-matched BD patients without neurological involvement were served as control.<sup>c</sup>Ocular involvement includes uveitis, retinal vasculitis, scleritis.

\*P&lt;0.05.

**Conclusions:** The parenchymal neurological involvement is a rare complication of BD with a high mortality. Its most frequent location is brainstem. Ocular involvement is a risk factor for pNBD. Early identification and active treatment are vital for a good prognosis.

### PET/CT IN PATIENTS WITH GIANT CELL ARTERITIS AFTER 1 YEAR OF TREATMENT WITH TOCILIZUMAB PLUS PREDNISONE TAPER OR ONLY PREDNISONE TAPER

A. Ishai<sup>1</sup>, E. Brouwer<sup>2</sup>, C. Maldini<sup>3</sup>, J.H. Stone<sup>1</sup>, G.F. Espigol-Frigole<sup>4</sup>, M.C. Cid<sup>4</sup>, D. Blockmans<sup>5</sup>, D. Carmellino<sup>6</sup>, M. Cimmino<sup>6</sup>, F. Muratore<sup>7</sup>, R. Slart<sup>2</sup>, C. Salvarani<sup>12</sup>, F. Narvaez Garcia<sup>8</sup>, S. De Vita<sup>9</sup>, B. Hellmich<sup>10</sup>, S. Dimonaco<sup>11</sup>, M. Kleearman<sup>12</sup>, A. Petho-Schramm<sup>13</sup>, K. Tuckwell<sup>11</sup>, N. Collinson<sup>11</sup>, A. Tawakol<sup>1</sup>, S. Unizony<sup>1</sup>. <sup>1</sup>MGH, Boston, USA; <sup>2</sup>Groningen University, Groningen, Netherlands; <sup>3</sup>Hospital Cordoba, Cordoba, Argentina; <sup>4</sup>IDIBAPS, Barcelona, Spain; <sup>5</sup>Gasthuisberg Hospital, Leuven, Belgium; <sup>6</sup>Genoa University, Genoa; <sup>7</sup>UNIMORE, Reggio Emilia, Italy; <sup>8</sup>Bellvitge Hospital, Barcelona, Spain; <sup>9</sup>Udine University, Udine, Italy; <sup>10</sup>Medius Klinik Kirchheim, Kirchheim-Teck, Germany; <sup>11</sup>Roche Products, Welwyn Garden City, UK; <sup>12</sup>Genentech, San Francisco, USA; <sup>13</sup>Roche Products, Basel, Switzerland

**Background:** The arterial uptake of <sup>18</sup>fluorine-2-deoxy-d-glucose (FDG) by positron emission tomography-computed tomography (PET/CT) has been used for the diagnosis of giant cell arteritis (GCA). The role for PET/CT in following disease activity and monitoring treatment effects, however, remains unclear

**Objectives:** To examine the degree of FDG uptake within the large arteries of GCA patients after 1 year of treatment

**Methods:** We studied a subgroup of patients enrolled in the GiACTA trial.<sup>1</sup> Patients received either tocilizumab (TCZ) given weekly or every other week plus a 26 week prednisone taper, or placebo (PBO) plus either a 26- or 52 week prednisone taper. PET/CTs were done according to site feasibility and not as part of the GiACTA protocol. For this analysis, the 2 TCZ and PBO groups, respectively, were combined. Patients had whole-body PET/CT imaging within 16 weeks of week 52 visit. The ascending aorta, carotid artery and subclavian artery territories were assessed by maximum standardised FDG uptake values (mSUV) measurement. For each territory, we calculated average, most diseased segment (MDS) and most diseased slide mSUVs and target background ratios (TBR). PET/CTs were read centrally by investigators blinded to the clinical and treatment data

**Results:** From 251 patients enrolled in GiACTA, 24 patients underwent PET/CT within 16 weeks of week 52 visit. Seventeen patients (71%) received TCZ plus a prednisone taper (TCZ group) and 7 patients received a prednisone taper alone (PBO group). There were no significant differences between groups in baseline characteristics (table 1). Mean (SD) cumulative prednisone dose at week 52 was 2.5 g (1.7 g) in the TCZ group and 3.2 g (1.2 g) in the PBO group (p=0.11). FDG

uptake was consistently numerically lower in all vascular territories in TCZ-treated patients compared to PBO-treated patients except in the ascending aorta. However, the between-group differences were statistically significant only in the left subclavian artery (table 2). Adjustment for selected confounders (new onset disease, baseline prednisone dose, prednisone dose at the time of PET/CT, cumulative prednisone dose, flare prior to PET/CT and clinical activity at the time of PET/CT) did not alter the conclusions derived from the univariate analyses

**Table 1 Baseline characteristics:** All results represent means (SD) except otherwise indicated. PBO=placebo, TCZ=tocilizumab

	PBO group (n=7)	TCZ group (n=17)	p-value
New onset disease, n (%)	6 (86)	9 (53)	0.19
Baseline prednisone dose (mg)	30 (30-50)	30 (20-40)	0.30
Cumulative prednisone dose (g) at week 52	3.2 (1.2)	2.5 (1.7)	0.11
Prednisone dose (mg) at PET time, median (IQR)	0 (0; 3)	0 (0; 7.5)	0.44
PET time point (weeks from baseline)	54.47 (5.75)	57.38 (8.33)	0.11
Primary outcome met, n (%)	4 (57)	11 (65)	1.00
Clinically active disease at the time of PET, n (%)	1 (14)	3 (18)	1.00
Disease relapse before PET, n (%)	3 (43)	8 (47)	0.61
TCZ treatment at the time of PET, n (%)	0 (100)	7 (41)	0.07

All results represent means (SD) except otherwise indicated. PBO = placebo, TCZ = tocilizumab

**Table 2 Results:** All results represent means (SD). mSUV=maximum standardised uptake value, MDS=most diseased segment, TBR=target to background ratio

	PBO group (n=7)	TCZ group (n=17)	p-value
<b>Left subclavian artery</b>			
Average mSUV	2.74 (0.77)	2.33 (0.42)	0.11
Average MDS mSUV	3.05 (0.90)	2.47 (0.46)	0.04
Hottest spot mSUV	3.23 (1.02)	2.56 (0.48)	0.04
TBR	2.94 (0.86)	2.47 (0.45)	0.09
<b>Right subclavian artery</b>			
Average mSUV	2.59 (0.86)	2.28 (0.43)	0.25
Average MDS mSUV	2.72 (0.88)	2.35 (0.42)	0.17
Hottest spot mSUV	2.82 (0.91)	2.49 (0.49)	0.26
TBR	2.76 (0.88)	2.41 (0.40)	0.19
<b>Left carotid artery</b>			
Average mSUV	2.51 (0.49)	2.36 (0.41)	0.50
Average MDS mSUV	2.64 (0.54)	2.52 (0.49)	0.66
Hottest spot mSUV	2.70 (0.54)	2.64 (0.54)	0.82
TBR	2.67 (0.52)	2.51 (0.43)	0.78
<b>Right carotid artery</b>			
Average mSUV	2.86 (0.77)	2.38 (0.44)	0.14
Average MDS mSUV	3.12 (0.95)	2.63 (0.65)	0.14
Hottest spot mSUV	3.23 (0.94)	2.76 (0.69)	0.16
TBR	2.98 (0.67)	2.54 (0.46)	0.31
<b>Ascending aorta</b>			
Average mSUV	2.85 (0.63)	2.86 (0.51)	0.93
Average MDS mSUV	2.99 (0.68)	2.98 (0.56)	0.97
Hottest spot mSUV	3.01 (0.71)	3.12 (0.61)	0.97
TBR	3.05 (0.65)	3.05 (0.61)	0.99
<b>Hottest spot total score</b>	<b>13.40 (4.08)</b>	<b>12.62 (3.30)</b>	<b>0.62</b>
<b>Average MDS total score</b>	<b>12.84 (4.01)</b>	<b>12.04 (3.06)</b>	<b>0.60</b>

All results represent means (SD). mSUV = maximum standardized uptake value, MDS = most diseased segment, TBR = target to background ratio

**Conclusions:** In this exploratory study, subclavian FDG-uptake was significantly reduced in GCA patients treated with TCZ plus prednisone versus prednisone monotherapy despite lower cumulative prednisone doses. A larger, carefully designed prospective study is required to fully understand the utility of PET/CT in the longitudinal evaluation of large-vessel vasculitis associated with GCA

FRI0494

### SPECTRUM OF VISUAL INVOLVEMENT IN GIANT CELL ARTERITIS

F. Laskou<sup>1</sup>, T. Aung<sup>1</sup>, D. Gayford<sup>1</sup>, S. Banerjee<sup>1</sup>, C.S. Crowson<sup>2</sup>, E.L. Matteson<sup>2</sup>, B. Dasgupta<sup>1</sup>. <sup>1</sup>Southend University NHS Trust, Westcliff-On-Sea, UK; <sup>2</sup>Mayo Clinic College of Medicine and Science, Minnesota, USA

**Background:** The dreaded complication of giant cell arteritis (GCA), irreversible sight loss (SL), is present in 15%–25% of patients at diagnosis. This is likely due to delayed presentation, recognition and treatment. Fast track pathways for urgent assessment of suspected GCA reduce SL with associated cost savings. Information regarding the burden of SL in GCA is required to guide health strategy and has been explored in this UK wide study.

**Methods:** This is a prospective observational multi-centre study of visual involvement attributable to GCA. Demographic, disease features and treatment information was collected on all patients with new or relapsing GCA with or without visual symptoms (VS) or SL. SL was defined as symptomatic loss of acuity, field of vision or diplopia ascribable to ischaemic complications of GCA. Patients with transient VS were not considered to have SL. Analyses were performed using chi-squared and rank sum tests.

**Results:** Patients were predominantly female (274/388) and Caucasian; 3 non-Caucasian (Asian British, Black/Afro-Caribbean and Turkish). VS were present in 135/388 patients (35%) from 19 UK sites. Of patients with VS, these were transient or intermittent SL (n=9,7%), diplopia (n=33,24%), blurred vision (n=17,13%), flashing lights (n=4,3%) and eye pain (n=7,5%). Transient or permanent loss of acuity occurred in 92 patients (48 anterior ischaemic optic neuropathy [AION], 6 central retinal artery occlusion [CRAO], 1 posterior ischaemic optic neuropathy, all attributed to GCA); 1 hemispheric retinal vein occlusion, 1 branch retinal artery occlusion, 1 peri-papillary haemorrhage, 1 vitelliform dystrophy macula. 8 had oculomotor nerve palsies (NP) (1 bilateral 3rd, 1 bilateral 6th and 6 unilateral 3rd or 6th NP). Patients with VS were older than those without (mean  $\pm$ SD age 75.9 $\pm$ 9.3 and 73.5 $\pm$ 8.5 respectively,  $p < 0.001$ ). Patients with VS had less headaches ( $p = 0.012$ ) and scalp tenderness ( $p = 0.05$ ) but more frequently tongue claudication ( $p = 0.014$ ), shorter symptom duration (3.9 $\pm$ 5.5 days,  $p = 0.001$ ), lower CRP although not statistically significant ( $p = 0.059$ ), were less likely to meet ACR criteria and to improve than those without VS ( $p < 0.001$ ). No association was found with comorbidities or deprivation index. SL in 54 (40%) patients was due to AION or CRAO. Transient CRAO or AION was described in 17 and 30/47 (64%) had permanent SL (data missing from 7 patients). Patients with AION/CRAO were older (80.9 $\pm$ 6.7 years) than those without AION/CRAO (73.3 $\pm$ 8.7 years,  $p < 0.001$ ). They had shorter symptom duration (4.2 $\pm$ 7.0 days,  $p = 0.024$ ), less likely to improve than those without AION/CRAO ( $p < 0.001$ ), less likely to have headaches ( $p < 0.001$ ) or polymyalgic symptoms ( $p = 0.002$ ), and more likely to have jaw claudication ( $p = 0.043$ ) and hypertension ( $p = 0.002$ ). Only 7 had diplopia on presentation. 5 patients experienced AION as manifestation of recrudescing disease.

**Conclusions:** VS often leading to SL in GCA requires urgent management. Patients with VS were older, without 'typical symptoms' such as headache and polymyalgia but more likely to have ischaemic symptoms such as jaw and tongue pain and hypertension. Recognition of VS associated features should be embodied in public and professional awareness programs to prevent permanent SL in GCA.

#### FRI0495 BEHÇET'S SYNDROME IN NEW YORK AND AMSTERDAM: EVOLUTION FROM PROBABLE BEHÇET'S TO ISG CRITERIA POSITIVE BEHÇET'S

F. Kerstens<sup>1,2</sup>, F. Turkstra<sup>1</sup>, C.J. Swearingen<sup>2</sup>, Y. Yazici<sup>2</sup>. <sup>1</sup>Amsterdam Rheumatology and Immunology Center, Reade, Amsterdam, Netherlands; <sup>2</sup>NYU Hospital for Joint Diseases, New York City, USA

**Background:** Behçet's syndrome (BS) is an auto-inflammatory vasculitis, most common in countries along the ancient Silk Road. Classification of BS most often is done with the International Study Group criteria (ISG criteria)<sup>1</sup>. ISG criteria positivity for BS is reached when a patient has recurrent oral ulceration and any two of the following symptoms: recurrent genital ulceration, uveitis, skin lesions and pathergy positivity. However, many other manifestations are reported<sup>1</sup>. Differences in clinical presentation can complicate classification of the diagnosis, especially in areas where the disease is low in prevalence. Thus, some patients are classified as "probable BS". In some of these cases patients developed additional symptoms over time and met the ISG criteria in a later stage.

**Objectives:** To describe characteristics of patients presenting with a probable diagnosis of BS in Amsterdam and New York and to study if patients who eventually met the ISG criteria differ from those who did not.

**Methods:** We included consecutive patients classified as possible BS to our out-patient clinics in New York and Amsterdam. Patients fulfilling ISG criteria at enrollment were excluded, as well as patients in whom an alternative diagnosis was made at enrollment. Baseline data were evaluated retrospectively and patients were divided into two groups: those developing ISG positive (ISG + or "true") BS during follow up and those who did not meet ISG criteria after follow-up (ISG-). Turkey, Asia, Middle and Far Eastern countries, Arabic countries and Northern Africa were considered endemic areas; Italian, Greek, Hispanic, Portuguese, African-American and Caucasian patients were considered not from endemic areas. Statistical analysis was performed using SPSS, with Chi-square tests or Fisher's exact tests for categorical data and independent sample t-tests for numerical data.

**Results:** 189 patients were included, of whom 20 were from Amsterdam. During follow up, 71 patients (37.6%) could be classified as "true" Behçet's syndrome after a mean period of 9.4 years ( $\pm$ 8.3 years) after onset of symptoms. Age,

gender, ethnicity, duration of symptoms at enrollment, duration of follow up as well as RAPID3 and almost all clinical manifestations at baseline were comparable for both groups. Labial ulcers and skin manifestations at enrollment were more frequently reported. Genital ulcers as a group was not significantly associated with developing "true" Behçet's, nor were specific skin manifestations such as erythema nodosum. We also considered HLA-B\*51, pathergy, erythrocyte sedimentation rate and C-reactive protein, but due to a large amount of missing data, we were unable to draw any significant conclusions for these variables.

Characteristics	All patients (n=189)	ISG + (n=71)	ISG - (n=118)	P-value
Age years (SD)	34.3 (13.7)	34.1 (13.4)	34.5 (14.0)	ns
Male n (%)	46 (24.3)	13 (18.3)	33 (28.0)	ns
Duration of follow up years (SD)	3.2 (2.4)	3.3 (2.5)	3.1 (2.4)	ns
Ethnicity: endemic area n (%)	43 (22.8)	14 (19.7)	29 (24.6)	ns
RAPID3 mean score (SD)	9.8 (6.8)	9.6 (6.9)	9.9 (6.7)	ns
Duration of symptoms years (SD)	7.3 (7.8)	7.7 (7.9)	7.0 (7.8)	ns
Oral ulcers n (%)	174 (92.1)	66 (93.0)	108 (91.5)	ns
Genital ulcers n (%)	108 (57.1)	47 (66.2)	61 (51.7)	ns
- Labia	63 (33.3)	31 (43.7)	32 (27.1)	0.019
Skin disease n (%)	58 (30.7)	31 (43.7)	27 (22.9)	0.003
Eye disease n (%)	33 (17.5)	17 (23.9)	15 (12.7)	ns
Deep venous thrombosis n (%)	4 (2.1)	2 (2.8)	2 (1.7)	ns

Arthritis n (%)	35 (18.6)	16 (22.5)	19 (16.1)	ns
Gastrointestinal disease n (%)	40 (21.2)	14 (19.7)	26 (22.0)	ns
Headache n (%)	12 (6.3)	5 (7.0)	7 (5.9)	ns
Epididymitis n (% of males)	3 (6.5)	0 (0)	3 (9.1)	ns

ISG +: patients who did fulfill ISG criteria after follow-up; ISG -: patients who did not fulfill ISG criteria after follow-up; SD: standard deviation; ns: not significant

Figure 1 Baseline data from all patients who were classified as probable Behçet's syndrome at enrollment

**Conclusions:** About a third of patients classified as probable Behçet's syndrome at enrollment develop new manifestations over time. Thus, they can be reclassified as ISG positive ("true") BS. Based on our data, presence of skin manifestations and labial ulcers at enrollment was significantly higher in the group eventually developing a ISG criteria positive BS.

#### FRI0496 POLYARTERITIS NODOSA: OVER 20 YEARS' CLINICAL EXPERIENCE

H.E. Sönmez<sup>1</sup>, B. Armağan<sup>2</sup>, G. Ayan<sup>3</sup>, K. Barut<sup>4</sup>, E.D. Batu<sup>1</sup>, A. Erden<sup>2</sup>, S. Uğurlu<sup>3</sup>, Y. Bilginer<sup>1</sup>, Ö. Kasapoğlu<sup>4</sup>, Ö. Karadağ<sup>2</sup>, S.A. Bilgen<sup>2</sup>, H. Özdoğan<sup>3</sup>, S. Özen<sup>1</sup>. <sup>1</sup>Department of Pediatric, Division of Rheumatology, <sup>2</sup>Hacettepe University Faculty of Medicine, Ankara; <sup>3</sup>Cerrahpaşa Medical School, Istanbul University, Istanbul, Turkey; <sup>4</sup>Department of Pediatric, Division of Rheumatology, Cerrahpaşa Medical School, Istanbul University, Istanbul, Turkey

**Background:** Polyarteritis nodosa (PAN) is a necrotizing vasculitis of predominantly medium size vessels.

**Objectives:** The present study aimed to summarise the characteristics of PAN patients, and also analyse the trend of decreasing PAN frequency in the last 25 years, in Turkey

**Methods:** Paediatric and adult PAN patients followed up in Hacettepe University and Istanbul University Cerrahpaşa Faculty of Medicine between 1990 and 2015, were included. The demographics, clinical findings and outcomes were evaluated retrospectively.

**Results:** One hundred thirty-three patients, including 66 children, were enrolled in the study. The mean follow-up duration was 13<sup>2-27</sup> years. Among 133 patients, 86 (64.7%) had fever, 108 (81.2%) had skin involvement, 54 (40.6%) had renal involvement, 43 (32.3%) had neurological involvement, 32 (24.1%) had gastrointestinal involvement, 10 (7.5%) had cardiac involvement, 6 (4.5%) had pulmonary involvement. The median (minimum-maximum) leukocyte count, erythrocyte sedimentation rate and C-reactive protein levels at the time of diagnosis were 10400 (6100-32000)/mm<sup>3</sup>, 58(2-132) mm/h and 5.22 (0-46) mg/dL, respectively. All patients were ANCA negative. Hepatitis serology was analysed in 121 patients and found positive in 13 of them. *MEFV* mutations were screened among 65 patients, 24 of them had mutations in at least one allele. Myalgia and skin involvement were significantly more frequent in children whereas neurologic involvement

was much more common among adults (table 1). The number of PAN patients declined significantly after 2010 (figure 1). 9 patients were re-categorised as DADA2 after 2014 and no patient were diagnosed with FMF+. PAN after 2008

**Abstract FRI0496 – Table 1.** Characteristics of paediatric and adult PAN patients

Features, n (%)	Patients (n=133)	Paediatric patients (n=66)	Adult patients (n=67)	P value
Gender, female	55 (41.4)	35 (53)	20 (29.8)	0.07
Fever	86 (64.7)	50 (75.7)	36 (52.9)	0.06
Myalgia	79 (59.4)	48 (72.7)	31 (46.2)	<b>0.01</b>
Abdominal pain	65 (48.9)	40 (60.6)	25 (37.3)	0.05
Weight loss	56 (42.1)	20 (30.3)	36 (53.7)	0.06
Arthralgia	87 (65.4)	48 (72.7)	39 (58.2)	0.06
Arthritis	23 (17.3)	11 (16.6)	12 (17.9)	0.58

<sup>a</sup>CRP, C reactive protein; GI, gastrointestinal; PLT, platelet; WBC, white blood cell

**Abstract FRI0496 – Figure 1.** Distribution of the PAN patients by years

**Conclusions:** Our results suggest a decrease in PAN in our country which may be due to improved healthcare and dissecting mimicking diseases. Further prospective studies with prolonged follow-up could help us to better understand the disease characteristics.

#### FRI0497 CLINICAL CHARACTERISTICS AND TREATMENT OUTCOMES OF PATIENTS WITH BEHÇET'S DISEASE AND VASCULAR INVOLVEMENT

H. Kim<sup>1</sup>, Y. Eun<sup>1</sup>, I.Y. Kim<sup>1</sup>, H. Jeong<sup>2</sup>, E.-J. Park<sup>3</sup>, J. Hwang<sup>4</sup>, J.Y. Chai<sup>5</sup>, J. K. Ahn<sup>6</sup>, J. Lee<sup>1</sup>, E.-M. Koh<sup>1</sup>, D.-K. Kim<sup>1</sup>, H.-S. Cha<sup>1</sup>. <sup>1</sup>Internal medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul; <sup>2</sup>Internal medicine, Soonchunhyang University Hospital, Bucheon; <sup>3</sup>Internal medicine, Seoul Medical center; <sup>4</sup>Internal medicine, National Police Hospital, Seoul; <sup>5</sup>Internal medicine, Bundang Jeseang Hospital, Seongnam; <sup>6</sup>Internal medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

**Background:** The international Chapel Hill Consensus Conference (CHCC) categorised Behçet's disease (BD) as variable vessel vasculitis, which was defined as vasculitis that can affect vessels of any size and type. Vascular manifestations

have been reported in up to 50% of patients with BD, most commonly as venous thrombosis.

**Objectives:** The aim of this study is to investigate characteristics and treatment outcomes of patients with vascular BD, particularly with large vessel involvement.

**Methods:** A retrospective review was performed on 2496 patients with ICD-10 code of Behçet's disease and/or aortic disease who visited Samsung Medical Centre between 2004 and 2014. Patients who were suspected to have BD and vascular involvement were enrolled.

**Results:** Eighty-three patients with clinical features of BD and vascular involvement were identified. Although less than half satisfied the classic International Study Group (ISG) criteria, greater proportion fulfilled the International Criteria for BD (ICBD), and all of the patients satisfied at least "suspected BD" according to the Japanese criteria. Fifty patients had arterial lesions including 34 with aorta involvement. Another 33 patients had venous thrombosis without arterial lesions. Patients showed a male predominance (87%) and a predilection of young age with the median of 42 years old. The most prominent type of arterial lesions was aneurysm (80%) with a high frequency of pseudoaneurysms. Among the aorta, the thoracic aorta was most commonly involved and 18 patients had aortic valve regurgitation. Seventy-five (90%) patients received glucocorticoids with a median initial dose of prednisolone of 30 mg per day and 68 (82%) received immunosuppressive treatment. Half of the patients had more than one relapse after stabilisation of the first vascular event. During the course, 44 patients underwent surgery and/or endovascular treatment and 60% of these patients had repeated treatment for the relapse. These included 31 aortic valve replacements on 13 patients.

**Conclusions:** Patients with vascular BD showed a predilection of young male and 60% of patients had arterial involvement. The aorta was affected in more than half of the patients who had arterial involvement. Aneurysmal change was frequent finding and relapse rate was high during disease course. Further studies into a practical and specialised diagnostic tool for vascular BD and optimal treatment strategies are required.

**Background:** Cystoid macular oedema (CME) is the most serious complication of uveitis. This potentially severe complication may lead to irreversible visual loss.<sup>1-2</sup>

**Objectives:** To compare efficacy and safety of Tocilizumab (TCZ) vs. Anti-TNF- $\alpha$  drugs in patients with refractory CME to conventional immunosuppressant (IS).

**Methods:** Multicenter study of patients with refractory CME to treatment with glucocorticoids and at least 1 conventional IS. The main objective was the improvement of macular thickness. Secondary objectives were the enhancement in best corrected visual acuity (BCVA) and the degree of ocular inflammatory activity.

**Results:** 59 patients/112 affected eyes. Causes of uveitis were: Behçet's disease (n=41), Birdshot's retinochoroidopathy (n=4), Juvenile Idiopathic Arthritis (n=9), Sarcoidosis (n=1) and idiopathic (n=4). No significant differences were observed at baseline in both groups (TCZ vs Anti-TNF- $\alpha$ ) in sex ( $\chi^2$ ; 8/17 vs. 15/19), mean age (35.6 $\pm$ 18.9 vs 40.0 $\pm$ 9.1), BCVA (0.40 $\pm$ 0.31 vs. 0.48 $\pm$ 0.31), Tyndall (1 [0-1] vs. 1 [0-2]), vitritis (1 [0-2] vs. 1 [0-3]) and macular thickness (431.8 $\pm$ 165.9 vs. 397.1 $\pm$ 138.1) (table 1).

25 patients were treated with TCZ as follows: 8 mg/kg/4 weeks (n=24) and 162 mg sc/2 weeks (n=1). Anti-TNF- $\alpha$  therapy was used in the remaining 34 as

follows: IFX (n=12) (5 mg/kg 0, 2 y 6 weeks and every 4–8 weeks) and ADA (n=22) (40 mg/sc/2 weeks).

We observed a rapid and sustained improvement in macular thickness after 1 year follow-up in both groups, without objectifying significant differences between them. In the same way, secondary ocular parameters also improved (table 1).

Abstract FRI0498 – Table 1

	TCZ	Anti-TNF- $\alpha$	P
<b>Baseline</b>			
BCVA	0.40 $\pm$ 0.31	0.48 $\pm$ 0.31	0.98
Tyndall	1 [0-1]	1 [0-2]	0.13
Vitritis	1 [0-2]	1 [0-3]	0.07
OCT	431.82 $\pm$ 165.99	397.18 $\pm$ 138.12	0.21
<b>1st month</b>			
BCVA	0.50 $\pm$ 0.30	0.61 $\pm$ 0.28	0.58
Tyndall	0 [0-0]	0 [0-0]	0.47
Vitritis	0 [0-0.5]	0.5 [0-1]	<0.01
OCT	330.86 $\pm$ 104.21	328.41 $\pm$ 86.53	0.25
<b>6th month</b>			
BCVA	0.56 $\pm$ 0.33	0.71 $\pm$ 0.31	0.73
Tyndall	0 [0-0]	0 [0-0]	0.04
Vitritis	0 [0-0.5]	0 [0-0]	<0.01
OCT	275.07 $\pm$ 73.80	264.90 $\pm$ 45.92	0.006
<b>1st year</b>			
BCVA	0.59 $\pm$ 0.33	0.72 $\pm$ 0.32	0.76
Tyndall	0 [0-0]	0 [0-0]	<0.01
Vitritis	0 [0-0.5]	0 [0-0]	0.36
OCT	259.10 $\pm$ 49.51	261.42 $\pm$ 37.71	0.14

**Conclusions:** TCZ and Anti-TNF- $\alpha$  are effective in the treatment of CME refractory to conventional therapy.

#### A MULTINATIONAL QUALITATIVE STUDY IN GIANT CELL ARTERITIS: PATIENT PERCEPTIONS OF DIAGNOSIS, TREATMENT, IMPACT ON HEALTH-RELATED QUALITY OF LIFE AND CONTEXTUAL FACTORS

J.C. Robson<sup>1</sup>, C. Almeida<sup>1</sup>, J. Dawson<sup>2</sup>, A. Bromhead<sup>3</sup>, S.L. Mackie<sup>4</sup>, C. Hill<sup>5</sup>, E. Hoon<sup>5</sup>, C. Davis<sup>9</sup>, R. Greenwood<sup>6</sup>, R. Luqmani<sup>2</sup>, B. Dasgupta<sup>7</sup>, C. Guly<sup>3</sup>, J. D. Pauling<sup>8</sup>, R. Watts<sup>2</sup>, E. Dures<sup>1</sup>. <sup>1</sup>University of the West of England, Bristol, Bristol; <sup>2</sup>University of Oxford, Oxford; <sup>3</sup>University Hospitals Bristol NHS Trust, Bristol; <sup>4</sup>University of Leeds, Leeds, UK; <sup>5</sup>University of Adelaide, Adelaide, Australia; <sup>6</sup>Research Design Service-South West, Bristol; <sup>7</sup>Southend University Hospital, Southend; <sup>8</sup>University of Bath, Bath, UK

**Background:** Giant cell arteritis (GCA) is the commonest form of systemic vasculitis caused by inflammation of the blood vessels around the head and neck, with the highest incidence in women aged 70–79 years (7.4 per 10 000 person-years). Patients present with headache, jaw claudication and polymyalgia rheumatica with visual loss in 20%. Treatment is with high dose glucocorticoids.

**Objectives:** Identify and define the range of patient experiences in relation to GCA, and effects on health related quality of life in patients from the United Kingdom and Australia.

**Methods:** Semi-structured qualitative interviews with patients from the UK and Australia explored health-related quality of life and patient perspectives on the experience of GCA. Interviews were recorded, transcribed and analysed. Patients were purposively sampled to include both genders, a range of disease durations and organ involvement (visual loss and large vessel involvement). Data were analysed with inductive thematic analysis and managed using NVivo 10. The sample size was determined by the point at which no new substantive themes emerged.

**Results:** Thirty-one interviews were conducted. Demographics and disease features shown in table 1. Individual sub-codes were identified then grouped into overarching themes: "Anxieties around getting a diagnosis of GCA", "Description of symptoms related to GCA and its treatment", "Lack of bodily strength, stability and stamina; difficulties with completing daily tasks", "Difficulties with participating in social activities, work and caring roles", "Not feeling normal and impact on general perception of health", "Anxiety and fear of the future". Contextual factors impacted on how patients experienced GCA including "Response to treatment and adverse effects", "Receiving support from family, friends and health care workers", "Adopting successful self-management techniques, e.g. keeping fit and active" and "Presence of pre-existing co-morbidities and development of secondary conditions e.g. cardiovascular disease, osteoporosis or diabetes".

Demographics		United Kingdom (n=25)	Australia (n=6)	Total (n=31)
<b>Sex, n (%)</b>	Male	9 (36.0)	1 (7.7)	10 (32.3)
	Female	16 (64.0)	5 (92.3)	21 (67.7)
<b>Age, n (%)</b>	<70 years	5 (20.0)	3 (50.0)	8 (25.8)
	≥70 years	20 (80.0)	3 (50.0)	23 (74.2)
	Mean	75	69	74
<b>Diagnostic test, n (%) *</b>	Biopsy	21 (84.0)	5 (83.3)	26 (83.9)
	Ultra/S	5 (20.0)	0 (0)	5 (16.1)
	CTA	2 (8.0)	0 (0)	2 (6.45)
	PET	2 (8.0)	1 (16.7)	3 (9.68)
<b>Visual Loss (%)</b>	Yes	10 (40.0)	2 (33.3)	12 (38.7)
<b>ESR≥50 or CRP≥10</b>	Yes	24 (96.0)	5 (83.3)	29 (93.6)
<b>Time from diagnosis, n (%)</b>	<1 year	13 (52.0)	4 (66.7)	17 (54.8)
	≥1 year	12 (48.0)	2 (33.3)	14 (45.2)
<b>Disease Active, n (%)</b>	Yes	11 (44.0)	4 (66.7)	15 (48.4)
	No	14 (56.0)	2 (33.3)	16 (51.6)
<b>Flare&lt;1 year, n (%)</b>	Yes	13 (52.0)	3 (50.0)	16 (51.6)
	No	10 (40.0)	3 (50.0)	13 (41.9)
	Never	2 (8.0)	0 (0)	2 (6.5)

**Conclusions:** Patients with GCA have described a range of themes of interest in relation to their disease. These data could be used as the basis of developing a patient reported measure of outcome in GCA.

**Background:** Giant cell arteritis (GCA) is a large vessel vasculitis with a predisposition for the cranial branches of the external carotid artery. However, aorta and/or its main branches may also be involved (1–3).

**Objectives:** To assess the vascular territories most frequently affected in a series of patients with GCA who presented extracranial vessel involvement.

**Methods:** Retrospective study of patients with GCA who presented compromise of extracranial vessels confirmed by PET/CT. Visual analysis of vascular uptake was performed on supra-aortic trunks (SAT), aortic arch (AA), thoracic aorta (TA), abdominal aorta (AA), iliac arteries (IA), lower limb arteries (LLA), and upper limb arteries (ULA). We carried out a comparative study between both sexes to see if there was any difference in the pattern of affection.

**Results:** We evaluated 68 patients with GCA (51W/17M) with a mean age of 68.06±8.33 years. The vascular territories affected were: TA (n=58, 85.29%), SAT (n=38, 55.88%), AA (n=28, 41.18%), LLA (n=17, 25%), IA (n=13, 19.12%) and ULA (n=6, 8.82%). We also made a study of the number of vascular territories affected: 1 vascular territory (n=13, 19.12%), 2 territories (n=22, 32.35%), 3 territories (n=18, 26.47%), 4 territories (n=12, 17.65%) and more than 4 territories (n=3, 4.41%). Likewise, a comparative study between both sexes was conducted, in which only statistical significance was achieved in the involvement of ULA, which was more frequent in men (table 1).

Abstract FRI0500 – Table 1

	Men (n=17)	Women (n=51)	p
Age, mean ± SD	69.3 ± 8.6	67.6 ± 8.6	0.48
<b>Vascular territories affected, n (%)</b>			
Supra-aortic trunks	8 (47.1)	30 (58.8)	0.57
Aortic arch	4 (23.5)	14 (27.4)	0.99
Thoracic aorta	12 (70.6)	46 (90.2)	0.11
Abdominal aorta	5 (35.3)	22 (43.1)	0.78
Iliac arteries	1 (5.9)	12 (23.5)	0.21
Upper limb arteries	4 (23.5)	2 (3.9)	0.04
Lower limb arteries	6 (35.3)	7 (13.7)	0.11
<b>Number of vascular territories affected, n (%)</b>			
1	5 (29.4)	8 (15.7)	0.37
2	5 (29.4)	20 (39.2)	0.66
3	5 (29.4)	13 (25.5)	0.99
4	1 (5.9)	11 (21.6)	0.27
>4	1 (5.9)	2 (3.9)	0.73

**Conclusions:** In patients with GCA the involvement of TA is very frequent, followed by the SAT and the AA. To a lesser extent, the AA and the LLA vessels are affected. The involvement of the IA and the ULA vessels is less frequent; the latter more frequently in men. On the other hand, the involvement of 2–3 vascular territories are the most frequent patterns.

FRI0501

#### NEGATIVE TEMPORAL ARTERY BIOPSIES: COMPARISON BETWEEN BIOPSY-NEGATIVE GCA AND NON-GCA PATIENTS

K. Yeruva, K.J. Warrington, C.S. Crowson, M.J. Koster. *Rheumatology, MAYO CLINIC, Rochester, USA*

**Background:** Temporal artery biopsy (TAB) plays a key role in diagnosis of giant cell arteritis (GCA). However, approximately 15%–20% of patients ultimately diagnosed with GCA have negative biopsies. Among patients with negative TAB, it is often challenging to identify patients with GCA from those with an alternate (non-GCA) diagnosis.

**Objectives:** To compare TAB-negative GCA with patients receiving a non-GCA alternate diagnosis.

**Methods:** Two cohorts were retrospectively identified through direct medical record review. The first cohort consisted of patients with TAB-negative GCA diagnosed between 1/1/1998 and 12/31/2013. The second cohort included all patients with a negative TAB performed between 1/1/2009 and 12/31/2010 in which a non-GCA alternate diagnosis was provided after a minimum of 6 months of follow up. Final diagnoses were confirmed by consensus among two rheumatologists and a

physician abstractor. Baseline characteristics were compared between the two cohorts using chi-square and rank sum tests.

**Results:** 110 patients with TAB-negative GCA and 195 non-GCA patients with a negative TAB were identified. Alternate diagnoses for non-GCA patients are listed in table 1. Age, sex, number of days on glucocorticoids prior to biopsy, and biopsy length were similar in both groups. Time from first symptom to diagnosis was longer in non-GCA patients [mean (SD); 2.6 (2.5) vs 1.5 (2.1) months; p<0.001] and fewer non-GCA patients fulfilled ≥3 ACR criteria for GCA (27% vs 64%; p<0.001). Although headache was the primary symptom in both cohorts (66% TAB-negative GCA; 68% non-GCA), patients with biopsy-negative GCA had more frequent anorexia, fatigue, fever, polymyalgia rheumatica, temporal artery tenderness and claudication (jaw, arm, or leg). Baseline transient (5% TAB-negative GCA; 6% non-GCA; p=0.58) and permanent (3% TAB-negative GCA; 3% non-GCA; p=0.86) vision loss were infrequently observed. ESR was higher in TAB-negative GCA patients [64.0 (35.1) vs 55.2 (67.4); p=0.002] compared to non-GCA patients but CRP did not differ [44.3 (53.6) vs 43.8 (61.9); p=0.39].

Abstract FRI0501 – Table 1

Alternate diagnosis, n (%)	Negative biopsy with alternate diagnosis (N=195)
Neurologic condition	75 (38%)
Isolated PMR	38 (19%)
Rheumatic disease other than PMR or GCA	26 (13%)
Non-arteritic AION	10 (5%)
Fever of unknown origin	9 (5%)
Infectious disease	7 (4%)
Non-malignant hematologic condition	7 (4%)
Malignant disease	6 (3%)
Other vasculitis	6 (3%)
Cervical arthritis	5 (3%)
Systemic disease of unknown etiology	5 (3%)
Other	1 (1%)

AION: anterior ischemic optic neuropathy; GCA: giant cell arteritis; PMR: polymyalgia rheumatica

**Conclusions:** In this cohort, neither headache nor vision loss at presentation were associated with an ability to discriminate between diagnosis of TAB-negative GCA compared to patients without GCA. ACR criteria may be helpful in identifying patients with TAB-negative GCA. Among patients with negative TAB, constitutional symptoms and claudication (jaw/limb) were more frequently associated with an ultimate diagnosis of TAB-negative GCA.

FRI0502

#### RISK OF CANCER IN PATIENTS DIAGNOSED WITH GIANT CELL ARTERITIS IN WESTERN NORWAY 1972–2012

L.K. Brekke<sup>1</sup>, A.P. Diamantopoulos<sup>2</sup>, B.-T. Fevang<sup>3</sup>, J. Assmus<sup>4</sup>, C.G. Gjesdal<sup>3</sup>.  
<sup>1</sup>Haugesund Hospital for Rheumatic Diseases, Haugesund; <sup>2</sup>Martina Hansens Hospital, Bærum; <sup>3</sup>Dept. of Rheumatology; <sup>4</sup>Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway

**Background:** A meta-analysis from 2014 reported a low but statistically significant increased malignancy risk among patients with giant cell arteritis (GCA), but individual epidemiological studies have shown conflicting results.<sup>1</sup>

**Objectives:** To determine the risk of cancer in GCA patients during a 41 year period.

**Methods:** Hospital-based retrospective cohort study including patients diagnosed with GCA in Bergen Health Area during 1972–2012. Patients were identified through computerised hospital records using the International Classification of Diseases (ICD)-coding system. Clinical information was extracted from patients' medical journals. We excluded patients if data were unavailable, if the reviewing rheumatologist found GCA to be an implausible diagnosis or if the American College of Rheumatology (ACR) 1990 classification criteria for GCA were not fulfilled. Each patient was matched for age, sex, and county of residence to 3 control subjects randomly selected from the Central Population Registry of Norway. Information on the occurrence of cancer was obtained from the Cancer Registry of Norway. The cumulative incidence of malignancy in cases and controls were estimated using Kaplan-Meier plots.

**Results:** The patient inclusion process and patient characteristics have been published previously.<sup>2</sup> A total of 792 patients were included, 566 (71.5%) women (mean age 73.5 years, SD 8) and 226 (28.5%) men (mean age 72.1, SD 9). There were 2314 matched controls (excluding duplicate controls and control subjects

which were also among the cases). The mean duration of follow-up for the GCA-patients was 7.2 years (SD 6.7). The mean duration of follow-up for the controls was 6.6 years (SD 6.1). The relative risk of malignancy during follow-up was higher for controls compared to cases during the majority of the observation period, but the overall difference was not statistically significant ( $p=0.060$ , figure 1). However, the subset of 528 patients (66.7%) with a positive temporal artery biopsy (TAB) had a statistically significant lower risk of malignancy compared to their matched controls ( $p=0.006$ ).

**Conclusions:** We did not find a significant difference in the risk of malignancy in the overall GCA cohort compared to their matched controls. However, we found a statistically significant reduced risk of malignancy during follow-up for the subset of GCA-patients with a positive TAB. This is in contrast to the results of a meta-analysis which found an increased risk of malignancy in the subgroup with positive TAB. Further studies are required to determine whether this is a true difference, and what the potential causes may be.

#### FRI0503 RISK FACTORS OF CARDIAC VALVULAR INVOLVEMENT IN PATIENTS WITH TAKAYASU'S ARTERITIS

L. Pan. *Rheumatology and Immunology, Beijing Anzhen Hospital, Capital Medical University., Beijing, China*

**Background:** Takayasu's arteritis (TA) patients with higher disease activity have more cardiovascular morbidity compared to the TA patients with low disease activity, and active group showed a higher incidence of significant aortic valve regurgitation<sup>[1]</sup> which may linked heart failure and poor prognosis.<sup>2</sup>

**Objectives:** The aim of this study is to investigate the imaging and serological features and evaluated disease activity in TA patients with valvular involvement, to find the risk factors of valvular involvement in those patients.

**Methods:** 103 patients of TA were divided into 2 groups according to with or without valvular involvement. We compared the difference of serological and imaging features in 2 groups. Logistic model was used to determine the risk factors of valvular involvement in TA patients.

**Results:** Aortic insufficiency (62.12%) was most common in valvular involvement group, followed by mitral insufficiency (59.09%), tricuspid involvement (54.55%) and pulmonary involvement (6.06%). In which of them, single valvular involvement was 36.36%, multiple valvular involvement was 63.64%. There were 12

(22.22%) patients developed to heart failure. In valvular involvement patients, most common angiographic type was Numano type V (53.30% vs. 32.43%,  $p=0.044$ ). The second was Numano type IIb ( $p=0.034$ ), which were significantly higher than that of non-valvular involvement group. Numano type I was most common type in non-valvular involvement patients, and the proportion was higher than that in the patients with valvular involvement ( $p=0.034$ ). At the same time, we analysed the involvement of pulmonary and coronary in the 2 groups. TA patients with valvular involvement showed a higher incidence of the coronary lesion than the patients without valvular involvement ( $p=0.036$ ) (figure 1). Serum level of IgA ( $p=0.032$ ) and IgG ( $p=0.015$ ) were significantly higher in the patients with valvular involvement than that the patients without valvular involvement. We also evaluated the parameters of TA disease activity between 2 groups, in patients with valvular involvement, level of CRP was higher than that of non-valvular involvement group ( $p=0.049$ ). Kerr score ( $p=0.036$ ) and ITAS ( $p=0.009$ ) were all higher than those in non-valvular involvement group (figure 2). Logistic regression showed that the risk of valve involvement in TA patients with elevated level of IgG is 23 times higher than the patients with normal level of IgG. ( $p=0.001$ , OR=22.068, 95% CI:3.676–132.488), the risk of valvular involvement in TA patients with Numano type IIb ( $p=0.002$ , OR=20.352, 95% CI:3.146–131.655) and V ( $p=0.001$ , OR=9.437, 95% CI:2.661–33.465) was 20.35 times and 9.44 times higher than other types.

**Abstract FRI0503 – Figure 1.** Angiographic type in TA patients with or without valvular involvement. The prevalence of Numano type IIb (21.21% vs. 5.41%,  $p=0.034$ ) and type V (53.30% vs 32.43%,  $p=0.044$ ) were higher in TA patients with valvular involvement, TA patients with valvular involvement showed a higher incidence of the coronary lesion than that of non-valvular involvement group (28.79% vs 10.81%,  $p=0.036$ ).

Note P: pulmonary; C: coronary

**Conclusions:** Our study showed that the level of IgA, IgG and CRP were significantly higher in TA patients with valvular involvement and the disease activity was higher in those patients. Elevated IgG, Numano type IIb and type V were the risk factors of valvular involvement in patients with TA.

**Background:** Diffuse alveolar haemorrhage (DAH) is a rare and severe manifestation of ANCA-associated vasculitides (AAV).

**Objectives:** To identify predictors of survival in patients with AAV-DAH.

**Methods:** A retrospective study of 102 consecutive patients (50% females; mean age 59±17 years) from 27 Italian Centres diagnosed with AAV-DAH was planned. Cox regression unadjusted analyses were performed.

**Results:** Among AAV patients, 47% had Granulomatosis with Polyangiitis (GPA), 47% Microscopic Polyangiitis (MPA) and 6% Eosinophilic Granulomatosis with Polyangiitis (EGPA). At DAH onset, mean BVAS was 20±8 and most patients had renal involvement (RI). Admission to Intensive Care Unit was needed in 27% of patients, while ventilatory support (VS) was required in 46%. At least one cardiovascular risk factor (CVRF) was recorded in 48%. Over a median follow-up of 39 months (25%–75% IQR 66 months), 19/102 patients (18.6%) died (figure 1). All patients received high-dose glucocorticoids in association with Cyclophosphamide (CYC 78%, mean cumulative dose 8±7 g) or Rituximab (37%). Plasma exchange was performed in 46%. Infections occurred in 38%. Age>65 years (HR 3.05 [95% CI 1.18–7.9], p=0.04), CVRF ≥2 (HR 8.85 [95% CI [AG7] 2.34–33.50], p=0.01), BVAS (v.3) (HR 1.07 [95% CI 1.01–1.13], p=0.01) were associated with mortality, whereas FFS was not. The need for VS (HR 4.54 [95% CI 1.48–13.85], p=0.008) and infections (HR 3.98 [95% CI 1.48–10.69] were also associated with mortality.

**Conclusions:** Older age, VS, CVRF and infections affect the survival in AAV. There is a need for specific outcome measures.

**FRI0505** **VALIDATION OF THE PROGNOSTIC VALUE OF THE HISTOPATHOLOGICAL CLASSIFICATION OF ANCA-ASSOCIATED GLOMERULONEPHRITIS: A META-ANALYSIS**

M. Wester Trejo<sup>1</sup>, E. van Daalen<sup>1</sup>, J. Schoones<sup>2</sup>, O. Dekkers<sup>2</sup>, J. Bruijn<sup>1</sup>, I. Bajema<sup>1</sup>. <sup>1</sup>Pathology, <sup>2</sup>Walaeus Library, <sup>3</sup>Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**Background:** In 2010, a histopathological classification of antineutrophil cytoplasmic autoantibody (ANCA)-associated glomerulonephritis (AAGN) was proposed by an international consortium of renal pathologists and nephrologists. It comprises four biopsy classes: focal, crescentic, mixed and sclerotic, the order of which was shown, in the initial publication, to correspond to increasing severity of renal impairment during follow-up.

**Objectives:** The aim of this meta-analysis was to evaluate the prognostic value of the phenotypical classes by means of validation studies that have been published since.

**Methods:** A literature search was performed using Web of Science, Google Scholar, PubMed and Embase in March 2017, selecting studies that associated histopathological class to renal outcome in adult patients with AAGN. The risk of developing end-stage renal disease (ESRD) during follow-up was compared between classes using a meta-analysis with random effects model. Weighted relative risks (RR) with 95% confidence intervals (95% CI) were reported.

**Results:** Nineteen studies were included with a total of 2408 patients. Using sclerotic class as a reference category, ESRD risk was lower in the crescentic class (RR 0.53, 95% CI 0.43–0.64); RR in focal was lower than in crescentic class (RR 0.27 95% CI 0.20–0.37). RR in crescentic compared to mixed class was 1.18 (95% CI 0.95–1.45); RR in focal compared to mixed class was 0.34 (95% CI 0.25–0.47).

**Conclusions:** Our meta-analysis shows that the risk for developing ESRD increased with more severe histopathological lesions. We found no difference between the crescentic and mixed classes, pointing towards a comparable risk profile with regard to ESRD. We are currently performing an individual patient data meta-analysis, as this technique is better equipped to deal with study heterogeneity. For the moment, this meta-analysis confirms the use of the histopathological classification system as a predictor of renal outcome in the prognostication of patients with AAGN.

FRI0506

### CLINICAL ANALYSIS OF BEHÇET'S DISEASE MANIFESTATIONS IN 453 EGYPTIAN PATIENTS: GENDER COMPARISON

M. Elshahaly<sup>1</sup>, I. Omar<sup>2</sup>, H. Bassiouni<sup>3</sup>. <sup>1</sup>Rheumatology, physical medicine and rehabilitation, Suez canal university, Ismailia; <sup>2</sup>Ophthalmology, Alexandria university, Alexandria; <sup>3</sup>Rheumatology, physical medicine and rehabilitation, Al-Azhar university, Cairo, Egypt

**Background:** Behçet's disease (BD) is characterised by the presence of vasculitis of veins and arteries of all sizes.<sup>1</sup> Persistent oral and genital ulcers are hallmarks of the disease. BD may be associated with inflammation of eyes, joints, vessels, GIT, nervous system, and other systems.<sup>2</sup> 70% of BD patients suffer from ocular complications mainly recurrent uveitis that may lead to loss of vision.<sup>3</sup> **Objectives:** To describe the demographic and clinical features including ocular manifestations of BD in Egyptian patients and to compare the incidence of disease complications between males and females.

**Methods:** 453 subjects fulfilling 1990 Classification criteria for BD were included. Detailed history, physical examination and complete ocular examination were done. Both, a rheumatologist and an ophthalmologist did clinical examination and follow-up. Further comparison of disease manifestations between both genders was done. Patients were followed up every 2 weeks for 4 years for monitoring of disease complications.

**Results:** Median (range) age of patients was 45<sup>32-63</sup> years old. Our sample included 297 (65.6%) males and 156 (34.3%) females. Patients' disease duration ranged between one to 16 years. At baseline, acute phase reactants (ESR and CRP) were significantly higher in females compared to males ( $p < 0.01$ ) indicating a higher disease activity.

Oral ulcers were present in 100% of patients. Prevalence of genital ulcers, erythema nodosum and joint involvement was similar between both sexes. Subcutaneous thrombophlebitis and follicular papules were more common in males compared to females ( $p = 0.009$  and  $p = 0.041$  respectively).

Recurrent iridocyclitis was found in 100% of patients. All ocular findings were significantly more common in females compared to males except retinal haemorrhages that were more common in males (49.8% vs 37.2%). Incidence of secondary cataract and glaucoma in addition to vitreous opacities were similar between both sexes.

14.8% of patients had GIT manifestations including Budd-Chiari syndrome in 10 males and 5 females; bloody diarrhoea was found in 10 males. Disturbed bowel habits were present in 27 males and 10 females.

Deep venous thrombosis (DVT) was found in 11.8% of males and 3.2% of females. Mediastinal vein syndrome was found in 3.7% of males only, pulmonary artery aneurysm in 1.3% of males and 3.2% of females. Aseptic meningitis and hemiplegia were found 3.4% and 3% of males respectively. 1.7% males and 3.2% females suffered from brain stem involvement. Superior sagittal sinus thrombosis was present in 3.4% females.

**Conclusions:** BD has wide range of complications most commonly oral ulcers and recurrent iridocyclitis. Surprisingly, disease activity was higher in females at baseline and ocular complications were more common in females compared to males.

### THE PREVALENCE OF LATENT TUBERCULOSIS INFECTION IN INDIAN PATIENTS OF TAKAYASU ARTERITIS

N.V. Negalur<sup>1</sup>, G. Ekbote<sup>1</sup>, D. Tanna<sup>1</sup>, N. Mendiratta<sup>1</sup>, R. Gupta<sup>1</sup>, A. Bhan<sup>2</sup>. <sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>CTVS, MEDANTA- THE MEDICITY, Gurgaon, India

**Background:** Studies have shown a correlation between Tuberculosis (TB) and Takayasu arteritis (TA). Some even postulate that infection with TB is required for the initiation of aortoarteritis. Hence, this project was undertaken to find an association of TB and TA by studying the prevalence of Latent Tuberculosis Infection (LTBI) in Indian TA patients.

**Objectives:** To study the prevalence of LTBI in Indian TA patients and see whether LTBI is more in these patients as compared to the historical cohort (40% in Indian population).

**Methods:** This was a cross sectional observational study. All consecutive patients with TA (satisfying the ACR 1990 criteria) were included prospectively from a period of May 2016 to December 2017. Their clinical, laboratory and radiological data were collected after obtaining informed consent. Patients were divided into groups based on the angiographic classification. LTBI was assessed by the Mantoux test and Quantiferon TB Gold test. Mantoux test (MT) was done with 5TU and results were read after 48-72 hours. An induration more than 10 mm was considered positive. Quantiferon TB Gold assay (QTB) was done by ELISA technique and (patient minus control) value  $> 0.35$  IU/ml was considered positive. A positive result of MT and /or QTB was considered positive for LTBI. Chest X-ray was included to access evidence of past or active TB lesions. Active infection was defined as clinical and microbiological and /or radiological evidence of TB. The study was approved by the Ethics committee of Medanta hospital.

**Results:** Out of 66 consecutive TA patients, 46 patients had tests available for LTBI and these were included in the analysis. The mean age of the cohort was 34.9 years with a median disease duration of 24 months. Males consisted of 11 patients whereas females formed the majority i.e. 35 patients (M: F = 1: 3.1). Angiographic Type V (54.3%) was the commonest in the cohort followed by Type IIB (17.3%), Type IV, I, IIA and III (15.2%, 8.6%, 2.1% and 2.1% respectively). LTBI positivity was present in 32.6% of the cohort; with 5 patients (10.8%) having both tests positive. 6 patients were MT positive without being QTB positive and 4 patients were only QTB positive. Eight patients had history of Tuberculosis out of which 1 was diagnosed with TB and TA simultaneously. Four patients were diagnosed as TA during the course of Anti tubercular treatment (ATT) between 4 to 6 months, whereas the rest were diagnosed after ATT completion. The mean duration of Anti tubercular treatment was 8 months. Koch's contact was seen in 7 patients.

**Abstract FRI0507 – Table 1.** Patient characteristics and LTBI

	Characteristic	Value	Percentage (%)
n=46	MT positive only	6	13
	QTB positive only	4	8.6
	Both MT and QTB positive	5	10.8
	LTBI positive	15	32.6
n=8	H/O TB	8/46	17.3
	TB LN	4	50
	Pulmonary TB	1	12.5
	(progression)		
	Intestinal TB	2	25
	TBM	1	12.5
	Empirical ATT for PUO	1	12.5
	MT	2	25
	QTB	0	0
	Both	1	12.5
	n=7	TB contact	7/46
MT		1	14.2
QTB		0	0
Both		0	0

**Conclusions:** The prevalence of LTBI in Indian Takayasu patients was 32.6%, which was not higher than the population prevalence (40% in the historical cohort). However, a larger cohort and further association studies are needed for the relationship between TA and Tuberculosis.

FRI0508

### ANALYSIS OF RISK FACTORS OF ADVERSE OBSTETRICAL OUTCOME IN PATIENTS WITH TAKAYASU ARTERITIS

N. Abisror<sup>1</sup>, A. Mekinian<sup>1</sup>, V. Le Guern<sup>2</sup>, N. Costedoat<sup>2</sup>, on behalf of Eric Hachulla, Marc Lambert, Nathalie Morel, Catherine Chapelon, Nihal Martis, Jean Gabriel Fuzibet, Pauline Belenotti, Laure Swiader, Robin Dhote, Luc Mouthon, Françoise Sarrot-Reynault, Marc Andre, Smail Amar, Jean Baptiste Gauthier, Pascal Cathebras, A. <sup>1</sup>Internal Medicine, Sorbonne Université, APHP, Hôpital Saint Antoine; <sup>2</sup>Internal medicine, Université Paris Descartes-Sorbonne Paris Cité, APHP, Centre de référence maladies auto-immunes et systémiques rares d'Ile de France, Hôpital Cochin, Paris, France

**Background:** Takayasu arteritis (TA) is a large-vessel vasculitis that affects young women of childbearing age. Several small case-series described the pregnancy outcome in TA patients with lack of study determining risk factors associated with adverse pregnancy outcome.

**Objectives:** We performed a French retrospective study, to determine the risk factors associated with obstetrical adverse outcome; and the relation between pregnancy outcome and TA disease activity.

**Methods:** French nationwide retrospective study of pregnancies that lasted at least 12 weeks of gestation (WG) in TA patients.

**Results:** Forty-three pregnancies occurred in 33 patients. The diagnosis of TA was preexisting in 29 patients, and done during pregnancy in 4.

For the 39 pregnancies in the 29 patients with a preexisting diagnosis of TA: steroids were maintained throughout pregnancy in 23/39 (59%) with a median dose of 5 mg/day<sup>2-40</sup> immunosuppressive treatment during pregnancy included azathioprine (n=9, 21%) or infliximab (TNF- $\alpha$  antagonist) (n=1, 2%). For the 4 pregnancies with TA diagnosis during, only one was treated by steroids. Aspirin (100 mg/day) was used in 27/43 pregnancies (63%) and antihypertensive drugs were used in 10 pregnancies (23%).

Before pregnancy, immunosuppressive treatment had been used in 16 patients: azathioprine (n=10, 30%), methotrexate (n=7, 21%), TNF- $\alpha$  antagonist (infliximab in 3 and adalimumab in 1; n=4, 12%) and cyclophosphamide (n=2, 6%).

Maternal adverse events were noted in 20 pregnancies (47%). The most frequent adverse event was arterial hypertension (n=12; 28%): 10 worsening of previous arterial hypertension and 2 *de novo* arterial hypertension. Other adverse events included pre-eclampsia (n=3; 7%), HELLP syndrome (n=1; 2%) and post-partum haemorrhage (n=2; 5%). No maternal death was observed.

There were 42 live births (98%) delivered at a median term of 38<sup>27-42</sup> WG with 9 (21%) before 37 WG and one medical termination of pregnancy for major IUGR at 21WG. IUGR was observed in 6 pregnancies (14%) associated with hypertension and pre-eclampsia or HELLP syndrome in 2 cases.

The median birth weight was 2940 [610-4310] grams. Five children (12%) required intensive care units hospitalisation. One premature boy (27 WG) died after 2 days. Treatment during pregnancy included steroids (n=25/43, 58%), azathioprine (n=9/43; 21%) and infliximab (n=1/43; 2%). Pre-eclampsia were less frequent in patients treated with steroids during pregnancy (p=0.02).

The risk of developing arterial hypertension was associated with previous chronic arterial hypertension, and an infra-diaphragmatic vasculitis injury (p=0.01 and p=0.04). Activity of TA was observed in the course of 12/43 pregnancies (28%).

**Conclusions:** We observed both a high rate of obstetrical complications and of live birth. A preexisting chronic arterial hypertension, the infra-diaphragmatic location of vasculitis and/or an active disease in the 6 months preceding the pregnancy were associated with an impaired pregnancy outcome. TA disease activity did not seem to be influenced by pregnancy.

#### FRI0509 THE FACTORS ASSOCIATED WITH ANXIETY/DEPRESSIVE DISORDERS IN BEHÇET'S DISEASE PATIENTS

P. Ovcharov<sup>1</sup>, T. Lisitsyna<sup>1</sup>, D. Veltishchev<sup>2</sup>, O. Seravina<sup>2</sup>, O. Kovalevskaya<sup>2</sup>, Z. Alekberova<sup>1</sup>, E. Nasonov<sup>1</sup>. <sup>1</sup>Nasonova Research Institute of Rheumatology; <sup>2</sup>Moscow Research Institute of Psychiatry, Moscow, Russian Federation

**Background:** The anxiety/depressive disorders (ADD) is a special psychopathological problem for Behçet's Disease (BD) patients. ADD has high rates in BD, but their causes aren't enough investigated.

**Objectives:** To determine the main factors associated with anxiety/depressive disorders in BD patients.

**Methods:** The investigation has been realised in accordance with the interdisciplinary program "Stress factors and mental disorders in immune-mediated inflammatory rheumatic diseases".

116 BD patients were enrolled in the study. The majority of patients were men (69,8%), natives of the North Caucasus (51,9%), with mean age (M $\pm$ m) 33,3 $\pm$ 0,98 years. All the patients met the criteria of the International Study Group for BD (1990) classification. The disease activity was assessed by scoring system BDCAF.

ADD were diagnosed by psychiatrist in accordance with the ICD-10 in semi-structured interview. The severity of depression was evaluated by Montgomery-Asberg Depression Rating Scale (MADRS) and anxiety – by Hamilton Anxiety Rating Scale (HAM-A). The severity of stress was evaluated by PSS-10 scale.

**Results:** ADD were diagnosed in 87 BD patients (75%). The dysthymia (29,3%) and recurrent depressive disorder (21,5%) prevailed in these patients, generalised anxiety disorder (6,03%) and single depressive episode (7,76%) were rare. Cognitive disorders of different severity were diagnosed in 87 (75%) patients. The presence of ADD didn't depend on gender and duration of the disease. The factors associated with ADD were found during Pearson correlations. Then linear regression analysis was done and obtaining prognostic model showed that ADD was associated with: sleep disorders ( $\beta=0,401$ ), asthenia ( $\beta=0,176$ ), cognitive disorders ( $\beta=0,145$ ), chronic stress ( $\beta=0,036$ ) and stress severity (PSS-10 score) ( $\beta=0,115$ ), age of eye damage ( $\beta=0,135$ ), onset of ADD before BD onset ( $\beta=0,147$ ), pure quality of life (QoL) estimated by visual analogue scale (VAS)

( $\beta=0,163$ ), gastrointestinal BD symptoms ( $\beta=0,101$ ), higher CRP level ( $\beta=0,174$ ), younger age of patients ( $\beta=-0,053$ ) and early childhood trauma (before 7 years old) ( $\beta=0,15$ ) (area under the ROC curve=0,957) (figure 1).

Figure 1 Area under the ROC curve=0957

**Conclusions:** The results demonstrated high prevalence of ADD in surveyed BD patients. ADD in BD is much more associated with early childhood trauma, chronic severe stress, onset before BD, younger age of patients, older age of eye damage, gastrointestinal involvement, higher CRP level, accompanied by sleep disturbances, asthenia, cognitive disorders and had a negative impact on QoL.

#### FRI0510 INCREASED EXPRESSION OF V-DOMAIN I $\kappa$ B SUPPRESSOR OF T-CELL ACTIVATION (VISTA) ON LEUKOCYTES OF GRANULOMATOSIS WITH POLYANGIITIS (GPA) PATIENTS

R. Hid Cadena<sup>1</sup>, J. Yuan<sup>1</sup>, M.G. Huitema<sup>2</sup>, A.M. Boots<sup>2</sup>, C. Stegeman<sup>3</sup>, E. Brouwer<sup>2</sup>, A. Rutgers<sup>2</sup>, P. Heeringa<sup>1</sup>, W.H. Abdulahad<sup>2</sup>. <sup>1</sup>Pathology and Medical Biology; <sup>2</sup>Rheumatology and Clinical Immunology; <sup>3</sup>Department of Internal Medicine/Division of Nephrology, University Medical Center Groningen, Groningen, Netherlands

**Background:** Vascular inflammation in GPA is the result from an inflammatory event combined with a highly specific immune response. Antineutrophil cytoplasmic antibodies (ANCA) specific for GPA are directed against neutrophil granule proteins. Neutrophils are known to play an important role in the pathogenesis of GPA. Under normal conditions, activation of immune cells is positively and negatively regulated by stimulatory and inhibitory checkpoint molecules. The right balance between the expression of both molecules is crucial in fine-tuning the immune response and preventing autoimmunity. Recently, VISTA (V-domain Ig suppressor of T cell activation) has been identified as a potent negative regulator of T cell activation.

**Objectives:** This study aimed to investigate the expression of VISTA on circulating leukocytes of GPA-patients and compare it with vasculitis control (VC) patients with Giant Cell Arteritis (GCA) and healthy controls (HC).

**Methods:** In a cross-sectional study, fresh blood samples were obtained from 43 GPA-patients in remission on immunosuppressive treatment, 24 VC and 34 sex and age-matched HC. The frequency of VISTA expression was determined on Th-cells (CD45RO<sup>-</sup> and CD45RO<sup>+</sup>), NK cells, monocyte subsets (classical/non classical/intermediate) and on neutrophils (suppressive/non suppressive subsets) by flow cytometry.

**Results:** The proportion of VISTA expressing Th-cells was significantly increased in GPA-patients compared with HCs, this increase could be seen in both, the CD45RO<sup>-</sup> compartment as well as in the CD45RO<sup>+</sup> compartment. NK cells from GPA-patients showed an increase in the proportion of VISTA expressing cells when compared to the VCs and HCs. Among monocyte subsets, a slight decrease in the proportion of VISTA on the Intermediate subset could be seen. Interestingly, on neutrophils a significant increase in the proportion of VISTA<sup>+</sup> cells was seen in GPA-patients in comparison to HCs and VCs. This increase was most pronounced in the suppressive neutrophil subset.

**Conclusions:** VISTA expression is increased in both naïve and memory Th cells of GPA patients in remission. Interestingly, neutrophils of GPA patients showed higher levels of VISTA and this was most pronounced in the suppressive neutrophil subset. Whether the increased expression of VISTA has functional consequences needs further investigation.

**FRI0511** **THYROID ARTERY INVOLVEMENT DETECTED BY COLOUR-DOPPLER ULTRASONOGRAPHY IN AN INCIPIENT, SINGLE CENTRE GIANT CELL ARTERITIS COHORT**

R. Ješe, Ž. Rotar, M. Tomšič, A. Hočevar. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Background:** The inflammation of thyroid arteries (ThA) is not commonly considered and investigated in giant cell arteritis (GCA).

**Objectives:** To estimate the frequency of the superior and/or inferior ThA involvement as detected by Colour Doppler Sonography (CDS).

**Methods:** We conducted a prospective single centre study between 1 October 2013 and 30 September 2017. The CDS of superior and inferior ThA was performed in all newly diagnosed, treatment naive GCA patients in addition to the routinely evaluated temporal, facial, occipital and large supraaortic arteries. The superior and inferior ThA were identified at their respective anatomical locations in close proximity to the thyroid gland and examined using the standard Doppler settings for temporal arteries. Arteries were evaluated in two planes for the highly specific halo sign. Laboratory thyroid function tests consisted of TSH, T3 and T4 measurements at the time of GCA diagnosis (prior to any steroid therapy). Characteristics of GCA cases with inflamed ThA were explored and compared to the GCA group without ThA involvement.

**Results:** During the 48 months we performed the CDS of the multiple arteries in 124 consecutive GCA patients (median age 74.7 (IQR 66.5–79.1) years, 65% female). We observed the halo sign on either superior or inferior ThA in 11 (8.9%) cases. All the patients with ThA involvement also had CDS signs of temporal artery involvement, which was confirmed by temporal artery biopsy in all 11 cases. There was a positive trend for correlation between fever ( $\geq 38^\circ\text{C}$ ) and/or dry cough in the patients with ThA involvement (fever: RR 2.99, CI 0.98–9.06,  $p=0.07$ ; dry cough: RR 2.73, CI 0.89–8.3,  $p=0.10$ ). Four patients reported symptoms consistent with thyroid gland pathology. None of the patients with ThA involvement had symptoms of polymyalgia rheumatica. No correlation was found with other clinical and demographic characteristics, including weight loss, headache, jaw claudication and visual disturbances.

Sixteen out of 124 GCA patients (12.9%) had a history of thyroid dysfunction (11 hypothyroidism, 1 hyperthyroidism, 1 euthyroid goitre; 3 patients had thyroid surgery because of either goitre or suspected malignancy). In 2/16 patients we also found CDS signs of ThA involvement, yet the thyroid function tests were normal at the time of GCA diagnosis in these patients. Laboratory signs of thyroid dysfunction were found in 3/11 (27.2%) patients with ThA involvement (2 latent hyperthyroidism, 1 latent hypothyroidism), none of these patients had previous history of thyroid disease.

**Conclusions:** In our incipient GCA cohort, a tenth of all patients had ultrasonographic signs of ThA involvement. To the best of our knowledge, this is the first study that systematically assessed the ThA involvement.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.2904

**FRI0512** **RISK OF OPPORTUNISTIC INFECTIONS IN PATIENTS WITH ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS USING JAPANESE HEALTH INSURANCE DATABASE**

R. Sakai, E. Tanaka, H. Nishina, H. Yamanaka, M. Harigai. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** It has been reported that patients with antineutrophil cytoplasmic antibody associated vasculitis (AAV) had a high risk of infections<sup>1–3</sup>. Among infections, opportunistic infections (OIs) influence patients' vital prognosis and complicate treatments. It is essential to investigate risk of OIs for appropriate management of patients with AAV. However, data about incidence of OIs and risk factors in patients with AAV is limited to date.

**Objectives:** To identify incidence and risk factors of OIs under the remission-induction therapy in patients with AAV using Japanese health insurance database.

**Methods:** This retrospective longitudinal population-based study was conducted using claims data provided by Medical Data Vision Co., Ltd. We defined individuals as AAV cases receiving remission-induction therapy if they met all of the following: 1) had at least one ICD10 code (M300 or M301 or M313 or M318); 2) had at least one prescription of oral corticosteroids (CS) with prednisolone (PSL)-equivalent dosage  $\geq 30$  mg/day, methylprednisolone (mPSL) pulse therapy, immunosuppressive drugs (IS) (cyclophosphamide, methotrexate, mycophenolate mofetil), or rituximab during hospitalisation between April 2008 and April

2017 and 3) had at least 7 days of hospitalisation. If patients had multiple hospitalizations for AAV remission-induction therapy defined as above, the first hospitalisation between April 2008 and April 2017 was analysed in this study. OIs were defined as follows: at least one ICD10 code and one prescription of predefined drugs for each OI during hospitalisation. We calculated incidence proportion and adjusted odds ratio (OR) of risk factors for OIs using a logistic regression model.

**Results:** Two thousands and two hundreds ninety nine patients were included in this study. The median age was 73 years and 55.2% were female. The number of patients with ICD10 code M300 for microscopic polyangiitis, M301 for eosinophilic granulomatosis with polyangiitis, M313 for granulomatosis with polyangiitis, M318 for AAV, and two or more of these ICD10 codes was 1015 (44.1%), 385 (16.7%), 234 (10.2%), and 665 (28.9%), respectively. mPSL pulse therapy, oral PSL  $\geq 30$  mg/d, at least one IS, and rituximab was used in 37.5%, 83.3%, 26.2%, and 5.4%. OI occurred in 203 patients (8.8%) and the most frequent OI was cytomegalovirus infection ( $n=79$ , 3.4%). The numbers (%) of candida infection, aspergillus infection, and pneumocystis jirovecii pneumonia were 28 (1.2), 24 (1.0), and 22 (1.0). No case with tuberculosis was observed. After adjusting for comorbidities, age by decade (OR: 1.34 [95% CI, 1.16–1.57]), IS or rituximab use (OR 1.60 [1.17–2.18]), mPSL pulse therapy (OR 2.62 [1.93–3.56]), PSL dosage per 1 mg (OR 1.02 [1.01–1.03]) were associated with occurrence of OIs significantly.

**Conclusions:** Older age, immunosuppressive treatments were identified as significant risk factors of OIs under the remission-induction therapy in patients with AAV using health insurance database.

**FRI0513** **THE IMPACT OF DEPRESSION, ANXIETY AND FATIGUE IN PATIENTS WITH BEHÇET'S DISEASE**

S. Can Sandikci<sup>1</sup>, S. Colak<sup>2</sup>, A. Omma<sup>2</sup>, M.E. Enecek<sup>3</sup>. <sup>1</sup>Rheumatology, Ankara Diskapi Yildirim Beyazit Training and Research Hospital; <sup>2</sup>Rheumatology, Ankara Numune Training and Research Hospital, Ankara; <sup>3</sup>Rheumatology, Mersin City Hospital, Mersin, Turkey

**Background:** Behçet's disease (BD) is a type of systemic vasculitis and inflammatory disease with unknown etiology which is associated with fatigue and lower quality of life (QoL).<sup>1</sup>

**Objectives:** In this study we aimed to assess the relationship between BDCAF and BDQoL, depression, anxiety and fatigue in Behçet's disease.

**Methods:** This is a cross-sectional study of 155 Behçet's syndrome (BS) patients and 107 healthy controls in Turkey. All subjects completed the Multidimensional Assessment of Fatigue (MAF) questionnaire, Hospital Anxiety and Depression (HADS) scale. Disease activity among BS patients was assessed using the Behçet's Disease Current Activity Form (BDCAF), and the physician's global assessment (PGA). And BD patients completed the Behçet's Disease Quality of Life (BDQoL) questionnaire.

**Results:** There was no significant difference with age and gender between the groups. BS patients had significantly higher HADS-anxiety (HADS-A), HADS-depression (HADS-D) and MAF scores than the healthy controls ( $p<0.05$ ) (table 1). BS patients with active disease had significantly higher MAF and HADS-A scores compared to inactive BS patients ( $p<0.05$ ). MAF scores showed positive correlations with HADS-A, HADS-D, BDCAF and BDQoL (table 2).

**Abstract FRI0513 – Table 1.** Comparison of BS patients and healthy controls

	Patients	Healthy controls	p
BDCAF	2.7±1.6	-	
BDQoL	9.4±9.2	-	
HADS-Anxiety	67 (%43.2)	11 (%10.3)	<b>0.001</b>
HADS-AnxietyScore	8 (0–21)	6 (0–13)	<b>0.004</b>
HADS-Depression	63 (%40.6)	23 (%21.5)	<b>0.001</b>
HADS-Depression Score	5 (0–20)	4 (0–10)	0.340
MAF	25.0 (6.5–48)	19.2 (7.3–44.2)	<b>0.000</b>

**Abstract FRI0513 – Table 2.** Correlations between MAF score and BDCAF, BDQoL, HADS-A, HADS-D in BS patients

Parametre	MAF score	
	R	p
HADSD	0459	<0001
HADSA	0548	<0001
BDQoL	0572	<0001
BDCAF	0359	<0001
DrVAS	0285	<0001
Patient VAS	0434	<0001
Age	0119	0141
Disease duration	0070	0384

**Conclusions:** Fatigue and anxiety is common in clinically active BS patients compared with healthy controls and inactive BD patients.

Matteo Foundation, Pavia; <sup>4</sup>Rheumatology Unit, Azienda Ospedaliera - Università Integrata Trieste, Trieste; <sup>5</sup>Clinica pneumologica, Università degli studi di Milano-Bicocca, Milano, Italy; <sup>6</sup>Department of Autoimmune Diseases; <sup>7</sup>Thorax Institute, Hospital Clínic, Barcelona, Spain; <sup>8</sup>Pneumology Unit, University and IRCCS Policlinico S. Matteo Foundation, Pavia; <sup>9</sup>Rheumatology Unit, University of Modena and Reggio Emilia, Modena; <sup>10</sup>Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

**Background:** Interstitial lung disease (ILD) is a possible manifestation of several rheumatic diseases. Although lung involvement is common in Anti-neutrophil cytoplasmic antibodies (ANCA) vasculitides (AAV), the presence of ILD is relatively rare. Moreover, a very small subgroup of patients may present ILD along ANCA positivity without other systemic signs of AAV.

**Objectives:** To describe the phenotypic characteristics of ILD patients with ANCA positivity without a definite diagnosis of AAV.

**Methods:** ANCA-ILD patients from 7 tertiary care hospitals (6 from Italy, 1 from Spain – 2 rheumatology centres, 4 pneumology centres, 1 internal medicine) were included. The mean follow-up was of 62.6±49.8 months. We collected epidemiologic, demographic, clinical, serological, pulmonary function test (PFT) data and high resolution computed tomography (HRCT) pattern.

**Results:** 19 patients with ANCA-ILD (M:F=9:10, mean age at diagnosis 66.2±8 years) were enrolled. The mean latency between the first respiratory symptom onset and the diagnosis was 26.4±37.0 months. Sixteen patients (84%) had ANCA-MPO positivity while 3 ANCA-PR3. Antinuclear autoantibodies were positive in 12 patients (63%).

Usual interstitial pneumonia was the main HRCT pattern (10, 52.6%), followed by non specific interstitial pneumonia (8, 42%, 1 associated with organising pneumonia), 1 combined pulmonary fibrosis and emphysema. Six patients with ILD-ANCA presented also a non-erosive oligoarticular inflammation (n=6).

During the follow-up, the majority of the patients (16/19) did not require oxygen therapy at last evaluation. However, 1 patient required continuous O<sub>2</sub>, 1

intermittent O<sub>2</sub>, 1 patient underwent lung transplant due to respiratory failure. Five patients required hospitalisation due to respiratory insufficiency. Two patients died, both for respiratory insufficiency.

All patients were treated with glucocorticoids as induction therapy (4 intravenous pulses), combined with an immunosuppressant in 11 cases: cyclophosphamide (3, 15%), azathioprine (6, 31%), mycophenolate (2, 10.5%), methotrexate (1, 5.5%) or rituximab (2, 10.5%).

**Conclusions:** the observation of ANCA positivity in patients with ILD may open new prospective in the assessment of interstitial lung diseases. Although most of patients had a good prognosis, up to 25% presented unfavourable respiratory outcome. Further prospective studies in larger cohorts and longer follow-up may clarify the prognosis of this particular lung disease and if ILD-ANCA should be classified as a distinct subset or an incomplete form of AAV.

**FRI0515 EFFECTIVENESS OF DIRECT-ACTING ANTIVIRAL THERAPY ON CRYOGLOBULINEMIA ASSOCIATED WITH HEPATITIS C VIRUS**

S. Zegarra Mondragon, J.R. Quiñones, J. Bachiller Corral, M. Vazquez Diaz. *Rheumatology, Hospital Ramon y Cajal (Spain), Madrid, Spain*

**Background:** Hepatitis C virus (HCV) is the most frequent cause of mixed cryoglobulinemia, reaching up to 30%–50% of patients with chronic infection. Cryoglobulinemia can manifest as arthritis, vasculitis, hypocomplementemia, peripheral neuropathy or renal involvement. A new direct-acting antiviral therapy against HCV is available for 4 years, and it achieves a sustained virologic response, close to the definition of cure for this viral infection.

**Objectives:** To evaluate the effectiveness of treatment with direct-acting antivirals in HCV-associated cryoglobulinemia and its clinical manifestations.

**Methods:** In a retrospective cross-sectional observational study, we enrolled all consecutive patients with positive serum cryoglobulins and HCV infection with high viral load. Patients with or without associated rheumatological or systemic manifestations were included. All of them were treated with a combination of the new antivirals: sofosbuvir +ledipasvir, or ombitasvir +paritaprevir +ritonavir +dasabuvir; during 8 to 24 weeks, between January 2014 and December 2016. Post treatment blood studies were made in all patients during the first year. Seronegativization of cryoglobulins and improvement of associated clinical manifestations after treatment were analysed.

**Results:** Thirty patients were included, 24 (80%) women. The median age of was 61.4 years. The HCV genotype: 1B in 76.6%, 1A in 16.6% and type 4 in the rest. Eighteen (60%) patients had systemic manifestations: 11 had joint involvement, 11 hypocomplementemia, 8 had leukocytoclastic vasculitis or skin ulcers, 5 Raynaud's phenomenon, 5 sensory-motor peripheral neuropathy, 3 renal involvement with glomerulonephritis, 2 Sjögren's syndrome and 1 patient with autoimmune hemolytic anaemia.

The sustained viral response was achieved in 29 patients (96.6%), maintaining an undetectable viremia after finishing the treatment. Cryoglobulins were negativized in 22 (73%) of patients, and complement was normalised in 36% of those who had hypocomplementemia before treatment. There was a clinical improvement in 54.2% of patients with previous associated rheumatologic or systemic manifestations. The arthritis and cutaneous vasculitis had better response than the other manifestations. No significant correlations were found between the serological and clinical responses.

**Conclusions:** Direct-acting antiviral therapy is very effective against HCV infection. It is also useful for the treatment of mixed cryoglobulinemia, negativizing cryoglobulins in almost 3/4 of the cases, and with clinical response in more than half of the patients, being more favourable in the cases of joint involvement and cutaneous vasculitis.

**Disclosure of Interest:** None declared

**FRI0516 INSIGHT INTO INFLAMMATORY CELL AND CYTOKINE PROFILES IN ADULT IGA VASCULITIS**

T. Kuret<sup>1</sup>, K. Lakota<sup>1,2</sup>, P. Žigon<sup>1</sup>, M. Ogric<sup>1</sup>, S. Sodin-Šemr<sup>1,2</sup>, S. Čučnik<sup>1,3</sup>, M. Tomšič<sup>1,4</sup>, A. Hočevar<sup>1</sup>. <sup>1</sup>Department of Rheumatology, University Medical Center Ljubljana, Ljubljana; <sup>2</sup>FAMNIT, University of Primorska, Koper; <sup>3</sup>Faculty of Pharmacy; <sup>4</sup>Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

**Background:** Immunoglobulin A vasculitis (IgAV) is a small vessel, immune complex vasculitis, involving skin, joints, gastrointestinal tract (GIT) and kidney. While different diagnostic/prognostic and inflammatory markers have already been studied in paediatric IgAV, data on adult cases are scarce<sup>1</sup>.

**Objectives:** To examine the inflammatory cell profile in peripheral blood and cytokine profile in sera of newly diagnosed, biopsy-proven and treatment-naïve adult

IgAV compared to healthy blood donors (HBD), and determine associations with IgAV clinical signs.

**Methods:** Flow cytometry of stained, lysed and fixed whole blood was performed in IgAV (n=30), and HBD (n=17) (Miltenyi). Cytokines were quantitated by multiplex bead assay (Luminex), ELISA (IL-6) and immunonephelometry (acute phase serum amyloid A (SAA)) in 57 IgAV vs. 53 HBD.

**Results:** Percentage of CD16<sup>+</sup> neutrophils was significantly higher, while percentages of CD3<sup>+</sup> T-cells (including CD4<sup>+</sup> and CD8<sup>+</sup> cells), as well as CD19<sup>+</sup> B-cells were significantly lower in peripheral blood of IgAV patients vs. HBD. The expression of I-selectin (CD62L) on CD16<sup>+</sup> neutrophils was significantly increased in IgAV vs. HBD, as were the sera levels of TNF- $\alpha$  (2-fold), IL-6 (3-fold), IL-8 (2.2-fold) and SAA (11.7-fold changed levels) (table 1). Association was found between GIT involvement and lower neutrophil expression of integrin  $\alpha$ M (CD11b) (median; IQR: 7.2; 4.2–16.0), compared to skin limited (17.8; 9.9–40.5) IgAV cases (p=0.047). There was no association found between different cytokines and IgAV clinical phenotype.

**Abstract FRI0516 – Table 1.** Cell profiles, neutrophil surface proteins and cytokines in IgAV patients compared to HBD

Cells (% of WBC)	MEDIAN (Q <sub>25</sub> - Q <sub>75</sub> )		P value	Cytokines (pg/ml)	MEDIAN (Q <sub>25</sub> - Q <sub>75</sub> )		P value
	HBD (n=15)	IgAV (n=15)			HBD (n=53)	IgAV (n=57)	
<b>Neutrophils</b>	51.0 (47.1– 56.9)	67.5 (63.6– 73.3)	<b>&lt;0.001</b>	IL-1 $\beta$	0.4 (0.4– 0.4)	0.4 (0.4– 1.5)	ns

<b>Neutrophil surface proteins (MFI)</b>	<b>HBD (n=17)</b>	<b>IgAV (n=30)</b>		IL-23	1.4 (1.4– 82.9)	1.4 (1.4– 118.6)	ns
<b>CD62L</b>	56.4 (44.9– 73.7)	86.5 (45.4– 107.5)	<b>0.036</b>	<b>TNF-<math>\alpha</math></b>	3.9 (0.8– 15.5)	8.1 (3.0– 20.2)	<b>0.003</b>
CD11b	8.7 (5.5– 27.4)	15.7 (6.4– 31.3)	ns	<b>SAA (<math>\mu</math>g/ ml)</b>	2.8 (1.9– 4.7)	32.8 (7.2– 168.0)	<b>&lt;0.001</b>

**Conclusions:** We found significant up-regulation of neutrophils and their CD62L expression, as well as sera levels of IL-6, IL-8, TNF- $\alpha$  and SAA in IgAV, implying a pathogenic role of neutrophils in IgAV. CD11b might represent a promising surface marker of GIT involvement in adult IgAV.

#### VESSEL WALL MORPHOLOGY IN GIANT CELL ARTERITIS– A LONGTERM SONOGRAPHIC FOLLOW-UP STUDY

E. Schegg<sup>1</sup>, C.T. Berger<sup>2</sup>, S. Imfeld<sup>3</sup>, D. Staub<sup>3</sup>, M. Recher<sup>4</sup>, D. Kyburz<sup>1</sup>, M. Aschwanden<sup>3</sup>, T. Daikeler<sup>1</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Translational Immunology, University Hospital Basel; <sup>3</sup>Department of Angiology; <sup>4</sup>Clinical Immunology, Basel, Switzerland

**Background:** Ultrasound (US) is a cornerstone in the diagnosis of GCA. Only limited data on how US documented large vessel wall thickening changes during treatment is available.

**Objectives:** To assess arterial vessel wall findings by US during long term follow-up in GCA patients with large vessel vasculitis (LVV) and to correlate findings with the disease course

**Methods:** Patients with GCA and US defined LV vasculitis were scheduled semi-annually for clinical and laboratory assessment as well as US of the temporal (TA), vertebral (VA), carotid (common, internal, external), subclavian (SA), axillary (AXA), deep (DFA), superficial (SFA) and common (CFA) femoral, and popliteal arteries (PA). US findings were classified as normal, moderate or marked vessel wall thickening.

**Results:** From 42 patients (16 male) with a median age of 75 years at diagnosis 28 had typical vessel wall thickening in the temporal artery and in at least one LV segment and 14 in the LV only. The following vessels (marked/moderate) were most often involved: PA in 11/21, SFA in 13/20, AxA in 14/5, SA in 8/13 patients respectively.

A reduction of the vessel wall thickening in the temporal artery during follow-up was found in 79% of patients after in median 7 months, with bilateral normalisation in 10 patients after in median 13 months.

In contrast 55% had no, 43% a partial and only one patient a complete reduction of thickening of all LV walls during follow-up. From initially marked supra-aortic LV segments 35% were moderate and 16% normal and from initially moderate LV 13% were normal at 1 year FU. From initially marked infra-aortic LV segments 36% were moderate and 3% normal and from initially moderate 10% were normal at 1 year FU.

Progression of vessel wall thickening in the LV during FU was seen in a total of 3 patients, in 2 of those, a clinical relapse of GCA was diagnosed one respectively 2 months before US.

There was no difference between patients with reduction of the vessel wall thickening and without during follow-up in respect to clinical parameters (relapse rate over the observation time, cumulative steroid dose after one year).

**Conclusions:** Regression of US morphological documented thickening of LV in patients with GCA is rare despite clinical remission. US remains sensitive for the diagnosis of LVV long after treatment initiation. Most plasticity is seen in the TA and more rarely in the supra-aortic segments.

#### INCIDENCE, CHARACTERISTICS AND MANAGEMENT OF GIANT CELL ARTERITIS IN FRANCE: A STUDY BASED ON NATIONAL HEALTH INSURANCE CLAIMS DATA

V. Devauchelle Pensec<sup>1</sup>, E. Hachulla<sup>2</sup>, M. Paccalin<sup>3</sup>, S. Gandon<sup>4</sup>, I. Idier<sup>5</sup>, M. Nolin<sup>6</sup>, M. Belhasen<sup>6</sup>, A. Mahr<sup>7</sup>. <sup>1</sup>Rheumatology, University Hospital, Brest; <sup>2</sup>Internal Medicine, University Hospital Claude Huriez, Lille; <sup>3</sup>Internal Medicine, University Hospital, Poitiers; <sup>4</sup>Clinical Operations, Roche SAS, Boulogne Billancourt; <sup>5</sup>Medical, Chugai Pharma France, Paris La Defense; <sup>6</sup>PELyon; EA 7425 HESPER, Université Claude-Bernard-Lyon1, Lyon; <sup>7</sup>Internal Medicine, University Hospital APHP Saint Louis, Paris, France

**Background:** Giant cell arteritis (GCA) is an immune-mediated, primary systemic vasculitis that affects large and medium-sized arteries. GCA may cause vision loss in up to 20% and requires long term glucocorticoids (GCs). There are currently few data available in France on the epidemiology, patients' (pts) characteristics, diagnosis and management of GCA in a real-world setting.

**Objectives:** The objectives of this study were to address these questions using Health insurance claims data.

**Methods:** This retrospective cohort study used the EGB (*Echantillon Généraliste des Bénéficiaires*) database which is a 1% random and representative sample of the French national Health insurance system. EGB contains anonymous demographic and comprehensive medical data on conditions with long-term disease (LTD) status, hospitalizations and reimbursement claims for medications dispensed in the community. The study used the data collected between January 1, 2007 and December 31, 2015. Inclusion criteria were: 1) age  $\geq 50$  years; 2) hospitalisation for GCA or LTD status for GCA (ICD-10 codes: M31.5/6); and 3) at least 4 drug dispensing of oral GCs within 6 months around the index date. The index date was defined as the date of 1<sup>st</sup> occurrence of GCA code and cases were considered as incident if the GCA code first occurred after  $\geq 2$  years of follow-up. Demographics, co-morbidities, diagnostic tests and therapies were analysed. A treatment sequence was defined as the start of a new drug or the resumption of the same drug after a stop  $\geq 3$  months. Annual incidence was calculated by using the people recorded in the EGB as denominator.

**Results:** Among the 7 52 717 pts recorded in the EGB, 241 pts fulfilled our criteria. Around 24 pts were newly diagnosed/year with an annual incidence of 7 to 10/100,000 people  $\geq 50$  years-old. 72% of the 241 pts were females, mean age was 77.5 ( $\pm 8.9$ ) years, mean follow-up 3.7 ( $\pm 2.6$ ) years. In the 12 months before index date, 74.3% of the pts had at least 1 proxy for hypertension, 39.4% for depression/insomnia and 33.6% for osteoporosis. After index date, temporal artery biopsy (TAB) was performed in 43.2%, high-resolution Doppler ultrasound in 35.3% and positron emission tomography (PET) in 11.6%. Among the 235 pts (97.5%) who had at least 1 drug dispensing of oral GCs, 198 pts (84.3%) used only GCs while 37 (16.7%) also received 1 to 3 adjunctive agents. Mean 1<sup>st</sup> GCs sequence duration was 17.2 months ( $\pm 16.5$ ) in 96.6%. 95 pts (40.4%) had a 2<sup>nd</sup> sequence, i.e. resume GCs and/or start a new drug for a duration of 6.7 months ( $\pm 8.1$ ) for GCS alone or 12.2 months ( $\pm 8.8$ ) for GCs+adjunctive drug. The most prescribed GCs-sparing agent was methotrexate (12.0%). Others were marginal: hydroxychloroquine 7 pts, azathioprine 4, cyclophosphamide 1, infliximab 1, adalimumab 2 and etanercept 1 pt.

**Conclusions:** These real-world data indicate an incidence of GCA in France of 7 to 10 cases/100,000 people  $\geq 50$  years-old and underline that most patients with GCA are treated with GCs alone whereas adjunctive agents, mainly methotrexate, are given to 17% of patients. The utilisation of TAB in only half of the patients might reflect a shift towards increasing use of imaging techniques to diagnosed GCA.

#### FRI0519 WORK PRODUCTIVITY IS IMPAIRED IN PATIENTS WITH BEHÇET'S SYNDROME

N. Serin, Y. Ozguler, S.N. Esatoglu, V. Hamuryudan, G. Hatemi. *Istanbul University Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey*

**Background:** Behçet's syndrome (BS) is most active during young adulthood and working years, thus affecting productivity. Work disability was previously reported especially among BS patients with eye, vascular and joint involvement.

**Objectives:** In this study, we aimed to evaluate the work productivity and instability of patients with BS compared to ankylosing spondylitis (AS) patients and healthy controls (HC).

**Methods:** 100 (80 M/20 F) consecutive BS patients who were routinely followed in our dedicated BS centre were studied. Patients with AS;<sup>26</sup> 22 M/4 F) who were followed in the rheumatology outpatient clinic of our unit and HC;<sup>30</sup> 18 M/12 F) were included as controls. Work Productivity and Activity Impairment Questionnaire (WPAI), Work Productivity Survey (WPS), Work Instability Scale (WIS) were used. Quality of life was assessed with the Behçet Disease Quality of Life (BDQoL) scale and disease activity with the Behçet's Disease Current Activity Index.

**Results:** Table 1 shows the characteristics of the included subjects. 28 of BS patients with only mucocutaneous, 28 with eye, 23 with vascular and 21 with neurologic involvement were included. Among BS patients 41% reported missing work days (mean 1.4 days/mo), and 49% reported that their productivity was reduced at least by half (mean 4.1 days/mo). The mean WIS score was 11.7 (5.8) in BS patients. 52 BS patients had moderate and 14 BS patients had high work instability. Patients with BS had significantly higher absenteeism (8.4% vs. 1.7%), presenteeism (37.6% vs. 9.3%), and daily activity impairment (27.5% vs. 8.6%) than HCs ( $p < 0.001$ ) assessed by WPAI. Scores were similar between BS and AS patients. WIS and WPS scores were also similar between BS and AS patients and worse than healthy controls. Work impairment was more pronounced in patients with eye involvement compared to mucocutaneous involvement ( $p = 0.006$ ) and there were no differences between other BS groups. The WPAI presenteeism score was moderately correlated with Behçet Disease Quality of Life scale score

( $r = -0.57$ ). Multivariate analysis showed that QoL (OR=0.77, 95% CI=0.66–0.88) and disease activity (OR=1.66, 95% CI=1.01–2.50) were related with WPAI-presenteeism.

**Abstract FRI0519 – Table 1.** Characteristics of the included subjects

	Behçet's syndrome (n=100)	Ankylosing spondylitis (n=26)	Healthy controls (n=30)
Male, n (%)	80 (80)	22 (85)	18 (60)
Mean (SD) current age,	36 $\pm$ 7.8	36 $\pm$ 6.4	31 $\pm$ 8.1
Mean (SD) disease duration	8 $\pm$ 5.5	7.46 $\pm$ 4.6	N/A
WIS (mean $\pm$ SD)	12 $\pm$ 6	11 $\pm$ 5.5	6 $\pm$ 4
WPAI-Absenteeism (mean $\pm$ SD)	8 $\pm$ 15	8 $\pm$ 19	2 $\pm$ 7
WPAI-Presenteeism (mean $\pm$ SD)	38 $\pm$ 29	32 $\pm$ 26	9 $\pm$ 21
WPS-Absenteeism (mean $\pm$ SD)	1.4 $\pm$ 3	1.2 $\pm$ 3	0.1 $\pm$ 0.3
WPS -Presenteeism (mean $\pm$ SD)	4 $\pm$ 7	4 $\pm$ 6	1 $\pm$ 3
BDCAF (mean $\pm$ SD)	4.47 $\pm$ 2.79	N/A	N/A
BSAS (mean $\pm$ SD)	21.47 $\pm$ 17.5	N/A	N/A
BDQoL (mean $\pm$ SD)	19.53 $\pm$ 8.3	N/A	N/A
BASDAI (mean $\pm$ SD)	N/A	3.3 $\pm$ 1.8	N/A
BASFI (mean $\pm$ SD)	N/A	2.8 $\pm$ 2.9	N/A

N/A: Not applicable; Behçet Disease Quality of Life: BDQoL; Behçet's Disease Current Activity Index (BDCAI); Behçet's Syndrome Activity Score (BSAS)

**Conclusions:** Work productivity is impaired in BS patients, especially among those with eye involvement. Work instability is frequent and correlated with disease activity and quality of life.

**FRIDAY, 15 JUNE 2018: Osteoarthritis**

#### FRI0520 DISCOVERY OF POTENTIAL BIOMARKERS FOR THE DIAGNOSIS OF EROSIIVE AND NODAL HAND OSTEOARTHRITIS

M. Camacho Encina<sup>1</sup>, V. Calamia<sup>1</sup>, F. Picchi<sup>1</sup>, I. Ortega<sup>2</sup>, P. Fernández Puente<sup>1</sup>, L. González Rodríguez<sup>1</sup>, C. Ruiz Romero<sup>1</sup>, F.J. Blanco<sup>1</sup>. <sup>1</sup>Rheumatology Research Group (GIR), ProteoRed, PRB2-ISCIII, INIBIC-Complejo Hospitalario Universitario de A Coruña (CHUAC), A Coruña; <sup>2</sup>Proteomics core Facility, PRB2-ISCIII, INIBIC-Hospital Universitario Reina Sofía, Córdoba, Spain

**Background:** Two different phenotypes of hand osteoarthritis (HOA) have been defined: nodal hand osteoarthritis (NHOA) and erosive hand osteoarthritis (EHOA). NHOA involve bone enlargement of the underlying interphalangeal joints, which may typically give rise to Heberden's nodes, synovitis and swelling. EHOA is a particularly aggressive form characterised by an abrupt onset, as well as signs of inflammation and subchondral erosions. In the absence of efficient diagnostic methods, searching for specific biomarkers for each subtype may help to characterise them.

**Objectives:** To define a panel of specific protein markers for the characterisation of EHOA and NHOA and its potential use in clinic.

**Methods:** A proteomic approach based on peptide labelling with Isobaric tags for relative and absolute quantitation (iTRAQ) was performed using two different sets of sera (n=55). Samples were classified in 4 groups of study (EHOA, n=10; non-EHOA, n=10; NHOA n=10; non-NHOA, n=5) and 2 control groups (rheumatoid arthritis (RA), n=10 and psoriatic arthritis (PSA), n=10). Serum proteins were digested and peptides from each condition to be compared were differentially labelled with iTRAQ reagents (Sciex). Then, samples were combined and analysed by two-dimensional liquid chromatography coupled to mass spectrometry in a TripleTOF 5600 Mass Spectrometer System (Sciex). Protein identification and quantitation was carried out using ProteinPilot software v.5.0.1.

**Results:** A total of 257 different proteins were identify with more than two peptides and a total score  $\geq 2$  at 95% confidence. In order to identify specific biomarkers for the characterisation of NHOA and EHOA phenotypes, each group was compared with the non-NHOA or non-EHOA respectively, and also with the control groups. After all the comparisons were made, 26 unique different proteins were found specific of the nodular phenotype. Vasorin (VAS) showed elevated levels in patients diagnosed with NHOA when compared to non-NHOA, RA and PSA groups. On the other hand, 36 unique proteins were identified in those patients with EHOA. Extracellular matrix protein 1 (ECM1) was found with higher concentrations in EHOA than in non-EHOA, RA and PSA patients. In addition, both HOA phenotypes were compared to the control groups and a panel of 30 different proteins

were defined. Among these proteins, vascular cell adhesion molecule-1 (VCAM1) was found increased in HOA compared to RA and PSA groups.

**Conclusions:** A specific protein profile for the characterisation of EHOA and NHOA disorders has been established. VAS showed elevated levels in patients with NHOA, whereas ECOM1 was increased in patients diagnosed with the erosive form of the disease. As none of them were identified in the other phenotype, they might be phenotype-specific biomarkers. In addition, VCAM1 was found with higher levels in both phenotypes of HOA when compared with RA and PSA and might be used to differentiate hand osteoarthritis from other rheumatic diseases.

**FRI0521** **COMBINING FRACTAL- AND ENTROPY-BASED BONE TEXTURE ANALYSIS FOR THE PREDICTION OF OSTEOARTHRITIS: DATA FROM THE MULTICENTER OSTEOARTHRITIS STUDY (MOST)**

R. Ljuhar<sup>1</sup>, Z. Bertalan<sup>1</sup>, S. Nehrer<sup>2</sup>, B. Norman<sup>3</sup>, H.-P. Dimai<sup>4</sup>, A. Fahrleitner-Pammer<sup>4</sup>, D. Ljuhar<sup>3</sup>. <sup>1</sup>Research and Development, ImageBiopsy Lab, Vienna; <sup>2</sup>Center for Regenerative Medicine and Orthopedics, Danube University, Krems; <sup>3</sup>Research and Development, Braincon Technologies, Vienna; <sup>4</sup>Department of Internal Medicine, Division of Endocrinology and Diabetology, Medical University of Graz, Graz, Austria

**Background:** Osteoarthritis (OA) is one of the leading causes of long-term pain and disabilities associated with musculoskeletal disorders. Effective treatment and disease-progression slowdown depend on early detection and quantification of risk. However, current disease parameters, like joint space width (JSW), have proven to be insufficient for the prediction of OA.

**Objectives:** The purpose of the present study was to investigate if combining fractal- and entropy-based bone texture analyses with joint space width (JSW) and joint space area (JSA) may improve prediction of OA. Conventional posterior-anterior (PA) knee radiographs of men and women were obtained from the Multicenter Osteoarthritis Study (MOST) database, which provides valuable information to identify and define modifiable biomechanical, bone and structural, nutritional, and other risk factors for new disease and progression of existing disease.<sup>1</sup>

**Methods:** Oriented fractal- and entropy based texture algorithms were developed, using state-of-the-art computer hardware and software as well as specific machine-learning algorithms. The selected subchondral area used for textural analyses included 4 regions of interest (ROI) in the proximal tibia and one on each condyle of the distal femur (figure 1). Furthermore, JSW and JSA were assessed using newly developed and fully automated software.

**Results:** 1092 conventional knee radiographs obtained from one study centre were screened for eligibility. Of these, a total of 574 radiographs (230 women, 344 men) met the inclusion criteria, i.e. a Kellgren & Lawrence (KL) score of 0 at baseline. At month 84, 41 female and 79 male patients had developed KL<sub>≥1</sub>, and 189 female and 265 male patients remained at KL0. Area-Under-the-Curve (AUC) for incident OA using JSW/JSA and clinical features was 0.67±0.08 for women, and 0.61±0.1 for men. In contrast, combining fractal/entropy-based texture, JSW/A and clinical features resulted in significantly improved AUC for women and men (0.80±0.07 for women and 0.69±0.1 for men, respectively). To test whether these differences in predicting incident-OA were significant, we performed classifier comparison: t=3.84; p<10<sup>-3</sup> for women, and t=3.38; p<10<sup>-3</sup> for men.

**Conclusions:** This study provides strong evidence, that a combination of fractal- and entropy-based textural analyses of plain subchondral bone radiographs together with JSW/A and clinical features is superior to JSW/A and clinical features alone in predicting incident OA in men and women.

**FRI0522** **VITAMIN D SUPPLEMENTATION IMPROVES DEPRESSION IN KNEE OSTEOARTHRITIS PATIENTS OVER 24 MONTHS**

S. Zheng<sup>1</sup>, L. Tu<sup>2</sup>, F. Cicuttini<sup>3</sup>, W. Han<sup>1</sup>, Z. Zhu<sup>1</sup>, B. Antony<sup>1</sup>, A. Wluka<sup>3</sup>, T. Winzenberg<sup>1,4</sup>, D. Aitken<sup>1</sup>, L. Blizzard<sup>1</sup>, G. Jones<sup>1</sup>, C. Ding<sup>1,5</sup>. <sup>1</sup>Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia; <sup>2</sup>Department of Rheumatology, The third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China; <sup>3</sup>Department of Epidemiology and Preventive Medicine, Monash University, Melbourne; <sup>4</sup>Faculty of Health, University of Tasmania, Hobart; <sup>5</sup>Clinical Research Centre, Zhujiang Hospital, Southern Medical University, Guangzhou, Australia

**Background:** Although depression is prevalent in osteoarthritis (OA) patients and the positive association between vitamin D deficiency and depression has been demonstrated, no study has examined the effect of vitamin D supplementation on depression in OA patients.

**Objectives:** To determine the effect of vitamin D supplementation and maintaining sufficient serum vitamin D on depression in patients with knee OA and vitamin D deficiency.

**Methods:** Participants with symptomatic knee OA and vitamin D deficiency were enrolled in a randomised, placebo-controlled trial and received 50,000IU vitamin D<sub>3</sub> (n=209) or placebo (n=204) monthly for 24 months. Serum 25-hydroxyvitamin D [25(OH)D] was measured at baseline, month 3 and 24. Depression was measured using the patient health questionnaire (PHQ-9), and knee symptoms were assessed using Western Ontario and McMaster Universities Arthritis Index (WOMAC) at baseline, month 3, 6, 12 and 24. Multilevel mixed-effect models were used to estimate the association between exposures and outcomes adjusting for potential confounders.

**Results:** Over 24 months, 340 participants (82.3% retention rate) completed the study. The prevalence and incidence of depression were 25.4% and 11.2%, respectively. Depression improved more in the vitamin D supplementation group (β: -0.45, 95% CI: -0.84 to -0.07) compared to the placebo group (β: 0.21, 95% CI: -0.19 to 0.61) (p=0.02) and in those participants who maintained vitamin D sufficiency (β: -0.44, 95% CI: -0.88 to -0.00) compared to those who did not maintain sufficiency (β: 0.40, 95% CI: -0.18 to 0.97) (p=0.02) over 24 months.

**Abstract FRI0522 – Table 1.** Effects of vitamin D supplementation over 24 months on change in PHQ-9

	Mean change, (95% CI)	Between-group difference change, mean (95% CI)	P value
Placebo Group (n=204)	0.21 (-0.19 to 0.61)	-0.66 (-1.22 to -0.11)	0.02
Vitamin D Group (n=209)	-0.45 (-0.84 to -0.07)		

Changes in outcomes are generated from mixed-effect models adjusted for age, sex and body mass index.

**Abstract FRI0522 – Table 2.** Effects of vitamin D status over 24 months on change in PHQ-9

	Mean change, (95% CI)	Between-group difference change, mean (95% CI)	P value
Not maintaining sufficient vitamin D (n=114)	0.40 (-0.18 to 0.97)	-0.83 (-1.56 to -0.11)	0.02
Maintaining sufficient vitamin D (n=226)	-0.44 (-0.88 to -0.00)		

Changes in outcomes are generated from mixed-effect models adjusted for age, sex and body mass index.

Abstract FRI0522 – Figure 1. Flowchart of the study

**Conclusions:** These findings suggest that vitamin D supplementation and maintaining sufficient vitamin D levels over 24 months may have beneficial effects on depression in patients with knee OA.

#### ZOLEDRONIC ACID PLUS PREDNISOLONE VERSUS ZOLEDRONIC ACID ALONE OR PLACEBO IN THE TREATMENT OF KNEE OSTEOARTHRITIS: A RANDOMISED TRIAL

G. Cai, L. Laslett, D. Aitken, T. Winzenberg, G. Jones. *Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia*

**Background:** Disease-modifying therapeutic options are needed for patients with osteoarthritis (OA). Zoledronic acid (ZA) is a potential option as it reduced both knee pain and knee bone marrow lesion (BML) size over 6 months in patients with knee OA. However, ZA infusions are often accompanied by a suite of side effects within 3 days of infusion (acute phase reactions (APRs)), which include flu-like symptoms. These may be caused by upregulation of pro-inflammatory cytokines. A preliminary study (n=20) suggested that a combination of ZA and prednisolone (VOLT01) was superior to ZA alone in reducing APR and knee pain in knee OA patients. A larger study was needed to confirm these findings and examine the new combination's effect on OA outcomes.

**Objectives:** To compare the effect of once-off infusion of ZA, VOLT01 and placebo on APRs, knee BML size and knee pain symptoms over 6 months in knee OA patients with significant knee pain and BMLs.

**Methods:** Knee OA patients  $\geq 50$  years with significant knee pain (defined as a 100 mm Visual Analogue Scale (VAS)  $\geq 40$  mm) and knee BMLs visualised on proton density weighted MRI were randomised to receive one infusion of ZA (5 mg in 100 ml saline), VOLT01 (5 mg ZA in 100 ml saline plus a 10 mg prednisolone bolus) or placebo (100 ml saline). Co-primary hypotheses were that VOLT01 would significantly reduce APRs compared to ZA, and that VOLT01 would be non-inferior to ZA in reducing BML size over 6 months. Secondary hypothesis was that VOLT01 would be non-inferior to ZA in improving knee pain and dysfunction (assessed using the Western Ontario and McMasters

Universities Osteoarthritis Index (WOMAC) and VAS) over 6 months. Mixed effect models were performed for data analyses. Analyses for change in knee pain and function scores were adjusted for baseline imbalanced values (baseline pain and utility scores, and pain medications). Non-inferiority margins were defined as 140 mm<sup>2</sup> for change in knee BML size and 8 mm for change in knee pain and function scores (WOMAC pain and function scores were averaged to a 100 mm VAS).

**Results:** 117 knee OA patients (63 females, mean  $\pm$  standard deviation (SD) age 62.2 $\pm$ 8.1 years) were enrolled. At baseline, mean  $\pm$ SD knee pain VAS score was 50.1 $\pm$ 18.9 mm and median BML size 370 mm<sup>2</sup>. APRs were more frequent in the two active treatment groups (ZA: 87%; VOLT01: 90%) than the placebo group (55%) (both p<0.01). Compared to placebo, neither ZA nor VOLT01 significantly reduced BML size (ZA mean difference [95% CI] -21.6 [-103.0 to +59.9], VOLT01 -62.0 [-142.5 to +18.4]) or knee pain scores (WOMAC pain: ZA 2.6 [-8.5 to +13.8], VOLT01 -8.1 [-18.8 to +2.6]; VAS pain: ZA 5.4 [-6.4 to +17.1], VOLT01 -7.7 [-19.0 to +3.6]) over 6 months, but WOMAC knee function improved significantly (-9.9 [-18.2 to -1.6], p=0.02) in VOLT01-treated group. VOLT01 was non-inferior to ZA in reducing knee BML size and superior to ZA in reducing knee pain and function scores (figure 1).

**Abstract FRI0523 – Figure 1.** Non-inferiority tests between VOLT01 and zoledronic acid for change in BML size, knee pain and function scores. Values represent the mean difference between VOLT01 and zoledronic acid. An upper bound of 95% CI for BML size less than 140 mm<sup>2</sup> or knee symptoms less than 8 indicates that a non-inferiority of VOLT01 to zoledronic acid is demonstrated.

**Conclusions:** Combining prednisolone with ZA does not appear useful for reducing APRs, though there may be a small benefit over ZA alone for knee symptoms. Neither showed evidence of disease modification by changing BML size.

#### CENTRAL SENSITISATION IN HAND OSTEOARTHRITIS AND ASSOCIATIONS WITH RADIOGRAPHIC SEVERITY, SYNOVITIS ON ULTRASOUND AND SYMPTOM DURATION

P. Steen Petersen<sup>1</sup>, T. Neogi<sup>2</sup>, K. Magnusson<sup>1</sup>, H.B. Hammer<sup>1</sup>, T. Uhlig<sup>1</sup>, T. K. Kvien<sup>1</sup>, I.K. Haugen<sup>1</sup>. <sup>1</sup>Departement of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; <sup>2</sup>Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, USA

**Background:** Patients with painful hand osteoarthritis (HOA) have enhanced central pain sensitisation (CS). Structural and inflammatory joint tissue damage over time might lead to CS. However, increased pain sensitisation can also represent an 'a priori trait' of a subgroup of patients.

**Objectives:** This study explored whether structural pathology, inflammation and symptom duration of HOA are associated with enhanced CS.

**Methods:** Through a cross-sectional study we included 300 subjects (89% women, median age 61 years (IQR 57, 67), mean body mass index (BMI) 26.5 (SD 4.9) kg/m<sup>2</sup>) with clinical and/or ultrasound verified HOA. All were examined with ultrasound (grey scale (GS) synovitis and power Doppler activity (PD)) and conventional radiographs of both hands. GS-synovitis was scored on a semi-quantitative 0–3 scale and PD to be present or not. The bilateral interphalangeal, metacarpophalangeal, first carpometacarpal and scaphotrapezotrapezoidal joints were scored for global HOA (using Kellgren and Lawrence scale (KL), 0–4). Erosive HOA in the interphalangeal joints was defined with the Verbruggen-Veys anatomical phase score (VV). In addition, participants answered a question about the year of onset of their hand symptoms.

CS was measured with temporal summation (TS), the increase in perceived pain to repetitive noxious stimuli, using a mechanical probe. First, probes with increasing weight (32, 64, 128, 256 or 512mN) were applied at the wrist until the patients reported pain of at least 4/10. The selected probe was applied to the wrist times at

1 Hz. Subjects reported pain on first, fifth and tenth touch. Enhanced TS is a marker of central sensitisation and we defined the magnitude of TS as TS- $\Delta$ : highest pain value of fifth or tenth touch minus the first pain value.

We analysed whether sum scores of KL (0–128), GS (0–90), PD (0–30), number of erosive interphalangeal joints (0–20) and symptom duration were associated with TS- $\Delta$  using separate models of linear regression with adjustments for age, sex and BMI.

**Results:** Median radiographic KL sum score was 28 (IQR 15, 44) and ultrasound sum scores (GS, PD) were 3 (IQR 1, 7) and 0 (IQR 0, 1), respectively. Median number of erosive joints was 0 (IQR 0, 1) and symptom duration was 6 (IQR 3, 13) years. Median TS- $\Delta$  among the participants was 1 (IQR 0, 2).

Neither KL sum score ( $p=0.18$ ), GS-synovitis sum score ( $p=0.18$ ), PD sum score ( $p=0.86$ ), number of joints with erosive HOA ( $p=0.078$ ) nor symptom duration ( $p=0.21$ ) were associated with TS- $\Delta$  (table 1).

Table 1 Associations between OA features and temporal summation \*

Associations between OA features and temporal summation *		
	Unstandardized beta (95% CI)	P-value
Symptom duration in years	0.015 (-0.01, 0.04)	0.21
Kellgren-Lawrence sum score	0.007 (-0.00, 0.02)	0.18
Grey scale synovitis sum score	-0.001 (-0.03, 0.03)	0.96
Power Doppler sum score	0.001 (-0.05, 0.06)	0.86
Number of erosive joints	0.070 (-0.01, 0.15)	0.08

\*Adjusted for sex, age and BMI.

**Conclusions:** We found no relationship between the severity of HOA pathology and CS. This is in line with the hypothesis that factors other than OA disease severity itself contribute to CS associated pain, and that CS may be a trait in some individuals. However, it does not exclude other aspects of HOA as an initiator of CS in a subgroup of patients.

#### ASSOCIATION BETWEEN DIETARY VITAMIN K INTAKE WITH KNEE SYMPTOMS AND BACK PAIN IN PATIENTS WITH KNEE OSTEOARTHRITIS

Z. Liao<sup>1,2</sup>, J. Chang<sup>2,3</sup>, Z. Zhu<sup>2,4</sup>, W. Han<sup>2,4</sup>, T. Meng<sup>2</sup>, S. Zheng<sup>2</sup>, T. Winzenberg<sup>2</sup>, A. Wluka<sup>5</sup>, F. Cicuttini<sup>5</sup>, C. Ding<sup>2,4</sup>. <sup>1</sup>Rheumatology and Immunology Division, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; <sup>2</sup>Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia; <sup>3</sup>Department of Orthopaedics, 4th Affiliated Hospital, Anhui Medical University, Hefei; <sup>4</sup>Clinical Research Centre, Zhujiang Hospital, Southern Medical University, Guangzhou, China; <sup>5</sup>Department of Epidemiology and Preventive Medicine, Monash University, Victoria, Australia

**Background:** Vitamin K could be implicated in structural change of osteoarthritis (OA), but current evidence is limited or conflicting so the association between vitamin K and OA symptoms remains unclear.

**Objectives:** This study aims to investigate the association of vitamin K intake with knee symptoms and structural features in people with knee OA.

**Methods:** The parent study, Vitamin D Effect on Osteoarthritis (VIDEO) study, was conducted between June 2010 and December 2013 in Tasmania and Victoria, Australia. Knee symptoms were assessed using the Western Ontario and McMaster University Index of osteoarthritis (WOMAC) and a Visual Analogue Scale (VAS) for pain. A validated Food Frequency Questionnaire (FFQ) (developed by the Cancer Council Victoria in Australia) was completed at baseline and used to determine dietary vitamin K intake. Knee Magnetic Resonance Imaging (MRI) scans were obtained according to a standardised protocol using a 1.5 T whole-body MRI unit. Cartilage volume, cartilage defects, bone marrow lesions and effusion volume were measured. The associations between vitamin K intake quartile and changes in clinical or MRI features were analysed using linear regressions.

**Results:** 261 participants were included at baseline and 213 completed 2 years of follow-up. There were no significant differences between two equal divisions with high or low level of vitamin K intake in term of baseline characteristics. As table 1 and figure 1 show, higher vitamin K intake quartiles were significantly associated with greater decrease in total WOMAC score and WOMAC function score over 24 months. Similar trends were seen in WOMAC pain score and stiffness score, though not statistically significant. There were no significant associations

between baseline vitamin K intake and changes in total cartilage volume, cartilage defects, bone marrow lesions and effusion volume over 24 months.

**Abstract FRI0525 – Table 1.** Associations between vitamin K intake quartile and changes in clinical symptoms over 24 months

		Value of change, Mean (SD)	Multivariable*, $\beta$ (95% CI)	P value	P for trend
Total WOMAC Score	Vitamin K intake quartile 1	-112.9 (327.7)	Reference:		<b>0.046</b>

FRI0526

#### THE IMPACT OF DISEASE CHARACTERISTICS IN KNEE AND HIP OSTEOARTHRITIS ON RECOMMENDATIONS FOR JOINT REPLACEMENT

J. Galloway<sup>1</sup>, A. Postler<sup>2</sup>, K. Albrecht<sup>1</sup>, A. Zink<sup>1</sup>, K.-P. Günther<sup>2</sup>. <sup>1</sup>Epidemiology, German Rheumatism Research Centre, Berlin; <sup>2</sup>University Center of Orthopedics and Traumatology, University Medicine Carl Gustav Carus Dresden, TU Dresden, Dresden, Germany

**Background:** Joint replacement in osteoarthritis (OA) is a major reason for hospitalisation in Germany.<sup>1</sup>

**Objectives:** Which factors are associated with recommendations for joint replacement in patients with symptomatic hip and/or knee OA?

**Methods:** A total of 9734 persons, insured in a large statutory health insurance in Germany (Barmer), who had a diagnosis of OA (ICD-10 codes M15 [polyarthrosis], M16 [coxarthrosis] or M17 [gonarthrosis]) in at least two quarters in 2014 were randomly selected, stratified by age, sex and diagnosis (M15/M16/M17). They were contacted by mail and asked to complete a questionnaire regarding sociodemographics, health behaviour, the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC, 0: no impairment- 100: extreme pain/stiffness/difficulty) and whether they had ever discussed total joint replacement (TJR) surgery with a physician. Patient-reported outcomes of the responders ( $n=3,564$ ) were linked to claims data on prescriptions of pain medication and physical therapy. Persons with a diagnosis of M15 ( $n=1,212$ ) were excluded from the present analysis. Patients who reported pain in the corresponding joints were analysed in three groups: OA of the knee, of the hip or of both. Logistic regression models

were used to assess which parameters (age, sex, BMI >30, prescription of opioids or physical therapy, WOMAC, whether the OA was mainly treated by an orthopaedist) were associated with having discussed a TJR.

**Results:** Of 2352 persons with knee or hip OA, 932 had symptomatic OA of the knee, 478 of the hip, 94 of both, and 848 did not report pain in the relevant joint(s). Mean age was 64 to 67 years, 63% to 68% were female and mean BMI was high, especially in patients with knee OA (29 kg/m<sup>2</sup>). 54%–74% had considerable impairment (WOMAC>39). 72%–83% had any pain medication, 12%–25% opioids and 33%–46% physical therapy. 63%–72% were treated by orthopaedists and 45%–50% had discussed TJR. In knee as well as hip and knee OA male sex and an orthopaedist as main treating physician was associated with having discussed a TJR (table 1). Age, WOMAC and opioid prescription was only associated with a higher OR of discussing a TJR in knee OA.

**Abstract FRI0526 – Table 1.** Results from multivariable logistic regression models showing parameters associated with having discussed TJR.

	OR for knee and hip OA (n=94), 95% CI	OR for hip OA (n=478), 95% CI	OR for knee OA (n=932), 95% CI
Orthopaedist is treating	7.2 (1.9,26.8)	1.6 (0.9,2.8)	1.7 (1.1,2.6)
Age, per 10 years	1.0 (0.56,1.8)	1.0 (0.8,1.3)	1.2 (1.1,1.5)
BMI≤30 vs>30	0.9 (0.2,3.6)	1.0 (0.6,1.8)	1.3 (0.9,2.0)
Male vs female	5.3 (1.3,21.8)	1.1 (0.6,1.8)	1.5 (1.1,2.2)
WOMAC, per 10%	1.3 (0.8,1.9)	1.1 (0.9,1.3)	1.3 (1.2,1.5)
Opioids	0.8 (0.1,6.1)	0.5 (0.2,1.2)	1.9 (1.0,3.3)
Physical therapy	1.1 (0.3,3.3)	1.1 (0.6,2.0)	1.2 (0.8,1.7)

**Conclusions:** Disease burden is highest in persons with concomitant knee and hip OA. Men are more likely to discuss TJR with their physician, but not in hip OA. Disease burden and treatment recommendations were only weakly associated. Therefore, other factors may be more important when considering surgery in knee and hip OA.

**Background:** Flexofytol is a Curcuma Longa extract with an increased bioavailability (bio-optimised) by mixing curcuma extract with polysorbate.

**Objectives:** To demonstrate the effects of Flexofytol on OA symptoms and soluble biomarkers.

**Methods:** 141 patients with symptomatic knee OA (mean age 61.8 years [min.45-max.86]; 80.1% female; mean K and L grade of the knee 2.4; mean BMI 29.7 kg/m<sup>2</sup>) were randomised in a prospective double blinded, 3 parallel groups, comparative and multicenter, study (NCT02909621). At inclusion, all patients took pain killers or anti-inflammatory drugs which were authorised during the study. Patients received 6 months continuous treatment with either high dose Flexofytol (n=49, 140.01 mg Curcuma longa L. extract/treatment), low dose Flexofytol (n=47, 93.34 mg Curcuma longa L. extract/treatment) or placebo (n=45, Sunflower seed oil fill ingredient). Each treatment corresponded to 3 oral capsules two

times a day to respect the blinding. All patients had clinical assessment (knee pain, knee function and patient global assessment of disease activity [PGADA]) and blood sampling for biomarkers measurements (usCRP and sColl2-1) at baseline (T0), 1 month (T1), 3 months (T3) and 6 months (T6). Additionally, patient compliance, satisfaction and tolerance were assessed at each timepoint following baseline. Primary outcome was the change at 3 months versus baseline in type II collagen degradation-specific biomarker sColl2-1 and VAS PGADA.

**Results:** Comparison of time evolution curves showed that sColl2-1 levels were lower in the treated groups but differences were not significant. The decrease in PGADA overtime was significantly more important in low dose group than in placebo group only at the 1 month evaluation timepoint (low dose ΔT1-T0, -12.5 mm vs placebo ΔT1-T0, -2 mm, p=0.035). Further, the knee pain relief was significantly higher in low dose group at T1 and T3 than in placebo (low dose ΔT1-T0, -16.5 mm vs placebo ΔT1-T0, -4 mm p=0.046; low dose ΔT3-T0, -36.5 mm vs placebo ΔT3-T0, -8 mm p=0.043). No difference was observed at T6. No differences were seen for any parameter when the high dose group was compared with the placebo group at any time point. The global KOOS score and its subscales significantly decreased overtime but changes were comparable in each group. Additionally, patient compliance was good and patient satisfaction remained stable overtime in each group. The ratio of patients with adverse events (AE) related to the product were similar in placebo and treated groups but the number of AE linked to the product was higher in the high dose group than in placebo (p=0.012).

**Conclusions:** Flexofytol, at a low dose, induced a rapid symptomatic relief on knee pain and a beneficial effect on the patient assessment of disease. This study also provides information on the dose to use and the design of a larger phase III clinical trial.

#### FRI0528 LONG-TERM EFFECTS OF VITAMIN D SUPPLEMENTATION AND MAINTAINING VITAMIN D SUFFICIENCY ON KNEE OSTEOARTHRITIS OVER 5 YEARS

B.S. Eathakkattu Antony<sup>1</sup>, S. Zheng<sup>1</sup>, J. Burgess<sup>2</sup>, C. Ding<sup>1</sup>. <sup>1</sup>Menzies Institute for Medical Research, University of Tasmania; <sup>2</sup>Dept of Endocrinology, Royal Hobart Hospital, Hobart, Australia

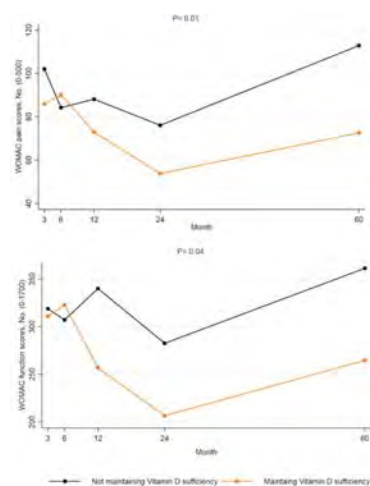

**Background:** Epidemiological studies suggest that vitamin D deficiency is associated with knee symptoms and structural progression of knee osteoarthritis (OA). However, randomised controlled trials (RCTs) failed to demonstrate a significant effect of vitamin D supplementation on OA, probably due to selecting OA participants with and without vitamin D deficiency, short duration of follow-up and a large proportion of participants in the placebo group reaching vitamin D sufficiency (61.3% of patients in the placebo group achieved a serum 25(OH)D level of >60 nmol/L at 3 months of a clinical trial).

**Objectives:** To examine whether those maintaining sufficient serum vitamin D levels over 5 years had reduced knee symptoms compared with those who did not maintain adequate vitamin D levels in patients with knee OA. We also explored the effect of 2 year vitamin D supplementation on knee symptoms compared to placebo after 3 years of cessation of treatment.

**Methods:** Participants with symptomatic knee OA and low 25-hydroxyvitamin D [25(OH)D] (12.5–60 nmol/L) were randomly assigned to receive monthly treatment with oral vitamin D3 (50 000 IU; n=209) or an identical placebo (n=204) for 2 years. 172 participants who enrolled in the study from Hobart were followed up after 3 years (5 years from baseline) of the cessation of the treatment to assess knee symptoms and vitamin D levels. Participants were classified as maintaining sufficient vitamin D group if they maintained serum 25(OH)D>50 nmol/L at month 3, 24 and 60 (n=79), and not maintaining sufficient vitamin D group (25(OH)D≤50 nmol/L at month 3, 26 and 60, n=62) groups. Knee symptoms were assessed at baseline, 3, 6, 12, 24 and 60 month using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC).

**Results:** The level of 25(OH)D dropped in the vitamin D group (87.0 nmol/L to 53.3 nmol/L) and slightly increased (53.3 nmol/L to 61.7 nmol/L) in the placebo group 3 years after the cessation of the treatment. Knee pain increased from the end of the study to 5 years of follow-up in the treatment (81.8 to 91.7) and placebo (75.8 to 101.1) groups. 16.7% of the participants in vitamin D and 18.5% of the participants in placebo group underwent total knee replacement (TKR) surgery. There were no significant differences in WOMAC symptoms, TKR rates or change in symptoms between Vitamin D and placebo groups after 3 years of cessation of the supplementation.

Participants who maintained adequate vitamin D levels over 5 years had significantly less WOMAC knee pain ( $\beta$ : -38.4, 95% CI: -69.2, -7.7) and physical dysfunction ( $\beta$ : -98.5, 95% CI: -193.8, -3.1) than participants with vitamin D deficiency over 5 years in multivariable analyses.

**Conclusions:** Vitamin D supplementation over 2 years did not result in significant differences in change in knee symptom score over 5 years compared to placebo. However, knee OA patients maintaining sufficient serum vitamin D levels over long-term had more improvement in knee pain and physical function than those who did not maintain adequate vitamin D levels, suggesting a beneficial effect of maintaining sufficient serum vitamin D for knee OA.

#### FRI0529 PREOPERATIVE PAIN SEEMS TO MODIFY THE EFFECT OF RADIOGRAPHIC OSTEOARTHRITIS SEVERITY ON POSTOPERATIVE PAIN AND FUNCTION 1 YEAR AFTER TOTAL KNEE ARTHROPLASTY

R. van de Water<sup>1</sup>, C. Leichtenberg<sup>1</sup>, R. Nelissen<sup>1</sup>, H. Kroon<sup>2</sup>, H. Kaptijn<sup>3</sup>, R. Onstenk<sup>4</sup>, S. Verdegaal<sup>5</sup>, T. Vliet Vlieland<sup>1</sup>, M. Gademann<sup>1,6</sup> on behalf of the LOAS Study group. <sup>1</sup>Department of Orthopaedics; <sup>2</sup>Department of Radiology, LUMC, Leiden; <sup>3</sup>Department of Orthopaedics, Lange Land Hospital, Zoetermeer; <sup>4</sup>Department of Orthopaedics, Groene Hart Hospital, Gouda; <sup>5</sup>Department of Orthopaedics, Alrijne Hospital, Leiderdorp; <sup>6</sup>Department of Clinical Epidemiology, LUMC, Leiden, Netherlands

**Background:** Radiographic osteoarthritis (OA) severity and pain play an important role in the indication for total knee arthroplasty (TKA). It is however unknown whether preoperative self-reported clinical pain modifies the effect of radiographic OA severity on postoperative pain and function in OA patients after TKA.

**Objectives:** To investigate whether preoperative self-reported clinical pain modified the effect of radiographic OA severity on postoperative pain and function in OA patients 1 year after TKA.

**Methods:** Data from the Longitudinal Leiden Orthopaedics Outcomes of Osteoarthritis Study (LOAS), a multicentre cohort study on outcomes after TKA were used. Radiographic OA severity was assessed with the Kellgren and Lawrence (KL) score (0–4). Pain and function were evaluated with the Knee Injury and Osteoarthritis Outcome Score (KOOS). After adjustment for confounders (BMI, age, gender and Mental Health Component Scores from the Short Form-12), multivariate linear regression analyses with an interaction term between KL-score and preoperative pain were performed.

**Results:** 560 patients were included. Both KL-score and preoperative pain were associated with postoperative pain ( $\beta$ : 6.1, 95% CI: 1.7–10.5 and  $\beta$ : 0.4, 95% CI 0.1–0.7) and function ( $\beta$ : 8.0, 95% CI: 3.7–12.3 and  $\beta$  0.5, 95% CI 0.2–0.8). A trend towards effect modification of preoperative pain on the association between KL-score and postoperative pain ( $\beta$  -0.1, 95% CI -0.2–0.0) and function ( $\beta$  -0.1, 95% CI -0.2–0.0) was found indicating that effect of preoperative pain on postoperative pain and function seems to become less important when more severe radiographic severity is present.

**Conclusions:** Patients with less preoperative pain and higher KL grades have better function and pain outcomes 12 months after TKA. However preoperative pain seems less important in patients with more severe radiographic OA.

**Acknowledgements:** This study was supported by the Dutch Arthritis Association [grant number LLP13].

#### FRI0530 TOTAL JOINT REPLACEMENT (TJR) AS CLINICAL ENDPOINT IN OA; PREVALENCE AND INCIDENCE RATES OF TJRS FROM THE PROSPECTIVE EPIDEMIOLOGIC RISK FACTOR (PERF I) STUDY

A.C. Bay-Jensen<sup>1</sup>, C. Bager<sup>1</sup>, A. Bihlet<sup>2</sup>, C.S. Thudium<sup>1</sup>, I. Byrjalsen<sup>2</sup>, H. B. Nielsen<sup>2</sup>, J.R. Andersen<sup>2</sup>, B.J. Riis<sup>2</sup>, C. Christiansen<sup>2</sup>, M.A. Karsdal<sup>1</sup>. <sup>1</sup>Rheumatology, Nordic Bioscience Biomarkers and Research; <sup>2</sup>Clinical Development, Nordic Bioscience, Herlev, Denmark

**Background:** Osteoarthritis (OA) is a heterogeneous disease described by a combination of joint pain, physical disability and radiographic alterations leading to joint failure and total joint replacement (TJR). Commonly used endpoints in OA trials are worsening of pain and joint space narrowing. TJR is normally not considered an endpoint. Age and female gender are considered as major risk factors for developing OA.

**Objectives:** We hypothesise that TJR can be used as an endpoint in OA outcome studies within reasonable time frame. To investigate the basis for this hypothesis, we explored the prevalence and incidence of TJR as a reflection of joint failure in the Prospective Epidemiologic Risk Factor (PERF I) study.

**Methods:** A total of 5,855 Danish postmenopausal women aged 49–88 enrolled in the Prospective Epidemiologic Risk Factor (PERF I) study during 1999–2001 (baseline). Three, six and twelve year follow-up data from the Danish National registry was collected in end of 2014, including occurrence of TJR, OA and other relevant diagnosis. Also, women where at baseline and in 2014 asked whether they had a TJR or OA. The biomarker C1M was measured in baseline serum samples. The PERF I study was carried out in accordance with ICH-GCP and the study protocol was approved by the local ethics committees.

**Results:** There were 798 women that had their first TJR between baseline and 12 year follow-up; giving an incidence proportion of 13.6%. The TJR women were on average 1 year older ( $p=0.010$ ) and heavier (1.7 kg/cm<sup>2</sup>,  $p<0.0001$ ), compared to women with no TJR in the follow-up period. The incidence after three and six years, of first ever TJRs, were 171 and 362 corresponding to an incidence proportions of 2.9% and 6.2%. Next we investigated the TJR incidence rates at 3, 6 and 12 years in different subgroup of women: 1) All, PERF I women that experience their first ever TJR (5855); 2) Prior TJR, had a TJR before baseline (266); 3) OA diagnose at baseline but no prior TJR (1757) and 4) OA diagnose at baseline and high C1M (>40 ng/mL, median) that after baseline underwent their first ever TJR (841). Group 1 is as described above. The 3, 6 and 12 incidence rates were 9.0, 17.3% and 29.7% for the prior TJR group, 6.2, 12.1% and 23.3% for the OA group, and 7.6, 13.6% and 25.1% for the OA +C1M group. The age-dependent prevalence and incidence for the first TJR. The prevalence was insignificant for the age group younger than 60 years old (<0.1%). The prevalence increased steadily from the age group 60 to age group 85; from 0.1% to 13.2%.

**Conclusions:** Within a timeframe of 3, 6 or 12 years TJR incidence for women with an OA diagnosis reached 6, 12% and 23%, which was a doubling compared to the All population. The incidence increased by adding a single diagnostic measure. This reflects that TJRs are frequent amongst elderly women and that if designed minutiously, such as including specific diagnostic criteria (e.g. biomarker, OA diagnose), it may be feasible to conduct clinical studies with TJR as an endpoint. However, special attention must be directed to the objectiveness of the criteria for TJR. This may build a case for design of outcome studies (joint failure) for developing drugs in OA.

FRI0531

**DETERMINANTS OF CLINICAL AND RADIOLOGICAL PROGRESSION OF HAND OSTEOARTHRITIS OVER 2 YEARS**

A. Neuprez<sup>1</sup>, A.H. Neuprez<sup>1</sup>, E. Maheu<sup>2</sup>, O. Bruyère<sup>1</sup>, J.-F. Kaux<sup>3</sup>, J.-Y. Reginster<sup>1</sup>.  
<sup>1</sup>Department of Public Health, UNIVERSITY OF LIÈGE, Liège, Belgium;  
<sup>2</sup>Rheumatology, AP-HP, Saint-Antoine Hôpital, Paris, France; <sup>3</sup>Rehabilitation and Sports Traumatology Department, University Hospital of Liège, Liège, Belgium

**Objectives:** The objectives of this prospective observational study were to assess the clinical and radiological changes in hand osteoarthritis (HOA) and to identify the determinants of these changes, over a two year period.

**Methods:** 203 patients were included in Liège Hand Osteoarthritis Cohort (LIHOC) and followed during 2 years. They met the American College of Rheumatology x-ray/clinical criteria for HOA. At baseline, demographic and clinical characteristics of the population were recorded. Various radiological and clinical parameters were selected to investigate progression.

**Results:** The general health measures remained stable over time. The number of nodes increased significantly over 2 years while the other clinical parameters did not vary significantly over time (number of painful joints at rest or at pressure and swollen joints). The pinch force decreased over time and the grip strength remained stable. The two tools assessing function (FIHOA and AUSCAN), showed a progressive deterioration over time (statistically significant for FIHOA ( $p < 0.05$ ) and borderline ( $p = 0.17$ ) significant for the AUSCAN). Almost all patients showed radiologic change during follow-up. Thus, the radiological scores deteriorated significantly over 2 years. An increase in Verbruggen and KL scores was present in 162 (92.04%) and 174 (98.86%) patients, respectively. 39 patients (22.16%) had new erosive joints.

From a clinical perspective, using backward logistic regression, diabetes (OR 2.67%–95% CI 1.13–6.33,  $p = 0.03$ ), high degree of radiologic severity (OR 1.23%–95% CI 1.09–1.39,  $p < 0.01$ ) and age between 40 and 60 (OR 2.67%–95% CI 1.21–5.90,  $p = 0.02$ ) at baseline are predictors of FIHOA worsening over-time. The predictors of AUSCAN progression included the pain intensity (OR 0.98%–95% CI 0.97–0.99,  $p < 0.01$ ) and the degree of radiologic severity (OR 1.06%–95% CI 1.01–1.12,  $p = 0.03$ ) at baseline.

The following factors are associated with radiological deterioration: symptomatic HOA (OR 2.17%–95% CI 1.04–4.51,  $p = 0.04$ ) and the number of severely affected joints at baseline (OR 1.11%–95% CI 1.04–1.18,  $p < 0.01$ ). In contrast, a high number of erosive or remodelled joints (OR 0.89%–95% CI 0.81–0.98,  $p = 0.02$ ) reduce the risk of radiological disease progression.

**Conclusions:** These results help to better understand the clinical and radiologic progression of HOA, as well as the determinants that have resulted in them.

FRI0532

**RELATIONSHIP BETWEEN PATIENT-REPORTED OUTCOMES AND PROPRIOCEPTIVE ACUITY IN PATIENTS WITH TOTAL KNEE ARTHROPLASTY**

B. Ünver<sup>1</sup>, M. Eymir<sup>1</sup>, V. Karatosun<sup>2</sup>. <sup>1</sup>School of Physical Therapy and Rehabilitation; <sup>2</sup>Department of Orthopaedics and Traumatology, School of Medicine, Dokuz Eylul University, Izmir, Turkey

**Background:** Total knee arthroplasty (TKA) is offered to patients who have end-stage knee osteoarthritis (OA) to reduce pain and improve functional performance. Pain and functional level in patients with TKA can be measured using self-report questionnaires such as the Numeric Pain Rating Scale (NPRS), Hospital for Special Surgery (HSS), Iowa Level of Assistance Scale (ILAS), and Iowa Ambulation Velocity Scale (IAVS). Proprioception plays an integral role in neuro-motor control of the knee joint and deficits in knee joint proprioception are well documented in individuals with knee osteoarthritis. However, the patient-reported functional level relevance of these deficits is not clear in both individuals with knee OA and with TKA.

**Objectives:** The aim of this study was to assess relationship between pre-/post-surgery patient-reported outcomes and proprioceptive acuity in patient with TKA due to knee OA.

**Methods:** The study group consisted of 68 patients (12 males, 56 females), who underwent primary TKR because of knee arthrosis were included in the study with mean age  $64.9 \pm 9.1$  years. Patients were evaluated regarding the knee proprioception (in knee joint angle  $15^\circ$ ,  $30^\circ$ ), pain (NPRS), HSS knee function score. Functional activities were evaluated using the ILAS and walking speed was evaluated using the IAVS. Patients were evaluated preoperatively and at discharge. All patients underwent the same rehabilitation program.

**Results:** While there were correlations in different rates in individuals with knee OA between patient-reported outcomes and proprioceptive acuity, there were no

correlations in individuals with TKA between patient-reported outcomes and proprioceptive acuity. Preoperatively, low-to-moderate significant correlations was found between pain and proprioceptive acuity deficit scores in knee joint angle  $15^\circ$ ,  $30^\circ$  ( $r = -0.196$ ,  $p = 0.046$  and  $r = -0.378$ ,  $p < 0.001$ , respectively). There were low significant correlations preoperatively between HSS knee score and proprioceptive acuity deficit scores in knee joint angle  $15^\circ$ ,  $30^\circ$  ( $r = 0.217$ ,  $p = 0.027$ , and  $r = 0.275$ ,  $p = 0.005$ , respectively). There were not significant correlations between proprioceptive acuity deficit scores and all other evaluation tests ( $p > 0.05$ ).

**Conclusions:** There were correlations in different rates in patients with knee OA between patient-reported outcomes and proprioceptive acuity, however there were no correlations in patients with TKA between patient-reported outcomes and proprioceptive acuity. These results suggest that patients who have knee OA and with poor proprioception show more limitation in functional ability and have more pain level. On the other hand, deficits in joint position sense in patients with TKA may be due to factors other than pain and functional disability. Poor proprioception in patients with TKA may be due to surgery related resection of articular cartilage, meniscuses, articular ligaments.

**ASIAN MITOCHONDRIAL DNA HAPLOGROUP B IS ASSOCIATED WITH THE DEVELOPMENT OF KNEE OSTEOARTHRITIS IN KOREAN**

B.S. Koo<sup>1</sup>, Y. Song<sup>2</sup>, S. Lee<sup>2</sup>, Y.-K. Sung<sup>3</sup>, K.-J. Shin<sup>4</sup>, N.H. Cho<sup>5</sup>, J.-B. Jun<sup>3</sup>.  
<sup>1</sup>Department of Internal Medicine, Inje University Seoul Paik Hospital, Inje University College of Medicine; <sup>2</sup>Department of Radiology; <sup>3</sup>Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases; <sup>4</sup>Department of Forensic Medicine, Yonsei University College of Medicine, Seoul; <sup>5</sup>Department of Preventive Medicine, Ajou University School of medicine, Suwon, Korea, Republic Of

**Background:** In our previous study, we have conducted a case-control study to demonstrate the mitochondrial DNA (mtDNA) haplogroups in the development of knee osteoarthritis (OA). However, there were no mtDNA haplogroups associated with the development of knee OA.

**Objectives:** The objective of this study was to elucidate the role of mtDNA haplogroups in the development of knee OA in prospective on-going community-based cohort.

**Methods:** This cohort was established in 2001 to investigate the epidemiologic characteristics of major chronic diseases in Korea by the Korean Genome and Epidemiology Study, Centre for Disease Control (KCDC). The epidemiologic data and knee radiographs were obtained from the second follow-up (2005–2006) and the sixth follow-up (2013–2014), and DNA was distributed from the fourth follow-up (2009–2010). The Kellgren-Lawrence (K/L) score was measured using a knee X-ray taken at each visit. The mtDNA was analysed by multiplex mutagenetically separated polymerase chain reaction to determine the mtDNA haplogroups (M, G, D, D4, D5, M7, M8, M9, M10, N, A, N9, R, F, B). The frequency of the mtDNA haplogroup was compared between the group with knee OA ( $K/L \geq 2$  or underwent total knee replacement arthroplasty) and the group without knee OA ( $K/L < 2$ ) at the 6th follow-up in the cohort of  $K/L = 0$  at the second follow-up. Multiple logistic regression was used to determine relative risk (RR) of mtDNA haplogroups for OA by adjusting sex, age, and body mass index (BMI).

**Results:** A total of 1115 epidemiological data, knee radiographs, and DNA samples were distributed. Of these, 572 were cohorts with  $K/L = 0$  in the second follow-up, and 438 underwent knee X-ray examination at the sixth follow-up visit. Among them, 160 were classified as Knee OA by K/L grading and 278 were classified as control group. The mean age ( $59.4 \pm 8.5$  and  $64.3 \pm 6.8$ ), the number of male patients (61 [21.9%] and 11 [6.9%]), and the mean BMI ( $24.0 \pm 3.1$  and  $25.0 \pm 3.0$ ) were significantly different between normal and OA group ( $p < 0.001$ ). In comparison of frequency of mtDNA haplogroup between two groups, haplogroup B was significantly higher in OA group (unadjusted  $RR = 1.794$ ,  $p = 0.030$  and adjusted  $RR = 2.346$ ,  $p = 0.005$ ).

**Conclusions:** Our data suggested that mtDNA haplogroup B contributed to the development of knee OA in Korean. Further study is ongoing to confirm the relationship between the progression of knee OA and mtDNA haplogroups.

FRI0534

### RADIOGRAPHIC OUTCOMES WERE ASSOCIATED WITH PAIN AND FUNCTION RESPONSES: POST-HOC ANALYSIS FROM A PHASE 2 STUDY OF A WNT PATHWAY INHIBITOR, SM04690, FOR KNEE OSTEOARTHRITIS TREATMENT

C. Swearingen<sup>1</sup>, J. Tambiah<sup>1</sup>, A. Gibofsky<sup>2</sup>, N. Lane<sup>3</sup>, T. McAlindon<sup>4</sup>, M. Hochberg<sup>5</sup>. <sup>1</sup>Samumed, LLC, San Diego; <sup>2</sup>Hospital for Special Surgery, New York; <sup>3</sup>UC Davis Medical Center, Davis; <sup>4</sup>Tufts Medical Center, Boston; <sup>5</sup>University of Maryland School of Medicine, Baltimore, USA

**Background:** SM04690, a small molecule intra-articular (IA) Wnt pathway inhibitor is in development as a potential disease modifying knee osteoarthritis drug. A phase 2, 52 week, randomised controlled trial evaluated changes in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain and Function and medial joint space width (mJSW). It was hypothesised that observed mJSW increases led to WOMAC subscore responder improvements. To address this question, a concordance analysis was performed.

**Objectives:** To evaluate concordance, or level of agreement, between mJSW and WOMAC Pain and Function 'responders.'

**Methods:** Subjects with ACR-defined knee OA, Kellgren-Lawrence (KL) grades 2–3, received 2 mL IA SM04690 (0.03, 0.07, or 0.23 mg) or placebo (PBO) in the target (most painful) knee. WOMAC Pain [0–50] and Function [0–170] were assessed at Weeks 0, 4, 13, 26, 39 and 52 and knee radiographs at Weeks 0, 26 and 52. Baseline-adjusted logistic regression group analyses estimated concordance between mJSW change and pain and function changes for responders who achieved both WOMAC Pain and Function improvements of >50% and >20 [scaled to 100] points. Receiver-operator characteristic (ROC) curves were generated with area under curve (AUC) to estimate concordance (AUC >0.7='acceptable' and >0.8='excellent' concordance<sup>1</sup>). ITT and two subgroups were analysed: 1) unilateral symptomatic knee OA (pre-specified: UNI) and 2) unilateral symptomatic knee OA without widespread pain or comorbid symptoms (Widespread Pain Index≤4 and Symptom Severity≤2, post-hoc: UNI-WP).

**Results:** 455 subjects were enrolled (mean age 60.3 [±8.7] years, BMI 29.9 [±4.6] kg/m<sup>2</sup>, 268 [58.9%] female, 292 [64.2%] KL Grade 3, 164 [36.0%] UNI knee OA).

In the ITT, approximately 53% were responders across all groups. In UNI, 20 (56%) 0.03 mg; 20 (63%) 0.07 mg; 23 (64%) 0.23 mg and 15 (47%) PBO, and in UNI-WP, 15 (56%) 0.03 mg; 16 (62%) 0.07 mg; 19 (70%) 0.23 mg and 12 (44%) PBO were responders. The 0.03 mg (UNI, NS; UNI-WP, p=0.047) and 0.07 mg (UNI, p=0.009; UNI-WP, p=0.013) doses also demonstrated increased mJSW compared to PBO at Week 52.

In ITT, no treatment group achieved AUC >0.7 (figure 1). In UNI, the 0.07 mg dose demonstrated 'acceptable' concordance between response and mJSW (AUC=0.783). In UNI-WP, the 0.07 mg dose showed 'excellent' concordance (AUC=0.825).

**Abstract FRI0534 – Figure 1.** ROC Curves Illustrating Concordance between WOMAC Pain and Function Response and mJSW Change by Treatment Group and Analysis Group

**Conclusions:** In this post-hoc analysis, treatment with SM04690 maintained or increased mJSW in the 0.03 and 0.07 mg doses compared to PBO over 52 weeks. In UNI and UNI-WP 0.07 mg cohorts, changes in mJSW were concordant with WOMAC Pain and Function response.

### THE CLINICAL AND RADIOGRAPHIC EARLY COURSE OF KNEE AND HIP OSTEOARTHRITIS OVER 10 YEARS IN CHECK (COHORT HIP AND COHORT KNEE)

D. Schiphof<sup>1</sup>, J. Runhaar<sup>1</sup>, J. Waarsing<sup>2</sup>, W. van Spij<sup>3</sup>, M. van Middelkoop<sup>1</sup>, S. Bierma-Zeinstra<sup>4</sup>. <sup>1</sup>Department of General Practice; <sup>2</sup>Department of Orthopaedics, ERASMUS MC, Rotterdam; <sup>3</sup>Department of Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht; <sup>4</sup>Department of General Practice and Department of Orthopaedics, ERASMUS MC, Rotterdam, Netherlands

**Background:** Osteoarthritis (OA) is the most prevalent joint disease and one of the leading causes of chronic pain and disability worldwide. Yet, relatively little is known about the early course of OA.

**Objectives:** To describe the clinical and radiological early course of hip and/or knee OA.

**Methods:** CHECK (Cohort Hip and Cohort Knee) is a multicenter, prospective observational cohort study of 1002 participants. Inclusion criteria were: 1) age 45–65 years at the time of inclusion, 2) pain in knee(s) and/or hip(s), 3) never or not longer than 6 months ago for the first time consulted a physician for these symptoms. Participants were included through general practitioners and advertisements. Visits took place at baseline, and at 2, 5, 8, and 10 year follow-up (T0, T2, T5, T8 and T10). At each visit, questionnaires, including joint pain presence (Numeric rating score, NRS), morning stiffness, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), were inquired, and physical examination, and x-ray imaging were performed. Clinical OA was defined by the clinical American College of Rheumatism (ACR) criteria. Radiographic OA (ROA) was defined as Kellgren and Lawrence score (K and L) of ≥2.

**Results:** 1002 participants (age 56±5 years (mean ±sd); 79% female; BMI 26±4 kg/m<sup>2</sup>) were included. 83% reported knee pain at baseline, 59% reported hip pain, and 42% reported both. 10 year follow-up data were complete for 85% of the participants. The total WOMAC score showed a median of 21 (range 0–80) at baseline and remained rather constant over time (T2=20 (0–83); T5=20 (0–86); T8=19 (0–88); T10=19 (0–81)). The same was observed for pain (NRS). At baseline, 520 participants fulfilled the clinical ACR criteria for knee and/or hip OA. Of these, only 91 (17.5%) participants subsequently fulfilled the ACR criteria at every follow-up visit. 138 participants did never fulfil the clinical ACR criteria for hip or knee OA. At baseline, 157 participants showed ROA in on or both knees and 161 participants showed ROA in on or both hips. After 10 years follow-up, 601 (60%) participants had ROA in one or both knees and 513 (51%) participants had hip ROA in one or both hips. Of those with hip OA in at least one hip, 256 (50%) had bilateral knee ROA at T10. Of the participants with knee OA in at least one knee, 256 (43%) had bilateral hip ROA at T10. Most joint replacements took place between 2 and 8 years follow-up (11 knees, 29 hips), predominantly in participants with multiple affected joints. Only 115 (13.5%) participants did not develop ROA of knee or hip.

**Conclusions:** Although mean pain scores remain fairly stable over time, individual scores tend to fluctuate over time. Therefore, only few participants constantly fulfil the clinical criteria for OA. More than half of the participants had ROA after 10 year follow-up and a large overlap of knee and hip ROA was observed. Numbers of joint replacements were highest in participants developing both hip and knee OA.

**Disclosure of Interest:** None declared

FRI0536

### PREGABALIN EFFICACY IN TREATMENT OF CHRONIC PAIN IN PATIENTS WITH KNEE OSTEOARTHRITIS

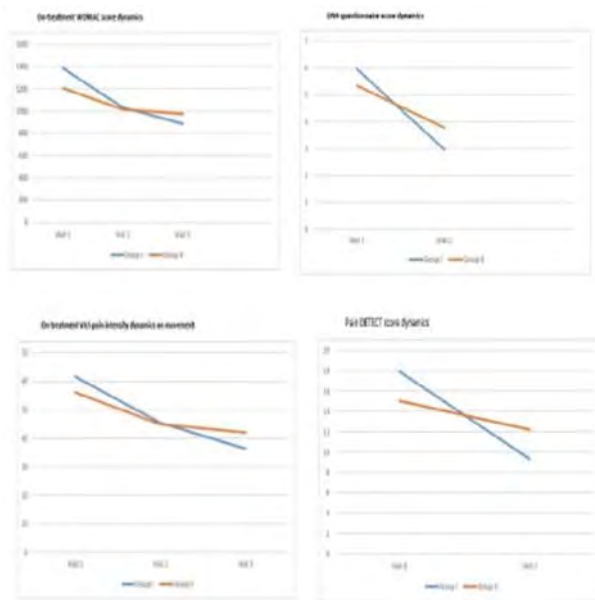

E. Filatova, E. Turovskaya, L. Alekseeva, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

**Background:** Modern methods of treatment of osteoarthritis have mainly anti-inflammatory action. A few studies show the effectiveness of centrally acting drugs for chronic pain in osteoarthritis (OA) of the knee.

**Objectives:** To study the efficacy of Pregabalin in treatment of chronic pain in patients with knee OA.

**Methods:** The study involved 60 female patients with knee OA having neuropathic pain component (NPC; DN4 >4). Mean age 59.82±4.46 y (min 49, max 65 years). All patients were randomly divided into two groups to be treated with 2 therapeutic regimens: aceclofenac +pregabalin (Group I) or aceclofenac (Group II) for 5 weeks (3 visits). All patients were subjected to clinical and neurological examination, total WOMAC score assessment, verification of neuropathic pain (NP) (questionnaire DN4 and Pain DETECT), and VAS pain intensity assessment at rest.

**Results:** The therapy was successful in both groups with respect to WOMAC score [figure 1] (Group I – 1385,30±365,83 vs 1034,70±402,37 vs 886,64 ±456,31; Group II – 1206,04±358,72 vs 1016,45±428,52 vs 976,55 ±408,02 respectively, p=0.01). Significant reduction of pain intensity at rest was documented in both groups [figure 2]. Group I 61,60±14.91 vs 45,34±16,14 vs 36,24±18,09; Group II 56,07±22,58 vs 44,86±18,68 and vs of 41,96±of 24.04, p=0.01, respectively). Therapeutic regimens in both groups had positive impact on NPC based on DN4 questionnaire and Pain DETECT scores. However, a combination of a NSAID with anticonvulsants agent (pregabalin) resulted in a more pronounced effect. Changes in DN4 values in Group I (visit1/visit3) were: 5.97 ±1,24/2,97±1,83 p=0.001; and in Pain DETECT values – 17,93±3,87/9,34±6,18, p=0.001; while in Group II DN4 scores were 5,35±0,93/3,79±2,29, p=0.001; and Pain DETECT – 15,03±5,26/12,24±6,29 p=0.02. [figures 3–4]

**Conclusions:** Complex therapy with the use of Pregabalin in patients with OA of the knee, with signs of NPC, allows not only effectively reduce pain intensity and improve functional activity of patients and, consequently, the quality of life.

**Disclosure of Interest:** None declared

#### FRI0537 NEUROPHYSIOLOGICAL DATA IN PATIENTS WITH CHRONIC PAIN IN KNEE OSTEOARTHRITIS

E. Turovskaia<sup>1</sup>, L. Alekseeva<sup>1</sup>, E. Filatova<sup>2</sup>, C. Chimenti<sup>3</sup>. <sup>1</sup>laboratory of osteoarthritis, V.A. Nasonova Research Institute of Rheumatology; <sup>2</sup>I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; <sup>3</sup>IOOF Senior's Homes Inc, Barrie, Canada

**Background:** Traditionally, chronic pain in OA is considered to be a classical model of nociceptive pain. Nociceptive mechanism can't explain the presence: referred pain, secondary hyperalgesia and other sensitive phenomena.<sup>1</sup> Recent studies has shown that besides nociceptive pain there is another mechanism that takes place in chronic pain OA –central sensitisation.<sup>2</sup> Explore of chronic pain OA can be reached only by a complex approach in examining patients with chronic knee OA that includes not only a rheumatological examination, but examination of the neurological sphere and algometria. At the moment there are only few studies dedicated to neurophysiological changes in pain OA<sup>3</sup>

**Objectives:** to assess pain system with neurophysiological examination in chronic pain OA

**Methods:** 46 chronic knee pain OA and 23 healthy group control women, 45–65 years old, were included. The study included clinical rheumatologic, neurological examinations, neuropathic pain scales (DN4 and Pain DETECT). Knee X-ray and

ultrasound studies. Neurophysiological examination included algometria with algometer and wind-up phenomena observed by Neuropen. Five test sites in the peripatellar region and one control site on tibialis anterior (5 cm distal to the tibial tuberosity) were located and marked for examination

**Results:** Neuropathic pain scales demonstrated neuropathic descriptors present in OA patients. Neurological examination revealed no somatosensory deficit. But examination of the sensitive sphere indicated hyperalgesia: primary hyperalgesia (increased sensitivity to pain in the damaged joint) and secondary hyperalgesia. Algometria revealed low pressure pain threshold (PPT) above injured knee and intact region compared with healthy group. (tab.1) PPT in intact region was compared between OA patients and control group by ROC-analysis. Max of PPT in intact region in patient with OA was –14,70, min – 1,80, mean value – 7,34. Mean value of PPT in control group was 15,18. Area under curve was- 0888. Sensitivity – 70%. Specificity – 83%. ROC-analysis demonstrated that low PPT in OA patients is a specific feature of central sensitisation (figure 1) Wind-up phenomena examination in intact region revealed significant difference of data in OA patients with referred pain and control group (4,3±2,1 vs 2,44±1,3 p=0,003)and OA patients without referred pain and control group (3,67±1,43 vs 2,44±1,3 p=0,011).

PPT data	OA patients n=46	Control group n=23	P
V1	7,04±2,92	15,13±5,08	0000
V2	8,41±4,39	14,86±4,5	0001
V3	7,75±3,45	16,08±4,97	0000
V4	4,57±2,2	11,27±4,98	0000
V5	4,41±2,1	10,7±4,8	0000
V6	7,34±3,66	15,18±5,07	0000

Diagonal segments are produced by ties.

Figure 1 Diagonal segments are produced by ties.

**Conclusions:** Chronic OA is a complex of mechanisms and includes nociceptive and central sensitisation. Neurophysiological changes: low ppt in demaged area and even intact region and wind-up phenomena were revealed in all OA patients and charecterises central sensitisation. Mechanism-oriented treatment should also target CNS, including anticonvulsant, and antidepressant agents.

**STRUCTURAL EFFECTS OF INTRA-ARTICULAR SPRIFERMIN IN SYMPTOMATIC RADIOGRAPHIC KNEE OSTEOARTHRITIS: A POST-HOC ANALYSIS OF CARTILAGE AND NON-CARTILAGINOUS TISSUE ALTERATIONS OF THE 2-YEAR DATA FROM A 5-YEAR RANDOMISED, PLACEBO-CONTROLLED, PHASE II STUDY**

F. Roemer<sup>1,2</sup>, J. Kraines<sup>3</sup>, A. Aydemir<sup>3</sup>, S. Wax<sup>4</sup>, M. Crema<sup>2</sup>, M. Hochberg<sup>5</sup>, A. Guermazi<sup>2</sup>. <sup>1</sup>Radiology, University of Erlangen-Nuremberg, Erlangen, Germany; <sup>2</sup>Radiology, Boston University School of Medicine, Boston; <sup>3</sup>EMD Serono, Billerica; <sup>4</sup>EMD Serono, Cambridge; <sup>5</sup>Rheumatology, University of Maryland, Baltimore, USA

**Background:** Sprifermin, a recombinant human fibroblast growth factor 18, is currently being investigated as a potential disease-modifying osteoarthritis (OA) drug. Recently, a dose-dependent increase in femorotibial cartilage thickness, as well as medial and lateral compartment cartilage, over two years was reported<sup>1</sup>.

**Objectives:** The aim of this post-hoc analysis is to evaluate potential effects of sprifermin on additional structure endpoints, based on semi-quantitative MRI assessment over 24 months.

**Methods:** Patients aged 40–85 years with symptomatic radiographic knee OA, KLG 2 or 3, and medial mJSW  $\geq 2.5$  mm in the target knee were randomised (1:1:1:1) to receive double-blinded placebo or sprifermin (30  $\mu$ g or 100  $\mu$ g), administered as 3 weekly intra-articular injections in cycles every 6 or 12 months. 1.5T or 3T MRIs were acquired at baseline, 6, 12, 18 and 24 month follow-up visits using a standard protocol (ClinicalTrials.gov identifier: NCT01033994).

MRIs were read using the Whole-Organ Magnetic Resonance Imaging Score (WORMS) system (time points of baseline, 12 and 24 months) by three trained musculoskeletal radiologists. Analyses of all sprifermin and placebo arms included multiple MRI-defined osteoarthritis features and multi-dimensional assessments: (a) delta-subregional approach (the difference in the *number of subregions* with worsening as compared to improvement) and (b) delta-sum approach (absolute *scores of all subregions*). Analyses were performed on a whole knee level and separately for medial, lateral, and patellofemoral compartments. To test for potential dose-response effects, Jonckheere-Terpstra (asymptotic) test was used. P-values were not adjusted for multiple testing.

**Results:** 549 patients were included. Dose-dependent treatment effect on cartilage morphology (i.e., less cartilage damage) was observed for the entire knee from baseline to 24 months using both delta sum and delta subregion approaches (table 1). For bone marrow lesions (BMLs), a dose-dependent treatment effect (improvement of BMLs) was observed from baseline to 24 months for the patellofemoral joint using both delta sum and delta subregion approaches but not the other compartments (table 2). No significant effects were seen for baseline to 24 month changes in Hoffa-synovitis, effusion-synovitis, menisci, or osteophytes.

**Conclusions:** This post-hoc analysis indicates that sprifermin has a positive effect on cartilage morphology, in addition to the previously reported effect on cartilage thickness. Sprifermin was also associated with BML improvement in the patello-femoral joint. There were no significant effects associated with sprifermin on other joint tissues assessed, and no safety concerns raised.

**A SAFETY, TOLERABILITY, PHARMACOKINETICS (PK) AND PHARMACODYNAMICS (PD) STUDY WITH INCREASING ORAL DOSES OF GLPG1972 ADMINISTERED DAILY FOR 29 DAYS SHOWS A STRONG BIOMARKER EFFECT IN PATIENTS WITH KNEE AND/OR HIP OA**

H.M. Deckx<sup>1</sup>, S. Hatch<sup>1</sup>, M. Robberechts<sup>1</sup>, S. Dupont<sup>2</sup>, J. Desrivot<sup>3</sup>, H. Coleman<sup>4</sup>, S. Larsson<sup>5</sup>, A. Struglics<sup>2</sup>, E.M. van der Aar<sup>1</sup>, A. Fiew<sup>1</sup>. <sup>1</sup>Clinical Development, Galapagos NV, Mechelen, Belgium; <sup>2</sup>Translational Science, Galapagos SASU, Romainville, France; <sup>4</sup>CRU, Covance, Daytona Beach, USA; <sup>5</sup>Clinical Sciences, Lund University, Lund, Sweden

**Background:** Osteoarthritis (OA) is characterised by structural changes of the joint, of which degradation of articular cartilage is one of the major signs<sup>1</sup>. The main proteoglycan component of the extracellular matrix of articular cartilage is aggrecan. GLPG1972 as a potent and selective inhibitor of ADAMTS-5, a key aggrecan-cleaving enzyme involved in cartilage degradation, is being developed as a potential disease-modifying OA drug (DMOAD). Aggrecan cleavage by ADAMTS-5 results in release of N-terminal ARGS neo-epitope fragments of which serum levels significantly decreased in healthy subjects treated with GLPG1972 during 14 days in a previous study<sup>2</sup>.

**Objectives:** To assess safety, tolerability, PK and PD (serum ARGS-aggrecan levels) during and following administration of GLPG1972 in patients with knee and/or hip OA.

**Methods:** This was a single centre, randomised, double-blind, placebo-controlled, age and gender stratified, ascending dose Phase Ib study, with three semi-sequential cohorts of 10 patients each, randomised to active drug or placebo in a 4:1 ratio. Doses tested were once daily 100, 200 and 300 mg. Treatment duration was 29 days. Patients had follow-up visits 14 and 21 days after last dosing for additional PD assessments. Methods for PD have been described previously<sup>3</sup>.

**Results:** Thirty patients were included. Of these, 24 patients (M/F rate 8/16, 14 aged 50–64 and 10 aged 65–75) received active medication.

All adverse events (AE) were mild and transient. No serious AEs were reported during the study; one female patient in the 300 mg group was discontinued after 15 days of treatment due to drug-related elevated transaminase values which returned to normal 9 days later while her bilirubin levels remained normal. There were no overall trends in lab abnormalities over time or significant changes in vital signs, ECG and Holter parameters.

Steady state in plasma exposure was reached after 3 days of dosing. Exposure increased dose-proportionally. Mean serum ARGS levels (SEM) decreased steadily over time in all patients receiving GLPG1972: -40% (2.9), -46% (4.5) and -53% (2.8) at day 15 compared to baseline in the 100, 200 and 300 mg group respectively. These levels remained stable until last dose on day 29, then consistently returned to pre-dose levels for all groups 14 and 21 days after last dose. Placebo group levels remained unchanged.

**Conclusions:** When administered daily for 29 days in patients with knee and/or hip OA, GLPG1972 at oral doses of 100, 200 and 300 mg q.d. was generally well tolerated and safe. Serum ARGS levels, as a marker for target engagement and potential proxy of cartilage degradation, showed a dose-dependent decrease over time up to 53% below baseline in the 300 mg group. These PK-PD findings are consistent with what we observed in a previous study in healthy subjects<sup>2</sup> and reinforce the rationale for developing GLPG1972 as a DMOAD.

#### FRI0540 IDENTIFICATION OF BIOMARKERS OF OA ASSOCIATED TO DEFECTIVE AUTOPHAGY

I. Lorenzo-Gomez<sup>1</sup>, N. Oreiro<sup>2</sup>, J.A. Pinto-Tasende<sup>2</sup>, F.J. Blanco<sup>1,2</sup>, B. Carames<sup>1</sup>.  
<sup>1</sup>Rheumatology Division. Cartilage Biology Group, The Institute of Biomedical Research of A Coruña (INIBIC); <sup>2</sup>Clinical Rheumatology Division, Complejo Hospitalario Universitario A Coruña (CHUAC), A coruña, Spain

**Background:** In osteoarthritis (OA), defects in cellular homeostasis, and in particular in autophagy, are evident and precede joint damage. In this sense, we have shown that there is a defect in autophagy in OA human chondrocytes and cartilage, and pharmacological activation of autophagy protects against joint damage. These data suggest that joint damage could be due, at least in part, to a failure of autophagy, by inducing an abnormal accumulation of cellular products related to disease.

**Objectives:** These observations represent a unique opportunity to identify and validate potential biomarkers associated with autophagy defects that could facilitate the development of therapeutic strategies to prevent OA progression.

**Methods:** A comparative analysis of 86 autophagy genes was performed in blood from non-OA and knee OA patients. Non-OA patients (Age: 61,17±1,370 years; BMI: 25,76±0,69; Sex: Females; n=12) and Knee OA patients (Age: 65,75±1,528 years; BMI: 30,25±0,88; Sex: Females; n=12, OA grade III-IV) were profiled using a human autophagy PCR array (PrimePCR autophagy human panel, BioRad) and analysed using the PrimePCR analysis software, Biorad. In addition, we performed a quantitative proteomic analysis of defective autophagy by genetic deletion of Atg5 in human OA chondrocytes by using iTRAQ (isobaric tags for relative and absolute quantitation) labelling coupled with on-line 2D LC/MS/MS. Protein identification and quantification were performed using Protein Pilot Software 4.0. Each MS/MS spectrum was searched in the Uniprot/Swissprot database for *Homo sapiens*.

**Results:** 16 autophagy-related genes were significantly down-regulated in blood from knee OA patients compared to non-OA patients. No significant up-regulation was observed in blood from Knee OA patients, however a trend-toward up-regulation was detected in several genes involved in the mTOR signalling pathway. Importantly, 5 key autophagy-related genes, such as, ATG16L2, ATG12, ATG7, ATG4B and MAP1LC3B involved in initiating autophagy, phagophore extension and autophagosome formation were significant downregulated in knee OA patients compared to non-OA patients (p<0.05). Interestingly, HSP90AA1 and HSPA8, a chaperone-mediated autophagy genes involved in stress response and protein folding, were significant downregulated (p<0.001) in blood from knee OA patients. In addition, several regulators of autophagy and apoptosis, such as BNIP3, BCL-2 and BCL2L1 were a significantly downregulated in OA patients (p<0.01). Total proteome screening in human OA chondrocytes with defective autophagy, showed a significant reduction of Heat shock protein HSP90-alpha (HSP90A1) (p<0.05), suggesting that reduced autophagy is associated to OA pathology and could be a potential biomarker for OA progression and development.

**Conclusions:** This approach represents a unique opportunity to identify and validate early-stage biomarkers associated with defective autophagy that could facilitate the development of therapeutic strategies to prevent joint damage.

#### FRI0541 INCREASING A PERSON'S OWN PHYSICAL ACTIVITY AND STRENGTH CAN MINIMISE CARTILAGE VOLUME LOSS IN OLDER-ADULTS: A BETWEEN- AND WITHIN-PERSON ANALYSIS ON A POPULATION-BASED PROSPECTIVE COHORT

I.P. Munugoda<sup>1</sup>, S. Balogun<sup>1</sup>, K. Wills<sup>1</sup>, F. Cicuttini<sup>2</sup>, G. Jones<sup>1</sup>, M.L. Callisaya<sup>1</sup>, D. Aitken<sup>1</sup>. <sup>1</sup>Menzies Institute for Medical Research, University of Tasmania, Hobart, Tasmania; <sup>2</sup>Department of Epidemiology and Preventive Medicine, Monash University Medical School, Melbourne, Victoria, Australia

**Background:** The relationship between physical activity (PA) and osteoarthritis (OA) has been controversial, with some studies showing a detrimental effect and others showing either no effect or a beneficial effect. Traditionally, analysis has

focused on examining the effect PA and/or strength have on OA between individuals (between-person comparison). Yet, how the variability in PA and strength over time within the same individual (within-person comparison) is associated with OA is not well recognised. Statistical methods, such as multilevel models that properly capture the within-person processes can be used to tell us whether changes within an individual over time relate to changes in OA outcomes in that same individual.

**Objectives:** This study aimed to investigate the associations of between-person and within-person variability in PA and leg strength with knee cartilage volume loss over 10.7 years in older adults.

**Methods:** 479 community-dwelling older-adults (50% female, mean age 61±6 years, range 50–80 years) were studied at baseline, 2.7, 5.1, and 10.7 years. PA (measured objectively as steps/day) and leg strength (measured objectively in kg) were assessed at all four time-points. Knee cartilage volume was measured using MRI at baseline and 10.7 years. Linear mixed-effect regression models were used to estimate the association of between-person and within-person variability in PA and leg strength with cartilage volume loss over 10.7 years. Models were adjusted for age, sex, body mass index and history of knee injury or surgery.

**Results:** Mean cartilage volume loss over 10.7 years was 465±231 mm<sup>3</sup>. No between-person associations existed between PA and cartilage volume loss (Beta: 18.8 per 1000 steps/day, 95% CI –6.1, 43.7). However, within-person variability in PA was protectively associated with changes in cartilage volume, such that having higher PA compared to an individual's average level of PA minimised their cartilage volume loss over time (Beta: 32.8 per 1000 steps/day, 95% CI 20.8, 44.6). Between-person effects showed that participants with greater leg strength lost less cartilage volume over time (Beta: 5.4 per 1 kg, 95% CI 3.1, 7.8). Within-person variability in leg strength was also protectively associated with changes in cartilage volume, such that having higher leg strength compared to an individual's average strength minimised their cartilage volume loss over time (Beta: 3.3 per 1 kg, 95% CI 2.1, 4.5).

**Conclusions:** Our unique analysis method adds a new perspective to the PA and OA debate. The implication of these findings demonstrate that individuals can minimise cartilage volume loss by increasing their own PA and strength, which supports the clinical recommendations of promoting PA and strength to prevent and treat OA.

#### FRI0542 POTENTIAL NOCICEPTIVE PAIN RELIEF OF INTRA-ARTICULAR SALINE CONTROL IN CLINICAL TRIALS OF KNEE OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMISED TRIALS

I. Simsek, T. Phalen, A. Bedenbaugh, J. Tambiah. *Samumed, LLC, San Diego, USA*

**Background:** Hyaluronic acid, corticosteroids and platelet-rich plasma (PRP) are widely used intra-articular (IA) therapies for the management of mild to moderate knee osteoarthritis (OA). Many trials evaluating the efficacy of IA-administered therapies commonly use IA saline injections as a placebo comparator arm. A previously published systematic review Altman et al, 2016 showed significant reductions in pain relief with IA saline in both the short- (3 months) and long-term (6–12 months).

**Objectives:** The aim of this updated systematic review and meta-analysis was to assess the clinical benefit and harm associated with use of IA saline in trials of IA therapies for patients with painful knee OA.

**Methods:** We searched MEDLINE and Embase databases for randomised controlled trials (RCTs) published up to and including October 12th, 2017. Two reviewers independently assessed the eligibility of potential reports and the risk of bias of included trials. We analysed short (≤3 months) and long-term (6–12 months) pain reduction from baseline of the saline arm of included trials using standardised mean differences (SMDs; estimated assuming a null-effect in a comparator group) that were weighted and pooled using a random-effects model. Pain scores were transformed to a 100-point scale when necessary. We summarised and presented treatment-related adverse events (AEs) descriptively.

**Results:** We included 46 RCTs, of which 44 provided sufficient data to be included in the meta-analysis for benefit. IA saline significantly improved short-term knee pain from baseline vs. a null effect for a comparator group across 36 studies involving 1908 patients (SMD –0.85, 95% CI –1.05 to –0.66; I<sup>2</sup>=87%). There was also significant reduction in long-term knee pain following IA injection with saline across 25 studies involving 1758 patients (SMD –0.78, 95% CI –1.02 to –0.55) with a substantial degree of heterogeneity (I<sup>2</sup>=90%). Thirty-three of the included trials reported on adverse events, none of which found any serious treatment-related AEs following IA injection with saline.

**Conclusions:** The pain relief observed with IA saline should prompt one to consider the added effectiveness of current IA treatments that use saline comparators in clinical studies, and challenges of classifying IA saline injection a "placebo."

**Background:** Hip and knee Osteoarthritis are a major public health problem. Data on the economic impact are scarce.

**Objectives:** The purpose of our study was to estimate the annual direct costs of patients followed for hip and/or knee osteoarthritis from the KHOALA cohort.

**Methods:** The KHOALA cohort is a French population-based multicenter cohort of 878 patients with symptomatic knee and/or hip OA, aged between 40 and 75 years old recruited between 2007 and 2009. Direct costs were collected annually for 5 years. Costs were annualised and expressed in euros per patient.

**Results:** Over the 5 years, the average total direct costs were € 2575 (sd 8085) per patient per year and median € 1015 (IQR 430–2500) (figure 1).

Drugs represented the main health expenditure item (>50% of total costs). However, the proportion attributable to osteoarthritis drugs accounted for less than 5% of total costs. The second item of expenditure was hospitalizations (hip and/or knee arthroplasty represents 7% of total average costs). Medical consultations were the third item of health expenditure (2.5% to 4% of total average costs). Physiotherapy represented 1% to 2% of total average costs.

Costs increased with older age, female sex, retirement, a high BMI, a high Charlson index and poor health status.

Abstract FRI0543 – Figure 1. Average annual total direct costs over 5 years per patient

**Conclusions:** These data are important results to describe the cost of care consumption of a sample of patients with symptomatic osteoarthritis of the hip and/or knee recruited to the general population in France. However, the specific cost attributable to osteoarthritis needs to be studied.

FRI0544

**URINARY 6-SULFATOXYMELATONIN EXCRETION AND GALECTIN-3 PLASMA LEVEL IN PATIENTS WITH OSTEOARTHRITIS**

K. Zaichko, O. Gumeniuk, M. Stanislavchuk. *The Department of the Internal Medicine, National Pirogov Memorial Medical University, Vinnytsya, Ukraine*

**Background:** Melatonin and galectin-3 are considered as factors in the development of immune-inflammatory and destructive changes in joints.<sup>1–5</sup> Melatonin has chondrogenic and antinociceptive properties,<sup>2, 4</sup> while galectin-3 plays an important role in cell-cell adhesion, macrophage activation, angiogenesis, and apoptosis.<sup>1, 3</sup> The clinical and pathogenetic significance of melatonin and galectin-3 in osteoarthritis remains on the discussion.

**Objectives:** To study the excretion of 6-sulfatexymelatonin (metabolite of melatonin) and galectin-3 level in the blood and evaluate their association with the clinical manifestation and life quality in patients with OA.

**Methods:** Study involved 141 patients with OA of knee joints (76.6% women), aged 58.4±7.91 years, duration of the disease 10.5±6.50 years (M±SD). 47 (33.3%) patients had knee and hip OA, 38 (27%) patients had reactive synovitis. The control group was presented by 36 practically healthy subjects (72.2% female) aged 57.1±9.95 years (M±SD). 6-sulfatexymelatonin (6-SMT) in urine and galectin-3 in blood were determined by ELISA. The severity of pain, stiffness, and physical functioning of the joints were evaluated by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Quality of life was evaluated by Short Form-36 (SF 36).

**Results:** It was established in patients with OA a decrease in 6-SMT excretion, (mean 25.3 vs 38.8 ng/mg creatinine in control, p<0.001). 6-SMT excretion correlated with age (r=–0.40; p<0.001) and was more significant in patients with knee +hip OA (mean 26.5 vs 23.0 ng/mg creatinine in patients with OA of the knee only, p<0.001). Lower levels of 6-SMT excretion associated with higher pain and with lower quality of life. Patients with OA had increased galectin-3 levels in the blood (mean 16.4 vs 10.1 ng/ml in the control, p<0.001). In patients with OA of knee and hip joints were estimated higher levels of galectin-3. Levels of galectin-3 were significantly higher in patients with synovitis (mean 21.5 vs. 13.8 ng/ml without synovitis, p<0.001). The increase of galectin-3 in the blood was associated with a marked increase of the total WOMAC index and with decrease of life quality. The level of galectin-3 directly correlated with age, disease duration (r=0.28, 0.23, p<0.01) and inversely correlated with 6-SMT excretion (r=–0.28; p<0.01).

**Conclusions:** Lower levels of melatonin and higher of galectin-3 were associated with higher WOMAC index and poorer quality of life in patients with OA. This association may reflect possible pathogenic role of melatonin and galectin-3 in OA.

**RISK FACTORS PREDICTING RADIOLOGICAL PROGRESSION OF KNEE OSTEOARTHRITIS**

L. Alekseeva<sup>1</sup>, S. Anikin<sup>1</sup>, N. Kashevarova<sup>1</sup>, E. Sharapova<sup>1</sup>, E. Taskina<sup>1</sup>, T. Korotkova<sup>1</sup>, T. Raskina<sup>2</sup>, E. Otteva<sup>3</sup>, A. Dubikov<sup>4</sup>, E. Zonova<sup>5</sup>, I. Vinogradova<sup>6</sup>. <sup>1</sup>FSBI V.A. Nasonova Research Institute of Rheumatology, Moscow; <sup>2</sup>FSBEI HE KemSMU MOH, Kemerovo; <sup>3</sup>Regional SBHI CDC MOH Khabarovsk kray, Khabarovsk; <sup>4</sup>Pacific State Medical University, Vladivostok; <sup>5</sup>FSBEI HE Novosibirsk State Medical University, MOH, Novosibirsk; <sup>6</sup>SHI Ulyanovsk regional affiliated hospital, Ulyanovsk, Russian Federation

**Background:** Currently a number of risk factors (RF) are considered to be responsible for radiological progression of knee osteoarthritis (OA), nevertheless key predictors of OA progression have not yet been established.

**Objectives:** To identify RF predicting radiological progression of knee joint osteoarthritis (OA) in a 5 year multicenter prospective study.

**Methods:** This study of RF predicting knee OA progression was the first with multicenter prospective design ever conducted in Russia. The study included 344 female patients 40–75 y.o with primary stage I-III knee OA (ACR criteria) from 6 centres. Radiological stage was identified by Kellgren J.- Lawrence J. grading

scale. The follow up (FUP) was 5 years. Individual patients' files described 90 parameters. Instrumental diagnostic methods included plain radiography of knee joints, dual energy X-ray absorptiometry (DEXA) of lumbar spine L1–4, femoral neck and subchondral tibia, ultrasound (US) and MRI examination of knee joints. OA progression was verified based on evolution of radiological stage. At baseline 24 pts (7%) had stage I OA, 227 (66%) – stage II, and 93 (27%) – stage III. Discriminant analysis was applied to verify most reliable RF predicting radiological progression.

**Results:** Radiological progression was documented in 45% participants during 5 year FUP. The groups with and without progression were comparable in terms of age and disease duration ( $>0.05$ ). Pts who progressed suffered more intensive knee pain – 68(52–72) vs 41(30–63) mm,  $>0.01$ , had higher body weight – 82(77–93) vs 72(65–81) kg,  $>0.01$ , had higher rates of knee synovitis (US) 44% vs 26%,  $>0.03$ , (RR=1.67, 95% CI 1.07–2.59) and mid-tibia bone marrow oedema – 60% vs 28%,  $>0.01$  (RR=2.12, 95% CI 1.34–3.35). The discriminant analysis showed that knee pain, excessive body weight, synovitis and mid-tibia bone marrow oedema (MRI) can be considered as predictors of OA radiological progression. A model capable of predicting OA course in an individual patient with high 88% accuracy, 87.7% sensitivity and 70% specificity has been developed based on identified RF and their coefficients. Area under the ROC-curve 0, 921 (95% CI 0,875–0,966).

**Conclusions:** Knee pain, excessive body weight, synovitis and bone marrow oedema should be considered as key RF predicting knee OA radiological progression.

#### FRI0546 RELATIVE EFFICACY OF DIFFERENT EXERCISES IN KNEE AND HIP OSTEOARTHRITIS

S.L. Goh<sup>1,2</sup>, M.S.M. Persson<sup>2</sup>, J. Stocks<sup>2</sup>, Y.F. Hou<sup>3</sup>, J.H. Lin<sup>3</sup>, M. Hall<sup>2</sup>, M. Doherty<sup>2</sup>, W. Zhang<sup>2</sup>. <sup>1</sup>University of Malaya, Kuala Lumpur, Malaysia; <sup>2</sup>University of Nottingham, Nottingham, UK; <sup>3</sup>Peking University, Peking, China

**Background:** All osteoarthritis (OA) guidelines recommend exercise as one of the core treatments for OA.<sup>1</sup> However, it is unclear whether one exercise is better than another and for which outcome. Due to the limited evidence that compare different types of exercise, we undertook this network meta-analysis (NMA).

**Objectives:** To determine the relative efficacy of different exercises for pain and self-reported function at (or nearest to) eight weeks.

**Methods:** Nine electronic databases were searched for eligible randomised controlled trials (RCTs) that compared any types of exercise. The search was first performed in December 2015 and was updated in December 2017. Studies comparing exercise with usual care or with another exercise were included for this NMA. Common comparators such as usual care were used to network different types of exercise. Frequentist NMA was used to estimate the relative effect size (ES), i.e. standard mean difference and its 95% confidence interval (CI).<sup>2</sup>

**Results:** 217 RCTs (n=20419) met the inclusion criteria. Of these, 89 trials (n=7070; 97 comparisons) were analysed for pain outcome (figure 1), whilst 87 trials (n=7039; 97 comparisons) were analysed for function. Mind-body exercise was the most effective for pain relief, closely followed by aerobic exercise (See the last column, table 1). While mind-body remained the best for improving function, strength and flexibility/skills exercise were better than aerobic exercise (See the last row, table 1). Single exercises were consistently better than mixed exercise.

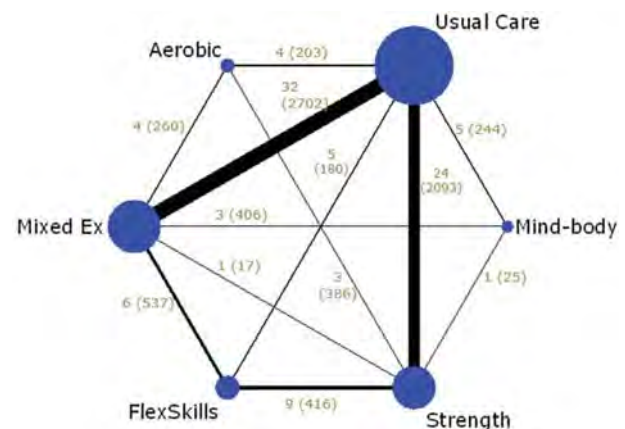

Table 1 Effect size (95% confidence interval) between different exercises

#### Pain outcomes:

Mind-body	0.05 (-0.49, 0.60)	0.42 (-0.04, 0.87)	0.51 (0.01, 1.02)	0.66 (0.23, 1.09)	1.07 (0.65, 1.49)
0.23 (-0.37, 0.84)	<b>Aerobic</b>	0.36 (-0.02, 0.75)	0.46 (0.0–0.91)	0.61 (0.23–0.98)	1.02 (0.65–1.39)
0.1 (-0.40, 0.60)	-0.13 (-0.57, 0.31)	<b>Strength</b>	0.09 (-0.22, 0.4)	0.24 (-0.02, 0.50)	0.65 (0.44–0.86)
0.16 (-0.40, 0.72)	-0.07 (-0.58, 0.43)	0.06 (-0.28, 0.40)	<b>Flex/Skills</b>	0.15 (-0.17, 0.47)	0.56 (0.25–0.87)
0.4 (-0.08, 0.87)	0.17 (-0.25, 0.58)	0.3 (0.01–0.59)	0.24 (-0.10, 0.58)	<b>Mixed exercise</b>	0.41 (0.23–0.59)
0.78 (0.32–1.25)	0.55 (0.14–0.96)	0.68 (0.45–0.92)	0.62 (0.28–0.96)	0.38 (0.17–0.60)	<b>Usual Care</b>

#### Functional outcomes:

**Note:** Exercises are in order from the top left to the bottom right. Pain outcomes are at the top and functional outcomes are at the bottom. Numbers in each cell represent effect size (95% confidence interval) between higher comparator versus lower comparator.

**Abstract FRI0546 – Figure 1.** Network diagram for pain

Aerobic: walking, cycling; FlexSkills: flexibility exercise, neuromotor training, proprioceptive training; Strength: resistance training; Mind-body: Tai-chi, Yoga; Mixed Ex: multi-component exercises

**Conclusions:** This exercise hierarchy and their relative efficacy provide a useful basis for patients and clinicians to select the most appropriate exercise whilst taking treatment goals (pain relief or functional improvement) and patient preference into consideration. The reason for the relative poor efficacy of mixed exercise warrants investigation as it contradicts current guidelines.

#### FRI0547 IN HAND OSTEOARTHRITIS, DECREASE IN SYNOVITIS RESULTS IN LESS JOINT PAIN; A LONGITUDINAL MAGNETIC RESONANCEIMAGING STUDY

S. Van Beest<sup>1</sup>, W. Damman<sup>1</sup>, R. Liu<sup>1</sup>, M. Reijnen<sup>2</sup>, F.R. Rosendaal<sup>3</sup>, J. L. Bloem<sup>2</sup>, M. Kloppenburg<sup>1,3</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology; <sup>3</sup>Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**Background:** Current treatment options to alleviate pain in hand osteoarthritis (OA) are limited in number, efficacy, and safety. Local inflammation and subchondral bone activity are interesting as potential treatment targets, since synovitis and bone marrow lesions (BMLs) have the ability to change over time and were shown to have positive cross-sectional associations with joint tenderness.

**Objectives:** To investigate the longitudinal associations between features on magnetic resonance (MR) imaging and joint tenderness in patients with primary hand OA over two years.

**Methods:** Eighty-five consecutively included patients (81.2% women, mean age 59.2 years) with primary hand OA (89.4% fulfilling ACR classification criteria) from a rheumatology outpatient clinic received contrast-enhanced MR imaging (1.5T) and physical examination of the right hand interphalangeal joints of digits 2–5 at baseline and at follow-up two years later. MR images were scored paired in unknown time order, following the Hand OA MRI scoring system: synovitis, BMLs, and osteophytes on a 0–3 scale (higher score reflects worse condition), with half-point increments allowed for synovitis and BMLs delta-scores. Joint tenderness upon palpation was assessed by trained research nurses on a 0–3 ordinal scale. We tested the associations between decreased MR features and decreased tenderness by calculating odds ratios on joint level (n=680), using generalised estimating equations to account for the within patient effects. Additional adjustments were made for change in MR-defined osteophytes, synovitis, and BMLs, when appropriate. Similarly, we tested the associations between increased MR features and increased tenderness, and we explored interactions between the different MR features by stratifying for one another.

**Results:** Decrease in synovitis was seen in 90 joints and decrease in BMLs in 56, however when restricted to the 116 joints with baseline tenderness, at follow-up: 76 had reduced tenderness, 21 decreased synovitis, and 13 decreased BMLs. A decrease in synovitis, but not in BMLs, was associated with attenuated tenderness (table 1). Of 678 joints without maximum baseline tenderness, at follow-up: 115 had increased tenderness, 132 increased synovitis, 96 increased BMLs, and 44 increased osteophytes. An increase in synovitis, osteophytes, and, to a lesser extent, BMLs, was associated with increased tenderness (table 2). Through stratification it became apparent that BMLs were merely an effect modifier of the synovitis-tenderness association.

**Table 1** The associations between decreased MRI features and decreased joint tenderness (in joints with tenderness and MRI feature present at baseline)

OR=Odds ratio; CI=confidence interval; \*Adjusted for patient effect; †Adjusted for patient effect and increase of MRI-defined synovitis/BML/osteophytes.

**Conclusions:** In hand OA, a decrease in MR-defined synovitis is associated with a decrease in joint tenderness. Furthermore, an increase in synovitis or osteophytes is associated with increased tenderness, which is further augmented by co-occurrence of BMLs. These findings support targeting synovitis in hand OA.

**FRI0548 ASSOCIATION OF OMERACT CORE DOMAINS OF PAIN AND FUNCTION WITH PATIENT SATISFACTION AFTER TOTAL JOINT REPLACEMENT**

S.M. Goodman<sup>1,2</sup>, B. Mehta<sup>1,2</sup>, L.A. Mandl<sup>1,2</sup>, J. Szymonifka<sup>3</sup>, M.P. Figgie<sup>4,5</sup>, I. Navarro-Millan<sup>1,2</sup>, M. Bostrom<sup>4,5</sup>, D.E. Padgett<sup>4,5</sup>, A.S. McLawhorn<sup>4,5</sup>, S. Lyman<sup>3</sup>, J. Singh<sup>6</sup>. <sup>1</sup>Rheumatology, Hospital for Special Surgery; <sup>2</sup>Rheumatology, Weill Cornell Medicine; <sup>3</sup>Biostatistics; <sup>4</sup>Orthopaedics, Hospital for Special Surgery; <sup>5</sup>Orthopaedics, Weill Cornell Medicine, New York; <sup>6</sup>Rheumatology, University of Alabama, Birmingham, USA

**Background:** Up to 20% of Total Joint Replacement (TJR) patients are dissatisfied, but this is difficult to study as it is challenging to pool data due to the lack of unified core outcome measures. The OMERACT TJR Special Interest Group has

recently endorsed a core domain set that include pain and function, and now seeks validation prior to development of a TJR trial core measurement set.

**Objectives:** To assess the association of pain relief and improved function with patient satisfaction 2 years after TJR.

**Methods:** We identified all patients undergoing total hip (THR) and knee (TKR) replacement in a hospital-based registry from 2007–2011, and evaluated those with 2 year satisfaction scores. Pain and function were measured using the Knee and Hip injury and Osteoarthritis Outcome Score (KOOS, HOOS) and satisfaction was measured using 5 primary questions, each rated on a Likert scale. Each question was weighted equally and a satisfaction summary score was calculated (range 0–100, higher scores corresponding to greater satisfaction). Expectations were measured using the validated HSS Expectations survey. Correlation was analysed with Spearman coefficients, and scores were compared by quartiles using the Kruskal-Wallis test.

**Results:** We included 4796 primary unilateral TKR and 4801 THR. 78% of TKR and 90.7% of THR were very satisfied with pain relief, and 6.5% of TKR and 2.5% of THR were somewhat or very dissatisfied (table 1). Satisfaction correlated moderately with pain (TKR  $\rho=0.61$ , THR  $\rho=0.47$ ) and function (TKR  $\rho=0.65$ , THR  $\rho=0.51$ ) at 2 years; there was no correlation with baseline expectations. When comparing satisfaction by pain, function and expectation quartiles, there were statistically significant differences (table 2); those with the best scores and greatest change in pain and function were the most satisfied.

**Abstract FRI0548 – Table 1.** Satisfaction Questions and Distribution

Satisfaction Questions and Distribution	n (%) n=4,796 TKR	n (%) n=4,801 THR
<b>Pain relief</b>		
Very satisfied	3754 (78.3)	4451 (92.7)

Scores are summarised as median [interquartile range] and compared using the Kruskal-Wallis test. \*The median 2-year pain score for THR was 100, so the third and fourth quartiles are the same; Quartiles differ for THR and TKR.

Scores are summarised as median [interquartile range] and compared using the Kruskal-Wallis test. \*The median 2 year pain score for THR was 100, so the third and fourth quartiles are the same; Quartiles differ from THR and TKR

**Conclusions:** These findings confirm that with increasing relief of pain and functional improvement, the strength of the association of 2 core domains with satisfaction increases, further validating these core domains for use in TJR clinical trials. A core outcome measurement set needs to be defined for use in TJR clinical trials that includes validated measures of these domains.

FRI0549

### OSTEOARTHRITIS (OA) AND RHEUMATOID ARTHRITIS (RA) PATIENTS HAVE SIMILAR DISEASE BURDENS AT FIRST VISIT TO AN ACADEMIC RHEUMATOLOGY SETTING, BUT OA PATIENTS HAVE A HIGHER BURDEN AT A 6-MONTH FOLLOW-UP VISIT

J. Chua, I. Castrejon, J.A. Block, A.-M. Malfait, T. Pincus. *Rheumatology, Rush University Medical Center, Chicago, USA*

**Background:** Osteoarthritis (OA) commonly is regarded as less severe than rheumatoid arthritis (RA). However, limited data are available for direct comparisons, largely because different measures traditionally are used in RA – primarily a HAQ (Health Assessment Questionnaire) vs OA – a WOMAC (Western Ontario and McMaster Universities Osteoarthritis Index). RAPID3 (Routine Assessment of Patient Index Data) on an MDHAQ (Multi-Dimensional HAQ) is a self-report index that is informative in RA and most rheumatic diseases, including OA.<sup>1</sup> A recent analysis of unselected patients from 4 rheumatology settings indicated that RAPID3 and other MDHAQ scores were similar or higher in OA versus RA patients,<sup>2</sup> but those findings were from a cross-sectional convenience sample of unselected patients likely affected by treatment, rather than from an initial visit prior to rheumatologic therapy.

**Objectives:** To analyse MDHAQ/RAPID3 scores in patients with a primary diagnosis of either OA or RA at their initial visit and at 6 month follow-up at an academic rheumatology centre.

**Methods:** At one site, all patients complete an MDHAQ/RAPID3 prior to seeing the rheumatologist. The 2-page MDHAQ/RAPID3 includes 0–10 scores for physical function (FN) (converted from 0–3) and visual analogue scale (VAS) scores for pain (PN) and patient global assessment (PATGL), compiled into a 0–30 RAPID3. New patients seen between 2013 and 2017 with physician-diagnosed primary OA or RA and complete RAPID3 data were studied. Mean FN, PN, PATGL and RAPID3 scores in RA and OA at baseline and 6 month follow-up (range 3–9 months) were compared for differences between first and second visits using t-tests, and between OA and RA using MANOVA.

**Results:** At first visit, mean RAPID3 was 15.9 in OA vs 15.3 in RA (table 1). At a mean of a 5 month (actual) follow-up visit, RAPID3 fell from 15.9 to 14.9 (-1.0, p=0.06) in OA vs 15.3 to 11.1 (-4.2, p<0.001) in RA, resulting in significantly higher scores in OA vs RA (table 1). These differences remained significant adjusted for age, sex, body mass index, and education level.

Mean and standard deviation (SD) at first visit and 5 month follow up visit MDHAQ/RAPID3 of patients with OA and RA seen in routine care

Measures	OA (n=109)	RA (n=102)	OA vs RA p value	OA vs RA p adjusted*
Initial visit				
Function (0–10)	3.15 (1.9)	2.89 (2.2)	0.34	0.60
Pain (0–10)	7.01 (2.3)	6.36 (2.9)	0.07	0.49
PATGL (0–10)	5.69 (2.8)	5.85 (3.0)	0.69	0.30
RAPID3 (0–30)	15.9 (5.9)	15.3 (7.0)	0.52	0.47
5 months follow-up visit				
Function(0–10)	2.93 (1.9)	2.24 (2.2)	<b>0.02</b>	<b>0.006</b>
Pain (0–10)	6.36 (2.5)	4.60 (3.0)	<b>&lt;0.001</b>	<b>0.03</b>
PATGL (0–10)	5.62 (2.7)	4.10 (3.2)	<b>&lt;0.001</b>	<b>0.001</b>
RAPID3 (0–30)	14.9 (6)	11.1 (7.6)	<b>&lt;0.001</b>	<b>0.001</b>

\*adjusted for age, sex, BMI and education

**Conclusions:** Patients with OA or RA have similar disease burdens at first visit to a rheumatology site, but OA patients have a considerably higher burden 5 months later, reflecting more effective treatments for RA than for OA. Nonetheless, OA is a severe disease at first visit, suggesting a need for further research in OA toward improved treatment and outcomes. MDHAQ/RAPID3 is feasible and useful to assess and monitor clinical status in routine care of patients with different rheumatic diseases.

### DIFFERENTIAL IMPACT OF OBESITY, STRUCTURAL SEVERITY AND THEIR COMBINATION ON THE EFFICACY OF VISCOSUPPLEMENTATION IN PATIENTS WITH KNEE OSTEOARTHRITIS. POST-HOC ANALYSIS OF A DOUBLE-BLIND, CONTROLLED, MULTICENTER, RANDOMISED TRIAL

T. Conrozier<sup>1</sup>, F. Eymard<sup>2</sup>, X. Chevalier<sup>2</sup>, J.-C. Balblanc<sup>1</sup>. <sup>1</sup>Rheumatology, Nord Franche Comté Hospital, Trevenans; <sup>2</sup>Rheumatology, Henri Mondor University Hospital, Paris, France

**Background:** It has been demonstrated that radiological severity and obesity were independent factors of VS failure and that the percentage of patients fulfilling the OMERACT-OARSI response criteria was only 41.7% in patients with both marked joint space narrowing and obesity while it was 87.1% in those who did not have any of these two risk factors.<sup>1</sup>

**Objectives:** The aim of the study was to assess the impact of obesity, radiographic severity and their combination on pain and function scores, 6 months after viscosupplementation in patients with knee osteoarthritis.

**Methods:** Post-hoc analysis of a prospective, double-blind, randomised, multi-centre, parallel-group trial, aimed to compare 2 viscosupplements (x 3 weekly intra articular injections of HANOX-M or Bio-HA) in patients with symptomatic knee OA. Patients were classified according to body mass index (BMI<or>=30 kg.<sup>2</sup>) and to OARSI radiological grade (1–2 versus 3). Responses in terms of WOMAC pain and function scores (differences between baseline and 6 months, as well as their variation over time) were compared according to BMI, radiological grade and to the combination of the 2 parameters.

**Results:** One-hundred and sixty-six patients from the intent-to-treat population, were analysed: Forty-seven patients (28.3%) were classified as obese (BMI ≥30 kg.<sup>2</sup>). At baseline WOMAC pain score was similar in obese and non-obese patients, whereas WOMAC function score was statistically higher in obese versus non-obese subjects. At month 6, WOMAC pain and function scores decreased significantly by 43.4% and 41.9% (p<0.0001). At month 6, WOMAC pain was significantly lower in non-obese than in obese patients (4.9±4.1 versus 7.1±4.9; p=0.008) and in patients OARSI grade 1–2 versus 3 (4.8±4.3 versus 6.4±4.5; p=0.009). WOMAC pain score, was 85.7% greater in obese/grade 3 patients than in non-obese/grade 1–2 subjects (7.8±5.1 versus 4.2±4.1, p=0.001). Lastly, the decrease of pain was twice greater in non-obese patients with OARSI 1–2 than that of obese patients with OARSI grade 3 (-5.7±4.3 versus -2.8±4.3, p=0.007). Similarly, WOMAC function score at month 6 was significantly higher in obese versus non-obese patients, in OARSI 3 versus OARSI 1–2 and in obese/grade 3 than in non-obese/grade 1–2.

**Conclusions:** This trial confirms that obesity and advanced stage are independent predictors of a lower response to viscosupplementation in knee OA. We identified a population sub-group (patients with both obesity and severe joint space narrowing) for who HA should not be recommended, regarding the weak benefit it provides.

FRI0551

### COMPARISON OF PHYSICAL ACTIVITY (PA) BETWEEN PATIENTS WITH DIFFERENT STAGES OF OSTEOARTHRITIS(OA) AND THE GENERAL POPULATION: A CROSS-SECTIONAL STUDY

T. Pelle<sup>1,2</sup>, A. Claassen<sup>1,2</sup>, J. Meessen<sup>3</sup>, W. Peter<sup>3</sup>, T. Vliet Vlieland<sup>3</sup>, K. Bevers<sup>2</sup>, J. van der Palen<sup>4</sup>, F. van den Hoogen<sup>1,2</sup>, C. van den Ende<sup>1,2</sup>. <sup>1</sup>Rheumatology, Radboud UMC; <sup>2</sup>Rheumatology, Sint Maartenskliniek, Nijmegen; <sup>3</sup>Orthopaedics, LUMC, Leiden; <sup>4</sup>Research Methodology, University of Twente, Enschede, Netherlands

**Background:** The benefit of Physical Activity (PA) in different stages of osteoarthritis (OA) is unambiguous considering the positive effects on pain and physical functioning. However, insight in the characteristics of PA (i.e. duration and

intensity) between patients in different stages of OA is scarce. Also, comparisons with the general population are understudied.

**Objectives:** To compare the amount (i.e. duration and intensity) of PA in patients in different stages of OA (i.e. patients in primary and secondary care, and post Total Joint Arthroplasty (TJA)) and the general population.

**Methods:** This study is based on secondary analyses of baseline data from four studies:<sup>1</sup> an effectiveness study of an educational program for OA patients in primary care,<sup>2</sup> a study on effectiveness of a multidisciplinary self-management program for generalised OA in secondary care,<sup>3</sup> a study among patients whom underwent TJA for end-stage OA in preceding 7–22 months, and<sup>4</sup> a nationwide study among the general population in the Netherlands (n=14,000) on general health.<sup>1</sup> In the current study only patients aged  $\geq 40$  years were included. The SQUASH questionnaire was used to assess PA in all 4 studies and to calculate adherence to PA recommendations, duration (hrs/wk) and intensity (MET.hrs/wk). To compare the amount (hrs/wk) and intensity (MET.hrs/wk) between different stages of OA and the general population, we applied multiple linear regression analysis, adjusted for age, gender and Body Mass Index (BMI).

**Results:** Demographic characteristics and adherence to PA recommendations are illustrated in table 1. Mean duration and intensity of PA in the general population were 41.3 hrs/week and 145.7 MET.hrs/week, respectively. Patients after TJA showed higher PA levels (both in terms of duration and intensity) than patients in secondary care and the general population (table 2).

**Abstract FRI0551 – Table 1.** Demographic characteristics of three OA stages and the general population in the Netherlands

	Primary care n=117	Secondary care n=144	Post-TJA n=519	General population n=4448
Age (years (SD))	68.3 (10.5)	59.9 (7.6)	70.1 (9.0)	59.2 (11.5)
Gender,% Female	59.8	85.4	65.3	51.8
Adherence to Dutch PA recommendations(% yes)	72.6	72.9	76.7	68.8

**Abstract FRI0551 – Table 2.** Relative difference (%) in mean duration (hours/week) and intensity (MET.hours/week) of PA between groups adjusted for age, gender and BMI.

MET.hrs/week	hrs/week	General population	Primary care	Secondary care	Post TJA
General population			0.3	5.4	-5.0*
Primary care	1.2			5.1	-5.2
Secondary care	-2.5		-3.6		-9.9*
Post TJA	5.3*		4.1		8.0*

\*Indicates p-value $\leq 0.05$ .

**Conclusions:** The results of this study show small non-significant differences in PA levels between primary care patients and the general population. Patients after TJA are more physically active than secondary care patients and the general population. However, low adherence rates to PA recommendations indicate the necessity to promote PA in a substantial group of OA patients.

#### FRI0552 SM04690, A WNT PATHWAY INHIBITOR: ANTI-INFLAMMATORY AND CARTILAGE PROTECTIVE EFFECTS IN PRECLINICAL OA MODELS

V. Deshmukh, T. Seo, C. Swearingen, Y. Yazici. Samumed, LLC, San Diego, USA

**Background:** Osteoarthritis (OA) is characterised by pain, swelling, and reduced function in the knee joint. Upregulated Wnt signalling drives OA through synovial inflammation, increased subchondral bone, and thinning cartilage.

**Objectives:** SM04690, a small molecule Wnt pathway inhibitor that demonstrated chondrogenic and anti-inflammatory properties preclinically<sup>1</sup>, was further evaluated to determine its potential to reduce inflammation, protect cartilage, improve joint health and modify pain in OA.

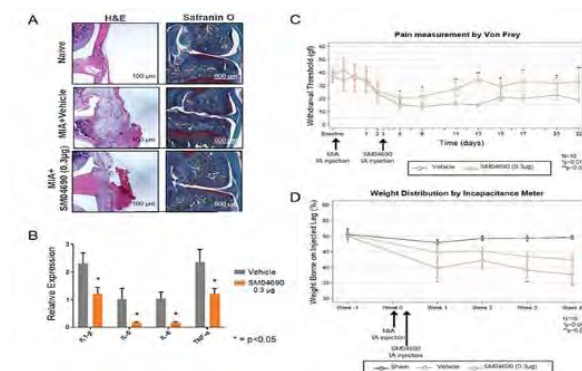

**Methods:** Cytokine secretion (IL-6 and TNF- $\alpha$ ) from IL-1 $\beta$ -stimulated and SM04690-treated synovial fibroblasts was measured by ELISA. A single intra-

articular injection of SM04690 or vehicle was evaluated in an *in vivo* rat knee monosodium iodoacetate (MIA) OA model. Joint inflammation was evaluated by H and E staining, inflammatory cytokines (IL-1 $\alpha$ , IL-1 $\beta$ , IL-6, TNF- $\alpha$  and IFN- $\gamma$ ) by qPCR, and cartilage protection by qPCR for matrix metalloproteinases (MMPs). Histological evaluation of cartilage health was performed using OARSI score and thickness by Safranin-O staining. Pain was measured as paw withdrawal threshold using Von Frey apparatus and weight distribution using incapitance metre and analysed using generalised estimating equation regression.

**Results:** SM04690 dose-dependently inhibited IL-1 $\beta$ -induced cytokine secretion in synovial fibroblasts (EC<sub>50</sub> ~30 nM; figure 1). In the rat MIA OA model, compared to vehicle, SM04690 injection reduced visible knee swelling, inflammatory cells, and proinflammatory cytokine and MMP production (p<0.05). SM04690 increased (p<0.01) paw withdrawal threshold from day 6 and improved weight distribution to the affected limb in treated rats, at multiple timepoints, compared to vehicle (figure 2). SM04690 increased Safranin-O stained cartilage thickness and decreased OARSI score (p<0.05) compared to vehicle.

**Abstract FRI0552 – Figure 1.** SM04690 inhibited inflammatory cytokine production in synovial fibroblasts *in vitro*

**Abstract FRI0552 – Figure 2.** SM04690 inhibited inflammatory cytokine production and decreased inflammation and pain in the MIA model of OA

**Conclusions:** In a rat MIA OA model, SM04690 injection reduced inflammation, protease production, and pain, with improved cartilage and joint health, compared to vehicle. Previously demonstrated regenerative effects in nonclinical studies<sup>1</sup>, along with anti-inflammatory properties, show SM04690 may improve symptoms and potentially provide disease modification in OA. Clinical studies are ongoing.

### FRI0553 THE ROLE OF AGE-RELATED SARCOPENIA IN OSTEOARTHRITIS OF LOWER EXTREMITY

Y. Safonova<sup>1</sup>, E. Zotkin<sup>2</sup>. <sup>1</sup>Rheumatology, Northwestern State Medical University named after Il Mechnikov, St. Petersburg; <sup>2</sup>Rheumatology, Research Institute of Rheumatology named after V.A. Nasonova, Moscow, Russian Federation

**Background:** Sarcopenia, defined as the age-related loss of muscle mass and low muscle function.<sup>1</sup> The prevalence of sarcopenia worldwide by meta-analysis of 35 articles was 10% (95% CI: 8%–12%) in men and 10% (95% CI: 8%–13%) in women, respectively.<sup>2</sup> A review of the literature on osteoarthritis (OA) and sarcopenia has shown that the age factor that contributes to the development of OA includes a decrease in muscle strength. In people with OD of the lower extremity, the frequency of falls was increased by a factor of 2–5.<sup>3</sup> OA contributed to the development of sarcopenia in elderly women.<sup>4</sup>

**Objectives:** Perform body composition and muscle analysis in patients with osteoarthritis and identify risk factors for sarcopenia that affect patients with osteoarthritis.

**Methods:** Prospective study of 159 women, mean age 74±13.3. The walking speed, handgrip strength were evaluated to apply the European Working Group on Sarcopenia. Assessment of appendicular skeletal muscle mass (ALM/h<sup>2</sup>) and total body fat were assessed using DXA, on Hologic Explorer machines. Covariates were determined by questionnaires and interviews.

**Results:** 31.45% of people with OA older than 65 years had sarcopenia. Patients with OA had a decrease in muscle strength and function, regardless of sarcopenia. Statistically significantly more frequent in patients with OA were lower indexes of lean mass index (ALM/h<sup>2</sup>) and body mass index (BMI) (p<0.01). The incidence of sarcopenia increased with age (p<0.01). 61.5% of patients with sarcopenia significantly more often had high values of c-reactive protein – CRP (x<sup>2</sup>=31.18, p<0.0001). Patients with sarcopenia were statistically significantly more likely to have vitamin D deficiency than patients without sarcopenia (x<sup>2</sup>=8.11, p<0.01). Cases of falls were observed in 90% of patients with sarcopenia (x<sup>2</sup>=79.29, p<0.001). Low physical activity 86% of patients with sarcopenia are statistically significantly higher than in patients without sarcopenia (95% CI: 73.3–94.2, p<0.01).

**Conclusions:** With age, patients with sarcopenia and OA had a significant decrease in muscle mass and physical activity, an increase in the incidence of falls. Patients with sarcopenia had high CRP levels and vitamin D deficiency than patients without sarcopenia.

## Diagnostics and imaging procedures

### FRI0554 WHICH AXIAL MAGNETIC RESONANCE IMAGING COMBINATION IS OPTIMAL FOR ASSESSING ACTIVITY IN SPONDYLOARTHRITIS?

M. Plier<sup>1</sup>, F. Lecouvet<sup>2</sup>, N. Michoux<sup>2</sup>, M.S. Stoenoiu<sup>1</sup>, B.R. Lauwerys<sup>1</sup>, A. Nzeusseu Toukap<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Cliniques Universitaires St-luc, Brussels, Belgium

**Background:** None

**Objectives:** To determine the optimal axial Magnetic Resonance Imaging (MRI) combination for assessing disease activity in spondyloarthritis

**Methods:** In this single centre cross-sectional study, patients with a known diagnosis of axial spondyloarthritis were selected. Clinical activity was defined by an Ankylosing Spondylitis Disease Activity Score-CRP (ASDAS-CRP) ≥1.3. Bone marrow oedema was quantified by the Berlin spine score and the global score for sacroiliac joints (SIJ). The ASDAS-CRP and MRI activity evaluation of the full spine and SIJ were available in the entire cohort. Receiver operating characteristic curves were done to test the performance of different MRI combinations in identifying patients with ASDAS-CRP ≥1.3. Performance was interpreted as follows: 0.61–0.70=fair, 0.71–0.80=moderate. A pairwise comparison of the area under the curves (AUC) was made to rank these MRI scores according to their diagnostic performance.

**Results:** 44 patients were assessed (30 were men; mean age was 37 years; mean disease duration was 5.0 years; median serum CRP level was 4.0 mg/L; mean ASDAS-CRP was 2.6; n=36 with ASDAS≥1.3, and n=8 for ASDAS<1.3). MRI activity score (MRIAS) performance was moderate for thoracic spine alone and SIJ in combination with thoracic spine or thoraco-lumbar spine or cervico-thoracic spine or total spine. Performance was fair for SIJ alone and total spine alone. MRIAS yielded the highest specificity for SIJ alone (Se=44%, Sp=100%), and the highest sensitivity for thoracic spine alone (Se=89%, Sp=50%). MRIAS for SIJ in combination with the thoracic spine yielded the highest AUC (0.78, p=0,0002). However, no significant difference was observed between MRIAS with a moderate performance (p>0.05, whatever AUCs comparisons).

**Conclusions:** For assessing disease activity in axial spondyloarthritis MRI of the SIJ in combination with the thoracic spine performed as good as MRI based on a more extended imaging of the spine.

**Disclosure of Interest:** None declared

### FRI0555 MUSCLE ELASTOGRAPHY AS A POTENTIAL NOVEL IMAGING BIOMARKER IN MYOSITIS

A.M. Alfuraih<sup>1,2,3</sup>, A.L. Tan<sup>2,3</sup>, P. O'Connor<sup>3</sup>, P. Emery<sup>2,3</sup>, R.J. Wakefield<sup>2,3</sup>.

<sup>1</sup>Radiology and Medical Imaging, Prince Sattam bin Abdulaziz University, Kharij, Saudi Arabia; <sup>2</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>3</sup>NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, UK

**Background:** Idiopathic inflammatory myopathies are a group of autoimmune muscle disorders characterised by muscle pain, stiffness and weakness. Diagnosis can be challenging; it relies on subjective clinical assessments, expensive MRI scans and invasive muscle biopsies. Novel quantitative ultrasound technologies like shear wave elastography could provide a new valuable non-invasive bedside imaging biomarker for diagnosis and management.

**Objectives:** 1-to determine if there are muscle elasticity differences between myositis patients and healthy controls. 2-to test the correlation between elasticity and measures of strength, function and muscle enzymes (disease activity).

**Methods:** Muscle elasticity, evaluated using shear wave velocity (SWV), was measured in 16 active myositis patients (5 males/11 females; 5 dermatomyositis, 5 polymyositis, 2 inclusion body, 4 undifferentiated) with a mean age of 51.3 years and 26 healthy controls (8 males/20 females) with a mean age of 42.0 years. Active myositis was defined as a decreased muscle strength and an elevated muscle enzyme. The investigated muscles included the four quadriceps [vastus lateralis (VL), rectus femoris (RF), vastus medialis (VM) and vastus intermedialis (VI)], the three hamstrings [biceps femoris (BF), semitendinosus (ST) and semi-membranosus (SM)] and the biceps brachii (BB). The myositis patients performed the expanded timed-get-up-and-go (ETGUG) test to assess walking function in addition to the handgrip strength and isokinetic knee extension/flexion tests to assess muscle strength. Mann-Whitney test and Spearman's correlation coefficients were utilised to test for difference and correlation respectively.

**Results:** Myositis patients had a significantly lower SWV (p<0.001) in all muscles except the BB (table 1 and figure 1). The mean elasticity difference ranged from 12% for VM to 21.1% for SM (table 1). Muscle enzyme (creatinine kinase) correlated with SWV for the VM (r=0.50; p=0.04) and BB (r=0.55; p=0.03). A strong correlation was detected between ETGUG walking time and VL (r=-0.73) as well as VI (r=-0.64). Handgrip strength correlated with VL, RF and BF (r=0.64, 0.56 and 0.62 respectively). There was, however, no significant correlation between SWV and isokinetic knee strength.

**Abstract FRI0555 – Table 1.** Mean SWV and differences in the examined muscles between myositis patients and controls

Muscle	Shear wave velocity (m/s)		Mean difference (95% CI)	Difference percentage	Significance (p value)
	Healthy	Myositis			
Vastus lateralis	1.74	1.42	-0.32 (0.19, 0.46)	18.4%	<0.001*
Rectus femoris	1.77	1.53	-0.24 (0.12, 0.34)	13.6%	<0.001*
Vastus medialis	1.66	1.45	-0.21 (0.06, 0.35)	12.7%	<0.001*
Vastus intermedius	1.89	1.60	-0.29 (0.11, 0.47)	15.3%	<0.001*
Biceps brachii	1.94	1.79	-0.15 (-0.01, 0.30)	7.7%	0.088
Biceps femoris	1.73	1.38	-0.35 (0.24, 0.46)	20.2%	<0.001*
Semitendinosus	1.72	1.45	-0.27 (0.09, 0.43)	15.7%	<0.001*
Semimembranosus	1.75	1.38	-0.37 (0.28, 0.45)	21.1%	<0.001*

**Conclusions:** Muscle elasticity in myositis patients has been shown to be 21% lower in comparison to healthy participants and seems to moderately correlate with disease activity, muscle strength and function. To our knowledge, this is the first study to show that shear wave elastography can detect changes in muscle elasticity in myositis patients. Further validation is required to evaluate the value of this novel ultrasound technology as an imaging biomarker for myositis.

### FRI0556 AUTOMATED SCORING OF KNEE OSTEOARTHRITIS (OA) ON ROUTINE RADIOGRAPHS IDENTIFIES DISEASE SEVERITY IN OA

A. Law<sup>1</sup>, L. Assi<sup>1</sup>, A. Harrison<sup>1</sup>, F.A. Howe<sup>2</sup>, N. Sofat<sup>1</sup>. <sup>1</sup>Institute of Infection and Immunity; <sup>2</sup>Molecular and Clinical Sciences Research Institute, St George's, University of London, London, UK

**Background:** Knee osteoarthritis (OA) causes pain and limited function of the knee, linked to cartilage loss, bone remodelling and inflammation<sup>1</sup>.

**Objectives:** We aimed to find out whether joint space measures can stratify patients into mild and advanced OA using an automated scoring tool<sup>2</sup>.

**Methods:** 86 weight-bearing radiographs (target joint: 41 left, 45 right knee) were analysed by using ImageBiopsy Lab software (JSx). Automated joint space (JS) measures were joint space width (JSW), minimum height (minH) and joint space area/region of interest (JSA/ROI, in mm<sup>2</sup>). JS measures were compared against Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) of pain, stiffness and function, with each subscale score normalised to a total score of 100. Body-mass index (BMI) and age data were available as potential covariates. Image analysis was initiated with landmarks automatically placed on the end of tibial plateau for each compartment, with fine manual adjustment of landmarks and contour spline if necessary. Clinical scores were compared between mild OA (n=24) and advanced OA (n=62); patient groups were defined according to their clinical pathway of standard care: medical management for early OA and knee replacement for advanced OA. SPSS Statistics 25 was used for analysis. An independent-samples t-test was used to compare the automated radiological and clinical scores between the groups of different OA severity. Subsequently the General Linear Model (GLM) was used to evaluate group differences with appropriate covariates and fixed factors.

**Results:** Joint space measures were strongly linked to the two clinical groups of OA severity (mild and advanced OA). Differences were significant in the medial JSA/ROI (p<0.001), medial JSW (p=0.001), medial MinH (p<0.001), WOMAC pain (p=0.001), stiffness and function (both p=0.003). Age (p=0.014) and BMI (p=0.019) were also different between the two groups of OA severity in the t-test, and were then used as co-variables in the GLM analysis along with gender and ethnicity as fixed factors. Medial JSA/ROI (p=0.027) and medial MinH (p=0.041) were still significantly different between mild and advanced OA in the multivariate test. Receiving Operating Characteristic (ROC) curves showed that medial JSA/ROI was the better discriminator for severity of OA (AUC=0.738) when compared to WOMAC scores (AUC=0.719 for WOMAC pain).

**Abstract FRI0556 – Figure 1.** Boxplots showing the relationship between stage of OA (mild and advanced) and (A) medial JSA/ROI, (B) lateral JSA/ROI

**Conclusions:** Medial joint space measures are possible markers for identifying the stage of disease if only radiographs were used. In particular, medial JSA/ROI may be utilised as an automated tool for characterising patient severity.

### FRI0557 THERMOGRAPHIC ANALYSIS OF HANDS AND WRISTS OF RHEUMATOID ARTHRITIS PATIENTS

A. Gatt<sup>1</sup>, A. Borg<sup>2</sup>, C. Mercieca<sup>2</sup>, A. Grech Scalpello<sup>1</sup>, L. Camilleri<sup>3</sup>, C. Gatt<sup>2</sup>, N. Chockalingam<sup>4</sup>, C. Formosa<sup>1</sup>. <sup>1</sup>Faculty of Health Sciences; <sup>2</sup>Faculty of Medicine and Surgery; <sup>3</sup>Faculty of Science, University of Malta, Msida, Malta; <sup>4</sup>Faculty of Health, Staffordshire University, Stoke on Trent, UK

**Background:** Thermography has been utilised in a number of studies in rheumatoid arthritis (RA),<sup>1</sup> however there is a paucity of evidence as regards to the possibility of applying this non-invasive technology to the detection of synovitis of the hands and wrists. With normative data having been already published,<sup>2</sup> it is now possible to compare the thermographic characteristics of RA patients without active synovitis to those with a normal thermal distribution in order to determine the baseline characteristics of RA hands and wrists. This would consequently provide a foundation against which further studies investigating RA patients with synovitis can be compared.

**Objectives:** To determine whether rheumatoid arthritis (RA) patients without active synovitis in their hands exhibit different baseline thermographic patterns of the fingers and palms when compared to healthy individuals

**Methods:** Data from 31 RA patients were compared to 51 healthy controls. Inclusion criteria were confirmed absence of synovitis by clinical examination and musculoskeletal ultrasound in rheumatoid patients. Thermographic imaging of the regions of interest (ROIs) were obtained as per established protocols<sup>2</sup>

**Results:** Significant differences were found between the mean temperatures of the palm regions and fingers of the healthy participants when compared to the palm regions and fingers of their RA counterparts (p=0.001), with the latter group exhibiting higher temperatures in all ROIs. No significant differences were found between ROIs of the palms and fingers of both hands in either group. Logistic regression models confirm that both palm and finger temperature increase significantly in RA

**Conclusions:** RA patients without active inflammation of the hands demonstrate a significantly higher mean temperature compared to healthy individuals. These findings provide evidence that baseline thermal data in RA differs significantly from healthy individuals. Thermal imaging may have the potential to become an adjunct assessment method of disease activity in patients with RA.

#### FRI0558 FURTHER VALIDATION OF THE US7 SCORE IN A LARGE COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS WITH DIFFERENT DISEASE STAGES

A.F. Podewski<sup>1</sup>, A.-M. Glimm<sup>1</sup>, I. Fischer<sup>2</sup>, G.A.W. Bruyn<sup>3</sup>, G.-R. Burmester<sup>1</sup>, M. Backhaus<sup>1,4</sup>, S. Ohrndorf<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Charité Universitätsmedizin Berlin, Berlin; <sup>2</sup>Biostatistics Tubingen, Tubingen, Germany; <sup>3</sup>Department of Rheumatology, MC Groep Hospitals, Lelystad, Netherlands; <sup>4</sup>Department of Internal Medicine – Rheumatology and Clinical Immunology, Park-Klinik Weißensee, Berlin, Germany

**Background:** Musculoskeletal ultrasound (US) is increasingly used in rheumatology clinical practice and research. Standardisation of US scanning techniques and definitions of pathologies is driven forward by the EULAR and OMERACT (Outcome measures in rheumatology) definitions and guidelines. However, no international consensus on a globally accepted US score system on patient level has been achieved so far. The US7 score, first published in 2009, assesses soft tissue lesions (synovitis, tenosynovitis/paratenonitis) as well as bone erosions of 7 preselected joints in one score.<sup>1</sup>

**Objectives:** The aim of this retrospective analysis was to further validate the US7 score by a detailed analysis of affected joint regions in patients with different RA disease stages.

**Methods:** The US7 score<sup>1</sup> examines the most commonly affected joints in RA, including the wrist, MCP2,3, PIP2,3 and MTP2,5 joints, for synovitis and tenosynovitis/paratenonitis and bone erosions from dorsal, palmar, ulnar (wrist), radial (only MCP2) and lateral (only MTP5) by greyscale (GS) and power Doppler (PD) US. In this retrospective analysis, our population of 524 patients with RA was divided into 3 subgroups – 69 patients (13.2%) with very early RA (max. 6 months disease duration), 98 patients with early RA (>6 month, ≤2 years of disease duration), and 343 patients (65.5%) with established RA (>2 years disease duration). Patients were examined at baseline, 3, 6 and 12 months after starting or changing therapy (csDMARD/bDMARD).

**Results:** MCP2 and the wrist (especially from dorsal) were most frequently affected by GS/PDUS synovitis in all groups. PDUS showed a slight tendency towards the dorsal versus the palmar joint side being more often affected in all groups. The group of established RA was more often affected by synovitis, while tenosynovitis/paratenonitis appeared more frequently in very early RA. Significant sensitivity to change within 12 months was detected by GSUS in the group of very early RA in all hand joint regions (for synovitis:  $p < 0.001$  MCP2,3 and wrist;  $p = 0.046$  PIP2;  $p = 0.001$  PIP3) and MTP2 ( $p = 0.024$ ), but not in MTP5 ( $p = 0.313$ ). PDUS demonstrated that the palmar sides of MCP2, PIP2 ( $p < 0.001$  for all) as well as the dorsal sides of MCP2 ( $p = 0.019$ ), MCP3 ( $p = 0.008$ ), PIP2 and 3 ( $p = 0.029$  both), MTP5 ( $p = 0.025$ ) and all wrist sides ( $p < 0.001$ ,  $p = 0.013$ ,  $p = 0.001$ , respectively) responded significantly to therapy, while MCP3, PIP3 palmar and MTP 2 dorsal did not show significant response ( $p = 0.054$ ,  $p = 0.494$ ,  $p = 0.172$ , respectively). In established RA, all joint regions included significantly responded to therapy (PIP2 GS:  $p = 0.004$ , all others  $p \leq 0.001$ ) in GS as well as PDUS.

**Conclusions:** Based on these results, we recommend to include wrist and MCP2 joints in a global US score on the patient level to monitor RA, independent of the disease stage, since they are<sup>1</sup> most commonly affected by synovitis and<sup>2</sup> most responsive to therapy. Tenosynovitis/paratenonitis is frequent in very early RA and should therefore be implemented in an US score monitoring early disease stages.

#### FRI0559 BIOMECHANICAL PROPERTIES OF RADIAL BONE ARE DIFFERENT BETWEEN AUTO-ANTIBODY POSITIVE AND NEGATIVE RHEUMATOID ARTHRITIS

F. Stemmler<sup>1</sup>, D. Simon<sup>1</sup>, A.-M. Liphardt<sup>1</sup>, M. Englbrecht<sup>1</sup>, J. Rech<sup>1</sup>, A. Hueber<sup>1</sup>, K. Engelke<sup>2</sup>, G. Schett<sup>1</sup>, A. Kleyer<sup>1</sup>. <sup>1</sup>Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU); <sup>2</sup>Institute of Medical Physics, Erlangen, Germany

**Background:** Functional properties of bone in rheumatoid arthritis (RA) are still not well characterised.

**Objectives:** This study aimed to define the impact of anti-citrullinated antibodies (ACPA) on biomechanical properties in RA.

**Methods:** Based on high-resolution peripheral quantitative computed tomography (HR-pQCT) data from the distal radius of ACPA-positive RA (RA+), ACPA-negative RA (RA-) and healthy controls (HC) micro-finite element analysis (μFEA) was carried out to measure failure load and stiffness of bone. (1) Comparisons of μFEA parameters between groups was calculated and multivariate models were used to determine the role of demographic, disease-specific and structural data of bone strength.

**Results:** A total of 276 subjects (96 RA+, 84 RA- and 96 HC) were analysed. Age and sex distributions were not significantly different between the three groups. In RA +but not in RA- failure load and stiffness were significantly decreased compared to HC (both  $p < 0.001$ ). Lower bone strength affected both female and male RA +patients and was related to longer disease duration. Impaired bone strength was correlated with altered bone density and microstructural parameters, which were all decreased in RA+. Multivariate models showed that ACPA status ( $p = 0.007$ ) and sex ( $p < 0.001$ ) were independently associated with reduced biomechanical properties of bone in RA.

**Conclusions:** In summary, μFEA showed that bone strength is significantly decreased in RA +but not in RA- disease.

#### FRI0560 QUANTITATIVE CT INDEXES IN THE EVALUATION OF INTERSTITIAL LUNG DISEASE RELATED TO RHEUMATOID ARTHRITIS

C. Bertolazzi<sup>1</sup>, M. Silva<sup>2</sup>, J. Rojas-Serrano<sup>3</sup>, A. Carnevale<sup>4</sup>, N. Sverzellati<sup>2</sup>, M. Gutierrez<sup>5</sup>, A. Alfaro-Rodriguez<sup>6</sup>, A. Ariani<sup>7</sup>. <sup>1</sup>Neurosciences Department, Instituto Nacional de Rehabilitación, Ciudad de Mexico, Mexico; <sup>2</sup>Clinical Sciences D., University of Parma, Parma, Italy; <sup>3</sup>Interstitial Lung Disease and Rheumatology Unit, Instituto Nacional de Enfermedades Respiratorias, Ciudad de Mexico, Mexico; <sup>4</sup>Morphology, Surgery and Experimental Medicine D., University of Ferrara, Ferrara, Italy; <sup>5</sup>Musculoskeletal and Rheumatic Diseases D; <sup>6</sup>Neurosciences D., Instituto Nacional de Rehabilitación, Ciudad de Mexico, Mexico; <sup>7</sup>Medicine U., Azienda Ospedaliero-Universitaria di Parma, Parma, Italy

**Background:** In rheumatoid arthritis (RA), interstitial lung disease (ILD) is the most common pulmonary complication and it is associated with poor prognosis.

The gold standard to detect ILD is the chest Computed Tomography (CT). CT semiquantitative scoring and quantitative methods are used to estimate the extension of ILD; however the first ones are time consuming and they have a considerable inter/intra-observer variability. Quantitative scores are based on the detection of the parameters of distribution of lung attenuation (also called quantitative CT indexes – QCTi).

Previously a good correlation between QCTi calculated through an open-source program (OsiriX) and semi-quantitative score performed by experienced radiologists was demonstrated in a cohort of systemic sclerosis (SSc) patients. Furthermore, the QCTi were demonstrated to be able to discriminate between SSc subjects with different mortality risk based on ILD extent (<20% vs >20%) or lung functional values.

**Objectives:** Main aim is to investigate if in RA-ILD there is a correlation between QCTi and semiquantitative scores. Secondary aims are: a) to verify if there is a difference of QCTi distribution in RA-ILD patients with severe vs mild ILD extent; b) to evaluate the discriminative ability of QCTi in identifying patients with severe ILD.

**Methods:** Two experienced radiologists assessed the ILD on chest CT of 45 patients with RA according to the semiquantitative score proposed by Goh et al. ILD extent <and >20% were considered mild and severe, respectively.

All CTs were blindly processed by a rheumatologist using OsiriX to obtain the QCTi (kurtosis, skewness, mean lung attenuation).

The semiquantitative scores and the QCTi were correlated through the Spearman rank test. QCTi distribution and discriminative ability were, respectively, verified using Mann-Whitney test and ROC curves.

**Results:** The majority of QCTi showed a statistically significant correlation of moderate degree ( $0.40 < r < 0.59$ ) with the semiquantitative assessment ( $p$ -value  $< 0.01$ ).

Patients with severe and mild ILD had dissimilar QCTi values ( $p < 0.001$ ). Among QCTi, kurtosis (tKurt) had the best discriminative ability (AUC=0.80, 95% CI 0.65 to 0.91,  $p < 0.0001$ ). The best tKurt cut-off value that identifies patients with severe pulmonary involvement was 3.67.

**Conclusions:** In RA-ILD, QCTi correlate with the CT semiquantitative scores. Our preliminary findings suggest that RA-ILD severity is related to QCTi. Moreover a QCTi (tKurt) has a cut-off that can discriminate patients with severe ILD. So, QCTi may become simple tools to help the rheumatologist to quickly evaluate the severity of ILD in RA patients and estimate the prognosis.

#### FRI0561 MACROPHAGE PET IMAGING FOR PREDICTING TREATMENT OUTCOME OF DE NOVO RHEUMATOID ARTHRITIS

N. Verweij<sup>1</sup>, S. Bruijnen<sup>1</sup>, L. Rasch<sup>1</sup>, S. Turk<sup>1</sup>, M. Yaqub<sup>2</sup>, A. Lammertsma<sup>2</sup>, O. Hoekstra<sup>2</sup>, D. van Schaardenburg<sup>1</sup>, A. Voskuyl<sup>1</sup>, W. Lems<sup>1</sup>, C. van der Laken<sup>1</sup>.  
<sup>1</sup>Dept. of Rheumatology, Amsterdam Rheumatology and Immunology Center – VU University Medical Center, <sup>2</sup>Dept. of Radiology and Nuclear Medicine, VU University Medical Center, Amsterdam, Netherlands

**Background:** Treatment of rheumatoid arthritis (RA) should be initiated as early as possible to prevent further damage and functional disability.<sup>1</sup> However, clinical assessment of treatment response usually takes 12 weeks or longer. Tools that detect earlier response can improve timely treatment decision. Previously, positron emission tomography (PET) using the macrophage tracer [11C]-(R)-PK11195 has shown promise for both early diagnosis and monitoring response to therapy in RA patients.<sup>2,3</sup>

**Objectives:** To determine the value of [11C]-(R)-PK11195 PET to identify RA responders and non-responders to COBRA-light therapy after 2 weeks of treatment.

**Methods:** Twenty RA patients (female 10/20, age 54±10 years) with clinically active *de novo* RA based on ACR/EULAR criteria<sup>4</sup> and at least two clinically active joints were included. All patients were given COBRA-light therapy (methotrexate and prednisolone). They received standard clinical care and (clinical) evaluations were performed at 0, 2, 4 and 12 weeks of treatment. Whole body [11C]-(R)-PK11195 PET-CT scans were acquired at baseline and after 2 weeks of treatment. An experienced reader blinded to clinical data scored the 44 joints of the Disease Activity Score (DAS44) visually from 0 to 3. PET response was predefined as either positive if there was a decrease in whole body PET score of  $\geq 10\%$  after two weeks, or as negative if the score increased or remained unchanged. PET outcome was compared with EULAR clinical response at 12 weeks.<sup>5</sup>

**Results:** After 12 weeks of COBRA-light treatment, 16 out of the 20 patients were classified as EULAR responders (13 'good' and 3 'moderate') and 4 patients as non-responders. At baseline, a total of 134 PET positive lesions were observed in the joints of 20 patients, ranging from 1 to 21 lesions per patient. Most frequently, lesions were located in hands and feet: 19% in the wrists (e.g. figure 1A), 37% in the small hand joints and 39% in the small feet joints. After 2 weeks of COBRA light treatment, the number of PET positive lesions decreased to 122 (e.g. figure 1B).

A positive whole body PET response was observed in 13 patients. Table 1 shows a side by side comparison between PET response after 2 weeks and EULAR response after 12 weeks. In 15 of the cases (75%), there was an agreement between the PET response and EULAR response.

		EULAR response at 12 weeks	
		Positive	Negative
PET response at 2 weeks	Positive	12	1
	Negative	4	3

**Abstract FRI0561 – Table 1.** Correspondence between early PET response and clinical EULAR response.

**Abstract FRI0561 – Figure 1**

**Conclusions:** This is the first study to explore the potential of macrophage PET for monitoring therapy in early RA. Preliminary visual assessment demonstrates its ability to monitor arthritis activity changes within 2 weeks of treatment. This offers a window of opportunity for development of precision medicine in the early phase of treatment. Future analyses are in progress to assess whether performance can be further improved by quantification of tracer uptake.

#### FRI0562 ASSOCIATION BETWEEN JOINT REGIONS WITH ULTRASOUND-DETERMINED SYNOVITIS AND SYSTEMIC INFLAMMATORY MARKERS

D. Nakagomi<sup>1</sup>, K. Ikeda<sup>2</sup>, K. Kobayashi<sup>1</sup>, S. Hanai<sup>1</sup>, M. Yamagata<sup>3</sup>, R. Koh<sup>1</sup>, S. Furuta<sup>2</sup>, H. Nakajima<sup>2</sup>, K. Kitamura<sup>1</sup>. <sup>1</sup>Third Department of Internal Medicine, University of Yamanashi, Chuo City, Yamanashi Prefecture; <sup>2</sup>Department of Allergy and Clinical Immunology, Chiba University Hospital; <sup>3</sup>Department of Rheumatology, National Hospital Organization, Shimoshizu Hospital, Chiba, Japan

**Background:** It is unknown which joint arthritis the inflammatory markers such as CRP or MMP-3 reflect.

**Objectives:** We analysed the association between joint regions with ultrasound-determined synovitis and systemic inflammatory markers.

**Methods:** We enrolled 152 patients with untreated arthritis and performed musculoskeletal ultrasound on 40 joints and determined a semiquantitative grade for power Doppler (PD) signals. We analysed the associations between PD scores in 8 joint regions and CRP/MMP-3 levels using multiple linear regression models with forced entry method.

**Results:** Mean age was 55 years and 112 patients were female. Median CRP and MMP-3 were 0.36 mg/dl and 65.7 ng/ml. Median total PD score was 2. Standard regression coefficients for 8 joint regions were  $-0.009$  for MCPs,  $0.05$  for PIPs,  $0.372$  for wrists,  $0.183$  for elbows,  $0.628$  for shoulders,  $0.377$  for knees,  $0.261$  for ankles, and  $-0.0131$  for MTPs in a regression model to explain CRP using PD scores as dependent variables. Standard regression coefficients for the same joint regions were  $-5.134$ ,  $-4.449$ ,  $24.061$ ,  $27.839$ ,  $22.508$ ,  $64.108$ ,  $36.501$ , and  $2.539$  to explain MMP-3.

**Conclusions:** Systemic inflammatory markers such as CRP and MMP-3 do not accurately reflect the inflammation in small joints. Conversely, it is necessary to weight the large joints for the global ultrasound synovitis score to represent the severity of systemic inflammation.

**FRI0563 MUSCULOSKELETAL ULTRASOUND (MSUS) IS SUPERIOR TO CLINICAL EXAMINATION REGARDING DETECTION OF ARTHRITIS IN PATIENTS WITH SYSTEMIC SCLEROSIS**

D. Feldmann<sup>1</sup>, R.E. Voll<sup>1</sup>, F. Koller<sup>2</sup>, S. Finzel<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany; <sup>2</sup>Department of Rheumatology, Immunology, and Allergology, Inselspital, University Hospital Bern, Bern, Switzerland

**Background:** Arthralgia is a frequent complaint in patients with systemic sclerosis (SSc). However, correct assessment of arthritis remains challenging especially in patients with severe scleroderma and/or soft tissue oedema.

**Objectives:** This study investigates the frequency of arthritis in SSc using musculoskeletal ultrasound (MSUS) compared to clinical investigation and in SSc.

**Methods:** Effusion, as well as synovitis in B- and PD-mode using MSUS was assessed in 31 consecutive patients with SSc; hand, finger, upper and lower ankle joints as well as metatarsophalangeal (MTP) joints were scanned totaling 1364 joints. In all patients carotid intima media thickness (CIMT) was assessed by Doppler ultrasound. Arthritis disease activity was assessed by the HAQ, and the DAS66/68, respectively; joint pain and patient global health (PGH) were quantified on a visual analogue scale (VAS). Skin involvement was measured using the modified Rodnan Skin Score (mRSS). CRF such as smoking, hypertension or positive family history were registered

**Results:** All patients were negative for ACPA and rheumatoid factors. 58.06% (n=18) of patients had joint pain, 22.58% (n=7) clinical joint swelling. In MSUS, 82 joints with effusion were detected in 23 patients (I°: n=50 joints, II°: n=32 joints). 25 joints in 11 patients were detected by B-mode synovitis (I°: 9 joints, II°: 16 joints). 7 joints in 3 patients showed PD-synovitis (I°: 2 joints, II°: 5 joints). In 10 patients MSUS could detect effusion where clinical examination could not; none of the clinically suspicious joints had effusion in MSUS. B-mode synovitis was detected in 3 clinically normal patients, in 6 patients with joint pain, and in 3 patients with joint pain and swelling. 1 patient with PD-synovitis each had TJC-/SJC-, TJC+/SJC+, or TJC+/SJC- at clinical examination. The overall correlation of MSUS with clinical examination was poor (p>0.05). B-mode synovitis and PD-mode synovitis prevailed the MTPs (60%, n=15% and 85.71%, n=6, respectively). For median nerves, a cutoff area of >13 mm<sup>2</sup> was deemed pathologic, >11 mm<sup>2</sup> and <13 mm<sup>2</sup> was intermediate. 11/31 patients had either pathologic or intermediate median nerves. Doppler ultrasound found 10 pathological CIMT in 8 individual patients; carotid plaques were detected in 25 carotid arteries in 20 patients. Patients with CIMT and/or carotid plaques were elderly (60.52 years±10.84), long term sick (156.48±123.19 months), and had at least one cardiovascular risk factor.

**Conclusions:** In patients with arthralgia MSUS could detect clinically not obvious arthritis. Especially in joints with soft tissue oedema and sclerotic skin MSUS was superior to clinical examination. Interestingly, arthritis was most frequently found in the MTP and wrist joints supporting recent data.<sup>1</sup> In this small cohort there was no significant correlation between CRP positivity and arthritis. Not surprisingly, carotid plaques were more frequent in elderly and/or long-term patients with one or more CRF. We plan to pursue this investigation in a larger cohort.

**FRI0564 ULTRASONOGRAPHIC EVALUATION OF SHOULDER TENDONS IN PATIENTS WITH HASHIMOTO'S DISEASE**

D.E. Buyuksireci<sup>1</sup>, D. Tecer<sup>2</sup>, B. Bolayir<sup>3</sup>, M.E.E. Yon<sup>4</sup>, M. Akturk<sup>3</sup>, F. Gogus<sup>5</sup>. <sup>1</sup>Department of Physical Medicine and Rehabilitation, Gazi University Faculty of Medicine, Ankara; <sup>2</sup>Department of Rheumatology, Mehmet Akif Inan Education and Research Hospital, Sanliurfa; <sup>3</sup>Department of Internal Medicine, Division of Endocrinology and Metabolism; <sup>4</sup>Department of Internal Medicine; <sup>5</sup>Department of Physical Medicine and Rehabilitation, Division of Rheumatology, Gazi University Faculty of Medicine, Ankara, Turkey

**Background:** Hashimoto's disease is an autoimmune disease characterised by autoantibody positivity in the blood and diffuse lymphocyte infiltration in the thyroid. Thyroxine is an important hormone in collagen and matrix metabolism. Low levels

of thyroid hormones or antibodies positivity may lead to tendon pathologies and subsequent shoulder pain in patients with Hashimoto's disease.

**Objectives:** 1) To investigate tendon thickness and pathologies in patients with Hashimoto's disease. 2) To investigate if shoulder pain in Hashimoto's disease is associated with ultrasonographic tendon pathologies.

**Methods:** Assuming a 0.5 mm mean difference and 0.7 mm SD of thickness at rotator cuff tendons with 80% power and 5% significance 119 female subjects (40 patients euthyroid Hashimoto's disease, 28 subclinical hypothyroid Hashimoto's disease and 51 healthy subjects) were recruited.<sup>1</sup> Participants were divided into three groups: Group 1: patients with subclinical hypothyroid Hashimoto's disease, Group 2: patients with euthyroid Hashimoto's disease, Group 3: healthy controls. A rheumatologist experienced in musculoskeletal ultrasonography and blind to clinical data of the patients evaluated the thickness of biceps, subscapularis, supraspinatus, infraspinatus tendons at both shoulders according to standard protocol.<sup>2</sup> The presence of subacromial bursitis, effusion, tendon rupture or tendinosis were recorded. The participants of TSH (thyroid stimulated hormone), free T3 (triiodothyronine), free T4 (thyroxine), anti TPO (thyroid peroxidase) and anti TG (thyroglobulin) antibodies levels were measured. In addition the presence and duration of shoulder pain of the participants were recorded.

**Results:** Height, weight, BMI (body mass index), free T3 and free T4 levels were similar between three groups (p=0.830, p=0.205, p=0.374, p=0.430 and p=0.497, respectively). Tendon thicknesses in patient groups are presented in table 1. Biceps brachii, subscapularis, supraspinatus and infraspinatus tendon thicknesses were increased significantly in both euthyroid Hashimoto's disease and subclinical hypothyroid Hashimoto's disease groups at dominant and non-dominant arms compared to healthy controls. However there was no such difference between euthyroid Hashimoto's disease and subclinical hypothyroid Hashimoto's disease groups. There was no correlation between levels of TSH, anti TPO, anti TG and tendon thickness. Two participants in three groups had shoulder pain for 1–3 months. These participants had no ultrasonographic shoulder tendon pathology.

**Abstract FRI0564 – Table 1.** Differences between euthyroid Hashimoto's disease, subclinical hypothyroid Hashimoto's disease and healthy controls in dominant and non-dominant arms.

**FRI0565** **ERAMRS: A NEW MR SCORING SYSTEM FOR EARLY RHEUMATOID ARTHRITIS**

F. Xiao<sup>1</sup>, J. Yue<sup>2</sup>, L.-S. Tam<sup>2</sup>, J. Griffith<sup>1</sup>. <sup>1</sup>Dept of Imaging and Interventional Radiology; <sup>2</sup>Dept of Rheumatology, The Chinese University of Hong Kong, Hong Kong, Hong Kong

**Background:** Early rheumatoid arthritis (ERA) is defined as having symptoms for less than 24 months and MRI allows quantification of several inflammatory features of ERA. Due to inclusion of some less relevant MR features and non-inclusion of other more relevant features, three MRI scoring systems currently employed are not ideally suited for use in ERA. We therefore devised a new more inclusive system suited for ERA, known as the ERA MR score ('ERAMRS'). The clinical relevance of this new ERAMRS system over the other MR scoring systems can be gauged by seeing how well these MR scoring systems correlate with clinical scoring systems.

**Objectives:** To (a) introduce a new scoring system (ERAMRS) for measuring the degree of inflammation on MR in early rheumatoid arthritis (RA) and (b) to see how well this ERAMRS system correlates with clinical scoring systems and serological parameters compared to currently used MR scoring systems.

**Methods:** 106 patients (81 females, 25 males, age, 53±12 years) with early (i.e. symptoms<24 months) untreated RA underwent clinical/serological testing as well as 3T MRI of the most symptomatic wrist. Clinical assessment included Patient Global Assessment (PtGA), Physician Global Assessment (PGA) and Simple Disease Activity Index (SDAI). Erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) were also measured. ERAMRS (Early Rheumatoid Arthritis Magnetic Resonance Score) was semi-quantitatively assesses wrist joints synovitis (no=0, mild=1, moderate=2, severe=3) and enhancement (no=0, mild=1, moderate=2, severe=3), tenosynovitis (no=0, mild=1, moderate=2, severe=3) and enhancement (no=0, mild=1, moderate=2, severe=3) as well as bone marrow oedema (no=0,<50% of the whole bone=1,>50% of the whole bone=2). Seven wrist joints, nine wrist tendons as well as 15 wrist bones were assessed. This ERAMRS method was compared to currently used methods of scoring inflammation on wrist MRI ('RAMRIS' [1], 'McQueen' [2] and 'MRI detected inflammation score' [3]).

**Results:** Synovitis was present in 104 (98%), bone marrow oedema in 77 (73%), and tenosynovitis in 82 (77%) of the 106 wrists at presentation. RAMRIS system had the lowest correlation (PtGA, PGA, SDAI, CRP) or no correlation (ESR) while the ERAMRS system had the highest correlation with clinical disease activity level scoring systems ( $r=0.44$ ,  $p<0.001$ ) and serological parameters ( $r=0.41$ ,  $p<0.001$ ) among these four scoring systems.

**Conclusions:** The ERAMRS system, designed to grade inflammation on wrist MRI in early RA, provided the best correlation with clinical scoring systems and serological parameters indicating its improved clinical relevance over other MR scoring systems.

**Background:** Myocardial disease is a major cause of death in systemic sclerosis (SSc). We hypothesised that the in SSc patients with suspected myocarditis, the Lake Louise criteria underdiagnose myocarditis compared to diagnostic models that incorporate parametric cardiovascular magnetic resonance (CMR) indices (extracellular volume fraction [ECV], native T1- and T2-mapping).

**Methods:** 32 patients with diffuse SSc (dSSc) and a clinical suspicion of myocarditis were prospectively evaluated with a 1.5 T scanner using the Lake Louise criteria, and the aforementioned parametric indices were determined. The Lake Louise criteria were compared with parametric indices individually and in two models (with and without taking late gadolinium enhancement [LGE] into account), with regard to diagnostic agreement.

**Results:** Native T1-mapping and ECV individually had the greatest discordance with the Lake Louise criteria. The presence or absence of LGE in the proposed parametric models did not lead to changes in identified patient proportions. Native T1-mapping led to the same proportion of diagnosis of myocarditis as either parametric model, with the exception of 2 patients. Most importantly, patients identified only by parametric models, had a significantly subtler presentation than those identified by the Lake Louise criteria, as exemplified by significantly lower T2 ratio, early gadolinium enhancement and T2-mapping values.

**Conclusions:** In dcSSc patients with a clinical suspicion of myocarditis, novel parametric models including native T1-mapping, T2-mapping and ECV, identified a significantly greater proportion of patients with myocarditis compared to those identified by the Lake Louise criteria, and native T1 mapping had the greatest utility in this cohort.

**FRI0567** **THE DIAGNOSTIC VALUE OF AUTOANTIBODY ISOTYPES IN RHEUMATOID ARTHRITIS**

D. Sieghart<sup>1</sup>, A. Platzer<sup>1</sup>, P. Studenic<sup>1</sup>, F. Alasti<sup>1</sup>, M. Grundhuber<sup>2</sup>, S. Swinarski<sup>2</sup>, S. Bluemel<sup>1</sup>, H. Haslacher<sup>3</sup>, J. Smolen<sup>1</sup>, G. Steiner<sup>1</sup>. <sup>1</sup>Department of Internal Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria; <sup>2</sup>ImmunoDiagnostic Division, Thermo Fisher Scientific, Phadia GmbH, Freiburg, Germany; <sup>3</sup>Department of Laboratory Medicine, MEDICAL UNIVERSITY OF VIENNA, Vienna, Austria

**Background:** Anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) are the most specific diagnostic markers of rheumatoid arthritis (RA). These antibodies are predominantly of the IgG (ACPA) or IgM (RF) isotype. Other subtypes of both antibodies – such as IgA – and other autoantibodies like RA33 have been repeatedly reported but their diagnostic value has still not been fully elucidated.

**Objectives:** To investigate the diagnostic value of IgA, IgG and IgM subtypes of RF, ACPA and RA33 antibodies in patients with RA and their potential predictive value regarding therapeutic response to methotrexate (MTX).

**Methods:** To determine the diagnostic specificity and sensitivity, sera from 290 RA patients (including 165 MTX starter), 261 disease controls and 100 healthy subjects were tested for the presence of IgA, IgG and IgM isotypes of RF, ACPA and RA33 by EliA<sup>TM</sup> (Thermo Fisher Scientific). Cut-offs for prototype anti-RA33 (IgA, IgG and IgM) and the IgM-ACPA EliA<sup>TM</sup> were calculated by Receiver Operating Characteristic (ROC) curve analysis against disease controls and healthy subjects. In addition, RF and ACPA had been routinely measured by nephelometry and the anti-CCP EliA<sup>TM</sup>, respectively.

**Results:** The most specific antibodies were IgG and IgA-ACPA as well as IgG-RF, closely followed by IgG- and IgA-RA33 while IgM isotypes were found to be less specific. However, IgM-RF was the most sensitive isotype (65%) followed by IgG-ACPA (59.5%) and IgA-RF (50.7%). Other subtypes were less prevalent ranging from 35% (IgA-ACPA) to 6% (IgA-RA33). Concerning RA33 antibodies, 14 patients were positive for IgA- and 18 for IgG-RA33. Interestingly, the major RA33 subtype was IgM which was detected in 43 patients. However, in contrast to RF and ACPA the overlap between the RA33 isotypes was marginal. RA33 antibodies as well as IgA-RF and IgA-ACPA were found to increase the diagnostic sensitivity of serological testing since they were found also in 22% of seronegative patients. Moreover, analysing IgM-RF by EliA<sup>TM</sup> proved more sensitive than RF measured by nephelometry which further reduced the number of seronegative patients. Thus, additional antibodies were detected in 30% of the seronegative population and, importantly, most patients had several antibodies, in contrast to disease controls which generally showed only one antibody species. The majority of antibody positive RA patients was found to be triple positive for RF, ACPA and either IgA-RF or IgA-ACPA. Among the 64 RA33 positive patients 48 were also positive for IgA-RF and/or IgA-ACPA (figure 1).

Interestingly, we found high levels of IgM-RF (>124 IU/ml) to be associated with achieving a SDAI50 response to MTX (17 of 24 cases). Furthermore, also the presence of RA33 antibodies was associated with a MTX response as 50% of RA33 positive patients (n=32) achieved a SDAI50 response compared to 34% in the RA33 negative population (p=0.034).

**Abstract FRI0567 – Figure 1.** Added diagnostic value of IgA-RF/ACPA and RA33 antibodies. Venn chart visualising the diagnostic overlap of RA33 and IgA antibodies with routine diagnostics (RF nephelometry, IgG-ACPA). The numbers of seronegative patients (n=85), RF and IgG-ACPA positive but RA33 and IgA-RF/ACPA negative patients (n=17) as well as patients positive for both RA33 and IgA-RF/ACPA but negative for RF and ACPA (n=4) are also indicated.

**Conclusions:** Thus, increasing the number of antibodies in serological routine testing would provide valuable additional information allowing to better distinguish between RA and other rheumatic disorders also in patients negative in current routine diagnostics and may provide valuable additional information regarding the prediction of treatment responses.

## FRI0568 MR – ENTEROGRAPHY FINDINGS OF INTESTINAL INFLAMMATION IN SPONDYLOARTHRITIS WITH HIGH FAECAL CALPROTECTIN LEVELS

I. Ergenc<sup>1</sup>, E. Uner<sup>2</sup>, R. Ergelen<sup>3</sup>, G. Haklar<sup>2</sup>, N. Imeryüz<sup>4</sup>, Ö. Atug<sup>4</sup>, P. Atagündüz<sup>5</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Biochemistry; <sup>3</sup>Radiology; <sup>4</sup>Gastroenterology; <sup>5</sup>Rheumatology, Marmara University School of Medicine, Istanbul, Turkey

**Background:** Intestinal inflammation is seen in half of patients with spondyloarthritis (SpA), and can be detected by faecal calprotectin (Fcal)<sup>1</sup>. Small bowel inflammation is detected by MR Enterography (MRE), accurately<sup>2</sup>.

**Objectives:** Definition of MRE changes in SpA patients with high Fcal levels.

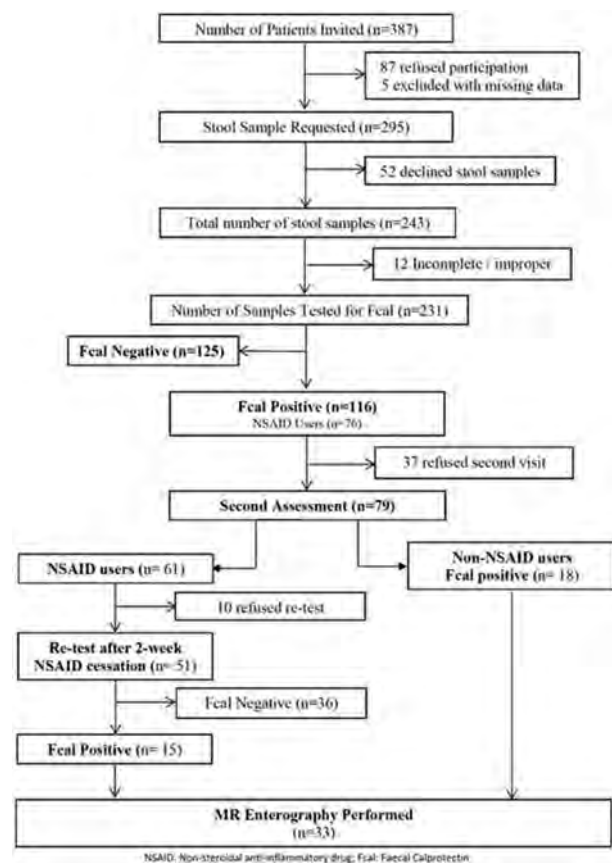

**Methods:** A total of 231 SpA patients, 50 healthy subjects and 50 inflammatory bowel disease (IBD) patients were included. Stool specimens were obtained and data on BASDAI scores, abdominal pain, diarrhoea, NSAID and TNF inhibitor usage were noted. Fcal was measured by IDK ELISA 2 weeks after the cessation of NSAID. MREs were obtained in Fcal >50 µg/g SpA patients. Contrast enhanced MRE was performed using 3 Tesla MRI device after 6 hours of fasting.

**Results:** Demographic and clinical characteristics are summarised in table 1 and flow diagram (figure 1). Median Fcal of SpA patients was higher than healthy controls and lower than IBD patients. Fcal levels were high in 15 (33.3%) of 45 healthy cases and all but two of them were NSAID users. The Fcal test was high in 45.9% (n=106) of SpA patients. There was no correlation between BASDAI index and Fcal results (r=0,08 p=0,42). Mean Fcal levels of active and in remission patients were 78.2±20 and 77.8±7.02 µg/g respectively (p=0.97). Fifty-two of the Fcal-high SpA patients were retested after cessation of NSAIDs for 14 days. In 15 patients Fcal levels remained elevated. MRE was performed 33 SpA patients with high Fcal levels. MRE findings were observed in 29 of 33 (87%) patients. Four out of 33 (%12,1) MRE imaging was totally normal. Patients with MRE findings had higher median Fcal levels than those with normal MRE imaging (98 vs. 52 µg/g p=0.002). All patients had increased mesenteric fat density and presence of mesenteric lymph nodes. Increased mesenteric vascularity (28/29), increased bowel wall enhancement (23/29) and thickness (18/29) were frequently detected.

Approximately one-third of the patients had a luminal stricture (13/29) and loss of haustration (12/13).

**Abstract FRI0568 – Table 1.** Demographic and clinical characteristics

	SpA (n=231)	Healthy Controls (n=45)	IBD (n=50)	P Value (SpA vs Healthy Controls)
Age (Mean±SD)	45.2±9.8	43.4±14.9	39.9 ±13.1	p=0.33
Gender (Female/Male)	117/114	27/18	18/32	p=0.25
NSAID Users (%)	%54.8	%53.3	%0	p=0.85
NSAID dose/2 wks	8.8±8.3	10,6±8.3	0	p=0.37
Anti-TNF users (%)	%53.0	%0	%36.0	
BASDAI (Mean±SD)	2,58 ±2,16			
BASDAI≥4 (n/%)	60/194 (%26)			
Fcal (Median, Min-Max)	45.4 (0– 830)	34.7 (2–324)	69.5 (0– 840)	p=0.004
Fcal high (>50 µg/g) (%)	%45.9 (n=106)	%33.3 (n=15)	%58.0 (n=29)	p=0.12
Fcal of NSAID Users (Median, Min-Max)	63 (0– 830)	54 (2–324)		p=0.30
Fcal of non-NSAID Users (Median, Min-Max)	27 (0– 507)	16 (2–72)		p=0.06

**Conclusions:** In SpA patients with high Fcal levels MRE detected inflammation of mucosal as well as serosal surfaces, as in early CD.

### TO WHAT EXTENT IS INTEROBSERVER RELIABILITY FOR DETECTING ULTRASOUND URATE CRYSTAL DEPOSITS DEPENDENT ON THE EXPERIENCE OF THE ULTRASONOGRAPHER?

J. Uson<sup>1</sup>, E. Garmendia<sup>2</sup>, C. Moragues<sup>3</sup>, J.J. de Agustín<sup>4</sup>, L. Mayordomo<sup>5</sup>, E. de Miguel<sup>6</sup>, H. Corominas<sup>7</sup>, J. Garrido<sup>8</sup>, E. Naredo<sup>9</sup>. <sup>1</sup>Rheumatology, Hospital Universitario Móstoles, Madrid; <sup>2</sup>Rheumatology, Hospital Universitario Cruces, Vizcaya; <sup>3</sup>Rheumatology, Hospital Universitario de Bellvitge, L'Hospitalet del Llobregat; <sup>4</sup>Rheumatology, Vall D'Hebron Hospital, Barcelona; <sup>5</sup>Rheumatology, Hospital Universitario Valme, Sevilla; <sup>6</sup>Rheumatology, Hospital Universitario la Paz, Madrid; <sup>7</sup>Rheumatology, Hospital Unversitario de Sant Pau, Barcelona; <sup>8</sup>Social psyschology and methodology, Universidad Autónoma; <sup>9</sup>Rheumatology, Hospital Fundación Jiménez Díaz, Madrid, Spain

**Background:** Musculoskeletal (MS) ultrasound (US) is used for diagnosing and managing gout in clinical practice and has the potential to become an outcome measure for clinical trials. Cartilage double contour sign (DC) and tophi(T) are elementary US lesions of urate crystal deposits. OMERACT MSUS Working Group developed the first consensus-based definitions for DC and T and showed that the reliability of the definitions ranged from moderate to excellent in static images and somewhat lower in patients when tested in highly experienced MS ultrasonographers.<sup>1</sup>

**Objectives:** To compare the agreement between a group of rheumatologist-ultrasonographers (RU) with a variable experience in MSUS with the agreement between rheumatologist-ultrasonographers highly experienced in MSUS and teachers (ExRU) for detecting DC and T in in patients.

**Methods:** 16 RU with a variable experience in MSUS were trained in the OMERACT U definitions for DC and T. Next, as a preliminary reliability exercise, they read 30 different US joint static images from gout patients and healthy subjects for the presence or absence of DC or T. Afterwards the RU group and a group of 5 ExRU consecutively, independently and blindly carried out each a reliability exercise in 5 subjects (3 crystal proven gout patients and 2 healthy controls) for the presence or absence of DC or T. Both groups performed a standardised 8 min bilateral grey-scale UU examination of the following: the suprapatellar knee recess for T, femoral knee cartilage for DC, medial and lateral knee compartments for T and dorsal first metatarsal phalangeal for T and metatarsal head for DC. Fleiss kappa was used to assess interobserver reliability. K values 0–0.20 were considered poor; 0.20–0.40 fair; 0.40–0.60 moderate; 0.60–0.80 good and 0.80–1 excellent.

**Results:** Kappa values were moderate for the RU group inter-reader agreement in static US images (K 0.514 for DC and 0.465 for T). However, there were significant differences between the interobserver agreement from both groups in patients, being kappa values fair (K 0.344 for DC and 0.305 for T) for the RU group while good for the ExRU group (K 0.674 for DC and 0.673 for T) ( $p < 0.001$  for DC and T). Worst agreement among RU and ExRU was for detecting DC in MTF joint.

	RU <sup>16</sup>			ExRU <sup>5</sup>			p
	kappa	Lower 95% CI	Upper 95% CI	kappa	Lower 95% CI	Upper 95% CI	
Tophi (T)	0.305	0.275	0.336	0.673	0.575	0.771	<0.001
Double contour (DC)	0.344	0.301	0.387	0.674	0.535	0.812	<0.001

CI, confidence interval

**Conclusions:** This study showed that although inter-reader agreement for gout lesions can be acceptable in static US images, interobserver agreement in patients is highly dependent on the experience of the ultrasonographers.

### SERUM KL-6 LEVEL REFLECTS SEVERITY OF INTERSTITIAL LUNG DISEASE ASSOCIATED WITH CONNECTIVE TISSUE DISEASE

J.S. Lee<sup>1</sup>, E.Y. Lee<sup>1</sup>, J.K. Park<sup>1</sup>, Y.-J. Ha<sup>2</sup>, E.H. Kang<sup>2</sup>, Y.J. Lee<sup>2</sup>, Y.W. Song<sup>1</sup>.

<sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital; <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul, Korea, Republic Of

**Background:** Measuring severity of interstitial lung disease (ILD) usually depends on the extent or pattern of imaging findings on computed tomography

(CT) and the parameters of pulmonary function test. Krebs von den Lungen 6 (KL-6) is a sialylated glycoprotein mainly expressed on the surface membrane of type II pneumocytes and bronchiolar epithelial cells. Serum level of KL-6 had been reported to be associated with presence or outcome of ILD associated with connective tissue diseases (CTD-ILD).

**Objectives:** We aimed to evaluate KL-6 as a potential biomarker reflecting severity of CTD-ILD.

**Methods:** Study population was a retrospective cohort of 549 Korean patients with rheumatoid arthritis (RA), systemic sclerosis (SSc), inflammatory myositis (IM), Sjogren's syndrome (SS), and systemic lupus erythematosus (SLE) who had concurrent ILD or not. Serum concentration of KL-6 (U/mL) was measured by Nanopia KL-6 assay (SEKISUI MEDICAL, Tokyo), using latex enhanced immunoturbidimetric assay method. Semi-quantitative grade of ILD extent (grade 1: 0%–25%, grade 2: 26%–50%, grade 3: 51%–75%, grade 4: 76%–100%) was evaluated by CT scan. To suggest cutoff value of KL-6 level to differentiate each semi-quantitative grade, receiver operating characteristic curves were drawn. Student t-test and Pearson's coefficient (PC) were applied to evaluate the correlation of KL-6 level and severity of ILD.

**Results:** The patients with CTD-ILD (n=165) had elevated serum level of KL-6 compared to CTD without ILD (n=384) (mean  $\pm$ SD, 741.0 $\pm$ 724.3 vs 236.1 $\pm$ 157.0 U/mL,  $p < 0.001$ ). In subgroup analysis, RA (563.9 $\pm$ 627.0 vs 231.3 $\pm$ 188.5,  $p < 0.001$ ), SSc (766.4 $\pm$ 754.6 vs 224.0 $\pm$ 120.3,  $p = 0.002$ ), IM (808.1 $\pm$ 746.9 vs 291.4 $\pm$ 238.6,  $p < 0.001$ ), and SS or SLE (884.9 $\pm$ 762.3 vs 225.7 $\pm$ 107.0,  $p < 0.001$ ) also had significant difference according to the presence of ILD. Semi-quantitative grade of ILD in CT scan was significantly proportional to KL-6 level among consecutive grade (figure 1). The optimal cutoff values to differentiate each semi-quantitative grade were 684.3 U/ml (grade  $\geq 2$ ; sensitivity 58.3%, specificity 91.8%), 689.7 U/ml (grade  $\geq 3$ ; 86.7%, 86.0%, respectively), and 958.3 U/ml (grade 4; 100%, 84.0%, respectively). Percent diffusion capacity for carbon monoxide (DLCO%) and forced vital capacity (FVC%) had negative correlation with KL-6 level (PC = -0.587,  $p < 0.001$ ; PC = -0.399,  $p < 0.001$ , respectively).

**Abstract FRI0570 – Figure 1.** Serum level of KL-6 of the ILD patients stratified by semiquantitative CT grade.

**Conclusions:** Serum levels of KL-6 were increased in CTD-ILD and had good correlation with CT grade, FVC, and DLCO. Higher serum level of KL-6 may reflect severity of CTD-ILD.

### ADDITIONAL SCREENING FOR LOW THORACIC BONE MINERAL DENSITY IN PATIENTS REFERRED FOR CARDIAC CT – A DANISH, MULTI-CENTRE, AND CROSS-SECTIONAL STUDY

J. Therkildsen<sup>1</sup>, S. Winther<sup>2</sup>, H.S. Jørgensen<sup>3</sup>, L. Nissen<sup>1</sup>, J. Thygesen<sup>4</sup>, P. Ivarsen<sup>5</sup>, E.-M. Hauge<sup>6</sup>, M. Böttcher<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Hospital Unit West, Herning; <sup>2</sup>Department of Cardiology; <sup>3</sup>Department of Nephrology; <sup>4</sup>Department of Clinical Engineering, Aarhus University Hospital; <sup>5</sup>Department of Nephrology; <sup>6</sup>Department of Rheumatology, Aarhus University, Aarhus, Denmark

**Background:** Quantitative computed tomography (QCT) can precisely and with high reproducibility measure spine bone mineral density (BMD) using cardiac computed tomography (CT) scans.<sup>1</sup> Standard for diagnosing osteoporosis is a dual-energy X-ray absorptiometry (DXA) scan.<sup>2</sup> Despite DXA being fast and with low radiation, many patients with osteoporosis goes undiagnosed.<sup>3</sup>

**Objectives:** The aim was to characterise the bone mineral density (BMD) status in a group of patients with low to intermediate risk of coronary artery disease (CAD).

**Methods:** This study is a retrospective, cross-sectional study analysing prospectively acquired data from the Dan-NiCAD study. Participants were patients with symptoms suggestive of CAD referred for a cardiac CT between 2014–09 and 2016–03. Patient data were collected from interviews. BMD was measured in 3 vertebrae starting from the left main coronary artery using QCT. We used the American college of radiology cut-off values for lumbar spine QCT to categorise patients into very low (<80 mg/cm<sup>3</sup>), low (80–120 mg/cm<sup>3</sup>), or normal BMD (>120 mg/cm<sup>3</sup>).

**Results:** Analyses included 1487 patients. Mean age was 57 years (range 40–80), 52% were women. The total number of patients with very low BMD was 179 (12%) (105 women, 74 men). The majority of patients with very low BMD was not previously diagnosed with osteoporosis (87%) and received no anti-osteoporotic treatment (90%). Compared to patients with normal BMD, individuals with very low BMD had more risk factors for osteoporosis such as higher age (p<0.001), predisposition to osteoporosis (p<0.001), and were more often former smokers (p<0.01).

**Conclusions:** Very low BMD seems present in a significant proportion of men and women, a majority of which were not diagnosed with osteoporosis or receiving anti-osteoporotic medication. Patients with very low BMD had more osteoporotic risk factors compared to patients with normal BMD. Additional screening for osteoporosis can potentially prevent osteoporotic fractures. However, thoracic spine QCT is a new method without diagnostic cut-off values and prospective studies regarding fracture risk prevention are missing.

### PREVALENCE OF ECHOCARDIOGRAPHIC FINDINGS IN CONNECTIVE TISSUE DISEASES – A RETROSPECTIVE COHORT STUDY

K. Weiss<sup>1</sup>, W.A. Schmidt<sup>1</sup>, A. Krause<sup>1</sup>, V.S. Schäfer<sup>2</sup>. <sup>1</sup>Medical Center for Rheumatology Berlin-Buch, Immanuel Krankenhaus Berlin, Berlin; <sup>2</sup>Medical Clinic and Policlinic III, Department of Oncology, Hematology, Immuno-Oncology and Rheumatology, University Medical Center Universitätsklinikum Bonn, Bonn, Germany

**Background:** Echocardiography is routinely performed in patients with connective tissue diseases (CTD), mostly to evaluate cardiac involvement or development of pulmonary arterial hypertension (paH). Despite its frequent application there is incomplete data for the range and frequency of findings.

**Objectives:** 1) To study the frequency of echocardiographic findings in routinely examined patients with different CTD. 2) To report which findings were associated

with a history of inflammatory cardiac involvement. 3) To analyse whether findings changed over time in patients with several examinations.

**Methods:** Retrospective chart review of all consecutive patients from a tertiary rheumatological referral centre with CTD diagnosis and echocardiographic examination between 01/01/2006 and 31/12/2015. For each echocardiographic finding, the proportion of patients per diagnosis with a pathological result in at least one examination was calculated. Each finding's frequency was compared between patients with and without previously documented inflammatory cardiac involvement; p<0.05 in Fisher's exact test was considered significant. For patients with more than one visit, we recorded how often findings developed or resolved between two consecutive examinations.

**Results:** 1004 patients with different CTD and a total of 1660 performed echocardiographies were analysed. Table 1 displays the frequency of findings in the whole cohort and for each CTD. The following findings were significantly more common in patients with known inflammatory cardiac involvement (n=109) than in those without (n=896): regurgitation of tricuspid valve (45.0% (n=49) of patients with cardiac involvement vs. 23.2% (n=206) of patients without, p<0.001) and of pulmonary valve (15.6% (n=17) vs. 6.1% (n=54), p=0.001); global hypokinesia (3.7% (n=4) vs. 0.4% (n=4), p=0.007); dilatation of left atrium (33.9% (n=37) vs. 17.5% (n=156), p<0.001), of left ventricle (LV) (11.0% (n=12) vs. 5.1% (n=45), p=0.025), of right atrium (15.6% (n=17) vs. 1.7% (n=15), p<0.001) and of right ventricle (15.6% (n=17) vs. 1.9% (n=17), p<0.001); signs of paH (28.4% (n=31) vs. 5.3% (n=47), p<0.001), and pericardial effusion (43.1% (n=47) vs. 6.5% (n=58), p<0.001). 314 patients had consecutive examinations; median interval between first and last examination was 40 months (SD: 28, range: 0.9–115). New development or resolution of findings between consecutive examinations was common. The findings which most commonly developed were mitral valve regurgitation in 24% (n=76) of patients, tricuspid regurgitation in 21% (n=67), aortic valve sclerosis in 18% (n=55) and LV dysfunction in 20% (n=62). The findings which most commonly resolved were mitral regurgitation in 15% (n=47) of patients, tricuspid regurgitation in 16% (n=49), aortic valve sclerosis in 10% (n=31) and LV dysfunction in 13% (n=42).

**Conclusions:** Echocardiographic examinations frequently revealed structural and/or functional abnormalities in patients with CTD. Some findings were associated with previous cardiac involvement and might be disease-related. When reevaluating a patient, findings had often newly developed or resolved since the last examination. Overall, repeated echocardiographic examinations may be a valuable part of follow-up in CTD patients.

### ULTRASONOGRAPHY AND HISTOLOGICAL DIAGNOSIS CONCORDANCE IN PATIENTS WITH SUSPECTED PRIMARY SJÖGREN SYNDROME

L. Barrio Nogal<sup>1</sup>, C. Bohórquez<sup>1</sup>, A. Perez Gómez<sup>1</sup>, A. Castelló<sup>2</sup>, M.J. León<sup>1</sup>, P. Pretel<sup>1</sup>, M. Álvarez de Mon<sup>1</sup>. <sup>1</sup>ESL-Reumatología, Hospital Universitario Príncipe de Asturias; <sup>2</sup>Centro Nacional de Epidemiología, Instituto de Salud Carlos III, Madrid, Spain

**Background:** Minor salivary gland biopsy (MSGB) is the most used diagnostic tool for primary Sjögren Syndrome (SS). The potential relevance of an alternative

non-invasive, fast, low cost and choice by the patient technique, like mayor salivary gland ultrasonography (MSGUS), has to be investigated.

**Objectives:** To evaluate the utility of MSGUS as a diagnostic tool for primary SS and to study the concordance with MSGB.

**Methods:** 36 patients were consecutively recruited with clinical and/or analytical suspicion of SS, from outpatient Rheumatology consultations from 2015–2017. All patients received a MSGB and a MSGUS. Two echographers performed two images readings with an interval of at least one week. They worked blinded for clinical and histological results. Demographics, clinical, serological, ESSPRI and ESDAI were recorded. The histological results were classified according to *Chisholm* and *Mason* score and the US results according to the system by *Cornec et al.* The final SS diagnosis was made using the 2002 classification criteria. Subsequently the data was analysed using the statistical software STATA/MP. Adjusted concordance intra and interobserver (kappa coefficient) was calculated for the diagnoses performed by US (normal/pathological). The validity of US and biopsy to diagnose SS according to the 2002 criteria was evaluated by calculating the percent agreement between the tests, along with the specificity, sensitivity, PPV, NPV and area below the curve (AUC). Further, the percent association of the diagnoses between serology and US were determined, and the statistical significance of it was evaluated with chi-square test.

**Results:** 94% were female, with an average age of 58 years. 69% were non-smokers. 89% showed pathological Schirmer test, 78% extraglandular features, 19% hypocomplementemia and 44% hypergammaglobulinemia. As for the serological data, 81% had positive ANAS, 44% antiRo52, 39% antiRo60% and 28% antiLa. 39% of the patients were RF positive. 69% fulfilled the 2002 classification criteria with an average ESSPRI of 5.3 and ESSDAI of 1.5. Using these criteria as a gold-standard, the total percentage agreement was 83.3% for US and 80.6% for biopsy (S 92, Sp 64.3%). A good concordance was found between both observers (kappa=0.8) along with intraobserver (kappa=0.64 and 0.78 for first and second observer respectively). The percentage of patients with positive antibodies (48% antiRo52, 41% antiRo60, 30% antiLa) had pathological US. Significant statistical differences were not found in patients with normal US ( $p>0.44$  in all associations explored).

**Conclusions:** MSGUS is a non-invasive imaging method useful for the diagnosis of primary SS in common clinical practice with a diagnostic value similar to the MSGB. MSGUS has good correlation intra and interobserver. There was no statistical significant association found between the positive autoimmune antibodies and US.

Pisani<sup>6</sup>, E. Quarta<sup>9</sup>, M. Rossini<sup>7</sup>, O. Viapiana<sup>7</sup>, M.L. Brandi<sup>1</sup>. <sup>1</sup>Department of Surgery and Translational Medicine, University of Florence, Metabolic Bone Diseases Unit, University Hospital of Florence, Florence, Italy, Firenze; <sup>2</sup>Department of Neurosciences and Rehabilitation, "Carlo Poma" Hospital, ASST, Mantova; <sup>3</sup>SC Rheumatology, ASL 3 Genovese, Genova; <sup>4</sup>Department of Medicine, Surgery and Neurosciences, University of Siena, Siena; <sup>5</sup>Department of Experimental and Clinical Medicine, University of Florence and SOD Rheumatology AOU, Florence, Italy, Firenze; <sup>6</sup>Institute of Clinical Physiology, National Research Council, Lecce; <sup>7</sup>Rheumatology Unit, Department of Medicine, University of Verona, Verona; <sup>8</sup>"Carlo Poma" Hospital, ASST, Mantova; <sup>9</sup>O.U. of Rheumatology, "Galateo" Hospital, San Cesario di Lecce, ASL-LE, Lecce, Italy

**Background:** Radiofrequency Echographic Multi Spectrometry (REMS) is an innovative densitometric technique able to automatically provide BMD values, which it has been shown to highly correlate with BMD obtained by DXA.<sup>1</sup>

**Objectives:** To evaluate the accuracy of REMS measurements in postmenopausal women's femoral neck health assessment versus DXA results in a multicenter clinical study.

**Methods:** In seven Italian referral centres for osteoporosis management, 1659 postmenopausal women (51–70 years old) were enrolled. Both DXA and REMS examinations were performed on each patient at femoral neck, in the strictest adherence to the corresponding guidelines. After excluding the scans affecting by errors, the REMS diagnostic accuracy was evaluated by assessing sensibility and specificity in the discrimination between "osteoporotic" and "healthy" patients; the degree of correlation between DXA-BMD and REMS-BMD was quantified through Pearson's correlation coefficient (r) evaluation. In addition, the agreement between DXA-BMD and REMS-BMD was measured calculating the root mean square error (RMSE).

**Results:** A strong correlation ( $r=0.94$ ,  $p<0.001$ ) was detected between BMD obtained by DXA and REMS – estimated BMD at femoral neck, with a low residual error ( $RMSE=0.034$  g/cm<sup>2</sup>). In addition to this, REMS resulted to have a high capability to discriminate osteoporotic from healthy patients (sensitivity=94.4%, specificity=95.6%).

**Conclusions:** Thanks to its high capability to identify osteoporotic patients, and the strong correlation with DXA parameters, REMS has been shown to be an accurate non-ionising approach to detect osteoporosis at femoral neck.

#### EVALUATION OF SCREENING QUESTIONNAIRES FOR PSORIASIS ARTHRITIS IN A SAMPLE OF PATIENTS WITH PSORIASIS IN A THIRD LEVEL HOSPITAL

M.D. Ruiz Montesino<sup>1</sup>, V. Moreira Navarrete<sup>1</sup>, A.M. Carrizosa Esquivel<sup>2</sup>, C. León Caro<sup>1</sup>, J.J. Pérez Venegas<sup>1</sup>, D. Mendoza Mendoza<sup>1</sup>. <sup>1</sup>Servicio De Reumatología. Hospital Universitario Virgen Macarena; <sup>2</sup>Servicio Dermatología. Hospital Universitario Virgen Macarena, SEVILLA, Spain

**Background:** Psoriatic arthritis (PsA) is an erosive joint inflammatory disease associated with psoriasis. Between 5% and 35% of patients with psoriasis may develop PsA. Screening questionnaires have been developed for dermatologists in order to make them suspect which patients should be referred to the rheumatologist for evaluation.

**Objectives:** To know the percentage of patients with PsA detected by the questionnaires in a group of psoriasis patients coming from an outpatient dermatology clinics.

**Methods:** The study was carried out in the rheumatology unit in collaboration with dermatology. Patients with cutaneous psoriasis who had not previously been diagnosed of any type of arthritis, from a dermatology clinic, were recruited consecutively. Patients were invited to participate in the study and referred to the rheumatology research unit where they signed the informed consent. Then, the questionnaires were administered.

**Results:** From November 2014 to December 2015, 53 patients were recruited: 30 women and 23 men. The mean age was 44 ( $\pm 13$ ) years. The average duration of psoriasis was 11 ( $\pm 9$ ) years. 61% had affected nails and skin. 11% of patients received no treatment for psoriasis and 13% received treatment with MTX or PUVA. The mean PASI was 3 ( $\pm 4$ ). The quality of life, measured by DLQI, was 1 ( $\pm 2$ ). 50% of patients had all the screening questionnaires positive. EARP was the questionnaire that tested positive in a higher percentage of patients, 70%. 68% of the patients had some painful joint and only 8% had some inflammation. Only 9 patients met CASPAR classification criteria and were diagnosed as PsA, of which 56% were in topical treatment by dermatology. These 9 patients had higher PASI than those undiagnosed and were the only ones who had swollen joints. The screening questionnaire that detected all these 9 patients was the EARP, but it was positive in 65% of patients who did not meet CASPAR criteria.

	S	E	VPP	VPN
ToPAS	0,55	0,61	0,22	0,87
PASE	0,33	0,81	0,27	0,85
PEST	0,44	0,70	0,23	0,86
EARP	1	0,36	0,24	1

**Conclusions:** The percentage of patients with PsA who was identified by EARP questionnaire was 100%, but with a high proportion of FP. PASE detected 33%, TOPAS 55% and PEST 44%. Therefore, questionnaires available are useless in daily clinical practice, due to lack of specificity or sensitivity. The development of a small questionnaire for dermatologist based on CASPAR criteria could be more effective

**FRI0576 PULMONARY ULTRASOUND IN THE ASSESSMENT OF INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS**

M. Moreno<sup>1</sup>, K. Almaguer<sup>1</sup>, J. Gutierrez<sup>1</sup>, A. Bernal-Gonzalez<sup>1</sup>, C. Bertolazzi<sup>1</sup>, E. Cruz-Arenas<sup>1</sup>, C. Pineda<sup>1</sup>, S. Ruta<sup>2</sup>, M. Gutierrez<sup>1</sup>. <sup>1</sup>Division of Musculoskeletal and Rheumatic Diseases, Instituto Nacional de Rehabilitación, Mexico city, Mexico; <sup>2</sup>Rheumatology department, Hospital Italiano, Buenos Aires, Argentina

**Background:** Interstitial lung disease (ILD) is an extra-articular complication in rheumatoid arthritis (RA) that may lead to severe impairment of respiratory function. High-resolution computer tomography (HRCT) is the most common imaging technique used in the assessment of ILD. However, the costs and the ionising radiation may limit its use in routine practice. Recently, US is generating interesting data that may support its use and validity in the assessment of ILD in rheumatic diseases<sup>1,2</sup>.

**Objectives:** To investigate the correlation between lung US and HRCT findings in the assessment of ILD in patients with RA.

**Methods:** Patients with diagnosis of RA according to ACR 2010 classification criteria with respiratory symptoms and previous diagnosis of ILD by HRCT were included. Clinical examination, pulmonary function test (PFT) and lung US were performed in all patients. Lung US was performed by a rheumatologist expert in US who was blinded to clinical and HRCT data. Serologic tests (anti-CCP, ESR, RF, ANA) were taken. Lung US was performed in 14 intercostal spaces (IS) and quantified according to the following semiquantitative scoring: grade 0=normal ( $\leq 5$  B-lines); grade 1=mild ( $\geq 6$  to  $\leq 15$  B-lines); grade 2=moderate ( $\geq 16$  to  $\leq 30$  B-lines); and grade 3=marked ( $\geq 30$  B-lines). The Warrick score (extension) was used to interpret the HRCT findings.

**Results:** A total of 32 patients with RA (25 women and 7 men) were included. Mean age was 59.37 ( $\pm$ SD 13.66) years, and the mean disease duration was 58.75 ( $\pm$ SD 52.52) months. Sixteen patients were smokers and 75% were positive to anti-CCP. Moreover, the mean of DAS-28 was 3.71 ( $\pm$ SD 1.01). A total 448 IS were assessed by US. Lung US was positive for ILD in 28 patients (87.5%). From those, 7 patients (21.8%) with severe ILD, 12 patients (37.5%) with moderate, 9 patients (28.1%) with mild. Four patients (12.5%) showed normal lung US assessment. A significant linear correlation was found between the US score and the HRCT score ( $p < 0.000$ ; correlation coefficient = 0.75). A negative correlation was found between US B-line assessments and DLCO ( $p \leq 0.000$ ). No association was founded with DAS28, anti-CCP, PFT. Sensitivity and specificity of ultrasound for ILD was 87.5% and 98% respectively.

**Conclusions:** Our study demonstrates that lung US may be a potential tool for the assessment of ILD also in patients with RA. It can be adopted in future as a screening tool to use at moment of the first diagnosis of RA.

**MRI-BONE MARROW OEDEMA COMBINED WITH LOW-DOSE CT SCANNING PERFORM OPTIMALLY IN THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS**

L. Ye<sup>1</sup>, M.A. Brown<sup>2,3</sup>, D. Chen<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Centre for Precision Medicine, First Affiliated Hospital, Wenzhou Medical University, Wenzhou, China; <sup>3</sup>Institute of Health and Biomedical Innovation, Queensland University of Technology, Princess Alexandra Hospital, Brisbane, Australia

**Background:** The evidence of sacroiliitis on radiography and MRI have been regarded as crucial for diagnosis of ankylosing spondylitis (AS) and axial spondyloarthritis (axSpA). Low-dose CT (ldCT) has advantages on sacroiliitis has not been taken into consideration until now.

**Objectives:** To compare the performance of plain radiography, ldCT, and MRI for facilitating the diagnosis of sacroiliitis in radiographic negative axial spondyloarthritis (nr-axSpA) or AS from suspected axSpA.

**Methods:** Patients presenting with chronic back pain (>3 months duration) were recruited and assessed by axSpA-experienced rheumatologists. Patients not meeting the ASAS clinical criteria for axSpA were recruited as controls, and divided into non-inflammatory and inflammatory groups on the basis of presence of inflammatory back pain and/or CRP/ESR elevation. The ASAS clinical axSpA or modified New York AS criteria were used to define nr-axSpA or AS cases respectively. Clinical variables, pelvic radiography, sacroiliac joint (SIJ) ldCT (voltage 120 kV, electricity 70mAs) and SIJ MRI (SPAIR, T1-weighted, T2-weighted sequences) were obtained in one week period. All images were read by two expert musculoskeletal radiologists independently and differences in initial reads resolved by consensus. Plain radiographic and ldCT SIJ images were graded 0–4 according to the modified New York criteria. MRI-BMO was defined by the presence of periarthral or subchondral BMO lesions. Fat deposition, sclerosis, erosions or bony ankylosis were regarded as signs MRI-structural lesions. Subjects were considered MRI positive if they had either BMO or structural lesions.

**Results:** 130 patients were included in the study and had SIJ radiography and ldCT, of whom 71 additionally had SIJ MRI. 28 (39.3% female, 36% B27 prevalence) non-inflammatory controls, 24 (33.3% female, 50% B27 prevalence) inflammatory controls, 34 (26.5% female, 86.3% B27 prevalence) nr-axSpA and 44 (36.4% female, 95.3% B27 prevalence) AS cases were recruited in total. Positive imaging results according to clinical diagnoses are given in the table. These findings show that ldCT had much higher sensitivity than radiography for nr-axSpA and similar specificity. Whilst no non-inflammatory control was positive for ldCT and only one for radiography, three inflammatory controls were positive for ldCT but negative for radiography, with two being negative by MRI, and all being HLA-B27 negative, suggesting that they may be false positives. MRI-BMO had the highest sensitivity for nr-axSpA, but had lower specificity, with 31% of non-inflammatory controls being positive for this modality, and lower sensitivity for AS. MRI-structural had intermediate performance with slightly lower sensitivity to ldCT for both AS and nr-axSpA, but lower specificity than ldCT, and lower sensitivity for nr-axSpA than MRI-BMO.

Abstract FRI0577 – Table 1

Diagnosis	Plain Radiography	ldCT	MRI-BMO	MRI-structural
AS	44/44 (100%)	44/44 (100%)	19/21 (90%)	20/21 (95%)
nr-axSpA	0/34 (0%)	15/34 (44.1%)	19/24 (79%)	10/24 (42%)
Non-inflammatory control	1/28 (3.6%)	0/28 (0%)	5/16 (31%)	6/16 (38%)
Inflammatory control	0/24 (0%)	3/24 (12.5%)	3/10 (30%)	1/10 (10%)

**Conclusions:** ldCT and MRI-BMO examination are more sensitive than either plain radiography or MRI-structural assessment, but MRI overall is less specific than plain radiography or ldCT. The relative position of these imaging modalities in screening patients for axSpA needs to be reconsidered in the light of these findings, also taking into account the costs involved.

**FRI0578 INCREASED VEIN WALL THICKNESS IN BEHÇET'S SYNDROME**

M. Gjeni<sup>1</sup>, E.S. Durmaz<sup>2</sup>, S. Akbaş<sup>2</sup>, A.S. Dikici<sup>2</sup>, I. Mihmanlı<sup>2</sup>, H. Yazıcı<sup>3</sup>, E. Seyahi<sup>3</sup>, <sup>1</sup>Department of Medicine; <sup>2</sup>Department of Radiology; <sup>3</sup>Department of Medicine, Division of Rheumatology, Cerrahpaşa Medical Faculty, Istanbul, Turkey

**Background:** Lower extremity vein thrombosis (LEVT) is the key feature of vascular involvement in Behçet's syndrome (BS). Vein wall thickness (VWT) is proposed to be a surrogate marker of venous disease. A pilot MR study done in 7 BS patients and controls, had demonstrated increased VWT and signal enhancement in the lower extremity veins of BS patients without vascular disease.<sup>1</sup> Another study, using USG, found that VWT was increased among BS patients without vascular disease compared to patients with ankylosing spondylitis and healthy controls.<sup>2</sup>

**Objectives:** We reassessed VWT in proximal lower extremity veins in BS patients with LEVT and suitable controls in a formal, masked protocol.

**Methods:** We studied 47 (40 M/ 7 F) BS patients with LEVT, 50 (43 M/ 7 F) BS patients without any vascular involvement and 38 (31 M/ 7 F) age and gender matched apparently healthy controls. Two independent radiologists, blinded to the diagnosis of BS, used USG to measure VWT of common femoral vein (CFV), superficial femoral vein (SFV) and vena saphena magna (VSM) in both legs.

**Results:** As shown in table 1, mean age at disease onset and the disease duration were similar between BS study groups. The mean age at thrombosis onset of the patients with LEVT was 26.4±5.8 years. There was good concordance between the 2 observers (kappa: 0.9) The mean VWT was significantly increased among both BS patients with LEVT and those without any vascular involvement when compared to the healthy controls while those with LEVT had the thickest veins.

**Abstract FRI0578 – Table 1.** Disease duration and VWT

	BS with vascular involvement (n=47; 40 M/ 7 F)	BS without vascular involvement (n=50; 43 M/ 7 F)	Healthy controls (n=38; 31 M/ 7 F)	P value

**FRI0579 DIAGNOSTIC UTILITY OF METATARSOPHALANGEAL SYNOVITIS IDENTIFIED BY ULTRASONOGRAPHY FOR EARLY RHEUMATOID ARTHRITIS**

M. Okamoto<sup>1</sup>, K. Fujikawa<sup>1</sup>, A. Mizokami<sup>1</sup>, Y. Endo<sup>2</sup>, M. Mine<sup>3</sup>, A. Kawakami<sup>2</sup>. <sup>1</sup>Rheumatology, Isahaya General Hospital, Isahaya; <sup>2</sup>Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki; <sup>3</sup>Rheumatology, Suga Orthopedic Hospital, Isahaya, Japan

**Background:** In patients with rheumatoid arthritis (RA), synovitis can occur at not only hand and finger joints but also the metatarsophalangeal (MTP) joints. However, power Doppler ultrasonography (PDUS) findings of the MTP joints and its diagnostic utility remain unclear in patients with early RA.

**Objectives:** The present study investigated whether the detection of MTP synovitis by PDUS is useful for the diagnosis of early RA.

**Methods:** The study enrolled 174 patients with suspected RA within 6 months of onset. We assessed the articular synovium using grey scale (GS) and power Doppler (PD) signals with a semi-quantitative method (grades 0–3) in both hand and finger joints (22 joints) and MTP joints (10 joints) by PDUS. In addition, we evaluated bone erosion and intermetatarsal bursitis. We defined GS grade  $\geq 1$  and PD grade  $\geq 1$  as PDUS synovitis. We evaluated the diagnostic accuracy of PDUS synovitis for RA.

**Results:** Of the 174 patients, 59 were diagnosed with RA and 115 did not have RA. Among the patients with RA, 47 (80%) had PDUS synovitis in the hand and finger joints and 32 (54%) had PDUS synovitis in the MTP joints. The frequencies of PDUS synovitis in each MTP joint, bone erosion of the fifth MTP joint, and intermetatarsal bursitis were significantly higher in patients with RA than in those without RA. The diagnostic accuracy of PDUS synovitis in the hand and finger joints was good, with a sensitivity of 80%, specificity of 77%, and accuracy of 78%. On considering the MTP joints in addition to the hand and finger joints, the diagnostic accuracy improved, with a sensitivity of 92%, specificity of 74%, and accuracy of 80%. In this study, 7 patients (12%) with RA had synovitis in the MTP joints and not in the hand and finger joints.

**Conclusions:** When synovitis cannot be detected in the hand and finger joints by PDUS, scanning of the MTP joints could be useful for the diagnosis of early RA.

**FRI0580** **QUANTITATIVE MRI OF SINGLE VS. MULTIPLE JOINTS IN JUVENILE IDIOPATHIC ARTHRITIS AS PREDICTIVE MEASURE OF CLINICAL OUTCOMES**

N. Tzaribachev<sup>1</sup>, O. Kubassova<sup>2</sup>, M. Hinton<sup>2</sup>, M. Boesen<sup>3</sup>. <sup>1</sup>*Pediatric Rheumatology Research Institute, Bad Bramstedt, Germany;* <sup>2</sup>*IAG, London, UK;* <sup>3</sup>*Department of Radiology, Copenhagen University Hospital Bispebjerg and Frederiksberg, Copenhagen, Denmark*

**Background:** Clinical examination of juvenile idiopathic arthritis (JIA) patients does not always adequately reflect disease activity, whereas quantitative Dynamic Contrast Enhanced (DCE)-MRI based biomarkers extracted from images of multiple joints have been shown to reliably predict the course of the disease<sup>1</sup>.

**Objectives:** To investigate the association between DCE-MRI measures of inflammation in a single and in multiple joints and the treatment related clinical changes.

**Methods:** 18 patients (12 girls, med. age 12.6 years, med. disease 1.2 years) with polyarticular JIA with more than 3 affected joints or intolerance to more than 3 months of MTX were given Etanercept. Their most clinically affected hand was imaged with DCE-MRI (0.2T Esaote C-Scan) at baseline, 3 and 6 months following the treatment. DCE-MRI was analysed using dedicated software package (DYNAMIKA, IAG). Dynamic Enhanced MRI Quantification (DEMRIQ-V) was calculated as the volume of enhancing voxels within Region of Interest placed around a single or multiple MCPJs. DEMRIQ-V was also weighted by the mean of Maximum Enhancement (ME) and Initial Rate of Enhancement (IRE), the parameters corresponding to the height and slope of the signal intensity vs time curves extracted from the enhancing voxels.<sup>2</sup> Clinical scores included active joint (AJ) count. Involvement of less than 3 AJ was considered a clinical response. The differences in DEMRIQ-V between the visits were analysed using t-test, assuming  $p < 0.05^*$  to be statistically significant and  $p < 0.025^{**}$  to be clinically meaningful.

**Results:** In all patients, in clinically unaffected joints, MRI was able to detect sub-clinical disease, and in all but 3 patients, significant and/or clinically meaningful changes were documented for DEMRIQ-ME. In 4 patients, DEMRIQ-V scores showed corresponding clinical changes whereas all other patients these markers were non-concordant. DEMRIQ-V score was predictive of clinical outcome:

- · in 5 patients, improvement of DEMRIQ-V at month 3 predicted response to treatment at month 6;
- · in 4 patients, increase or persistence of a high DEMRIQ-V at month 3 predicted non-response to treatment at month 6;
- · DEMRIQ-V measured in a single most affected joint was as predictive as when it was measured in all MCPJs.

**Conclusions:** We conclude that DCE-MRI's ability to detect early disease can reliably support clinical examination. Use of DEMRIQ-V and DEMRIQ-ME scores, which either followed clinical response (DEMRIQ-ME) or predicted clinical outcomes at 6 months (DEMRIQ-V) in most patients can support early clinical and research decisions.

**FRI0581** **ULTRASONOGRAPHY IN THE DETECTION OF JOINT DESTRUCTION IN RA PATIENTS: A COMPARISON WITH CONVENTIONAL RADIOGRAPHY**

O. Alekseeva, A. Smirnov, S. Glukhova, A. Volkov, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

**Background:** RA evolves erosive polyarthritis resulting in destructive changes in the joints. Ultrasonography (US) is used in current practice as early diagnostic modality for identification of structural damage to the articular surfaces.

**Objectives:** To compare US and radiographic assessment of hands and feet joint destruction in RA patients, and to evaluate the contribution of early US detection of damage into long-term RA outcomes.

**Methods:** 75 patients with RA, mean age 54.0,<sup>44.0;</sup> <sup>62.0</sup> disease duration <sup>7.4;</sup> <sup>20</sup> months, were treated with MTX and biologics according to Treat-To-Target concept. Hands and feet US were analysed before initiation of treatment and in 3, 6, 9 and 12 months after. Deepening of the bony contour  $>2$  mm in width and  $>1$  mm

in depth, visualised in 2 orthogonal planes, was considered as the key US sign of destructive changes (erosions) according to OMERACT criteria. A binary scoring system (presence/absence of erosions) of the joints examined was used. Radiographs were obtained at baseline, at 12 month and 4 years, radiographic changes were assessed using Sharp/van der Heijde modified scoring method. Radiographic progression was documented based on Sharp/Van der Heijde modified score changes during the follow up.

**Results:** There was a significant correlation between the counts of joints with erosions obtained with two diagnostic methods – US and radiography. This correlation was moderate before initiation of therapy ( $r=0.37$ ;  $p=0.0008$ ), and weak – after 12 month follow up ( $r=0.28$   $p=0.016$ ). During one year US showed increase in the count of joints with erosions (from 1 [0; 2] to 2<sup>1; 3</sup>) while radiography did not show any significant change (from 0 [0; 1] to 0 [0; 1]).

Bland-Altman analysis showed statistical agreement between the results obtained by two methods. Mean difference between the two modalities before initiation of treatment was  $-0.42$  (95% CI  $-0.68$ ;  $-0.16$ ), and at 12 month follow up  $-1.16$  (95% CI  $-1.52$ ;  $-0.80$ ), which is comparable with actual values. We identified the relationship between the difference in variables and the count of affected joints before and 12 month after initiation of treatment ( $r=-0.35$ ,  $r=-0.53$  respectively). 8% of variables were outside 2 standard deviations at baseline, and 4% – at 12 month. Logistic regression analysis showed no relationship between annual radiological progression and US diagnosed increasing count of joints with erosions at 3, 6 and 9 months follow up. However, dynamic radiographs assessment at 4 years revealed a correlation with US diagnosed count of joints with erosions at 6 month and 9 month follow up ( $r=0.24$ ,  $p=0.03$ ;  $r=0.24$ ,  $p=0.04$ , respectively). Quality indicator of US diagnosed count of erosions at 6 month follow up: OR=2.8 95% CI 1.05–7.5,  $p=0.037$ , with 71% sensitivity and 54% specificity; Quality indicator of US diagnosed count of erosions at 9 month follow up: OR=2.73 95% CI 1.02–7.27,  $p=0.041$ , with 64% sensitivity and 61% specificity. Quantitative assessment of the dynamics at these time periods did not show any relationship.

**Conclusions:** Therefore, our study confirms the relevance of US in assessment of bone erosions in spite of week agreement with radiography data. We found a prognostic value of US-diagnosed erosions during the first year of follow up for long-term (4 years) clinical outcomes, and the relevance of control assessment at 6 month after initiation of treatment.

**FRI0582** **CHANGE IN MUSCLE VOLUME AND MUSCLE FAT FRACTION AS POTENTIAL NON-INVASIVE BIOMARKERS OF DISEASE PROGRESSION: MACHINE LEARNING FRAMEWORK FOR QUANTITATIVE ANALYSIS OF MRI DATA**

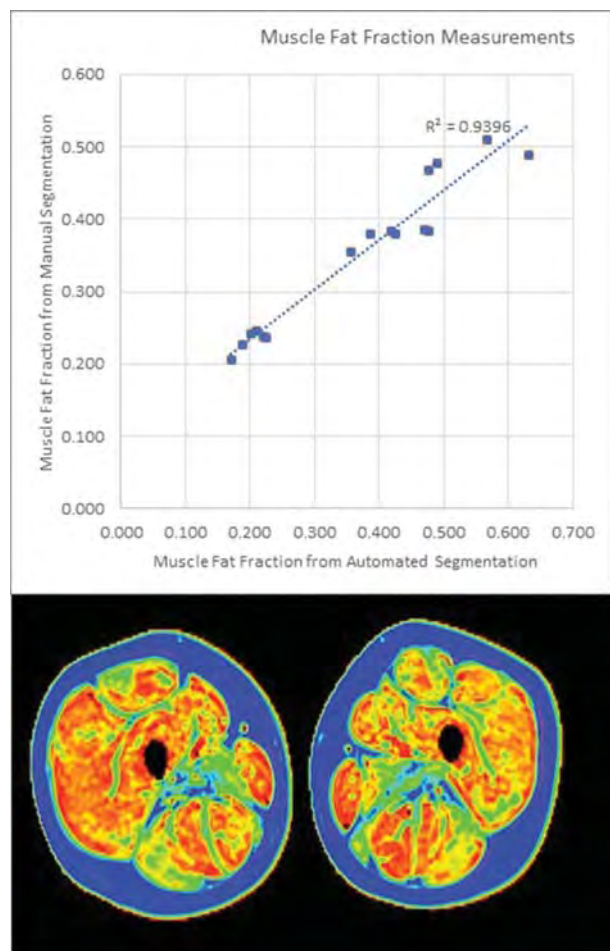

D. Fischer<sup>1</sup>, P. Hafner<sup>1</sup>, S. Schmidt<sup>1</sup>, M. Hinton<sup>2</sup>, J. Gonzalez<sup>2</sup>, O. Kubassova<sup>2</sup>. <sup>1</sup>*Division of Neuropaediatrics, University of Basel Children's Hospital, Basel, Switzerland;* <sup>2</sup>*IAG, London, UK*

**Background:** Change in muscle volume and muscle fat fraction are potential non-invasive biomarkers of disease progression in a number of diseases, including sporadic inclusion body myositis<sup>1</sup> and osteoarthritis<sup>2</sup>. Their measurement from magnetic resonance images (MRI) usually involves time consuming manual segmentations of the images by trained readers, which limits the use of these biomarkers in clinical research and practise.

**Objectives:** In this study, we present a novel unsupervised k-means-classifier based image processing framework, developed for machine learning approach to segmentation of thigh muscles from MRI and the subsequent calculation of fat fraction from Dixon images. Further, we present validation of the new approach against manual segmentation using longitudinal retrospectively acquired data.

**Methods:** Axial MR images from the upper thighs including in-phase and out of phase sequences were recorded in a group of 8 subjects at baseline and at a follow up. The 16 imaging time points were manually segmented by an expert reader, who delineated the muscle. For these regions the mean fat fraction was calculated from the in-phase and out of phase Dixon images. The fully automated segmentation was then run on the same images and the resulting fat fractions compared with the manual results. The proposed k-means approach classifies each image pixel according to signal intensity and creates image masks for bone, muscle and fat in three dimensions. The pixel counts from bone, muscle and fat are automatically measured to produce the volume and mean fat fraction.

**Results:** We compared the mean fat fraction for the two approaches and found linear correlation was good ( $R^2=0.9396$ ). Manual segmentations typically took 40 min or more to execute, compared to the automated segmentations, which required less than 5 min on a standard desktop computer

Example Fat Fraction Map

Abstract FRI0582 – Figure 1. Example Fat Fraction Map

**Conclusions:** In the present study, we reported a segmentation framework based on unsupervised k-means to measure muscle volume and fat fraction. It offers time savings versus manual segmentations and correlates well with fat fraction measurements. This could be useful for muscle quantification in the fields of osteoarthritis, sports medicine and rehabilitation. Further studies are planned to compare sensitivity of automatically acquired measures to clinical progression.

### CLINICAL UTILITY OF ANA-ELIA VS ANA-IMMUNOFLUORESCENCE IN CONNECTIVE TISSUE DISEASE

O. Alsaed<sup>1</sup>, L. Alamilah<sup>1</sup>, O. Al-Radideh<sup>2</sup>, M. Elkhalfa<sup>3</sup>, A.-W. Al-Allaf<sup>1</sup>. <sup>1</sup>Medicine/Rheumatology; <sup>2</sup>Internal Medicine; <sup>3</sup>laboratory medicine and pathology, Hamad Medical corporation, Doha, Qatar

**Background:** Antinuclear antibody (ANA) detection by indirect immunofluorescence technique (ANA-IIF) is the standard test for connective tissue disease (CTD) screening for last 5 decades, which has low specificity and it is labour intensive. ANA detection by fluoroenzyme immunoassay (ANA-Elia) has been developed recently as an alternative method to include 17 ANA-targeted recombinant antigens.

**Objectives:** Compare the sensitivity and specificity of the new ANA-Elia with conventional ANA-IIF.

**Methods:** Randomly selected 1458 patient's sera from primary and secondary health care were tested for both the standard ANA-IIF (Diasorin S.P.A, saluggia, Italy) and the new ANA-Elia (Phadia GmbH, Ferieiburg, Germany). ANA-Elia is fluoroenzyme immunoassay performed on the Phadia-250 automated platform. It contains 17 ANA-targeted recombinant antigens; dsDNA, Sm-D, Rib-P, PCNA, U1-RNP (70, A, C), SS-A/Ro (52 and 60), SS-B/La, Centromere B, Scl-70, Fibril-larin, RNA Polymerase III, Jo-1, Mi-2, and PMScl. Result with ratio >1.0 considered positive for the new technique. For ANA-IIF our lab cut off for positive test is  $\geq 1:80$ . Patients were evaluated in our rheumatology clinic for fulfilling the corresponding international clinical criteria for various connective tissue diseases.

**Results:** 75.7% were females with mean age of  $43 \pm 13$  years. 201 (11.5%) patients confirmed to have clinical CTD as follow: 142 SLE, 24 Sjogren's syndrome, 15 scleroderma, 7 MCT, 10 Myositis and 10 undifferentiated CTD. The specificity of ANA-Elia at cut off ratio of >1 and ANA-IIF at titer of  $\geq 1:80$  was almost equal, 88.5% and 87.6% respectively. However, ANA-Elia has higher sensitivity (74.5%) as compared to ANA-IIF (61.6%). At a higher cut off ratio of >2 and titer of  $\geq 1:160$ , the specificity improved to 93.6%–92.6% respectively.

	ANA-Elia		ANA-IIF	
	>1	>2	$\geq 1:80$	$\geq 1:160$
<b>Sensitivity</b>	74.5%	67.6%	61.6%	50.7%
<b>Specificity</b>	88.5%	93.6%	87.6%	92.6%

**Conclusions:** The ANA testing with the newly developed, use friendly, fully automated and less labour intense method of ANA-Elia can replace the standard conventional ANA-IIF with better specificity.

### FLUORESCENCE OPTICAL IMAGING ENHANCEMENT IS ASSOCIATED WITH JOINT PAIN IN HAND OSTEOARTHRITIS

O. Maugesten<sup>1</sup>, S. Ohndorf<sup>2</sup>, S.V. Hestetun<sup>1</sup>, B. Slatkowsky-Christensen<sup>1</sup>, T. K. Kvien<sup>1</sup>, T. Uhlig<sup>1</sup>, I.K. Haugen<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; <sup>2</sup>Dept. of Rheumatology and Clinical Immunology, Charité Univ.smedizin, Berlin, Germany

**Background:** Joint inflammation plays a role in the pathogenesis of hand osteoarthritis (OA), and previous studies have presented an association between pain and synovitis detected by MRI and ultrasound. No previous hand OA studies have explored the validity of fluorescence optical imaging (FOI), a novel imaging technique demonstrating altered microcirculation in wrist and finger joints, as a sign of inflammation.

**Objectives:** The aims of the current study were to quantify the distribution of FOI findings in different joint groups in hand OA patients and explore the association between FOI findings and self-reported pain and tender joints on clinical examination.

**Methods:** The NOR-HAND study is an observational hand OA study, in which 251 patients (88% female, median age 61 (interquartile range 56–66) years) underwent FOI of both hands, bilateral clinical examination for tender joints on palpation and movement, and self-reported their pain in individual joints during the last 24 hours and the last 6 weeks on the homunculus. The FOI-scan was performed after the administration of an intravenous fluorescence dye (indocyanine green, ICG) and 360 images (1/second) were produced in 6 min. Based on the inflow and washing out of the dye the pictures were divided into 3 phases. Ultimately, the prima vista mode (PVM) represented a composite picture of the first 240 images of the examination. For each phase, fluorescence enhancement in the joints was graded from 0–3 based on signal intensity (grade 1=diffuse red, grade 2=intense red and diffuse white <50% of the joint, grade 3=intense white >50% of the joint). To study the association between FOI findings and pain in the same joint we applied logistic regression analyses with generalised estimating equations adjusting for age and sex. Separate models were applied for each of the FOI phases and pain outcomes.

**Results:** The median (interquartile range) number of DIP/PIP joints with FOI enhancement within each patient ranged from 0 (0–0) in phase 1,  $14^{11-16}$  in phase 2, 3 (0–8) in phase 3 and  $9^{7-11}$  in PVM. CMC-1 and MCP-joints showed no and uncommon enhancement on the examination, respectively, regardless of the phase, and the associations between FOI and pain were therefore analysed in the DIP and PIP joints only. FOI enhancement in the DIP and PIP joints was associated with pain in the same joint, consistent for all three pain outcomes. A dose-

response relationship was found for phase 2, phase 3 and PVM, but not in phase 1 (table 1). Few joints showed enhancement in phase 1 and a clear dose-response relationship was found for pain during the last 24 hours only (data not shown).

Associations between FOI Enhancement and Pain in the same DIP and PIP Joints.			
	Self-reported pain last 24 hours	Self-reported pain last 6 weeks	Tender joint on clinical exam
	OR (95 % CI)	OR (95 % CI)	OR (95 % CI)
<b>FOI phase 1</b>			
Grade 0	1.00 (ref.)	1.00 (ref.)	1.00 (ref.)
Grade 1-3	1.50 (0.94, 2.40)	1.92 (1.20, 3.09)	2.42 (1.37, 4.25)
<b>FOI phase 2</b>			
Grade 0	1.00 (ref.)	1.00 (ref.)	1.00 (ref.)
Grade 1	1.26 (1.02, 1.55)	1.15 (0.93, 1.44)	2.15 (1.81, 2.55)
Grade 2	1.94 (1.58, 2.38)	1.92 (1.52, 2.41)	2.69 (2.21, 3.26)
Grade 3	2.25 (1.61, 3.15)	2.53 (1.73, 3.69)	4.00 (2.85, 5.59)
<b>FOI phase 3</b>			
Grade 0	1.00 (ref.)	1.00 (ref.)	1.00 (ref.)
Grade 1	1.76 (1.42, 2.17)	1.73 (1.40, 2.14)	2.15 (1.77, 2.61)
Grade 2+3*	2.29 (1.30, 4.06)	2.51 (1.33, 4.73)	3.21 (1.91, 5.39)
<b>FOI Prima Vista Mode</b>			
Grade 0	1.00 (ref.)	1.00 (ref.)	1.00 (ref.)
Grade 1	1.36 (1.14, 1.61)	1.38 (1.14, 1.68)	2.20 (1.88, 2.56)
Grade 2**	2.37 (1.88, 2.98)	2.33 (1.81, 3.00)	3.22 (2.57, 4.04)

\* Grades 2 and 3 combined due to few joints with grade 3 in phase 3. \*\* No joints with grade 3 in prima vista mode (PVM).

**Conclusions:** In this first hand OA study, FOI enhancement was frequently found in the DIP and PIP joints, whereas the method seems insensitive to detect inflammation in the CMC-1 joints. FOI enhancement was related to self-reported pain and to tender joints on clinical examination, supporting the validity of the FOI examination in patients with hand OA.

**FRI0585** **PREVALENCE OF ANTI-ACETYLATED PROTEIN ANTIBODIES IN INFLAMMATORY ARTHRITIS, OSTEOARTHRITIS, CONNECTIVE TISSUE DISEASES AND ITS DISCRIMINATIVE CAPACITY AS DIAGNOSTIC MARKER FOR EARLY RHEUMATOID ARTHRITIS**

P. Studenic<sup>1</sup>, H. Bang<sup>2</sup>, A. Alunno<sup>3</sup>, D. Sieghart<sup>1</sup>, D. Aletaha<sup>1</sup>, S. Blüml<sup>1</sup>, H. Haslacher<sup>1</sup>, J.S. Smolen<sup>1</sup>, G. Steiner<sup>1</sup>. <sup>1</sup>Internal Medicine 3, Division Of Rheumatology, Medical University Vienna, Vienna, Austria; <sup>2</sup>Orgentec Diagnostika GmbH, Mainz, Germany; <sup>3</sup>Rheumatology Unit, Department of Medicine, University of Perugia, Perugia, Italy; <sup>4</sup>Department of Laboratory Medicine, Medical University Vienna, Vienna, Austria

**Background:** Numerous post-translationally modified proteins have been described as auto-antigens in rheumatoid arthritis (RA) patients. Antibodies (abs) against acetylated (ac) peptides (AAPA) have recently been reported in RA patients, but not yet been evaluated in other inflammatory and non-inflammatory

rheumatologic conditions; therefore their specificity (spec) and sensitivity (sens) remains unclear.

**Objectives:** To determine the prevalence of AAPA in RA, healthy subjects and other rheumatic diseases in order to evaluate their diagnostic potential for discriminating RA, healthy and other rheumatic diseases.

**Methods:** We obtained serum samples of patients with early untreated RA, established RA (>3 years), osteoarthritis (OA), systemic lupus erythematosus, granulomatosis with polyangiitis (GPA), polymyositis, axial spondyloarthritis, primary Sjögren's syndrome and healthy subjects. AAPA were measured by ELISA using peptides derived from mutated vimentin (acetylation of lysine or ornithine in position 7 or 2 (inverse peptide), as antigen. Receiver operating characteristics and logistic regression analyses were used to assess the discriminative capacity of AAPA.

**Results:** Areas under the curves (AUC) were significant in early RA (eRA; n=120; 75% female, mean disease duration: -0.07±0.51 years, mean symptom duration 1.49±2.01 years) versus healthy subjects for IgG-abs against ac lysine, inverse lysine and ornithine (AUC of 0.666, 0.687, 0.800, respectively). We chose a cutoff of 20 U/ml putting an emphasise on high spec, with balanced sens (ac-lysine: spec: 97.0%; sens: 32.5%;+likelihood ratio (LR) 10.7, CI: 3.4–33.7; ac-inverse-lysine: spec: 80.7%; sens: 42%;+LR 2.2, CI: 1.3–3.6; ac-ornithine: spec: 93.9%; sens: 39.2%;+LR 6.5; CI: 2.9–14.5). Analyses of positivity for multiple ab-reactivity revealed increasing +LR by number of abs, with 100% specificity when all 3 AAPAs are detected (table 1). Testing this cutoff against OA patients showed similar specificities, but with lower +LR (2 AAPA:+LR 3.48, CI: 1.9–6.6). Sens is increased when testing established RA versus healthy controls, with ac-ornithine performing best (ac-lysine: 49.2%, CI: 42.0–56.5; ac-inv-lysine: 35.2%, CI: 28.5–42.4; ac-ornithin: 53.9%, CI: 46.6–61.0)

We found that practically only RA patients showed three different AAPA reactivities (in eRA: 39% positive for ac-ornithine abs, 33% for ac-lysine abs, 48% for inverse ac-lysine abs). Polymyositis and GPA patients showed the lowest prevalence of AAPA (**Graph 1A**).

Among eRA patients 17% were found to be exclusively positive for AAPA, while 39% were also positive for rheumatoid factor (RF) and anti-citrullinated antibodies (ACPA) (distribution in **Graph 1B**). Also in RF- and ACPA- patients the presence of one AAPA identified RA patients vs. healthy subjects with a spec of 77.7% and those with 2 AAPA reactivities with even 97% respectively.

**Abstract FRI0585 – Table 1.** Sensitivity, specificity, positive and negative likelihood ratio (LR) for identifying early RA patients against healthy controls by the number of AAPA reactivities

N of AAPA	Sensitivity	95% CI	Specificity	95% CI	+LR	95% CI	-LR	95% CI
>0	60	50.7- 68.8	77.78	68.3- 85.5	2.7	1.8- 4.0	0.51	0.4- 0.7
>1	36.67	28.1- 45.9	96.97	91.4- 99.4	12.1	3.9- 37.8	0.65	0.6- 0.8
>2	10	5.3- 16.8	100	96.3- 100.0			0.9	0.8- 1.0

**Graph 1A:** Prevalence (in%) of IgG antibodies against the 3 different acetylated peptides using 20 U/ml as cutoff

**Graph 1B:** Venn diagram, outlining the distribution and overlap of AAPA (blue circle), ACPA (striped circle) and RF (rose circle) in early rheumatoid arthritis patients (n=120)

**Conclusions:** AAPA are highly prevalent autoantibodies in early RA, closing a further gap of seronegativity, with only 24.6% of early RA patients remaining negative for RF, ACPA or AAPA. In particular, multiple reactivity to AAPA increased the specificity for eRA, also adding diagnostic value beyond RF and ACPA.

### LONGITUDINAL ASSESSMENT OF CORTICAL INTERRUPTIONS AND VBMD IN RA AND HEALTHY SUBJECTS USING HR-pQCT

M. Peters<sup>1</sup>, J. van den Bergh<sup>2</sup>, P. Geusens<sup>3</sup>, A. Scharmgaa<sup>1</sup>, D. Loeffen<sup>4</sup>, R. Weijers<sup>4</sup>, B. van Rietbergen<sup>5</sup>, A. van Tubergen<sup>1</sup>. <sup>1</sup>Rheumatology, MUMC; <sup>2</sup>Rheumatology, MaastrichtUMC and UHasselt, Maastricht, Netherlands; <sup>3</sup>Rheumatology, MaastrichtUMC and UHasselt, genk, Belgium; <sup>4</sup>Radiology, MUMC, Maastricht; <sup>5</sup>Faculty of Biomedical Engineering, TU Eindhoven, Eindhoven, Netherlands

**Background:** Preservation, repair and progression of cortical interruptions in finger joints has been observed in RA using conventional radiography, MRI, ultrasound and high-resolution peripheral quantitative computed tomography (HR-pQCT). Accurate and quantitative information about such changes over time, however, is still lacking.

**Objectives:** To evaluate changes over one year in cortical interruptions (number, surface area and volume), bone density (vBMD) and micro-structural parameters from HR-pQCT scans of finger joints in RA and healthy subjects (HS) using a recently developed semi-automatic algorithm for cortical interruptions detection.<sup>1</sup>

**Methods:** Baseline and 1 year follow up HR-pQCT scans of finger joints of 32 patients with RA (221 joints, 53% on biologic DMARDs (bDMARDs)) and 32 HS (117 joints) were analysed for changes in cortical interruption, density and morphological parameters. Mean changes (at the group level) and proportions of joints (at the joint level) with changes beyond least significant changes were calculated after correction for baseline damage.

**Results:** At baseline, 530 interruptions (3.25/joint) were identified in RA, and 136 (1.45/joint) in HS. The mean of the interruption parameters did not change in either group, except for a significant increase in number of interruptions in PIP joints in RA. However, the proportion of joints showing repair in interruption volume was higher in RA than in HS (6.6% versus 1.7%,  $p=0.041$ ). Changes in cortical interruption parameters were negatively correlated with changes in cortical BMD and thickness ( $p<0.01$ ). Mean vBMD decreased more and more joints showed loss of vBMD in RA than in HS ( $-4.4$  versus  $-1.1$  mgHA/cm<sup>3</sup> and 26.7% versus 12.9%, respectively, both  $p<0.01$ ). Proportionally more joints showed interruptions and loss of vBMD in patients with synthetic DMARDs (sDMARDs) compared to bDMARDs (6.1% versus 1.8% and 31.3% versus 17.2%, respectively, both  $p<0.05$ ).

**Conclusions:** Using HR-pQCT based semi-automatic cortical interruption analysis a large number of interruptions was identified in RA and HS. Cortical interruptions, vBMD and micro-structural parameters were more impaired in RA, of which vBMD and micro-structural parameters further deteriorated. Patients on sDMARDs had more joints with progression in number of interruptions and more loss of vBMD compared to bDMARDs.

### LOW BACK PAIN DUE TO ENTHESOPATHY OF ERECTOR SPINE MUSCLE: A COMPARATIVE US AND MRI STUDY IN PATIENTS WITH ILIAC CREST PAIN SYNDROME

P.T. Todorov<sup>1</sup>, M. Kalcheva<sup>2</sup>, A. Marinkov<sup>3</sup>, A. Batalov<sup>4</sup>. <sup>1</sup>Rheumatology, Medical University, Kaspela University Hospital, Plovdiv; <sup>2</sup>Radiology, Specialized imaging Laboratory "Rusev", Sofia; <sup>3</sup>Rheumatology, Kaspela University Hospital; <sup>4</sup>Rheumatology and Internal Diseases, Medical University Plovdiv, Kaspela University Hospital, Plovdiv, Bulgaria

**Background:** Iliac crest pain syndrome (ICPS) is a regional pain syndrome, that is particularly common in patients with low back pain (LBP). It is characterised clinically by pain perceived maximally at the most medial part of the posterior iliac crest, and patients' recognition of the pain provoked by a systematic digital palpation in this area, as "their" typical one. Though ICPS is very frequently encountered in LBP, the exact etiology of this syndrome was not established. Based on anatomical data, it was suggested that ICPS could be caused by a tendopathy/ enthesopathy of erector spine (ES) muscle attachments to the medial iliac crest (MIC).<sup>(1)</sup> In a previous anatomical and ultrasound (US) study we showed that this in fact might be the case.

**Objectives:** The purpose of this study was, regarding the existing clinical diagnostic criteria for the ICPS as a "gold standard", to establish the sensitivity,

specificity, positive and negative predictive values (PPV and NPV) and the overall accuracy of the US and the Magnetic Resonance Imaging (MRI) assessment of the entheses of the ES muscle at the MIC in patients with LBP and features indicative of ICPS.

**Methods:** 25 patients (9 men, 16 women, mean age 43.12±11.83, mean BMI 25.07±2.36) with anamnesis of chronic "nonspecific" (after lateral X-ray and standard clinical examination) LBP perceived maximally in the region of the MIC uni- or bilaterally were included. First a systematic palpation of the posterior MIC bilaterally was performed to diagnose ICPS clinically. Then in two successive days each patient underwent MRI examination of the lower back (lumbar and sacroiliac regions), with an enlarged field of view in the sagittal plane, and a standardised US examination of the ES terminal tendons and entheses bilaterally. The MRI were assessed by a radiologist with 10 years of experience in MRI. The sonographies were performed by a rheumatologist with 7 years of experience in US and analysed in regards with the OMERACT definition of enthesopathy. As a single US lesion at any enthesis is a common finding, the presence of at least two pathological features were required to classify given entheses as abnormal.

**Results:** ICPS was identified clinically in 20 of the patients (15 unilateral and 5 bilateral), thus 25 of the total 50 entheses were clinically pathological. Comparing to the clinical findings, the calculated sensitivity, specificity, PPV, NPV and overall accuracy of the US and the MRI assessments of the ES entheses at the MIC are placed in table 1:

	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Accuracy (95% CI)
US	88% (69%–97%)	80% (60%–93%)	82% (67%–91%)	87% (69%–93%)	84% (71%–93%)
MRI	64% (43%–82%)	80% (59%–93%)	76% (58%–88%)	70% (56%–80%)	71% (59%–85%)

**Conclusions:** This study shows that enthesopathy of the ES muscles could be the unrecognised cause for most of the cases of ICPS –a regional syndrome particularly common in LBP. US performed better than the MRI in diagnosing this pathological condition, that may reflect the fact that radiologists are not used to assess these structures. The good diagnostic properties of US in ICPS could be of value when assessing patients with otherwise "nonspecific" LBP.

### ULTRASOUND COULD HAVE PREVENTED DMARD ESCALATION IN RHEUMATOID ARTHRITIS WITH FIBROMYALGIA

R. Chakr<sup>1</sup>, J.C.O. Santos<sup>1</sup>, L.D.S. Alves<sup>1</sup>, N. P. B. D. Andrade<sup>1</sup>, A. Ranzolin<sup>2</sup>, C. V. Brenol<sup>1</sup>. <sup>1</sup>Universidade Federal do Rio Grande do Sul, Porto Alegre; <sup>2</sup>Universidade Federal de Pernambuco, Recife, Brazil

**Background:** Despite the growing body of evidence, the proper use of ultrasound (US) in monitoring disease activity still needs better understanding.<sup>1,2</sup> As an objective measure, US could prevent overtreatment in situations of overestimation of clinical disease activity, such as fibromyalgia, present in up to 20% of patients with rheumatoid arthritis (RA).<sup>3–5</sup>

**Objectives:** To verify how ultrasound (US) could impact rheumatoid arthritis (RA) treatment decision in real life when fibromyalgia (FM) was also present.

**Methods:** A retrospective cohort study was performed from 2011 through 2016, including RA patients with FM. Patients were grouped according to US examination (Group DAS28: never performed US examination; Group US: at least one US exam). RA was considered active if DAS28  $\geq 3.2$  in Group DAS28 or PD  $\geq 2$  in any single joint in Group US.

**Results:** Out of 230 RA patients, 22 women with concomitant FM (Group DAS28=10 and Group US=12) were seen in 280 visits from 2011 through 2016. DAS28 was 4.4 (2.5–6.3) vs. 4.0 (2.0–5.0) ( $p=0.592$ ) in Groups DAS28 and US, respectively.

DMARD treatment was escalated in 12.9% of visits in Group DAS28 versus 8.2% in Group US ( $p=0.791$ ) (table 2). The relative risk (RR) for DMARD escalation in Group US compared to Group DAS28 was 1.08 (95%CI 0.60–1.95). However, in 74% of visits in Group US, DMARD was escalated despite a negative US result. In a theoretical scenario where US result oriented treatment decision, DMARD was escalated in 3.6% of visits in Groups DAS28 and US, respectively (table 1). Also, in this US-based scenario, the RR for DMARD escalation in Group US compared to Group DAS28 was 0.39 (0.19–0.83).

The proportion of visits with US evaluation increased over time, nonetheless the level of agreement between US synovitis (PD  $\geq 2$ ) and DMARD escalation

decreased (figure 1). Despite indicating US examination more frequently, rheumatologists did not base their DMARD escalation decision on PD synovitis.

**Abstract FRI0588 – Table 1.** Visits distribution according to DMARD escalation and groups

	Group DAS28 (n=175)	Group US (n=105)	
	DAS28	Observed	Theoretical
DMARD escalated*	36 (12.9)	23 (8.2)	10 (3.6)
DMARD not escalated*	139 (49.6)	82 (29.3)	95 (33.9)

\*Numbers (%) of visits;  $p=0.791$  (chi-square test) between Group DAS28 and Observed Group US;  $p=0.012$  (chi-square test) between DAS28 and Theoretical Group US

**Abstract FRI0588 – Figure 1.** Proportion of visits with US evaluation (bars) and level of agreement between US synovitis ( $PD \geq 2$ ) and DMARD escalation (kappa coefficients;  $P < 0.001$  for all).

**Conclusions:** In this real-life study of RA patients with FM, the growing use of US for evaluating RA activity over time was associated with an increasing discordance between US result and clinical judgement. When clinical judgement and US findings were discordant, RA treatment decision was mostly based on clinical judgement. If US result oriented treatment decision, DMARD escalation risk would be 61% smaller.

#### A JOINT PROCEDURAL RECOMMENDATION ON FDG-PET/CT(A) IMAGING IN LARGE VESSEL VASCULITIS AND POLYMYALGIA RHEUMATICA FROM THE CARDIOVASCULAR AND INFLAMMATION & INFECTION COMMITTEES OF THE EANM, THE CARDIOVASCULAR COUNCIL OF THE SNMMI, THE PET INTEREST GROUP (PIG), AND ENDORSED BY THE ASNC

R. Slart on behalf of Members of EANM Cardiovascular, EANM Infection & Inflammation Committees, SNMMI Cardiovascular Council, PET Interest Group, and ASNC. *Medical Imaging Center, departments of Nuclear Medicine and Radiology, University Medical Center Groningen, Groningen, Netherlands*

**Background:** [18F]-fluorodeoxyglucose positron emission tomography combined with anatomical computed tomography angiography, (FDG-PET/CTA) is increasingly used in Large Vessel Vasculitis (LVV, consisting of Giant Cell Arteritis (GCA) and Takayasu Arteritis (TA)) and Polymyalgia Rheumatica (PMR), and may be of value for optimal diagnosis, disease activity monitoring, and evaluation

of damage development. There are currently no general accepted procedural guidelines regarding PET imaging acquisition for LVV and PMR.

**Objectives:** The aim of our study is to provide recommendations and statements, based on the available evidence in the literature combined with consensus of experts in the field, for patient preparation, FDG-PET/CT(A) acquisition and interpretation.

**Methods:** A systematic literature review was conducted to retrieve data on FDG-PET/CT(A) imaging in LVV and PMR. Expert consensus was used to propose recommendations in the absence of sufficiently robust data. Levels of evidence and grades of recommendations were attributed to the statements of different indications according to published criteria.

**Results:** Based on the literature review combined with expert consensus recommendations and statements that could be formulated: see table 1.

Recommendations and statements	Level of evidence	Grade
Fasting the patient for at least 6 hours prior to FDG administration	II	B
Normal blood glucose levels are desirable, but glucose levels below 10 mmol/L (180 mg/dL) are acceptable	II	B
FDG/PET within three days after start of GC is optional as a possible alternative	III	B
A minimum interval of 60 minutes is recommended between FDG administration and acquisition for adequate biodistribution	III	B
Use of a standardized grading system	II	B
Typical FDG joint uptake patterns should be evaluated and reported if present	II	B
Normalization of the arterial wall uptake to the background activity of venous blood pool provides a good reference to assess vascular inflammation	II	B
Normalization of the arterial wall uptake to the background activity of venous blood pool provides a good reference to assess vascular inflammation	II	B
Based on the available evidence, FDG-PET imaging has high diagnostic performance for the detection of LVV and PMR	II	B
CTA and FDG-PET have complementary roles in the diagnosis of LVV	III	B
CTA has incremental value in detecting structural vascular changes and potential complications of vasculitis	II	A
FDG-PET/CT(A) may be of value to evaluate response to treatment by monitoring functional metabolic information and detecting structural vascular changes	III	C

**Conclusions:** This joint recommendation highlights that standardisation and general consensus regarding the optimal procedural performance of FDG-PET/CT(A) imaging in LVV and PMR are highly needed. Some recommendations and statements could be formulated however, there are also a lot of open issues which need to be studied for optimal performance of FDG-PET/CT(A) in the diagnosis, (treatment)monitoring and future theranostics in LVV/PMR to increase the levels of evidence and improve the grades of the recommendations.

#### ULTRASOUND EXAMINATION OF THE WRIST JOINTS: FREQUENCY OF CRISTAL DEPOSITS (CHONDROCALCINOSIS) IN PATIENTS WITH DIFFERENT ARTHROPATHIES

R. Osipiants<sup>1</sup>, M. Eliseev<sup>2</sup>, S. Vladimirov<sup>2</sup>, K. Ilinykh<sup>2</sup>. <sup>1</sup>RUDN University; <sup>2</sup>V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Hand involvement in the rheumatic diseases is often precocious and predominant as compared to other skeletomuscular regions. The Ultrasound (US) has an important role in early calcium pyrophosphate deposition disease (CPPD) diagnosis. Recent studies suggest a positive association of CPPD and other rheumatic disease.<sup>1,2</sup>

**Objectives:** To investigate the frequency of the US features of chondrocalcinosis (CC) at the triangular fibrocartilage complex (TFC) of the wrist in patients (pts) with different arthropathies.

**Methods:** A total of forty persons were included in the study and were divided into 4 groups (on ten in each group): basic group – CPPD pts (crystal-proven at synovial fluid analysis; median age 58.5 (range 45–63) years; 6M/4F) and the control groups – rheumatoid arthritis pts (RA, ACR/EULAR 2010 age 50.5 (44–56) years; 3M/7F), psoriatic arthritis pts (PsA, CASPAR criteria; age 50(37–59) years; 3M/7F), healthy volunteers (age 37.5 (33–55) years; 3M/7F). All subjects were carefully age and gender matched with the CPPD pts. US examinations (“Voluson-i” (GE, USA), 4–13 MHz probe) were performed by one examiner. TFC of the wrist was assessed to detect US findings of crystal deposits.<sup>3</sup> The Mann-Whitney U-test was applied for intergroup comparison.

**Results:** In all CPPD pts (100%) CC of TFC was detected in at least one joint. In the control groups intra-cartilaginous hyperechoic spots were found in 6 of 10

cases with RA (60% vs. 100%,  $p=0.029$ ), in 2 with PsA (20% vs. 100%,  $p<0.01$ ), 3 cases in healthy volunteers (30% vs. 100%,  $p<0.01$ ).

**Conclusions:** The results of the present study indicate that US is a very sensitive and specific technique for detecting calcifications in patients with crystal-related arthropathy. The US findings were detected a trend of association between CC and RA. However, more studies, involving a larger number of pts, are required.

#### WHOLE-BODY MRI DEMONSTRATES REDUCTION OF INFLAMMATION IN PERIPHERAL JOINTS AND ENTHESES DURING TNF-INHIBITOR TREATMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS, BUT ALSO AGE-DEPENDENT PERSISTENT INFLAMMATION IN JOINTS PRONE TO OSTEOARTHRITIS

S. Krabbe<sup>1,2</sup>, M. Østergaard<sup>1,2</sup>, I. Eshed<sup>3</sup>, I.J. Sørensen<sup>1,2</sup>, J. Møller<sup>4</sup>, B. Jensen<sup>1</sup>, O.R. Madsen<sup>1,2</sup>, M. Klarlund<sup>1</sup>, S.J. Pedersen<sup>1</sup>. <sup>1</sup>Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet; <sup>2</sup>Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark; <sup>3</sup>Department of Diagnostic Imaging, Sheba Medical Center, affiliated to the Sackler School of Medicine, Tel Aviv University, Israel; <sup>4</sup>Department of Radiology, Herlev Hospital, Herlev, Denmark

**Background:** Patients with predominantly axial spondyloarthritis (axSpA) may also have inflammation of peripheral joints and entheses. Using a whole-body MRI (WBMRI) approach, peripheral joints and entheses can be assessed objectively and followed during treatment.

**Objectives:** To describe the localization and extent of inflammation of peripheral joints and entheses by WBMRI in patients with axSpA initiating TNF-inhibitor therapy, and to assess treatment-induced changes.

**Methods:** Fifty-three patients that fulfilled the ASAS criteria for axSpA were included. MRI of SIJs and spine and WBMRI of peripheral joints and entheses were performed at baseline and 4/16/52 weeks after starting TNF inhibitor treatment. 75 peripheral joints and 30 peripheral entheses were scored in chronological order by an experienced musculoskeletal radiologist (IE). Osteitis, synovitis and enthesal soft tissue inflammation were scored separately [0(none)/1(mild)/2 (moderate/severe)]. A WBMRI peripheral joint and entheses index (WBMRI index) was derived by summing scores of all peripheral lesions.

**Results:** Median age (IQR/range) was 35 years. (28–44/22–73); median symptom duration was 5 years. (3–13/0–31); 53% were male. Baseline median WBMRI index (n=53) was 7.4–14; 0–40 after 52 weeks (n=46) 4 (2–9; 0–26). WBMRI index decreased mean 0.6 at week 4 ( $p=0.17$ , paired t-test), 2.3 at week 16 ( $p<0.001$ ) and 3.2 at week 52 ( $p<0.001$ ). Thirty-seven patients (70%) had a relatively low baseline WBMRI index ( $\leq 10$ ) with minor change over time, while patients with higher baseline scores tended to change more (figure 1A). The most frequently involved sites ( $\geq 15\%$  of patients) were typical for SpA (sternoclavicular joint/planter fascia) or osteoarthritis (carpometacarpal-1/metatarsophalangeal-1 synovitis). In univariate analysis, WBMRI index at week 52 was associated with age (2.5 higher per 10 years increase in age,  $p<0.001$ ) and male sex (3.6 lower in men,  $p=0.021$ ), but not with body-mass index, HLA-B27, C-reactive protein or ASDAS at week 52. In multivariate regression with age and sex as covariates, only age was significantly associated with WBMRI index (2.3 per 10 years increase in age,  $p<0.001$ ) whereas sex was not ( $p=0.24$ ).

In univariate analysis, higher age was not significantly associated with change in WBMRI index, but when adjusted for baseline WBMRI index, higher age was associated with a less prominent reduction in WBMRI index (+0.9 per 10 years increase in age).

#### A Individual patient trajectories

#### B Most frequently involved sites ( $\geq 15\%$ of patients) for 46 patients with available data at baseline and 52 weeks of follow-up

	Baseline	52 weeks
<b>JOINTS:</b>		
Wrist synovitis	23	20
CMC1 synovitis	17	7
Ankle synovitis	11	7
MTP1 synovitis	15	10
MTP2-5 synovitis	9	5
Sternoclavicular synovitis	13	10
Sternoclavicular osteitis	16	11
Manubriosternal osteitis	7	5
Acromioclavicular synovitis	14	13
Shoulder synovitis	8	5
Knee synovitis	7	3
<b>ENTHESES:</b>		
Plantar fascia osteitis	7	4
Plantar fascia soft tissue infl.	6	2
Tuberculum humeri osteitis	8	8
Pubic symphysis osteitis	8	2
Greater trochanter soft tissue infl.	17	12

**Conclusions:** Inflammation of peripheral joints and entheses decreased over time in a cohort of patients with predominantly axSpA. Most patients had WBMRI index above zero during follow-up, and this was related to age and involved sites prone to osteoarthritis. Thus, the WBMRI Index may capture both disease activity related to axSpA and age-related degenerative changes.

#### SCORING MRI INFLAMMATION AND STRUCTURAL LESIONS IN SACROILIAC JOINTS OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS: IS INTER-READER RELIABILITY DEPENDENT ON THE NUMBER OF MRI SLICES?

S. Krabbe<sup>1,2</sup>, G. Kröber<sup>3</sup>, M. Østergaard<sup>1,2</sup>, S.J. Pedersen<sup>1</sup>, J. Møller<sup>4</sup>, I. J. Sørensen<sup>1,2</sup>, B. Jensen<sup>1</sup>, O.R. Madsen<sup>1,2</sup>, M. Klarlund<sup>1</sup>, U. Weber<sup>3,5</sup>. <sup>1</sup>Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet; <sup>2</sup>Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen; <sup>3</sup>King Christian X's Hospital for Rheumatic Diseases, Gråsten; <sup>4</sup>Department of Radiology, Herlev Hospital, Herlev; <sup>5</sup>University of Southern Denmark, Odense, Denmark

**Background:** The SPARCC sacroiliac joint (SIJ) scoring system assesses 6 semicoronal MRI slices for inflammation and 5 slices for structural lesions in patients with axial spondyloarthritis (axSpA).<sup>1,2</sup> However, the cartilaginous SIJ compartment may show 1–2 additional slices anteriorly or posteriorly, depending on body size and scan orientation/tilt.

**Objectives:** To investigate inter-reader reliability of an “all slices” approach versus the standard SPARCC scoring of 6/5 slices.

**Methods:** Fifty-three patients with axSpA were treated with TNF inhibitor and had MRIs obtained at weeks 0/4/16/52. An experienced (UW) and two newly trained (GK, SK) blinded readers independently scored 199 SIJ MRI scans in chronological order. The cartilaginous SIJ compartment was scored slice by slice by the SPARCC 6/5 slices approach and by all available cartilaginous slices. Initially, the most anterior and posterior slices covering the cartilaginous compartment and the transitional slice were identified. The transitional slice was defined as the most anterior cartilaginous slice with the first portion of the ligamentous compartment, clearly visible on the left and/or right side. We scored SIJ inflammation, fat metaplasia, erosion and backfill, and a combined erosion and backfill score was created. Inter-reader reliability for reader pairs SK-UW/GK-UW/SK-GK was assessed using percent agreement (for individual scores) and intra-class correlation coefficients for sum scores.

**Results:** Pairwise percent agreement was 67%/63%/79% for identification of anterior slice, 47%/56%/44% for posterior slice and 69%/68%/72% for transitional slice. Using the “all slices” approach, readers UW/SK/GK scored mean 7.2/7.7/7.0 slices per MRI scan.

“6/5 slices” and “all slices” correlated closely with each other for status scores at baseline/status scores at week 52, and change scores at week 52; BME 0.983/0.985/0.983; fat metaplasia 0.994/0.982/0.953; erosion 0.981/0.974/0.957; backfill 0.993/0.983/0.978; combined erosion and backfill 0.983/0.971/0.919.

Inflammation (standard 6 slices)		Inflammation ("all slices")		Inflammation (extra slices in "all slices" not part of 6 slices)

Change score (baseline to week 52)	1 (0 to 3)	0.33/0.41/0.66	2 (0 to 4)	0.35/0.41/0.74	0 (0-1)	0.01/0.22/0.58
Combined erosion and backfill (standard 5 slices)		Combined erosion and backfill ("all slices")		Combined erosion and backfill (extra slices in "all slices" not part of 5 slices)		
Scores	ICC(3,1)	Scores	ICC(3,1)	Scores	ICC(3,1)	
Status score at baseline	10 (2-14, 0-18)	0.68/0.47/0.73	12 (2-16, 0-24)	0.70/0.68/0.73	1 (0-3, 0-7)	0.52/0.31/0.66
Status score at week 52	8 (1-11, 0-20)	0.57/0.49/0.78	10 (4-14, 0-24)	0.41/0.71/0.79	1 (0-3, 0-8)	0.46/0.36/0.71
Change score (baseline to week 52)	-1 (-3 to 0)	0.22/0.18/0.45	-1 (-2 to 0)	0.18/0.25/0.30	0 (-1 to 0)	0.09/0.08/0.40

Scores reported as median (IQR), range. ICCs are ICC(3,1), single rater. Agreements, in pairwise comparisons (SK-UW/UK-UW/SK-GK). N = 53 for status score at baseline; N = 46 for status score at week 52 and change score (baseline to week 52).

**Conclusions:** The standardised 6/5 slices SPARCC methods had equal reliability as compared to evaluation of all cartilaginous slices. There was limited reliability to identify the posterior slice in the "all slices" approach, as opposed to good reproducibility to determine the transitional slice in the "6/5 slices" approach. Combining erosion and backfill scores tended to result in superior reliability compared to the 2 lesions separately, indicating a challenge to identify the transition from erosion to backfill.

#### MANTOUX TEST IS INADEQUATE TO DEFINE ALL SUBJECTS WITH LATENT TUBERCULAR INFECTION

S. Arya<sup>1</sup>, S. Kumar<sup>1</sup>, A. Nath<sup>2</sup>, P. Kapoor<sup>3</sup>, A. Aggarwal<sup>1</sup>, R. Misra<sup>1</sup>, S. Sinha<sup>1</sup>.  
<sup>1</sup>Clinical Immunology and Rheumatology; <sup>2</sup>Pulmonary Medicine; <sup>3</sup>DOTS Centre, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

**Background:** Latent TB infection (LTBI), defined as 'a state of persistent immune response to *Mycobacterium tuberculosis* without clinically-manifested disease', inflicts a third of the world's population and nearly 10% of LTBI positive persons develop TB within 2-5 years. The tuberculin skin test (TST) and, more recently, interferon gamma release assays (IGRAs) are most commonly used for detection of LTBI. However, in a high TB burden setting such as India, both the assays have been found to grossly underestimate the true prevalence of LTBI, since almost equal number of new TB cases emerged from the test-positive and test-negative groups during the follow-up<sup>1</sup>.

**Objectives:** This study was aimed at exploring whether an *in vitro* CD3 + T cell response to PPD can complement the *in vivo* TST response for the determination of true prevalence of LTBI in healthy Indians.

**Methods:** In this ongoing study, 80 apparently healthy workers (age 19-61 years) at SGPGIMS have been recruited. Their demographic data, including BCG vaccination status and duration of contact with TB patients, was recorded. TST was performed with 5 TU of PPD. Blood T cell (CD3+) responses to PHA (a mitogen, used as positive control) and PPD were determined by flow cytometry in terms of expression of the proliferation-induced nuclear protein Ki67.

**Results:** 48% of the study subjects showed positivity for TST (skin induration  $\geq 10$  mm) and the size of reaction could be correlated with age. There was no association between BCG vaccination status and TST positivity. 72% of the TST positive and 62% of TST negative persons showed positivity for CD3 + T cell response to PPD. Positivity for either assay was found to be 82%.

**Conclusions:** By combining TST with CD3 + T cell responses, the positivity for PPD was enhanced from 48% (TST alone) to 82%. Therefore, both the assays could be considered as complementary. It remains to be seen whether these assays, either singly or jointly, show a correlation with the emergence of TB in our study population during the follow-up.

#### RETROCALCANEAL BURSTITIS PRECEDES OR ACCOMPANIES ACHILLES TENDON ENTHESITIS IN THE EARLY PHASE OF RHEUMATOID ARTHRITIS

T. Suzuki, Y. Hidaka, Y. Seri. Division of Allergy and Rheumatology, Japanese Red Cross Medical Center, Tokyo, Japan

**Background:** We had reported the frequencies of various pathologies detected by ultrasound (US) in symptomatic ankles and heels in rheumatoid arthritis (RA) patients<sup>1</sup>. Through that study, we recognised that Achilles tendon (AT) involvement is not rare in RA, because retrocalcaneal bursitis (RCB), AT enthesitis, AT tendonitis and AT paratendonitis was detected in 27%, 22%, 13%, and 6% of the symptomatic ankles examined, respectively. Recently, it has been reported that RA and SpA patients did not differ in enthesial abnormalities seen on US<sup>2</sup>. However, we think that there is fundamental difference between the inflammation of synovio-enthesial complexes in RA and that in SpA.

**Objectives:** This study aims to investigate characteristics of enthesial abnormalities in RA by evaluating the association between US-detected RCB or AT enthesitis and clinical data.

**Methods:** We reviewed consecutive records of 100 ankles in 74 RA patients (fulfilling the 2010 criteria) who underwent US examination of symptomatic ankles because of clinical need. The patients consist of 52 women and 22 men (median age 63.3 years, range 26-83 years) with median disease duration of 4.2 months (range 0.23 months to 19.4 years), as described previously. 55/74 (74%) of them were positive for RF and/or ACPA. The association between presence of RCB or AT enthesitis in a narrow definition (i.e., insertional tendinitis) and clinical data were analysed using Fisher's exact test or Mann-Whitney U test.

**Results:** Among the overall 100 ankles, the frequency of RCB-positive/AT enthesitis-negative ankles, that of RCB-positive/AT enthesitis-positive ankles and that of RCB-negative/AT enthesitis-positive ankles were all more than 10%. Interestingly, the frequency of RCB-negative/AT enthesitis-positive ankles among the 62 ankles with early RA (disease duration <6 months) was significantly lower as compared to that among the 38 ankles with established RA (p=0.00595). Similarly, the frequency of RCB-negative/AT enthesitis-positive ankles among the 58 ankles of untreated patients was lower as compared to that among the 42 ankles of already-treated patients. The disease duration was significantly longer in the RCB-negative/AT enthesitis-positive ankles than in the rest of the ankles (43.8±74.6 months vs. 16.7±35.3 months, p=0.0179).

**Conclusions:** McGonagle et al. advocated the concept of synovio-enthesal complex and suggested that the inflammation occurs primarily at the enthesis and spreads to adjacent synovial tissues such as bursae in SpA patients. Our cross-sectional data indirectly indicated that RCB precedes or accompanies AT enthesitis in a narrow definition in the early phase of the RA, suggesting that the inflammation around the enthesis of RA patients occurs primarily at the synovial tissues and spreads to the enthesis in an opposite way. In addition, the isolated AT enthesitis without RCB in the established and/or treated RA patients may suggest several possibilities as follow: 1. Enthesitis is more refractory to RA treatment than bursitis; 2. Enthesitis is partially due to the degenerative changes related to damages and deformities caused by RA synovitis; 3. US-detected enthesitis in RA basically represents repair process rather than ongoing inflammation.

#### FRI0595 THE BEACH TOOL: A QUANTITATIVE MRI-BASED METHOD FOR MEASURING OEDEMA AND FAT METAPLASIA IN SPONDYLOARTHRITIS

T.J. Bray<sup>1</sup>, A. Dudek<sup>1</sup>, N. Sakai<sup>1</sup>, K. Rajesparan<sup>1</sup>, C. Fisher<sup>2</sup>, C. Ciurtin<sup>2</sup>, D. Sen<sup>2</sup>, A. Bainbridge<sup>3</sup>, M.A. Hall-Craggs<sup>1</sup>. <sup>1</sup>Centre for Medical Imaging; <sup>2</sup>Centre for Adolescent Rheumatology, UCL; <sup>3</sup>Medical Physics, UCLH, London, UK

**Background:** Magnetic resonance imaging (MRI) is an important part of diagnostic pathways in spondyloarthritis (SpA), and can be used to stratify patients and assess severity. However, measurements of the burden of inflammation currently rely on qualitative assessment, which is subjective and time-consuming thus impractical for clinical practice. There is a need for a more objective, faster method for measuring inflammation and damage with potential for automation, and quantitative MRI is a candidate tool.

**Objectives:** We aimed to provide proof-of-principle for the BEACH (Bone Oedema and Adiposity quantification with Apparent diffusion coefficient and Chemical shift imaging with histograms) tool, which quantifies bone marrow oedema and fat metaplasia – features of active and chronic inflammation – in the SIJs.

**Methods:** Fifty-three patients aged 12–24 years with either SpA or mechanical back pain were recruited prospectively, and underwent quantitative MRI consisting of diffusion weighted imaging (DWI) and fat fraction (FF) mapping,<sup>2,3</sup> and conventional MRI scans. Apparent diffusion coefficient (ADC) and FF maps were assessed using the BEACH tool, which automatically propagates ROIs on sub-chondral bone after the observer defines the SIJ. Pixel values were analysed to derive the histographic parameters for ADC and FF: median, 10th, 25th, 75th and 90th percentiles (denoted ADC<sub>10</sub>, ADC<sub>25</sub>, FF<sub>10</sub>, FF<sub>25</sub>, etc), and P<sub>high</sub> and plough (the proportion of high and low value pixels respectively).

Conventional MRI scans were assessed using visual scoring.<sup>4</sup> Patients were deemed to have active inflammation if their inflammation score was  $\geq 2$ , and to have fat metaplasia if this score was  $\geq 3$ . Quantitative measurements were compared between inflamed and non-inflamed SIJs.

**Results:** Use of the BEACH tool is demonstrated in figure 1(a)-(f). Example ADC histograms are shown in (g),(h).

**ADC<sub>75</sub>, ADC<sub>90</sub>, and P<sub>high(ADC)</sub> were significantly increased in inflamed SIJs ( $P=0.041$ ,  $0.006$  and  $0.003$  respectively), although median ADC values did not differ significantly between inflamed and uninfamed joints ( $P=0.31$ ). Diagnostic performance was superior for histographic parameters (AUC=0.59, 0.67 and 0.69) than for the median (AUC=0.54): Median FF, FF<sub>75</sub>, FF<sub>90</sub> and P<sub>high(FF)</sub> were all significantly increased in SIJs with fat metaplasia compared to those without (all  $p<0.0001$ ). Diagnostic performance was superior for histographic parameters FF<sub>75</sub>, FF<sub>90</sub> and P<sub>high(FF)</sub> (AUC=0.89, 0.92 and 0.92) than for the median (AUC=0.87).**

**Conclusions:** ADC and FF measurements can differentiate between inflamed and non-inflamed SIJs, and between joints with and without fat metaplasia. Compared to simple averages such as the median, histographic parameters can increase diagnostic performance for detecting inflammation and fat metaplasia. There is minimal subjectivity associated with ROI placement using the BEACH tool, which can potentially make inflammation scores more reproducible.

#### FRI0596 FEASIBILITY OF JOINT STRUCTURAL ANALYSIS IN HEMOCHROMATOSIS HAND ARTHROPATHY USING HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY – FIRST RESULTS AND CLINICAL CORRELATIONS

U.R. Heilmeyer<sup>1</sup>, A.J. Burghard<sup>1</sup>, P. Kapoor<sup>1</sup>, R.E. Voll<sup>2</sup>, S. Finzel<sup>2</sup>. <sup>1</sup>Radiology, UCSF, San Francisco, USA; <sup>2</sup>Rheumatology, University Hospital, Freiburg, Germany

**Background:** Hereditary Hemochromatosis (HH) is a common inherited disorder and characterised by an excess iron accumulation in several organs with consecutive organ dysfunction.<sup>1</sup> Apart from the liver, the joints are a major site of excess iron deposition. Joint pain counts among the most frequent (>50%), earliest, and most debilitating symptoms of HH.<sup>2</sup> To date, joint health status in HH patients is routinely assessed on hand radiographs.<sup>3</sup> However, plain radiography is a low-resolution, 2D-technique with limited sensitivity to detect early joint changes or to monitor subtle progression of joint damage.<sup>4</sup> With the advent of high-resolution peripheral quantitative computed tomography (HR-pQCT), a promising imaging tool has emerged allowing for *in vivo* 3D characterisation of human joint microstructure at a spatial resolution of 130  $\mu\text{m}$ .<sup>5</sup> Due to its high sensitivity to detect and monitor subtle, short-term joint changes, HR-pQCT has been successfully applied to patients with RA.<sup>6</sup> However, to date, HR-pQCT has not been used to characterise joint and bone changes seen in HH arthropathy.

**Objectives:** Here, we aimed to investigate in a cohort of HH patients 1) if the usage of HR-pQCT is feasible on HH patients; 2) to quantify joint microstructure of metacarpophalangeal joints (MCP2–4) in this specific patient group; and 3) investigate the relationship between HR-pQCT-derived joint microstructural parameters and clinical outcomes.

**Methods:** 25 HH patients were enrolled and their HH history and treatment were recorded. MCP joints of all patients were imaged at a clinical HR-pQCT system (XtremeCT, Scanco Medical AG). 330 images were acquired covering MCP 2, 3 and 4. The joint space (JS) morphology of each MCP was quantified from the HR-pQCT images semi-automatically<sup>4</sup> and volume (JSV), joint space width mean (JSW), JSW variance (JSW.SD), and JSW asymmetry (JSW.AS) were calculated.

**Results:** Out of the 75 MCP joints available for analysis, 79% were successfully segmentable, and 19% required semi-manual intervention to separate the individual bones. 3 joints were excluded due to motion artefacts, and 1 joint was unsegmentable. HH patients were 32–72 years old, in 64% male, and had been diagnosed with HH 2 months to 40 years ago. 15% were pain free at the study

date. HH patients with pain showed significantly lower JSV at MCP 2 and 4 ( $p=0.009$ ) and exhibited a significantly higher joint asymmetry in MCP 3 ( $p=0.012$ ) compared to their pain free colleagues. When looking at clinical correlations we found that time since HH diagnosis was positively correlated with the MCP4 JSV asymmetry ( $R^2=0.451$ ,  $p=0.040$ ) and MCP 4 JSV.SD ( $R^2=0.475$ ,  $p=0.030$ ). The number of phlebotomies since diagnosis was strongly correlated with the JSV.SD (MCP2-4:  $0.4552 < 0.581$ ,  $p < 0.050$ ) at all MCP sites.

**Abstract FRI0596 – Figure 1.** 3D surface reconstructions of the MCP3 with the local joint space width mapped into the joint space in pseudo-colour. Blue and green colours reflect narrow joint space width, while red colours code for a broader joint space width. A) 55 year old male with a BMI of 21.9 kg/m<sup>2</sup> who has been diagnosed with hemochromatosis 8 years ago, but received only occasionally phlebotomies. B) 48 year old male (BMI 22.9 kg/m<sup>2</sup>) with a diagnosis of hemochromatosis of 8 years who received regular phlebotomies every 2 months. Both patients presented at the study date with hand pain. Note the larger and more symmetrical joint space width in patient B.

**Conclusions:** Our study provides the first evidence that joint space assessment of MCPs via HR-pQCT in patients with hereditary hemochromatosis is feasible and can provide a thorough structural joint characterisation and thus support the physician in his initial HH arthropathy assessment. Our findings suggest, that regular phlebotomies since diagnosis may preserve joint space morphology leading to a more evenly maintained joint space. However, larger studies are needed to validate our results.

Lambert<sup>5</sup>. <sup>1</sup>CaRE Arthritis Ltd; <sup>2</sup>Medicine, University of Alberta, Edmonton, Canada; <sup>3</sup>Copenhagen Center for Arthritis Research, Copenhagen, Denmark; <sup>4</sup>Children's Hospital of Philadelphia, Philadelphia, USA; <sup>5</sup>Radiology, University of Alberta, Edmonton, Canada; <sup>6</sup>Hospital for Special Surgery, New York, USA; <sup>7</sup>Rigshospitalet, Graasten, Denmark; <sup>8</sup>University of New South Wales, Sydney, Australia; <sup>9</sup>Mahidol University, Bangkok, Thailand; <sup>10</sup>Copenhagen University Hospital, Copenhagen, Denmark; <sup>11</sup>Hospital for Sick Children, Toronto, Canada; <sup>12</sup>Radiology, Hospital Balgrist, Zurich, Switzerland; <sup>13</sup>McMaster Children's Hospital, Hamilton, Canada; <sup>14</sup>The Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, UK; <sup>15</sup>Pediatrics, University of Alberta, Edmonton, Canada; <sup>16</sup>Ente Ospedaliero Cantonale, Lugano, Switzerland; <sup>17</sup>Gentofte hospital, Copenhagen, Denmark; <sup>18</sup>NYU Center for Musculoskeletal Care, New York, USA; <sup>19</sup>St. Vincent's University Hospital, Dublin, Ireland

**Background:** The application and appropriate use of imaging-based scoring instruments is usually based on passive learning from published manuscripts while real-time interaction with instrument developers is often non-feasible. Moreover, most instruments lack knowledge transfer tools that would facilitate attainment of pre-specified performance targets for reader reliability.

**Objectives:** 1. To develop a web-based calibration module for the SPARCC MRI SIJ Inflammation Score based on consensus scores from these instrument developers, experiential game psychology, and real-time iterative feedback. 2. To test

the feasibility and attainment of pre-specified performance targets for reader reliability.

**Methods:** The scoring of inflammatory lesions of the SIJ on MRI using the SPARCC method is based on SIJ quadrants and the calibration module is comprised of 50 DICOM cases, each with scans from baseline and 12 weeks after the start of TNF inhibitor therapy. Scans are scored blinded-to-time-point. Continuous visual real-time feedback regarding concordance/discordance of scoring per SIJ quadrant with expert readers is provided by a color-coding scheme. Reliability is additionally assessed by real-time intra-class correlation coefficient with the first ICC data being provided after 20 cases. Accreditation for SPARCC BME score is achieved with status and change score ICC of  $>0.8$  and  $>0.7$  and is based on the final 20 cases. 26 readers scored the SPARCC BME module (7 rheumatology fellows, 2 chiropractors, 1 undergraduate, 8 rheumatologists, 8 radiologists) with 21 having no prior experience. Feasibility was assessed by 8-item survey.

**Results:** The majority of readers achieved accreditation for SPARCC BME score on the basis of sufficient reliability with instrument developers for both status and change scores, irrespective of prior experience (table 1). All readers who completed the module a second time, 6 months after the first exposure, achieved accreditation for SPARCC BME score. All readers rated the modules as easy and intuitive with average time for reading each case for SPARCC BME being 8 min.

**Abstract FRI0597 – Table 1**

	Status Score			Change Score		
	Mean ICC (95%CI)	Median ICC	N (%) Achieving ICC $>0.80^*$	Mean ICC (95% CI)	Median ICC	N (%) Achieving ICC $>0.70^*$

### FRI0598 THE AGREEMENTS BETWEEN CLINICAL SIGNS AND ULTRASOUND-DETERMINED JOINT INFLAMMATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

X. Sun, X. Deng, W. Xie, Y. Geng, L. Ji, X. Zhang, Z. Zhang. Department of Rheumatology and Clinical Immunology, Peking University First Hospital, Beijing, China

**Background:** The identification of synovial inflammation in rheumatoid arthritis (RA) patients mainly depends on the presence of tenderness and/or swelling joints by physical examination, however not entirely reliable. Ultrasound, especially the synovial hyperplasia evaluated by grey scale (GS) and synovitis by power Doppler (PD), is more sensitive in reflecting joint inflammation, but their clinical significance has not been fully understood<sup>[1]</sup>.

**Objectives:** To investigate the agreement between clinical-detected signs and US features of joint inflammation in wrists and hands, and further determine the grades of GS synovial hyperplasia and PD synovitis which correspond to presence of tenderness or swelling in an individual joint in RA patients.

**Methods:** Twenty-two joints, including bilateral wrists, proximal interphalangeal (PIP) and metacarpophalangeal (MCP) joints, were respectively evaluated by clinical and ultrasound examination by different rheumatologists in 258 RA patients. Ultrasound-determined joint inflammation, including synovitis, tenosynovitis/peritendinitis, were detected, by using semi-quantitative scoring systems (0–3) for GS

synovial hyperplasia and PD synovitis, and qualitative scoring systems (0/1) for tenosynovitis/peritendinitis.

**Results:** The median age of 258 enrolled patients were 51.4 years with 82.9% females. Their median disease duration was 55 months, and median disease activity score based on 28 joint count were 4.6. In a total of 5676 joints assessed, 968 joints (17.1%) were swollen and 1296 joints (22.8%) were tender, while on ultrasonography GS synovial hyperplasia was present in 801 (14.1%) joints, PD synovitis in 476 (8.4%) joints and tenosynovitis/peritendinitis in 108 (1.9%) joints. The general agreement between clinical signs and ultrasound-determined joint inflammation in all joints was fair ( $\kappa=0.365$ ,  $p<0.01$ ). In wrists, joint tenderness showed higher  $\kappa$  coefficient ( $\kappa=0.329$ ,  $p<0.01$ ) with ultrasound-determined joint inflammation than swelling ( $\kappa=0.263$ ,  $p<0.01$ ), while on the contrary, swelling showed higher  $\kappa$  coefficient ( $\kappa=0.156-0.536$ ,  $p<0.01$ ) with ultrasound-determined joint inflammation than tenderness ( $\kappa=0.061-0.355$ ,  $p<0.05$ ) in MCP and PIP joints. Both synovial hyperplasia and synovitis detected by ultrasound had consistently higher agreement with tenderness/swelling than tenosynovitis/peritendinitis. Joint tenderness and swelling had the highest  $\kappa$  coefficient with GS  $\geq 1$  synovial hyperplasia in most MCP and PIP joints, while with GS  $\geq 2$  synovial hyperplasia in wrists. For all 22 joints, PD  $\geq 1$  synovitis had the highest  $\kappa$  coefficient with clinical tenderness and swelling.

**Conclusions:** Synovitis had better agreement with clinical signs than tenosynovitis/peritendinitis. Joint swelling showed better agreement with these ultrasonographic changes than tenderness for MCP and PIP joints, while the opposite for wrists. The minimal requirements of synovial hyperplasia/synovitis which correspond to clinical signs are GS  $\geq 1$  for MCP and PIP joints, GS  $\geq 2$  for wrists, but PD  $\geq 1$  for any joint.

**FRI0599 THE RELEVANCE OF THERMOGRAPHY AND NAILFOLD CAPILLAROSCOPY IN OLDER PATIENTS WITH PRIMARY AND SECONDARY RAYNAUD'S PHENOMENON**

S. van Vugt<sup>1,2</sup>, Y. Vreeburg<sup>3</sup>, L. van Vugt<sup>2,3</sup>, G. Schardijn<sup>2</sup>. <sup>1</sup>Artis Natura Magistra Zoo; <sup>2</sup>Specialisten polikliniek Buitenveldert; <sup>3</sup>VU medical center, Amsterdam, Netherlands

**Background:** Raynaud's phenomenon (RP) is defined as episodic attacks of artery and arteriole vasoconstriction. To differentiate between the benign RP (pRP) and the form associated with connective tissue diseases (sRP) the capillary morphology can be studied using nailfold capillaroscopy (nCS). However, abnormal morphology can also be caused due to age-related changes and has been described in patients with diabetes and cardiovascular disease. In addition, this technique cannot provide functional information. Thermal imaging (thermography; TG) is a non-invasive technique which enables quantification of cutaneous blood vessel function. In veterinary medicine, thermal

imaging is applied for various clinical settings. A combined approach using both nCS and TG could improve the differentiation between pRP and sRP.

**Objectives:** The aim of this pilot study was to determine which technique (TG versus nCS) allows the best discrimination amongst older patients with pRP and sRP.

**Methods:** Thirty patients with RP (pRP, n=21; sRP, n=9) underwent nCS (Olympus SZ51) and TG (Flir B 620). Nailfold morphologic features were measured and scored on capillary density, giant capillaries, ramification and hemorrhages. The patients were divided into three categories: normal, slightly abnormal (slightly enlarged capillaries) and severely abnormal (destruction of capillary structure and hemorrhages).

TG of the hand was performed before, directly after and 10 min after a cold challenge test with cold manchetts of 3°C. Rewarming and reperfusion were monitored and baseline images and rewarming curves were analysed.

**Results:** Capillary abnormalities with nCS were found in all patients with sRP (9/9) and in 52% (11/21) of patients with pRP. Out of 11 pRP patients with altered capillary morphology, 7 (63%) had a cardiovascular disease.

TG demonstrated a lower average temperature at baseline in the pRP group compared to the sRP group (d 1.68°C,  $p<0,01$ ). In patients with pRP temperature decreased after cold induction (-2.34°C,  $p=0,01$ ), whereas in sRP patient temperature stayed consistent (+0.07°C,  $p=0,46$ ) (table 1). In both groups temperature increased ten minutes after cold induction (pRP +2.62°C,  $p<0,01$ ; sRP +1.57°C,  $p<0,01$ ).

The gradient of the rewarming curve was significantly lower in patients with sRP compared to the pRP group (median 0.16 vs. 0.26 °C/min;  $p=0.015$ ).

**Abstract FRI0599 – Table 1**

Average temperature of the fingers before the immersion in cold water (in °C)	Average temperature of the fingers just after the immersion test (in °C)	Average temperature of the fingers 10 min after removing the hand from cold water (in °C)	Average temperature recovery speed (in °C/min)
---	--	---	--

Primary Raynaud Phenomenon 29.49 27.15 29.77 0.26 Secondary Raynaud Phenomenon 31.17 31.24 32.81 0.16 Capillaroscopy abnormalities 25.80 25.60 27.92 0.23 Secondary Raynaud phenomenon and Capillaroscopy abnormalities 27.99 28.15 31.52 0.34

**Conclusions:** Nailfold capillaroscopy and thermography can reliably be used to measure microvascular damage and dysfunction. TG is better suitable to differentiate between older patients with pRP and sRP.

Furthermore, in presence of cardiovascular disease, TG appears to be a more reliable technique than nCS for differentiating between patients with pRP and sRP.

**FRI0600 METHODS FOR THE ANALYSIS OF ADHERENCE DATA FROM A MEDICATION EVENT MONITORING SYSTEM (MEMS): A SYSTEMATIC REVIEW**

L. Hartman<sup>1</sup>, W. Lems<sup>1</sup>, M. Boers<sup>1,2</sup>. <sup>1</sup>Amsterdam Rheumatology and Immunology Center ARC; <sup>2</sup>Department of Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands

**Background:** Medication adherence can be measured with several methods: medication bottles with an electronic cap are regarded as the gold standard. The cap contains an electronic device which records the date and time of each

opening and closing of the bottle. This is termed Medication Event Monitoring System (MEMS). To our knowledge, there is no standard method to summarise and analyse the adherence data from MEMS.

**Methods:** A literature search was conducted in July 2017 in the databases PubMed, Embase and Cochrane. Search terms were related to the following MESH search terms: medication (non)adherence/compliance, medication persistence, chronic disease/illness, chronically ill, medical electronics, treatment, (drug) therapy, data analysis, statistical study.

**Results:** We identified 1493 articles, and immediately excluded 1127 off-topic articles and 48 double entries after screening of title and abstract. In the end, 207 articles were included.

The mean age of the patients in the studies was 52 (SD 46) years. A total of 62 different health conditions were studied. Most patients had HIV (29%) or heart failure (10%). The MEMS cap was used for a median of 3 months (IQR: 4; range: 1 week-24 months).

**Outcome measures:** Most studies computed an adherence score, expressed as the percentage of days on which the correct dose of medication was taken. The threshold to mark people as adherent was most frequently (38 studies) set at 80% (range 67%–95%). Timing compliance (i.e. the percentage of doses taken at the appropriate time) and dose compliance (i.e. the percentage of correct doses taken on each day) were also calculated in several studies (in 14% and 23%, respectively). In addition, a few studies (4%) calculated 'drug holidays', i.e. periods of a certain number of days on which the medication bottle was not opened, followed by a bottle opening.

**Statistical analyses:** Multilevel modelling and slopes in combination with one-sample t-tests were used to examine adherence patterns over time.

Ten studies assessed an intervention to improve adherence. Generalised Estimating Equation (GEE) model (n=4), ANOVA, McNemar's exact test, multilevel modelling, a summary analysis (details not reported), T-test or Wilcoxon test were used to compare the differences in adherence before and after an intervention.

**Conclusions:** Apart from the adherence score threshold, often set at 80% of days with correct medication dosing, we found that many different outcome measures and methods were used for the analysis of MEMS data, pointing to a lack of standardisation. Apparently, there is no consensus on the best outcome measures and a lack of validation studies that compare different methods to analyse MEMS data.

## FRI0601 THE NATURE AND EXTENT OF DATA ITEMS COLLECTED ACROSS EUROPEAN PREGNANCY REGISTERS – FIRST RESULTS OF THE EUROPEAN NETWORK OF PREGNANCY REGISTERS IN RHEUMATOLOGY (EUNEP)

Y. Meissner<sup>1</sup>, A. Strangfeld<sup>1</sup>, N. Costedoat-Chalumeau<sup>2</sup>, F. Förger<sup>3</sup>, A. Molto<sup>2</sup>, M. Wallenius<sup>4</sup>, R. Fischer-Betz<sup>5</sup>. <sup>1</sup>German Rheumatism Research Center, Berlin, Germany; <sup>2</sup>Université Paris-Descartes, Internal medicine department, Hôpital Cochin, Paris, France; <sup>3</sup>University Hospital, Bern, Switzerland; <sup>4</sup>University Hospital, Trondheim, Norway; <sup>5</sup>Department and Hiller Research Unit of Rheumatology, Heinrich-Heine University, Düsseldorf, Germany

**Background:** There is a high unmet need of robust data on the outcomes of pregnancies and drug safety in various inflammatory rheumatic diseases (IRD). The aims of the European Network of Pregnancy Registers in Rheumatology (EuNeP) are to bring together experts who run pregnancy registers, to define a core data set and to perform concerted data analyses.

**Objectives:** To describe data items collected in existing multicentre European pregnancy registers in rheumatology.

**Methods:** A comprehensive survey on details of the registers was performed encompassing patient enrolment, inclusion criteria, demographics, disease specific and general outcomes, medical treatment, course and outcome of pregnancy and outcomes of the child. Free text answers were possible for all questions. Questionnaires were sent to the principle investigator(s) of the participating studies. The completed questionnaires were reviewed, and responses were evaluated descriptively. Only data items collected during pregnancy are shown.

**Results:** The following registers are involved in the collaboration: EGR2 (France), RePreg (Switzerland), REVNATUS (Norway) and Rhekiss (Germany). All registers collect data prospectively and nationwide. Patients can be included before pregnancy (child wish) or during pregnancy in all registers, and in RePreg also up

to week 8 postpartal. Enrolment during pregnancy is possible up to gestation week 12 or thereafter in some specific cases (EGR2), week 20 (Rhekiss) or during complete pregnancy (RePreg and REVNATUS). All registers capture data via IT-based systems, REVNATUS documented on paper until 2016. During pregnancy, data is reported once every trimester by physicians and patients. Current figures, baseline characteristics and included IRD are presented in the table. Most of the data items that are independent of the underlying IRD are collected by all registers (figure 1). However, there are differences in the way data is collected and in the level of details.

	EGR2	RePreg	REVNATUS	Rhekiss
<b>No. of enrolled patients</b>	879	64	513*	777
<b>No. of observed pregnancies</b>	780	32	287	595
<b>No. of completed pregnancies</b>	446	6	266	344
<b>No. of participating units</b>	66	16	13	91
<b>Year of register start</b>	2014	2017	2006 <sup>IT</sup> 2016	2015
<b>Patient age (yrs), mean (SD)</b>	32.1 (4.8)	33.6 (4.0)	30.8 (4.8)	32.4 (4.2)
<b>Patient disease duration (yrs), mean (SD)</b>	7.3 (6.1)	11.0 (7.4)	6.5 (6.8)	11.2 (81.7)
<b>Diagnoses, N (%)</b>				
<b>RA</b>	60 (6.9)	23 (35.9)	139 (27.1)	225 (29.0)
<b>PsA</b>	0**	11 (17.2)	44 (8.6)	66 (8.5)
<b>SpA</b>	55 (6.3)	24 (37.5)	107 (20.9)	101 (13.0)
<b>JIA</b>	-	-	78 (15.2)	43 (5.5)
<b>Systemic lupus erythematosus</b>	238 (27.4)	-	67 (13.1)	162 (20.8)
<b>Other connective tissue diseases</b>	371 (42.6)	-	36 (7.0)	129 (16.6)
<b>Other IRDs</b>	146 (16.8)	6 (9.4)	42 (8.2)	51 (6.6)

\*Only patients enrolled in the IT-System are considered. \*\* PsA patients are included as peripheral SpA.

Figures in the bars represent the numbers of reporting registers. \*Only for selected diseases in one register. Abbreviations: (m)HAQ, (modified) Health Assessment Questionnaire; IRD, Inflammatory Rheumatic Disease; PFO, Patient Reported Outcome.

**Abstract FRI0601 – Figure 1.** Figures in the bars represent the numbers of reporting registers.

**Conclusions:** Although the registers in this collaboration have similar designs, we found considerable differences in data items collected. In particular, the level of details of documented data and the information on disease-specific characteristics varied. Harmonisation of data collected in pregnancy registers would facilitate collaborative analysis.

**Acknowledgements:** This work was supported by a research grant from FOREUM Foundation for Research in Rheumatology.

Wiek<sup>15</sup>, A. Zink<sup>16</sup>, S. Ramiro<sup>17</sup>, F. Buttgerit<sup>18</sup>. <sup>1</sup>Hospital of Bruneck, Bruneck, Italy; <sup>2</sup>Maastricht University Medical Center and CAPHRI Research Institute, Maastricht, Netherlands; <sup>3</sup>FH Joanneum, University of Applied Sciences, Bad Gleichenberg; <sup>4</sup>Medical University Vienna, Vienna, Austria; <sup>5</sup>ASL3-Azienda Sanitaria Genovese, Genova, Italy; <sup>6</sup>University Medical Center Utrecht, Utrecht, Netherlands; <sup>7</sup>University of Zagreb School of Medicine, Zagreb, Croatia; <sup>8</sup>University Hospital of Geneva, Geneva, Switzerland; <sup>9</sup>Sorbonne Universités, UPMC University Paris, Paris, France; <sup>10</sup>Diakonhjemmet Hospital, Oslo, Norway; <sup>11</sup>Centro Hospitalar Médio Tejo, Lisbon, Portugal; <sup>12</sup>Mayo Clinic College of Medicine, Rochester, USA; <sup>13</sup>Hospital General Universitario de Elda, Elda, Spain; <sup>14</sup>University of Debrecen, Debrecen, Hungary; <sup>15</sup>EULAR Standing Committee of PARE; <sup>16</sup>Deutsches Rheuma-Forschungszentrum, Berlin, Germany; <sup>17</sup>Leiden University Medical Centre, Leiden, Netherlands; <sup>18</sup>Charité University, Berlin, Germany

**Background:** EULAR has developed several recommendations and strategies for early referral, diagnosis and treatment of rheumatic diseases. These strategies, however, can only be implemented if sufficient manpower is available. An estimation of how many rheumatologists are needed to meet current and future population needs must be provided in order to counsel health care planners and decision makers. Current methods used for forecasting manpower are disparate, as are the variables incorporated into workforce projection models. Consequently, projections for the need of rheumatologists may vary by a factor of five between studies.<sup>(1)</sup>

**Table.** EULAR points to consider for the conduction of workforce requirement studies in rheumatology

No	Recommendation	LoA	LoE*
1	Workforce models should integrate supply, demand and needs of the respective geopolitical entity (e.g. municipality, region, state, country), and should express results as full time equivalents and as number of rheumatologists	9.5 (0.9) 95%≥8	5
2	Workforce models should provide projections over a period of 5-15 years	9.1 (1.1) 90%≥8	5
3	Workforce models should not assume a current balance between supply and need	9.0 (0.7) 100%≥8	5
4	Workforce models should, where possible, rely on several data sources and include uncertainty analyses	9.8 (0.4) 100%≥8	5
5	Workforce models should be regularly updated; updates should include an analysis of the actual performance (i.e. prediction validity) of the previous model	9.5 (0.6) 100%≥8	5
6	Workforce needs for patient care should be based on the prevalence and referral rates of diseases managed by rheumatologists as well as on an estimation of time needed per patient	9.7 (0.7) 100%≥8	5
7	Workforce needs for patient care should consider current and future demographics, sociocultural characteristics of the population and disease patterns	9.5 (0.9) 95%≥8	5
8	Workforce needs and supply should consider work outside rheumatology patient care (e.g. administrative tasks, research, teaching, non-rheumatologic disease management), as well as patient care performed by other health professionals in rheumatology	9.4 (0.9) 95%≥8	5
9	Workforce supply should account for demographic composition of rheumatologists, the number of rheumatologists entering and leaving the workforce, and generational attitudes of rheumatologists towards scope of practice and work-life balance	9.1 (2.3) 85%≥8	5
10	Workforce models should consider the effects of medical developments, including new technologies, medications, artificial intelligence and e-health, on demand and supply	9.4 (1.1) 85%≥8	5

Numbers in column 'LoA' indicate the mean and SD (in parentheses) of the LoA, as well as the percentage of task force members with an agreement ≥8.  
LoA, Level of agreement; LoE, level of evidence according to Oxford Centre for Evidence-Based Medicine 2011 levels of evidence  
\*study design does not correspond to any of the levels of the OCEBM.

**Objectives:** The aim of this project was to develop EULAR points to consider on the methodology of future workforce calculation models for rheumatologists in order to produce reliable, standardised and realistic estimates.

**Methods:** The EULAR Standardised Operating Procedures were followed. A systematic literature review (SLR) was conducted to retrieve workforce models in rheumatology and other specialities. The task force consisted of 20 experts (rheumatologists, health professionals and representatives of PARE) from 11 EULAR countries and the USA. Points to consider were based on expert opinion informed by the SLR, followed by group discussions with consensus obtained through informal voting. The level of agreement with the recommendations was voted anonymously.

**Results:** A total of 10 points to consider were formulated (table 1). The task force recommends models integrating supply (=workforce available to rheumatology), demand (=health services requested by the population) and needs (=health services that are considered appropriate to serve the population). Projections of workforce requirements should consider all factors relevant for current and future workload in and outside rheumatology patient care. Forecasts of workforce supply should consider demography and attrition of rheumatologists, as well as the effects of new developments in health care.

**Conclusions:** These are the first EULAR points to consider providing guidance on the methodology and the parameters to be applied in future national and international workforce requirement studies in rheumatology.

### THE POTENTIAL USES OF AN INFODEMOLOGY APPROACH FOR HEALTH-CARE SERVICES IN RHEUMATOLOGY

A. Gallardo-Castro<sup>1</sup>, G. Martinez-Arroyo<sup>2</sup>, S. Ramos-Gomez<sup>2</sup>, A. Villarreal-Castellanos<sup>1</sup>, A.S. Meza-Lopez<sup>1</sup>, A. Barajas-Ochoa<sup>2</sup>, E.K. Rojero-Gil<sup>1</sup>, J. D. Castillo-Ortiz<sup>2</sup>, L.P. Bustamante-Montes<sup>1</sup>, C. Ramos-Remus<sup>1</sup>. <sup>1</sup>Universidad Autonoma de Guadalajara; <sup>2</sup>Unidad de Investigacion en Enfermedades Cronicas-Degenerativas, Guadalajara, Mexico

**Background:** Infodemiology can help achieve the patient-centred care model. It is the science of determinants and distribution of information on electronic media. It can provide data to develop, collect, and evaluate metrics and indicators for information and communication patterns that are related to epidemiologic data or are useful for public health, policy making or even clinical practice. Google Trends (GTr) and Google AdWords (GAd) are two useful tools to assess demand-based infodemiology indicators. Its use is scanty in rheumatology.

**Objectives:** To illustrate the potential use of GTr and GAd, we present three case-studies: A) What search terms related to rheumatology are typed by people in Mexico (MX), the United States of America (USA), and Canada (CAN)? B) What is the search volume for specific DMARDs typed by people in MX, USA, and CAN?, and C) What is the positioning of the search term "arthritis" compared with two non-rheumatic diseases ("hepatitis C", "breast cancer") among MX, USA, and CAN?

**Methods:** GTr output is a relative search volume (the biggest volume is transformed to 100 and the rest are given as a proportion of it) and GAd output is the average number of searches per unit of time. We ran 3 different queries (MX, USA, CAN) for each case-study using GTr and GAd for years 2015–2017. Results were exported to a database for further analysis. Search volumes were adjusted per country's population and expressed as crude rates (searches per million; spm) when appropriate.

**Results:** To look for information on "rheumatology" people used 298 (MX), 654 (USA), and 637 (CAN) associated terms. "Arthritis" had 656, 550, and 548 associated terms in MX, USA, and CAN, respectively. For "arthritis treatment" there were 635, 569, and 569 associated terms in MX, USA, and CAN, respectively. Regarding DMARDs, there were 1,053 million searches during this period: methotrexate (28.5%), adalimumab (15.6%), rituximab (10.4%), and infliximab and etanercept (8.6% each). However, for every b- or tsDMARD search, there were fourteen (USA, CAN) to fifty-eight (MX) "turmeric" searches for the "treatment of arthritis". In 2015, search volume for "arthritis" was 120, 638, and 668 spm in MX, USA, and CAN, respectively. For 2016 and 2017 figures remained similar for MX and CAN, but showed a 12% increase for the USA. In MX, "hepatitis C" had 114 spm in 2015, with a 32% increase by 2017. The USA and CAN had 1131 and 648 spm in 2015, with a 5% increase and an 8% decrease by 2017, respectively. For "breast cancer", search rates were 4 times higher than for "arthritis" for the three years in MX, with an average increase of 250% each October, concurrent with public awareness campaigns. In the USA and CAN, search volume was 36% and 56% less than that for "arthritis", with a 57% and 33% increase each October, respectively.

**Conclusions:** Infodemiology can have an added value to traditional research designs. It can serve for diverse purposes, such as assessing the penetration and impact of public awareness campaigns, patients' perceived needs, the appearance of new remedies, the positioning of diseases, disease-related cultural differences in ethnic groups, people perceptions on specific health-care systems, etc.

FRI0604

### TRENDS OF INFORMED CONSENT FORMS FOR INDUSTRY-SPONSORED CLINICAL TRIALS IN RHEUMATOLOGY OVER A 17-YEAR PERIOD: READABILITY, AND ASSESSMENT OF PATIENTS' HEALTH LITERACY AND PERCEPTIONS

A.S. Meza-Lopez<sup>1</sup>, A. Gallardo-Castro<sup>1</sup>, A. Villarreal-Castellanos<sup>1</sup>, A. Barajas-Ochoa<sup>2</sup>, J. Yanez<sup>3</sup>, L.P. Bustamante-Montes<sup>1</sup>, C. Ramos-Remus<sup>1</sup>. <sup>1</sup>Universidad Autonoma de Guadalajara; <sup>2</sup>Unidad de Investigacion en Enfermedades Cronico-Degenerativas, Guadalajara; <sup>3</sup>Campus Ciudad de Mexico, Universidad Iberoamericana, Mexico, Mexico

**Background:** The therapeutic arsenal in rheumatology has improved drastically during the last 20 years with the availability of biological and synthetic disease-modifying antirheumatic drugs. All these drugs required randomised controlled trials (RCTs) with thousands of rheumatic patients. All these patients went through the informed consent process and signed corresponding informed consent forms (ICFs).

**Objectives:** To assess trends in the length and readability of ICFs for industry-sponsored RCTs over a 17 year period. Additionally, to assess the health literacy (HL) and perceptions on ICFs among participants of current RCTs.

**Methods:** The grammatical readability (GR) of six pre-defined ICF sections (global, introduction, methods, risks/benefits, rights/responsibilities, and voluntary participation statement) of pivotal ICFs from industry-sponsored RCTs conducted at an outpatient rheumatology clinic during a 17 year period was assessed by using the INFLESZ instrument. Differences in GR were assessed by company, by disease and by study phase (95% CI of the mean and proportions; statistical significance assumed if no overlap), and by the years ICFs were written (1999—2005, 2006—2010, and 2011—2016; Kruskal-Wallis test). HL of patients was assessed with the SALHSA (inadequate, adequate) and S-TOFHSA (inadequate, marginal, adequate) instruments. Differences by age and schooling were determined by one-way ANOVA. Patient's perceptions and opinions on the ICF were assessed using a structured, self-reported, in-office questionnaire on an independent patient sample that had signed a pivotal ICF in the past 6 months.

**Results:** Thirty-nine ICFs about 22 drugs (18 biological or targeted synthetic DMARDs; 13 currently available on the market) from 13 pharmaceutical companies were analysed. The global mean readability was 57±3 (95% CI 56–58), and all ICFs were categorised as either "somewhat difficult to read" or "average". Readability remained at these levels without significant changes from 1999 to 2016. The "somewhat difficult" reading score was significantly more frequent in the "rights and responsibilities" and in the "informed consent statement" sections (p<0.001). The mean length of the ICFs written between 1999 and 2005 was 13±5 pages, with a significant increase thereafter (22±8 pages, p<0.01). Depending on the instrument, of 95 patients participating in the HL assessment, between 18% and 44% had limited HL. Of 90 patients participating in the perceptions questionnaire, 84% reported understanding the ICF well. However, 2%–57% misunderstood basic concepts, including the study drug name, randomization and placebo.

**Conclusions:** It seems that the considerable progress that has been made in medical research methods over time has not produced improvements in the process of informed consent in the industry-sponsored RCTs. The disparity between the readability of ICFs with patients' HL and their comprehension of ICFs continues, even after decades of attempts of regulatory agencies and numerous published suggestions.

FRI0605

### THE DEVELOPMENT PROCESS OF MOBILE HEALTH APPLICATIONS FOR SELF-MANAGEMENT IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES IS HETEROGENEOUS AND OFTEN INCOMPLETE: RESULTS OF A SYSTEMATIC LITERATURE REVIEW

A. Najm<sup>1</sup>, E. Nikiforou<sup>2</sup>, L. Gossec<sup>3</sup>, F. Berenbaum<sup>4</sup>. <sup>1</sup>Rheumatology department, Nantes University Hospital, Nantes, France; <sup>2</sup>Academic Rheumatology Department, King's College London, London, UK; <sup>3</sup>Rheumatology Department, Sorbonne Universités, UPMC University Paris; <sup>4</sup>Department of Rheumatology, Inflammation-Immunopathology-Biotherapy Department, Pierre and Marie Curie University, Saint-Antoine hospital, Sorbonne University, Paris, France

**Background:** Mobile health (mHealth) is exponentially growing in the current era, providing new potential and transforming the face of healthcare delivery. While the increasing availability of applications (apps) may enable people with rheumatic and musculoskeletal diseases (RMDs) to better self-manage their health, there is a general lack of evidence on ways to ensure appropriate development and evaluation of apps.

**Objectives:** To obtain an overview of existing mHealth apps for self-management in patients with RMDs, regarding content and development methods in particular, through a systematic literature review.

**Methods:** A search was performed up to December 2017 using EMBASE, Pubmed, Cochrane library, Web of Science and Psychinfo databases, with relevant key words and MeSH terms addressing three key domains: RMDs, self-management and mHealth. Double screening was performed on 15% of all abstracts against agreed inclusion criteria. For each publication relevant to an app for RMDs, the content, the aims, the target population of the apps and their development strategies were noted. The analysis was descriptive.

**Results:** Of 562 abstracts, 57 full text were screened. 39 articles were included in the analysis. 13 articles referred to an app linked to a connected device. Most of the apps targeted rheumatoid arthritis patients (n=11), juvenile idiopathic arthritis (n=7) and osteoarthritis (n=8). The development process of the app was poorly described in 19/39 (48.7%) of the studies (figure 1). Only 6/39 (15.4%) included patients, and 14/39 (35.9%) included health professionals or physicians in the development of such apps. Moreover, a qualitative phase occurred in only 6/39 (15.4%) of the cases. The app was tested and evaluated by physicians in 6/39 (15.4%). Patients were more frequently involved in app evaluation (29/39, 74.4%) but mostly indirectly through their adherence to the app. Only few of the apps published on were commercially available (5/39, 12.8%), 4/5 are free. One app is currently under development.

Abstract FRI0605 – Figure 1. Description of the development process of the apps in the 39 articles.

**Conclusions:** The development process of most apps was poorly described and potentially not satisfying in many studies. Despite patient willingness to use mHealth apps for self-management of their RMDs, a strong effort needs to be made to provide a standard and ensure quality and safety of newly-developed apps. This work will further inform EULAR points to consider for development, evaluation and implementation of mobile health applications for self-management of RMDs by patients.

### THE LIFT STUDY'S DIRECT-TO-PATIENT DESIGN PROVIDES RELIABLE SELF-REPORTED DATA FROM LUPUS PATIENTS

A. Cheeks, L. Borisov, K. Warren, R. Terbruggen. DxTerity Diagnostics, Rancho Dominguez, USA

**Background:** Direct-to Patient (D2P) clinical studies that rely upon social media, mobile connectivity, wearables, self-collected patient samples, and patient reported outcome data have the potential to revolutionise health research by enabling population-scale studies without the cost and complexity of traditional multi-site trials. D2P studies are particularly interesting for longitudinal studies where the burden of participants travelling to a central site is high; however, the quality and reliability of patient reported outcome data is unclear<sup>1</sup>.

**Objectives:** The study evaluated the accuracy of self-reported data from a subset of patients in a 1000+participant D2P lupus study (www.thelifstudy.com) by comparing patient-reported data to medical records as well as genomic testing of individuals using participant-collected fingerstick blood samples.

**Methods:** The study was reviewed and approved by a central IRB (WIRB; Puyallup, WA). Subjects were recruited online across the U.S using social media. Electronically consented participants with self-reported lupus were asked to complete online surveys about their disease and drug history as well as provide medical record review (MRR) consent. A third party firm was employed for MRR and an independent physician summarised the following information: 1) participant age 2) confirmation of lupus 3) current lupus medications and 4) current steroid medications.

**Results:** Of the 1043 participants enrolled over the first 6 weeks of the study, 327 had completed all aspects of the study. Thirty-seven participants (11%) were selected at random for MRR. Average age was 44±12 years with 35 females and 2 males. Self-reported (SR) age at time of enrollment was 100% confirmed by MRR. Lupus diagnosis was confirmed in 100% of the participants by the MRR directly or by conclusion of the independent physician based upon review of the medical record. SR and MRR drug information showed variable concordance upon review, with several patients reporting medications at the time of the survey that were not confirmed in their medical records (table 1). Percent agreement was determined by comparing the SR vs. the MRR for each participant (data not shown). Overall, there was an 88% agreement between SR and MRR for each of the medications where at least 1 participant reported prescription.

**Abstract FRI0606 – Table 1.** Common Lupus Medications and Steroids (n=36 unless otherwise noted)

Medications	SR		MR		% Agreement
	Yes	No	Yes	No	
cyclophosphamide	0	36	0	36	100%
methotrexate	4	32	2	34	94.4%
azathioprine	2	34	2	34	100%
cyclosporine	0	36	0	36	100%
belimumab	6	30	5	31	97.2%
chloroquine	0	36	0	36	100%
hydroxychloroquine (n=35)	26	10	21	14	77.1%
mycophenolate	6	30	4	32	94.4%
leflunomide	0	36	0	36	100%
steroids (n=37)	12	25	13	24	64.9%

**Conclusions:** Using a D2P study design, the resulting SR data corresponded well with the MRR for subject age, lupus diagnosis, and lupus medications. While there were some discrepancies in use of medications, many of these could be explained by the time-dependency of our questionnaire, where the date of prescription in the MRR was just outside of the 30 day window. The LIFT Study shows that a D2P study design is an effective method to rapidly enrol lupus patients and decrease study costs while collecting reliable self-reported data.

#### FRI0607 HOW TO DESIGN CLINICAL TRIALS TO BE MORE PATIENT ORIENTED: AN EXAMPLE FROM PREVENTATIVE TREATMENTS FOR RHEUMATOID ARTHRITIS

N. Bansback<sup>1</sup>, M. Hudson<sup>2</sup>, C. Koehn<sup>3</sup>, T.-L. Laba<sup>4</sup>, M. Harrison<sup>1</sup>. <sup>1</sup>University of British Columbia, Vancouver; <sup>2</sup>University of McGill, Montreal; <sup>3</sup>Arthritis Consumer Experts, Vancouver, Canada; <sup>4</sup>University of Sydney, Sydney, Australia

**Background:** It is widely acknowledged that many clinical trials do not always provide results that are meaningful to patients. We sought to utilise market research techniques, widely used in non-health consumer product development, to understand patient preferences that could improve the design of clinical trials. We use an example from preventative treatments in patients with preclinical asymptomatic RA where many trials are being designed or ongoing.

**Objectives:** To consider how to inform trial design for: i) which outcome/s should be primary? ii) what difference in the primary outcome between arms is important? iii) will patients want to use the intervention if it meets its primary endpoint/s?, and iv) does an alternative strategy exist that patients would prefer?

**Methods:** We developed a discrete choice experiment and surveyed first-degree relatives of patients. Focus groups of RA patients, first-degree relatives of RA patients and rheumatologists identified 5 key attributes of treatment (reduction in risk of RA, how treatment is taken, chance of side effects, certainty in estimates, health care providers opinion). DCE data was analysed using a conditional logit regression models to estimate the significance and relative importance of attributes in influencing preferences. We predicted uptake using estimates from the opt-out data analysed using a logit model.

**Results:** 288 first-degree relatives of people with RA started and completed all tasks in the survey. The majority of the sample were aged between 18 and 39 years (60%), and 60% female. All attributes levels significantly influenced preferences for treatments, but how treatment is taken (oral vs. infusion  $\beta$ 0.983,  $p < 0.001$ ) was the most influential, followed in similar magnitude by increasing risk

reduction (60 to 24 in 100) ( $\beta$ 0.922,  $p < 0.001$ ), matching of patient and health care professional preferences ( $\beta$ 0.900,  $p < 0.001$ ), and reducing risk of side effects ( $\beta$ 0.839,  $p < 0.001$ ). If a risk reduction of RA from 60 in 100 over 5 years to 44 in 100 is realised with only minor, reversible side-effects likely, then the uptake of hydroxychloroquine was predicted to be 86%. If all treatments currently under study in the pre-clinical phase of RA were assumed to be options for the asymptomatic phase and met hypothesised outcomes, the uptake of oral methotrexate was predicted to be 46% and hydroxychloroquine 20%. Predicted uptake of biologic drugs was 6% for abatacept and 4% for rituximab.

**Conclusions:** The study illustrates how market research can be used to design clinical trials that address patient centred priorities and outcomes. The results illustrate that a trial of preventative treatments for RA should: i) be powered to detect both a difference in preventing the development of RA, and the increase in minor side-effects, ii) require a significant reduction in risk of developing RA if any side-effects are possible. We calculate iii) that hydroxychloroquine would be likely to be used by pre-clinical asymptomatic patients, but biologics would likely not, iv) and that methotrexate should also be explored as an earlier option.

#### FRI0608 A SYSTEMATIC REVIEW AND CRITICAL APPRAISAL OF ECONOMIC EVALUATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS

S. P. Gavan<sup>1</sup>, I. N. Bruce<sup>2,3</sup>, K. Payne<sup>1</sup>. <sup>1</sup>Manchester Centre for Health Economics, <sup>2</sup>Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, The University of Manchester, <sup>3</sup>NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom

**Background:** New strategies to manage systemic lupus erythematosus (SLE), including the use of biomarkers to target novel or existing therapies, will require evidence of relative cost-effectiveness before being recommended in routine clinical practice. Decision-analytic model-based economic evaluations can synthesise all available evidence to estimate the cost-effectiveness of health technologies. Complexities in the diagnosis, management, and progression of disease pose challenges when estimating the cost-effectiveness of care for SLE. No systematic appraisal of economic evaluations in SLE has been published to date.

**Objectives:** To identify and critically appraise all economic evaluations of treatments for SLE.

**Methods:** A systematic review of published economic evaluations in SLE was performed. Studies were included if they had reported a full economic evaluation of any pharmacological therapy for SLE. Medline and Embase were searched electronically from inception until November 2016. The search strategy comprised disease-specific terms for SLE and published filters to identify economic evaluations. Abstracts were screened independently by two reviewers and read in full by one reviewer. Key features (study characteristics, data sources, methods of analysis, and results) were extracted from each economic evaluation. The Consolidated Health Economic Evaluation Reporting Standards (CHEERS) statement was used to appraise whether each economic evaluation had reported eighteen items with respect to its methods and results in full, partially, or not at all.

**Results:** The search strategy identified 2,001 abstracts and six published economic evaluations of treatments for SLE were included in the systematic review. These studies considered azathioprine (n=4), mycophenolate mofetil (n=3), cyclophosphamide (n=2), and belimumab (n=1) as relevant comparator therapies. The types of decision-analytic model included individual patient-level simulations (n=3), decision trees (n=2), and a cohort Markov model (n=1). Six elements of the CHEERS statement were reported incompletely across the sample: (1) target population, (2) choice of comparators, (3) measurement and valuation of preference-based outcomes, (4) estimation of resource use and costs, (5) choice and structure of the decision-analytic model, and (6) characterisation of heterogeneity.

**Conclusions:** The choice of treatments that are available currently for SLE are limited and this is reflected in the quantity of economic evaluations published to date. The incomplete reporting of methods within these economic evaluations highlighted notable gaps within the literature. Deficiencies in the evidence base manifest as parameter and structural uncertainties within decision-analytic model-based economic evaluations which, ultimately, affect the estimated expected cost-effectiveness of care. Greater use of existing datasets for SLE, including those from randomised controlled trials and observational cohort studies, can reduce these uncertainties in subsequent economic evaluations of strategies to manage SLE.

### EUROPEAN MEDICINES AGENCY'S GUIDELINE ON THE CLINICAL INVESTIGATION OF MEDICINAL PRODUCTS FOR THE TREATMENT OF RHEUMATOID ARTHRITIS

D. Da Silva<sup>1</sup>, E. Rook<sup>2</sup>, N. Semis-Costa<sup>1</sup>, J. Mueller-Berghaus<sup>3</sup>, R. Vesely<sup>1</sup> on behalf of The Rheumatology and Immunology Working Party of the Committee for Medicinal Products for Human Use from the European Medicines Agency.

<sup>1</sup>European Medicines Agency, London, United Kingdom, <sup>2</sup>Medicine Evaluation Board, Utrecht, Netherlands, <sup>3</sup>Paul-Ehrlich-Institut, Langen, Germany

**Background:** The European Medicines Agency (EMA) in consultation with regulatory authorities in the EU Member States prepares scientific guidelines, to help drug developers prepare marketing authorisation applications. The scope of the rheumatoid arthritis (RA) guideline is to provide a European common position on the clinical evaluation of new medicinal products.

**Objectives:** The EMA guideline is an update of the Points to Consider adopted in 2003. A revision of the guideline was required as the pharmacological therapy of RA has advanced. Treat-to-target strategies are now employed, and the optimum treatment goal is remission, or at least low disease activity (LDA). New classification criteria for RA have been developed and validated by the ACR-EULAR, which allows for earlier DMARD use. Increasing knowledge of the risk associated with DMARDs has been gained from trials and registries.

**Methods:** The guideline has been prepared by the Rheumatology-Immunology Working Party of the EMA. The guideline was revised based on literature, and recent trial and safety data from regulatory dossiers of RA products. External experts, investigators, industry and patient representatives were consulted ("Public consultation"), and in person during a Targeted consultation meeting in 2016.

**Results:** New primary endpoints (PE) were defined, reflecting treatment targets LDA or remission, in place of the previous PE of ACR20. Different validated scales may be used (either DAS28-ESR, DAS28-CRP, SDAI, or CDAI). The PE of choice should be corroborated by other outcomes as secondary endpoints. E.g if DAS28-CRP is chosen, more stringent outcomes like SDAI and DAS-ESR, or CDAI, which is independent of biomarkers CRP or ESR, should point at the same direction.

A distinction is made between study populations of DMARD naïve patients, where remission at 3 months is considered as a realistic target and methotrexate a suitable comparator; and patients irresponsive (or insufficiently responsive) to prior DMARDs, where LDA at 3–6 months is considered as an acceptable endpoint. For patients with long-standing disease irresponsive to multiple DMARDs, including two biologic DMARDs of different classes, ACR20 is still acceptable.

Long-term safety data of 12 months should be available before marketing authorisation.

The ultimate goal of RA treatment is the prevention of structural joint damage. However, showing an effect on structural damage has become increasingly challenging, since the placebo control should be kept short, and milder or more controlled patients may be eligible for studies of new DMARDs. Therefore, maintenance of remission and LDA could serve indirectly as an indicator for the prevention of structural damage, provided that these clinical outcomes are compelling, and routine monitoring by X-ray does not indicate a deviating trend as compared to an established comparator.

**Conclusions:** The EMA guideline on the development of products in the treatment of RA has undergone major revisions regarding the choice of endpoints and study design. The revision comes into force in July 2018.

FRI0610

### PATIENT NON-ATTENDANCE CHARACTERISTICS AT RHEUMATOLOGY OUTPATIENT CLINICS WITHIN A LARGE MULTI-ETHNIC REGION

A. Takyi<sup>1</sup>, K. Sunmboye<sup>2</sup>. <sup>1</sup>Rheumatology, University of Leicester, <sup>2</sup>University of Leicester Hospital, Leicester, United Kingdom

**Background:** Patient non-attendance for outpatient appointments is increasingly becoming more important in an era where resources have to be used in the most cost effective way. The Leicestershire region of the United Kingdom has a very diverse multi-ethnic population of just over 1 million people. Across 3 large hospital sites the University Hospitals of Leicester, United Kingdom caters for the rheumatology needs of this diverse population.

**Objectives:** The aim of our observational study was to identify the patient characteristics of the non-attenders and investigate if ethnicity and socioeconomic class contribute to the non-attendance rate.

**Methods:** The study was based on patient appointments scheduled at a busy rheumatology outpatient clinic across three large hospital sites from January 2017 to June 2017. Extensive data on various outcomes such as cancellation on the part of the patients and non-attendance from the patients without giving formal notice were collected from the main electronic administrative systems of three hospitals in the region. The data for the appointment characteristics were also collected. Logistic regression was used for statistical analysis.

**Results:** Of the 22,011 appointments scheduled over the study period. The non-attendance rate of 3.5% was recorded for this study period without the patients giving notice. The age range of the study population was 16 to 95 years. The median age was 50 years. Majority (24%) of non-attenders were in the 45–54 year age bracket. The 85–95 year age group had the lowest non-attendance rate at 2%. When the data was analysed for ethnicity, the percentage of patients who did not attend in the black Asian and minority ethnic group (BAME) was 44%. Only 33% of the study population were recorded on the hospital database as employed. The remainder included retirees (29%), students (4%) whilst the remaining 34% were either unemployed or we had no formal recording of their employment status.

**Conclusions:** The cost implications of missed appointments is so significant that even small percentage reductions in non-attendance rates could lead to significant savings. Various studies have identified many contributory factors such as age and ease of access to hospital facilities.

Few studies have looked at the role of ethnicity and socioeconomic class. From our data there was a significant (P value <0.05) difference between the employed and unemployed group. The working class group also had a significant non-attendance rate which suggests that more can be done at looking at the appointment scheduling by the health service provider.

Patient factors are likely to play a role in the BAME group not attending hospital appointments. The existing letter and text reminder service might need to explore several language options as this may play a contributory role in non-attendance rates. Addressing these issues may go a long way in ensuring that existing resources are not wasted due to non-attendance.

### ENGLISH LANGUAGE PROFICIENCY AND TOTAL KNEE/ HIP REPLACEMENT OUTCOMES: IS THERE A RELATIONSHIP?

B. Mehta<sup>1,2,3</sup>, J. Szymonifka<sup>4</sup>, S. A. Dey<sup>1</sup>, I. Y. Navarro-Millan<sup>1,2</sup>, S. V. Grassia<sup>4</sup>, L. A. Mandl<sup>1,2</sup>, A. R. Bass<sup>1,2</sup>, L. A. Russell<sup>1,2</sup>, M. L. Parks<sup>5,6</sup>, M. P. Figgie<sup>5,6</sup>, Y.-Y. Lee<sup>4</sup>, J. T. Nguyen<sup>4</sup>, S. M. Goodman<sup>1,2</sup>. <sup>1</sup>Rheumatology, Hospital for Special Surgery, <sup>2</sup>Rheumatology, Weill Cornell Medicine, <sup>3</sup>Columbia Mailman School of Public Health, <sup>4</sup>Biostatistics, <sup>5</sup>Orthopaedics, Hospital for Special Surgery, <sup>6</sup>Orthopaedics, Weill Cornell Medicine, New York, United States

**Background:** Health care disparities are recognized for medical and surgical outcomes in patients with Limited English Proficiency (LEP) (1).

**Objectives:** The purpose of this study is to assess the association of LEP on Total Knee Replacement (TKR) and Total Hip Replacement (THR) outcomes.

**Methods:** Individual patient-level variables were obtained from a single institution TKR and THR registry between 5/1/07 and 2/1/11. Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and function scores at baseline and 2 years after elective TKR and THR were collected and retrospectively analyzed. We used census tract LEP-“Less than very well” as recommended for screening individuals, since individual LEP data is not collected in most cohorts. We obtained census level data using patients’ geocodable addresses (2). Only patients from closest states (NY, NJ and CT) were included. Data was analyzed using univariate and multivariable linear mixed effects models, with census tracts variables treated as random effects.

**Results:** Table 1 describes the characteristics of the patients with THR (n=4009) and TKR (n=3898). In univariable analyses, for every percent increase in LEP, the WOMAC scores at baseline and 2 year were universally decreased and are statistically significant (p value <0.001). However in the multivariable model when adjusted for neighborhood poverty age, BMI, sex, comorbidities, and the Gini

coefficient these changes were not statistically significant, suggesting potential confounders (table 2). While women had worse baseline and 2-year WOMAC pain and function scores (all  $p \leq 0.04$ ), this difference was not significantly influenced by neighborhood LEP (all interaction NS).

**Methodology:** Categorical variables are summarized as frequency (percent). Continuous variables are summarized as mean <?> standard deviation

**Methodology:** Univariate and multivariable linear mixed-effects models were analyzed, with census tracts treated as random effects. In addition to neighborhood Limited English Proficiency; variables included in the model were; age, BMI, sex,  $\geq 1$  comorbidity; neighborhood percent poverty (<10%, 10% – < 20%, 20% – < 30%, 30% – < 40%,  $\geq 40%$  [reference group]), neighborhood Gini coefficient was also included.

Table 1. Total Joint Replacement Patient characteristics

Characteristic	Total Hip Replacement (n=4009)	Total Knee Replacement (n=3593)
<b>Patient demographics</b>		
Age at surgery (year), mean $\pm$ SD	65.6 $\pm$ 10.6	67.8 $\pm$ 9.5
Sex: female, n (%)	2169 (53.9%)	2346 (65.3%)
BMI (kg/m <sup>2</sup> )	27.9 $\pm$ 5.8	30.0 $\pm$ 5.8
Race, n (%)		
White	3794 (94.8%)	3568 (99.5%)
Black	131 (3.3%)	174 (4.9%)
Asian	23 (0.6%)	24 (0.7%)

III-IV	699 (17.5%)	469 (13.0%)
One or more comorbidity	695 (17.3%)	1057 (29.4%)
<b>Census tract characteristics</b>		
Poverty, n (%)		
<10%	2325 (58.0%)	2787 (77.6%)
10% – <20%	307 (7.7%)	311 (8.7%)
20% – <30%	115 (2.9%)	129 (3.6%)
30% – <40%	49 (1.2%)	28 (0.8%)
$\geq 40%$	13 (0.3%)	27 (0.8%)
Percent poverty, mean $\pm$ SD	6.2 $\pm$ 8.5	8.8 $\pm$ 1.2
Limited English Proficiency (LEP), n (%)		
<10%	2981 (74.4%)	2787 (77.6%)
10% – <20%	614 (15.3%)	650 (18.4%)
20% – <30%	209 (5.2%)	251 (7.0%)
30% – <40%	120 (3.0%)	113 (3.1%)
$\geq 40%$	85 (2.1%)	97 (2.7%)
Percent LEP, mean $\pm$ SD	3.6 $\pm$ 9.6	9.2 $\pm$ 10.0
Gini coefficient, mean $\pm$ SD	0.45 $\pm$ 0.07	0.45 $\pm$ 0.07
<b>Patient-reported outcomes</b>		
Baseline survey results, mean $\pm$ SD		
WOMAC pain	53.3 $\pm$ 17.8	54.8 $\pm$ 17.5
WOMAC function	49.5 $\pm$ 18.0	50.7 $\pm$ 17.6
2-year survey results		
WOMAC pain, mean $\pm$ SD	35.7 $\pm$ 11.3	37.9 $\pm$ 13.8
WOMAC function, mean $\pm$ SD	51.1 $\pm$ 13.1	52.8 $\pm$ 13.1

Table 2. Impact of every 10% change in neighborhood limited English proficiency on WOMAC pain and function

Time-point	WOMAC pain Estimate $\pm$ SE	p-value	WOMAC function Estimate $\pm$ SE	p-value
<b>Total Hip Replacement</b>				
Baseline (Univariable)	-1.4 $\pm$ 0.3	<0.001	-1.7 $\pm$ 0.5	<0.001
2-year (Univariable)	-0.8 $\pm$ 0.2	<0.001	-1.2 $\pm$ 0.2	<0.001
Baseline (Multivariable)	-0.6 $\pm$ 0.3	0.10	-0.8 $\pm$ 0.3	0.07
2-year (Multivariable)	-0.4 $\pm$ 0.2	0.054	-0.6 $\pm$ 0.2	0.01
<b>Total Knee Replacement</b>				
Baseline (Univariable)	-1.1 $\pm$ 0.3	<0.001	-1.3 $\pm$ 0.3	<0.001
2-year (Univariable)	-1.0 $\pm$ 0.3	<0.001	-1.4 $\pm$ 0.3	<0.001
Baseline (Multivariable)	-0.8 $\pm$ 0.3	0.02	-0.7 $\pm$ 0.3	0.13
2-year (Multivariable)	-0.2 $\pm$ 0.3	0.43	-0.2 $\pm$ 0.3	0.54

**Conclusions:** Patients coming from neighborhoods with lower english proficiency have worse pain and function scores in unadjusted models. However when adjusted for potential confounders, the difference is not significant. Community factors which contribute to healthcare disparities are multidimensional, prospective studies collecting individual LEP data would be warranted to study this aspect in detail.

**FRI0612 HOW EFFECTIVE ARE INTERVENTIONS TARGETING PATIENT ACTIVATION IN PEOPLE WITH LONG TERM PHYSICAL CONDITIONS? A SYSTEMATIC REVIEW**

B. Jones<sup>1,2</sup>, S. Hewlett<sup>1,2</sup>, D. Harcourt<sup>3</sup>, A. Hunt<sup>2</sup>, E. Dures<sup>1,2</sup>. <sup>1</sup>Centre for Health and Clinical Research, University of the West of England (UWE), <sup>2</sup>Academic Rheumatology, University Hospitals Bristol NHS Foundation Trust, <sup>3</sup>Centre for Appearance Research, University of the West of England (UWE), Bristol, United Kingdom

**Background:** Patient activation is an increasingly referenced concept in the self management of long term physical conditions. It refers to someone’s ability to take an active role in self-managing their health. There has been a substantial increase in the number of studies trailing interventions targeting patient activation in a variety of formats. The findings from this review will contribute to maximising the impact of current rheumatology interventions, and to increase the understanding of patient activation to develop a framework to describe its core components within a rheumatology context.

**Objectives:** This study aimed to identify the effectiveness of interventions targeting patient activation in people with long-term conditions, including rheumatoid arthritis.

**Methods:** Studies that were randomised control trials of interventions targeting patient activation in adults with long term physical conditions were included in the review. PsycINFO, Medline, AMED, CINAHL, and ProQuest were searched during January 2017, as well as a variety of grey literature locations, snowballing and hand-searching to identify potential studies for inclusion. The Cochrane Collaboration’s Risk of Bias Tool was used to determine the methodological quality of included studies, and any differences were resolved by the two reviewers. Authors were contacted if any additional information was required to extract data or to clarify risk of bias.

**Results:** 17 papers were included in the review. There was a great deal of heterogeneity in the types of interventions available targeting patient activation in a variety of populations, and a meta-analysis was not possible as a result. Interventions were delivered via face to face, telephone, internet and resource-based approaches. The studies also included a mix of group and individually delivered interventions. Outcome measures used also varied, including both direct and proxy measures for patient activation.

The findings suggest that in studies with interventions that are more structured, there appear to be a trend towards differences in patient activation scores between groups in favour of the intervention. It is possible that these increases in patient activation may occur with an increase in health literacy, as the literature suggests an association between the two constructs. This is discussed in terms of a proposed model for patient activation for rheumatology.

**Conclusions:** There is some initial evidence for the benefit of increasing structure in interventions targeting patient activation. There is no evidence for a medium of delivery that is most effective in people with long term conditions. Studies would benefit from reporting information about engagement and adherence to interventions to understand the mechanisms behind engaged participants becoming more active in managing their health. There is a need for increased research into patient activation within Rheumatology.

**FRI0613 USEFULNESS OF SMARTPHONES APPLICATIONS IN THE FOLLOW-UP OF PATIENTS WITH INFLAMMATORY RHEUMATOLOGICAL DISEASES: ARE THEY REALLY BENEFICIAL IN OBJECTIVE TERMS?**

C. A. Guillen-Astete<sup>1</sup>, B. Laso-Jimeno<sup>2</sup>. <sup>1</sup>Rheumatology Department, Moncloa University Hospital, <sup>2</sup>Ramon y Cajal University Hospital, Madrid, Spain

**Background:** The use of computer programs developed for their use through smartphones has been incorporated into the health field. In recent years there have been countless new applications aimed at easing the work of the clinician through access to commonly used tools, image atlases, real-time information or to facilitate the monitoring of patients. In this last group, there are different applications oriented to multiple purposes.

**Objectives:** The aim of this study is to assess the performance of two personally developed applications for the follow-up of patients with gout and rheumatoid arthritis (ReumApp-Gota and ReumApp-AR).

**Methods:** We surveyed 65 patients who were users of ReumaApp-Gota and 35 patients who were users of ReumaApp-AR. All were direct users with at least 6 months of experience with the application. Both applications were developed by the author of the work on a free distribution platform and whose extension and

contents have been discussed in a previous abstract. The survey was completed upon request and in the presence of the reference clinician throughout the last quarter of 2017. The survey assessed three areas: therapeutic and hygienic-dietetic adherence, the perception of personalized follow-up and overall practical utility. In parallel, the number of annual attacks of patients using ReumaApp-Gota and the relative annual reduction of the uric acid level in peripheral blood were determined. In the case of patients using ReumaApp-AR, the demand for unscheduled visits due to flares of RA and the relative reduction of DAS28 were evaluated. In both cases, their results were compared with cohorts of patients who had not used any of the applications (35 of the drop group and 29 of the AR group).

**Results:** Users of ReumAPP-Gota: Improvement in adherence 25/65, personalized follow-up is perceived 56/65, has utility in day-to-day 52/65. Users of ReumAPP-AR: Improve adherence 31/35, personalized follow-up is perceived 30/35, has utility in day to day 29/35. The number of annual gout attacks in patients users of the APP was 1.32 OF 0.45 and that of non-users was 1.27 OF 0.52 ( $P=0.848$ ), the relative annual reduction of patients with gout users of the APP was 36.6 OF 6.6 % and that of non-users 33.7 of 11.2% ( $P=0.106$ ). The number of urgent visits in a year of patients with RA users of the APP was 0.55 of 0.12 and that of the non-users group 0.83 of 0.29 ( $P<0.001$ ). The relative reduction of the DAS28 of patients using the APP was 34.9 of 5.9% and of the non-users was 31 of 7.7% ( $P<0.025$ ).

**Conclusions:** Although the use of applications for smartphones seems to generate a greater sense of medical vigilance on the part of patients and is globally considered useful, its impact on the therapeutic adherence in patients with gout is low and is reflected in the objective results of reduction of plasma uric acid figures and the number of annual attacks. In the case of patients with RA the use of the application significantly reduces the need for urgent visits, most likely because it allows the clinician to contact the patient priorly when certain parameters entered exceed certain margins. But on the other hand the relative reduction of DAS28 may be due to the fact that patients not users of the application are usually older than those who accept its use.

#### FRI0614 PHYSICIAN-PATIENT INTERACTIONS IN AFRICAN AMERICAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Drenkard<sup>1</sup>, G. Bao<sup>1</sup>, T. T. Lewis<sup>2</sup>, B. F. Pobiner<sup>3</sup>, J. Priest<sup>3</sup>, S. S. Lim<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Epidemiology, Emory University, Atlanta, <sup>3</sup>GlaxoSmithKline, North Carolina, United States

**Background:** African American (AA) patients with systemic lupus erythematosus (SLE) are at high risk for poor outcomes. Patient characteristics and disease severity influence physician-patient interactions, which in turn can impact outcomes.

**Objectives:** Examine the relationships between physician-patient interactions and demographics, disease activity, and depression in AA SLE patients.

**Methods:** The Georgians Organized Against Lupus (GOAL) is a population-based cohort of patients with a documented diagnosis of SLE. We conducted a cross-sectional analysis of patient-reported data among 698 AA participants (out of 863 GOAL participants). We assessed patients reports of physician-patient interactions (communication, patient-centered decision making, and physician interpersonal style) through the Interpersonal Processes of Care survey (IPC-29), disease activity through the Systemic Lupus Activity Questionnaire, and depression through the Patient Health Questionnaire-9. We used non-parametric tests to assess IPC-29 by demographics, linear trend test to assess demographic-adjusted scores of IPC-29 by disease activity and depression, and multivariate logistic regression to assess the association of disease activity and depression with suboptimal IPC scores.

**Results:** Lowest IPC-29 scores were for patient-centered decision making, specifically for the "asked patient" subdomain (how often doctors assessed patients' problems to follow recommendations and treatment) in women compared with men (mean score 3.1±1.4 and 3.6±1.4, respectively;  $p=0.02$ ). Scores for the "assumed socioeconomic level" subdomain (how often doctors make assumptions about a patient's socioeconomic level) in the interpersonal style domain were higher (worse) in patients aged 18–34 (mean score 1.6±0.9), compared to those aged 35–55 (mean score 1.5±0.9;  $p=0.03$ ). Patients with higher educational attainment ( $\geq$ college) reported poorer mean scores for most communication and interpersonal style scales than those with  $\leq$ high-school. We found significant linear trends of poorer scores for all communication scales across more severe

disease activity and depression, and poorer scores for all interpersonal style scales across more severe disease activity. Neither disease activity nor depression was associated with worse patient-centered decision-making. In multivariate models depression was associated with suboptimal quality of communication (OR 1.2; 95% CI 1.04–1.4) and interpersonal style (OR 1.1; 95% CI 1.0–1.3); and disease activity increased the odds of suboptimal communication (OR 1.1; 95% CI 1.0–1.3).

**Conclusions:** In AA patients with SLE, perceptions of physicians' communication, shared decision-making, and physicians' interpersonal style vary by sex and education. While disease activity and depression were associated with worse reports of physician-patient communication and interpersonal style, neither disease activity nor depression influenced shared-decision making. Our data suggest that in addition to standard of care treatment, AA SLE patients with active disease and depression might need provider-based interventions focused on communication and interpersonal style.

#### FRI0615 NORMALISED TOXICITY TO PREGABALIN DID NOT INCREASE WITH CHANGES IN APPROVAL MECHANISM AND USE IN AUSTRALIA

C. McMaster<sup>1</sup>, D. F. L. Liew<sup>1,2,3</sup>, E. Joules<sup>4</sup>, J. Robinson<sup>5</sup>, S. Greene<sup>5</sup>, R. R. C. Buchanan<sup>2,3</sup>, A. G. Frauman<sup>1,3</sup>. <sup>1</sup>Clinical Pharmacology and Therapeutics, <sup>2</sup>Rheumatology, Austin Health, Heidelberg, <sup>3</sup>Medicine, University of Melbourne, Parkville, <sup>4</sup>Pharmacy, <sup>5</sup>Victorian Poisons Information Centre, Austin Health, Heidelberg, Australia

**Background:** Pregabalin is a potent antagonist of neuronal voltage-gated calcium channels used to treat neuropathic pain. Although first registered with the Therapeutic Goods Administration (TGA) in April 2005, rapid uptake of pregabalin in the Australian market only came after its listing on the Pharmaceutical Benefits Scheme (PBS) with a streamlined code on 1st March 2013 for the indication of neuropathic pain. Recently, there has been concern raised about the growing off-label use of pregabalin for chronic pain syndromes and the subsequent potential for undue adverse drug reactions (ADRs).<sup>1</sup>

**Objectives:** The aim of this study was to measure how broadening access to pregabalin in Australia affected the rate of pregabalin-associated ADRs, and whether such an effect was disproportionate to the change in pregabalin prescription rates.

**Methods:** We extracted ADRs reported in the TGA Database of Adverse Event Notifications (DAEN) between 1st January 2009 and 18th October 2017, in which pregabalin was thought to have been causative. We also extracted calls to the Victorian Poisons Information Centre (VPIC) between 1st January 2009 and 31st December 2017 in which pregabalin was a reported exposure. For both databases, ADR rates were annualised, with the missing DAEN ADR reports between 19th October 2017 and 31st December 2017 imputed using a linear model based on year-to-date ADR rates. The annual ADR rates were normalised by dividing by the estimated number of pregabalin prescriptions filled (in millions), to obtain a normalised Toxicity Index (number of ADRs per million scripts). Because the data was annualised, the 1st January 2013 was used as the approximate starting date of PBS streamlined listing.

**Results:** The estimated number of pregabalin prescriptions filled in Australia increased over the study period from 155,336 in 2009 to 3,739,421 in 2017. A total of 886 ADRs were reported to VPIC over the study period, and 1056 reported to DAEN (1076 after extrapolation). The mean Toxicity Index (TI) for the VPIC database was 539 ADRs/million scripts before PBS streamlined listing, and 298 ADRs/million scripts after; there was no evidence that the TI had increased ( $p=0.9$ , one-tail t-test). Similarly, the TI for the DAEN database was 441 ADRs/million scripts prior to PBS streamlined listing, versus 85 ADRs/million after; there was no evidence that TI increased ( $p=0.98$ , one-tail t-test).

**Conclusions:** After adjusting for the total volume of scripts dispensed, the rate of ADRs involving pregabalin in both the VPIC and DAEN databases did not increase after a streamlined approval mechanism was adopted, leading to significantly increased use. These data do not support the emergence of undue adverse drug reactions from increased off-label use of pregabalin.

#### COST-EFFECTIVENESS OF SWAPPING STRATEGY FOR ESTABLISHED PSORIATIC ARTHRITIS AND IMMEDIATE VERSUS STANDARD SWAPPING STRATEGY FOR EARLY PSORIATIC ARTHRITIS

D. Wu<sup>1</sup>, T. Xu<sup>2,3</sup>, I. T. Cheng<sup>1</sup>, S. H.M. Lam<sup>1</sup>, J. Yue<sup>1</sup>, P. Wong<sup>1</sup>, E. K. Li<sup>1</sup>, T. K. Li<sup>1</sup>, L.-S. Tam<sup>1</sup>. <sup>1</sup>Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, <sup>2</sup>China Center for Health Development Studies, Peking University, <sup>3</sup>Department of Health Policy and Administration, Peking University School of Public Health, Beijing, China

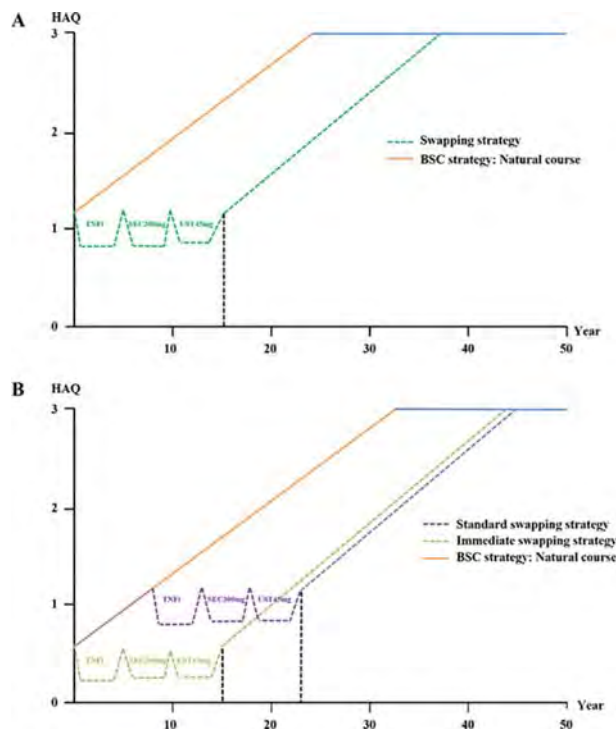

**Background:** For patients with psoriatic arthritis (PsA) failing the first TNF-inhibitor, switching to biologic DMARDs [bDMARDs] with different mechanism of actions (swapping strategy) may be superior than switching to another anti-TNF (cycling strategy) [1,2].

**Objectives:** To evaluate the cost-effectiveness of 1) swapping strategy for established PsA and 2) immediate versus standard swapping strategy for early PsA from the Hong Kong (HK) societal perspective

**Methods:** Based on comparative effectiveness from network meta-analysis of randomized controlled trials and treatment-specific withdrawal and serious adverse event rate, a swapping York model with life time horizon was developed to evaluate swapping strategy relative to best supportive care (BSC) for PsA failing the first anti-TNF. Initial response to bDMARDs was determined using the Psoriatic Arthritis Response Criteria. The impact of biologics on the arthritis component of the disease is modelled via a change in the HAQ and the impact of the skin component measured using the Psoriasis Area and Severity Index. The model was specified for two hypothetical subpopulations including patients with 1) established PsA (age=47, HAQ=1.22, figure 1A) received five swapping strategies and 2) early PsA [3] (age=40, HAQ=0.71, figure 1B) received immediate (start bDMARDs after diagnosis) or standard (initially given BSC and then start bDMARDs when HAQ increase to 1.22) use of the most cost-effective swapping strategy. Both subpopulations were further classified according to the level of concomitant psoriasis [mild to moderate psoriasis (MMP, PASI=0.73) or moderate to severe psoriasis (MSP, PASI=12.5)]. All five swapping strategies started with an anti-TNF (infliximab, adalimumab, etanercept, certolizumab or golimumab), followed by secukinumab 300 mg and then ustekinumab 45 mg. The cost-effectiveness of each strategy was determined using a willingness-to-pay (WTP) threshold of £32,356/ quality-adjusted life-year (QALY) (HK Gross Domestic Product per capita).

**Results:** For the base-case scenario, all five swapping strategies are cost-effective versus BSC strategy for established PsA, which are associated with greater QALY gain and lower treatment related direct costs, psoriasis cost and

productivity loss. In established PsA with MMP and MSP, etanercept swapping strategy is likely to be the most cost-effective strategy with an incremental cost £9,518.93 and £9,084.58 per QALY gained over BSC strategy respectively. For early PsA with MMP and MSP, the base-case results indicated that standard etanercept swapping strategy was cost-saving (£-50,635.74 and £-67,843.32) and more effective (1.20 and 1.32 QALYs); while immediate etanercept swapping strategy was costlier (£13294.95 and £8986.16), more effective (3.82 and 3.27 QALY), and had relative low ICER (£3482.36 and £2745.35 per QALY gained) relative to BSC strategy.

**Conclusions:** Swapping strategy showed favorable cost-effectiveness for established PsA as well as early PsA. The increased costs of biologic agents are offset by the gain in benefits from long-term HAQ reduction.

#### UPTAKE ON FLU AND PNEUMONIA VACCINATION AT THE RHEUMATOLOGY CLINIC AT A UK DISTRICT GENERAL HOSPITAL- ARE WE BETTER THAN 10 YEARS AGO?

E. Ntatsaki<sup>1</sup>, A. Tahir<sup>1</sup>, A. Jiskani<sup>1</sup>, A. Mohammed<sup>1</sup>, V. Vassiliou<sup>2</sup>, R. Watts<sup>1</sup>. <sup>1</sup>Rheumatology, Ipswich Hospital NHS Trust, Ipswich, <sup>2</sup>Medical School, University of East Anglia, Norwich, United Kingdom

**Background:** Patients with rheumatic diseases are at increased risk of contracting infection due to the disease itself or because of the use of immunomodulatory medication. EULAR has developed recommendations and supports vaccination against influenza and pneumococcal infections in immunocompromised patients<sup>1</sup>. Despite convincing data regarding the efficacy of vaccination with the use of disease-modifying anti rheumatic drugs (DMARDs), previously published data from our trust in 2007 showed that uptake of vaccination was suboptimal especially in those aged <65 years<sup>2</sup>.

**Objectives:** To establish the influenza or pneumococcal (pneumovax) vaccination uptake and explore reasons for reduced uptake in patients attending a rheumatology clinic.

**Methods:** Prospective audit of 100 patients attending the Rheumatology clinic in a UK district hospital using an anonymised survey during November to December 2017 and comparison with the data of 10 years ago.

**Results:** A total of 100 questionnaires were given out, with return rate of 98%. Female:male ratio was 3.8:1, mean age 55±17. Most patients were treated for RA (24%), Psoriatic arthritis (20%), Ankylosing spondylitis (14%) and others, see figure 1. Regarding immunosuppression 16% were on biologics and 78% on DMARDs. Most were on methotrexate (26%), Prednisolone (16%), hydroxychloroquine (12%), sulfasalazine (12%) whereas biologics were <10% each (see figure 1).

With regards to vaccination for influenza, overall 47% had received the vaccine (see table 1). Of those who did not take the vaccine 35% had an allergy or did not believe it was effective, but 65% were not offered the vaccine. A total of 52% commented that a health professional had discussed influenza vaccination with them, 42% mentioned that this was never discussed and 6% were unsure. In RA population uptake was 48% compared to 44% 10 years ago ( $p=0.81$ ).

Regarding pneumovax 29% commented that a health professional had discussed pneumococcal vaccination and only 28% had received the vaccine. Of those who did not take the vaccine 12% had an allergy or did not believe it was effective, and 83% were not aware that the vaccine existed or were not offered the vaccine. In RA population uptake was 61% compared to 62% 10 years ago ( $p=0.62$ ). RA patients had better vaccination than psoriatic patients for influenza ( $p=0.03$ ), but not pneumovax ( $p=0.52$ ).

UPTAKE OF VACCINE	Influenza vaccination	Pneumonia vaccination
All patients -2017	47%	28%
RA patients- 2007	62%	44%
RA patients- 2017	16/23 (61%)	11/23 (48%)
Psoriatic Arthritis	6/18 (33%)	6/18 (33%)
Prednisolone	10/14 (71%)	9/14 (64%)
Methotrexate	14/22 (63%)	11/19 (58%)

**Conclusions:** Although this is a small audit conducted in a routine rheumatology clinic in the UK, it is of concern that with increased patient education seen in the last 10 years, vaccination for influenza and pneumococcus has not improved. Perhaps healthcare professionals are not discussing this with the patients sufficiently. Further patient and healthcare involvement is required to reverse the declining trend and protect our patients.

#### FRI0618 CONCORDANCE WITH LATEST GUIDELINES FOR DMARD SCREENING AND MONITORING IN SECONDARY CARE

E. Cefai<sup>1</sup>, D. Xhaxho<sup>1</sup>, C. Mercieca<sup>1</sup>, A. Borg<sup>1</sup>. <sup>1</sup>Mater Dei Hospital, tal-groqq, Malta

**Background:** DMARDs need to be prescribed safely. Screening and monitoring for toxicity is essential when using these medications. The British Society of

Rheumatology (BSR) has recently published guidance on screening and monitoring of non-biologic DMARDs.

**Objectives:** The aim of this audit was to assess current practice on synthetic DMARD screening and monitoring within our rheumatology department, in a secondary care setting, using the BSR 2017 guidelines as the standard of care.

**Methods:** 81 consecutive adult patients who were started on synthetic DMARDs in 2016 were recruited. The data required was collected from case notes and isoform clinical manager after obtaining data protection clearance. DMARDs included Hydroxychloroquine (HCQ), Methotrexate (MTX), Sulfasalazine (SSA), Azathioprine (AZA) and Leflunomide (Lef). Baseline screening was assessed by checking for documentation of height, weight, baseline blood tests including virology and documentation of known lung disease and smoking with the relevant investigations when necessary. Specialist nurse referral and content of consultation was assessed for discussion regarding fertility/pregnancy when relevant, intercurrent illnesses and vaccinations. Drug-specific screening and monitoring included folic acid prescription (FA) for MTX, TPMT testing for AZA, ophthalmic review for HCQ as well as weight and blood pressure (BP) monitoring for Lef. Finally all patients were checked for regular blood monitoring at weeks 2,4,6 and every 3 months thereafter with the exception of SSA & HCQ monotherapy. Calibri (Body)

**Results:** Weight and height were not documented in 50.6% and 66.7% of patients respectively. Baseline blood tests were present in all but 1 patient with the exception of virology. The latter was present in 6.2% of cases only. Smoking status was assessed in 92.6% of cases. CXR and pulmonary function tests were warranted for 9 patients but were only done in 4 cases. 98.8% of patients were referred to the specialist nurse for DMARD education. Discussion on fertility and pregnancy, where applicable, was discussed in 95% of cases, vaccinations in 97.5% of cases and advice regarding management of intercurrent illnesses in 2.5% of cases. Drug monitoring at 2, 4 and 6 weeks was done in 33.3%, 90.1% and 80.2% of cases respectively. BP and weight were checked for all patients on Lef whilst blood monitoring for SSA monotherapy persisted after 1 year in 80% of cases. Drug specific recommendations including FA prescription, TPMT testing and ophthalmic reviews were done in all patients.

**Conclusions:** This audit showed a high level of concordance with the BSR monitoring guidelines for synthetic DMARDs. Aspects that require improvement have been highlighted. By ensuring that there is proper documentation of all aspects pertaining to the work-up prior to starting a patient on a DMARD, one can then introduce screening and monitoring schedules targeted at the prevention and early detection of adverse treatment outcomes.

#### FRI0619 PREDICTORS AND TEMPORAL TREND OF SEASONAL INFLUENZA VACCINATION IN AUTO-IMMUNE RHEUMATIC DISEASES IN THE UK: A NATIONWIDE PROSPECTIVE COHORT STUDY

G. Nakafero<sup>1</sup>, M. Grainge<sup>2</sup>, P. Myles<sup>2</sup>, C. Mallen<sup>3</sup>, W. Zhang<sup>1</sup>, M. Doherty<sup>1</sup>, J. Van-Tam Nguyen<sup>2</sup>, A. Abhishek<sup>1</sup>. <sup>1</sup>Academic Rheumatology, <sup>2</sup>Epidemiology and Public Health, University of Nottingham, Nottingham, <sup>3</sup>Primary care and Health Sciences, Keele University, Keele, United Kingdom

**Background:** Autoimmune rheumatic diseases (AIRDs) are associated with an increased risk of influenza and its complications which may be compounded by the use of potent disease modifying anti-rheumatic drugs (DMARDs). In the United Kingdom, seasonal influenza vaccination (SIV) is recommended for people older than 65 years, and for those at a higher risk of influenza due to underlying diseases or immunosuppressive treatment. Understanding SIV uptake in AIRD patients on DMARDs could identify subsets who need targeted effort to optimise SIV uptake in this group.

**Objectives:** To [1] examine temporal trends in uptake of SIV; [2] explore disease and demographic factors associated with receiving the SIV; and [3] calculate the proportion of people with AIRDs who are vaccinated in time before the seasonal flu virus circulates.

**Methods:** 32,751 people with AIRDs prescribed DMARDs between 2006 and 2016 were identified from the Clinical Practice Research Datalink (CPRD). CPRD is one of the world's largest prospective databases of primary care records, and includes primary-care medical, prescription and immunisation data on 8% of the UK population at any one time. The proportion of eligible cases vaccinated between 01/September of one year and 31/March of the next year (flu-season) was calculated and stratified by age, presence of additional indications for vaccination, AIRD type, and number of DMARDs prescribed. We used Joinpoint regression analysis to determine the temporal trend in SIV uptake while Poisson regression with robust error variance was used to examine the univariate and multivariate association between age, sex, AIRD type, additional indication for being vaccinated, total number of different DMARDs prescribed in the 12-month period with receiving SIV. The analysis was conducted in the open source Joinpoint regression software and Stata-MP.

**Results:** SIV uptake was high in those  $\geq 65$  years old (82.3% and 80.7% in 2006–07 and 2015–16 respectively). However, it was significantly lower in other age groups, but improved over time with 51.9% and 61.9% in the 45–64 year age group, and 32.3% and 50.1% in the <45 year age group being vaccinated in 2006–07 and 2015–16 respectively. While 64.9% of the vaccinations in those  $\geq 65$  years old occurred by the 3rd November (week 9 in Graph 1), in time to mount a protective immune response before the influenza activity becomes substantial in the UK, only 38.9% in the 45–64 year and 26.2% in the <45-year age group without any other reason for vaccination received SIV before this date (Graph 1). Men, those without additional indications for vaccination, and those on single DMARDs were significantly less likely to be vaccinated.

**Conclusions:** The uptake of SIV is low in the under 65s, and many do not get vaccinated in time to confer immunity. Additional effort is required to promote the timely uptake of SIV in this population. To our knowledge, this is the first study to assess temporal trends in uptake of SIV among AIRDs and to compare uptake across different AIRDs.

#### FRI0620 LOW EDUCATIONAL ATTAINMENT IS ASSOCIATED WITH POOR PATIENT STATUS AT THE INITIAL VISIT OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) OR OSTEOARTHRITIS (OA) AT THE INITIAL VISIT TO A RHEUMATOLOGY SETTING, WITH SIMILAR PATTERNS IN PATIENTS WITH EITHER DIAGNOSIS

J. Schmukler<sup>1</sup>, I. Castrejon<sup>1</sup>, T. Pincus<sup>1</sup>, J. Block<sup>1</sup>. <sup>1</sup>Rheumatology, Rush University Medical Center, Chicago, United States

**Background:** Low educational attainment is associated with a higher prevalence, morbidity, and mortality of many diseases, including rheumatoid arthritis (RA) (J Chronic Dis 1985; 38:973–84) and osteoarthritis (OA) (J Clin Epidemiol 1992;45:139–47). These associations often are attributed to limited access of disadvantaged people to medical services (Ann Intern Med 1998;129:412–6), although some have suggested that these differences are explained primarily by differences in patient self-management (Ann Intern Med 1998;129:406–11).

**Objectives:** To study clinical status of patients with RA or OA, all of whom had access to rheumatology care, at their initial visit.

**Methods:** All patients with all diagnoses seen at an academic rheumatology site complete a self-report multidimensional health assessment questionnaire (MDHAQ) at each visit. MDHAQ includes 30–10 scales for physical function (FN), pain (PN) and global assessment (PATGL), compiled into a 0–30 routine assessment of patient index data (RAPID3). Patient-reported FN, PN, PATGL and RAPID3 were compared in new patients with a primary diagnosis of either RA (n=66) or OA (n=66) at a first visit in 3 groups according to years of formal education, <12, 12, and >12 years, using analysis of variance (ANOVA).

**Results:** Mean MDHAQ scores were quite similar in OA vs RA, and varied similarly according to education level (table 1). In all patients, mean RAPID3 was 15.4 in OA vs 15.3 in RA; in those with <12 years, 18.2 in OA vs 19.8 in RA; in those with 12 years, 15.9 in OA vs 16.0 in RA; in those with >12 years, 14.0 in OA vs 13.7 in RA (p=0.11 for OA, p=0.04 for RA) (table 1). FN scores were 3.9 in both groups with <12, 3.3 in both groups with 12, and 2.3 in OA vs 2.4 in RA patients with >12 years of education (p=0.02 for OA, p=0.08 for RA). PN scores were 7.3 and 8.5 for OA vs RA with <12 years, 7.1 and 6.2 for OA vs RA with 12 years, and 6.7 vs 5.9 for OA vs RA patients with >12 years of education (p=0.69 for OA, p=0.02 for RA). PATGL was 7.0 vs 7.4 for OA vs RA with <12 years, 5.5 and 6.5 for OA vs RA with 12 years, and 5.1 and 5.4 in OA vs RA patients with >12 years of education (p=0.14 for OA, p=0.12 for RA).

Table 1 Mean & standard deviation (SD) for 0–10 physical function, pain, patient global assessment and 0–30 RAPID3 of patients with RA or OA at first visit, by formal education level

OA – measures	Total N=66	Groups by level of education (years)			p
		<12 (n=12)	12 (n=21)	>12 (n=33)	
Function (0–10)	2.9 (2.0)	3.9 (1.5)	3.3 (2.3)	2.3 (1.7)	0.02
Pain (0–10)	6.9 (2.3)	7.3 (1.7)	7.1 (2.4)	6.7 (2.5)	0.69
PATGL (0–10)	5.6 (2.9)	7.0 (2.1)	5.5 (3.1)	5.1 (2.9)	0.14
RAPID3 (0–30)	15.4 (6.0)	18.2 (3.9)	15.9 (6.8)	14.0 (5.9)	0.11
RA – measures	Total N=66	Groups by level of education (years)			p*
		<12 (n=12)	12 (n=21)	>12 (n=33)	
Function (0–10)	2.9 (2.2)	3.9 (3.0)	3.3 (2.1)	2.4 (1.8)	0.08
Pain (0–10)	6.4 (2.9)	8.5 (1.5)	6.2 (3.4)	5.9 (2.7)	0.02
PATGL (0–10)	6.0 (3.0)	7.4 (3.1)	6.5 (3.3)	5.4 (2.8)	0.12
RAPID3 0–30)	15.3 (7.2)	19.8 (6.3)	16.0 (8.1)	13.7 (6.5)	0.04

**Conclusions:** Low education was associated with RAPID3 and all component scores similarly in RA and OA. Differences according to formal education level were greater than by diagnosis, which were negligible. These variations do not appear attributable to differences in access to medical services.

#### FRI0621 HOSPITAL ADMISSIONS AND READMISSIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS. ASSOCIATED FACTORS AND DIRECT HEALTH-CARE COSTS IN A THIRD LEVEL UNIVERSITY HOSPITAL

J. E. Ruiz-Sarà<sup>1</sup>, N. Lozano-Rivas<sup>1</sup>, P. Castillo Dayer<sup>1</sup>, C. García-Belando<sup>1</sup>, A. Paños-Iniesta<sup>1</sup>, L. F. Linares<sup>1</sup>, A. Bermudez<sup>1</sup>, F. A. Martínez-Angosto<sup>1</sup>, J. Martínez-Ferrín<sup>1</sup>, M. J. Moreno<sup>1</sup>, M. Castaño<sup>1</sup>, P. Mesa del Castillo<sup>1</sup>, F. García Gambín<sup>2</sup>, F. Andrade Rodado<sup>3</sup>, C. Marras-Fernández Cid<sup>1</sup>. <sup>1</sup>Rheumatology Department, University Hospital Virgen Arrixaca, <sup>2</sup>Evaluation department University Hospital Virgen Arrixaca, Murcia, <sup>3</sup>Intensive Care Unit, Vega Baja Hospital, Orihuela, Alicante, Spain

**Background:** In last years, the direct health-care costs derived from admissions and readmissions to Rheumatology departments of patients with Rheumatoid Arthritis (RA) have diminished. Presumably, the higher survival rate and the amount of comorbidities of these patients have derived in an increased of admissions and direct costs to other medical and surgical departments.

**Objectives:** To describe the admission and readmission causes of all patients with RA admitted during 2015 and 2016 and to identify factors associated to readmission. Finally to estimate the costs derived from these events in the same period.

**Methods:** All electronic medical reports were revised; demographic, medical and therapeutic data, as well as diagnosis at discharge were collected. A descriptive analysis followed by a logistic regression analysis were done to identify readmission-associated variables. Financial analysis was done by calculating the price of the stay according to established in 2015-scale.

**Results:** 240 admissions of 158 patients were found. Mean age 63.8 years, 69% women and mean evolution of RA of 13.1 years. At admission, 53% were on oral steroids and 45% with synthetic DMARD. Admissions were mainly distributed in Internal Medicine department (26%). Infections were the most frequent admission cause (33%), followed by cardiovascular events (20%) and oncological processes (13%). Forty-nine patients (31%) were readmitted, 47% due to infections. Age (OR/year 1.02 CI 95% 1.00–1.04), diabetes (OR 2.1 CI 95% 1.1–4.4) and chronic kidney disease (OR 3.3 CI 95% 1.0–10.2) were the associated risk factors. There were a total of 2172 days of stay with an estimated cost of 530420 euros and 783 days of stay due to readmissions with a total cost of 203218 euros. Departments which generated more costs either for admissions or readmissions were Oncology (65064 euros/19585 euros respectively) and Intensive Care (68011 euros/42651

respectively). Costs for admission and readmission in Rheumatology department were 5230 and 3175 euros respectively.

**Conclusions:** Admission and readmission of patients with RA are mostly due to infections and cardiovascular causes. Estimated direct costs are higher for patients admitted to Intensive Care Unit or Oncology

**Disclosure of Interest:** None declared

FRI0622

### TRENDS IN ENCOUNTERS WITH RHEUMATOLOGISTS IN A PUBLICLY-FUNDED SINGLE PAYER HEALTHCARE SYSTEM

J. Widdifield<sup>1</sup>, S. Bernatsky<sup>2</sup>, V. Ahluwalia<sup>3</sup>, C. Barber<sup>4</sup>, L. Eder<sup>5</sup>, B. Kuriya<sup>5</sup>, V. Ling<sup>6</sup>, A. Lyddiatt<sup>7</sup>, M. Paterson<sup>6</sup>, J. Pope<sup>8</sup>, C. Thorne<sup>9</sup>. <sup>1</sup>Sunnybrook Research Institute, Toronto, <sup>2</sup>McGill University, Montreal, <sup>3</sup>William Osler Health System, Brampton, <sup>4</sup>University of Calgary, Calgary, <sup>5</sup>University of Toronto, <sup>6</sup>Institute for Clinical Evaluative Sciences, <sup>7</sup>Ontario Rheumatology Association, Toronto, <sup>8</sup>Western University, London, <sup>9</sup>Southlake Regional Health Centre, Newmarket, Canada

**Background:** Rheumatology workforces are challenged by too few physicians, increasing incidence and prevalence of MSK diseases (and complexity of co-morbid conditions) in aging populations, and expanding therapeutic options that increase demand for service. Understanding trends in rates of rheumatology encounters with new and existing patients will help to identify why patients have delays to rheumatology care and mobilize efforts to help meet patients' needs.

**Objectives:** To describe trends in patient encounters with rheumatologists over time in Ontario, Canada.

**Methods:** We analyzed administrative health data from 2000 to 2013 in Ontario, Canada, where all 13 million residents are covered by a publicly-funded healthcare system and access to rheumatologists is dependent upon referrals. During this time, Ontario had a stable rheumatology supply of 1 rheumatologist per 75,000 population (0.7 FTEs/75,000). We determined annual incident, follow-up and total patient encounters seen by rheumatologists. Rates were calculated using the total population of Ontario residents 18 and older, each year. Diagnosis codes assigned at each encounter were used to assess changes in the case-mix of patients under rheumatology care over time.

**Results:** From 2000 to 2013, the proportion of all Ontario residents seen by rheumatologists was constant over time (2.7%). The total number of rheumatology encounters increased from 561,452 to 742,952 but the total encounter rate remained relatively stable over time (table 1). The annual new consultation rate significantly declined over time from 1.6 to 0.8 new patients per 100 population. Both the annual proportion of incident patients and the ratios of incident to established patients and incident to total patient encounters declined significantly over time. We observed a shift in the diagnostic case-mix over time: encounter rates for systemic inflammatory conditions significantly increased over time and encounter rates for non-systemic conditions (OA, regional MSK conditions) decreased. The volume of rheumatoid arthritis (RA) encounters increased the most, with 17% of all rheumatology encounters related to RA in 2000 versus 32% in 2013.

Table 1 Trends in rheumatology encounters over time, rates expressed per 100

Year	Total Number of Unique Patients (%) <sup>1</sup>	Total Patient Encounters	Total Encounter Rate <sup>2</sup>	New Consultation Rate <sup>3</sup>	Proportion of New Patients out of all Unique Patients	Proportion of New Patients out of Total Encounters	Ratio of New / Established Patients
2000	245486 (2.7%)	561452	6.2	1.6	59%	26%	1.5
2001	255289 (2.8%)	586581	6.4	1.4	52%	23%	1.1
2002	263139 (2.8%)	599278	6.4	1.4	48%	21%	0.9
2003	250176 (2.6%)	571368	6.0	1.2	44%	19%	0.8
2004	258751 (2.7%)	599821	6.2	1.1	41%	18%	0.7
2005	273462 (2.8%)	634730	6.5	1.1	40%	17%	0.7
2006	286309 (2.9%)	663302	6.7	1.1	39%	17%	0.6
2007	280072 (2.8%)	652933	6.5	1.0	35%	15%	0.5
2008	282959 (2.8%)	667337	6.5	0.9	34%	14%	0.5
2009	284158 (2.7%)	685195	6.6	0.9	33%	14%	0.5
2010	285103 (2.7%)	693667	6.6	0.9	32%	13%	0.5
2011	288422 (2.7%)	725807	6.9	0.8	31%	12%	0.5
2012	281754 (2.6%)	698384	6.5	0.8	31%	12%	0.4
2013	293704 (2.7%)	742952	6.8	0.8	30%	12%	0.4

<sup>1</sup> Percentage represents the proportion of Ontario Residents seen by a rheumatologist  
<sup>2</sup> Numerator: Total rheumatology encounters; Denominator: Total population  
<sup>3</sup> Numerator: Number of new patients; Denominator: Total population

**Conclusions:** The significant decline in new patient consultation rates over time helps illustrate the growing supply-demand mismatch in rheumatology care. An increasing fraction of rheumatology encounters in Ontario are with established

patients, which may be limiting access for new consultations and increasing wait times. We also observed a shift in the patient case-mix over time with rheumatologists seeing/prioritizing more systemic inflammatory conditions. Our findings provide new inputs for rheumatology workforce planning models.

FRI0623

### COST-EFFECTIVENESS ANALYSIS FOR THE TREATMENT OF EARLY RHEUMATOID ARTHRITIS WITH BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS (DMARDS) COMPARED TO STANDARD OF CARE IN SINGAPORE

J. N. Chua<sup>1</sup>, M. Lahiri<sup>2</sup>, P. P. Cheung<sup>2</sup>, J. Yoong<sup>1</sup>. <sup>1</sup>School of Public Health, National University of Singapore, <sup>2</sup>Rheumatology, National University Hospital, Singapore, Singapore

**Background:** Biologic disease modifying anti-rheumatic drugs (bDMARDs) are known to be effective in controlling disease activity and reducing radiographic progression in patients with rheumatoid arthritis (RA) who have failed methotrexate (MTX). The cost-effectiveness of bDMARDs in comparison to combination conventional synthetic DMARD (csDMARD) therapy in Asian countries has not been well studied, and their place in the DMARD escalation algorithm is unclear.

**Objectives:** To assess the cost-effectiveness of step-up combination csDMARD versus bDMARD therapy for patients who have failed initial MTX monotherapy over one year.

**Methods:** We prospectively recruited all adult patients with inflammatory polyarthritis (IP) affecting  $\geq 2$  peripheral joints and symptom onset after September 1, 2012 from the only two hospitals serving Western Singapore to the Singapore Early Arthritis Cohort (SEAC). Baseline data on demographics, time of symptom onset and DMARD prescription, utility values (EQ-5D) and costs were collected by face to face interview, chart review, hospital financial records and assessment by a trained nurse. A cost-effectiveness analysis (CEA) was then performed using a decision tree comparing four sequences of DMARD therapy: MTX and infliximab, MTX and etanercept, triple therapy (TT) [MTX, sulphasalazine (SSZ) and hydroxychloroquine (HCQ)] and combination MTX and HCQ. An effective treatment was defined as achieving Disease Activity Score 28 (DAS28 (ESR)) < 2.6; "remission". A treatment switch to a rescue therapy (MTX and adalimumab) was factored in case of not achieving remission or if serious adverse event was experienced. Cost and utility (using Singapore preference weights<sup>1</sup>) information were derived from patients diagnosed with rheumatoid arthritis in the SEAC database as of June 16, 2017. Efficacy, rates of adverse events, disutility from adverse events, indirect costs and cost of serious adverse events were assumed from literature. One-way and probabilistic sensitivity analysis with 10,000 runs was performed.

**Results:** For the base case, the treatment with MTX and etanercept was dominated by conventional TT. The incremental cost of switching from TT to MTX and infliximab was SGD\$16,118. The net gain in quality-adjusted life years (QALY) was 0.02. The incremental cost-effectiveness ratio (ICER), representing the additional cost of one unit of QALY gained by MTX and infliximab compared with TT, was \$1,024,785/QALY. The probabilistic sensitivity analysis predicted that triple therapy would be the preferred treatment (89.6%) at a willingness-to-pay threshold of SGD\$70,000.

Table 1

Arm	Incremental Cost	QALY	Incremental QALY	ICER
Triple Therapy	-	0.90	-	-
MTX + HCQ	2,587	0.88	-0.02	Dominated
MTX + etanercept	16,024	0.89	-0.01	Dominated
MTX + infliximab	16,117	0.91	0.02	1,024,785

**Conclusions:** Our model suggests that the ICER of bDMARD therapies explored do not compare favorably to csDMARD therapies. In the Singapore context, societal funding for bDMARDs can only currently be recommended after failure of combination csDMARD.

### MUSCULOSKELETAL PROBLEMS AMONGST TRAIN OPERATORS: A COLLABORATIVE APPROACH TO IDENTIFY SOLUTIONS

J. Erwin<sup>1</sup>, J. Howarth<sup>1</sup>, L. Chauhan<sup>2</sup>, A. Webster<sup>2</sup>, A. Woolf<sup>1</sup>. <sup>1</sup>Research Development & Innovation, Royal Cornwall Hospitals NHS Trust, Truro, <sup>2</sup>Occupational Health, TfL, London, United Kingdom

**Background:** Transport for London (TfL) Occupational Health Dept identified musculoskeletal (MSK) problems as matters of concern in train operating staff on 3 of the underground lines (JNP). These issues were contentious and the subject of continued discussion between the management of TfL, train operators, Unions and other stakeholders. The Bone and Joint Research Group (BJRG) were invited to undertake work to provide insight into the MSK health issues of train operators from a neutral perspective.

**Objectives:** To assess the problems and issues relating to the musculoskeletal health of train operators.

**Methods:** A steering committee was created with representatives from the train operators, the Unions, TfL managers and other stakeholders. Participants were recruited to 6 focus groups. Separate focus groups were held for operators, managers and for other stakeholders. The groups were asked to discuss the status of their own MSK health, the impact of work on their MSK health, the support they receive from their employer and others, barriers and facilitators to maintaining MSK health, the role of managers in improving MSK health in the workplace and what interventions would improve MSK health.

The focus groups were recorded transcribed and analysed using Thematic Analysis.

The findings informed a survey of JNP train operators. The survey was co-produced and endorsed by the BJRG, TfL and the Unions and circulated to train operators. The survey included questions on demographics, lifestyle, work role, posture training, MSK problems, actions taken and ideas on how MSK risks could be managed and MSK health protected and improved.

**Results:** 20% of train operators (338) completed the survey. Respondents reflected the demographic profile of the total JNP train operators. 72% reported not receiving adequate posture training. 74% experienced MSK pain, either currently or in the past. Of these 52% were currently in pain. The average number of months in pain was 59. Lower back, neck and shoulders were the most frequently reported sites of pain. 74% said the pain was caused by or worsened by work. An average of 7 days of work was lost per year due to MSK problems. 44% had not told their manager. Most respondents said their MSK health could be improved by improvements to their seating and cab ergonomics.

Participants acknowledged that it is an individual's responsibility to look after their own MSK health and suggested ways to do this. These included changing position when driving, stretching, improved posture, employing good manual handling techniques, exercising outside of work and eating healthily.

**Conclusions:** MSK problems are a significant issue among JNP train operators and structural problems are perceived to be the main cause. Operators are aware of their own role in maintaining their MSK health both at work and at home. The study illustrates that it is possible to work effectively and collaboratively with a range of workplace stakeholders to achieve a common goal of improved MSK health. The active involvement of all stakeholders throughout the process and the engagement of a neutral research organisation increased "buy-in" and gave credibility to the project. The findings are currently being considered by the steering committee to produce a series of recommendations at the policy, operational and individual level to protect the MSK health of train operators.

### DIFFERENT STRATEGIES TO IMPLEMENT THE EULAR GUIDELINE FOR CARDIOVASCULAR RISK MANAGEMENT IN DAILY PRACTICE

J. Weijers<sup>1</sup>, P. Dessein<sup>2</sup>, D. Galarza-Delgado<sup>3</sup>, M. González-Gay<sup>4</sup>, B. Kuriya<sup>5</sup>, E. Myasoedova<sup>6</sup>, A. Semb<sup>7</sup>, S. Wållberg-Jonsson<sup>8</sup>, P. van Riel<sup>1,9</sup> on behalf of Trans-Atlantic Cardiovascular Consortium for Rheumatoid Arthritis (ATACC-RA). <sup>1</sup>IQ healthcare, Scientific Center for Quality of Healthcare, Radboud university medical center, Nijmegen, Netherlands, <sup>2</sup>Rheumatology Division, Universitair Ziekenhuis and Vrije Universiteit, Brussels, Belgium, <sup>3</sup>Department of Rheumatology, University of Nuevo Leon, Medicine School and University Hospital, Mexico, San Nicolás de los Garza, Mexico, <sup>4</sup>Division of Rheumatology, Hospital Universitario Marques de Valdecilla, Santander (Cantabria), Spain, <sup>5</sup>Division of Rheumatology, Department of Medicine, Faculty of Medicine, University of Toronto, Toronto, Canada, <sup>6</sup>Division of Rheumatology, Department of Internal Medicine, Mayo Clinic, Rochester, MN, United States, <sup>7</sup>Preventive Cardio-Rheuma Clinic, Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, <sup>8</sup>Department of Public Health and Clinical Medicine/Rheumatology, University of Umeå, Umeå, Sweden, <sup>9</sup>Rheumatology, Bernhoven, Uden, Netherlands

**Background:** The updated EULAR cardiovascular risk management (CVRM) guideline recommends cardiovascular disease risk assessment at least once every five years in all patients with rheumatoid arthritis (RA).<sup>1</sup> A literature search indicates that this guideline is marginally applied in clinical practice.<sup>2</sup> An important factor explaining dissimilarities in the quality of CVRM could be the different strategies being used to implement this guideline in daily care.

**Objectives:** This study describes the differences in cardiovascular risk identification and management for patients with RA between outpatient clinics of the members of the Trans-Atlantic Cardiovascular Consortium for Rheumatoid Arthritis (ATACC-RA).

**Methods:** A questionnaire was sent to all members of ATACC-RA, which included 16 questions about 'the organisation and responsibility of CVRM in their hospital', 'the screening of cardiovascular risk factors', 'communication about CVRM between medical professionals' and 'availability of data regarding CVRM'.

**Results:** Six out of eight outpatient clinics reported that they work according the EULAR CVRM recommendations. Three strategies to organise CVRM in daily practice could be distinguished: 1) The treating rheumatologist performs CVRM during the outpatient visits; 2) Cardiologists, rheumatologists and/or a general practitioners co-operate in a cardio-rheuma-clinic/team with different tasks and responsibilities and 3) the general practitioner screens and treats cardiovascular risk factors. Six outpatient clinics reported that they have (digital) data about the current CVRM status of their RA patients and are willing to share them to compare the quality of the CVRM care between the different strategies.

**Conclusions:** Each cardiovascular risk management strategy was based on agreements between medical professionals about who is responsible to perform CVRM. However, each strategy is also (partly) dependent of the national health-care system and financial resources. Independent of how CVRM is organised, communication and feedback between medical professionals about the current CVRM status of each RA patient, are important factors to perform CVRM adequately. Further analyses on the effectiveness of the various systems are warranted.

**FRI0626** **SCREENING FOR TUBERCULOSIS BEFORE TNF INHIBITOR THERAPY REMAINS SUBOPTIMAL: A MULTI-SPECIALTY, REAL WORLD, NATIONWIDE EXPERIENCE IN THE UNITED STATES**

K. Ladak<sup>1</sup>, T. J. Pan<sup>2</sup>, C. MacLean<sup>3</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Value Office, <sup>3</sup>Hospital For Special Surgery, New York, United States

**Background:** Tumor necrosis factor- $\alpha$  inhibitors (TNFi's) effectively treat various autoimmune conditions, but drastically increase the risk of tuberculosis (TB) reactivation. Multiple international guidelines recommend screening for TB prior to initiating TNFi therapy. In the United States, this has also been incorporated into the Medicare Merit-Based Incentive Payment Systems (MIPS) quality measures, which affect physician remuneration.

**Objectives:** To determine the proportion of patients screened for TB prior to initiating TNFi therapy.

Table 1 Baseline Characteristics of Patients Who Initiated New TNFa Inhibitor Therapy

	Total (n = 78,088)
Age, mean $\pm$ SD years	44.8 $\pm$ 12.4
Sex	
Male	30,467 (39.0)
Female	47,621 (61.0)
Geography <sup>†</sup>	
Urban	64,937 (83.2)
Rural	11,191 (14.3)
Underlying Autoimmune Disease <sup>†‡</sup>	
Rheumatologic	39,675 (50.8)
Gastrointestinal	17,487 (22.4)
Dermatologic	13,773 (17.6)
Ophthalmologic	651 (0.8)
TNFi Inhibitor	
Adalimumab	37,576 (48.1)
Etanercept	23,210 (29.7)
Infliximab	12,810 (16.4)
Certolizumab	2,445 (3.1)
Golimumab	2,047 (2.6)
Steroids Use	
No	42,134 (54.0)
Yes	35,954 (46.0)
Prescribed non-biologic DMARD	
No	37,652 (48.2)
Yes	40,436 (51.8)
HIV	39 (0.0)
Travel <sup>#</sup>	30 (0.0)
Institutionalization	2 (0.0)

\* The ages of the patients are those at the index event.  
<sup>†</sup> Some data missing, percentages calculated from number of patients with available information.  
<sup>‡</sup> 5.5% of patients contributed to multiple categories  
<sup>#</sup> Surrogates for travel include malaria diagnosis, prophylaxis, yellow fever vaccine.

**Methods:** We retrospectively analyzed patients in the Truven MarketScan Database from 2011–2015. This is the largest dataset of its kind and contains deidentified inpatient and outpatient health information on over 100 million patients. We included patients  $\geq$ 18 years old in our cohort who were initiating TNFi therapy, based on at least 1 filled prescription. To ensure these were new TNFi starts, we excluded patients without a 6-month washout period (i.e. during which time they could not be receiving biologic DMARDs). Continuous enrollment in the database was required during the washout period and 3 months after TNFi initiation. Our primary outcome was whether patients were screened for TB during the 6-month washout period, either by interferon gamma release assays (IGRA) or tuberculin skin testing (TST). Sensitivity analysis was performed to extend the eligible screening period to 12 months pre-drug. Descriptive statistics were represented as means and medians for continuous variables and as frequencies and percentages for categorical variables.

**Results:** We identified 78,088 patients starting a TNFi. The mean age was 44.8 years and the cohort was 61% female. Adalimumab and Etanercept were the most common TNFi's. Regarding indication for TNFi, 50.8% of patients had a rheumatologic diagnosis, 22.4% gastrointestinal, 17.6% dermatologic, and 0.8% ophthalmic. Most patients received care from a rheumatologist, while 16.4% were managed by primary care alone. 36,918 (47.3%) were not screened for TB in the 6-month washout. By extending the pre-drug washout to 12 months, the proportion of unscreened patients improved mildly to 40.7%. 48.5% were screened by IGRA, 27% by TST, and 24.5% unknown. Steroid use, DMARD use and urban residence were associated with increased TB screening rates.

**Conclusions:** Screening for latent TB prior to initiating TNFi therapy was poor, such that only 52.7% received appropriate pre-drug screening. Our study population of over 78,000 patients starting a new TNFi represents nationwide, real world data across various specialties in the United States. As clinicians, these results suggest we need to improve compliance with guidelines and quality measures.

**FRI0627** **INADVERTENT YELLOW FEVER VACCINATION OF PATIENTS WITH IMMUNE MEDIATED INFLAMMATORY DISEASE IN PRIVATE PRACTICE.**

L. Fernandes<sup>1</sup>, M. Pippa<sup>1</sup>, C. Macedo<sup>1</sup>, J. Brudniewski<sup>1</sup>, F. Palacios<sup>1</sup>, H. Mahlmann<sup>1</sup>, L. Aliberti<sup>1</sup>, J. Kochen<sup>1</sup>, R. Aurichio<sup>1</sup>, E. Dourador<sup>1</sup>, F. Omura<sup>1</sup>, F. Hehn<sup>1</sup>, M. Baricelli<sup>1</sup>, P. Lerner<sup>1</sup>, S. Lee<sup>1</sup>, M. Anauate<sup>1</sup>, E. Azeka<sup>1</sup>, L. Rodrigues<sup>1</sup>, T. Silva<sup>1</sup>, M. Costa<sup>1</sup>, A. Hayata<sup>1</sup>, G. Pileggi<sup>2</sup>, I. Laurindo<sup>1,3</sup>. <sup>1</sup>Gare Study Group, <sup>2</sup>Hcfmp, <sup>3</sup>Uninove, São Paulo, Brazil

**Background:** Yellow Fever (YF) is an endemic disease, in specific areas of Brazil. Since 1942, no new urban cycle cases have been observed. Yet, in early 2017, outbreaks of YF were reported in many states, outside the endemic areas, where YF was not considered a risk. Hence, new and some fatal cases have been reported including in highly populated areas close to the city of São Paulo. As it has been widely broadcasted, population searching for vaccination significantly increased and cases of inadvertent vaccination have been registered.

**Objectives:** To analyze the consequences of inadvertent YF primo-vaccination in patients with immune mediated inflammatory diseases (IMID).

**Methods:** Observational study (12/2017–01/2018), 54 rheumatologists from private practice at different areas of São Paulo included specific YF information in their patients' orientations and actively searched for IMID patients that have received YF vaccination (YFV) inputting the data in a web-based questionnaire.

**Results:** 56 patients received YFV; female 42 (75%), mean ( $\pm$ SD) age= 56 $\pm$ 14 yr, median disease duration= 7 yr (6 months-45 yr), Diagnosis: RA (n=39; 72%), PsA (n=5), AS (n=4), 2 SLE, 3 vasculitis, 2 SS, one ReA and 2 UA. Treatment: 30 (54%) were considered under current strong immunosuppression (CE $\geq$ 20 mg, MTX>20 mg, leflunomide, tofacitinib and biologic agents (BA); 18 (32%) were on biologic agents (9 anti-TNF, 2 abatacept, 3 tocilizumab, 1 rituximab, 1 patient each secukinumab and tofacitinib). Remaining patients were receiving csDMARDs isolated or in combination, with or without low CE ( $\leq$ 10 mg).

Vaccination: 54 (96%) cases were primo YFV and 43 (80%) related inadvertent YFV. Adverse events (AE): 7 patients (13%) had AE after a median of 4 days (hours-60 days); 3 of them were on BA, corresponding to 17% of the total subjects on various BA. Severity of AE: 4 patients had mild AE (local pain, vertigo, fever, headache, myalgia), in 2 of them, symptoms promptly resolved while 2 needed medical assistance (one was on tocilizumab). Of the 3 remaining cases, one had severe reaction one hour after YFV (probably anaphylaxis); Finally, 2 patients had severe AE requiring hospitalization: one had meningitis (RTX+MTX) and other (ADA+MTX), abdominal pain, myalgia, fever, headache, vertigo and increased liver enzymes. No fatal events were observed. Concerning the vaccine effect on disease activity, only 5 (9%) patients related worsening of the disease after YFV, but 2 of them also presented AE.

**Conclusions:** The small number of reports precludes any conclusion about rate/severity of AE and YFV in immunosuppressed rheumatic patients. Nevertheless, it emphasized the necessary awareness and careful analysis of the risk-benefice of YFV in this population. The interference of YFV on IMID disease activity seems to be marginal. On the other hand, this descriptive analysis clearly demonstrated persistence of patient's unfamiliarity with concepts of immunosuppression and its consequences, disclosing another unmet need in the management of patients with RD.

**FRI0628 DIGITAL TECHNOLOGIES TO PROMOTE SELF-MANAGEMENT IN MUSCULOSKELETAL HEALTH: A SYSTEMATIC REVIEW**

L. Sammut<sup>1</sup>, N. Arafin<sup>2</sup>, Y. Prior<sup>2</sup>. <sup>1</sup>Rheumatology, University Hospital Southampton NHS Foundation Trust, Southampton, <sup>2</sup>School of Health Sciences, University of Salford, Manchester, United Kingdom

**Background:** With the emergence of musculoskeletal conditions as a major threat to health status and one of the largest causes of health care expenditures, the role of self-management strategies has emerged. Digital media as a platform for self management interventions in musculoskeletal health is a new and evolving landscape in health care.

**Objectives:** To review the published evidence to support the self-management of rheumatic and musculoskeletal conditions through digital technologies.

**Methods:** MEDLINE, EMBASE, PsycINFO, Global Health, The Cochrane Library (Cochrane Database of Systematic Reviews, Cochrane Central Register of Controlled Trials (CENTRAL), Cochrane Methodology Register), and Web of Science (science and social science citation index) were searched and the papers selected were screened by two independent reviewers. Methodological validity prior to inclusion was assessed using the appropriate critical appraisal tools developed by the Critical Appraisal Skills Programme (CASP).

**Results:** Database searches identified 5179 studies. Five randomised controlled trials assessing digital media in the self management of musculoskeletal diseases were selected. The participants in the studies were predominately females with a mean age of 50. The mean number of participants in the studies was 140.8 (range 92–228). Two studies targeted self management strategies for patients diagnosed with rheumatoid arthritis [1, 2]. One study included fibromyalgia patients [3] and the two other studies included patients that reported arthritis pain [4] or general non cancer related pain [5]. A robust and meaningful comparison between the studies was infeasible because of heterogeneity between studies and small sample size in the studies. Positive effects of self-management were demonstrated in arthritis self-efficacy, pain, physical functioning, opioid misuse and overall quality of life.

**Conclusions:** All studies showed an improvement in a number of different self-management outcomes. Digital media may be effective in the delivery of self-management programmes of patients with rheumatic and musculoskeletal conditions. Further research is necessary to increase the scope of these findings using rigorous study designs so we can harness the full potential of digital technologies as a medium for delivering self-management interventions.

**FRI0629 PATIENT-TARGETED SMARTPHONE APPS FOR SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW AND ASSESSMENT OF FEATURES AND QUALITY**

M. Pourahmat<sup>1,2\*</sup>, M. A. De Vera<sup>1,3</sup>. <sup>1</sup>Arthritis Research Canada, Richmond, <sup>2</sup>Faculty of Medicine, <sup>3</sup>Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, Canada

**Background:** Smartphone apps are readily accessible eHealth tools that may support the self-management of patients with systemic lupus erythematosus (SLE). However, knowledge on the availability and quality of apps targeted to this population is limited.

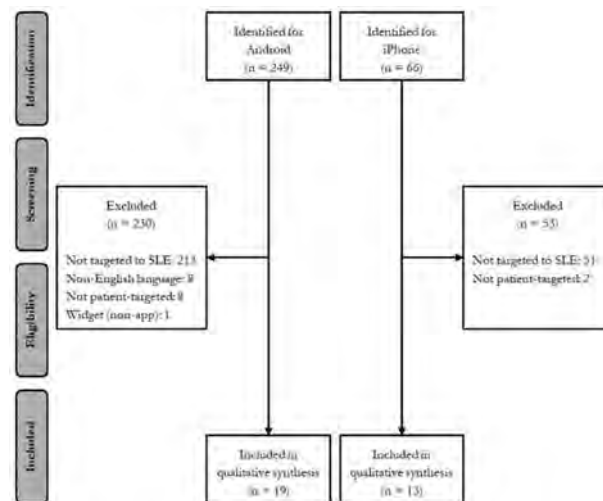

**Objectives:** To identify smartphone apps targeted to patients with SLE and to classify their functions and assess their quality using a reliable and objective scale.

**Methods:** We applied a systematic review framework to the search, screening, and assessment of apps. Android and iPhone apps were searched on the Google Play Store and the App Store, respectively in January 2018. Search terms included "lupus" or "SLE". Apps were included if they were: (1) smartphone-based; (2) compatible with the Android or the iOS operating systems; (3) in the English language; (4) targeted to people with SLE; and (5) available for download in either of the two app stores. Apps were excluded if they were: (1) targeting a condition other than SLE; (2) including only treatment algorithms; or (3) explicitly only for health care providers. App name, platform (Android, iPhone), developer, current version, cost, and user star ratings and comments were extracted. The Mobile App Rating Scale was used to classify the apps.

**Results:** We identified 315 apps, including 249 from the Google Play Store and 66 from the App Store (figure 1). Of these, 32 met inclusion criteria (19 Android, 13 iPhone).

Of the 19 Android apps, 16 were free to download and the remaining cost 2.93 – 5.65 CAD. The focus across apps were mainly to increase patient well-being. The theoretical background or strategies behind the apps varied, the most common ones included: providing information/education regarding SLE for the user (14 apps), providing advice/tips/strategies/skills training for SLE management (9 apps), and providing capabilities for monitoring/tracking of symptoms (6 apps). The user star ratings of the apps ranged from 1.5 – 5.0 stars (out of 5.0) and the number of user ratings ranged from 1 – 288. Common user critiques indicated the need for increased functionality in entering and tracking symptoms in apps that provided this feature.

Of the 13 iPhone apps, 10 were free to download and the remaining cost 2.79 – 6.99 CAD. The focus across apps were mainly to increase patient well-being. The theoretical background or strategies behind the apps varied, the most common ones included: providing information/education regarding SLE for the user (9 apps), providing capabilities for monitoring/tracking of symptoms (6 apps), and providing advice/tips/strategies/skills training for SLE management (5 apps). No user ratings or comments were available.

**Conclusions:** Applying a systematic review framework, we identified and classified 32 apps mainly focusing on increasing patient well-being in SLE. These findings have practical implications for helping patients identify potential eHealth tools to support self-management of SLE.

**FRI0630 CAN COMMUNITY PHARMACY SERVICES BE THE MISSING LINK IN ACHIEVING EARLY DIAGNOSIS OF PSORIATIC ARTHRITIS?**

P. Mehra<sup>1</sup>, M. K. Nisar<sup>2</sup>. <sup>1</sup>Farley Hill pharmacy, <sup>2</sup>Rheumatology, Luton & Dunstable University Hospital, Luton, United Kingdom

**Background:** There is an urgent need to look at New Models of Care to improve quality of care for patients whilst providing the best value for money. Community Pharmacy has been an untapped resource which can assist in achieving the goals of managing long term conditions. Psoriasis is one such example affecting 1% to 3% of the population with upto 40% of these patients at risk of developing psoriatic

arthritis (PsA). There is plenty of evidence that early diagnosis of PsA remains suboptimal leading to poorer outcomes.

**Objectives:** The objective of this proof-of-concept study was to utilise community pharmacists in collaboration with the local Rheumatology service to screen patients with psoriasis aiming to achieve earlier diagnosis of PsA.

**Methods:** A pilot site was identified including a community pharmacy with a neighbouring GP surgery. An educational session was organised with the team to help them understand the need for the project. Logistics were finalised and a dedicated teaching was delivered covering PsA and Psoriasis Epidemiology Screening Tool (PEST) tool. PEST was chosen for its high sensitivity and specificity and positive NICE recommendation.

The dispensing personnel highlighted all patients requesting prescribed standard psoriasis-treating topical applications to the pharmacists. They confirmed the history of psoriasis with the patients, ensured the absence of a formal diagnosis of arthritis and offered the PEST questionnaire. Those who scored positive were signposted to their GPs for further consultation. The data was gathered anonymously and analysed to assess the utility of the service.

**Results:** 37 patients were identified during the 12-week proof of concept phase. 24 (65%) participants were women. Median age of the group was 48 years (range 19–73). 23/37 (62%) were white Caucasians with eight Asian and three each of Afro-Caribbean or Mixed race background. 18/37 (48%) answered yes to three or more of five-question PEST tool thereby scoring positive. Ten (27%) replies were negative and another nine (24%) declined to participate. No reasons were offered for not filling in the questionnaire. Two of the positive patients have since been reviewed by GP and referred to Rheumatology for further evaluation.

**Conclusions:** To our knowledge, this is the first study ever conducted utilising community pharmacists to employ a screening questionnaire to help early identification of possible PsA patients. This novel approach of involving community pharmacy helps explore new and proactive ways of early detection of psoriasis patients at risk of PsA and challenges the traditional model of confining the screening process to GPs in primary care. Early findings have already identified nearly half of this cohort with hitherto potentially undiagnosed PsA. This pioneering development highlights a new model of care streamlining the diagnostic pathway thereby providing better quality of care. Considering over 90% of psoriasis is managed in primary care, it would also encourage quicker assessment by a rheumatologist without burdening the already busy GP practices. Focused strategy and better utilisation of community pharmacists can be pivotal to providing better care for PsA patients in the long term.

Szekanez<sup>15</sup>, D. Wiek<sup>16</sup>, A. Zink<sup>17</sup>, C. Dejaco<sup>18</sup>, S. Ramiro<sup>19</sup>. <sup>1</sup>MUMC, Maastricht, Netherlands, <sup>2</sup>FH JOANNEUM, University of Applied Sciences, Bad Gleichenberg, Graz, Austria, <sup>3</sup>Charité University Berlin, Berlin, Germany, <sup>4</sup>Medical University Vienna, Vienna, Austria, <sup>5</sup>Locomotor System, ASL3-Azienda Sanitaria Genovese, Genova, Italy, <sup>6</sup>UMC Utrecht, Utrecht, Netherlands, <sup>7</sup>University of Zagreb School of Medicine, Zagreb, Croatia, <sup>8</sup>Centro Hospitalar Médio Tejo, Lisbon, Portugal, <sup>9</sup>Columbia UMC, New York, United States, <sup>10</sup>University Hospital of Geneva, Geneva, Switzerland, <sup>11</sup>Sorbonne Universités, UPMC University Paris, Paris, France, <sup>12</sup>Diakhjemmet Hospital, Oslo, Norway, <sup>13</sup>Mayo Clinic College of Medicine, Rochester, United States, <sup>14</sup>Hospital General Universitario de Elda, Elda, Spain, <sup>15</sup>University of Debrecen, Debrecen, Hungary, <sup>16</sup>EULAR Standing Committee of PARE, Zurich, Switzerland, <sup>17</sup>Deutsches Rheuma-Forschungszentrum, Berlin, Germany, <sup>18</sup>Medical University Graz, Hospital of Bruneck, Graz, Austria, <sup>19</sup>LUMC, Leiden, Netherlands

**Background:** Workforce requirement studies should be conducted in order to ensure the right number of people with the right skills, in the right place at the right time to deliver organizational objectives.

**Objectives:** As part of the EULAR project to develop points to consider for the conduction of workforce studies in rheumatology, we reviewed the literature on workforce prediction with the aim to develop a workforce prediction quality appraisal tool and apply it to existing studies in rheumatology.

**Methods:** Two literature searches were performed in Ovid MEDLINE, EMBASE, CINAHL, Cochrane Library and the grey literature comprising: (1) an update of a previous systematic literature review (SLR) of workforce prediction studies in rheumatology[1] and (2) a hierarchical SLR of workforce prediction studies in other medical fields. We extracted data on type of model used, details on need, demand and supply factors considered in the model, and other relevant aspects such as regional heterogeneity or uncertainty analyses. Based on the results, key

general as well as specific need/demand, and supply factors for workforce calculation in rheumatology were identified and each factor was assigned a quality level (low, moderate, high). The quality appraisal tool was applied to the existing workforce modeling studies in rheumatology.

**Results:** Data was extracted from 14 original workforce prediction studies in rheumatology and 10 SLRs in other fields. Studies used a variety of prediction models based on a heterogeneous set of need and/or demand and/or supply factors. While only a few studies attempted to empirically validate the prediction quality of the model (n=3), the consensus was that an integrated model including all these factors is expected to have the highest validity. Based on the different factors considered in existing studies, our quality appraisal tool included the three groups of factors: general factors (e.g. type of the model, stakeholder involvement), need/demand factors (e.g. scope of diseases covered by rheumatologists, morbidity, demography) and supply factors (e.g. time dedicated to clinical work, entry to profession, demographic composition of workforce) (table 1). The majority of studies scored low or moderate on most of the factors.

Table 1 Workforce prediction quality appraisal tool

Factor*	Evidence grading	N of studies
<b>General factors</b>		
Type of model	<b>Low:</b> model that was only based on demand or need or supply factors	N=4
	<b>Moderate:</b> integrated model that considered demand, need and supply [supply (s)=demand (d) at baseline]	N=0
	<b>High:</b> integrated model that considered demand, need and supply (s<=>d at baseline)	N=4
Regional heterogeneity	<b>Low:</b> regional heterogeneity was not considered	N=8
	<b>Moderate:</b> calculations were performed on national level but anticipated regional discrepancies are discussed	N=4
	<b>High:</b> calculations took into account relevant regional profile of the country	N=2
<b>Need/demand factors</b>		
Scope of diseases covered by rheumatology specialty	<b>Low:</b> either not listed or not deemed representative (e.g. insufficient number of disease groups, unjustified author's estimate etc.)	N=3
	<b>Moderate:</b> stated but the probability that they are representative is limited	N=0
	<b>High:</b> stated and the probability that they are representative is high	N=6
Projection of population development	<b>Low:</b> not considered or only size of population is included	N=6
	<b>Moderate:</b> age or/and sex structure and/or other factors were included but using single data source and not relying on published statistics	N=5
	<b>High:</b> age or/and sex structure and/or other factors were included using more than one source and relying on published statistics or national population projections	N=0
<b>Supply factors</b>		
Time spent on clinical (rheumatologic) care	<b>Low:</b> not considered	N=4
	<b>Moderate:</b> % of time dedicated to clinical duties was defined without detailed estimation of number, duration, and type of visit OR % of time dedicated to clinical duties was calculated through estimating the number, duration and type of visits, but using single data source	N=10
	<b>High:</b> % of time dedicated to clinical duties was calculated through estimating the number, duration and type of visits, using more than one published data source	N=0
Demographic trends in workforce	<b>Low:</b> not considered	N=6
	<b>Moderate:</b> one demographic trend (e.g. ageing, feminization, millennial trend) was considered	N=3
	<b>High:</b> more than one demographic trends were considered	N=5

\* 6 out of the 21 factors of the tool are depicted in this excerpt

**Conclusions:** The existing evidence on workforce prediction in rheumatology and other fields is scarce, heterogeneous and of low or moderate quality. The workforce prediction quality appraisal tool will enable future evaluation of workforce prediction studies. This review informs the EULAR points to consider for the conduction of workforce requirement studies in rheumatology.

#### IMPACT OF A TIGHT CONTROL MULTIDISCIPLINARY RHEUMATOLOGY PROGRAM ON THE QUALITY OF LIFE OF PATIENTS WITH AUTOIMMUNE DISEASES IN COLOMBIA

R. Pineda-Tamayo<sup>1</sup>, M.-A. Alzate<sup>1</sup>, D. Hernandez-Parra<sup>1</sup>, D. Echeverry<sup>1</sup>, P. Ortiz-Salazar<sup>1</sup>, A. Rojas-Villarraga<sup>1</sup>. <sup>1</sup>Clinical information group, Artmedica IPS, Medellín, Colombia

**Background:** Autoimmune diseases are chronic inflammatory pathologies of complex etiology and variable clinical expression that usually affect young individuals, generating chronic pain and altering their functionality. Therefore, one of the mainstays of the treatment is to improve the quality of life (QoL) of these patients

**Objectives:** To determine the impact of a tight control multidisciplinary rheumatology program in the QoL of patients with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and seronegative spondyloarthropathies (SpA).

**Methods:** A analytical quasi-experimental study was conducted were 3812 patients with RA, 590 patients with SLE and 605 patients with SpA were included and followed between February 2015 and December 2016. Two separated measurements of QoL were developed through the EuroQol Five Dimensions Questionnaire (EQ-5D) by time trade-off (TTO) valuation technique and the visual analogue scale valuation technique (EQ-VAS). Sociodemographic characteristics

were analyzed with univariate statistic. The impact on QoL was determined by McNemar test and repeated measures analysis of variance (rANOVA)

**Results:** The most affected dimensions of the EQ-5D were pain/discomfort and anxiety/depression, while the least affected was self-care. When comparing each dimension before and after the entry to the tight control program, a significant increase in the proportion of patients that perceive level 1 for each aspect evaluated was found. In addition, significant improvement was found in the global EQ-VAS (table 1)

Table 1 Percentage of the levels of EuroQol by dimension according to the diagnosis

		RA N=3812		SLE N=590		SpA N=605		Total N=5007		P- Value
		Initial (%)	Final (%)	Initial (%)	Final (%)	Initial (%)	Final (%)	Initial (%)	Final (%)	
<b>Mobility</b>	1	43	55,7	59,8	45,4	56,5	65,9	46,1	52,6	0,003
	2	54,9	42,1	38,8	52,8	41,5	32,4	53,4	46,4	
	3	2	2,2	1,4	1,8	2	1,7	0,5	1	
<b>Self-care</b>	1	61	69,1	76,9	62,7	70,1	79,2	59	67,4	0,001

	3	1,1	1,5	1,2	1,1	1,4	1,4	0,7	0,3	
<b>Usual activities</b>	1	48	55,8	61,4	49,7	56,8	68	48,6	52,2	0,001
	2	47,9	41,3	35,8	46,5	40,8	30	47,9	45,5	
	3	4,1	2,9	2,9	3,9	2,7	2	3,5	2,3	
<b>Pain/discomfort</b>	1	23,3	31,7	33,2	24	32	40,3	19,7	25,8	0,002
	2	53,3	54,4	50,7	53,4	54,1	48,6	56,9	57,2	
	3	23,4	13,9	16,1	22,5	14	11	23,5	17	
<b>Anxiety/depression</b>	1	56,5	65,6	53,9	56,1	65	66,1	56,5	60,7	0,001
	2	33,4	27,5	35,9	33,8	27,8	26,3	34,2	31,7	
	3	10,2	7	10,2	10,1	7,1	7,6	9,3	7,6	
<b>Global VAS mean (SD)</b>		68,8 (19,8)	70,4 (22,6)	72 (19,8)	68,8 (19,9)	70,5 (22,2)	75 (18,6)	65,7 (20,5)	65,9 (21)	0,001

Significant statistical differences were found for all the dimensions in each pathology (initial vs final) except:

<sup>1</sup> Self-care in SLE (p=0,719)

<sup>2</sup> Usual activities in SpA (p=0,337)

<sup>3</sup> Anxiety/depression in SpA (p=0,27)

<sup>4</sup> Global VAS in SpA (p=0,889)

**Conclusions:** The tight control multidisciplinary rheumatology program is an efficient strategy to improve the QoL and the health perception of patients with chronic autoimmune diseases which impacts on the functionality, performance of everyday activities and productivity

FRI0633

#### HOW DO WE IMPLEMENT THE EULAR RECOMMENDATION THAT RHEUMATOLOGISTS CAN SEE EARLY ARTHRITIS PATIENTS WITHIN SIX WEEKS AFTER SYMPTOM ONSET? A FIVE-YEAR COMPARATIVE STUDY OF AN EARLY ARTHRITIS RECOGNITION CLINIC.

R. M. Ten Brinck<sup>1</sup>, B. T. van Dijk<sup>1</sup>, H. W. van Steenberghe<sup>1</sup>, A. H. van der Helm-van Mil<sup>1</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Centre, Leiden, Netherlands

**Background:** Early treatment of inflammatory arthritis (IA) associates with improved outcomes. Therefore, the first recommendation in the 2016 update of the EULAR guidelines for management of early IA states that patients presenting with IA should be seen by a rheumatologist ≤6 weeks. Data on how to implement this recommendation are lacking. A screening clinic situated in between primary and secondary care, the Early Arthritis Recognition Clinic (EARC), has previously shown to increase early identification of rheumatoid arthritis patients. However, it is unknown if this effect is sustained when applied for several years and if this approach is of added value to identify patients within the 6-week limit set by EULAR.

**Objectives:** To study if an EARC approach can lead to sustained early identification of patients with IA (as compared to regular referral to our Early Arthritis Clinic (EAC)) and to determine the efficacy to identify patients ≤6 weeks after symptom onset.

**Methods:** To promote early recognition of IA, the EARC was initiated in September 2010 in the Netherlands. General practitioners (GPs) were instructed to refer to this screening clinic without a scheduled appointment if they were unsure about the presence of IA (instead of a 'wait-and-see' approach or performing additional tests). At the EARC, patients were seen for a 5-minute visit by an experienced rheumatologist who performed a full 66-joint examination for clinical synovitis. GPs can also refer directly to the EAC, where patients are seen <2 weeks' time. Thus, GPs in our region can refer directly for a full visit in secondary care, or to a short visit to a screening clinic that is situated in between primary and secondary care. Patients identified with IA at the EARC or after (direct) referral to the EAC between September 2010 and December 2014 were compared for symptom duration at IA identification.

**Results:** Of the 1,151 patients visiting the EARC, 475 (41%) were diagnosed with IA. Firstly, proportions of patients with IA at the EARC were studied per year. These remained stable over time: 45% in 2010, 39% in 2011, 45% in 2012, 42% in 2013 and 36% in 2014. Clinical characteristics of these patients were similar over time. In the same period 675 referred patients were diagnosed with IA at the EAC; these were compared to the 475 IA patients that were identified via the EARC. Demographic characteristics were similar. However, median symptom duration of the IA patients in the EARC-group versus the EAC-group at identification of IA were 10.7 vs 17.0 weeks in 2010 (p<0.0001), 7.3 vs 13.7 weeks in 2011 (p=0.0001), 6.3 vs 9.8 weeks in 2012 (p=0.056), 5.6 vs 10.7 weeks in 2013 (p=0.012) and 5.7 vs 8.3 weeks in 2014 (p=0.060). Proportions of patients with IA seen by a rheumatologist ≤6 weeks in the EARC-group versus the EAC-group were: 34% vs 19% in 2010, 43% vs 20% in 2011, 43% vs 33% in 2012, 48% vs 30% in 2013 and 44% vs 33% in 2014.

**Conclusions:** A screening clinic in between primary and secondary care has sustainable benefit with regards to early identification of inflammatory arthritis and allows >40% of patients to be identified within the timelines as recommended by EULAR.

**Disclosure of Interest:** None declared

FRI0634

#### COST SAVINGS OF USING HLA-B\*27 TAG SNP GENOTYPING TO DETERMINE HLA-B\*27 STATUS IN A CANADIAN POPULATION

S. Mital<sup>1</sup>, D. O'Rielly<sup>1,2</sup>, H. V. Nguyen<sup>1</sup>, P. Rahman<sup>3</sup>. <sup>1</sup>Pharmacy, <sup>2</sup>Genetics, <sup>3</sup>Medicine, Memorial University, St. John's, Canada

**Background:** HLA-B\*27 is a useful genetic marker for screening axSpA [1,2] to determine who can benefit from rheumatologic evaluation in a primary care setting [3]. Currently, entire HLA-B locus tests are the gold standard for determining HLA-B\*27 status but they are expensive. With a sensitivity of 97.6%, the cheaper HLA-B\*27 tag-SNP assay could offer a less expensive yet rigorous testing option. Specifically, the HLA-B\*27 tag-SNP assay could be ordered as first-line screening test for patients with inflammatory axial pain by primary care doctors, with the HLA-B locus assay only requested by rheumatologists for patients with a negative tag-SNP test result but a strong clinical suspicion of HLA-B\*27 positivity. Economic impact of this hybrid testing strategy is not yet established.

**Objectives:** To determine the cost savings of using the hybrid testing strategy instead of giving HLA-B locus assay to all patients with inflammatory axial pain.

**Methods:** We estimated the total cost of using the HLA-B\*27 tagSNP assay for a sample of 510 patients who underwent the test between August 1, 2016 and July 31, 2017 in Newfoundland and Labrador, Canada. We compared this cost with the cost that would have been incurred if these same patients were instead tested with the HLA-B locus test.

**Results:** Total cost of testing 510 patients with HLA-B locus test was \$30,557 at an average cost of \$60 per test. Cost of testing these patients with HLA-B\*27 tagSNP assay was \$1,673 (with average cost per test of \$3.28). Among those who tested negative on the HLA-B\*27 tagSNP assay, 2.3% (~10 patients) would be falsely diagnosed negative. The HLA-B locus test would be ordered in half of these patients after medical history is reviewed by a rheumatologist. Hence, total costs of testing 510 patients with the HLA-B\*27 tagSNP assay were \$1,963. Consequently, cost savings from using HLA-B\*27 tagSNP assay instead of HLA-B locus tests were \$28,594 for this sample of 510 patients. This amounted to a 94% reduction in costs relative to the scenario where all patients are tested with HLA-B locus tests.

**Conclusions:** Screening for HLA-B\*27 status among axSpA patients of Caucasian descent with HLA-B\*27 tag-SNP testing with the gold standard HLA-B locus test only requested for those in whom such need is determined by rheumatologists can result in significant cost savings relative to giving HLA-B locus tests to all patients with inflammatory axial pain.

**Acknowledgements:** 1. Robinson PC, Brown MA. *Mol Immunol.* 2014;57:2–11.

**Conclusions:** Persistence appears to be a driver of cost-effectiveness of SC-TNFi treatment in patients with AS, especially when a societal perspective is taken. Therefore, prescribing the SC-TNFi with the best persistence may be a cost-effective strategy.

#### BARRIERS TO REMAIN IN WORK: RESULTS FROM THE NATIONAL RHEUMATOID ARTHRITIS SOCIETY SURVEY (NRAS)

S. Verstappen<sup>1,2</sup>, L. Lunt<sup>1</sup>, A. Bosworth<sup>3</sup>, M. Bezzant<sup>3</sup>, K. Walker-Bone<sup>2</sup>. <sup>1</sup>Centre for Musculoskeletal Research, the University of Manchester, Manchester, <sup>2</sup>ARUK/MRC Centre for Musculoskeletal Health and Work, Southampton, <sup>3</sup>NRAS, Maidenhead, United Kingdom

**Background:** Problems at work and work loss are still major socio-economic consequences for patients with Rheumatoid Arthritis (RA), employers and the society. Currently, there is a lack of understanding what the main barriers and facilitators are to remain in paid work. For patients and employers identifying these barriers and facilitators will enable them to make the right adjustments at a personal level. For policy makers these factors can determine future policies, aiming to reduce the overall socio-economic burden of RA.

**Objectives:** i) To understand reasons for work loss in people with RA; and ii) to compare problems at work in employed RA patients and those who had to stop working due to RA.

**Methods:** An online survey about employment was sent to UK NRAS members and distributed to non-members via social media including questions about problems at work in those employed or problems related to work in those who had to stop working or retire early due to RA. Rates of problems related to work were compared using Chi2 tests.

**Results:** 891 patients who completed the survey were in paid employment and 189 had stopped working due to RA or retired early due to their RA. Median [IQR] symptom duration was 12.5 [7.5–23.2] years and the majority were women (91%). Main reasons for leaving work included (patients could tick all that applied): unable to carry out duties (73%); time off sick (46%); fatigue (74%); problems with colleagues (12%); need for specific adaptations (11%); unable to travel to work (13%); lack of family support (3%); lack of support from employer (33%); and side effects of medication (24%). The majority of patients left their job >5 years earlier

than they had expected (72%) and 62/172 (36%) mentioned that their employer had not been helpful in assisting them to stay in work. For those in employment, the main challenges to remain in work were: demanding role; RA symptoms; no reasonable adjustments; commuting to work; and lack of understanding. Compared to patients in employment at time of survey, those who had to stop work due to their arthritis, reported having significantly serious problems regarding commuting to work, lack of understanding employers/colleagues, time off due to flare or medical appointments, health and safety and reluctance to make adjustments in their last job (table 1). Lack of family support was not significantly significant.

	not at all serious/ not very serious		neither serious nor non-serious		serious / very serious		P
	Employed	Stopped working due to arthritis	Employed	Stopped working due to arthritis	Employed	Stopped working due to arthritis	
Getting to and from work	326/609 (53%)	58/166 (35%)	136/609 (22%)	36/166 (22%)	142/609 (24%)	72/166 (43%)	<0.001
Lack of understanding from colleagues	300/603 (50%)	38/159 (24%)	129/603 (21%)	42/159 (26%)	174/603 (29%)	79/129 (50%)	<0.001
Health and Safety issues	303/594 (51%)	56/161 (35%)	170/594 (29%)	41/161 (25%)	123/594 (21%)	64/161 (40%)	<0.001
Time of medical appointments	162/624 (26%)	62/167 (37%)	108/624 (17%)	39/167 (23%)	154/624 (25%)	66/167 (40%)	<0.001
Lack of family support	378/617 (61%)	93/147 (63%)	113/617 (18%)	29/147 (20%)	128/617 (21%)	25/147 (17%)	0.577
Time off when having a flare or unwell	245/603 (41%)	29/165 (18%)	107/603 (18%)	17/165 (10%)	257/603 (43%)	119/165 (72%)	<0.001
Employer reluctant to make adjustments	282/538 (52%)	38/151 (25%)	114/538 (21%)	35/151 (23%)	122/538 (23%)	78/151 (52%)	<0.001
Lack of understanding employer	283/573 (49%)	36/156 (23%)	118/573 (21%)	37/156 (24%)	178/573 (31%)	93/156 (60%)	<0.001

**Conclusions:** Barriers to remain in work with RA are multi-factorial and related to the disease, nature of the work and understanding from employers and colleagues. Increasing understanding about RA amongst employers and colleagues in addition to often simple work adjustments, such as adaptations in the workplace and the opportunity to work more flexible, can prevent problems at work and work loss in the long-term and reduce the socio-economic burden.

#### A NOVEL GROUP CLINIC MODEL FOR NEW PATIENTS ENHANCES PATIENT ACTIVATION

T. Jones<sup>1,2</sup>, A. Morbi<sup>3</sup>, M. Grove<sup>1</sup>, F. Birrell<sup>1,4</sup>. <sup>1</sup>Northumbria Healthcare NHS Foundation Trust, Newcastle upon Tyne, <sup>2</sup>University of Sunderland, Sunderland, <sup>3</sup>Imperial College, London, <sup>4</sup>Newcastle University, Newcastle upon Tyne, United Kingdom

**Background:** Group clinics are a widely used, key alternative care model in USA (as shared medical appointments and other labels), especially in centres of excellence like the Cleveland Clinic. They are increasingly seen as 'a transformative innovation'<sup>1</sup> and recognised as an effective solution to the universal health-care challenges: increasing demand and limited resource<sup>2</sup>. We have extensive experience of follow up group clinics for inflammatory arthritis patients since 2008 with a co-designed model integrating patient and team views<sup>3</sup>. Qualitative research showed robust themes associated with successful delivery: Efficiency, Empathy, Education, Engagement and Empowerment. 'Patient activation' describes the knowledge, skills and confidence a person has in managing their own healthcare, but there is no published data in group clinics. A group model has also never been used for seeing new patients in secondary care, so this is an original application of an established care model.

**Objectives:** To show feasibility for new patients seen in a group setting and assess patient experience, including activation.

**Methods:** A mixed methods pilot study. New patients awaiting Rheumatology appointments were invited to pilots at one of two hospitals: 1) with experience of group clinics 2) without. Patients agreeing to attend knew this was a new application of an established innovation with an option to stay for a focus group or be interviewed by telephone afterwards. Sessions were videoed for educational purposes and qualitative interviews were conducted under existing research approvals with relevant consents for both. Numerical data included Patient Activation Measure before/after the two-hour clinic, EQ-5D and a standard feedback tool. Qualitative data was analysed using nVivo and compared to previously identified themes.

**Results:** 19 patients were seen in two two-hour clinics (mean 13 mins/patient vs. 30 mins/patient usual care), including complex patients with multiple diagnoses. 69 patients were phoned, of whom 16 did not answer, 20 declined, 6 failed to attend, 3 declined to see a Rheumatologist at all, 2 were deemed not suitable and 3 already had an appointment. Feedback was very positive: median 10 (IQR 8–10) across all domains, so was consistent with usual clinics and follow up group clinics. Free text positive comments far outweighing the negative. EQ-5D showed a highly impacted group (mean global health index 54 vs. UK age norm 77). Patient Activation Measure showed significant improvement over each two-hour

session: (54–63 & 67–74;  $p < 0.03$ ). Qualitative analysis mapped to previous themes will be summarised at the meeting.

**Conclusions:** It is feasible and effective to see new patients in a group setting with an experienced team. New patients group clinics have a powerful effect in empowering patients and may become an important option for hard to manage patients especially where resources are limited.

#### FRI0639 THE IMPACT OF DISEASE ACTIVITY AND PAIN LEVEL ON PRODUCTIVITY IN RHEUMATOID ARTHRITIS (RA) PATIENTS

J. Galloway<sup>1</sup>, J.-P. Capron<sup>2</sup>, F. De Leonardis<sup>3</sup>, W. Fakhouri<sup>4</sup>, T. Burke<sup>5</sup>. <sup>1</sup>King's College Hospital, London, United Kingdom, <sup>2</sup>Eli Lilly & Company, Brussels, Belgium, <sup>3</sup>Eli Lilly & Company, Geneva, Switzerland, <sup>4</sup>Eli Lilly and Company, London, <sup>5</sup>HCD Economics, Daresbury, United Kingdom

**Background:** Rheumatoid arthritis (RA) is a disabling and progressive chronic autoimmune disease with associated burden in terms of work disability.

**Objectives:** To investigate the impact that RA associated pain and disease activity have on the level of work impairment patients experience, using data from the Burden of Rheumatoid Arthritis across Europe: a Socioeconomic Survey (BRASS).

**Methods:** Data were extracted from BRASS, a societal perspective observational RA dataset across 10 European countries (EU5, Denmark, Sweden, Hungary, Poland and Romania). 476 RA specialising clinicians provided information on 4,079 adult patients; of these, 2,087 patients completed corresponding questionnaires about the burden of RA. 646 patients were included in the analysis, having completed a patient questionnaire and with the physician having provided a DAS28-CRP score.

Descriptive analysis was used to explore the association between pain level, disease activity and productivity impairment due to RA. Summary measures were derived from BRASS data in which the Work Productivity and Activity Impairment Questionnaire was used to quantify impairment caused by the patient's RA, taking into account not only the proportion of time the patient is absent, but also the impact on their ability to perform their job. The relationship between disease severity (as measured by DAS28-CRP score), pain level (measured across 4 categories from 'no pain', 'mild', 'moderate' to 'severe pain') and overall work impairment was further explored using a generalised linear model where pain level and severity were modelled as explanatory variables against the overall work impairment outcome, while adjusting for covariates including age, gender and BMI.

**Results:** Of the 646 included in the analysis, average age was 54.6(14.1) years; mean (standard deviation), average DAS28-CRP score was 3.1(1.2), and average disease duration was 7(10) years; median (interquartile range). Descriptive analysis indicated that with greater levels of pain and/or disease activity, patients suffered increased levels of both work and activity impairment. The average marginal effect of covariates was calculated from regression outputs. Both pain level and DAS28-CRP score independently had a statistically significant association with work impairment; a unit increase in DAS28 score meant an increase in work impairment of 4.7% ( $p=0.011$ ), whereas existence of 'mild', 'moderate' or 'severe pain' versus 'no pain' increased impairment by 33.3%, 43.4% and 45.0% respectively ( $p < 0.05$ ), with confounders age, gender, BMI and either DAS28-CRP or pain level held constant.

**Conclusions:** Results from this large, multinational survey in Europe show that subjective domains of the disease, such as pain, could be as important as objective measures of RA activity in affecting a patient's ability to work; analysis suggested both pain and severity independently have a significant impact on work and activity impairment due to RA.

## Validation of outcome measures and biomarkers

#### FRI0640 AUTOANTIBODIES TO TWO NOVEL PEPTIDES IN SERONEGATIVE AND EARLY RHEUMATOID ARTHRITIS IN THREE LARGE INDEPENDENT COHORTS

L. De Winter<sup>1</sup>, P. Vandormael<sup>1</sup>, V. Stouten<sup>2</sup>, H. W. van Steenbergen<sup>3</sup>, P. Geusens<sup>1,4,5</sup>, J. Lenaerts<sup>6,7</sup>, A. H. M. van der Helm-van Mil<sup>3</sup>, P. Verschueren<sup>2</sup>, V. Somers<sup>1</sup>. <sup>1</sup>Biomedical Research Institute, Hasselt University and transnationale Universiteit Limburg, School of Life Sciences, Hasselt, <sup>2</sup>Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, KU Leuven, Leuven, Belgium, <sup>3</sup>Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, <sup>4</sup>ReumaClinic, Genk, Belgium, <sup>5</sup>Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands, <sup>6</sup>Reuma Instituut, <sup>7</sup>Jessa Hospitals, Hasselt, Belgium

**Background:** Despite recent progress in biomarker discovery for RA diagnostics, still over one third of RA patients are seronegative for RF and ACPA, a number which is even higher in early disease. In both the University of Hasselt (UH) cohort ( $n=292$ ) and Leiden Early Arthritis Clinic (EAC) cohort ( $n=600$ ), 38% of RA patients were seronegative for RF and ACPA. Testing for novel autoantibodies to UH peptides UH-RA.1 and UH-RA.21, reduced the serological gap from 38% to 29% in the UH cohort ( $P=0.03$ ) and from 38% to 32% in the EAC cohort ( $P=0.01$ ), with associated specificities in rheumatic controls ranging from 88–96%<sup>1</sup>.

**Objectives:** Our aim is to validate the reactivities of autoantibodies against UH-RA.1 and UH-RA.21 peptides in early and seronegative RA patients from the CareRA cohort.

**Methods:** Peptide enzyme-linked immunosorbent assays have been developed to screen for the presence of antibodies to UH-RA peptides. Cut-off for seropositivity was defined by 2 x SD above the mean antibody level of the healthy control group<sup>1</sup>. Antibody reactivity to UH-RA.1 and UH-RA.21 was evaluated in baseline samples, collected before the start of treatment, of 223 early RA patients from the CareRA cohort.

**Results:** Antibodies to UH-RA.1 and UH-RA.21 were found in respectively 5% and 21% of the baseline samples from the CareRA cohort. These antibodies were found in similar levels in both RF/ACPA seropositive and seronegative patients. In the CareRA cohort, 24% of patients were seronegative for RF and ACPA and combining the presence of autoantibodies to UH-RA.1 and UH-RA.21 with RF/ACPA serology, reduced the seronegative population from 24% to 18% ( $P=0.13$ ).

**Conclusions:** Screening for antibodies against novel UH peptides UH-RA.1 and UH-RA.21 has now been performed in three large independent cohorts. This study validates the presence of antibody reactivity to these UH-RA peptides in seronegative and early RA. This might reinforce current diagnostics and improve early diagnosis and intervention in RA.

#### FRI0641 DETECTION OF CHANGES IN SLE DISEASE ACTIVITY IS HIGHLY IMPROVED WITH SLE-DAS AS COMPARED TO SLEDAI: DERIVATION AND PRELIMINARY VALIDATION OF THE SLE DISEASE ACTIVITY SCORE (SLE-DAS)

D. Jesus<sup>1</sup>, A. Matos<sup>2</sup>, C. Henriques<sup>2</sup>, M. Zen<sup>3</sup>, A. Doria<sup>3</sup>, D. S. JAP<sup>1,4</sup>, L. Inês<sup>1,4,5</sup>. <sup>1</sup>Rheumatology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, <sup>2</sup>Polytechnic Institute of Viseu, CI&DETS, Viseu, Portugal, <sup>3</sup>Division of Rheumatology, University of Padova, Padova, Italy, <sup>4</sup>Faculty of Medicine, University of Coimbra, Coimbra, <sup>5</sup>Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal

**Background:** SLEDAI is a widely used instrument to measure disease activity of systemic lupus erythematosus (SLE). However, it lacks sensitivity to discriminate improvement/worsening as it only scores items categorically and does not include several relevant lupus features, such as hemolytic anemia.

**Objectives:** To derive and validate a SLE Disease Activity Score (SLE-DAS) with improved sensitivity to change, while maintaining the high specificity and simplicity of use of the SLEDAI.

**Methods:** 324 patients fulfilling ACR'97 and/or SLICC'12 classification criteria for SLE and regularly followed at a tertiary care lupus clinic from January 2014 to December 2017 were included. At each outpatient visit, clinical and laboratory data were collected and disease activity (last 30 days) was scored with Physician Global Assessment (PGA) (0–3 scale) and SLEDAI-2K. To derive the SLE-DAS

we analyzed data from the study visit with higher disease activity from each patient, applying multivariate linear regression analysis, with PGA as dependent variable/gold-standard. Independent variables tested in the models included items from SLEDAI-2K and continuous variables for swollen joint count, proteinuria, platelet and white blood cells counts. Some features absent from SLEDAI, such as hemolytic anemia, gastrointestinal and cardiopulmonary involvement were added to the model.

To assess correlation validity we performed a Spearman's correlation between the SLE-DAS, PGA and SLEDAI-2K at last follow-up visit. We tested performance of SLEDAI-2K (change  $\geq 4$ ) and SLE-DAS to discriminate a clinically meaningful worsening and improvement in SLE disease activity (change in PGA  $\geq 0.3$ ) using Receiver Operating Characteristic (ROC) curve analysis. We determined the best cut-offs values of SLE-DAS to detect changes in PGA  $\geq 0.3$  and calculated the sensitivity, specificity, positive and negative predictive values (PPV, NPV). Statistical significance was set at 0.05.

**Results:** The final SLE-DAS model included 17 items. The SLE-DAS score at last follow-up visit presented high correlation with PGA ( $\rho=0.975$ ,  $p<0.0005$ ) and SLEDAI-2K ( $\rho=0.94$ ,  $p<0.0005$ ). For improvement in PGA  $\geq 0.3$ , in ROC analysis a change in SLE-DAS presented a much higher performance [area under curve (AUC)=0.927 (95% CI=0.885–0.969,  $p<0.0005$ )] than SLEDAI-2K [AUC=0.787 (95% CI=0.718–0.857),  $p<0.0005$ ] (figure 1). For worsening of PGA  $\geq 0.3$ , change in SLE-DAS and SLEDAI-2K presented an AUC of 0.994 (95% CI=0.988–1.000,  $p<0.0005$ ) and 0.914 (95% CI=0.870–0.959,  $p<0.0005$ ), respectively (figure 1). The optimal discriminative cut-off for either a PGA increase or reduction was change in SLE-DAS  $\geq 1.72$  (table 1).

**Table 1** Performance of SLE-DAS and SLEDAI-2K to detect change in SLE disease activity

	$\Delta$ SLE-DAS $\geq 1.72$				$\Delta$ SLEDAI-2K $\geq 4$			
	Sens	Spec	PPV	NPV	Sens	Spec	PPV	NPV
<b>Improvement</b> <b>PGA <math>\geq 0.3</math></b>	82.1	96.9	87.3	95.4	44.8	96.5	76.9	87.0
<b>Worsening</b> <b>PGA <math>\geq +0.3</math></b>	93.1	97.7	90.0	98.5	46.6	99.6	96.4	89.5

Sens: Sensitivity(%); Spec: Specificity(%); PPV: Positive predictive value(%); NPV: Non predictive value(%).

**Figure 1** Receiver operating curve (ROC) comparing the performance of SLE-DAS and SLEDAI-2K to detect a clinical meaningful improvement (A) and worsening (B) in SLE disease activity.

**Conclusions:** The SLE-DAS presents good construct validity and much higher discriminative power to detect changes in SLE disease activity as compared to SLEDAI-2K. External validation in another SLE cohort is underway.

#### FRI0642 SEPTIC ARTHRITIS SCREENING WITH A FAST DIAGNOSTIC TOOL USING MID INFRARED SPECTROSCOPY: A MULTI-CENTRIC STUDY

J.-D. Albert<sup>1</sup>, M. Le Corvec<sup>2</sup>, A. Martin<sup>3</sup>, X. Guennoc<sup>3</sup>, C. David<sup>4</sup>, S. Hoang<sup>4</sup>, C. Guedes<sup>4</sup>, M. Ferreyra<sup>4</sup>, E. Hoppe<sup>5</sup>, B. Legoff<sup>6</sup>, S. Jousse-Joulin<sup>7</sup>, H. Tariel<sup>2</sup>, O. Sire<sup>8</sup>, A. Jolivet-Gougeon<sup>9</sup>, P. Guggenbuhl<sup>1</sup>, O. Loreal<sup>10</sup>. <sup>1</sup>Rheumatology, CHU de Rennes, <sup>2</sup>DIAFIR, RENNES, <sup>3</sup>Rheumatology, CH Saint-Brieuc, Saint-Brieuc, <sup>4</sup>Rheumatology, CH de Bretagne Atlantique, Vannes, <sup>5</sup>Rheumatology, CHU Angers, Angers, <sup>6</sup>Rheumatology, CHU Nantes, Nantes, <sup>7</sup>Rheumatology, CHU de Brest, Brest, <sup>8</sup>IRDL, FRE CNRS 3744, Vannes, <sup>9</sup>Microbiology, CHU de Rennes, <sup>10</sup>Institut Numecan, INSERM U1241, Rennes, France

**Background:** Septic arthritis diagnostic is an emergency which implies a treatment with antibiotics and hospitalization. The diagnosis is based on the cyto-bacteriological examination of the synovial fluid (SF), but direct bacteriological examination is insensitive and the result of the culture is obtained only after several days. Therefore, there is still a need for a rapid, simple and reliable method for

the positive diagnosis of septic arthritis. Such method must allow avoiding both unrecognized septic arthritis leading to major functional consequences, and over-diagnosis that will induce unnecessary expensive hospitalization and unjustified treatment with consequences in term of health and social costs.

Mid-infrared (MIR) spectroscopy, that gives a metabolic profiling of biological samples, has been proposed for early and fast diagnosis.

**Objectives:** The objective of this study was to confirm <sup>(1)</sup> the interest of mid-infrared (MIR) spectroscopy to discriminate synovial fluid samples from patients with septic arthritis from other causes of joint effusion.

**Methods:** Synovial fluids from patients referred for suspected arthropathies were prospectively collected in six hospitals in western France and stored at -80°C. The infrared absorption spectrum was acquired for each of the frozen samples using a chalcogenide fibre sensor. The most informative spectral variables (allowing to discriminate between septic arthritis and non-septic arthritis with reference to cytobiological examination) were selected and then used to develop an algorithm. Non-frozen synovial fluids were also analysed at Rennes University Hospital, the pilot centre, to validate the algorithm.

**Results:** The cohort consists of synovial fluid samples from patients exhibiting various etiologies. These samples (n=402), by using SF bacteriological analysis and culture and 16S PCR analysis were classified as septic arthritis (n=30) or non septic arthritis (n=372).

On the frozen samples the performances of the algorithm show a sensitivity of 97%, a specificity of 71%, a **VPN of 99%** and a VPP of 21%, the area under the ROC curve (AUROC) was 0.91.

**Conclusions:** This study confirms the interest of optical fibre infrared spectroscopy for the discrimination between septic and non septic synovial fluids. The high negative predictive value and the very short time (about ten minutes) required to obtain the result makes it possible to quickly rule out an infection diagnosis, which could make it possible to avoid unnecessary hospitalization and antibiotic therapy.

#### FRI0643 AUTOANTIBODY STATUS IS NOT ASSOCIATED WITH EARLY TREATMENT RESPONSE TO FIRST-LINE METHOTREXATE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

J. S. Dekkers<sup>1</sup>, S. A. Bergstra<sup>1</sup>, A. Chopra<sup>2</sup>, M. Tikly<sup>3</sup>, J. E. Fonseca<sup>4</sup>, K. Salomon-Escoto<sup>5</sup>, T. Huizinga<sup>6</sup>, D. van der Woude<sup>6</sup>. <sup>1</sup>Rheumatology, LUMC, Leiden, Netherlands, <sup>2</sup>Rheumatology, Centre For Rheumatic Diseases, Pune, India, <sup>3</sup>Division Of Rheumatology, University of Witwatersrand, Johannesburg, South Africa, <sup>4</sup>Rheumatology Research Unit, Lisbon Academic Medical Centre, Lisbon, Portugal, <sup>5</sup>Department Of Rheumatology, UMass Memorial Medical Center, Massachusetts, United States, <sup>6</sup>Department Of Rheumatology, LUMC, Leiden, Netherlands

**Background:** In rheumatoid arthritis (RA), the relationship between autoantibody status and treatment response to methotrexate remains unclear. As methotrexate is the most widely used anti-rheumatic drug in clinical practice, it would be important to know whether the presence of autoantibodies is associated with better treatment response, since patients may benefit from treatment tailored to "autoantibody status".

**Objectives:** We investigated the relationship between autoantibody status and remission in newly diagnosed RA-patients treated with first-line methotrexate.

**Methods:** RA-patients initially treated with methotrexate were selected from an international observational database (METEOR). Patients were stratified into autoantibody-positive (rheumatoid factor (RF)- and/or anti-citrullinated-protein antibodies (ACPA)-positive) or -negative (RF- and ACPA- negative). The effect of autoantibody status on the chance of achieving remission within 3 to 6 months was analysed using Cox-proportional hazards regression.

**Results:** Data from 1826 RA-patients were available for analysis. DAS remission was achieved in 17% (318/1,826). This was similar in autoantibody-positive (17% (282/1629)) and -negative patients (18% (36/197)). Hence, autoantibody positivity was not associated with remission (HR0.89, 95%CI 0.57;1.38). Similar findings were found when stratified for methotrexate monotherapy (HR0.75, 95%CI 0.41;1.37) or combination treatment (HR0.76, 95%CI 0.37;1.54). Good physical

function (HAQ<0.5) was achieved in 33% (530/1590) of all patients. Autoantibody-positivity was also not associated with HAQ<0.5 (HR1.05, 95%CI 0.71;1.57).

MTP & systemic DMARD n (%)	1,826	353 (19)	1,629	339 (21)	197	13 (7)
MTP & biological DMARD n (%)	1,826	36 (2)	1,629	34 (2)	197	7 (4)

RA, Rheumatoid Arthritis; ACPA, anti-cyclic citrullinated peptide antibody; RF, rheumatoid factor; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; VAS, visual analogue scale for health perception; DAS, disease activity score; HQI, Health Assessment Questionnaire; IQR, Interquartile Range; MCP, methotrexate; MTP, methotrexate plus peripheral; DMARD, disease-modifying anti-rheumatic drug.

**Conclusions:** In conclusion, we found that autoantibody status was not associated with early remission in newly diagnosed RA-patients receiving methotrexate in real-world clinical practice. These results do not support the hypothesis that treatment should be tailored to “autoantibody status” when it comes to initiating methotrexate therapy as first-line anti-rheumatic treatment. Rather, our results indicate that that methotrexate is effective as primary anchor drug regardless of autoantibody status.

FRI0644

**THE USE OF MRI-DETECTED SYNOVITIS TO DETERMINE THE NUMBER OF INVOLVED JOINTS FOR THE 2010 ACR/EULAR CLASSIFICATION CRITERIA FOR RHEUMATOID ARTHRITIS – IS IT OF ADDITIONAL BENEFIT?**

A. C. Boer<sup>1,2</sup>, D. Boeters<sup>1</sup>, A. H. M. van der Helm – van Mil<sup>1,2</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden, <sup>2</sup>Rheumatology, Erasmus Medical Center, Rotterdam, Netherlands

**Background:** The 2010 ACR/EULAR classification criteria have been developed, as early classification of Rheumatoid Arthritis (RA) is important. The 2010-criteria states that imaging can be used to determine the number of joints with synovitis. This seems reasonable as previous studies on Magnetic Resonance Imaging (MRI) in early arthritis patients have shown that synovitis is present in a substantial number of joints that were neither swollen nor tender at clinical examination. Although the development of the 2010-criteria was primarily data-driven, the suggestion to also use advanced imaging modalities to detect synovitis was based on expert opinion. Scientific data supporting the use of MRI is lacking.

**Objectives:** To assess the value of MRI-detected synovitis to determine the number of involved joints on the performance of the 2010-ACR/EULAR classification criteria for RA.

**Methods:** 277 consecutive patients with a clinical diagnosis of RA or undifferentiated arthritis (UA) were studied. They underwent contrast enhanced 1.5T MRI of MCP-, wrist- and MTP-joints at baseline. Two outcomes were studied after 1 year follow-up: disease modifying anti-rheumatic drugs (DMARD)-initiation and fulfilling the 1987-criteria. Test characteristics were calculated when the number of involved joints was determined with and without MRI-detected synovitis.

**Results:** At baseline, 143 of 277 patients did not fulfil the 2010-criteria when the number of involved joints was determined by clinical evaluation of swelling and tenderness. When MRI-detected synovitis was also considered 69 patients had increased joint counts. Of these, 36 patients received more points for the item ‘number of involved joints’ and 14 reached ≥6 points and now fulfilled the 2010-criteria for RA. Thus, 10% of patients that were formally classified as UA were additionally classified as having RA.

Without considering MRI-detected synovitis, the sensitivity of the 2010-criteria was 62% and the specificity 90%, for DMARD initiation as outcome. With the addition of MRI-detected synovitis, the sensitivity increased to 67% and the specificity decreased to 84%. The AUC changed from 0.76 to 0.75. The net proportion of correctly reclassified patients was -2.4%. Of the additionally classified patients, 64% (9/14) were started on DMARDs and were considered true positives, whereas 36% (5/14) were not treated with DMARDs and developed alternative clinical diagnoses during the first year.

Results for the outcome 1987-criteria fulfilment after 1-year were similar. The sensitivity changed from 79% to 81% and the specificity from 78% to 71% the proportion of correctly reclassified patients was -5.1%.

**Conclusions:** To our knowledge, this study is the first providing evidence on the value of MRI-detected synovitis in addition to tender and swollen joints for the classification of RA. We did not find an increased accuracy of the 2010 criteria when incorporating MRI-detected synovitis. Further research on this subject in other longitudinal cohorts is needed, but at present there is no scientific proof that MRI-detected synovitis is of additional benefit for classifying RA.

**ANTI-DRUG ANTIBODIES TO CERTOLIZUMAB PEGOL ARE ASSOCIATED WITH LOW DRUG LEVELS AND REDUCED CLINICAL RESPONSE AT 3 MONTHS IN PATIENTS WITH INFLAMMATORY JOINT DISEASES. DATA FROM THE NOR-DMARD STUDY.**

J. E. Gehin<sup>1</sup>, G. L. Goll<sup>2</sup>, D. J. Warren<sup>1</sup>, S. W. Syversen<sup>2</sup>, J. Sexton<sup>2</sup>, E. K. Strand<sup>3</sup>, T. K. Kvien<sup>2</sup>, N. Bolstad<sup>1</sup>, E. Lie<sup>2</sup>. <sup>1</sup>Department of Medical Biochemistry, Oslo University Hospital, <sup>2</sup>Department of Rheumatology, Diakonhjemmet Hospital, Oslo, <sup>3</sup>Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway

**Background:** Anti-drug antibodies (ADAb) to biological drugs predispose patients to low drug levels and lack of treatment response. For certolizumab pegol (CP) knowledge about the frequency and clinical relevance of ADAb is limited in patients with inflammatory joint diseases (IJD).

**Objectives:** To assess the frequency and clinical relevance of early ADAb development in patients with inflammatory joint diseases treated with CP.

**Methods:** Patients from the NOR-DMARD study (n=310) with a clinical diagnosis of rheumatoid arthritis (RA, n=91), psoriatic arthritis (PsA, n=61), axial spondyloarthritis (axSpA, n=116) and other IJD (42) starting treatment with CP, who had available biobank sample at 3 months follow-up, were included. Serum samples are non-trough samples collected at 3 months. Drug concentrations were analysed using an in-house immunofluorometric assay automated on the AutoDEL-FIA immunoassay platform. ADAb was detected by a principal assay measuring neutralising ADAb and two confirmational tests (antigen-bridging test and a 3-step immunofluorometric assay). Patients with RA, PsA and axSpA were included in response analyses. Treatment response was defined by EULAR good/moderate response in RA, DAS28 improvement ≥0.6 in PsA, and ASDAS clinically important improvement (CII) in axSpA.

**Results:** After 3 months of treatment, 19 of 310 (6.1%) patients were ADAb positive (5 RA, 4 PsA, 6 axSpA and 4 other IJD). ADAb positive patients had significantly lower CP levels than ADAb negative patients, median 1.0 (IQR 0.2–6.8) vs 34.4 (IQR 21.2–44.7) mg/L (P<0.001). Response data were available for 245 patients. Of these, only 1/11 (9%) ADAb-positive patients was classified as a responder, while 10/11 (91%) were non-responders. Among ADAb-negative patients with response data, 129/234 (55%) were responders, while 105/234 (45%) were non-responders.

**Conclusions:** ADAb against CP were detected in 6.1% of patients after 3 months of treatment and were associated with low drug levels and reduced treatment response. These results suggest that drug levels and ADAb may be important for monitoring efficacy of treatment with TNF inhibitors, but the clinical significance needs to be examined in randomised clinical strategy trials.

**SYNOVIAL TISSUE HISTOPATHOLOGY FINDINGS IN EARLY RA. IS IT USEFUL? ANALYSIS OF THE BELGIAN CAP48 COHORT.**

C. Galant<sup>1</sup>, L. Meric De Bellefon<sup>2</sup>, B. Lauwerijs<sup>2</sup>, T. Sokolova<sup>2</sup>, M. Stoenoiu<sup>2</sup>, V. Badot<sup>3</sup>, A. Nzeusue<sup>2</sup>, F. Houssiau<sup>2</sup>, P. Durez<sup>2</sup>. <sup>1</sup>Pathology, <sup>2</sup>Rheumatology, Cliniques universitaires Saint-Luc – Université Catholique de Louvain – Institut de Recherche Expérimentale et Clinique (IREC), <sup>3</sup>Internal Medicine, Centre Hospitalier Universitaire Brugmann, Brussels, Belgium

**Background:** The development of ultrasound-guided synovial biopsy will enable synovial tissue collection from small joints and will facilitate histopathological studies, thus improving the understanding of early rheumatoid arthritis (ERA). The CAP48 cohort is an original multicentre prospective observational study of early

Rheumatoid Arthritis (RA) patients up to 50 years old supported by a charity program of the Belgian French speaking radio-television (RTBF).

**Objectives:** The objectives of this cohort are to observe if a tight control favour remission at 6 months and to define synovial markers for severity and response to therapy.

**Methods:** RA patients fulfilling the ACR/EULAR 2010 criteria and naïve to DMARDs therapy were recruited. Synovial biopsies before treatment were obtained using an ultrasound guided needle biopsy (US-NB) of the small joints or miniarthroscopy of the knee. RA disease activity measures including DAS28CRP domains were evaluated every 3 months and treatment was adapted by the treating physician. Tissues were assessed for quality. Retrieved tissue was fixed, stained and paraffin embedded for blinded tissue pathology description.

**Results:** A synovial biopsy was performed in 37 patients using US-NB in n patients. Patients were classified according 4 types of synovial histopathology findings. Baseline characteristics of the cohort is summarized in table 1. All patients in the diffuse lymphoid group were ACPA negative and the majority of the ACPA positive patients were classified in the pauci immune and fibrous group. As shown in figure 1, the pauci immune ERA group showed lower DAS28-CRP response than the other groups.

Table 1

	All patients n=37	Group 'Diffuse' n=17	Group 'Nodules' n=7	Group 'Pauci- Immun' 'Fibrous' n=13
Age mean (SD)	34.4 (± 1.9)	31.3 (± 2.9)	36.1 (± 4.4)	33.0 (± 5.8)
Gender	30F/7M	14F/3M	5F/2M	11F/2M
ACPA % (n=)	37.8% (n= 14)	0% (n=0)	57.1% (n=4)	76.9% (n=10)
RF % (n=)	48.6% (n=18)	11.8% (n=2)	85.7% (n=6)	76.9% (n=10)
Erosion % (n=)	35.1% (n=13)	17.6% (n=3)	57.1% (n=4)	38.4% (n=5)
Baseline DAS28-CRP	4.60 (± 0.23)	4.52 (± 1.50)	5.00 (± 1.37)	4.76 (± 1.44)

**Conclusions:** Synovial tissue analysis could provide a step change towards personalized medicine in daily clinical practice for disease stratification and treatment selection of ERA. In the CAP48 cohort, a high number of these young and ERA patients achieved remission at 6 months but a lower response was observed in the pauci immune group. Further analyses are ongoing to define individual synovial markers of severity and response.

FRI0647

#### ESTIMATION OF MINIMUM CLINICALLY IMPORTANT DIFFERENCE IN FIBROMYALGIA FOR FIQR USING BPI AS THE ANCHOR MEASURE

S. Surendran<sup>1</sup>, C. B. Mithun<sup>1</sup>. <sup>1</sup>Rheumatology, Amrita Institute of Medical Sciences, Kochi, India

**Background:** The FIQ (Fibromyalgia Impact Questionnaire) was first published in 1991 and had 19 items which were recalled over a week. The scoring system is highly reliable and is recognised as an outcome measure that covers the multiple domains of Fibromyalgia<sup>1</sup>. A prior study by Bennett et al<sup>2</sup> have shown that 14% change in the FIQ total score represents the Minimum Clinically Important Difference(MCID) in the Fibromyalgia. The FIQ was revised in 2009 to the 20 item

Fibromyalgia Impact Questionnaire Revised or FIQR. However, there has been no study done for assessing the MCID of the FIQR in Fibromyalgia.

**Objectives:** The aim of our study is to estimate the MCID for Fibromyalgia Impact Questionnaire Revised using anchor-based methodology with average pain score on Brief Pain Inventory as the anchor.

**Methods:** We have used data from our prospectively followed cohort of fibromyalgia patients. They were treated as per protocol with duloxetine in escalating doses. Data from this cohort was used to estimate the MCID for the FIQR using anchor-based methodology The anchor used was the average pain score on Brief Pain Inventory(BPI). The MCID for BPI average pain score was calculated by Mease et al to be 30%<sup>3</sup>. Thus, all patients in our cohort having an improvement of greater than 30 % were classified as responders. All other patients were non-responders. Within these two groups, the means and standard deviations of the FIQR scores at baseline and at the end of treatment were obtained. The MCID was calculated as the difference in the unadjusted mean change in the FIQR scores between the "non-responder" group and the group with "responder group". It was also expressed as a percentage reduction from the mean baseline FIQR.

**Results:** Table 1 shows the mean and standard deviation of FIQR scores at baseline, endpoint and the mean change along with the calculated MCID. Table 1

Anchor status	No. of patients	Baseline Mean ± SD	Endpoint mean ± SD	Mean change ± SEM	MCID
Responder	58	58.50 ± 19.03	26.62 ± 14.76	31.88 ± 2.53	27.04
Non-responders	18	62.17 ± 16.97	57.33 ± 13.00	4.83 ± 3.75	

**Conclusions:** Based on our data, we suggest that a "27.04 point" or "45.5 %" improvement on the FIQR score represents the minimum clinically important difference for FIQR in fibromyalgia patients presenting with moderate to severe pain. Strengths of this work include the usage of prospectively followed patient population for analysis, protocol-based treatment with duloxetine and representation of a local population which more is applicable to our clinical practice. That MCID obtained for the FIQR score is much higher than the 14 % which was the MCID obtained for the older FIQ score may suggest a population-based variation in improvement of outcome measures.

#### DIRECTLY COMPARING LATENT FUNCTIONAL ABILITY IN ADOLESCENTS WITH JIA USING THE CHAQ AND HAQ: AN ITEM RESPONSE THEORY ANALYSIS

S. J. W. Shoop-Worrall<sup>1,2</sup>, M. O. Voshaar<sup>3</sup>, M. van de Laar<sup>3,4</sup>, W. Thomson<sup>1,2</sup>, K. L. Hyrich<sup>1,2</sup>, J. E. McDonagh<sup>1,2</sup>, S. M. M. Verstappen<sup>1,2</sup> on behalf of CAPS. <sup>1</sup>The University of Manchester, <sup>2</sup>Manchester Foundation Trust, Manchester, United Kingdom, <sup>3</sup>Department of Psychology, Health & Technology, University of Twente, <sup>4</sup>Department of Rheumatology, Medisch Spectrum Twente, Enschede, Netherlands

**Background:** Measuring and comparing functional ability in adolescents with JIA is challenging due to the use of multiple questionnaires, including the proxy-completed Childhood Health Assessment Questionnaire (P-CHAQ), the adolescent version (A-CHAQ) and the Health Assessment Questionnaire (HAQ).

Item response theory (IRT) allows items on multiple questionnaires to be linked to an underlying continuous variable. This allows scores to be corrected for characteristics of the administered items, thus making them comparable between different questionnaires. Recently, a common reporting metric for functional ability was developed in a combined dataset of 16386 patients with various inflammatory rheumatic diseases, including 1029 paediatric patients with JIA.

**Objectives:** i) To cross-validate the item response models using three functional ability questionnaires in adolescents with JIA. ii) To assess agreement between overall function scores obtained from the different questionnaires.

**Methods:** Adolescents aged 11 to 17 with JIA were enrolled to a UK, multicentre inception cohort, the Childhood Arthritis Prospective Study (CAPS). In a sub-

study, adolescents were asked to complete the A-CHAQ and HAQ and their guardians the P-CHAQ. Adolescents were selected if at least two of the questionnaires had been completed simultaneously within the first year following diagnosis.

Fit of the item response models was assessed by comparing model expected item scores with those observed in CAPS for each item (i.e. residuals). An item response model was considered to adequately describe item response behaviour of CAPS patients when the mean of the residuals was  $<\pm 5\%$ . Agreement of overall questionnaire IRT scores were then compared using limits of agreement (2SD) and intra-class correlations.

**Results:** Of 303 adolescents, 61% were female and median age at JIA diagnosis was 13 years (range 11 to 17). Raw HAQ scores consistently fell below both CHAQ scores.

IRT model fit in the CAPS population was good, with 1% of item residuals  $>\pm 5\%$ . When modelled using IRT, the mean differences in overall scores approximated zero, with narrow limits of agreement, at 15 (PCHAQ vs ACHAQ), 12 (PCHAQ vs HAQ) and 10 (ACHAQ vs HAQ), on a 0–100 scale. High intra-class correlations between overall scores were evident (range 0.83 to 0.90). There was therefore high agreement between IRT-modelled scores obtained for different questionnaires. A scale characteristic curve (figure 1) illustrates the relationship between the expected scores for CHAQ and HAQ questionnaires with the latent functional ability variable.

Figure 1 Comparing CHAQ and HAQ scores with latent function.

**Conclusions:** IRT models for functional ability previously developed in a mixed population of adult and paediatric patients with inflammatory arthritides are applicable to adolescents with JIA in CAPS. IRT scores across CHAQ and HAQ measures had high agreement. IRT scores for functional ability can therefore be used in clinical practice and research to directly compare scores on the CHAQ and HAQ. This will be important as adolescents transfer from paediatric to adult rheumatology.

#### FRI0649 SYSTEMIC LEVELS OF TYPE VI COLLAGEN METABOLITES ARE ELEVATED IN RA PATIENTS AND MODULATED BY TREATMENT WITH ANTI-IL6R THERAPY

C. S. Thudium<sup>1</sup>, N. S. Gudmann<sup>1</sup>, M. Karsdal<sup>1</sup>, A.-C. Bay-Jensen<sup>1</sup>. <sup>1</sup>Biomarkers & Research, Nordic Bioscience, Herlev, Denmark

**Background:** Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by progressive inflammation systemically and local joint deterioration. Chronic inflammation leads to elevated levels of tissue remodeling and release of extracellular matrix (ECM) metabolites into circulation. Type VI collagen (Col-VI) is found at the interface between the interstitial- and the basement membrane where it binds other matrix proteins and support cell-cell interactions. Blood levels of Col-VI metabolites (C6M) have been associated with increased tissue turnover and disease activity in animal models and clinical studies of lung<sup>1</sup> and liver<sup>2</sup> fibrosis and ankylosing spondylitis<sup>3</sup>. These studies indicate that systemic levels of C6M are released ubiquitously from many organs and may be modulated by anti-inflammatory treatments. Treatment with the  $\alpha$ IL-6 receptor agent Tocilizumab (TCZ) results in decreased ECM remodeling

**Objectives:** Investigate the modulation of Col-VI metabolites in circulation by TCZ treatment and its association with treatment response.

**Methods:** Systemic Col-VI metabolism was measured in the LITHE study (n=740), a one year double blind, placebo controlled phase III parallel group study

in patients receiving placebo, 4 mg/kg or 8 mg/kg TCZ in combination with MTX. Col-VI degradation was measured using the C6M assay, measuring a specific MMP generated metabolite at bl, w4 and w16. The odds ratio (OR) of treatment response (ACR20, 50 or 70) at  $>$ median decrease was calculated using logistic regression, adjusting for age, sex, BMI, dis. duration (model 1) and treatment (model 2).

**Results:** TCZ treatment dose dependently reduced of Col-VI metabolites in serum at w4 in both 4 and 8 mg/kg (9% ns and 46%  $p<0.0001$ ) doses compared to placebo and the reduction persisted throughout the study. Patients with a high suppression of Col-VI turnover were more likely to respond to treatment compared to patients with low suppression. In patients with high suppression after 4 weeks the OR and ACR20 response at w16 was 1.6 (95% CI, 1.16–2.20), although this was not significant when adjusting for treatment. The OR of ACR50 was 2.2 (95% CI, 1.507–3.296) and for ACR70 2.6 (95% CI, 1.407–4.631).

Table 1 Association of high/low C6M median % change with ACR response after 16 weeks using logistic regression

Determinant	Model	Outcome		ACR20		ACR50		ACR70	
		OR (95% CI)	p-value	OR (95% CI)	p-value	OR (95% CI)	p-value		
$\Delta$ C6M % week 4	Model 1	1.596 (1.160–2.198)	0.004	2.228 (1.507–3.296)	<0.001	2.553 (1.407–4.631)	0.002		
	Model 2	1.319 (0.929–1.873)	0.122	1.820 (1.189–2.785)	0.005	2.390 (1.265–4.517)	0.007		

**Conclusions:** Suppression of Col-VI turnover was significantly associated with a higher level of response to TCZ treatment in RA patients after already 4 weeks. We hypothesize that there is an increased systemic connective tissue turnover in RA and connective tissue metabolites may be used as indicators of treatment response.

#### FRI0650 THE DIAGNOSTIC VALUE OF THE AESKULISA PR3 SENSITIVE & AESKULISA MPO IN THE EUVAS-COHORT

K. Prager<sup>1</sup>, N. Marte<sup>1</sup>, E. Csernok<sup>2</sup>, A. Lerner<sup>3</sup>, T. Matthias<sup>3</sup>. <sup>1</sup>R&D, Aesku.

<sup>2</sup>Diagnostica GmbH & Co. KG, Wendelsheim, <sup>3</sup>Department of Internal Medicine, Vasculitis-Center Tübingen-Kirchheim, Medius Klinik Kirchheim, Kirchheim-Teck, <sup>3</sup>R&D, Aesku.kipp Institute, Wendelsheim, Germany

**Background:** Anti-neutrophil-cytoplasmic-antibodies directed against proteinase-3 (PR3-ANCA) and myeloperoxidase (MPO-ANCA) are serological hallmarks of small vessel vasculitis, particularly granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA). In a recent multicentre European-Vasculitis-Study-Group (EUVAS) evaluation, the performance of IIF was compared to that of various antigen-specific immunoassays.

**Objectives:** The aim was to evaluate the diagnostic accuracy of the third-generation antigen-specific immunoassays PR3-ANCA (AESKULISA-PR3-sensitive) and MPO-ANCA (AESKULISA-MPO) and to compare these data with the results from the other assay (Orgentec).

**Methods:** 257 samples from the EUVAS cohort were tested for the presence of ANCA by PR3-ANCA ELISA (AESKULISA-PR3-sensitive) and MPO-ANCA ELISA (AESKULISA-MPO). Newly diagnosed GPA/MPA (n=66) patients and diseased controls (n=191): systemic lupus erythematosus (n=60), systemic sclerosis (n=10), rheumatoid arthritis (n=90), Scleroderma (n=11) and Sjögren's syndrome (n=30) were analyzed.

**Results:** In AAV patients, ANCAs were detected with both methods in 56 cases; divergent results were obtained in only 1 patient sample. 191 patients with other rheumatic diseases were analyzed and only 13 vs 11 (AESKU/Orgentec) were

positive for ANCA (SLE, sclerosis, RA, RA/RV). This study shows that the PR3- and MPO-ANCA ELISA are highly specific (93.2%/94.2%) and sensitive (85.9%/85.9%) in the detection of ANCA to identify AAV or conditions known to be associated ANCA.

**Conclusions:** Our comparison of PR3- and MPO-ANCA ELISAs showed (i) a high diagnostic performance of these PR3- and MPO-ANCA ELISAs to discriminate AAV from disease controls. (ii) very good correlation between the other methods tested. In conclusion, these novel assays can be used as screening method for detection of ANCA-associated diseases.

**Disclosure of Interest:** None declared

Pierantoni Hospital, Forlì, <sup>10</sup>Rheumatology Unit, University of Modena and Reggio Emilia, Azienda Ospedaliero-Universitaria, Policlinico di Modena, Modena, <sup>11</sup>Rheumatology Unit, Santa Chiara Hospital, Trento, <sup>12</sup>Rheumatology Unit, University of Modena and Reggio Emilia, Azienda Ospedaliero-Universitaria, Policlinico di Modena, Modena, <sup>13</sup>Department of Clinical Sciences, Section of Radiology, University of Parma, Parma, <sup>14</sup>Radiology Unit, Ospedale G. Da Saliceto, Piacenza, <sup>15</sup>Department of Medical Sciences, Section of Rheumatology, University of Ferrara and AOU Sant'Anna, Ferrara, <sup>16</sup>Department of Clinical Sciences, Section of Radiology, University of Parma, Parma, Italy

**Background:** Interstitial Lung Disease (ILD) is the main cause of death in Systemic Sclerosis (SSc). Serious lung involvement increase the hospitalization rate and sometimes oxygen therapy is required.

An prompt treatment in ILD-SSc patients is essential, but nowadays there is not a feasible method to identify patients with poor prognosis.

Although chest Computed Tomography (CT) is the gold standard to detect ILD, there is no standardized assessment of its severity. Quantitative CT (QCT) is an innovative and operator independent method to assess ILD-SSc extent and severity. An increasing number of evidences confirm that QCT is extremely useful for detecting SSc-ILD with the worst prognosis. However is not well established if QCT can predict death or comorbidity associated to ILD.

**Objectives:** The main aim of this study is to verify if QCT predict 8-years mortality or clinical worsening (i.e. hospitalization for respiratory complications or chronic oxygen therapy) in SSc.

**Methods:** Consecutive SSc patients (according to ACR/EULAR classification criteria) from ten different centers underwent a chest CT. Their clinical history was carefully recorded in the following 96 months. A rheumatologist post-analyzed every CT with an open source DICOM viewer in order to obtain QCT indexes. Patients were clustered in two subgroups: according to QCT indexes' cutoff previously found (see Ariani et al., 2017). The survival time of each patient was considered the time interval between the CT date and death, hospitalization related to lung worsening, beginning of chronic oxygen therapy or last medical examination

**Results:** We enrolled 342 patients; during the 8-years follow-up 15.5% (53/342) died and 4.4% (15/342) had a clinical worsening. The Kaplan-Meier survival analysis demonstrates a worse survival in patients with QCT indexes above or below the previously observed cutoffs. (p<0.01). In particular the QCT index cutoff which the best performance was total lung kurtosis (tKurt) equal to 4.89 (p<0.0001).

#### REFERENCES:

The QCT indexes' cutoffs previously found (see Ariani, et al., 2017) identify the SSc-ILD subjects with an high risk of 8-years mortality and comorbidity. These findings suggest that QCT could become a pivotal assessment in SSc management because its role in identifying patients with poor prognosis and who deserve an early aggressive treatment.

#### FRI0652 THE DEVELOPMENT AND VALIDATION OF FAMILIAL MEDITERRANEAN FEVER QUALITY OF LIFE SCALE (FMF-QOL)

C. Unal<sup>1</sup>, M. T. Duruo<sup>2</sup>. <sup>1</sup>PMR Department, <sup>2</sup>PMR Department, Rheumatology Division, Marmara University School of Medicine, Istanbul, Turkey

**Background:** Quality of life (QoL) was negatively affected in FMF patients. A QoL scale specific to FMF is not existing in the literature.

**Objectives:** To develop valid and reliable quality of life scale in familial Mediterranean fever (FMF).

**Methods:** The psychometric method was used to develop the FMF-QoL. In the first step, the question pool was formed by using existing QoL scales in the literature. Outpatients with FMF according to Livneh criteria were recruited. After patients' interviews, some identical and irrelevant questions eliminated and new ones were added by an expert committee. Cognitive debriefing interviews concerning QoL were done with another 20 FMF patients. Minor changes (few words) after these interviews were made. In the second step, the preFMF-QoL with 101 questions was formed and it was filled out by FMF patients. Confirmatory factor analysis (CFA) by varimax rotation, assessment of data' skewness and kurtosis, evaluation of invalid questions and participants were performed. After this, the internal consistency with Cronbach alpha was calculated. The face, content and construct validities were assessed. Convergent validity which was the relation of the FMF-QoL with functional parameters (Euro Health Impact Scale (EURO-HIS), Short Form 36 (SF36), Beck Depression Inventory for Primary Care (BDI-PC), Jenkins Sleep Scale (JSS), Health Assessment Questionnaire (HAQ) and the discriminant validity which was the relation of the FMF-QoL with nonfunctional parameters such as demographic and clinical characteristics were analyzed. The Mann Whitney U test, Kruskal-Wallis test and Spearman correlation coefficient (rho) were used to compare quantitative variables.

**Results:** In our study, the FMF-QoL was applied to 125 FMF patients however 123 (84 women) patients were designed to statistical analysis. It has been determined by the expert committee that the face and content validity of the FMF-QoL was good. According to the factor analysis the FMF-QoL were represented by 4 factor groups (eigenvalues >1) which were physical impact, social and recreational impact, psychological impact, and sleep impact factors. All question's factor loadings after Varimax rotation were bigger than 0.5 and the cumulative variance of the scale was 68.11%. The strongest correlation of the FMF-QoL was found with other QoL scales like EUROHIS (rho: -0.64, p<0.01) and SF36-physical functioning subscale (rho: -0.63, p<0.01). The correlations between the FMF-QoL and other functional parameters were found to be moderate [BDI-PC (rho: 0.46, p<0.01), JSS (rho: 0.44, p<0.01), HAQ (rho: 0.44, p<0.01)]. This shows that the FMF-QoL has good convergent validity. In the discriminative validity, most of the parameters had not significant correlation with the FMF-QoL. Only the number of attacks in the previous year, age and education level were correlated moderately with the FMF-QoL. This shows the FMF-QoL has discriminative validity.

**Conclusions:** The FMF-QoL scale was developed with psychometric method. It is a valid and reliable disease specific scale which has 20 questions with 4 factors. It is already a practical, not time consuming that can be used in the clinical follow-up and the treatment evaluation.

#### FRI0653 VALIDITY OF POLYMYALGIA RHEUMATICA DIAGNOSES, AND CLASSIFICATION CRITERIA, IN PRIMARY HEALTH CARE

C. Fors<sup>1,2</sup>, U. Bergström<sup>1,2</sup>, M. Willim<sup>2,3</sup>, E. Pilman<sup>4</sup>, C. Turesson<sup>1,2</sup>. <sup>1</sup>Rheumatology, Department of Clinical Sciences, Malmö, Lund University, <sup>2</sup>Department of Rheumatology, Skåne University Hospital, Malmö, <sup>3</sup>Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund, <sup>4</sup>Landborgen Primary Health Care Centre, Helsingborg, Sweden

**Background:** Polymyalgia rheumatica (PMR) is an inflammatory disorder that mainly affects elderly women, and usually is diagnosed in primary health care (PHC). A number of classification criteria have been proposed, most recently the American College of Rheumatology (ACR)/ European League Against Rheumatism (EULAR) criteria from 2012 (1). The ACR/EULAR criteria were developed in a cohort of patients recruited from rheumatology clinics.

**Objectives:** To examine the validity of PMR diagnoses in primary care, and to validate the use of classification criteria for PMR in a retrospective survey of a PHC cohort.

**Methods:** Patients were recruited from two PHC centers. All patients with a registered diagnosis of PMR between 2000 and 2013 in the patient administrative system were identified. The electronic case records, including hospital records,

for all patients were reviewed through June 2015. Patients with a diagnosis of PMR prior to 2000, or at another care facility, and those with an incorrectly registered PMR diagnosis code, were excluded. In a structured review of the case records, information required for classification according to the ACR/EULAR criteria, the Bird criteria, the Healey criteria, the Chuang&Hunder criteria and the Jones&Hazelman criteria was extracted. For the ACR/EULAR criteria, a modified version, in which patients who had never been tested for rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) only required 2 points to be classified as having PMR, was used. Furthermore, as duration of morning stiffness (MS) was usually not recorded, criteria components for MS were considered to be fulfilled whenever MS was mentioned in the records. The reference method was an independent review, with assessment of the long term disease course and differential diagnoses, by an experienced rheumatologist with access to all electronic records.

**Results:** A total of 305 patients with a registered diagnosis of PMR were reviewed. Of these, 117 were excluded. Among 188 with an incident PMR diagnosis at the study sites during the study period, 49 (26 %) fulfilled the modified ACR/EULAR criteria, whereas 145 (77 %) fulfilled the Bird criteria and 93 (49 %) fulfilled the Healey criteria. Patients could not be classified according to the Chuang&Hunder or the Jones&Hazelman criteria due to missing data in most patients for several components. RF and ACPA were tested in only 42 cases (4 positive) and 29 cases (none positive), respectively. The PMR diagnosis was verified using the reference method in 113 cases (60 % of total; 68 % female, mean age at diagnosis 75 years). Among those fulfilling the modified ACR/EULAR criteria, the diagnosis was verified in 84 % of the patients. The corresponding proportion for the Bird criteria was 66 %, and for the Healey criteria 74 %.

**Conclusions:** In this study of patients with PMR diagnosed in PHC, the diagnosis could be verified in 60 % of the patients. This underlines the heterogeneity of PMR patients and related diagnostic procedures in PHC. A modified version of the ACR/EULAR criteria can be used to identify patients with a valid PMR diagnosis in retrospective surveys, but does not capture all PMR patients. The modified ACR/EULAR criteria appear to be more stringent than some of the older criteria sets.

#### IS THE PATIENT-ACCEPTABLE STATUS SIMILAR ACROSS 7 DOMAINS OF HEALTH IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)? POST-HOC ANALYSES FROM THE VALIDATION IN 549 PATIENTS OF THE RHEUMATOID ARTHRITIS IMPACT OF DISEASE (RAID) SCORE

C. Duarte<sup>1,2,\*</sup>, T. Kvien<sup>3</sup>, J. A. Pereira da Silva<sup>1,2</sup>, L. Gossec<sup>4</sup> on behalf of RAID Working Group EULAR. <sup>1</sup>Centro Hospitalar e Universitário de Coimbra, <sup>2</sup>Faculdade de Medicina Universidade de Coimbra, Coimbra, Portugal, <sup>3</sup>Diakonhjemmet Hospital, Oslo, Norway, <sup>4</sup>Sorbonne Université, Paris, France

**Background:** Patient Acceptable Symptom State (PASS) is the highest acceptable level of symptoms which patients consider satisfactory. In the Rheumatoid Arthritis Impact Disease (RAID) questionnaire, seven domains of health of importance for RA patients are collected.<sup>1</sup>. It is possible that levels judged acceptable by patients vary according to the domain of health.

**Objectives:** To explore the relationship between seven RA domains of health (collected in the RAID) and PASS, and to define their PASS cut-off values.

**Methods:** This is a *post-hoc* analysis of the cross-sectional study for RAID validation. Each of 7 domains (table 1) was evaluated through a Numeric Rating Scale from 0 (best) to 10 (worst). PASS was calculated using the anchored method based on patients' perspective. Disease activity was assessed based on the DAS28–3 values (joint counts and ESR). Comparison of patients in PASS or not was assessed through Mann-Whitney or Chi-square test, as adequate. Variables with  $p < 0.05$  were included in multivariate logistic regression (Forward Conditional) analysis. The thresholds of PASS for each domain was calculated using the receiver-operating characteristic (ROC) curve and the optimal cut-off was determined through Youden Index. 75th percentile analyses were also performed (not shown).

**Results:** 549 patients [78% female, mean age 56.7 years, mean disease duration 12.3 years, mean (SD) DAS 28–3 2.7(1.2)] were analysed. The majority of patients (60.7%) considered themselves to be in PASS. Disease activity (DAS 28–3 mean 2.3 vs 3.4,  $p < 0.01$ ) and all seven domains of health were significantly lower in patients in PASS versus not in PASS ( $p < 0.001$ ). In multivariate analyses, lower disease activity (OR 0.72; 95%IC 0.56–0.92), lower pain (OR 0.75; 95%

IC:0.65–0.86) and better physical well-being (OR 0.74 95%; IC:0.65–0.85) were associated with being in PASS.

The cut-off for PASS was  $\leq 4.2$  for the total RAID score but varied across the seven domains (table 1), with Pain ( $\leq 5$ ) and Fatigue ( $\leq 5$ ) having the highest acceptability cut-offs. Sleep Disturbance and Coping were the domains with lowest thresholds compatible with PASS ( $\leq 3$ ).

**Table 1** Thresholds for Acceptable Status for each RAID domain, AUC: Area Under the Curve, and sensitivity and specificity versus PASS

Domain	Cut-off	AUC	Sensitivity (%)	Specificity (%)
Pain	$\leq 5$	0.84	80.5	72.9
Function	$\leq 4$	0.82	69.7	80.8
Fatigue	$\leq 5$	0.75	74.9	62.2
Sleep	$\leq 3$	0.70	64.2	67.4
Emotional Well-Being	$\leq 4$	0.76	75.0	64.5
Physical Well Being	$\leq 4$	0.81	69.3	77.1
Coping	$\leq 3$	0.79	65.5	77.1

**Conclusions:** Pain and physical well-being appeared as major drivers of PASS. The cut-offs defining PASS were not the same for all RAID domains, indicating that being in PASS doesn't mean the same acceptable severity for all domains of health. This observation suggests that individualised management, for each domain, should be considered.

#### TITLE: THE CONSISTENCY OF OUTCOMES REPORTED IN TRIALS OF SYSTEMIC SCLEROSIS. IMPROVING OVER TIME?

D. J. Sumpton<sup>1,2,3,\*</sup>, A. Bigot<sup>4</sup>, B. Sautenet<sup>5</sup>, J. C. Craig<sup>2,3</sup>, G. Hassett<sup>6</sup>, V. Thakkar<sup>7,8</sup>, P. Tugwell<sup>9</sup>, A. Tong<sup>2,3</sup>. <sup>1</sup>Department of Rheumatology, Concord Repatriation General Hospital, <sup>2</sup>Sydney School of Public Health, The University of Sydney, <sup>3</sup>Centre for Kidney Research, The Children's Hospital Westmead, Sydney, Australia, <sup>4</sup>Service de Médecine Interne, <sup>5</sup>Service de Néphrologie, Hôpital Bretonneau, CHRU Tours, Tours, France, <sup>6</sup>Department of Rheumatology, Liverpool Hospital, Sydney, <sup>7</sup>Department of Rheumatology, Liverpool Hospital, <sup>8</sup>School of Medicine, Western Sydney University, Sydney, Australia, <sup>9</sup>Department of Medicine, University of Ottawa, Ottawa, Canada

**Background:** Standardisation of outcome domains and measures in trials in rheumatology has generally improved the consistency and relevance of outcomes reported in rheumatic conditions over the last two decades. The Outcome Measures in Rheumatology (OMERACT) 'core response set' for trials in Systemic Sclerosis (SSc) was developed in 2008 and comprises 11 domains and 31 measures<sup>1</sup>.

**Objectives:** We aimed to assess the scope, and consistency of outcomes reported in trials of SSc, and the uptake of this core response set.

**Methods:** MEDLINE, Cochrane CENTRAL, Embase and clinicaltrials.gov were searched to identify randomised clinical trials published between 2000 and June 2016 in adults with SSc. Outcomes and measures were recorded for each trial and classified into domains. The scope and consistency of domains were compared between those trials published from 2000 to 2010 and 2011 to mid-2016 to determine whether has been uptake of the core domain and measurement set reported. A two-year lag between publication of the core set in 2008 and start of the second-time period was set to allow to allow for core response set uptake.

**Results:** Overall 114 trials (4860 patients, median sample size of 33) were identified. The majority of trials were interventions for immunotherapeutic agents or vasodilators and included a total of 2736 measures (of 78 domains), with a mean of 24 measures per trial. The proportion of trials reporting any outcome from the each domain is listed: (% of 2000–2010 trials, % of 2011–2016 trials, change in %): health-related quality of life and function (42.6, 56.5, +13.9); skin (39.7, 47.8, +8.1); pulmonary (33.8, 43.5, +9.7); global health (14.7, 21.7, +7.0); gastrointestinal (4.4, 10.9, +6.5); ; cardiac (13.2, 15.2, +2); biomarkers of ESR/CRP (7.4, 8.7, +1.3%) musculoskeletal (5.9, 6.5, +0.6); Raynaud's phenomenon (20.6, 19.6, -1.0) renal (14.7, 10.9, -3.8); digital ulcers (23.5, 19.6, -3.9%). Six measures had a greater than 5% increase in reporting frequency across trial periods: HAQ-DI (from 38.2% to 47.8%), SF-36 (from 17.6% to 28.3%), Modified Rodnan Skin

Score (from 38.2 % to 47.8%), pulmonary function tests (from 30.9% to 43.5%), measures of dyspnoea (4.4% to 10.9%) and patient global disease (from 10.3% to 21.7%).

**Conclusions:** There was a wide range of domains reported in trials in systemic sclerosis. The uptake of domains and measure as per the core response set is low in SSc trials compared to other rheumatic diseases with only modest improvement in reporting of 6 out of 31 measures. Improvements in reporting of specific measures align with the recent development of a composite response index in systemic sclerosis (CRISS)2.

#### FRI0656 PREDICTIVE VALIDITY OF PRESENTEEISM MEASURES WITH DUAL ANSWER KEYS IN INFLAMMATORY ARTHRITIS

M. Donaldson<sup>1,2</sup>, A. Kobza<sup>2,3</sup>, D. E. Beaton<sup>4</sup>, H. Xie<sup>2,5</sup>, E. C. Sayre<sup>2</sup>, M. A. M. Gignac<sup>4,6</sup>, D. Lacaille<sup>1,2</sup>. <sup>1</sup>University of British Columbia, Vancouver, <sup>2</sup>Arthritis Research Canada, Richmond, <sup>3</sup>University of Ottawa, Ottawa, <sup>4</sup>Institute of Work and Health, Toronto, <sup>5</sup>Simon Fraser University, Burnaby, <sup>6</sup>University of Toronto, Toronto, Canada

**Background:** Employment studies in arthritis have emphasized the importance of decreased productivity at work, or presenteeism. However, consensus is still lacking on how to best measure this construct. Instruments used include the Work Limitations Questionnaire (WLQ), which measures the amount of time people are limited, and the Workplace Activity Limitations Scale (WALS), which measures the degree of difficulty. We modified the response keys of the WLQ and WALS, creating a dual answer key assessing both degree of difficulty and amount of time with difficulty. Previous work by our group has shown that scores obtained from combining responses to the dual answer keys exhibit good internal consistency, criterion and construct validity.

**Objectives:** The objective of this study was to evaluate the ability of the combined scores to predict future work cessation and number of work days missed due to arthritis.

**Methods:** A longitudinal study used baseline and 6-month data from the RCT of an employment intervention, the "Making It Work" Program. Inclusion criteria were: inflammatory arthritis, age 19–59, working at baseline, and concerns about arthritis affecting work. 327 participants were included (RA:173, PsA:48, SLE:42, AS:64). Combined scores were obtained by i) multiplying, and ii) adding, the scores of difficulty and time answer keys at the item level. We assessed the predictive ability of the combined scores, and the original scores, of the WALS and WLQ to predict work cessation due to arthritis within 6 months using binary logistic regression models, or number of work days missed due to arthritis using zero-inflated Poisson models.

**Results:** WLQ and WALS original and combined scores were significant predictors of future work cessation and number of work days missed. The WLQ combined scores predicted work cessation better than the original score (AIC:117.6 & 118.2 for multiplicative and additive combinations, respectively vs. 125.4 for time) and work days missed (AIC:2179.8 & 2177.8 vs. 2188.7). WALS original score (ie. degree of difficulty) predicted work cessation better than combined scores (AIC:95.8 vs. 109.3 & 109.4). However, WALS combined scores predicted number of work days missed better (AIC:1696.9 & 1673.4 vs. 1795.2).

**Conclusions:** Combined scores from dual answer keys applied to the WLQ and WALS significantly predicted future work cessation and number of work days missed. Using combined scores, rather than original answer keys, improved the ability of the WLQ to predict both work cessation and work days missed, but only improved the ability of the WALS to predict work days missed.

#### FRI0657 CONSTRUCT VALIDITY AND RESPONSIVENESS OF THREE STIFFNESS ITEMS IN RHEUMATOID ARTHRITIS: AN APPLICATION OF THE OMERACT FILTER 2.1

E. T. Craig<sup>1,\*</sup>, C. O. Bingham III<sup>1</sup>, S. J. Bartlett<sup>2</sup>, U. Haque<sup>1</sup>, A. Leong<sup>3</sup>, A.-M. Orbai<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Johns Hopkins University, Baltimore, United States, <sup>2</sup>Center for Mind Body Research, McGill University, Montreal, Canada, <sup>3</sup>Patient Research Partner, Santa Barbara, United States

**Background:** Stiffness is frequent and important to people with rheumatoid arthritis (RA), but measuring it is an unmet need. Qualitative research with people with RA has shown that stiffness duration, severity and interference have face and content validity. These items are being evaluated to develop a patient reported outcome measure (PROM) for stiffness.

**Objectives:** To evaluate individual stiffness item measurement properties using the OMERACT Filter 2.1.

**Methods:** Consecutive patients in a longitudinal RA cohort were enrolled. Participants completed 3 items assessing stiffness severity, interference, and duration. PROMs collected included patient global assessment (PGA), pain VAS, self-reported flare (Y/N), PROMIS measures, and patient global impression of change (PGIC). Physician assessments included 28 tender/swollen joint counts, and global (EGA). Disease activity indices were CDAI and DAS28-CRP. Stiffness construct validity was assessed using Spearman correlation coefficients. To assess discrimination in groups expected to change vs stable groups, we calculated standardized response means (SRMs) using multiple anchors.

**Results:** 196 patients with RA were included. **Construct validity:** all stiffness items correlated highly with pain; moderately with DAS-28 CRP and CDAI; and low with joint counts and EGA. Stiffness severity and interference correlated highly with PGA, pain interference and fatigue. Stiffness interference correlated highly with physical function. **Discrimination:** all stiffness items had moderate effect size for resolution of flare, and for 'much improved' by PGIC. Interference had moderate effect for improved CDAI category and for 'little improved' by PGIC. Stiffness duration had large effect for new RA flare, and 'much worse' by PGIC; severity and interference had moderate effect for RA flare; severity had moderate effect for worsened CDAI and for 'little worse' and 'much worse' by PGIC (Tb).

Table 1 Discrimination of stiffness items by anchor in RA longitudinal sample (n=181). SRM=mean change/pooled SD of change. SRM >0.8 large, 0.5–0.79 moderate, 0.2–0.5 small effect.

Stiffness Anchors	Duration SRM	Severity SRM	Interference SRM
<b>Flare status (n=181)</b>			
Flare to No flare (improved) (n=26)	0.67	0.68	0.54
No flare to No flare (unchanged) (n=111)	0.01	0.01	0.14
Flare to Flare (unchanged) (n=14)	0	0.19	0.27
No flare to Flare (worse) (n=30)	0.81	0.60	0.54
<b>PGIC vs baseline (n=181)</b>			
Much improved (n=26)	0.52	0.61	0.79
Little improved (n=25)	0.43	0.46	0.60
No change (n=68)	0.08	0.08	0.11
Little worse (n=49)	0.41	0.67	0.42
Much worse (n=13)	1.05	0.59	0.39
<b>CDAI vs baseline (n=181)</b>			
Better CDAI category (n=45)	0.25	0.21	0.61
Unchanged CDAI category (n=87)	0.07	0.12	0.04
Worse CDAI category (n=49)	0.48	0.52	0.29

**Conclusions:** In this cohort of RA patients there is emerging evidence for good construct validity for stiffness duration, severity and interference; moderate discrimination for improvement in RA disease state, and moderate to high discrimination for worsening RA. Additional items are being tested to assemble an instrument for measuring stiffness in RA.

**Disclosure of Interest:** None declared

#### FRI0658 PROGNOSTIC MARKERS FOR RESPONSE ACCORDING TO THE NEW ACR/EULAR 2016 RESPONSE CRITERIA FOR IDIOPATHIC INFLAMMATORY MYOSITIS

E. Espinosa-Ortega<sup>1</sup>, M. Holmqvist<sup>2</sup>, M. Dastmalchi<sup>1</sup>, I. Lundberg<sup>1</sup>, H. Alexanderson<sup>1</sup>. <sup>1</sup>Rheumatology Unit, Department of Medicine, Karolinska Institutet, <sup>2</sup>Institutionen för medicin, Solna, Stockholm, Sweden

**Background:** Idiopathic inflammatory myopathies (IIM) is a heterogeneous group of chronic, inflammatory diseases with varying response to treatment. To

date there is no biomarker to predict such response. Autoantibodies are found in up to 80% of patients with IIM; myositis associated (MAA) and myositis specific antibodies (MSA) are associated with certain clinical features. Whether MSAs can be used as biomarkers to predict response to treatment is unknown.

**Objectives:** To investigate predictors of response according to the New ACR/EULAR 2016 response criteria for idiopathic inflammatory myositis using a national rheumatology register.

**Methods:** Patients with IIM who were included in the Swedish Rheumatology Quality Register (SRQ) between January 1st, 2003 and December 31st, 2015 within 12 months of diagnosis were included in this study. Response was assessed at the visit registered closest to one year after inclusion. IIM subgroup (dermatomyositis (DM), polymyositis (PM) and overlap myositis), autoantibody profile, time to diagnosis and treatment were categorized into dichotomous variables. Time to diagnosis (from first symptoms) less than 3 months was considered as early; initial dose of glucocorticoids was considered high when >45 mg. The ACR/EULAR 2016 criteria for Clinical Response were applied to measure response, and it was categorized in minimal (20–39/100), moderate (40–59/100) and major (>60/100) response. The association between response and clinical characteristics was assessed by multinomial logistic regression.

**Results:** 179 patients were included. Median age at inclusion was 58.9 years (Interquartile range (IQR) 46.7–68.6), 65% were female and 49% had ever smoked. Thirty-three percent had DM, 45% PM and 22% overlap myositis. Lung disease was present in 37% and cancer within  $\pm 3$  years from IIM diagnosis was present in 13%. Ninety-one percent were given glucocorticoid treatment, 72% immunosuppressive drugs, 22% cyclophosphamide and 13% a biological drug. **Response rates.** Two thirds (62%) were responders, 23% had minimal, 20% moderate and 18% major response. Minimal response was associated with high initial glucocorticoid dose (OR 3.4, CI95% 1.4–8.1); moderate response to high initial glucocorticoid dose (4.8 CI95% 1.9–11.8) and major response to early diagnosis (OR 3.9 CI95% 1.3–11.9), and high initial glucocorticoids dose (OR 9.5 CI95% 3.0–29.8). No associations between IIM subgroup, autoantibody profile and response rates were observed.

**Conclusions:** Early and intensive treatment with high doses of glucocorticoids was associated with high rates of clinical response. These data suggest that early intensive immunosuppressive treatment is important in IIM.

FRI0659

#### INVESTIGATION OF SELF-REPORTED PAINFUL JOINT COUNT AS OUTCOME MEASURE IN HAND OSTEOARTHRITIS

F. Kroon<sup>1</sup>, J. van der Plas<sup>1</sup>, S. van Beest<sup>1</sup>, W. Damman<sup>1</sup>, M. Kloppenburg<sup>1,2</sup>.

<sup>1</sup>Rheumatology, <sup>2</sup>Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**Background:** Hand osteoarthritis (OA) research is in need of disease-specific validated instruments to measure patient-reported outcomes. Self-reported painful joint count (PJC) could be useful to assess pain, including information about the distribution of painful joints, while being less time-consuming than assessor-reported tender joint count (TJC).

**Objectives:** To investigate the metric properties of self-reported PJC compared to assessor-reported TJC to measure pain.

**Methods:** Symptomatic hand OA patients from the Hand Osteoarthritis in Secondary care (HOSTAS) study marked which joints were painful on standardized hand diagrams. Pain upon palpation was scored on similar diagrams by trained nurses, who were unaware of patients' scores. Self- and assessor-reported joint counts were calculated as the sum of painful/tender joints of both hands (range 0–30). Patients also rated pain on visual analogue scale and completed Australian/Canadian Hand Osteoarthritis index pain subscale, Short Form-36 Mental/Physical Component Summary scales, and Hospital Anxiety and Depression Scale. Radiographs were scored according to Kellgren-Lawrence. MRIs of the right distal and proximal interphalangeal joints (DIPs/PIPs) were evaluated for bone marrow lesions and synovitis. Validity was investigated by assessing correlations between self-reported PJC and assessor-reported TJC, and of both joint counts with other outcome measures. Absolute agreement on joint level, and patient level intra-class correlation coefficients (ICCs) were calculated.

**Results:** Of 524 hand OA patients (86% women, mean age 61, 90% fulfilling ACR criteria), 506 (96.9%) reported  $\geq 1$  painful joint (median PJC 8 [interquartile range (IQR) 4–13]), while nurses reported  $\geq 1$  tender joint in 426 (81.3%) patients (TJC 3 [1–7]). Patients and assessors both most frequently reported pain/tenderness in DIP 2–3, PIP 2–3 and the thumb base, and least often in metacarpophalangeal joints (MCPs) 2–5. Correlation between the joint counts was 0.38. Correlations of both joint counts with other measures were comparable, ranging from 0.11 to 0.37 (table 1). Absolute agreement was highest in MCPs 2–5 and lowest for thumb base, DIP 2–3 and PIP 2–3 (range 61%–89%). ICC between joint counts was 0.28 (95% confidence interval 0.08–0.14).

**Table 1** Correlation coefficients for painful joint count (PJC), tender joint count (TJC), and selected clinical and imaging outcomes.

	Self-reported PJC	Assessor-reported TJC
Self-reported PJC	-	
Assessor-reported TJC	0.38**	-
VAS pain	0.37**	0.37**
AUSCAN pain	0.36**	0.36**
SF-36 PCS	-0.30**	-0.27**
SF-36 MCS	-0.12**	-0.11**
HADS depression scale	0.14**	0.15**
Kellgren-Lawrence score	0.08	0.04
MRI synovitis†	0.22*	0.21*
MRI BML†	0.14	0.22*

AUSCAN, Australian/Canadian osteoarthritis hand index; BML, bone marrow lesion; HADS, Hospital Anxiety and Depression Scale; MCS, mental component summary; MRI, magnetic resonance imaging; PCS, physical component summary; SF-36, Short Form 36; VAS, visual analogue scale. \* $p < 0.05$ ; \*\* $p < 0.01$ ; †Joint count of DIP and PIP joints of right hand (n=92) was used (range 0–8).

**Conclusions:** Hand OA patients reported more painful joints than assessors reported tender joints. Self-reported PJC correlated weakly with assessor-reported TJC, and other instruments measuring pain and physical health. Divergent correlations with mental health and imaging scores were even lower. Agreement between patients and assessors was highest in joints with low prevalence of pain/tenderness, but overall agreement was low. Despite apparent advantages, these results suggest that self-reported PJC and assessor-reported TJC cannot be used interchangeably, and further study of PJC as an outcome measure in hand OA is warranted.

**USEFULNESS OF MICHIGAN HAND OUTCOMES QUESTIONNAIRE (MHQ) IN HAND OSTEOARTHRITIS**

F. Kroon<sup>1</sup>, A. Boersma<sup>1</sup>, A. Boonen<sup>2</sup>, S. van Beest<sup>1</sup>, F. Rosendaal<sup>3</sup>, M. Kloppenburg<sup>1,3</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden, <sup>2</sup>Rheumatology, Maastricht University Medical Center, Maastricht, <sup>3</sup>Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**Background:** Several tools are available to measure hand pain and function in hand osteoarthritis (OA), though all have their disadvantages, e.g. being not freely available (Australian/Canadian Hand OA Index, AUSCAN), outdated (Functional assessment In Hand OA, FIHOA) or a single-item tool (Visual Analogue Scale, VAS). The MHQ is free to use, validated in other diseases, and has 6 scales assessing pain, function (overall function and activities of daily living [ADL]), and 3 unique domains: work performance, aesthetics, satisfaction (all range 0–100, and higher is better except for pain).

**Objectives:** To investigate truth and discrimination of MHQ in hand OA.

**Methods:** At baseline (n=383) and two-year follow-up (n=293) symptomatic hand OA patients from the Hand Osteoarthritis in Secondary care (HOSTAS) cohort completed questionnaires (MHQ, AUSCAN, FIHOA, VAS pain). Work status was categorized into (fulltime/part-time) employed, reduced working capacity (sick leave or partial/complete disability to work), or not in the workforce (unemployed or retired). Reduced working capacity could be due to hand OA or other causes. Anchor questions assessed whether level of pain/function was acceptable or unacceptable, and different (worse, unchanged or improved) compared to baseline. Number of joints with deformities was assessed, and split into tertiles (<3, 3–5, >5). To appraise validity of MHQ pain and function domains correlation with existing instruments (Spearman correlation coefficients,  $r_s$ ) was evaluated. Using external anchors to categorize patients, validity of the unique domains and discrimination of all domains was visualized in cumulative probability plots (figure 1), and mean between-group difference (MD) was calculated with linear regression.

**Results:** At baseline patients (84% women, median age 60.3, 90% fulfilling ACR criteria) reported moderate pain (median, interquartile range MHQ pain 45, 31.3–60) and functional impairment (MHQ overall function 57.5, 50–67.5; ADL 80.5, 68.2–89.6). MHQ pain and function scales correlated well with existing instruments (table 1). Patients with reduced working capacity had worse MHQ work performance scores than employed patients (MD -25.7, 95% confidence interval [CI] -32.8; -18.6), and scores were worse if it was due to hand OA than when there was another cause (MD -21.4, -37.1; -5.8). MHQ aesthetics scores were worse in patients with more deformities (MD -1.03, -1.60; -0.45 per additional deformity). Patients with 'unacceptable' pain/function had worse MHQ satisfaction scores (eg. pain: MD -27.2, -37.1; -17.3). All instruments measuring pain/function could discriminate between patients with acceptable vs. unacceptable pain/function (not shown). MHQ ADL scale and AUSCAN function outperformed MHQ overall function and FIHOA in discriminating between patients whose function improved vs. worsened over time (not shown). For discrimination of change in pain over time, MHQ and AUSCAN pain both outperformed VAS pain.

**Conclusions:** MHQ performs at least as good and may replace existing instruments in measuring pain and function in hand OA. In addition, MHQ provides information on work performance, aesthetics and satisfaction, which is not measured by other questionnaires. Sensitivity-to-change has to be assessed in future trials.

**Background:** The incidence of subtalar joint (STJ) disease in patients with rheumatoid arthritis (RA) is greatly increased between five and ten years of disease duration and regularly precedes changes in the tibiotalar joint [1]. The joint is notoriously difficult to assess clinically and frequently overlooked in favour of the more accessible tibiotalar joint.

We hypothesized that US might be used as a reliable outcome measure to evaluate synovitis of the STJ in patients with RA. The objectives of this study were first, to develop an expert consensus derived definition of synovitis and scanning protocol for the STJ and second, to test the reliability of the definitions and protocol.

**Objectives:** To evaluate the intra- and interobserver reliability of the US assessment of STJ synovitis in patients with RA.

**Methods:** Following a Delphi process, twelve sonographers conducted an US reliability exercise on 10 RA patients with hindfoot pain. The anteromedial, posteromedial, and posterolateral STJ was assessed using B-mode and power Doppler (PD) techniques according to an agreed US protocol and using a 4-grade semi-quantitative grading score for synovitis (synovial hypertrophy (SH) and power Doppler (PD) signal) and a dichotomous score for the presence of joint effusion (JE). Intraobserver and interobserver reliability were computed by Cohen and Light kappa ( $\kappa$ ). Weighted  $\kappa$  coefficients with absolute weighting were computed for B-mode and PD signal.

**Results:** Mean weighted Cohen's kappa for SH, PD, and JE, was 0.80 (0.62–0.98), 0.61 (0.48–0.73), and 0.52 (0.36–0.67), respectively. Weighted Cohen's kappa for SH, PD, and JE in the anteromedial, posteromedial and posterolateral STJ was -0.04–0.79, 0.42–0.95, and 0.28–0.77; 0.31–1, -0.05–0.65, and -0.2–0.69; 0.66–1, 0.52–1, and 0.42–0.88, respectively. Weighted Light kappa for SH was 0.67 (95%CI 0.58–0.74), 0.46 (0.35–0.59) for PD, and 0.16 (0.08–0.27) for JE. Weighted Light kappa for SH, PD, and JE was 0.63 (0.45–0.82), 0.33 (0.19–0.42) and 0.09 (-0.01–0.19), for the anteromedial; 0.49 (0.27–0.64), 0.35 (0.27–0.4), and 0.04 (-0.06–0.1) for posteromedial, and 0.82 (0.75–0.89), 0.66 (0.56–0.8), and 0.18 (0.04–0.34) for posterolateral STJ, respectively.

**Conclusions:** Ultrasound is a feasible and reliable tool for assessing synovitis of the posterolateral STJ in RA, but not for the anteromedial and posteromedial STJ. SH can be reliably detected in B-mode and PD mode, but this is not true for JE.

FRI0662

**CALPROTECTIN S100 A8/A9 IN A SOUTH AFRICAN RHEUMATOID ARTHRITIS (RA) COHORT**

P. Meyer<sup>1</sup>, G. Van Rooyen<sup>2</sup>, R. Anderson<sup>3</sup>, M. Ally<sup>2</sup>, L. Winchow<sup>4</sup>, N. Govind<sup>4</sup>, M. Ticky<sup>4</sup>, H. Bang<sup>5</sup>. <sup>1</sup>Department of Immunology, University of Pretoria, National Health Laboratory Service, <sup>2</sup>Department of Rheumatology, Steve Biko Academic Hospital, <sup>3</sup>Department of Immunology, University of Pretoria, Faculty of Health Sciences, Pretoria, <sup>4</sup>Department of Rheumatology, Chris Hani Baragwanath Academic Hospital, Johannesburg, South Africa, <sup>5</sup>Orgentec Diagnostika GmbH, Friedrich-Alexander Universität Erlangen Nürnberg, Nürnberg, Germany

**Background:** Calprotectins (CLP) S100 A8/A9 are small calcium binding proteins [1] belonging to the group of damage-associated molecular patterns (DAMPs) or alarmins. They play a key role in the inflammatory response in RA. [2, 3] The measurement of CLP S100 A8/A9 in serum may be a useful strategy to optimize management of patients with RA. [4]

**Objectives:** To evaluate serum calprotectin S100 protein (A8 and A8/A9) levels in a South African RA Cohort in relation to disease severity at presentation in comparison with traditional RA-associated autoantibodies.

**Methods:** This was an observational, single-centre study, involving patients attending the Rheumatology Clinic of the Department of Internal Medicine, Chris Hani Baragwanath Academic Hospital (CHBAH) and University of the Witwatersrand, South Africa. The cohort consisted of 128 ethnic black RA DMARD-naïve patients. The study was approved by the local ethics committee and patients gave informed consent to participate.

**Results:** The baseline demographics and clinical data of the cohort are summarized in table 1. Calprotectin S100 A8 demonstrated a statistically significant association with disease severity [(both SDAI ( $p=0.005$ ) and DAS 28 ( $p=0.016$ )] by linear regression analysis. Calprotectin S100A8/A9 also showed significant associations with SDAI ( $p=0.010$ ) and DAS28 ( $p=0.022$ ) figure 1.

**Table 1** Clinical and demographic data of patients with RA

Sex	Freq	Percent	Cum
Male	23	17.97	17.97
Female	105	82.03	100.00
DAS 28	25	19.53	19.53
Inactive			
DAS 28	57	44.53	64.06
Moderate			
DAS 28	46	35.94	100.00
Very Active			
SDAI	9	7.03	7.03
Remission			
SDAI	16	12.50	19.53
Low DA			
SDAI	45	35.16	54.69
Mod DA			
SDAI	58	45.31	100.00
High DA			
CCP	10	7.81	7.81
Negative			
CCP	118	92.19	100.00
Positive			
RF	8	6.25	6.25
Negative			
RF Positive	120	93.75	100.00
MCV	7	5.47	5.47
Negative			
MCV	121	94.53	100.00
Positive			

**Conclusions:** Unlike those of traditional autoantibodies, serum levels of calprotectin correlate strongly with disease severity of RA patients. These findings suggest that calprotectin S100 is a promising biomarker for assessment and monitoring of disease activity in RA.

#### FR10663 THE FINE SPECIFICITY OF ANTI-DRUG ANTIBODY RESPONSES TO ORIGINATOR AND BIOSIMILAR INFLIXIMAB: ANALYSES ACROSS FIVE DISEASES FROM THE 52-WEEK RANDOMIZED NOR-SWITCH STUDY

G. L. Goll<sup>1</sup>, N. Bolstad<sup>2</sup>, I. Iria<sup>3,4</sup>, R. A. Klaasen<sup>2</sup>, K. K. Jorgensen<sup>5</sup>, I. C. Olsen<sup>1</sup>, A. Valido<sup>6,7</sup>, M. J. Saavedra<sup>6,7</sup>, J. E. Fonseca<sup>6,7</sup>, K. Lundin<sup>8</sup>, D. J. Warren<sup>2</sup>, E. Haavardsholm<sup>1</sup>, J. Jahnsen<sup>5</sup>, T. K. Kvien<sup>1</sup>, J. Goncalves<sup>3,4</sup>. <sup>1</sup>Dept of Rheumatology, Diakonhjemmet Hospital, <sup>2</sup>Dept of Medical Biochemistry, DNR-Oslo University Hospital, Oslo, Norway, <sup>3</sup>Faculdade de Farmacia, Universidade de Lisboa, <sup>4</sup>iMed, Research Institute for Medicines, Lisbon, Portugal, <sup>5</sup>Dept of Gastroenterology, Akershus University Hospital, Lørenskog, Norway, <sup>6</sup>Rheumatology Research unit, Ins. de Medicina Molecular, Lisbon Academic Medical center, <sup>7</sup>Rheumatology and Metabolic Bone Diseases Dept, Hospital de Santa Maria, Lisbon, Portugal, <sup>8</sup>Dept of Gastroenterology, RH-Oslo University Hospital, Oslo, Norway

**Background:** Norway's government funded the NOR-SWITCH study to investigate switching from originator infliximab (INX) to biosimilar CT-P13 in Crohn's disease (CD), ulcerative colitis (UC), spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) and chronic plaque psoriasis (Ps). Previously, the main analyses have been published<sup>1</sup>. Immunogenicity is associated with treatment failure and is of particular concern in switching<sup>2</sup>.

**Objectives:** To evaluate the consistency and fine specificity of anti-drug antibody (ADAb) responses to INX and CT-P13, in arthritis and IBD patients, after switching from INX to CT-P13.

**Methods:** The study included adult patients with CD, UC, SpA, RA, PsA or Ps<sup>1</sup>. Assays for drug serum levels and ADAb have been described<sup>1</sup>. ADAb positive sera were tested for cross-reactivity to 5 batches of INX and CT-P13. We quantified IgG4 ADAb, testing for functional inhibition. Infliximab peptides were used to compare epitope recognition of positive sera. Immunogenic infliximab-epitopes were identified by ELISA and sera compared across diseases.

**Results:** We tested 15 controls, 15 arthritis, 21 IBD patients. No Ps patients had ADABs in our study. All 23 anti-CT-P13 and 13 anti-INX sera cross-reacted with INX and CT-P13, respectively. ADAb concentrations to INX or CT-P13 correlated strongly (r values between 0.92 and 0.99,  $p<0.001$  for all experiments, Spearman's correlation test). Sera negative for CT-P13 ADAb (10 healthy controls, 5 RA patients) were also anti-INX negative. IgG4 ADAb in all sera recognized 5 different batches of CT-P13 and INX. All positive sera had similar functional inhibition of CT-P13 or INX TNF-binding capacity, showing reduced binding to CT-P13 in the presence of 5 different batches of CT-P13 and INX. 60%-79% of patients recognized 7 synthetic peptides corresponding to major anti-infliximab epitopes, with no significant differences between CT-P13 and INX ADAb. Three minor epitopes in framework regions of infliximab showed reduced antibody reactivity in 30%-50% of patients. Stratifying by diagnosis, we found two epitopes in the variable and constant heavy-chains of infliximab specifically recognized in IBD patients but not rheumatic patients.

**Conclusions:** ADABs to INX also recognize CT-P13, with similar epitopes. We found no consistent difference in ADAb epitope specificity between diagnoses. However, two specific minor epitopes are only recognized by IBD patients which might reflect the importance of HLA background for ADAb.

#### FRI0664 BIOMARKERS FOR RELAPSE IN PATIENTS WITH ADULT ONSET STILL'S DISEASE TREATED WITH IL-6 INHIBITOR.

H. Yamada<sup>1</sup>, Y. Kaneko<sup>1</sup>, T. Takeuchi<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Keio University, Shinjuku, Tokyo, Japan

**Background:** Symptoms and laboratory data in patients with adult onset Still's disease patients (AOSD) at relapse are often non-specific. Especially in AOSD patients treated with tocilizumab, IL-6 receptor inhibitor, inflammatory markers such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are almost normal despite flared disease activity.

**Objectives:** To identify useful biomarkers for assessing disease activity and relapse in AOSD patients treated with tocilizumab.

**Methods:** Consecutive AOSD patients diagnosed by Yamaguchi's criteria in our institution from January 2007 until January 2018 were reviewed. Clinical information was collected from their medical charts. Relapse was defined as a case who required immunosuppressive treatment intensification for AOSD according to their attending physicians. Biomarkers were compared between before relapse and at relapse.

**Results:** Forty eight patients with AOSD were enrolled. Thirty relapses during the observation period of 3.5 years were identified. At relapse, white blood cell count (WBC), CRP, ESR, serum ferritin levels, and serum lactate dehydrogenase (LDH) levels significantly increased compared to before relapse (WBC,  $12123 \pm 1238$  / $\mu$ L vs  $7184 \pm 607$  / $\mu$ L,  $P=0.002$ ; CRP,  $4.37 \pm 1.08$  mg/dL vs  $0.32 \pm 0.18$  mg/dL,  $P=0.003$ ; ESR  $39.1 \pm 7.78$  mm/hr vs  $6.67 \pm 1.46$  mm/hr,  $P=0.001$ ; ferritin,  $78.9 \pm 30.9$  ng/mL vs  $24.9 \pm 3.8$  ng/mL,  $P=0.036$ ; LDH,  $374.8 \pm 48.1$  IU/mL vs  $214.7 \pm 16.8$  IU/mL,  $P=0.005$ ). Six patients were identified to experience relapse with fever, active synovitis, rash or lymphadenopathy while treated with tocilizumab. In patients treated with tocilizumab, while neither CRP nor ESR increased in all patients at relapse (CRP < 0.30 mg/dL in all; ESR,  $4.50 \pm 1.04$  mm/hr vs  $3.75 \pm 1.18$  mm/hr,  $P=0.893$ ), LDH was significantly elevated at relapse compared to before relapse ( $451.2 \pm 92.1$  IU/mL vs  $211.2 \pm 24.6$  IU/mL,  $P=0.04$ ). WBC and serum ferritin levels tended to increase but with no significant difference (WBC:  $14620 \pm 1547$  / $\mu$ L vs  $9500 \pm 2285$  / $\mu$ L,  $P=0.21$ ; ferritin,  $236.4 \pm 91.2$  ng/mL vs  $49.2 \pm 24.2$  ng/mL,  $P=0.091$ ).

**Conclusions:** Instead of CRP and ESR, LDH level was a useful clinical biomarker for relapse of AOSD, especially in those treated with tocilizumab.

**Disclosure of Interest:** None declared

#### FRI0665 IMPACT OF THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE RESULTS ON WHETHER RHEUMATOLOGISTS CHANGED BIOLOGIC THERAPY FOR RA PATIENTS

J. Curtis<sup>1</sup>, K. Ford<sup>2</sup>, L. Chen<sup>1</sup>, H. Yun<sup>1</sup>, F. Xie<sup>1</sup>. <sup>1</sup>University of Alabama at Birmingham, Birmingham, <sup>2</sup>Myriad Genetics, Inc., South San Francisco, United States

**Background:** The multi-biomarker disease activity (MBDA) score is a validated test used to assess disease activity for patients with rheumatoid arthritis (RA). How it is used in clinical practice in the U.S. is unclear.

**Objectives:** We evaluated the likelihood that rheumatologists would add or switch biologic therapies based on the MBDA test result.

**Methods:** Using previously published methods, we linked results of MBDA tests obtained as part of routine clinical care to 2012–2014 Medicare fee for service claims data for RA patients. We characterized patients as being on a biologic or targeted synthetic DMARD in the 90 days prior to the MBDA test and evaluated biologic/tofacitinib treatment changes in the 90 days following the MBDA test. MBDA test scores were classified as low (<30), moderate (30–44), and high (>44). The unit of analysis was the 90-day interval before and after each MBDA test score. Alternating logistic regression was used to compute odds ratios (OR) to quantify the likelihood that patients made any change (add or switch), accounting for the clustered nature of the data (intervals nested within patients, and patients nested within doctor practices) and physician-level variability, controlling

for patient age and sex. Sensitivity analyses used a 6-month interval for outcome ascertainment after the MBDA test.

**Results:** Using previously validated methods, a total of 27,621 unique RA patients were linked to 44,438 MBDA test scores. For the 27,256 intervals where RA patients were not on biologic therapy when the MBDA score was obtained, a total of 13.2% of patients added a biologic. Patients with high MBDA scores were significantly more likely to add a biologic (table 1). For the 17,182 intervals where RA patients were already on a biologic, a total of 19.1% of patients switched or stopped the biologic that they were taking. Patients with lower MBDA scores were significantly more likely to stay on their therapy, whereas those with higher scores were more likely to stop and/or switch biologics. After adjustment, results from the regression analyses showed that patients with moderate MBDA scores were 1.47 (95% 1.29–1.67)-fold more likely to add or switch biologics, and those with high MBDA scores were 2.54 (95% CI 2.19–2.94)-fold more likely to add or switch biologics. Men (OR=0.90, 95% 0.82–0.98) and older patients (OR=0.92 per 5 year increment, 95% CI 0.91–0.93) were less likely to add or switch therapy, even after controlling for variability between physicians (OR=1.10, 95% CI 1.02–1.19). These results were robust and ORs were numerically larger when extending the interval to 6 months.

Table 1 Proportion of patients who added or switching biologics after the MBDA test

MBDA Score	Non-biologic users who added a biologic after the MBDA test N=27,256	Biologic Users Who Switched or Stopped their Current Biologic after the MBDA test N=17,182
Low (<30)	8.4%	14.0%
Moderate (30–44)	10.8%	16.2%
High (>44)	16.3%	23.1%
Chi-square p value	<0.0001	<0.0001

**Conclusions:** Results from the MBDA score were significantly associated with the likelihood that a physician added or switched biologic therapies, with either type of change being more frequent when the MBDA score was high. Further evaluation of outcomes after switching, conditional on the MBDA score, is warranted.

#### FRI0666 CIRCULATING MIR-99B-5P AS A PREDICTOR OF EROSION PROGRESSION IN EARLY RHEUMATOID ARTHRITIS: A 1-YEAR FOLLOW-UP STUDY BY HR-pQCT

J. Yue<sup>1</sup>, J. F. Griffith<sup>2</sup>, J. Xu<sup>3</sup>, F. Xiao<sup>2</sup>, L. Shi<sup>2</sup>, D. Wang<sup>2</sup>, P. C. Wong<sup>1</sup>, E. K. Li<sup>1</sup>, M. Li<sup>1</sup>, T. K. Li<sup>1</sup>, T. Y. Zhu<sup>3</sup>, V. Hung<sup>3</sup>, L. Qin<sup>3</sup>, L.-S. Tam<sup>1</sup>. <sup>1</sup>Department of Medicine & Therapeutics, <sup>2</sup>Department of Imaging and Interventional Radiology, <sup>3</sup>Department of Orthopedics & Traumatology, Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hong Kong

**Background:** Bone erosion is a key feature of RA reflecting both disease severity and progression. HR-pQCT is an in-vivo clinical imaging system allowing detailed analysis of bone structure, including bone erosion. Several circulating microRNAs have already been suggested as potential biomarkers in RA.

**Objectives:** To determine whether plasma cell-free circulating miRNAs are 1) associated with bone erosion at presentation and 2) predictive of erosion progression at 12 months as determined by HR-pQCT in patients with early rheumatoid arthritis (ERA).

**Methods:** In this prospective study, 124 ERA patients were treated with a tight control protocol aiming at remission by using conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs). The second metacarpophalangeal joint (MCP2) was assessed for erosions by HR-pQCT at baseline and after 12 months. Plasma cell-free circulating miRNAs at baseline were identified by microRNA array in 10 treatment-naïve ERA patients with maximal erosion volume at MCP2; in 10 treatment-naïve ERA patients without erosion; and in 6 age- and sex-matched healthy controls. The 4 most dysregulated miRNAs were identified by TaqMan<sup>®</sup> qRT-PCR in these same 20 ERA patients. Thereafter, the expression of these 4 selected miRNAs was validated in all 124 ERA patients at baseline.

**Results:** Of the 377 screened miRNAs, 155 miRNAs were detectable. 94 (60.6%) of these detectable miRNAs were upregulated in ERA patient with erosions, with 13 (8.4%) upregulated more than twofold. 61 (39.4%) miRNAs were

downregulated in ERA patients with erosions, with 6 (3.9%) downregulated more than twofold. A total of 16 miRNAs were differentially expressed ( $P < 0.05$ ) and 4 were possibly differentially expressed ( $P \leq 0.1$ ) between ERA patients with and without erosions. At baseline, expressions of miR-143-3p, miR-145-5p and miR-99b-5p were significantly higher in ERA patients with erosions than those without erosions ( $P < 0.05$  for all). After 12 months of csDMARDs treatment, 31.7%, 47.7%, and 20.6% of the ERA patients had erosion progression, stable erosion and partial erosion repair respectively. Logistic regression analysis revealed baseline expression of miR-99b-5p to be an independent predictor of erosion progression at 12 months (Exp [B]= 4.203, 95% CI 1.166–15.147,  $P=0.028$ ) (table 1).

	Univariate			Multivariate		
	P value	Exp (B)	95% CI	P value	Exp (B)	95% CI
Depth	0.068	0.479	0.217–1.056	0.085	0.177	0.025–1.269
Width	0.108	0.746	0.522–1.067	0.871	1.069	0.481–2.373
RF+	0.102	3.833	0.764–19.224	0.087	5.407	0.784–37.317
ACPA>250U	0.062	3.281	0.941–11.439	0.084	4.238	0.822–21.843
miR99b-5p	0.075	2.512	0.913–6.905	0.028	4.203	1.166–15.147

**Conclusions:** Increased level of cell-free circulating miR-99b-5p was associated with erosions at presentation in ERA patients and could predict erosion progression as assessed by HR-pQCT over a period of 12 months, indicating that it may well serve as a biomarker of poor response to csDMARDs. Whether early biologic DMARDs use in these miR-99b-5p positive patients could reduce or prevent progression of erosion will need to be addressed in future studies.

#### FRI0667 DEVELOPMENT AND VALIDATION OF A RHEUMATOLOGIST SATISFACTION WITH PRACTICE SCALE- "THE RHEUMATOLOGIST SATISFACTION SCALE" (RSS)

K. Sheth<sup>1</sup>, A. Valenzuela<sup>1</sup>, S. Shoor<sup>1</sup>, P. Ritter<sup>1</sup>, K. Lorig<sup>1</sup>. <sup>1</sup>Stanford University, Palo Alto, United States

**Background:** Rheumatology practice improvement research routinely measures patient satisfaction and disease-specific outcomes but seldom considers the satisfaction of physicians who deliver the care. Studies suggest that physician dissatisfaction may pose a barrier to implementing quality improvement efforts. There is a paucity of succinct measures of physician satisfaction.

**Objectives:** As part of a Performance Improvement Project, in an academic rheumatology practice and an affiliated practice, we developed and piloted a simple questionnaire to study physician satisfaction in Rheumatology.

**Methods:** Thirty-five rheumatologists in the academic or private setting were sent opened-ended questions to determine the factors that made them satisfied or dissatisfied with respect to their rheumatology practice. From the responses we formed 14 questions on a 0 to 10 scale centering on satisfaction and dissatisfaction. We then administered the questionnaires to a small pilot of 30 rheumatologists in academic and/or private setting.

**Results:** Our sample included 30 rheumatologists, from whom 60% were faculty members, 27 % were fellows. 53% (N=16) were males and the majority (77%) were salaried. Racial distribution was 57% white, 40% Asian, with 7% Hispanic/Latino ethnicity. The most common practice setting was academic medicine (80%, N=24), followed by multi-specialty group (10%, N=3), private practice (7%, N=2), and rheumatology group (3%, N=1). 40% (N=12) and 37% (N=11) had been in practice <5 and >30 years, respectively. Coefficient Alpha for each factor was 0.54 (raw), 0.66 (standardized) for satisfaction and 0.60 (raw), 0.60 (standardized) for dissatisfaction. Based on the results of this survey, mean satisfaction factor in rheumatologists was high (8.6±0.99). 91.3% of rheumatologists (N=21) had mean satisfaction factor >8 (range 5.5–9.9). The ability to make a difference in patient's life and having the opportunity to work with great colleagues were the strongest contributors to physicians' satisfaction (mean 9.2±1.1 and 9.4±0.8, respectively). Time spent on documentation and getting inappropriate referrals that are not in the scope of practice were among the strongest contributors to physicians' dissatisfaction (mean 3±1.9 and 3.9±1.3, respectively). None of the items were highly correlated with each other. This work has now been expanded to more than 150 rheumatologists including in the United States(US) and Latin American countries. Analysis is in progress.

**Conclusions:** A simple and practical questionnaire to measure physician satisfaction was developed and successfully piloted on a predominately academic sample of rheumatologists. The strongest correlates of physician satisfaction

were the "ability to make a difference in a patient's life" and to "work with great colleagues" whereas the greatest correlates of dissatisfaction were "time spent on documentation" and "inappropriate referrals." With further testing on a larger sample from the US and Latin American countries, we aim to gain a deeper understanding of how the cultural differences and practice of medicine may affect physician satisfaction. It is hoped that, this scale will serve as a means of determining aids and barriers to improving rheumatology practice for both patients and physicians and become a useful tool in rheumatology performance practice implementations and studies.

Pinheiro<sup>7</sup>, E. Soriano<sup>8</sup>, N. Wulfrat<sup>9</sup>, A. Zink<sup>10</sup>, M. van de laar<sup>2,11</sup>. <sup>1</sup>Psychology, Health & Technology and Arthritis center Twente, University of Twente, <sup>2</sup>Department of Rheumatology and Clinical Immunology, Medisch Spectrum Twente, Enschede, Netherlands, <sup>3</sup>Division of Rheumatology, University Hospitals of Geneva, Geneva, Switzerland, <sup>4</sup>Rheumatology department, Pitié Salpêtrière hospital, Paris, France, <sup>5</sup>Dept of Rheumatology & Immunology, Singapore General Hospital, Singapore, Singapore, <sup>6</sup>University of Nebraska Medical Center, Omaha, United States, <sup>7</sup>Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, <sup>8</sup>Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, <sup>9</sup>Wilhelmina Children's Hospital, Utrecht, Netherlands, <sup>10</sup>Rheumatology and Clinical Immunology, Charité University Medicine Berlin, Berlin, Germany, <sup>11</sup>Department of Psychology, Health and Technology, University of Twente, Enschede, Netherlands

**Background:** Physical function is a core outcome domain in clinical trials in various inflammatory rheumatic diseases. It is also included in the recently developed International Consortium for Health Outcomes Measurement (ICHOM) standard set for patients with inflammatory arthritis. Physical function patient reported outcome measures (PROMs) are commonly collected in patient registries and are used by decision makers in ways that require outcomes to be aggregated across different data sources. A major barrier to such initiatives is that many different physical function PROMs are in widespread use, and results cannot be meaningfully compared across them, if the traditional scoring procedures based on summing of the individual item scores are used. This is because summed scores depend on both patient- and item characteristics. To facilitate standardization of physical function outcome measurement, we developed a common metric for ten commonly used physical function PROMs using item response theory (IRT), that can be used to adjust PROM scores for item characteristics.

**Methods:** Data of 16.386 patients with inflammatory arthritis from the United States National Databank of Rheumatic Disease, the Swiss Clinical Quality Management Registry, the National Database of the German Collaborative Arthritis Centres, the Dutch Rheumatoid Arthritis Monitoring Study, and several smaller observational studies were used to map the items of 10 commonly used physical function PROMs on a continuous latent physical function variable. The resulting common metric was cross-validated in an independent dataset of 243 patients with gout, osteoarthritis or polymyalgia rheumatica, in which four of the linked PROMs were administered

**Results:** Our analyses supported that all 97 items of the 10 included PROMs relate to a single underlying physical function variable and that responses to each item could be described by the generalized partial credit IRT model. In the cross-validation analyses we found congruent mean scores for four different PROMs when the IRT based scoring procedures were used.

**Conclusions:** We showed that scores obtained using the IRT based common metric developed in this study can be used to make physical function outcomes obtained using different physical function PROMs comparable.

#### FRI0669 PHYSICIAN GLOBAL ASSESSMENTS FOR DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS ARE ALL OVER THE MAP!

M.A. Turk<sup>1</sup>, J. Pope<sup>2</sup>. <sup>1</sup>Biochemistry, <sup>2</sup>Rheumatology, Schulich School of Medicine and Dentistry, London, Canada

**Background:** Assessments of disease activity in rheumatoid arthritis (RA) determine the course of treatment. Physician global assessments of disease activity (MD globals) are important outcomes in trials as they are part of the CDAI and

SDAI composite scores. MD globals may vary between physicians based on their age, sex, practice setting, experience, and years in practice.

**Objectives:** Our research goal was to determine which factors contribute to the variability of MD globals. We expected assessments to be lower as physician experience increased.

**Methods:** After obtaining ethics approval, we surveyed rheumatologists who were members of the Canadian Rheumatology Association with RA patient scenarios where each was rated as a MD global for disease activity from 0 – 10. The cases covered a range of disease activity; to determine extreme cases and cases in between. There were some scenarios where a change in status was given (i.e. a rating with one disease state and then the patient returned and another rating was given by each participant when the patient was obviously better or worse). Kappa, Intra-class correlation (ICC) coefficients, and linear mixed models were used to analyze the data

**Results:** We received 145 responses from eligible physicians spanning the above categories (approximately 40% response rate). Contrary to our original hypothesis, MD global assessments were not significantly different between physicians in any category (number of RA patients seen per year, years of experience, age, sex, type of practice [community vs. university], and self-reported expertise in RA). Moreover, the range of answers for the same scenario was as high as 7.6 out of a possible 10, indicating vast discrepancies between physicians. We checked to ensure the questions were not answered backwards by individuals using the scenarios where a patient changed disease activity over time. The agreement was highest in the extreme scenarios (very low and very high disease activity, but in the spectrum in between agreement was extremely poor). Some scenarios outlined changes in individual patients, however physicians surveyed were often in disagreement as to how well the patient recovered or worsened. The change in MD globals between one time and the next in the cases had better agreement than the actual scores.

normal population do not predict the CV risk in RA patients adequately due to the additional systemic inflammatory burden which is pathogenic for CV disease. Recently, Solomon et al developed the ERS-RA Risk Score, a newly and expanded CV risk score predicting the 10 year CV event risk in RA patients<sup>2</sup>. This is based on a cohort from the Consortium of Rheumatology Researchers of North America registry. In this abstract we present the results of a validation test performed with the ERS-RA Risk Score in the Dutch CARRÉ study<sup>3</sup>.

**Objectives:** To perform a validation test of the ERS-RA Risk Score in the Dutch CARRÉ study.

**Methods:** We validated the ERS-RA Risk Score in the CARRÉ cohort by performing a ROC curve analysis. The CARRÉ study is a Dutch cohort study investigating CVD and its risk factors in RA-patients who have been followed prospectively for at least five years. RA patients registered at Reade (location Jan van Breemen institute in Amsterdam, the Netherlands) participated if they fulfilled the 1987 ACR classification criteria, were diagnosed between 1989 and 2001, and were aged between 50 and 75 years. In contrast to the cohort used in study of Solomon et al, the CARRÉ study used the HAQ instead of the m-HAQ and the CARRÉ lacks the Predictor's Global Assessment to calculate the CDAl. However, to approximate the true outcome of the m-HAQ and the CDAl we conducted the following modifications of the CARRÉ cohort data. To calculate the CDAl we estimated the Predictor's Global Assessment as 70%, 80%, 100%, 110%, 120% and 130% of the Patient's Global Assessment. Furthermore, we approximated the m-HAQ score 50% lower than the HAQ score as described in a recent published article<sup>4</sup>.

**Results:** The CARRÉ study included 352 RA patients with 60 CV events over a 10 year follow up period. The mean age was 63.3 years of which 121 (34%) male participants. The ROC curve analysis shows an area under the curve of 0.603–0.612 depending on the predicted Predictor's Global Assessment (see figure 1).

**Figure 1.** ROC curve analysis of the ERS-RA Risk score in the CARRÉ cohort with different approximated CDAl scores

**Conclusions:** This research emphasizes the need to establish stringent evaluation criteria of disease activity as rated by the physician in RA; particularly if remission and low disease activity is used clinically by CDAl or SDAI. Perhaps a catalogue examples of patient scenarios of MD globals that range from 0 to 10 should be developed, standardized and agreed upon; to decrease the wide variability of ranking by rheumatologists.

### ADAPTATION AND VALIDATION OF THE ANKYLOSING SPONDYLITIS QUALITY OF LIFE (ASQOL) QUESTIONNAIRE FOR USE IN SERBIA

M. I. Zlatkovic-Svenda<sup>1</sup>, M. M. Radak-Perovic<sup>1</sup>, J. Milicevic<sup>2</sup>, R. Stojanovic<sup>1</sup>, B. Lazovic<sup>3</sup>, P. Ostojic<sup>1</sup>, J. Wilburn<sup>4</sup>, S. McKenna<sup>5</sup>. <sup>1</sup>Institute of Rheumatology, University of Belgrade School of medicine, Belgrade, <sup>2</sup>Hospital Center Uzice, General hospital Pozega, Uzice, <sup>3</sup>University Clinical Hospital Center Zemun, University of Belgrade School of Medicine, Belgrade, Serbia, <sup>4</sup>Galen Research Ltd, <sup>5</sup>School of Health Sciences, University of Manchester, Oxford Road, Manchester, United Kingdom

**Objectives:** To translate and adapt a Serbian version of the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire and to validate it in Serbian speaking AS patients.

**Methods:** The ASQoL development was conducted in three stages. The first stage comprised of a dual-panel translation: a bilingual panel (to provide the initial translation into the target language) and a lay panel (where items are assessed by people of average and below average education levels for comprehension and "naturalness" of language). The second stage involved cognitive debriefing interviews to assess the applicability, relevance and comprehensiveness of the new questionnaire. The third stage was a psychometric evaluation of the new questionnaire to assess construct validity, convergent validity and known-group validity. Convergent validity determined associations between ASQoL and NHP section scores by using Spearman's rank correlation coefficients. Known-group validity was evaluated by testing of the ASQoL ability to distinguish between groups of patients who differed according to perceived general health, incidence of flare-ups and perceived disease severity. Nonparametric tests for independent samples (Mann-Whitney U test for two groups or Kruskal-Wallis one-way analysis of variance for three or more groups) were used. Internal consistency was assessed using Cronbach's alpha coefficient. Reproducibility was measured by test-retest reliability.

**Results:** Cognitive debriefing interviews were conducted with 10 AS individuals (50% male), aged 38,4 (8,8) years. A few items (i.e. chronically and 'I get frustrated...') were not fully understood by all participants and were amended to be more natural sounding in Serbian. The Serbian ASQoL was deemed relevant, clear and easy to complete. Psychometric evaluation was conducted in 60 patients (70% male), aged 37,9 (11,1) years. No significant differences in ASQoL scores were found between males and females or between older and younger patients ( $p=0.41$ ,  $p=0.16$ ). Considering convergent validity, the ASQoL correlated the most strongly with the Pain ( $r=0.79$ ) and Emotional reactions ( $r=0.78$ ) sections of the NHP. The ASQoL highly correlated with the Physical mobility ( $r=0.77$ ) and Energy scales ( $r=0.75$ ), indicating the importance of these factors on QoL in AS. The ability of the Serbian ASQoL to detect meaningful differences was demonstrated by ASQoL scores according to patients perceived general health ( $p<0.05$ ) and disease severity ( $p<0.05$ ). Cronbach's alpha coefficient for the ASQoL was 0.95 at Time 1 and 0.91 at Time 2, indicating good internal consistency. Test-retest reliability was good, with a correlation coefficient of 0.84.

**Conclusions:** The Serbian version of the ASQoL demonstrated good psychometric properties proving it to be a valid and reliable tool for use in routine clinical practice and in clinical trials.

FRI0672

### ANTI-SACCHAROMYCES CEREVISIAE ANTIBODIES IN SPONDYLARTHROPATHIES: PREVALENCE AND ASSOCIATIONS WITH DISEASE PHENOTYPE

R. M. Ferreira<sup>1</sup>, F. Aguiar<sup>1</sup>, T. M. Rocha<sup>1</sup>, S. Ganhão<sup>1</sup>, A. Águeda<sup>2</sup>, M. Guerra<sup>3</sup>, S. Pimenta<sup>1</sup>, M. Bernardes<sup>1</sup>, L. Costa<sup>1</sup>. <sup>1</sup>Rheumatology, São João Hospital Centre, Porto, <sup>2</sup>Rheumatology, Centro Hospitalar Baixo Vouga, Aveiro, <sup>3</sup>Rheumatology, Centro Hospitalar Vila Nova Gaia, Gaia, Portugal

**Background:** It has been speculated that increased gut inflammation is of aetiopathogenic importance in the development of Spondylarthropathies (Spa). Serological markers, as anti-Saccharomyces cerevisiae antibodies (ASCA), which are rarely positive in healthy controls (<5%), possess clinical significance in inflammatory bowel disease (IBD) management.<sup>1</sup> Because Spa and IBD share similarities and even subclinical intestinal inflammation may be present in a high number of Spa patients, evaluation of this antibodies has gained increasing relevance.

**Objectives:** To investigate the status and frequency of ASCA in Spa patients and the association of these serological markers with the clinical profile.

**Methods:** We performed a retrospective study including SpA individuals treated with biologic therapy, followed at our Rheumatology department. Classification of SpA was based on the ASAS criteria. Medical records were obtained by consulting the national database (Reuma.pt). ASCA IgA and IgG levels were measured in the period time between 2016 and 2017 and determined by ELISA. The quantitative ASCA results were expressed in RU/ml and 20 was established as the cut-off point. X<sup>2</sup> or Fisher tests were used for analysis of categorical variables and t-test or Mann-Whitney for continuous variables (SPSS 23.0). The adopted significance was of 0.05.

**Results:** We included 231 Spa patients, 117 of which were men (51%), with a mean age of 48.6±12.5 years. The median disease duration was 17 years [min:2; max: 53]. In total, 39% of the patients had isolated axial form (n=90), 10% isolated peripheral form (n=23) and 51% presented axial and peripheral involvement (n=118). Nine patients had associated IBD [7 cases with Crohn Disease (CD) and 2 with Ulcerative Colitis (UC)] and 66 patients presented concurrent psoriasis (28.6%). Ninety-three patients (40%) were HLA-B27+ and 59 (26%) presented history of uveitis (current or previous). ASCA IgA were positive in 14% of the whole sample (n=33; 14 patients with isolated axial form, 4 with isolated peripheral form and 15 with axial and peripheral form). ASCA IgG positivity was found in 5% of the Spa (n=12; 7 patients with isolated axial form, 1 with isolated peripheral form and 4 with both forms). The median ASCA IgA and IgG titers were 72 RU/ml [min:22;max:200] and 45.5 RU/ml [min:28;max:200], respectively. We found no statistically significant difference in the number of ASCA IgA or IgG-positive patients in CD vs UC ( $p=0.722$ ;  $p=0.583$ ). Current age and at diagnosis, disease duration, gender, active or past smoking habits were similar between ASCA IgA or IgG-positive and negative groups. Also, disease phenotype including peripheral arthritis, axial involvement, psoriasis, HLA-B27 positivity and uveitis were unrelated to ASCA IgA and IgG status.

**Conclusions:** Our results showed that Spa patients presented an increase of ASCA IgA positivity, in agreement to previous data. No relationship of ASCA status was found with the demographic aspects or clinical presentation. In the future, our purpose is to investigate the relationship between antibody reactivity and endoscopic findings.

FRI0673

### DO PATIENT REPORTED OUTCOME MEASUREMENT INFORMATION SYSTEM (PROMIS) COMPUTER ADAPTIVE TESTS CORRELATE WITH DISEASE ACTIVITY IN JUVENILE IDIOPATHIC ARTHRITIS?

R. Trachtman<sup>1</sup>, E. T. Murray<sup>1</sup>, J. Szymonifka<sup>1</sup>, A. B. Adams<sup>1</sup>, N. Pan<sup>1</sup>, S. F. Taber<sup>1</sup>, K. B. Oneil<sup>1</sup>, L. A. Mandl<sup>1</sup>. <sup>1</sup>Hospital for Special Surgery/Weill Cornell Medicine, New York, United States

**Background:** The importance of patient-reported outcomes is increasingly recognized both in clinical care and in research. PROMIS is an NIH-supported collection of patient-reported outcome measures, covering a variety of domains that are designed without disease specificity. While 'short forms' have been studied in juvenile idiopathic arthritis (JIA), PROMIS computer adaptive tests (CATs) have not.

**Objectives:** This study evaluates whether PROMIS CATs correlate with disease activity in patients with JIA.

**Methods:** A convenience sample of patients with JIA (N=21) were recruited from a single center. Patients aged 10-17 years completed all available pediatric PROMIS CATs, and parents of patients aged 2-9 years completed all available parent proxy PROMIS CATs (fatigue, pain interference, peer relations, anxiety, depressive symptoms, and mobility). Correlation of the CATs t-scores with disease activity, as measured by the Juvenile Disease Activity Score-71 (JADAS-71), (0-101, higher being worse) was evaluated using Spearman correlation coefficients.

**Results:** All families approached completed the PROMIS CATs: 13 patients and 8 parents (table 1). Median age was 12.7 years (range 1.3 - 18.6 years), and mean JADAS-71 score was 9.58 (SD 2.07). 69% of patients completed PROMIS CATs remotely via smartphone. Anxiety ( $r=0.74$ ,  $p=0.006$ ), depressive symptoms ( $r=0.84$ ,  $p<0.001$ ), and pain interference ( $r=0.64$ ,  $p=0.018$ ) CATs correlated

strongly with JIA disease activity (table 2). Among parent proxy CATs, only anxiety correlated with disease activity ( $r=0.71$ ); however the association was not statistically significant.

Table 1 Patient characteristics

Characteristic	N=26 patients
Age, years, median [IQ range]	12.7 [6.0, 14.5]
Male	8 (30.8%)
White or Caucasian	20 (76.9%)
Insurance	
Medicaid	6 (23.1%)
Device	
Smartphone	18 (69.2%)
iPad	3 (11.5%)
Location	
In hospital	8 (30.8%)
Remotely	18 (69.2%)

Table 2 Spearman correlation coefficients for PROMIS domains and JADAS71 score

PROMIS domain	JADAS71 score Spearman correlation coefficient
<b>PATIENT SCORES</b>	
Fatigue T-score	0.488
<b>Pain Interference T-score</b>	<b>0.640</b>
Peer Relations T-score	-0.345
<b>Anxiety T-score</b>	<b>0.738</b>
<b>Depressive Symptoms T-score</b>	<b>0.840</b>
Mobility T-score	-0.671

**Conclusions:** Our results demonstrate that the PROMIS CATs are feasible to administer in an outpatient pediatric rheumatology setting. Anxiety, depressive symptoms, and pain interference were significantly correlated with disease activity, even though mean disease activity was relatively low. This underscores the negative effect on quality of life of even mild disease. Parent proxy CATs showed poor correlations with disease activity, suggesting parents are inaccurate in assessing important aspects of their child's health. Larger prospective studies are needed to evaluate the sensitivity of PROMIS CATs to change in disease activity over time.

#### FRI0674 APPLICABILITY OF THE PSAID12 QUESTIONNAIRE AS A CORE OUTCOME MEASUREMENT IN PSA CLINICAL TRIALS: AN EVALUATION USING OMERACT FILTER 2.1 INSTRUMENT SELECTION CRITERIA

R. Holland<sup>1</sup>, P. Højgaard<sup>1</sup>, B. Shea<sup>2</sup>, D. Beaton<sup>2</sup>, P. Tugwell<sup>2</sup>, M. de Wit<sup>1,2</sup>, W. Tillett<sup>1</sup>, R. Christensen<sup>1</sup>, N. McHugh<sup>1</sup>, P. Mease<sup>1</sup>, A.-M. Orba<sup>1</sup>. <sup>1</sup>Group for Research and Assessment of Psoriasis and Psoriatic Arthritis, <sup>2</sup>Outcome Measures in Rheumatology, International Organisation, -

**Background:** The Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA)–Outcome Measures in Rheumatology (OMERACT) Psoriatic Arthritis (PsA) Core Set working group is in the process of selecting core outcome measurements for PsA randomised trials, following OMERACT Filter 2.1 for instrument selection<sup>1</sup>. The Psoriatic Arthritis Impact of Disease questionnaire (PsAID12) passed the first two steps (domain match and feasibility) at the GRAPPA 2017 annual meeting and is a candidate instrument to measure PsA specific health related quality of life (HRQOL)/Life impact.

**Objectives:** To conduct a systematic review (SR) of the PsAID literature to review the measurement properties in the OMERACT Filter 2.1, assess specifically construct validity (truth) and discrimination of the PsAID12 questionnaire based on available evidence, and to identify gaps in knowledge that need to be covered in order for PsAID12 to pass Filter 2.1.

**Methods:** A SR of PsA patient reported outcomes (PROs) was performed January 1 2017 and updated by hand search (22/11/2017). All articles assessing the measurement properties of the PsAID12 were reviewed. Strength of evidence was rated using COSMIN-OMERACT Good Methods checklist, and performance of measurement properties using the OMERACT standards<sup>1</sup>. We extracted data on domain match (face and content validity), construct validity, test-retest reliability, longitudinal construct validity, clinical trials discrimination, and thresholds of meaning.

**Results:** We identified six studies (129–474 patients in each study) assessing the measurement properties of the PsAID12 in adults with PsA. Domain match: PsAID12 was developed with 12 patient research partners, 139 patients who ranked domain importance and cognitive interviews with 65 patients. Construct validity: Three studies assessed correlation of the PsAID12 with PROs and clinical outcomes, and one study with two PROs. There was strong correlation with measures of function (n=3 studies,  $r>0.66$ ), participation (1,  $r>0.69$ ), disease

activity (2,  $r=0.64–0.87$ ), and measures of pain, fatigue and stiffness (1 each,  $r>0.83$ ); moderate-strong with patient and physician global (3,  $r=0.49–0.84$ ); and moderate with 66/68 joint counts (1,  $r=0.4–0.57$ ) and dactylitis (1,  $r=0.49$ ). Test-retest reliability was high (0.91 (95%CI 0.87–0.94) and 0.95 (0.92–0.96)). Longitudinal construct validity was good with moderate to large standardized response mean (SRM) 0.74 (n=53, changed therapy) and 0.91 (n=71, changed therapy and rated themselves improved). The patient acceptable symptom state (PASS) was 4 in a single study. The minimal clinically important improvement (MCII) varied between 3 (original PsAID development study) and 1.25 (subsequent UK study).

**Conclusions:** This review suggests there is evidence for excellent content validity and reliability and good construct validity and responsiveness of the PsAID12 questionnaire as a measure of HRQOL in PsA. MCII and discrimination in clinical trials need to be defined.

#### FRI0675 RABIOPRED, AN INNOVATIVE THERANOSTIC TOOL TO ASSIST CLINICIANS SELECT AN OPTIMAL ANTI-TNF ALPHA BIOLOGICAL THERAPY FOR RHEUMATOID ARTHRITIS PATIENTS

S. Danilin<sup>1</sup>, E. Schordan<sup>1</sup>, M. Coq<sup>1</sup>, S. AIT ABBI NAZI<sup>1</sup>, M. Mehdi<sup>1</sup>, H. Firat<sup>1</sup>, N. Arber<sup>2</sup>, V. Breuil<sup>3</sup>, A.-L. Demoux<sup>4</sup>, A. Gül<sup>5</sup>, J.-E. Gottenberg<sup>6</sup>, G. Hatem<sup>7</sup>, T. Huizinga<sup>7</sup>, N. Inanc<sup>8</sup>, J. Vencovsky<sup>9</sup>, C. Jorgensen<sup>10</sup> on behalf of RABIOPRED Consortium – Horizon 2020 SME Instrument program. <sup>1</sup>FIRALIS, Huingue, France, <sup>2</sup>Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, <sup>3</sup>CHU Nice, Nice, <sup>4</sup>AP-HM, Marseille, France, <sup>5</sup>Istanbul Medical University, Istanbul, Turkey, <sup>6</sup>CHU Strasbourg, Strasbourg, France, <sup>7</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>8</sup>Marmara University, Istanbul, Turkey, <sup>9</sup>Institute of Rheumatology, Prague, Czech Republic, <sup>10</sup>CHU Montpellier, Montpellier, France

**Background:** TNF alpha blockers form 2nd line treatment choice for Rheumatoid Arthritis (RA) patients. Up to 30% of RA patients do not respond to TNF alpha blockers for unknown reasons, causing a significant impact on patients' outcome and healthcare industry. Therefore, there is an unmet need for a tool to predict treatment response that could help clinicians to choose an optimal treatment for RA patients.

**Objectives:** By using Immuno-Detect, an innovative targeted gene sequencing panel of 2155 mRNA targets associated with immune-inflammatory pathways, we aimed to develop an algorithm, RABIOPRED, that predicts non-response to TNF alpha blockers.

**Methods:** Paxgene samples obtained at baseline from 68 patients naïve to TNF alpha blockers were directly profiled without extraction with Immuno-Detect panel on HTG EdgeSeq platform, a combination of a nuclease protection assay & next generation sequencing (NGS). Patients were treated with Infliximab, Etanercept or Adalimumab and disease activity score was measured based on DAS28 score at 3 months. Response to treatment was assessed by categorizing the patients according to EULAR response criteria. Gene combinations were selected using variable importance score (VIS). Predictive modeling performance was evaluated using the area under the curve (AUC) and confusion matrix.

**Results:** Analytical validation of Immuno-Detect panel shows a very high reproducibility on Paxgene and extracted RNA samples with correlation factor of 0.975 and 0.96 respectively. In paxgene samples, among 2155 genes, 1172 mRNAs are significantly expressed with a mean CV of 9.77% (976 mRNAs and mean CV of 11.98% for RNA). Most expressed target represent only 5% of the total reads and only 20 targets are reaching 1% of total reads showing a very well balanced panel. Performance of our predictive model shows an AUC of 0.905 with 0.88 accuracy. Our algorithm predicts non-responders to TNF alpha blockers with the sensitivity of 0.78 and positive predictive value of 0.91. This algorithm will be further validated within the ongoing RABIOPRED Proof-of-Performance study (ClinicalTrials.gov Identifier: NCT03016260) based on 720 patients treated by anti-TNF alpha drugs (5 originators & 3 biosimilars) launched in December 2016.

**Conclusions:** We are showing that Immuno-Detect panel accurately measures mRNA expression using HTG-EdgeSeq NGS platform. This panel can be further used to build signatures to predict TNF alpha blocker's non-response. The algorithm obtained in the current study will be later on validated in a multi-centric proof-of-performance clinical study.

FRI0676

### RESPONSIVENESS OF PATIENT REPORTED OUTCOMES MEASUREMENT INFORMATION SYSTEM (PROMIS®) COMPUTERIZED ADAPTIVE TESTS (CATS) IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

S. Kasturi<sup>1</sup>, J. Szymonifka<sup>2</sup>, J. Berman<sup>2</sup>, K. Kirou<sup>2</sup>, A. Levine<sup>2</sup>, L. Sammaritano<sup>2</sup>, L. A. Mandi<sup>2</sup>. <sup>1</sup>Medicine/Rheumatology, Tufts Medical Center, Boston, <sup>2</sup>Medicine/Rheumatology, Hospital for Special Surgery, New York, United States

**Background:** The accurate measurement of patient reported outcomes is a priority for patient-centered care in SLE, a chronic systemic disease with significant impact on quality of life. PROMIS CATs are precise measures of physical, mental, and social health with construct validity in SLE. The longitudinal responsiveness (sensitivity to change) of PROMIS CATs in SLE patients is unknown.

**Objectives:** To evaluate the responsiveness of PROMIS CATs in SLE outpatients using patient and physician-derived anchors.

**Methods:** Adult SLE patients were recruited from an SLE Center of Excellence. Subjects completed 14 selected PROMIS CATs at two visits a minimum of one month apart. SLE disease activity was measured with a patient global assessment of change, a physician global assessment and the physician-derived SELENA-SLEDAI. Responsiveness of PROMIS scores was evaluated using known-groups validity. Effect sizes were compared across groups of patients who differed in their patient global assessment of change, physician global assessment, and SELENA-SLEDAI using Wilcoxon rank-sum tests.

**Results:** A diverse cohort of 228 SLE patients, including 45 (19.8%) patients flaring by SELENA-SLEDAI, completed baseline surveys. Follow up surveys were completed by 190 (83%). There was poor agreement between patient and physician global assessments (weighted kappa statistic [95% CI]=0.16 [0.04–0.28]). Using the patient-based anchor, Anger, Pain Interference, and Physical Function CATs showed low to moderate responsiveness (table 1). Using the physician global assessment, only Anxiety CAT showed low to moderate responsiveness (effect size -0.27, -0.17, and 0.06 [p=0.03] with ≥0.5 point decrease, <0.5 point change, and ≥0.5 point increase respectively), while with the SELENA-SLEDAI as anchor, only Applied Cognition-Abilities CAT showed responsiveness (0.34, -0.01, 0.0 [p<0.01] with ≥3 point decrease, <3 point change, and ≥3 point increase respectively).

PROMIS CAT	Patient Global Assessment of Change			p-value
	Better (n=74)	Same (n=79)	Worse (n=33)	
Ability to Participate in Social Roles	0.14	0.00	0.00	0.19
<b>Anger</b>	<b>-0.37</b>	<b>-0.08</b>	<b>0.00</b>	<b>0.03</b>
Anxiety	-0.38	-0.04	-0.02	0.13
Applied Cognition-Abilities	0.15	0.00	-0.03	0.30

<b>Pain Interference</b>	<b>0.00</b>	<b>0.00</b>	<b>0.25</b>	<b>0.02</b>
<b>Physical Function</b>	<b>0.15</b>	<b>0.01</b>	<b>-0.14</b>	<b>0.02</b>
Satisfaction with Social Roles & Activities	0.18	0.00	0.00	0.21
Sleep Disturbance	0.00	-0.14	-0.04	0.50
Sleep-Related Impairment	-0.07	0.00	-0.02	0.95

**Conclusions:** PROMIS CATs showed modest responsiveness to patient-reported, but generally not physician-derived changes in lupus health status in domains of anger, pain interference, and physical function. These data suggest that certain PROMIS CATs are precise and sensitive tools which may be used to measure and monitor important aspects of the patient experience of lupus not captured by physician-derived metrics. Further studies are needed to evaluate the responsiveness of PROMIS CATs in populations with greater SLE disease activity and more regular follow up.

### PREVALENCE AND SEROLOGICAL PROFILE OF ANTI-DFS70 POSITIVE SUBJECTS: DATA FROM A ROUTINE ANA COHORT

T. Carbone<sup>1,2</sup>, V. Pafundi<sup>2</sup>, G. Tramontano<sup>1</sup>, M. Gilio<sup>1</sup>, C. Esposito<sup>1</sup>, M. C. Padula<sup>1</sup>, A. A. Padula<sup>1</sup>, S. D'Angelo<sup>1</sup>. <sup>1</sup>Rheumatology Institute of Lucania – IReL, <sup>2</sup>Immunopathology Laboratory, San Carlo Hospital, Potenza, Italy

**Background:** Anti-Dense Fine Speckled 70 (DFS70) antibodies are a common finding in clinical laboratory referrals. High prevalence of DFS70 autoantibodies in

healthy population and usual negative association with Antinuclear Antibody (ANA)-associated autoimmune rheumatic diseases were reported.

**Objectives:** The aim of this study was to evaluate the prevalence of anti-DFS70 antibodies in a routine diagnostic laboratory setting and their association with other circulating serum autoantibodies.

**Methods:** Consecutive sera submitted for ANA screening were analyzed for anti-DFS70 antibodies by indirect immunofluorescence (IIF) (n=3175, 1030 men and 2145 women) then confirmed by Immunoblotting. IIF DFS70 positive adult patients were recruited previous written consent and tested for the following autoantibodies: anti-ENA, anti-dsDNA, -anti-TPO, anti-TG, anti-tTG, aCL, anti-PCA, AMA, ASMA, anti-LKM, anti-MPO, anti-PR3 and ASCAs.

**Results:** The prevalence of anti-DFS70 antibodies was 1.7% (n= 55) in the whole population and 4.6% in the ANA-positive samples. Comparison between DFS70 IIF and Immunoblotting showed an excellent correlation between the two methods (R=0.99). Analysis of anti-DFS70 antibodies titers distribution revealed that 63% of the total cohort showed high titers (≥1:640). Gender difference (female: male, 4:1) was observed in anti-DFS70 positive group and in anti-DFS70 negative/ANA positive group. The prevalence of anti-DFS70 positive female (2.1%, 45/2145) was statistically significant higher than males (1.0%, 10/1030) (p<0.05). The comparison among referring sources evidenced a prevalence of anti-DFS70 positive subjects from Endocrinology Department (9.1% versus 2.6% from Haematology, 2.1% from outpatients, 1.6% from Neurology, 1.2% from Internal Medicine, 1% from Cardiology, 0.6% from Rheumatology). Of note, our data evidenced isolated reactivity of anti-DFS70 autoantibodies in males group, while 51% of females showed concomitant disease-marker autoantibodies.

**Conclusions:** We found a prevalence of anti-DFS70 antibodies in adult sera from routine ANA cohort of 1.7%. The serological profile of DFS70-positive females required further investigations in order to define the presence of serum autoantibodies. Anti-DFS70 reactivity in male population may represent an exclusive biomarker predicting the absence of other autoantibodies.

FRI0678

### VALIDITY OF THREE 0–10 VISUAL ANALOG SCALES (VAS) FOR QUANTITATIVE PHYSICIAN ASSESSMENT OF INFLAMMATION, DAMAGE, AND DISTRESS TO SUPPLEMENT A PHYSICIAN GLOBAL ASSESSMENT 0–10 VAS

T. Pincus<sup>1</sup>, I. Castrejon<sup>1</sup>, J. A. Block<sup>1</sup>. <sup>1</sup>Rheumatology, Rush University Medical Center, Chicago, United States

**Background:** Rheumatologists generally view their primary goal as control of inflammation in order to prevent long-term damage, and quantitative assessment involves measures of inflammatory activity (lab tests, joint counts, and indices). Although structural damage and patient distress (fibromyalgia, depression, etc.) are widely recognized, these problems generally are described narratively, and not assessed quantitatively. Recent advances in control of inflammation, as well as increased degenerative diseases in an aging population and recognition of a high prevalence of fibromyalgia, may have shifted rheumatologists' patient mix more prominently toward damage and distress vs inflammation.

**Objectives:** To analyze physician global assessment (DOCGL) on a 0–10 visual analog scales (VAS), and 3 additional 0–10 VAS for inflammation, damage, and distress, as well as estimates of the proportion of each to explain DOCGL.

**Methods:** Rheumatologists at one academic site complete a 0–10 DOCGL VAS, 3 further 0–10 VAS to assess inflammation (reversible disease) (DOCINF), joint and other organ damage (irreversible disease) (DOC DAM), and patient distress (fibromyalgia, depression), etc. (DOCSTR), in routine care. The proportion of DOCGL attributed to inflammation, damage, and distress (total=100%) also is estimated. Mean values were analyzed in a cross-sectional study of 570 patients, and compared in subgroups with rheumatoid arthritis (RA), osteoarthritis (OA), or fibromyalgia (FM), using t tests and analysis of variance (ANOVA).

**Results:** Mean DOCGL VAS was 4.4/10 in all patients, 4.4 in 131 with OA, 4.6 in 98 with RA, and 5.2 in 89 with FM (table 1). Highest mean scores were seen for DOCINF in RA, DOC DAM in OA, and DOCSTR in FM (p<0.001), indicating face validity. Nonetheless, mean DOC DAM was higher than DOCINF in all groups, including RA, and mean estimates of the proportion of DOCGL attributed to damage was greater than to inflammation in all groups (table 1). Scores for DOCSTR were higher than for DOCINF in all groups other than RA.

**Table 1** Mean VAS Scores and % of clinical management decision attributed to inflammation, damage, and distress in patients with rheumatic diseases

Mean VAS Scores	ALL	RA	OA	FM	P*
	N=570	N=98	N=1311	N=89	
VAS DOCGL	4.4 (1.6)	4.6 (1.8)	4.4 (1.5)	5.2 (1.6)	0.04
VAS DOCINF	1.8 (2.0)	2.8 (2.4)	0.7 (1.1)	0.8 (1.3)	<0.001
VAS DOCDAM	3.1 (2.2)	3.8 (2.3)	4.4 (1.8)	1.7 (1.9)	<0.001
VAS DOCSTR	2.1 (2.9)	1.2 (2.2)	1.5 (2.5)	6.0 (2.5)	<0.001
p (DOCINF vs DOCDAM)	0.001	0.01	<0.001	<0.001	
p (DOCINF vs DOCSTR)	0.11	<0.001†	<0.001	<0.001	
<b>Mean % of clinical management decision attributed to...</b>					
% inflammation	29 (31)	39 (29)	12 (19)	6 (11)	<0.001
% damage	48 (35)	52 (30)	73 (31)	18 (23)	<0.001
% distress	22 (34)	9 (20)	15 (27)	76 (27)	<0.001

\*ANOVA – RA vs OA vs FM † -only comparison in which DOCINF higher than DOCSTR

**Conclusions:** VAS scores and estimates of the proportions of DOCGL attributed to damage were higher than for inflammation in all groups, including RA patients as a group. Control of inflammation remains a primary concern for rheumatologists, but has improved considerably in recent years, and damage and distress may have become more prominent in routine care. Systematic quantitation of inflammation, damage, and distress, in addition to DOCGL, appears feasible and of value in routine clinical care.

#### FRI0679 HIGH SENSITIVITY CARDIAC TROPONIN T IN PSORIATIC ARTHRITIS PATIENTS: A CROSS-SECTIONAL CONTROLLED STUDY

V. Eurer<sup>1</sup>, S. Shenhar-Tsarfaty<sup>2</sup>, S. Berliner<sup>2</sup>, U. Arad<sup>1</sup>, D. Paran<sup>1</sup>, O. Rogowski<sup>2</sup>, I. Shapira<sup>2</sup>, H. Matz<sup>3</sup>, O. Elkayam<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Internal Medicine, <sup>3</sup>Dermatology, Tel Aviv Medical Center, Tel Aviv, Israel

**Background:** High sensitivity cardiac troponin (hs-cTnT) is a biomarker for cardiovascular disease (CVD) in the general population. (1) Psoriatic arthritis (PsA) confers an increased risk for CVD (2) but there are no biological markers to stratify CVD risk in PsA patients.

**Objectives:** To determine the level of serum hs-cTnT in a PsA cohort and controls without inflammatory disease, and further characterize the PsA cohort with detectable hs-cTnT.

**Methods:** Serum hs-cTnT level was measured with a sandwich immunoassay method in a consecutive PsA cohort (n=96). The control cohort was based on apparently healthy individuals recruited during routine annual health examination, Tel-Aviv Medical Center Inflammatory Survey (TAMCIS) (n=6,052). hs-cTnT was measured in carefully matched controls (n=88), manually selected from the TAMCIS, based on gender, age, BMI, hypertension, and hyperlipidemia prevalence. Hs-cTnT  $\geq 5$  ng/L was used as a cutoff for the detectable level. Multiple regression analysis was used to determine the factors associated with hs-cTnT.

**Results:** The characteristics of the PsA cohort are presented in table 1. Remarkably, in the majority of patients, both skin and joint disease were well controlled. PsA and TAMCIS cohorts had a similar range of age (51.5 vs 48 yr) but different gender representation: 47% vs 72.5% of males (p<0.001). PsA exhibited a higher prevalence of traditional CVD risk factors compared to the TAMCIS cohort: BMI 28 vs 26.5 (p=0.002), current smokers 20.8% vs 10.1% (p=0.002), hypertension 25% vs 15% (p=0.007), dyslipidemia prevalence 34% vs 27% (p= 0.101), diabetes 19.8% vs 4.6% (p<0.0001). Due to these differences, a matched control group was used for comparison of troponin. Detectable hs-cTnT was present in 29.5% of the PsA patients compared to 19.3% in the controls. (p=0.114) Factors associated with detectable hs-cTnT in PsA were consistent with traditional factors and included male gender (p=0.007), age (p=0.005), hypertension (p<0.001), and DM (p<0.001). No correlation between detectable hs-cTnT level and psoriasis/PsA duration, disease severity, treatment with DMARDs or biologics was found.

**Table 1** Characteristics of the PsA cohort (n=96)

Gender, % males	47%
Age, years	51.5±13
Psoriasis duration	17±13
Psoriasis activity: remission/mild/moderate to severe	34%/56%/10%
PsA duration	9.4±8.1
PsA activity: remission/low/moderate/severe	37%/33%/22%/8%
Concomitant sDMARDs treatment (%)	49%
Concomitant biologic treatment (%)	65%
Biologic treatment exposure (past or present) (%)	71.8%

**Conclusions:** This is the first study to report a detectable hs-cTnT level in up to 30% in patients with well controlled PsA, asymptomatic for CVD, warranting a special attention to monitoring CVD risk factors and manifestations in this group. Traditional CVD risk factors but not measures of disease activity were associated with detectable hs-cTnT. The latter may be explained by a potential positive impact of anti-rheumatic therapies on the cardiovascular profile. Further prospective studies addressing the predictive role of hs-cTnT for CVD events in PsA are needed.

#### FRI0680 TETHERIN, A NOVEL TYPE I INTERFERON BIOMARKER ON BLOOD LEUCOCYTES CAN CAPTURE INTERFERON STATUS AND CORRELATES WITH USTEKINUMAB (STELARA) THERAPY RESPONSE IN PSORIATIC DISEASE.

Y. M. El-Sherbiny<sup>1</sup>, L. Savage<sup>1</sup>, A. Alase<sup>1</sup>, E. Vital<sup>1</sup>, M. Wittmann<sup>1</sup>, P. Emery<sup>1</sup>, D. McGonagle<sup>1</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University Of Leeds, Leeds, United Kingdom

**Background:** Recently Ustekinumab, an IL12/23 p40 monoclonal antibody that is licensed for Psoriatic Arthritis and Psoriasis, showed promising results in phase II trials in SLE- a prototype IFN mediated disease. We previously confirmed a novel IFN gene scoring system associated with the different SLE symptoms (manuscript in review). Additionally, we also recently validated in two independent cohorts the value of BST2/ tetherin as IFN-I biomarker assay correlates with clinical activity and predicts clinical flare in SLE. Given that psoriasis has several SNPs in the IFN pathway; Thus mechanistic studies of the effect of Ustekinumab on the IFN pathway can be explored in this disease setting.

**Objectives:** This work tested the hypothesis that a novel interferon type I (IFN-I) status markers in the blood and skin of Ustekinumab treated psoriasis patients might correlate with therapy responses and provide insights into how p40 blockers may affect IFN pathways in a relevant human disease model.

**Methods:** Skin biopsies and peripheral blood at baseline (before therapy, 24weeks, 54 weeks) from 23 Ustekinumab patients with psoriasis who had ultrasound imaging confirmed subclinical enthesopathy) were recruited. Cellular immunophenotyping was performed using multi-parameter flow cytometry to detect tetherin on (Monocyte, B cells, T cells and neutrophils). All data was compared to age-matched samples from healthy controls (HC). Skin biopsies were digested and RNA extracted, qPCR of common ISGs genes were analysed in lesional and peri-lesional at corresponding time points.

**Results:** Tetherin showed a higher level of expression on blood subsets of psoriasis compared to HC at baseline on Monocytes, T cells, NK cells and B cells (p=0.003, =0.005, =0.035, =0.002) compared to the baseline. No significant changes observed between baseline and 2nd visit 24 weeks. Interestingly, a substantial reduction in tetherin expression at (52 weeks) in psoriasis was observed in all subsets in Monocytes, T cells, NK cells and B cells (all p<0.0001) correlating with patient response to therapy. IFN signature by TaqMan revealed higher expression in skin biopsies distinctive ISGs compared to HC, e.g. IFI27, STAT1, IFI16 and IRF7 all corrected post-Ustekinumab therapy to normal levels. Paired analysis revealed a stronger IFN signature in lesional biopsies vs non-lesional biopsies, e.g. IFI27 (p=0.0312, Wilcoxon matched pair-rank test).

**Conclusions:** Psoriasis which is genetically and mechanistically linked to IFN-I signatures shows responses to Ustekinumab therapy that correlate with improvement in IFN-I signatures in blood and tissues. Given that whole blood ISG signatures were complex and weakly correlating with disease activity. We provide a convenient, validated method to analyse IFN pathway in routine clinical practice using tetherin which could be a future research tool for the cell-specific IFN-I response. These studies support the idea that p40 efficacy in psoriasis is associated with IFN-I pathway modulation and relevant for exploring how p40 blockers may exert potential benefit in SLE.

#### FRI0681 FOUR COMORBIDITY INDEXES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

Y. J. Huang<sup>1</sup>, C. F. Kuo<sup>1</sup>, J. S. Chen<sup>1</sup>, S. F. Luo<sup>1</sup>. <sup>1</sup>*Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan, Province of China*

**Background:** Previous studies have reported an increased risk of multiple comorbidities in people with RA therefore it is necessary to systematically quantify the comorbidity burden of these patients.[1] The comorbidity index is a tool developed under this concept and has multiple clinical and research uses.

**Objectives:** We compared four comorbidity indexes in patients with rheumatoid arthritis in Taiwan (Charlson Comorbidity Index (CCI), Elixhauser Comorbidity Index (ECI), Mutimorbidity index (MMI), Rheumatic Disease Comorbidity Index (RDCI))

**Methods:** All patients with rheumatoid arthritis diagnosed during 1998–2008 in Taiwan were identified using the Taiwan National Health Insurance Database and followed up to 31 Dec 2013. Score accumulation between periods during diagnosis (4 months before and after initial diagnosis) and before/after the diagnostic period was compared. Poisson regression was used to calculate incidence rate ratio.

**Results:** Among 24767 patients with rheumatoid arthritis, median age at diagnosis is 51 years old and female is 79.2%. The mean score at diagnosis is 0.8 in CCI, 2.8 in ECI, 0.7 in MMI and 1.3 in RDCI. The annual percentage changes are 11.0%, 11.3%, 9.7% and 6.8%, respectively. The score of four comorbidity indexes increased with time after rheumatoid arthritis was diagnosed. The incidence rate ratios (IRR) for any increase in comorbidity score during versus before diagnostic period are higher than after versus before diagnostic period. (IRR 1.8 [CI 1.68 to 1.92] vs. 1.57 [CI 1.47 to 1.69] in CCI, IRR 2.77 [CI 2.67 to 2.87] vs. 2.44 [CI 2.36 to 2.53] in ECI, IRR 1.33 [CI 1.26 to 1.40] vs. 1.26 [CI 1.19 to 1.33] in MMI, IRR 1.47 [CI 1.41 to 1.54] vs. 1.31 [CI 1.26 to 1.37] in RDCI)

Table 1 Incidence rates (IR) per 1000 patient months and incidence rate ratios (IRR) for occurrence of any disease in comorbidity index before, during, and after diagnosis\* in patients with incident rheumatoid arthritis, 2001–2008, Taiwan.

Comorbidity indexes	Before diagnosis		During diagnosis		After diagnosis		IRR (95% CI)
	No of events	Crude IR	No of events	Crude IR	No of events	Crude IR	
CCI	1,311	0.007	2,353	0.013	2,062	0.012	1.80 (1.68 to 1.92)
ECI	4,099	0.023	11,933	0.064	10,011	0.057	2.77 (2.67 to 2.87)
MMI	2,249	0.013	2,985	0.017	2,828	0.016	1.33 (1.26 to 1.40)

Figure 1 Mean scores of comorbidity indexes from diagnosis year by Rheumatoid arthritis

**Conclusions:** Our study showed that comorbidities continue to accumulate after the initial diagnosis. The comorbidity tends to occur during diagnostic period in patients with rheumatoid arthritis. Different comorbidity indexes are all good at assessing comorbidity burden. Clinicians should screen different comorbidities, determine primary prevention and control disease activity to improve the functional status, quality of life and mortality of rheumatoid arthritis.

#### FRI0682 EXERCISE MAY DECREASE SYNCOPE SECONDARY TO POSTURAL CHANGE IN FEMALES WITH RHEUMATOID ARTHRITIS: PILOT STUDY

D. C. Janse Van Rensburg<sup>1</sup>, J. A. Ker<sup>2</sup>, C. C. Grant<sup>1</sup>, L. Fletcher<sup>3</sup>. <sup>1</sup>*Section Sports Medicine*, <sup>2</sup>*Dept of Internal Medicine*, <sup>3</sup>*Dept of Statistics, University of Pretoria, Pretoria, South Africa*

**Background:** The autonomic nervous system (ANS) regulates the heart rate via sympathetic and parasympathetic influences. Literature has shown that rheumatoid arthritis (RA) patients suffer from autonomic dysfunction. This may consequently lead to syncope with possible falls after posture change i.e. rising from supine to the standing position. Previous research has shown general improvement of the ANS after exercise, but not in specific relation with posture change.

**Objectives:** To determine the effect of exercise on posture change (supine to standing position) in females with RA as measured by short-term heart rate variability (ANS function).

**Methods:** Patients with confirmed RA were randomly selected to a control group (RAC) or an exercise group (RAE). The RAE group (n=19) trained two to three times per week under supervision. The RAC group (n=18) continued with their current sedentary lifestyle. The medium intensity exercise programme lasted for

12 weeks. No change in medication was allowed during this time. ANS function and balance were determined by quantification of the variability of the inter-beat interval detected with the Polar 810i heart rate monitor system. Frequency domain analyses were used for quantification, including LF (ms<sup>2</sup>) – indicating mainly sympathetic influence, HF (ms<sup>2</sup>) – indicating parasympathetic influence, and LF/HF – indicator of autonomic balance.

**Results:** The two groups matched regarding baseline demographic data (age, sex, disease activity, disease duration). Due to small sample sizes and variables not following a normal distribution, non-parametric Mann Whitney U analyses were performed on the heart rate variability parameters. Comparing posture change (i.e. standing value minus supine value) from pre- to post intervention, all frequency domain parameters changed as anticipated (i.e. vagal withdrawal and increased sympathetic influence) for the RAE group. For the RAC group the measurements deteriorated.

**LF (ms<sup>2</sup>):** RAE -1.03 to 22.03 (stronger sympathetic influence); RAC 43.45 to -31.21 (weaker sympathetic influence)

**HF (ms<sup>2</sup>):** RAE -24.03 to -33.34 (better vagal withdrawal); RAC -191.7 to -114.1 (less vagal withdrawal)

**LF/HF:** RAE 10.57 to 15.04; RAC 2.9 to 7.6

**Conclusions:** From these preliminary results it appear that exercise may indeed improve autonomic function in RA patients, in such a way that posture change will not be an added burden for falls in an already otherwise compromised population.

### FRI0683 INVESTIGATION OF THE RELATIONSHIP BETWEEN PLANTAR PRESSURE DISTRIBUTION AND LUMBAR MULTIFIDUS MUSCLE THICKNESS

C. Karartı<sup>1</sup>, S. Bilgin<sup>2</sup>, Y. Dadalı<sup>3</sup>, E. Dülger<sup>2</sup>, B. Büyükturan<sup>1</sup>, Ö. Büyükturan<sup>1</sup>. <sup>1</sup>Ahi Evran University, Department of Physiotherapy and Rehabilitation, Kirsehir, <sup>2</sup>Department of Physiotherapy and Rehabilitation, Hacettepe University Institute of Health Sciences, Ankara, <sup>3</sup>Ahi Evran University, Department of Radiology, Kirsehir, Turkey

**Background:** Lumbar multifidus is a muscle which is responsible for lumbopelvic stability primarily. Foot-ankle posture and function disorders affecting the lumbopelvic region muscles and biomechanics, cause increased stress in the lumbopelvic region and may cause low back pain in many studies (1,2,3). However, it is not known whether the lumbar multifidus muscle is affected by this condition (4,5).

**Objectives:** Plantar pressure distribution can change due to foot-ankle postural disorders. Our aim is to examine whether the plantar pressure distribution affects the lumbar multifidus muscle thickness.

**Methods:** 40 healthy young adults aged 18 to 25 years were included in the study. Static and dynamic pedobarographic assessments were performed to determine the plantar pressure distribution, on a 3x1 meter sensed walking platform with the DIASU Digital Analysis System<sup>®</sup>. Peak pressures (N/cm<sup>2</sup>) of 9 zones of the foot (medial of heel, lateral of foot, 5 metatarsal, thumb and 2,3,4 and 5. digits) were recorded. Ultrasonographic imaging was used to assess lumbar multifidus muscle thickness.

**Results:** There was statistically significant correlation between lumbar multifidus muscle thickness and peak pressure medial of heel and 1. metatarsal bone in static pedobarographic analysis (p<0.05). As the peak pressure on the medial part of foot increased, m. lumbar multifidus muscle thickness was reduced. There was statistically significant correlation between lumbar multifidus muscle thickness and pressure medial of heel and 2,3,4. and 5. digits in dynamic pedobarographic analysis (p<0.05). As the peak pressure on the medial part of foot increased, m. lumbar multifidus muscle thickness was reduced.

**Conclusions:** Our results show that plantar pressure distribution affected lumbar multifidus muscle thickness. Based on these results, the lumbopelvic region and foot posture should be considered together in therapeutic interventions.

### FRI0684 EFFICIENCY OF COMPLEX REHABILITATION PROGRAM IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING ABATACEPT

E. Orlova<sup>1</sup>, D. Karateev<sup>2</sup>, A. Kochetkov<sup>1</sup>. <sup>1</sup>Department of Rehabilitation Medicine, Federal Medical Biological Agency, <sup>2</sup>1st Department of internal medicine, Moscow Regional Research and Clinical Institute ("MONIKI"), Moscow, Russian Federation

**Background:** Rehabilitation techniques (physical exercises, physiotherapy, occupational therapy, patient education) help to manage rheumatoid arthritis (RA) in addition to drug treatment [1–4].

**Objectives:** To evaluate the efficiency of 12-month complex rehabilitation program in patients with RA receiving abatacept.

**Methods:** 50 patients with RA (94% females, 72% with moderate disease activity by DAS28, age of 18 to 57 years, disease duration of 10 months to 12 years) were included and randomized into 2 groups. All patients received abatacept (intravenously 10 mg/kg (mean 750 mg) once every 4 weeks or subcutaneously 125 mg once a week) with methotrexate 20–25 mg per week. 28 study group patients underwent 12-months complex rehabilitation program: laser therapy of 12 to 16 min (infrared low intensity laser radiation, wavelength of 0,89 micrometers, pulse frequency of 1000 to 1500 Hz) for hand, knee, ankle, shoulder and elbow joints, 3 courses for 14 sessions with a mean interval of 3,2 months; 45-min dynamic exercises using gym apparatus Enraf-Nonius under the supervision of a trainer 3 times a week; 45-min exercises for hands 3 times a week; 45-min occupational therapy (joint protection strategies, use of assistive devices and adaptive equipment), 10 sessions; wrist, ankle and knee orthoses, orthopedic insoles; education program (4 daily 90-min studies). 22 patients received only drug therapy (control). Tender and swollen joint count, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), joint pain on 100-mm VAS, DAS28, HAQ, RAPID3, hand grip strength, the average powers of knee extension and ankle flexion by EN-TreeM movement analysis were evaluated at baseline and at 12 months.

**Results:** After 12 month in the study group tender joint count decreased by 69,3% (p<0,01), swollen joint count – by 66,2% (p<0,01), ESR – by 63,7% (p<0,01), CRP – by 58,5% (p<0,01), pain on VAS – by 82,3% (p<0,01), DAS28 – by 39,6% (ΔDAS28=2,89±0,99, p<0,05), HAQ – by 72,2% (ΔHAQ=1,73±0,44, p<0,01), RAPID3 – by 78,3% (ΔRAPID3=8,45±0,85, p<0,01). The grip strength of a more affected hand enhanced by 57,1% (p<0,01), of a less affected – by 46,2% (p<0,05). The average extension power of a weaker knee increased by 72,1% (p<0,01), of a stronger – by 65,8% (p<0,01). The average flexion power of a more affected ankle joint elevated by 48,9% (p<0,05), of a less affected – by 69,4% (p<0,01). In the study group there were statistically significant differences from the control group in the most parameters (p<0,05), excluding CRP, ESR, DAS28 and the average flexion power of a more affected ankle joint (p>0,05). After 12-months in the study group there was significantly more frequently a good response to treatment according to the EULAR criteria (DAS28) (85,7% vs 63,6% in the control group, p<0,05).

**Conclusions:** 12-month complex rehabilitation program relieves pain, improves quality of life, functional status, motion activity and helps to control disease activity in patients with RA receiving abatacept.

### FRI0685 HAND FUNCTIONS ARE AFFECTED DEPENDING ON THE CURVE PATTERN IN IDIOPATHIC SCOLIOSIS

G. Yagci<sup>1</sup>, D. A. Ozcan<sup>1</sup>, C. Ayhan<sup>1</sup>, Y. Yakut<sup>2</sup>. <sup>1</sup>Physiotherapy and Rehabilitation, Hacettepe University, Ankara, <sup>2</sup>Physiotherapy and Rehabilitation, Hasan Kalyoncu University, Gaziantep, Turkey

**Background:** Idiopathic scoliosis (IS) is a three-dimensional deformity and causes postural distortions in head, trunk, scapular region and upper extremities. Hand functions have not been evaluated in relation to lateral curvature of the spine in IS previously. There is a need to evaluate possible changes in hand functions with scoliotic curve in idiopathic scoliosis.

**Objectives:** The aim of this study was to investigate hand functions in individuals with idiopathic scoliosis.

**Methods:** Ninety-four individuals with mild or moderate idiopathic scoliosis (Cobb angle range: 10° – 45°) were included. Curves were classified as single thoracic (n= 18), single thoracolumbar (n= 33), single lumbar (n= 22) and double curves (n= 21). Assessments included hand dexterity with Minnesota test, hand reaction time with Nelson test, hand-eye coordination with finger-to-nose test, throwing accuracy with Functional Throwing Performance Test, and upper extremity stability with the Closed Kinetic Chain Upper Extremity Stability Test. One-way ANOVA was used to compare continuous variables between different curve pattern groups and a Tukey's hsd means comparison was used to examine the nature of the significant difference found by ANOVA. In addition, Student's t test was used to compare the parameters between the convex and concave side of the curve for each group.

**Results:** Hand-eye coordination and throwing accuracy was significantly worse in thoracic curve pattern group than lumbar ones for both convex and concave sides of the curve. There was no difference between curve patterns in terms of hand dexterity, hand reaction time and upper extremity stability. When compared with concave side, hand dexterity was greater in the convex side for thoracic curves (p<.05). For double curves, convex side had better hand dexterity and reaction time than concave side (p<.05). But there was no difference between convex and concave side for thoracolumbar and lumbar curve patterns (p >.05).

**Conclusions:** This study showed that hand function is affected, depending on the curve pattern in idiopathic scoliosis. There is no knowledge about how hand function is affected in patients with scoliosis in the literature. Further research following these findings may lead to an understanding of the change in hand functions and its relation with scoliosis-related characteristics, such as age, curve magnitude and trunk deformity.

FRI0686

#### THE EFFECT OF FOOT ORTHOSES ON BALANCE IN RHEUMATOID ARTHRITIS PATIENTS: A RANDOMIZED CLINICAL TRIAL

J. Z. Gaino<sup>1</sup>, M. B. Bertolo<sup>2</sup>, C. S. Nunes<sup>1</sup>, C. M. Barbosa<sup>1</sup>, Z. Sachetto<sup>2</sup>, M. Davitt<sup>1</sup>, E. D. P. Magalhães<sup>2</sup>. <sup>1</sup>Unicamp, Campinas, Brazil, <sup>2</sup>Rheumatology, Unicamp, Campinas, Brazil

**Background:** Rheumatoid patients(RA)have increased rate of falls and an impaired balance. Foot orthoses are commonly used in RA. Despite the evidence of pain relief with foot orthoses, it is not clear if their use can improve or even impair balance in RA.

**Objectives:** The aim of this study was to evaluate the effect of foot orthoses on balance of RA patients.

**Methods:** 94 RA patients in the outpatient clinic of the Rheumatology Division of Unicamp were randomly assigned to intervention group/IG(n=48)with foot orthoses or control group/CG(n=46)without orthoses. At initial visit, subjects were assessed regarding:sociodemographic and clinical data(number of falls in last year, fear of falling, disease duration, rheumatoid factor, Imedication, visual impairment, vertigo, physical activity, body mass index, comorbidity index, foot tactile sensitivity, number of lower limbs swollen and tender joints count, disease activity-CDAI and disability-HAQ). Subjects answered The Foot Function Index-FFI and were submitted to Berg Balance Scale-BBS, the Timed Up and Go-TUG and the 5-Time Sit Down-to-Stand up-SST5 tests.IG subjects received custom made insoles according to each foot needs. After four weeks, subjects were reassessed for FFI, BBS and TUG. To compare baseline values of groups, the chi-squared test, Fisher's exact test and Mann-Whitney test were applied.ANOVA for repeated measures was used to compare differences between groups and times for BBSTUG and FFI. Effect size was analyzed using the Cohen's d test. All data were analyzed with a 5%level of significance.

**Results:** 81 subjects completed the research protocol,40 in the IG and 41 in the CG. Groups were similar at baseline for most variables with exception of

comorbidity index(worst index in IG) and race(p<0.05). After four weeks, FFI-total, FFI-Pain, FFI-activity limitation disclosed a significant improvement only in IG. Significant differences between times were noted for TUG and BBS only in IG. Interaction group versus time was significant for FFI and BBS. Subjects from IG reported a mean wearing time of 7.32hs/day. Adverse effects were noted in ten subjects(foot pain, hot foot).

Comparison between IG and CG at baseline (t1) and after 4 weeks (t2)

Variables	IG vs CG, p <sup>*</sup>	t1 vs t2, p <sup>*</sup>	Interaction groups vs time, p-value	Effect Size <sup>**</sup>
FFI-pain	0.0001	<0.0001	0.001 <sup>a</sup>	-0.60
FFI- disability	0.050	0.001	0.036 <sup>b</sup>	-0.28
FFI-activity limitation	0.007	0.004	0.011 <sup>a</sup>	-0.61
FFI-Total	0.002	<0.0001	0.001 <sup>a</sup>	-0.57
TUG	0.454	<0.0001	0.079 <sup>c</sup>	No interaction
BBS	0.358	0.0001	0.011 <sup>b</sup>	0.35
NCS	0.422	0.102	0.022	0.44

\*ANOVA for repeated measures (variables converted into ranks) \*\* d de Cohen

**Conclusions:** Foot orthoses were well accepted and worn during long periods with FFI and balance tests (BBS, TUG)improvement. Prospective placebo controlled studies are recommended to assure the possibility to use insoles as adjuvant interventions to improve balance in RA.

FRI0687

#### EFFECT OF PERINEURAL INJECTION THERAPY IN MODERATE AND SEVERE KNEE OSTEOARTHRITIS; A COMPARATIVE STUDY

M. H. Abu-Zaid<sup>1</sup>, S. A. Tabra<sup>1</sup>, S. Elmorsy<sup>1</sup>. <sup>1</sup>Rheumatology and Rehabilitation, Faculty of Medicine Tanta University Egypt, Tanta, Egypt

**Background:** Osteoarthritis (OA) is the most common rheumatologic disease. Knee OA is the most common form of symptomatic OA. It is the fourth most important global cause of disability in women and the eighth most important cause in men<sup>1</sup>.

Studies found that subcutaneous prolotherapy is an effective treatment for several painful conditions. Some author hypothesizes that subcutaneous prolotherapy injections induce apoptosis of proliferating peptidergic nociceptors and neovessels by reducing vascular endothelial growth factor levels and restoring effective repair processes, with reduction of pain<sup>2</sup>.

**Objectives:** To assess the effectiveness of perineural injection therapy as a new modality in management of pain, physical function, ambulation activity, disability and psychological status in moderate and severe knee osteoarthritis.

**Methods:** In this study; we selected 100 patients with moderate and severe knee osteoarthritis diagnosed clinically and radiologically by plain x-ray. Patients were classified into four equal groups (25 patients in each group). Group I received 6 weekly subcutaneous injections of 0.5–1 ml of buffered dextrose 5% in each chronic constriction injury points and tender points around knee. Group II received therapeutic continuous US three times weekly for 6 weeks using 1-MHz US head, set to an intensity of 1 W/cm<sup>2</sup> for 10 min. Group III received combined perineural and US therapy. Group IV received sham US. All patients received 15 min of quadriceps isometric exercise of both knees.

Assessments were performed at baseline, at the end of the treatment and after three and six months. using the following measurements: Primary outcome was pain on movement assessed by visual analog scale (VAS). Secondary outcomes consisted of the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scores, 50 meters walking time, Lequesne index, Hospital Anxiety and Depression Scale (HADS).

**Results:** No baseline differences existed between all groups. The improvement in group IV was non-significant (p>0.05), while there was significant improvement in all other groups (p<0.05) in all primary and secondary outcomes after treatment, 3 and 6 months later. In comparing groups I, II, III the best improvement was in

group III then group I then group II after treatment and 3 months later but there was no significant difference between the three groups after 6 months follow up.

#### FAST ACCESS TO ASSESSMENT SUPPORT AND TREATMENT (FAAST): INNOVATION TO IMPROVE SERVICE

R. Laxminarayan<sup>1</sup>, A. Dean<sup>2</sup>, L. Bembridge<sup>2</sup>, S. Redfern<sup>2</sup>, H. Nutland<sup>2</sup>, M. Nisar<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Physiotherapy, Queen's Hospital, Burton on Trent, United Kingdom

**Background:** Physiotherapy is integral to rheumatology MDT. Early physiotherapy interventions optimise education, self-management and enhance outcomes. Delay in first physiotherapy assessment leads to non engagement, altered clinical features and adverse outcomes<sup>1</sup>. Our physiotherapy service provided appointment based assessments. Each new patient appointment was for 60 minutes. We had an average of 43 day wait to see routine patients. Non attendance rate was high, patients did not value the benefits of physiotherapy and therapist was not able to provide input in patient management.

To improve service, a new system of Fast Access to Assessment, Support and Treatment (FAAST) was introduced in April 2017, allowing patients same day access to physiotherapy on the day of referral.

**Objectives:** 1. To assess the impact of FAAST on non-attendance rate and subsequent visits.

2. To analyse the type of interventions, time spent on assessment and benefits on resource utilisation.

**Methods:** Patients completed a body chart to document their symptoms and a baseline Burton-Patient Reported Outcome Measure (B-PROM)<sup>2,3</sup>. These informations allowed the therapist to assess patients' priorities. Physiotherapist and patient then decided upon the appropriate and possible intervention on the day and subsequent visits. Follow up appointments were made based on clinical need and patient's convenience. We collected data prospectively on type of intervention, time spent on assessment, attendance to subsequent sessions and compared to the data from conventional physiotherapy clinics.

**Results:** FAAST project started in April 2017. This ran parallel to the conventional clinic. Now it is the main portal of referral to physiotherapy. We present data from April 2017 to November 2017. 495 out of 952 patients referred in this period were assessed in the FAAST clinic.

1. Average wait time in conventional clinic was 43 days for routine and 19 days for urgent. In FAAST clinic, every patient was assessed by the physiotherapist on the day of referral eliminating waiting time. Average time to second review after FAAST clinic was 23 days.

2. Type of assessment was decided on the first visit to FAAST clinic. About 70% patients were booked for one to one sessions and about 15% were booked into group sessions designed for specific disease conditions. FAAST assessment

helped to identify patients needed to be referred to other specialist therapy areas also.

3. Non-attendance rate for the first appointment in conventional clinic for preceding three year period was 13%. Every patient referred to FAAST clinic attended the first appointment and non-attendance at second appointment improved to 9.5%.

4. Average time spent by the therapist at first FAAST clinic was 29 minutes which equated to saving of 242 hours compared to conventional clinic. Pre FAAST era, 100 new patients were seen a month on an average. Since FAAST clinic started, this increased to 136 a month.

**Conclusions:** 1. FAAST clinic achieves its objective of reducing waiting times and non-attendance rate.

2. Average assessment time was flexible, saved time and helped to improve efficiency of the clinic.

3. Assessment and intervention on the day of assessment helped to target the therapy more effectively.

#### A CONSERVATIVE TREATMENT OPTION FOR CARPAL TUNNEL SYNDROME: EXTRACORPOREAL SHOCK WAVE THERAPY. PROSPECTIVE, RANDOMIZED, DOUBLE BLIND PLACEBO CONTROLLED STUDY

R. Kocak Ulucağöy<sup>1</sup>, F. G. Yurdakul<sup>1</sup>, H. Bodur<sup>1</sup>. <sup>1</sup>Physical Medicine and Rehabilitation, Ankara Numune Training and Research Hospital, Ankara, Turkey

**Background:** Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy that occurs as a result of median nerve compression at the wrist. Extracorporeal shock wave therapy (ESWT) is specified as a treatment with high amplitude acoustic waves that focus on a region of the body. While ESWT is frequently used to treat musculoskeletal disorders such as plantar fasciitis and tendinitis, in recent years ESWT has become a new treatment option in CTS. Positive results have been reported from limited number of studies which were assessed efficacy of ESWT in CTS treatment. On the other hand it is noteworthy that the number of patients in these studies is not high and there is no clear consensus on the concept of shock wave energy density and frequency due to lack of experience (1,2,3).

**Objectives:** To evaluate the efficacy of ESWT in CTS and compared to wrist splint treatment in this prospective, randomized double-blind, placebo-controlled trial.

**Methods:** One hundred eighty-nine patients with mild/moderate CTS were included. Patients were assigned to 4 different treatment groups (1-Splint, 2-Splint + ESWT, 3-ESWT, 4-Splint+ placebo ESWT) by using stratified randomization to ensure balance of the treatment groups respect to the various combinations of the prognostic variables in terms of in terms of age, gender, and severity of CTS. 168 patients completed the study at third month. ESWT was performed on the area included 2 cm proximal to the pisiform bone. It was applied with 1000 shots, 0.05 mJ/mm<sup>2</sup> intensity of energy and frequency of 5 Hz. (3 weeks, once a week). Wrist splint with suitable size and neutral position was suggested. Patients were evaluated at baseline, first and third month. Pain, finger pinch strength, Boston Carpal Tunnel Questionnaire (BCTQ), Leeds Neuropathic Symptom and Finding Assessment (LANSS) and electrophysiological examination were assessed.

**Results:** Demographics, clinical characteristics of the patients are shown in table 1. Significant pain and functionality improvement was found in all groups (p<0.05) at first and third months. The improvements in clinical and electrophysiological variables were compared between four groups In group 2, baseline- first month finger pinch increase was higher than groups 1 and 4, and the baseline- third month finger pinch increase was higher than group 4. In group 2, the increase in mMNVCV was higher than group 1.

Table 1 Baseline demographic and clinic characteristics of patients

	Group 1 n=47	Group 2 n=47	Group 3 n=45	Group 4 n=50	p
Age (year)	48.1 ± 10.13	48.38 ± 10.12	50 ± 8.56	48.48 ± 9.79	0.325 <sup>‡</sup>

LANSS	9.85 ± 6.81	9.13 ± 5.93	9.56 ± 6.15	9.45 ± 5.95	0.900
Neuropathic pain + ** (n, %)	30 (41.7%)	27 (38.6%)	26 (40.6%)	24 (29.3%)	0.361 <sup>†</sup>

Group 1: Only wrist splint treatment, Group 2: ESWT + wrist splint treatment, Group 3: Only ESWT, Group 4: Placebo ESWT + wrist splint treatment, n: number of patients, DM: Diabetes mellitus, HT: Hypertension; VAS: Visual Analog Scale, (0-10 cm), BCTQs: Boston Carpal Tunnel Symptom Severity Score, BCTQf: Boston Carpal Tunnel Functional Capacity Score, LANSS: Leeds Assessment of Neuropathic Symptoms and Signs; kg: Kilogram, <sup>†</sup> Chi square test<sup>‡</sup> one way analysis of variance (kruskal wallis analysis was used for parameters without normal distribution)

\* difference between Group 1 and Group 2 p=0.021

‡ difference between Group 2 and Group 3 p=0.006

† difference between Group 2 vs Group 4, p=0.018

\*\* LANSS score ≥ 12

**Conclusions:** In the group with ESWT and using wrist splint together, it was found that the improvement of hand function and electrophysiological measures was higher than other groups. ESWT, a valuable and practical treatment modality without serious side effects, reduces pain, neuropathic symptoms, disability and improves electrophysiological findings for patients with mild to moderate CTS.

#### COMPARISON OF EFFECTIVENESS OF DIFFERENT STRETCHING EXERCISES COMBINED WITH PRESSURE RELEASE TECHNIQUE ON LATENT TRIGGER POINTS IN THE PECTORALIS MINOR MUSCLE

T. Birinci<sup>1</sup>, R. Mustafaoglu<sup>2</sup>, E. Kaya Mutlu<sup>3</sup>, A. Razak Ozdinciler<sup>3</sup>. <sup>1</sup>Istanbul Medeniyet University, Faculty of Health Sciences, Division of Physiotherapy and Rehabilitation, <sup>2</sup>Istanbul University, Faculty of Health Sciences, Division of Neurological Physiotherapy and Rehabilitation, <sup>3</sup>Istanbul University, Faculty of Health Sciences, Division of Physiotherapy and Rehabilitation, Istanbul, Turkey

**Background:** A myofascial trigger point (MTrP) is a hyperirritable spot located in a palpable taut band of skeletal muscle which are painful upon compression, stretching, or overload of the muscle. It is well known that latent triggerpoint (LTrPs), highly prevalent in healthy subjects, are usually silent even though they can easily develop into ATrPs under the influence of perpetuating factors; therefore LTrPs need to be treated.

**Objectives:** To investigate which type of stretching exercise using after a single-session ischemic compression is more effective for muscle length, pressure pain threshold (PPT), pulmonary function, and respiratory muscle strength in subjects with latent trigger point in the pectoralis minor (PM) muscle.

**Methods:** Two-hundred-six individuals were screened for possible inclusion criteria. Fourty subjects were randomized to the Group-1 (ischemic compression with modified contract-relax PNF stretching), Group-2 (ischemic compression with static stretching), Group-3 (ischemic compression with myofascial release) or Group-4 (no intervention). The assessments were performed at baseline, immediately after the intervention, and at 24-hours later. The pectoralis minor length (PML) was measured using a standard tape measure. Then, pectoralis minor index (PMI) was calculated. Rounded shoulder posture (RSP) was assessed by the measuring the distance between the posterior border of the acromion and the table 1. Digital algometer was used to evaluate the PPT; spirometer and respiratory pressure meter were used to assess pulmonary function and maximal respiratory pressure, respectively.

**Results:** Improvements were found for PML and PMI between baseline and immediately after intervention in Group-1 and Group-3 (p<0.05). RSP showed a significant improvement only in Group-3 (p=0.03), whereas there was a statistically significant improvement for PPT value in Group-1 immediately after intervention (p=0.005). Significant difference were found in the PEmax at baseline to 24-hours later in Group-1 (p<0.05). There was a statistically significant difference in the PIMax and PEmax in Group-3 (p<0.05).

**Conclusions:** For effective trigger point therapy, ischemic compression should be followed by myofascial release or contract-relax PNF stretching exercises.

#### EFFECT OF AN EDUCATIONAL INTERVENTION BASED ON CLINICAL SIMULATION IN THE DIAGNOSIS OF PSORIATIC ARTHRITIS IN LATIN AMERICAN DERMATOLOGISTS

S. A. Mora Alfonso<sup>1,2</sup> on behalf of Sociedad para la Investigación, atención y educación en enfermedades reumáticas Inverder Sas, D. G. Fernández Ávila<sup>2,3</sup> on behalf of Sociedad para la Investigación, atención y educación en enfermedades reumáticas Inverder Sas. <sup>1</sup>Rheumatology, Universidad de la Sabana, <sup>2</sup>Rheumatology, Sociedad para la Investigación, atención y educación en enfermedades reumáticas Inverder Sas, <sup>3</sup>Pontificia Universidad Javeriana - Hospital Universitario San Ignacio. Bogotá, Colombia, Bogotá, Colombia

**Background:** Previously our group has shown the use of clinical simulation in rheumatology, an area in which it had not been used. We demonstrated the effectiveness of an educational intervention based on clinical simulation to improve the diagnostic approach to RA<sup>1</sup>, so we wanted to apply this same principle in the learning of Psoriatic Arthritis (PsA) and SpA (Spondyloarthritis).

**Objectives:** This paper wants to quantify the rate of improvement in the diagnosis of Psoriatic Arthritis (PsA) among a group of Latin American dermatologists who received an educational intervention based on clinical simulation.

**Methods:** Observational study before and after

**Results:** 192 Latin American dermatologists received an educational intervention based on clinical simulation. The topic of this educational intervention was based on PsA. A workshop that includes clinical simulation models of feet, fingers and a mannequin with prominent entheses was created for this purpose. It was used an strategy of problem-based learning. The workshop lasted 5 hours and it was divided into two parts: the first was about the clinical approach of joint pain and lumbar pain diagnosis and relevant aspects of PsA. The second part focused on clinical cases applied to clinical simulation models, applying the knowledge acquired during the theoretical phase. Participants made a several stations where they could appreciate for periods of 15 minutes each simulator of 3 feet, 6 simulated fingers and a mannequin where they can identify entheses, dactylitis, arthritis, psoriasis lesions and improve visual and tactile sensitivity in each semiologic findings for the diagnosis of PsA. The participants filled out a pre and post test, which included 6 (six) clinical cases with simulators and photographs of hands and feet of patients with suspected PsA. 192 participants (82 %

women) from 5 Latin American countries (Argentina, Brazil, Colombia, Mexico and Peru), average age 42.43 years (SD 6.2 years). Dermatologists obtained an improvement in the correct diagnosis of PsA of 56,1 % (the correct diagnosis increased from 33,1 % to 89,2 %). the total number of exams requested in the cases presented decreased significantly, from an average of 9 to 3 exams requested by each clinical case presented. 95 % of participants would recommend to other colleagues to make this workshop. 98,8 % believe that this educational intervention will improve the diagnostic approach to patients with suspected PsA.

**Conclusions:** The present research is a pioneer and innovator in the rheumatology education. We have shown the usefulness of clinical simulation given by an improvement in the diagnostic sensitivity towards the diagnosis of PsA, highlighting the semiology as a key element at the time of making the diagnosis. A significant decrease in the total number of exams requested for each of the clinical cases analyzed was documented, which can have a positive effect on costs for the national health systems in each country of the participating dermatologists.

#### ANTI-TNF TREATMENTS FOR WOMEN WITH CHRONIC INFLAMMATORY DISEASES: COMPARING ATTITUDES AND PERCEPTIONS OF PHYSICIANS IN EUROPE AND THE US

A. Tincani<sup>1</sup>, P. Taylor<sup>2</sup>, R. Fischer-Betz<sup>3</sup>, C. Ecoffet<sup>4</sup>, E. Chakravarty<sup>5</sup>. <sup>1</sup>Università degli Studi di Brescia, Brescia, Italy, <sup>2</sup>Botnar Research Centre, Oxford, United Kingdom, <sup>3</sup>Rheumatology & Hiller Research Unit, University Hospital, Düsseldorf, Germany, <sup>4</sup>UCB Pharma, Brussels, Belgium, <sup>5</sup>Oklahoma Medical Research Foundation, Oklahoma City, OK, United States

**Background:** For Women of Childbearing Age (WoCBA) with chronic inflammatory diseases (CID), onset, diagnosis and treatment initiation often overlap with peak reproductive years. High disease activity is associated with increased risk of pregnancy complications and adverse outcomes, and achieving disease control in these patients (pts) is therefore an important goal. Tumour necrosis factor antagonists (anti-TNFs) are effective treatments, but few data are available on how physicians utilise them in clinical practice for this specific pt group.

**Objectives:** To help better understand physicians' perceptions and attitudes towards treating WoCBA pts with anti-TNFs during pregnancy and lactation, and gain insights into differences between Europe- and US-based physicians.

**Methods:** The survey was conducted online in the US in July 2017, and in EU5 (France, Italy, Spain, UK and Germany) in Nov/Dec 2017, through SERMO Real-Time. WoCBA were defined as female pts aged 18–45. Participants included

rheumatologists (RH), gastroenterologists (GI), dermatologists (DM) and obstetricians/gynaecologists (OB). Here, we present data for RH and OB.

**Results:** 203 healthcare professionals (HCPs) from the US participated, of whom 50 were RH and 50 OB; 401 HCPs from EU5 participated, of whom 152 were RH and 114 OB; over half of the female pt population with CID among the prescribing specialists were WoCBA. Overall, EU5 HCPs were less inclined to prescribe anti-TNF treatments for WoCBA pts; compared to the other specialists, US RH (43%) had the highest proportion of WoCBA pts prescribed anti-TNFs (EU5 RH: 33%; EU DM: 24%; US DM: 27%; US GI: 31%). However, HCPs' comfort with prescribing anti-TNF treatments consistently declined in both US and EU5 with onset of family planning (figure 1A). EU5 RH (61%) and OB (67%) were more likely to recommend discontinuation of anti-TNFs before conception than US HCPs (RH: 46%; OB: 62%); similarly, >50% EU5 RH and OB agreed that women should stop anti-TNFs post-conception (US RH: 34%; OB: 54%). These findings may be explained by the fact that more US HCPs strongly agreed on making disease control during pregnancy their priority (US RH: 42% vs EU5 RH: 25%) and that controlled disease reduces risk of pregnancy complications (US RH: 42% vs EU5 RH: 28%), as well as the observation that more EU5 RH (34%) than US (12%) were very concerned about adverse events, including infection or poor birth outcomes, in pregnant pts taking anti-TNFs. More EU5 than US RH strongly believed breastfeeding pts should not take anti-TNFs, although a high degree of uncertainty was indicated (figure 1B).

**Figure 1A** HCP level of comfort with anti-TNF treatment prescription for WoCBA patients.

**1B** HCP agreement on discontinuation of anti-TNFs during breastfeeding. HCP: healthcare professional; OB: obstetricians/gynaecologists; pts: patients; RH: rheumatologists; TNF: tumour necrosis factor; WoCBA: Women of Childbearing Age.

**Conclusions:** Our survey demonstrates the variability in confidence in clinical management of women with CID and highlights differences in physicians' attitudes between RH vs OB and EU vs US. Uncertainty and concerns about risks of anti-TNF use during pregnancy and breastfeeding are common, emphasising the need for better information and education of HCPs, especially in Europe, regarding the appropriate use of anti-TNFs during pregnancy and breastfeeding.

### FEARS AND MISCONCEPTIONS OF WOMEN WITH CHRONIC RHEUMATIC DISEASES ON THEIR JOURNEY TO MOTHERHOOD

A. Tincani<sup>1</sup>, P. Taylor<sup>2</sup>, R. Fischer-Betz<sup>3</sup>, C. Ecoffet<sup>4</sup>, E. Chakravarty<sup>5</sup>. <sup>1</sup>Università degli Studi di Brescia, Brescia, Italy, <sup>2</sup>Botnar Research Centre, Oxford, United Kingdom, <sup>3</sup>Rheumatology & Hiller Research Unit, University Hospital, Düsseldorf, Germany, <sup>4</sup>UCB Pharma, Brussels, Belgium, <sup>5</sup>Oklahoma Medical Research Foundation, Oklahoma City, OK, United States

**Background:** Recent EULAR 'Points to Consider' provide guidance on management and treatment of Women of Childbearing Age (WoCBA) with chronic rheumatic diseases (CRD: RA, axSpA, PsA). However, it is still unclear if these patients (pts) feel adequately supported to make informed treatment decisions around pregnancy and breastfeeding.

**Objectives:** To gain insight into perspectives of women with CRD regarding disease management and pregnancy, and assess whether current clinical practice provides adequate support.

**Methods:** WoCBA (aged 18–45 years) from Germany, France, UK, Italy, Spain (EU5), the US and Japan participated in a 20-min online survey (Jul–Oct 2017; InSites Consulting). We report data from pts with moderate-severe CRD who were pregnant or had been pregnant in the past 2–5 years.

**Results:** 622/1052 participants had CRD (RA, n=298; axSpA, n=182; PsA, n=142) and resided in the EU5 (n=306), US (n=293) and Japan (n=23). 87% pts reported having moderate CRD; 49% WoCBA stated that they had actively planned their most recent pregnancy. Fewer than half (46%) of WoCBA visited a healthcare professional (HCP) before pregnancy, of whom 53% consulted a rheumatologist among other HCPs (figure 1A). Although guidelines recommend addressing family planning/pregnancy in women with CRD before conception, 69% pts who visited an HCP before pregnancy had to initiate these discussions with their HCPs. 54% WoCBA admitted delaying their decision to become a mother; their main fear was passing on health issues to their child (figure 1B). 32% pts reported having inadequately controlled disease activity during pregnancy; 51% experienced disease improvement, 22% disease worsening. 82% pts visited an obstetrician/gynaecologist (OB/GYN) across trimesters, 68% a rheumatologist among other HCPs (figure 1A); 65% had a treatment plan aligned between different HCPs. Stopping treatment during pregnancy was largely driven by fear of harming the foetus (78%). Among the 113 pts on anti-TNFs, 22% decided to stop treatment themselves at the start of/during pregnancy, and 47% were advised to stop by their HCP. Although 89% pts reported discussing breastfeeding with an HCP (OB/GYNs were most influential), 66% mothers felt they had to decide between treatment and breastfeeding. While information provided by their HCP was generally satisfactory, pts still felt they lacked information on the impact of treatment decisions on pregnancy (38%) and breastfeeding (24%).

**Conclusions:** Despite current treatment recommendations, WoCBA with CRD continue to have many fears and misconceptions about their journey to motherhood, due to lack of guidance and consistent information regarding family planning, pregnancy and breastfeeding. Survey findings suggest that women's decisions to delay pregnancy and interrupt their treatment may be linked to a need for greater awareness of disease management options to optimise pregnancy outcomes. Access to this information, consultation with specialists and OB/GYNs earlier in the pregnancy planning process, and an aligned treatment plan could help prevent unnecessary decisions.

**Figure 1A)** Obstetricians/gynaecologists are the main healthcare professionals consulted during pregnancy. **1B)** WoCBA with chronic rheumatic diseases are concerned about pregnancy [a] n=622; [b] Multiple answers were possible; n=334. WoCBA: Women of Childbearing Age.

FRI0694

### TWITTER: A NEW PLATFORM FOR PUBLIC HEALTH CAMPAIGNS: SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS AS EXAMPLES

M. Mohameden<sup>1</sup>, B. Alkhair<sup>2</sup>, C. Yuvienco<sup>1</sup>. <sup>1</sup>Internal Medicine, University of California San Francisco Fresno, Fresno, <sup>2</sup>Internal Medicine, Blake Medical Center, Bradenton, United States

**Background:** Social media is widely used these days and has the capacity to distribute information widely and rapidly to a large audience. Twitter is a popular social network site with hundreds of millions of users and over 500 million Tweets being sent each day. Patients commonly receive information about their condition from social media sites including Twitter. Patient education plays an important role in the management of systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). The role of Twitter and its present application in SLE and RA patients' education was analyzed.

**Methods:** Twitter advanced search function was used to retrieve all tweets (English language only) containing the words systemic lupus erythematosus, lupus and/or SLE, as well as rheumatoid arthritis over one week (October 23, 2017 to October 29, 2017). Contents of collected tweets were analyzed, and tweets were categorized into 2 groups: general public (editorial/blogging, social/conversational, and advertisement tweets) and professional sources (tweets from physicians, rheumatologists, including hyperlinks to academic publications and websites of professional organizations, and educational tweets by awareness groups).

**Results:** Over the one-week timeframe, a total of 618 tweets mentioned lupus, systemic lupus erythematosus and/or SLE, and a total of 178 tweets mentioned rheumatoid arthritis. In the respective disease groups, tweets assigned to the professional sources category were 32% of the total tweets for SLE (200/618) and 51% for RA (92/178). Tweets sent by physicians constituted 2.6% (21/796) and by rheumatologists 1% (8/796) of the total tweets. Tweets with links to reliable sources (defined as hyperlinks to academic publications, professional organizations and awareness groups) were 23% of the total tweets. Finally, educational tweets by patient advocate groups were 10% of the total tweets.

**Conclusions:** Twitter has the capability of engaging a wide audience in a topic-specific conversation. Thus, it can be used as cost-effective platform for public health campaigns and to distribute evidence-based knowledge to educate patients. At this time, disease-specific search revealed a smaller percentage of content is employed for public health education and awareness. Links to reliable sources were 23% of the total tweets, indicating shortage of contribution from healthcare organizations and professionals. Majority of tweets were in the general public category (including tweets by patients) indicating an audience waiting for professional input. Health advocates should use Twitter to construct public health campaigns. Further research should be conducted to examine approaches to target specific Twitter users that engage in SLE and RA conversations.

**Disclosure of Interest:** None declared

FRI0695

### DMARD MONITORING GUIDELINES AND SHARED PRESCRIBING IN PRIMARY CARE – IS MORE EDUCATION REQUIRED?

G. Choudhury<sup>1</sup>, M. K. Nisar<sup>1</sup>. <sup>1</sup>Rheumatology, Luton & Dunstable University Hospital, Luton, United Kingdom

**Background:** DMARDs remain the mainstay of inflammatory arthritis therapy. Though an effective treatment, these drugs have the potential to cause serious harm. Vigilant drug monitoring, reflected in recently updated BSR guidelines, is necessary to prevent potentially life threatening complications. National Patient Safety Agency has also issued several alerts regarding DMARDs and methotrexate overdose remains a 'never event'. Prescribing medications, including DMARDs for rheumatology patients, is one of the chief responsibilities of primary care doctors.

**Objectives:** We undertook a pilot survey of regional GPs to understand their level of prescribing confidence with an aim to develop a targeted teaching program.

**Methods:** Based on BSR DMARD monitoring audit tool and regionally approved shared care guidelines, a focus group discussion with GP educators and CCG Medicine Optimisation Team was organised. Ten items were unanimously identified as core knowledge required for safe prescribing. A questionnaire was created based on these elements. GPs were surveyed at their educational meeting in our academic institution. Replies were compiled to ascertain their understanding of safe prescribing and troubleshooting DMARD related issues.

**Results:** There are 95 actively practicing GPs in the region. 41 (43%) GPs contributed to the survey. 22 (56%) were men. 27 (65%) had been practicing for 5–15 years (range <5 to >20 years). 34 (83%) regularly prescribed DMARDs. Only 15/41 (36%) felt confident in prescribing whereas 7/41 (17%) were neutral and remaining 46% did not feel confident. 49% participants were able to rightly answer questions pertaining to safe prescribing. Again most (70%) felt unable to confidently manage blood-monitoring issues such as neutropenia or abnormal liver function tests. Only four (9%) were able to correctly address the concerns related to administration of live vaccines whilst taking DMARDs. Nine GPs were unaware of avoiding trimethoprim co-prescription with methotrexate.

**Conclusions:** To our knowledge, this is the first survey to demonstrate that there are serious shortcomings in GPs' understanding of safe DMARD prescribing. Lack of confidence amongst front line medical staff remains the main cause of this issue. Despite frequent education bulletins and alerts from national bodies including NICE, BSR and NPSA and active measures taken in recent past to identify better ways to address the concerns, this study highlights major knowledge gaps among everyday prescribers in primary care. Dedicated strategy and better collaboration with GPs, with focus on drug monitoring education, are pivotal to providing better care for patients prescribed DMARDs in the community.

#### FRI0696 PATIENT ACTIVATION AND ADHERENCE TO BIOLOGICAL THERAPY: PRELIMINARY RESULTS

A. Sendra-García<sup>1,2,3</sup>, M. A. Portes-Peralta<sup>4</sup>, A. Moya-Gil<sup>1</sup>, J. P. Ordovás-Baines<sup>1</sup>, J. J. Alegre-Sancho<sup>2</sup>, M. Climente-Martí<sup>1</sup>. <sup>1</sup>Pharmacy Department, <sup>2</sup>Rheumatology Department, Dr. Peset University Hospital, Valencia, <sup>3</sup>Foundation for the Promotion of Health and Biomedical Research of Valencia, FIsABIO, <sup>4</sup>Pharmacology Department, University of Valencia, Valencia, Spain

**Background:** Medication non-adherence is associated with treatment failure. Some authors show a positive relationship between patient activation and both, adherence to treatment for chronic conditions and improved outcomes.

**Objectives:** To present preliminary results of a study measuring adherence to biological therapy and its relationship with the Patient Activation Measure (PAM) in the outpatient setting.

**Methods:** Ambispective longitudinal observational descriptive study in a general tertiary university hospital.

Patients on treatment with the same biological drug for  $\geq 6$  months were included in order of arrival. Patients with some degree of mental disability, which prevented understanding of the purpose and parameters of the study, were excluded.

Demographic variables (sex, age, environment, educational level), diagnosis and treatment were collected. To measure adherence, the Simplified Medication Adherence Questionnaire (SMAQ), validated in Spain, and the medication possession ratio (MPR) were used. Patients were considered as non-adherent if MPR<80% and/ or non-adherent SMAQ. To measure patient's ability to play an active role in their health care, PAM questionnaire, consisting on 13 items and validated in Spain, was used. It sorts patients into 4 activation levels, which were grouped together into not activated (PAM 1–2) or activated (PAM 3–4). Relationship between adherence to treatment, as a combined variable, and PAM was analyzed using chi-square, considering significance level  $p < 0.05$ . Statistical analysis were performed with spss v17.0.

**Results:** Fifty patients (58% women) were included. Mean age: 48 years (95% CI: 33 to 63); 92% lived in urban areas, 28% completed elementary education, 44% high-school and 28% university studies.

Diagnosis: rheumatoid arthritis (38%), Crohn's disease (20%), psoriasis (20%), ankylosing spondylitis (16%) and psoriatic arthritis (6%). Treatment: adalimumab (44%), etanercept (16%), tocilizumab (16%), secukinumab (12%), ustekinumab (6%), golimumab (4%) and ixekizumab (2%). Median time on the biological drug treatment: 26 months (IQR 53). PAM level: 2, 16, 54 and 28% for levels 1,2,3 and 4, respectively.

Table 1 Global distribution and relationship between adherence and PAM

n(%)	Adherent patients			Total
	SMAQ	MPR	Combined	
	38 (76%)	29 (59%)*	23 (47%)*	
<b>Activated patients</b>				
Yes	32 (78%)	25 (63%)*	20 (50%)*	41 (82%)
No	6 (67%)	4 (44%)*	3 (33%)*	9 (18%)
$\chi^2$ ; p	0,524; 0,668	0,991; 0,456	0,819; 0,472	

\*1 lost patient.

The proportion of adherent patients was 47% (23/49), being higher (50%) among the activated patients compared to the non-activated patients (33%), even though the differences were not statistically significant.

**Conclusions:** Among biologic treated patients, 82% show a high degree of activation on their disease and treatment self-management. However, only 47% were adherent to treatment, when combining the SMAQ questionnaire and the medication possession ratio quantification.

The greater proportion of adherence found among patients with a higher degree of activation could indicate a positive relationship between activation and adherence, so analyzing and promoting patient activation seems important in order to improve adherence to biologic drugs.

#### FRI0697 EXPECTATIONS, MOTIVATING FACTORS AND BARRIERS TO BASIC RESEARCH AMONG YOUNG RHEUMATOLOGISTS IN GERMANY– RESULTS OF A NATIONAL ONLINE SURVEY

J. Mücke<sup>1</sup>, M. Schneider<sup>1</sup>, U. Wagner<sup>2</sup>, H. Schulze-Koops<sup>3</sup>, A. Skapenko<sup>3</sup>, J. Leipe<sup>3</sup>. <sup>1</sup>Policlinic for Rheumatology, Heinrich-Heine-University, Duesseldorf, <sup>2</sup>Department of Rheumatology, University Hospital, Leipzig, <sup>3</sup>Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, University of Munich, Germany

**Background:** In Germany, the number of clinical fellows, who decide for a scientific career in basic research, is decreasing, leading to a growing lack of junior physician scientists (PS) highly needed to advance basic research.<sup>1</sup> Structured mentoring and funding programs as well as other incentives might be necessary to attract young physicians and support starting a scientific career in basic science.

**Objectives:** To identify expectations, motivating factors and barriers of final year medical students interested in rheumatology, of fellows and of physicians in rheumatology to start a scientific career in basic research.

**Methods:** An online survey was distributed by email and via facebook and twitter to members of the German Network of Young Rheumatologists (rheumadocs), medical students in their final year participating in a student program of the German Society for Rheumatology (DGRh), and by direct contact to PS. The questions focused on demographics, scientific background (including experience in basic research), expectations such as scientific self-realization, acquirement of a postdoctoral degree, enhanced career options, as well as motivating factors (e.g. "fun", financial benefits, travel bursaries, mentoring programs and others) and barriers (e.g. positions in basic science, exemption from clinical duties, lack of experience and/or assistance in fund-raising and scientific methods) with regard to a career in basic research.

**Results:** Of the 91 responders, 75% was aged below 35 years (11% <25 yrs, 32% 25–29 yrs, 57% >29 yrs) and 58% were female. 19% were currently working in basic research. 23% were students. 35% were fellows currently in the clinic. 23% were primary attendants. Basic research experience was reported by 49% of all clinicians. Only 10% indicated not to be interested in performing basic research. Among the students, 48% were currently performing a laboratory-based medical thesis. Of interest, no substantial differences in expectations or barriers were found between students, PS and clinicians. As to motivational factors, PS named time spent in research accounted for rheumatology training (74%), support by excellence programs (71%) and enhanced career options with a postdoctoral degree (65%) more often than clinicians and students (57%, 50% and 42% respectively). Other common motivational factors were "fun" (76%) and travel bursaries for international meetings (62%). Financial benefits in terms of standard or even senior physician salaries were no major motivators (41% and 24%, respectively). Regarding expectations, 71% indicated scientific self-realization, 58% named enhanced career options. 78% indicated lacking exemption from clinical

duties and lack of experience in fund-raising and scientific methods (58% and 48%) as a barrier for basic research.

**Conclusions:** This study shows a high interest among young rheumatologists and students to work in basic research, and indicates a need for programs, which facilitate the start of a career as physician scientist by providing a general framework with no drawbacks regarding rheumatology specialty training, (at least partial) exemption from clinical duties and support in development of research projects.

#### FRI0698 SURVEY OF 1,318 PATIENTS ON THEIR KNOWLEDGE OF THE PULMONARY MANIFESTATIONS OF RHEUMATOID ARTHRITIS AND THEIR NEEDS IN TERMS OF INFORMATION AND FOLLOW-UP

C. Beller<sup>1</sup>, P. Preiss<sup>1</sup>, Y. Allanore<sup>2</sup>. <sup>1</sup>AFPrC, <sup>2</sup>Cochin Hospital, Paris, France

**Background:** Pulmonary involvement is one of the main extraarticular manifestations of rheumatoid arthritis (RA) and can be influenced by the different therapies used to treat RA. In order to detect any pulmonary changes and rapidly institute appropriate care when necessary, the participation of the patient is essential. Patients must report any respiratory symptoms to their doctor who can then adapt the clinical examination and determine the need for additional investigations.

**Objectives:** Evaluate patients' knowledge about the pulmonary manifestations of RA, their follow-up and their needs in terms of information.

**Methods:** A 20 item questionnaire was developed by a group of patients and posted online using Survey Monkey software with a link sent to 6,702 members of the Association Française des Polyarthritiques. Anonymous responses were collected between November 8–23, 2017.

**Results:** 1,318 patients answered the questionnaire (19.7% response rate). Among the 1,297 patients with rheumatoid arthritis (RA): 1,110 were women (86.1%), the mean age was 60.3 years [16–86], 54% (701/1,284) were diagnosed with RA more than 10 years earlier, 76.4% (927/1,213) were on pharmaceutical maintenance treatment and 44.11% (535/1,213) on biologic therapy, and 56% (679/1,213) had received pneumococcal vaccination.

45.5% (552/1212) of respondents did not know that RA could affect the lungs. Among the others, two-thirds (417/659) had been informed of this by their rheumatologist.

39.8% (481/1,209) reported possible respiratory symptoms or dry cough. Among them, 69.1% (188/272) of those who knew that RA could affect the lungs had discussed their symptoms with their rheumatologist, 62.9% (171/272) were referred to a pulmonologist and 83.2% (188/272) were prescribed specific tests (x-ray, CT scan, etc.). Among respondents who did not know that RA could affect the lungs, only 32.8% (67/204) discussed their symptoms with their rheumatologist, 32.4% (66/204) were referred to a pulmonologist and 52.7% (107/207) underwent further tests.

In 44.6% (149/334) of cases, the specific tests revealed lung changes.

86.5% (1016/1,174) of respondents expressed the need to be better informed about the lung manifestations of RA and 60.4% (709/1,174) felt that they did not receive a thorough evaluation of their pulmonary status. Those who were referred to a pulmonologist gave an average score of 5.38/10 for the coordination between rheumatologist and pulmonologist.

Among the solutions proposed, the respondents would find it very appropriate (8 to 10/10): 76.2% (895/1,174) to be informed if they are among those at risk; 74% (869/1,174) to be alerted to symptoms that should prompt them to react; 60% (707/1,174) to benefit from regular monitoring of their respiratory status by the rheumatologist. On the other hand, regular consultation with the pulmonologist was considered very appropriate by only 48% (563/1,174).

**Conclusions:** The rate of participation in this survey illustrates patients' interest and need for information on this subject. The high percentage of patients (45.5%) who had not been informed about the risks of RA-related pulmonary involvement proves that there is room for improvement in patient education so that patients can be able and aware of how to detect any symptoms that need to be brought to the attention of their rheumatologist.

#### FRI0699 RHEUMATOLOGY TALKS TO THE COMMUNITY: RESULTS OF AN EDUCATIONAL INTERVENTION

S. P. Chinchilla<sup>1,2</sup>, J. Atxotegi<sup>2,3</sup>, I. Urionaguena Onaindia<sup>3</sup>, F. Perez-Ruiz<sup>1,3,4</sup>.

<sup>1</sup>Biocruces Health Research Institute, Barakaldo, <sup>2</sup>University of the Basque Country (UPV/EHU), Bilbao, <sup>3</sup>Rheumatology Division, OSI Ezkerraldea-Enkarterri-Cruces. Hospital Universitario Cruces, <sup>4</sup>University of the Basque Country (UPV/EHU), Barakaldo, Spain

**Background:** Rheumatology is a relatively new medical specialty, and mostly unknown to the general population. Thanks to close collaboration between rheumatologists and primary care physicians (PCP), and the availability of revolutionary drugs in the last decades, it has become a fundamental part of the management of patients with musculoskeletal disorders.

Besides information to PCP, it is equally important that the population is aware of what rheumatology is, and the diseases it treats. We decided to inform the population about the most prevalent disorders: osteoarthritis (OA), osteoporosis and gout, through talks in both urban and rural settings.

**Objectives:** To evaluate the short-term acquired knowledge after rheumatology talks in people from the general population.

**Methods:** Through a consulting firm, informative talks were offered in different city councils. They were finally conducted in 5 urban and rural towns between March 2016 and January 2017. The activity dissemination was in charge of each council and offered to the whole community.

Each talk lasted about 1.5 hours: a theoretical part in both co-official languages during 60 minutes, with some questions from the audience afterwards, as well as the completion of a 6-multiple choice-question survey evaluating some concepts from the talk. Topics included were: an explanation of what is rheumatology, and general aspects of OA, osteoporosis and gout. The answers to the survey were classified as correct and incorrect.

**Results:** 94.3% of the audience answered the survey. A total of 174 surveys from 5 towns were recovered. There was a higher participation from urban locations (40.2% of the total attendance). Despite being an educational activity for the whole community, the audience was mostly female (90.3%), with a median age of 69 years (IQR 63 to 74 years). Regarding language, 13.2% of attendees answered the survey in the other language.

Concerning the topics, 66.5% answered correctly about the definition of rheumatology and 87% about foods to avoid in gout. OA and osteoporosis had two questions each, with 92.5% of correct answers in the former and 80.2% in the latter. Osteoporosis recorded the highest percentage of correct answers within the survey (96.9%), in a question related to calcium-rich foods.

When comparing rural and urban locations, there were only statistically significant differences in the question related to gout, with a greater percentage of correct answers amongst attendees of rural towns (94.7 vs 75.8% respectively).

#### Percentage of correct answers in community survey after talk

**Conclusions:** According to our results, Rheumatology talks seem to be more attractive to elderly female population.

Knowledge acquired after talks has been good for OA and osteoporosis, both being prevalent conditions in this group of patients. We believe it is important to encourage rheumatology-related educational activities for the general population, and that these activities should be adjusted to the demographic characteristics of the focus group.

### PATIENTS AND RELATIVES COPING WITH INFLAMMATORY ARTHRITIS: A TEAM WORK

M. Brignon<sup>1</sup>, C. Vioulac<sup>2</sup>, E. Boujut<sup>2</sup>, C. Delannoy<sup>3</sup>, C. Beauvais<sup>4</sup>, J.-S. Giraudet Lequentrec<sup>4</sup>, D. Poivret<sup>5</sup>, J. Kivits<sup>1</sup>, A. Untas<sup>2</sup>, A.-C. Rat<sup>1</sup>. <sup>1</sup>EA4360, Université de Lorraine, Nancy, <sup>2</sup>EA 4057, <sup>3</sup>Paris Descartes University, <sup>4</sup>APHP, Paris, <sup>5</sup> Metz, France

**Background:** Adjustment to inflammatory arthritis (IA) is complex for the patient but also for the relative and there is room for improvement in the support provided to the dyad

**Objectives:** to explore patients and relatives experience of IA, their difficulties, mutual expectations, communication, coping strategies and needs

**Methods:** Participants were recruited by 7 rheumatologists during their consultations. Eligibility criteria were: having a rheumatoid arthritis (RA) or a spondyloarthritis (SpA). Relatives were invited to participate by the patients. Face to face interviews with the dyad were conducted by 3 psychologists with an interview guide built by the project working group. A thematic analysis was conducted by 2 psychologists, following a general inductive approach

**Results:** 20 patients and their relative (18 partners, 1 mother, 1 friend) were included: 13 RA and 7 SpA, median disease and couple duration 10 (range 1–36) and 28 years (range 1.5–57). The analysis revealed 4 main themes: disease leaved together, impact of the disease on the relationship, social impact of the disease on the dyad, difficulties and needs of the relative. Disease leaved together: dyads explained the new roles of the relative: providing material help, understanding and emotional support, acting as a driving force, take part of medical care (medical decisions, support in adhesion, searching for information). Communication around the disease is an important theme; reasons to avoid talking about the disease were: not focusing on the disease, respecting the need to be alone, words are not always needed. For other dyads, talking about the disease allows for improving knowledge about the disease or for security reasons. Impact of the disease on the relationship: if they do not feel the IA has changed their relationship, they acknowledged some tensions because of the disease: disease get too much attention in their relationship, lack of communication create tensions. Social impact of the disease on the dyad: social isolation was highlighted: patients need sometimes to be alone, invisibility of the disease creates misunderstandings, people around don't realize what it means to live with IA. Unpredictability of the symptoms makes it difficult to organize everyday life and to have projects. Difficulties and needs of the caregiver were rarely raised when the dyads were interviewed together: sometimes disease is not well accepted by the caregiver, not being able to help is frustrating, finding the right way to help is difficult. Knowledge of the disease and the patient symptoms are important needs expressed by the caregiver

**Conclusions:** The current qualitative study offers new insights into the perception of patient and relative of their shared life with the disease and is a first step to develop interventions to support them. This study has highlighted the importance of the recognition of the role of the relative in the disease management. Joint approach to treatment is a basis for coping with the disease. This supposes: 1) a good understanding of one another, which can be improved by providing information on the disease, its symptoms and coping strategies to both the patient and the relative 2) shared determination of relative roles 3) good communication skills

FRI0701

### FRENCH SPECIALISTS AND IMMUNE-RELATED ADVERSE EVENTS OF CANCER IMMUNOTHERAPY: A STATE OF THE ART FROM SEVERAL NATIONAL EXPERT NETWORKS.

M. Kostine<sup>1</sup>, C. Richez<sup>1</sup>, J.-E. Gottenberg<sup>2</sup>, O. Lambotte<sup>3</sup>. <sup>1</sup>Bordeaux University Hospital, Bordeaux, <sup>2</sup>Strasbourg University Hospital, Strasbourg, <sup>3</sup>Le Kremlin-Bicêtre, Paris, France

**Background:** Immunotherapeutic strategies with immune checkpoint inhibitors (ICI) are now commonly used in treating patients with advanced-stage cancer. An important proportion of patients experiences inflammatory or autoimmune side

effects, also known as immune-related adverse events (irAEs), as a consequence of dysregulated immunity which can affect any organ system (1). A recent survey conducted by our colleagues from United States highlighted that rheumatologists had limited experience and lacked confidence in the management of rheumatic irAEs (2).

**Objectives:** To evaluate the knowledge of French specialists regarding ICI and irAEs through an online survey.

**Methods:** The online survey has been sent in January 2018 to several French national expert networks: Société Française de Rhumatologie (SFR), Club Rhumatismes et Inflammations (CRI), Société Nationale de Médecine Interne (SNFMI), Groupe d'Etude Thérapeutique des Affections Inflammatoires du Tube Digestif (GETAID) and Société Française d'Endocrinologie (SFE).

**Results:** 349 French specialists participated to this study: rheumatologists (n=159), internists (n=112), endocrinologists (n=55), gastroenterologists (n=22) and one respiratory physician. As detailed in table 1, participants were mainly working in academic or hospital with various levels of experience in clinical practice. Overall, half of the specialists reported some basic knowledge of ICI and irAEs. Around 25% either have never heard about these therapies and their side effects or were not knowledgeable. The majority of the participants has never or rarely managed irAEs (31% and 40% respectively), and only 11% declared being very confident in treating such patients. The type of content requested for education was mainly about treatment algorithms (80%) followed by clinical description of irAEs (59%) then general information on ICI (mechanism of action, administration, efficacy).

Table 1 Demographics and knowledge of ICI and irAEs among french specialists, n (%)

**MECHANISM AND SIGNIFICANCE OF COMPLEMENT C3 RECEPTOR IN COLLAGEN-INDUCED RHEUMATOID ARTHRITIS MICE MODEL**

L. Dan<sup>1</sup>, L. ke<sup>2</sup>. <sup>1</sup>Departement of Rheumatology and Immunology, Xi'an No. 5 Hospital; <sup>2</sup>Core Research Laboratory, he Second Affiliated Hospital of Xi'an Jiaotong University, xi'an, China

**Background:** Rheumatoid arthritis (RA) is a kind of chronic autoimmune disease, mainly manifested as small joint synovitis. Disease progression appears joint swelling, bone and cartilage damage, deformity and activity limited. The etiology of RA is still unclear and is generally considered to be an immune-mediated inflammatory disease. The activation pathway and regulation function of the complement system have become the hotspot of the research of RA pathogenesis. Previous studies have found that C3<sup>-/-</sup> mice had lower levels of antibodies to collagen in the Type II collagen-induced rheumatoid arthritis (CIA model), and the molecular mechanism is unclear. The small fragment C3a and large segment iC3b produced by C3 activation are the main effect products, and their biological effects are performed by combining with the specific receptor, C3aR and CD11b respectively.

**Objectives:** To investigate the mechanism of C3a and C3b, the cleavage products of complement C3 in rheumatoid arthritis, binding to their corresponding receptors, the signalling pathway of complement activation and the effect on arthritic conditions.

**Methods:** This study was intended to establish a CIA model on C3aR knockout and CR3 knockout mice (C3aR<sup>-/-</sup> or CD11b<sup>-/-</sup>) to investigate the effect of complement C3a-C3aR signalling and iC3b-CR3 signalling on rheumatoid arthritis. Methods using C57BL/6 background transgenic mice (Gifted by King's College London), Mice were divided into 3 groups according to the experimental mouse strains: C3aR<sup>-/-</sup> group, CD11b<sup>-/-</sup> group and WT control group. The clinical score of the joints in each group was measured after the establishment of the CIA model through collagen induction. Moreover, joint specimens were collected for pathologic grading. Besides, the level of CD4<sup>+</sup>T cell, CD8<sup>+</sup>T cell, Th17/Treg ratio and the level of IFN-gamma of NK cell in mouse spleen were detected by flow cytometry.

**Results:** 1. The clinical score of C3aR<sup>-/-</sup> group was slightly lower than that of WT group, and the clinical score of CD11b<sup>-/-</sup> group was significantly higher than that of WT group; 2. Pathological score (12 points): The CIA scores of CD11b<sup>-/-</sup> group, C3aR<sup>-/-</sup> group and WT group were 9.35±0.75, 4.81±0.63 and 5.85±0.55 respectively. The CIA scores of CD11b<sup>-/-</sup> group was significantly higher than that of WT group, which were consistent with clinical score; 3. Through the flow cytometry detection, compared with the WT group, CD4<sup>+</sup>T cell, CD8<sup>+</sup>T cell and Th17 percentage increased significantly, and Treg cell decreased. In addition, the secretion of IFN-gamma of Splenic NK cell was significantly reduced.

**Conclusions:** iC3b as well as C3a could bind to their respective complement receptor, and express different influence in the immune mechanism of RA, The iC3b-CD11b signalling has a protective effect in RA, while the C3a-C3aR signalling has an inflammatory aggravation effect. Through this study, it helps us to invent the drug related to complement components and their receptors, and further be used in the clinical treatment of RA.

**Background:** Activating Fc $\gamma$ -receptors on neutrophils associate with the Fc-receptor  $\gamma$ -chain (FcR $\gamma$ ), an immunoreceptor tyrosine-based activation motif (ITAM) containing transmembrane adapter molecule. Previously, we carried out *in vitro* experiments that showed not only a chaperon-like function of FcR $\gamma$ , but also a signalling role through its intracellular ITAM-tyrosines.

**Objectives:** Here, we investigated the participation of these tyrosines in an auto-antibody-induced arthritis model (in the KBxN serum transfer arthritis, for the

development of which neutrophils and Fc-receptors are essential) using wild type and ITAM tyrosine mutant (Y65F/Y76F) transgenic mice.

**Methods:** The experimental animals expressed wild type or ITAM tyrosine mutant (Y65F/Y76F) Fc-receptor  $\gamma$ -chain on the FcR $\gamma$ <sup>-/-</sup> genetic background. The arthritis was initiated by a single intraperitoneal injection of control or arthritic serum. The severity of joint inflammation was followed by clinical scoring, measuring ankle thickness changes and detecting joint dysfunction. Homozygous transgenic mice were identified by quantitative PCR.

**Results:** Compared to wild type mice, FcR $\gamma$  knockout animals failed to exhibit a measurable joint inflammation. Surprisingly, the arthritis could not develop in wild type FcR $\gamma$  transgene heterozygous mice. To enhance the expression level of the wild type transgene (which was approximately one third of the expression of the mutant transgene), we crossed our wild type transgene heterozygous mice with each other. As a consequence, wild type FcR $\gamma$  transgene homozygous mice on the  $\gamma$ -chain knockout background were able to undergo arthritic development. In contrast, FcR $\gamma$  knockout mice carrying the ITAM-mutant FcR $\gamma$  transgene (both at heterozygous and homozygous forms) were fully protected from the development of arthritis despite of comparable neutrophil cell surface Fc $\gamma$  receptor expressions.

**Conclusions:** Our *in vivo* experiments show that the intracellular Fc receptor  $\gamma$ -chain ITAM tyrosines play a critical role in the initiation and progression of an auto-antibody-induced experimental arthritis model, confirming a signalling, rather than just a chaperon-like function of the molecule.

**Background:** Dendritic cells (DCs) direct the immune response against pathogens while maintaining self-tolerance by instructing T/B cells in lymphoid organs and peripheral tissues. However, their aberrant activation can lead to chronic inflammation and autoimmunity. Based on the distinct transcriptomics, function and distribution, DCs can be broadly categorised as plasmacytoid and myeloid (conventional) DCs. Based on recent single cells sequencing and secretome data, can be divided into CD141<sup>+</sup> DCs (DC1), DC2\_A (DC2) defined as "CD1c<sup>high</sup>CD32B<sup>high</sup>CD36<sup>neg</sup>CD163<sup>neg</sup>" and DC2\_B (DC3) defined as "CD1c<sup>low</sup>CD32B<sup>neg</sup>CD163<sup>high</sup>CD36<sup>high</sup>." In addition, populations of CD1c<sup>+</sup>CD141<sup>+</sup>CD16<sup>+</sup> DC (named DC4), that shares some gene expression with CD16<sup>+</sup> monocyte and inflammatory DC (infDC). Most to date studies on Rheumatoid Arthritis patients investigated DCs in circulation or in synovial fluid (SF). This provided important insight into epigenetic changes in DC-precursors before they enter synovial tissue, e.g. RA blood CD1c<sup>+</sup> have deregulated microRNA-34a driven epigenetic control of anti-inflammatory Axl pathway<sup>2</sup> or into the influence of inflammatory milieu on DCs, respectively. However, neither (peripheral blood) PB or SF are major sites for DC regulated T/B cell activation; instead, DCs control immune responses in the appropriate structures of lymphoid organs and tissues.

**Objectives:** In this study, we sought to investigate myeloid DCs in synovial tissue with the prospect of better understanding their role in driving autoimmunity in RA.

**Methods:** We developed a flow cytometry sorting strategy to characterise the phenotype of distinct myeloid DC subsets in multiple biological compartments (PB, SF and synovial tissue). Synovial tissue (ST) biopsies (RA n=9; Psoriatic arthritis n=3) were digested with liberase prior the analysis. Peripheral blood DCs (RA n=19, Psoriatic arthritis n=16, healthy donors n=12), and SF DC (n=3) were used as comparators. Synovial tissue, SF and PB DCs were sorted and micro-RNAs, pro-inflammatory and regulatory cytokine expression analysed by amplified qPCR. In addition, DCs were mapped in synovial tissue in RA (n=8), PsA (n=7) and control non-inflammatory OA (n=5) by immunohistochemistry.

**Results:** Myeloid DCs are scarce in control non-inflammatory OA synovial tissues and their number increased substantially in PsA and RA tissues. Phenotyping data revealed that all myeloid DC subsets can be present in inflamed RA and PsA synovium. However, CD1c<sup>+</sup> DC populations (DC2/DC3) were the most abundant in RA synovial tissues and the gene expression analysis of CD1c<sup>+</sup> sorted from RA synovial biopsies showed an increase in the expression of epigenetic regulator of inflammatory response miR-155 and IL-6, TNF and IL-23 as compared to circulating cells.

**Conclusions:** CD1c<sup>+</sup>DCs from RA synovial tissues had epigenetically regulated activated phenotype (miR-155 and miR-34a<sup>2</sup>) that through the production of cytokines could maintain tissue activation of autoreactive Th1 and Th17 cells and contribute to inflammation.

#### SAT0004 INTRA-ARTICULAR INJECTION OF ADIPOSE-DERIVED MESENCHYMAL STROMAL CELLS REDUCE EXPERIMENTAL OA PATHOLOGY VIA IL-1B-MEDIATED REALLOCATION AND ENHANCED PHAGOCYTOSIS OF POLYMORPHONUCLEAR LEUCOCYTES

S. van Dalen<sup>1</sup>, M. van den Bosch<sup>1</sup>, A. Blom<sup>1</sup>, P. van der Kraan<sup>1</sup>, T. Vogt<sup>2</sup>, L. Casteilla<sup>3</sup>, P. van Lent<sup>1</sup>. <sup>1</sup>*Experimental Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands;* <sup>2</sup>*Institute of Immunology, University of Munster, Munster, Germany;* <sup>3</sup>*STROMAlab, University of Toulouse, Toulouse, France*

**Background:** Injection of adipose-derived mesenchymal stromal cells (ASCs) into knee joints after induction of experimental inflammatory osteoarthritis (CiOA) reduces development of joint pathology.<sup>1</sup> This protection is only achieved when ASCs are applied in early CiOA, which is characterised by synovitis and high levels of S100A8/A9 and IL-1 $\beta$ , suggesting that inflammation boosts the protective effect of ASCs.<sup>2</sup>

**Objectives:** To examine the role of synovitis in ASC-mediated amelioration of CiOA pathology.

**Methods:** CiOA was induced by intra-articular collagenase injection. Knee joint sections were stained with haematoxylin/eosin and immunolocalization of polymorphonuclear leucocytes (PMNs) and ASCs was performed using antibodies for NIMP-R14 and CD271, respectively. Chemokine expression induced by IL-1 $\beta$  or S100A8/A9 was assessed with qPCR and Luminex. Migration of PMNs through transwell membranes towards ASC-conditioned medium (CM) was examined using flow cytometry. ASC-PMN co-cultures were analysed microscopically and with Luminex. Phagocytic capacity of PMNs was measured with labelled zymosan particles.

**Results:** Intra-articular injection of saline in knee joints of day 7 CiOA induced a flare already after 6 hours, characterised by particularly PMNs scattered throughout the synovium. Although ASC injection resulted in comparable numbers of PMNs, these cells however, were clustered around ASCs. IL-1 $\beta$ -stimulation of ASCs *in vitro* strongly increased expression of PMN-attracting chemokines KC, CXCL5, and CXCL7, whereas S100A8/A9 did not. Migration of PMNs towards CM of IL-1 $\beta$ -stimulated ASCs (IL-1 $\beta$ -CM) was significantly enhanced (2.9-fold increase) when compared to CM of non-stimulated ASCs (NS-CM). After 6 hours co-culturing PMNs with IL-1 $\beta$ -stimulated ASCs, the number of clustered PMNs per ASC was significantly increased. Interestingly, association of PMNs with ASCs significantly diminished the release of KC protein by ASCs (69% lower after 24 hour), and also strongly reduced the release of S100A8/A9 protein by the PMNs. Moreover, phagocytic capacity of PMNs was strongly enhanced after priming with CM of IL-1 $\beta$ -stimulated ASCs.

**Conclusions:** Local application of ASCs in inflamed CiOA knee joints results in attraction and clustering of PMNs with ASCs in the synovium, which is likely mediated by IL-1 $\beta$ -induced up-regulation of chemokine release by ASCs. This results in lowered S100A8/A9 levels and enhanced phagocytic capacity of PMNs, enabling the clearance of debris to attenuate synovitis and promote tissue repair.

#### SAT0005 INTERLEUKIN-33 AMELIORATES MURINE LUPUS VIA INDUCTION OF REGULATORY T CELLS AND M2 MACROPHAGE POLARISATION

M.Y. Mok<sup>1</sup>, K. Law<sup>2</sup>, W.Y. Kong<sup>1</sup>, Y. Lo<sup>2</sup>, E. Ng<sup>1</sup>, C. Luo<sup>2</sup>, F. Huang<sup>3</sup>, G. Chan<sup>4</sup>, K. Chan<sup>3</sup>. <sup>1</sup>*Department of Biomedical Sciences, City University of Hong Kong, Kowloon;* <sup>2</sup>*Department of Medicine;* <sup>3</sup>*Department of Pathology;* <sup>4</sup>*Department of Paediatrics, University of Hong Kong, Hong Kong*

**Background:** The levels of IL-33, a Th2 promoting cytokine, and the soluble form of its receptor ST2 were reported to be elevated in serum of patients with active systemic lupus erythematosus (SLE), suggesting a role of the IL-33/ST2 axis in the pathogenesis of SLE.

**Objectives:** This study aims to examine the effect of IL-33 in disease severity of murine lupus.

**Methods:** IL-33 was injected intraperitoneally 3 times per week to pre-diseased MRL/lpr mice aged 12 weeks for 6 weeks. Control group was given 1% BSA injection. Urine protein was monitored weekly by albustix and protein assay. Immunophenotyping of splenocytes was examined by flow cytometry. Splenic CD11b<sup>+</sup> monocytic cells were isolated by microbeads for mRNA examination.

**Results:** IL-33-treated mice (n=9) developed significantly less proteinuria compared to BSA-treated group (n=9). Kidney histology of the IL-33-treated group showed remarkably less mesangial deposit, diffuse proliferative glomerular changes and crescents, and had significantly lower renal composite score compared to controls (median 2.0 vs 9.9, p<0.001). Kidneys of these mice expressed lower mRNA levels of TNF- $\alpha$  (32.1 $\pm$ 14.7 vs 77.0 $\pm$ 27.8, p<0.001), IL-6 (median 0.6 vs 4.7, p=0.003), IL-1 $\beta$  (31.1 $\pm$ 10.1 vs 77.8 $\pm$ 24.6, p<0.001) and iNOS (p=0.006). Immunophenotyping of splenocytes showed significantly increased CD4<sup>+</sup>CD25<sup>+</sup>regulatory T (Treg) cells (4.0% $\pm$ 1.2% vs 2.2 $\pm$ 0.2%, p<0.001) that expressed remarkably higher Foxp3 (76.0% $\pm$ 5.0% vs 59.3 $\pm$ 12.6%, p=0.002). Splenic extracts showed predominant Gata3 (0.37 $\pm$ 0.20 vs 0.12 $\pm$ 0.09, p=0.01) and Foxp3 (0.42 $\pm$ 0.16 vs 0.17 $\pm$ 0.11, p=0.002) mRNA in IL-33-treated mice. These Treg cells expressed high cell surface ST2 (8.9% $\pm$ 2.7% vs 4.5 $\pm$ 2.0%, p=0.008). There was significant expansion of splenic CD11b<sup>+</sup> population in IL-33-treated mice (17.8 $\pm$ 10.5 vs 8.8 $\pm$ 3.0, p=0.01) that expressed significantly higher CD206 (5.2% $\pm$ 0.9% vs 2.9 $\pm$ 0.9%, p=0.002). Isolated splenic CD11b<sup>+</sup> cells expressed significantly higher mRNA of Arg1, FIZZ1 and Ym-1 and IL-10 (all p=0.01) with reduced expression of iNOS (p=0.02). Kidney extracts of IL-33 treated mice also had elevated mRNA levels of M2 markers including Arg1 (median 199.8 vs 36.1, p=0.004) and FIZZ1 (median 25.0 vs 2.7, p<0.001) and reduced MCP-1 (12.7 $\pm$ 6.5 vs 35.1 $\pm$ 12.0, p<0.001). There was also significantly higher levels of mRNA of Foxp3 (median 43.0 vs 20.8, p=0.006) and Gata 3 (1.7 $\pm$ 0.5 vs 0.9 $\pm$ 0.5, p=0.008) but lower Rorc (2.6 $\pm$ 1.0 vs 3.8 $\pm$ 0.8, p=0.008) and Tbx21 (12.6 $\pm$ 6.0 vs 29.6 $\pm$ 13.7, p=0.003) in the kidneys.

**Conclusions:** Exogenous IL-33 led to significantly less proteinuria and renal inflammation. These mice had significantly higher splenic Treg cells with prominent Foxp3 expression. Isolated CD11b<sup>+</sup> cells from spleen and kidney extracts demonstrated mRNA levels of M2 macrophage polarisation.

#### SAT0006 P2X7 RECEPTOR IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE). EXPLORING A NOVEL PATHOGENETIC PATHWAY IN LUPUS RELATED SEROSITIS

F. Furini<sup>1</sup>, A. Bortoluzzi<sup>1</sup>, A.L. Giuliani<sup>2</sup>, F. Di Virgilio<sup>2</sup>, M. Govoni<sup>1</sup>. <sup>1</sup>*Dept of Medical Sciences, Section of Haematology and Rheumatology, University of Ferrara, Cona (Fe);* <sup>2</sup>*Dept of Morphology, Surgery and Experimental Medicine, Section of Pathology, Oncology and Experimental Medicine, University of Ferrara – ITALY, Ferrara, Italy*

**Background:** Recent studies have focused attention on the involvement of innate immunity and in particular on the activation of NLRP3 inflammasome by purinergic signalling mediated by P2  $\times$  7 receptor (P2  $\times$  7R), in SLE pathogenesis.<sup>1</sup> Serositis are typical SLE manifestations often associated with increased inflammatory indices and promptly responding to colchicine whose action could be mediated by its effect on microtubules during P2  $\times$  7R assembly.

**Objectives:** To explore the role of innate immune system in SLE evaluating expression and activity of P2  $\times$  7R and NLRP3, comparing patients with positive and negative history of serositis with healthy control subjects (HC).

**Methods:** We studied SLE patients with (LS) or without (LN) history of serosites and HC matched for sex and age. Demographic, clinical, therapeutic and clinimetric data were retrospectively collected. After isolation of peripheral blood mononuclear cells (PBMCs) from whole blood by centrifugation on Ficoll gradient, P2 x 7R and NLRP3 expression were evaluated by RT-PCR analysis while activity was analysed after stimulation with BzATP (P2 x 7R agonist), by measuring intracellular calcium changes using Fura2-AM fluorescent probe. Finally *in vitro* IL-1 $\beta$  and IL6 production by short term cultured PBMCs (in RPMI and after stimulation with either LPS or BzATP or BzATP +LPS), and IL-1 $\beta$  and IL6 plasma levels were evaluated by ELISA.

**Results:** 30 HC and 31 patients were enrolled: 13 (40,6%) LS vs 18 (59,4%) LN. 30 were female. No significant differences about demographic, disease activity and serological features were found between LS and LN and almost all patients were taking low dose steroids and immunomodulatory therapy (table 1). No significant difference in plasmatic levels of IL-1 $\beta$  and IL-6 were found between SLE and HC also considering separately the LS group. RT-PCR analysis of PBMC from SLE subjects showed reduced P2 x 7 and slightly augmented NLRP3 expression. *In vitro* IL-1 $\beta$  release was diminished in SLE patient (both LS and LN) respect to HC (especially comparing LN vs HC) while IL-6 levels appeared to be higher in SLE patients (especially LN) (table 2).

**Conclusions:** P2 x 7R expression and activity appeared to be reduced in SLE compared to HC as demonstrated by evaluation of intracellular calcium changes and IL-1 $\beta$  levels produced by PBMC. Conversely, IL-6 was released at higher levels from PBMC of patients compared to HC, thus suggesting that production of this cytokine could be mediated by another pathway (possibly TLR pathway<sup>2</sup>). Other P2 x 7 dependent responses, such as pyroptosis or T and B lymphocyte functions, need to be investigated. Overall, these preliminary results suggest that P2 x 7R and inflammasome activation do not seem to be the main pathogenetic pathway in SLE patients with history of serositis.

**SAT0007 DISTINCT MACROPHAGE PHENOTYPE AND BIOENERGETIC PROFILES IN RHEUMATOID ARTHRITIS**

M.M. Hanlon<sup>1</sup>, T. McGarry<sup>1</sup>, M. Canavan<sup>1</sup>, C. Lowe<sup>2</sup>, S. Wade<sup>1</sup>, D.J. Veale<sup>2</sup>, U. Fearon<sup>1</sup>. <sup>1</sup>*Molecular Rheumatology, Trinity Biomedical Sciences Institute;* <sup>2</sup>*Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, Dublin, Ireland*

**Background:** Diversity of macrophage subsets within the joint remains unknown. The concept of macrophage polarisation into M1 inflammatory macrophages and M2 tissue-resolving macrophages, paralleled by changes in the bioenergetic cell profile, has received much attention. Hence, we aimed to examine the phenotype of macrophages within the inflamed RA joint, along with the metabolic and inflammatory capacity of RA monocyte-derived macrophages compared to healthy individuals.

**Objectives:** To examine the phenotype, metabolic and inflammatory profile of pro-inflammatory and anti-inflammatory macrophages within the inflamed RA joint.

**Methods:** Blood obtained from healthy and RA donors, CD14 +cells sorted and differentiated into macrophages for 8 days. Macrophages were polarised to either M1 (LPS and IFN $\gamma$ ) or M2 (IL-4). Markers of polarisation, metabolism and inflammation were quantified by Real Time-PCR. Seahorse technology measured the major energy-using pathway, oxidative phosphorylation (OCR). Finally, synovial tissue (ST) was digested to yield a single cell suspension, this was then stained using a panel of fluorochrome antibodies (CD45, CD40, CD68, CD64, CD163, CD206, CD253), and subsequently analysed using FlowJo software.

**Results:** M1 macrophages were confirmed by increased expression of KLF6 while M2 macrophages expressed high TGM2, PPARG and STAB1. M1 cells had significantly higher expression of pro-glycolytic genes (HIF1 $\alpha$ , HK2, LDHA, PFKFB3 and PKM2), which were deficient in M2 macrophages and higher compared to healthy control. This was paralleled by higher pro-inflammatory cytokines levels (IL-8, OSM, MCP-1, RANTES IRAK-1, CCR5 and SOCS3) in M1 vs M2 macrophages, with RA derived macrophages showing higher expressions of pro-inflammatory mediators compared to healthy control. G6PD, PHD3 and PDK1/2 were significantly decreased in M1 yet increased in M2 macrophages, and along with this seahorse technology demonstrated that M2 macrophages have higher baseline OCR. Finally, ST analysis determined approximately 40% of CD45 +cells are positive for the pan-macrophage marker CD68. Interestingly, the classical paradigm of M1 and M2 macrophages is not found. Instead, a spectrum of macrophages were identified with approximately 57% of ST macrophages expressing M2 markers (CD206, CD163) with the M1 activation marker CD40.

**Conclusions:** This study demonstrated distinct metabolic profiles in M1/M2 RA macrophages; their opposing roles in perpetuating and resolving inflammation, respectively. We have identified, for the first time, a transitional subtype of tissue-specific macrophages, suggesting that these cells remain plastic and function according to their microenvironment.

This study demonstrated distinct metabolic profiles in M1/M2 RA macrophages; their opposing roles in perpetuating and resolving inflammation, respectively. We have identified, for the first time, a dominant transitional subtype of tissue specific macrophages with at least six other phenotypically distinct subtypes also present, suggesting that these cells remain plastic and function according to their microenvironment.

**SAT0008 DYSREGULATION OF THE CIRCULATING AND RENAL CLUSTERIN IN LUPUS NEPHRITIS**

H.-J. Ma<sup>1,2</sup>, C. Liu<sup>1</sup>, B.-Y. Shi<sup>1</sup>, L.-Y. Sun<sup>1</sup>. <sup>1</sup>*Department of Rheumatology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing;* <sup>2</sup>*Department of Rheumatology and Immunology, The First Affiliated Hospital of Xinxiang Medical University, Xinxiang, China*

**Background:** Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease with lupus nephritis (LN) as one of the main causes of poor prognosis. Although the complement system participates in the development of LN, the exact mechanism is not clear. The present study was to investigate the pathogenesis of LN by detecting the levels of Clusterin (CLU, one of complement regulatory proteins) in the plasma and renal specimens of patients with LN.

**Objectives:** To determine the circulating and renal Clusterin levels and its clinical associations in patients with LN.

**Methods:** Plasma Clusterin levels were examined by enzyme-linked immunosorbent assay in 66 SLE including 50 LN patients and 40 healthy controls. Immunohistochemical method was used to detect the expression of Clusterin in renal biopsy tissues of 16 LN patients. Severity of LN was assessed according to the abbreviated version of the International Society of Nephrology/Renal Pathology Society classification.

**Results:** Plasma levels of Clusterin were significantly decreased in active LN patients when compared to healthy controls ( $p < 0.05$ ). Plasma Clusterin levels were negatively correlated with CRP, SLEDAI, and 24 hours proteinuria ( $p < 0.01$ ,  $p < 0.05$ , and  $p < 0.05$ ). In sixteen patients with lupus nephritis, we found that the expression of Clusterin in glomeruli was significantly enhanced in severe LN when compared to mild LN (figure 1,  $p < 0.05$ ).

**Abstract SAT0008** – Figure 1. Deposition of Clusterin in LN. \* $P < 0.05$ .

**Conclusions:** Decreased Clusterin could involve in the pathogenesis of LN, and the role of renal Clusterin need to be further explored. These findings suggested that Clusterin would be a therapeutic target for lupus nephritis in the future.

#### SAT0009 TYROSINE KINASE PATHWAYS IN MONOSODIUM-URATE CRYSTAL-INDUCED INFLAMMATORY RESPONSES

K. Futosi, T. Németh, A. Mócsai. *Department of Physiology, Semmelweis University School of Medicine, Budapest, Hungary*

**Background:** Deposition of monosodium urate (MSU) crystals in the joints or other tissues is a hallmark in the pathogenesis of gout. The urate crystal-induced inflammation is known to be mediated mainly by neutrophils besides monocytes and macrophages. Although MSU crystal-mediated signal transduction is in the focus of recent investigations, the molecular mechanism is only partially characterised.

**Objectives:** In this study, we investigated the role of Src family kinases in MSU crystal-induced *in vitro* activation of primary murine and human neutrophils and their *in vivo* significance in experimental model of gout.

**Methods:** Bone marrow isolated neutrophils from wild type and triple Src family kinases-deficient (Hck<sup>-/-</sup>Fgr<sup>-/-</sup>Lyn<sup>-/-</sup>) mice or vehicle and Src-inhibitor treated human neutrophils were stimulated with different concentration of MSU crystals. The superoxide production of the cells was measured by a luminometric assay, while the supernatants of MSU crystal activated cells were analysed by using various enzyme-linked immunosorbent assay (ELISA) kits. The phagocytosis of the urate crystals by neutrophils was followed by videomicroscopy and flow cytometry. Gouty arthritis was induced by injection of MSU crystals into the hind paws of the experimental mice and was assessed by ankle thickness measurements and detection of the synovial cytokine levels by ELISA.

**Results:** The MSU crystal-induced superoxide release, cytokine production and the crystal-phagocytosis were abrogated in Src family kinases-deficient murine or in Src-inhibitor treated human neutrophils. In contrast to wild type animals, Src family kinases-deficient mice showed significantly decreased paw swelling and neutrophil accumulation at the site of inflammation. In line with this, the synovial levels of interleukin-1 $\beta$  and CXCL2 were also strongly reduced in Src family kinases-deficient mice compared to wild type animals.

**Conclusions:** Src family kinases play an indispensable role in MSU crystal-induced superoxide and cytokine production as well as crystal-phagocytosis of neutrophils. The fact, that Src family kinases-deficient mice are partially protected from crystal-induced inflammatory reactions indicate the important role of these kinases in *in vivo* gouty arthritis. These kinases are also play important role in the

development of *in vivo* gouty arthritis as the. Identification of these key players in urate crystal-induced intracellular signalling pathways in neutrophils leads to a better understanding of the pathogenesis of gout and may help to develop novel therapeutic strategies in MSU crystal-associated inflammatory diseases.

#### SAT0010 EXCESSIVE FORMATION OF NEUTROPHIL EXTRACELLULAR TRAPS HAVE A DIFFERENT ROLE IN THE PATHOGENESIS OF ANCA-ASSOCIATED VASCULITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

L.S. van Dam<sup>1</sup>, T. Kraaij<sup>1</sup>, S.W. Kamerling<sup>1</sup>, H.U. Scherer<sup>2</sup>, T.J. Rabelink<sup>1</sup>, C. van Kooten<sup>1</sup>, Y.O. Teng<sup>1</sup>. <sup>1</sup>*Nephrology*; <sup>2</sup>*Rheumatology, LUMC, Leiden, Netherlands*

**Background:** Renal involvement in ANCA-associated vasculitis (AAV) and systemic lupus erythematosus (SLE) manifests as autoimmune-mediated glomerulonephritis (AIGN). In AAV, crescentic lesions and a pauci-immune immunofluorescence is typically seen while in SLE endo- and extracapillary proliferative lesions and a full-house immunofluorescence is seen. Although these are clinically divergent autoimmune diseases, neutrophil extracellular traps (NETs) are postulated to be involved in their pathogenesis. NETs are immunogenic, extracellular DNA structures harbouring relevant ANCA- and nuclear auto-antigens. However, it is still unclear how and if NETs can act as a common pathway for both AAV and SLE.

**Objectives:** To increase our understanding of the potential pathogenic role of NETs in AAV and SLE, the aim of this study was to compare the characteristics of *ex vivo* AAV- and SLE-induced NET formation.

**Methods:** *Ex vivo* NET formation was quantified by our highly-sensitive NET quantification assay using 3D-confocal microscopy<sup>1</sup> for 82 AAV, 56 SLE patients and 10 healthy controls (HC). Live cell imaging was used to study the morphology and kinetics. Qualitative characteristics of NETs were investigated by immunofluorescence microscopy that detected co-localisation of NET-markers, including citrullinated histon-3 (CitH3) and high mobility group box-1 (HMGB1). Also, the presence of IgG, IgM or IgA autoantibodies on AAV- and SLE-induced NETs was studied. Autoantibodies as trigger of NET formation were investigated by depleting serum from IgG and NET inhibition assays were performed using peptidylarginine deiminase-4 (PAD4) and NADPH inhibitors.

**Results:** Quantifying *ex vivo* NET formation demonstrated excessive NET formation for both AAV and SLE as compared to HC. AAV-induced NET formation (median [Q1 – Q3]: 20.7 [9.6–74.1]) was significantly higher compared to SLE-induced NET formation (5.6 [2.3–14.3];  $p < 0.0001$ ). Secondly, live cell imaging revealed lytic NET formation in AAV peaking after 2–4 hours while in SLE non-lytic NET formation with neutrophil clustering occurred within minutes. Thirdly, the presence of CitH3 was significantly higher on AAV-induced NETs, whereas SLE-induced NETs contained significantly more HMGB1. AAV-NETs were triggered independent of IgG, in contrast to IgG dependence of SLE-NETs. Intriguingly, immunofluorescence staining of immunoglobulins revealed a pauci-immune expression on AAV-NETs compared to a full-house expression of IgG, IgM and IgA on SLE-NETs. Both PAD4 and NADPH were involved in AAV- but not in SLE-induced NET formation. To further corroborate on these differences, we found that SLE-NETs were enriched for oxidised mitochondrial DNA as demonstrated by TOMM20 and MitoSOX.

**Conclusions:** This study demonstrates that excessive NET formation in AAV is intrinsically different to NET formation in SLE. AAV-NETs are characterised by a suicidal lytic PAD4- and NADPH-dependent expulsion of citrullinated NETs, whereas SLE-NETs are characterised by rapidly-induced clusters with HMGB1, enriched for mitochondrial DNA and enhanced immune complex formation altogether supporting a pro-inflammatory role of NETs in the pathophysiology of SLE, including immune-complex mediated, full-house lupus nephritis.

SAT0011

### MERTK+ MONOCYTES ARE EXPANDED IN THE PERIPHERAL BLOOD OF PATIENTS WITH ACTIVE IGG4-RELATED DISEASE AND INFILTRATE AFFECTED ORGANS

L. Rovati<sup>1,2</sup>, E. Della Torre<sup>1,2</sup>, C. Sciorati<sup>1</sup>, E. Rigamonti<sup>1</sup>, M. Lanzillotta<sup>1</sup>, E. Bozzalla Cassione<sup>1</sup>, E. Bozzolo<sup>1</sup>, L. Dagna<sup>1</sup>, A. Manfredi<sup>1</sup>. <sup>1</sup>Unit of Immunology, Rheumatology, Allergy and Rare Diseases, San Raffaele Scientific Institute and Università Vita-Salute San Raffaele, Milan, Italy; <sup>2</sup>Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, USA

**Background:** IgG4-Related Disease (IgG4-RD) is a multi-organ fibro-inflammatory disorder characterised by tumefactive lesions with well-defined histological features including lymphoplasmatic infiltrate rich in IgG4<sup>+</sup> plasma cells, storiform fibrosis and obliterative phlebitis<sup>1</sup>. Alternatively-activated macrophages (M2) have also been reported to abundantly infiltrate IgG4-RD lesions, but their role in IgG4-RD pathogenesis remains elusive. M2 macrophages have been recently shown to modulate innate and adaptive immune responses as well as tissue fibrosis by direct interaction with stromal cells<sup>2-4</sup>. Both these roles can be mediated by Mer tyrosine kinase (MerTK), a member of the TAM – Tyro3, Axl and MerTK-receptor family, which is highly expressed on M2 macrophages<sup>5</sup>. The relevance of MerTK and of its ligands Protein S (ProS) and Growth arrest-specific protein 6 (Gas6) in IgG4-RD has never been assessed before.

**Objectives:** To assess a pathogenetic relevance of the MerTK-ProS/Gas6 axis in IgG4-RD.

**Methods:** Immunohistochemical studies for CD68, CD163 and MerTK were performed on 8 cases of IgG4-RD involving different organs. MerTK expression within the different circulating monocyte subsets was quantified by flow cytometry both in 11 active untreated IgG4-RD patients and in 10 healthy controls (HC). Plasma levels of ProS, Gas6 and of their decoy receptor – soluble Mer (sMer) – were measured by ELISA in 34 IgG4-RD patients and 20 HC.

**Results:** MerTK was abundantly expressed in IgG4-RD lesions both within the inflammatory infiltrate and in the newly formed fibrous tissue. The pattern of MerTK expression was similar to that of the M2 macrophage marker CD163 (figure 1). Total circulating monocytes and their subsets were not expanded in active untreated IgG4-RD compared to HC. However, MerTK<sup>+</sup> monocytes were significantly increased in the peripheral blood of patients with IgG4-RD compared to HC ( $p < 0.001$ ). Plasma levels of Gas6 and ProS were significantly higher in IgG4-RD patients compared to HC ( $p = 0.003$  and  $p = 0.01$ , respectively), while the plasma level of sMer was comparable to that of HC. The number of MerTK<sup>+</sup> monocytes correlated positively with the number of circulating plasmablasts ( $r = 0.6$ ;  $p < 0.05$ ) and negatively with Gas6 plasmatic concentration ( $r = -0.7$ ;  $p < 0.05$ ).

**Abstract SAT0011 – Figure 1.** Distribution of macrophages and MerTK-expressing cells in the lung (A-B), pancreas (C-D) and biliary tree (E-F) of IgG4-RD patients. Each set of sections was stained with MerTK, CD68 as a marker of both M1 and M2 macrophages and CD163 as a marker of M2 macrophages.

**Conclusions:** A subset of MerTK<sup>+</sup> M2 macrophages abundantly infiltrates IgG4-RD fibrotic lesions and their MerTK<sup>+</sup> monocyte precursors are expanded in the peripheral blood of patients with active IgG4-RD. MerTK ligands are also increased in IgG4-RD, suggesting an augmented activation of MerTK signalling pathways. Further studies are needed to better characterise this monocyte/macrophage subpopulation, to understand its role in IgG4-RD and to identify possible biomarkers and therapeutic targets.

SAT0012

### C-REACTIVE PROTEIN: NOT ONLY A MARKER, BUT ALSO A CAUSE OF INFLAMMATION THROUGH METABOLIC REPROGRAMMING OF HUMAN MACROPHAGES

M. Newling<sup>1</sup>, L. Sritharan<sup>1</sup>, B. Everts<sup>2</sup>, L. de Boer<sup>3</sup>, S. Zaat<sup>3</sup>, D. Baeten<sup>1</sup>, J. den Dunnen<sup>1</sup>. <sup>1</sup>Clinical Immunology and Rheumatology, Academic Medical Center (AMC), Amsterdam; <sup>2</sup>Parasitology, Leiden University Medical Center (LUMC), Leiden; <sup>3</sup>Medical Microbiology, Academic Medical Center (AMC), Amsterdam, Netherlands

**Background:** C-reactive protein (CRP) is an acute-phase protein produced in high quantities by the liver in response to infection and during chronic inflammatory disorders such as rheumatoid arthritis (RA). As a consequence, CRP is in widespread clinical use as a general marker of inflammation. Although CRP is known to facilitate clearance of cell debris by phagocytic cells by binding to its ligand phosphocholine on dead cells, additional functions of CRP are still not completely understood.

**Objectives:** Here, we set out to investigate whether CRP, which is present in high concentrations in synovial fluid of active RA patients, also plays a role in the orchestration of inflammation in the inflamed joint.

**Methods:** Human macrophages were differentiated from blood monocytes of healthy volunteers. Cells were stimulated with complexed CRP (c-CRP) and/or ligands for Toll-like receptors (TLRs), mimicking the stimuli in the inflamed joint. Responsible signalling pathways were identified using small molecule inhibitors and RNA interference. Metabolic pathways were identified using specific inhibitors and the Seahorse metabolic analyzer.

**Results:** Strikingly, we here provide evidence that CRP is not only a marker, but also a cause of inflammation by strongly amplifying the production of RA-associated pro-inflammatory cytokines. We show that complex formation of CRP as a result of binding to its ligand phosphocholine selectively enhanced TNF $\alpha$ , IL-1 $\beta$ , and IL-23 production by human macrophages. While c-CRP did not induce cytokine production individually, c-CRP synergized with TLRs to amplify cytokine gene translation. We identified Fc gamma receptor I and IIa (Fc $\gamma$ RI and Fc $\gamma$ RIIa) as the main receptors responsible. Moreover, we unravelled the responsible molecular mechanism of c-CRP-induced inflammation, which crucially depends on signalling through kinases Syk and PI3K, resulting in enhanced gene translation of pro-inflammatory cytokines through metabolic reprogramming, particularly through amplified glycolysis and fatty acid synthesis.

**Conclusions:** These data indicate that CRP is not only a marker, but might also be a cause of inflammation in RA patients by selectively promoting RA-associated pro-inflammatory cytokine production by human macrophages, thereby exacerbating pathology. From a therapeutic point of view, inhibition of c-CRP-induced immune activation, e.g. by targeting the identified molecular mechanisms, may be a valuable tool to suppress inflammation.

SAT0013

### IL-1A AND ADAMTS5 MEDIATED TISSUE DAMAGE IN HUMAN CARTILAGE EXPLANTS LEADS TO GENERATION OF TLR2 ACTIVATING DAMPS

N. Sharma<sup>1,2</sup>, T.G. Christiansen<sup>3</sup>, M. Karsdal<sup>2</sup>, A.-C. Bay-Jensen<sup>2</sup>, C.S. Thudium<sup>2</sup>.  
<sup>1</sup>Department of Biomedical science, University of Copenhagen, Copenhagen;  
<sup>2</sup>Nordic Bioscience, Herlev; <sup>3</sup>Orthopaedicsurgery unit, Gentofte University Hospital, Gentofte, Denmark

**Background:** The innate immune system is important for the initiation and development of joint diseases such as rheumatoid arthritis (RA) and Osteoarthritis (OA). Exogenous TLR (Toll like receptor) ligands are abundant in the synovial joints of RA and OA patients and induce the first immune response. Stimulation of TLRs results in an increased immune response and is characterised by induction of cytokines expression which in turn causes tissue damage and results in generation of more DAMPs. Hence, resulting in a self-perpetuating loop of TLR activation and TLR mediated tissue damage.

**Objectives:** The aim of this study was to investigate the effect of degradation fragments of human cartilage generated *ex vivo* or *in vitro*, on TLR-2 activation in a TLR-2 reporter cell system.

**Methods:** Human cartilage biopsies retrieved from OA patients undergoing total knee replacement at Gentofte hospital were used to generate human explants (HEX). HEX were cultured for 21 days either without (w/o) treatment or in the presence of IL-1 $\alpha$  (10 ng/ml, 5 ng/ml and 2.5 ng/ml). Unconditioned media incubated without cartilage tissue was used as control. Tissue degradation was verified by measuring the release of aggrecan neo-epitope biomarkers AGNx1 and FFGV into the conditioned media (CM). Correspondingly, human cartilage was digested with ADAMTS5 for different time intervals (16 hour, 24 hour and 88 hour) at 37°C. The digested cartilage was removed by centrifugation and the supernatant was stored. Crushed cartilage in buffer alone was used as a control set up for each time point and buffer alone was subtracted as background. The CM and digested media (DM) was tested in the SEAP (secreted embryonic alkaline phosphatase) reporter gene based HEK hTLR2 cell line. The HEK null 1 parent cell line was used as a control. Pam3CSK4 was used as a positive control for the hTLR2 cell line.

**Results:** IL-1 $\alpha$  induced aggrecan degradation was confirmed by increased exAGNx1 and exFFGV release in the conditioned media compared to w/o (p<0.01) (figure 1a). CM from IL-1 $\alpha$  treated explants induced a significant signal in the hTLR2 cells compared to w/o CM or to UCM with IL-1 $\alpha$  (p<0.0001). (figure 1b). Similarly, DM showed a significant induction in the hTLR2 cells after 88 hours compared to undigested human cartilage. (p<0.0001) (figure 1c).

**Conclusions:** IL-1 $\alpha$  induced cartilage degradation leads to the release of aggrecan fragments into the CM, and this CM as well as *in vitro* cleavage products from ADAMTS-5 digestion of human cartilage was able to activate the TLR2 receptor *in vitro* in a specialised reporter cell system. These data indicate that DAMPs may be released from human cartilage in the presence of pro-inflammatory cytokines and proteolytic enzymes. The released fragments can lead to TLR2 activation and cause further inflammation. These data suggest that DAMPs may play a role in the onset and maintenance of inflammation in diseases such as OA and RA.

### DRUG REPURPOSING TO BLOCK TLR4-ASSOCIATED INFLAMMATION IN OA CHONDROCYTES

E. Franco-Trepal<sup>1</sup> on behalf of Musculoskeletal Pathology Group, A. Alonso-Perez<sup>1</sup> on behalf of Musculoskeletal Pathology Group, M. Guillan Fresco<sup>1</sup> on behalf of Musculoskeletal Pathology Group, A. Jorge Mora<sup>1</sup> on behalf of Musculoskeletal Pathology Group, V. López<sup>2</sup> on behalf of NEIRID LAB, O. Gualillo<sup>2</sup> on behalf of NEIRID LAB, R. Gómez<sup>1</sup> on behalf of Musculoskeletal Pathology Group on behalf of Musculoskeletal Pathology Group. <sup>1</sup>Musculoskeletal Pathology Group; <sup>2</sup>Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain

**Background:** The rising prevalence of rheumatic diseases in our society has caused a dramatic impact on the welfare of the population as well as becoming an economic burden to the health system. Osteoarthritis (OA), the most common rheumatic disease, is defined by joint-space narrowing due to progressive cartilage degradation. Despite the growing knowledge in OA pathophysiology, no treatment has yet proved to be efficient enough. The activation of innate immune receptors, such Toll-like receptor 4 (TLR4), by damage-associated molecular patterns (DAMPs) has been involved in chondrocyte-mediated inflammatory responses. There are currently no available drugs aimed to block TLR4-mediated inflammatory responses. Nonetheless, there are already known drugs being employed in other indications that could have this activity; namely amitriptyline, naloxone, and thalidomide.

**Objectives:** Determine the ability of amitriptyline, naloxone and thalidomide to block TLR4-mediated innate immune responses in chondrocytes.

**Methods:** The effect of amitriptyline, naloxone and thalidomide on TLR4-mediated inflammatory responses was determined in mouse chondrogenic cell line (ATDC5) and in human primary OA chondrocytes. The mRNA expression of key inflammatory factors lipocalin-2 (LCN2), interleukin-6 (IL-6), and monocyte chemoattractant protein-1 (MCP-1) was studied by RT-PCR. Cell viability was tested using the methyl-thiazolyl-tetrazolium (MTT) reagent and nitrite accumulation (nitric oxide production) in cell culture media was assessed by Griess reaction and validated by determining nitric oxide synthase 2 (NOS-2) mRNA expression.

**Results:** The co-stimulation of human OA chondrocytes with the TLR4 agonist LPS [100 ng/ml] and amitriptyline [1  $\mu$ M], reduced the mRNA expression of LCN2 (90%), IL-6 (95%) and MCP-1 (87%). The pre-stimulation of naloxone [100  $\mu$ M] with LPS also reduced the mRNA expression of LCN2 (53%), IL-6 (78%) and MCP-1 (79%). Similar results LCN2 (63%), IL-6 (74%), and MCP-1 (78%) were obtained upon the pre-stimulation of these cells with thalidomide [500  $\mu$ M]. The anti-inflammatory effect of these drugs on these pro-inflammatory factors was also observed but lowered in ATDC5 cells. Consistent with these results in ATDC5 cells these drugs also reduced the expression of mRNA NOS-2 gene expression as well as nitrite accumulation in the cell culture medium. At the studied concentrations, amitriptyline, naloxone and thalidomide did not affect to chondrocytes viability.

**Conclusions:** The data presented here have shown that amitriptyline, naloxone and thalidomide block TLR4 innate immune responses in human OA chondrocytes. These drugs have passed many toxicology and safety tests for their clinical use and could be ready for its repurposing in the management of TLR4-mediated OA cartilage inflammation.

SAT0015

### IDENTIFICATION AND CHARACTERISATION OF HIGH MOLECULAR WEIGHT HMGB1 PROTEIN COMPLEXES: IMPLICATIONS FOR STRESS RESPONSE, INNATE IMMUNITY AND AUTOIMMUNE DISEASE

W. Willis, L. Wang, T.T. Wada, M. Garder, O. Abdouni, G. Valiente, S. Agarwal, M. A. Freitas, L.-C. Wu, W.N. Jarjour. *The Ohio State University, Columbus, USA*

**Background:** High mobility group box one protein (HMGB1) is a chromatin associated protein, which in response to stress or injury translocates from the nucleus to the extracellular milieu to serve as an alarmin. HMGB1 has a remarkable ability to form complexes with proinflammatory molecules. This is underscored by the emerging role of HMGB1 in rheumatic diseases such as systemic erythematous (SLE), where the presence of HMGB1 in complex with endogenous nuclear

components such as dsDNA or nucleosomes was shown to play an important role in breaking immune tolerance against nuclear antigens.<sup>1</sup> Although the function of HMGB1 is in-part determined by the complexes it forms with other molecules, structural modifications in the HMGB1 polypeptide that may regulate complex formation have not been described.

**Objectives:** In this study we investigated the presence of HMGB1 in large protein complexes (HMGB1c) in human plasma. The objectives of this study were to isolate and characterise HMGB1c as well as to determine the mechanism of its formation.

**Methods:** We examined the presence of HMGB1c in plasma from SLE patients and healthy controls using semi-denaturing detergent agarose gel electrophoresis (SDD-AGE) followed by Western blot analysis. Immunoblotting, coimmunoprecipitation, confocal microscopy, and mass spectrometry were used to detect and characterise novel high molecular weight HMGB1 variants *in vitro* as well as in cell lines and primary cells. Mechanisms of HMGB1c formation were delineated via mass spectrometry, RNA interference, and *in vitro* enzyme reactions.

**Results:** In this study we note the presence of high molecular weight, denaturing resistant HMGB1 protein complexes (HMGB1c) that were present in the plasma of SLE patients and to a much lesser extent, healthy subjects. Similarly, HMGB1c were induced when cells were incubated with endotoxin or alum. Here we report that HMGB1c formation is catalysed by the calcium-activated protein crosslinking enzyme transglutaminase-2 (TG2). HMGB1-TG2 interaction was demonstrated via coimmunoprecipitation as well as by confocal microscopy after co-transfection of cells with plasmids encoding fluorescent-tagged HMGB1 and TG2 constructs. Moreover, HMGB1c formation was suppressed in cells by TG2 siRNA. Crosslink site mapping and analysis by mass spectrometry revealed that HMGB1 can be crosslinked to TG2 as well as a number of additional proteins, including human autoantigens.

**Conclusions:** TG2 catalyses the formation of high molecular weight HMGB1 protein complexes. Given the immunoadjuvant properties of HMGB1 and the implication of TG2-mediated protein complex formation as a possible mechanism by which immune tolerance can be broken to self-molecules,<sup>2</sup> these findings have significant physiological implications for the role of HMGB1 in cellular stress responses and innate immunity in lupus.

## Cytokines and inflammatory mediators

### SAT0016 IL-12 SUPPRESS TR1 CELLS IN THE SJÖGREN'S SYNDROME

G. Yao, J. Qi, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

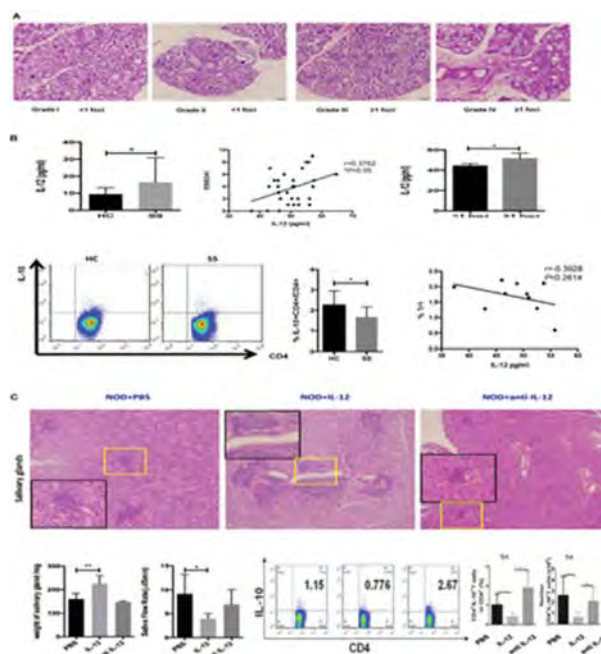

**Background:** Sjögren's syndrome (SS) is a systemic autoimmune disorder characterised by lymphocytic infiltration of salivary and lacrimal gland leading to dry mouth and eye dryness progressively. It is known that pro-inflammatory cytokines and dysfunction of immune cells play an important role in the pathogenesis of SS. The regulatory T cell type 1 (Tr1) cells have strong immunosuppressive properties and alleviate inflammatory diseases. However, the role of Tr1 cells in SS and the underlying mechanism is still not fully understood.

**Objectives:** This study aims to determine the association of Tr1 cells with the disease pathogenesis using a murine model of SS and patients with SS.

**Methods:** The frequencies of Tr1 cells in blood, cervical lymph nodes and their association with disease severity were determined in SS mice. Since proinflammatory interleukine 12 (IL-12) have the ability to regulate the generation of Tr1 cells, the serum IL-12 and its association with disease severity and Tr1 cells were also examined. The involvement of IL-12 and a Tr1 response was examined by recombinant IL-12 treatment or anti-IL-12 antibody neutralisation in SS mice and

monitored for SS development. The mouse naive CD4<sup>+</sup> cells were treated with IL-12 under Tr1 polarising condition. The frequency of Tr1 cells and their association with IL-12 and disease activity were verified in SS patients.

**Results:** Tr1 cells significantly decreased in SS mice and patients with SS, which correlated negatively with disease activity and proinflammatory IL-12 (figure 1A, B). IL-12 suppressed Tr1 cell polarisation *ex vivo*. SS mice treated with the recombinant IL-12 displayed significantly lower saliva flow rates and pronounced inflammation and tissue damage in salivary glands, accompanying with reduction of Tr1 cells. However, anti-IL-12 antibody treatment profoundly increased the numbers of Tr1 cells and ameliorated the reduction in salivary secretion and inflammation and tissue damage in salivary glands in SS mice (figure 1C).

**Conclusions:** Our findings indicate that proinflammatory IL-12 with its capacity to inhibit Tr1 cell generation may be a critical pathogenic factor in Sjögren's syndrome. Targeting IL-12 and Tr1 cells may be a novel therapeutic strategy for the treatment of Sjögren's syndrome.

### SAT0017 THE RHEUMATOID FACTOR RESPONSE IS COMPOSED OF MULTIPLE REACTIVITIES AGAINST DIFFERENT EPITOPES

W. Falkenburg<sup>1,2</sup>, J. Koers<sup>2</sup>, P. Oijevaar-de Heer<sup>2</sup>, D. van Schaardenburg<sup>1,3</sup>, G. Wolbink<sup>4</sup>, T. Rispens<sup>2</sup>. <sup>1</sup>Rheumatology, Amsterdam Rheumatology and Immunology Center | Reade; <sup>2</sup>Immunopathology, Sanquin Research; <sup>3</sup>Rheumatology, Amsterdam Rheumatology and Immunology Center | Academic Medical Center; <sup>4</sup>Amsterdam Rheumatology and Immunology Center | Reade, Amsterdam, Netherlands

**Background:** Rheumatoid arthritis (RA) is a complex autoimmune disorder in which autoantibodies likely play an important role. Rheumatoid factors (RFs) are autoantibodies that bind to the constant domain (Fc) of immunoglobulin G (IgG). It is known that they can bind in various ways; most RA patients probably have multiple types of RFs that all bind different parts of antibodies. It is presently unknown how this differs between patients. Furthermore, it is possible that RF responses in RA have a different reactivity pattern compared to those present in other diseases and in RF +healthy donors. Currently, these RA-specific RFs have not yet been identified.

**Objectives:** To develop a method to identify and dissect different RF responses, to classify the RF response in different stages of RA, and to characterise differences in reactivity between RF responses in the context of RA and RF responses in other diseases or healthy donors.

**Methods:** Variants of human IgG antibodies to which only a few different types of RFs can bind at a time were generated and used as target antibodies in newly

developed ELISA-based RF assays. RF responses were analysed in healthy donors, arthralgia patients at risk for RA and RA patients at different disease stages.

**Results:** RF responses in all cohorts were shown to be primarily directed against epitopes at the interface of the second and third IgG heavy chain domains (CH2-CH3) and the tip of the CH3 domain. The generated target antibodies were able to separate these RF responses and discriminate them from RF responses targeting epitopes outside these reactivity hotspots. Furthermore, certain RF responses against the CH2-CH3 interface were shown to depend on the presence of a single specific amino acid residue.

Pilot experiments using the target antibodies in clinical cohorts revealed that, in arthralgia patients and RA patients at various disease stages, the pattern of RF reactivity differs between individual patients as well as between cohorts. The degree to which an RF response against the CH2-CH3 interface depends on the single specific amino acid residue varied substantially between patients. One particular RF response pattern, RFs binding only the CH3 domain, was found exclusively in non-RA patients and healthy donors.

**Conclusions:** Using newly developed target IgGs, RF responses against different epitopes can be characterised. RF response patterns differ between RA and non-RA cohorts and between RA patients. These new tools may lead to identification of RA-specific RF responses and provide more insight into the pathogenic role of these autoantibodies.

SAT0018

### BLOOD CHEMOKINE SYSTEM PROFILE ASSOCIATED WITH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

A. Petrackova<sup>1</sup>, G. Gabcova<sup>1</sup>, M. Skacelova<sup>2</sup>, Z. Mikulkova<sup>1</sup>, A. Smrzova<sup>2</sup>, M. Schubertova<sup>2</sup>, F. Mrazek<sup>1</sup>, P. Horak<sup>2</sup>, E. Kriegova<sup>1</sup>. <sup>1</sup>Department of Immunology, <sup>2</sup>Department of Internal Medicine III – Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, Czech Republic

**Background:** Chemokine receptors and their chemokine ligands (chemokine system), key mediators of inflammatory and immune cell trafficking, are involved in the pathogenesis of rheumatoid arthritis (RA). There is still limited information of blood chemokine system signature associated with disease activity.

**Objectives:** To identify RA-associated chemokine system signature using highly sensitive multiplex Proximity Extension ImmunoAssay (PEA) in serum together with analysis of CCR5, CCR6 and CXCR3 expression in blood cell subsets and assess its relationship with disease activity as evaluated by activity score (DAS28).

**Methods:** We investigated the serum levels of 92 inflammation-related proteins in 78 Czech patients with RA by PEA (Proseek Multiplex, Olink Bioscience, Sweden). Disease activity was assessed by means of DAS28 and subgroups were formed based on the disease activity, where DAS28 of  $\geq 3.2$  was taken as active RA (inactive RA, n=40; active RA, n=38). The expression of CCR5, CCR6 and CXCR3 receptors were analysed using 6-colour flow cytometry (BD FACSCanto II) on T and B lymphocytes, NK, dendritic cells, and monocytes in peripheral blood from 11 patients with active RA and 9 age-matched healthy control subjects. Statistical tests (Mann-Whitney U test, Spearman correlation) were performed using GenEx (Sweden) and GraphPad Prism 5.01 (CA, USA). *P*-values  $\leq 0.05$  was considered as significant.

**Results:** In patients with active RA, 16 serum proteins were upregulated ( $P_{corr} \leq 0.05$ ). Top-ranked proteins distinguishing active and inactive RA were CCL20, CXCL9, CCL7, CXCL10, IL-6, sCD137, and CXCL1 ( $P_{corr} < 0.03$ ). Levels of all these proteins positively correlated with disease activity ( $r > 0.30$ ,  $p < 0.006$ ) and the best correlation was observed for chemokines CCL20 ( $r = 0.495$ ,  $p = 0.000004$ ) and CCL7 ( $r = 0.442$ ,  $p = 0.00005$ ). Based on these results we analysed the expression of corresponding chemokine receptors: CCR5, CCR6, and CXCR3 in blood cells. Expression of CCR6 was increased on CD4 +T and CD8 +T lymphocytes ( $p = 0.008$ ,  $p = 0.01$  respectively) and on total and activated NK cells ( $p = 0.01$ ,  $p = 0.004$  respectively) in active RA compared with healthy controls. Regarding CCR5, decreased percentage of CCR5 positive CD4 +T lymphocytes were registered in RA patients compared with healthy controls ( $p = 0.008$ ). No differences were observed in the expression of CXCR3 on investigated immune cell populations.

**Conclusions:** We identified the blood chemokine system signature associated with disease activity in RA further supporting a critical role of CCL20/CCR6 axis in the ongoing inflammation related to the disease activity in RA.

### TNF- $\alpha$ REGULATES PLASMACYTOID DENDRITIC CELLS BY SUPPRESSING IFN- $\alpha$ PRODUCTION AND ENHANCING TH1 AND TH17 CELL DIFFERENTIATION

A. Psarras<sup>1,2</sup>, A. Antanaviciute<sup>3</sup>, I. Carr<sup>3</sup>, M. Wittmann<sup>1</sup>, P. Emery<sup>1</sup>, G. Tsokos<sup>2</sup>, E. M. Vital<sup>1</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; <sup>2</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, USA; <sup>3</sup>Leeds Institute for Data Analytics, University of Leeds, Leeds, UK

**Background:** Human plasmacytoid dendritic cells (pDCs) play a vital role in modulating immune responses. pDCs can produce massive amounts of type I IFNs in response to nucleic acids via toll-like receptors (TLRs) and they are known to possess weak antigen-presenting properties inducing CD4<sup>+</sup> T cell activation. Previous data showed a cross-regulation between TNF- $\alpha$  and IFN- $\alpha$  but the effect of TNF- $\alpha$  on pDCs remains unclear.

**Objectives:** To investigate how TNF- $\alpha$  regulates the immune function of human pDCs.

**Methods:** Fresh PBMCs were treated with TNF- $\alpha$ , TLR7 and TLR9 synthetic agonists. pDCs were immunophenotyped using flow cytometry. RNA from sorted pDCs was extracted and sequenced using Smart-seq2 for sensitive full-length transcriptome profiling. For pDC/T cell co-culture, fresh or TNF- $\alpha$ -treated pDCs were cultured with naïve CD4<sup>+</sup> T cells for 5 days. The production of cytokines was measured by intracellular staining and ELISA.

**Results:** Upon stimulation with TLR7 and TLR9 agonists, there were three main pDC populations: non-producers, TNF- $\alpha$ -producers, TNF- $\alpha$ /IFN- $\alpha$ -producers. Exogenous TNF- $\alpha$  significantly reduced the production of both IFN- $\alpha$  and TNF- $\alpha$  in TLR9-stimulated pDCs but only IFN- $\alpha$  in TLR7-stimulated pDCs. Neutralisation of autologous TNF- $\alpha$  with anti-TNF antibody partially sustained IFN- $\alpha$  secretion by TLR9-stimulated pDCs after 24 hours. Exogenous TNF- $\alpha$  significantly promoted pDC maturation by upregulation of costimulatory molecules and chemokine receptors such as CD80, CD86, HLA-DR, and CCR7. RNAseq data analysis suggested that TNF- $\alpha$  inhibits IFN- $\alpha$ /TNF- $\alpha$  production by interfering with the NF- $\kappa$ B pathway, promotes antigen processing and presentation pathways as well as T cell activation and differentiation. Indeed, TNF- $\alpha$ -treated pDCs induced *in vitro* higher CD4<sup>+</sup> T cell proliferation and favoured Th1/Th17 polarisation.

**Conclusions:** Although pDCs possess weak antigen-presenting properties, TNF- $\alpha$  can enhance pDC maturation by switching their main role as IFN- $\alpha$ -producing cells to a more conventional DC phenotype. The functional status of pDCs might be strongly influenced by overall inflammatory environment and TNF- $\alpha$  might regulate IFN- $\alpha$ -mediated aspects of a range of autoimmune and inflammatory diseases.

### IMPACT OF IL12B SINGLE NUCLEOTIDE POLYMORPHISMS ON CIRCULATING PRO-INFLAMMATORY CYTOKINES IL-12P40 AND IL-23 IN ANKYLOSING SPONDYLITIS

M.G. Ivanova<sup>1</sup>, I. Manolova<sup>2</sup>, R. Stoilov<sup>1</sup>, L. Miteva<sup>2</sup>, S. Stanilova<sup>2</sup>. <sup>1</sup>Clinic of Rheumatology, University Hospital "St. Iv. Rilski", Medical Faculty, Medical University, Sofia; <sup>2</sup>Department of Molecular Biology, Immunology and Medical Genetics, Medical Faculty, Trakia University, Stara Zagora, Bulgaria

**Background:** Ankylosing spondylitis (AS) is an immune-mediated rheumatic disease belonging to the spectrum of axial spondyloarthritis, characterised mainly by chronic inflammatory back pain and radiographic sacroiliitis. Since genetic factors have been shown to be major determinants of susceptibility to the disease and contribute to amplification of immune responses, polymorphic variability in immune response genes are of interest. The interleukin-12p40 gene (IL12B) encodes the p40 polypeptide chain, which, together with p19, composes IL-23, a member of the IL-12 superfamily.

**Objectives:** In this study, we examined functional association between two IL12B polymorphisms – IL12B<sub>pro</sub> (rs17860508) and IL12B 3' UTR A/C (rs3212227), and cytokine production of both pro-inflammatory cytokines IL-12p40 and IL-23 in AS patients.

**Methods:** A total of 69 AS patients with a mean age 43±16 years and 257 healthy individuals from Bulgarian population were genotyped. Genotyping for the rs3212227 was performed by restriction fragment length polymorphisms-PCR assay and for the rs17860508 by allele specific-PCR. Serum IL-12p40 and IL-23 concentrations measurement was done using ELISA test.

**Results:** We found significant differences in the genotype ( $p = 0.029$ ) and allele ( $p = 0.006$ ) frequencies of rs17860508 polymorphism between AS patients and controls. An association between AS and the rs17860508 polymorphism was established under the allelic model (allele 2 vs. allele 1; OR=1.698), the dominant model (1.2+2.2 vs. 1.1; OR=2.427), and the co-dominant model (2.2 vs. 1.1;

OR=2.812; 1.2 vs. 1.1; OR=2.252). Genotype and allele frequencies of rs3212227 polymorphism of the IL12B were similar in cases and controls. The mean ( $\pm$ SEM) levels of IL-12p40 and IL-23 in AS patients (176.5 $\pm$ 20.7 pg/ml; 26.98 $\pm$ 3.4 pg/ml, respectively) was significantly higher than in controls (88.8 $\pm$ 9.6 pg/ml; 12.1 $\pm$ 1.5; respectively) ( $p$ <0.001). Stratification based on *IL12B* *pro* 1.1 and 1.2 genotypes than controls. Highest IL-23 serum levels were associated with *IL12B* *pro* 2.2 genotype. With regard of polymorphic variability of *IL12B* 3' UTR, AC genotype in AS has been linked to a higher IL-12p40 production and lower one of IL-23.

**Conclusions:** Allelic variants in the *IL12B* genes have the potential to alter the expression of both IL-12p40 and IL-23 cytokines in specific manner for AS patients. Carriage of the *IL12B* *pro* variant 1-allele and of the 3'-UTR A-allele in the genotype regardless of homo- or heterozygosity could enhance systemic IL-12p40 and IL-23 levels.

#### SAT0021 INNATE LYMPHOID CELLS ARE NOT A MAIN SOURCE OF IL-17A IN THE INFLAMED SPONDYLOARTHRITIS JOINT

N. Yeremenko<sup>1,2,3</sup>, I.C.J. Blijdorp<sup>1,2,3</sup>, L.J.J. Van Mens<sup>1,2</sup>, S. Menegatti<sup>4</sup>, S. Chen<sup>1,2,3</sup>, H.S. Hreggvidsdottir<sup>1,2,3</sup>, T. Noordenbos<sup>1,2</sup>, T.E. Latuhihin<sup>1,2,3</sup>, J. H. Bernink<sup>3,5</sup>, L. Rogge<sup>4</sup>, H. Spits<sup>3,5</sup>, D.L.P. Baeten<sup>1,2,3</sup>. <sup>1</sup>Department of Clinical Immunology and Rheumatology, <sup>2</sup>Amsterdam Rheumatology and Immunology Center, <sup>3</sup>Laboratory of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands; <sup>4</sup>Immunology, Institut Pasteur, Paris, France; <sup>5</sup>Department of Cell Biology and Histology, Academic Medical Center, Amsterdam, Netherlands

**Background:** Clinical trials of the anti-IL-17A antibody secukinumab demonstrated the crucial role of IL-17A cytokine in the pathogenesis of spondyloarthritis (SpA), however, its cellular source in this condition remains controversial. Group 3 innate lymphoid cells (ILC3s) have been recently identified in a number of different tissues as potent producers of proinflammatory cytokines, including IL-17A and IL-22.

**Objectives:** In this study we set out to characterise the presence and composition of ILCs and investigate whether these cells are the important source of IL-17A in the synovial tissue of patients with SpA.

**Methods:** Matched synovial tissue (ST), synovial fluid (SF) and peripheral blood (PB) were obtained from SpA and rheumatoid arthritis (RA) patients with actively inflamed knee joints. ILCs subsets were characterised by flow cytometry. Gene expression analysis at the single-cell level was performed directly *ex vivo* and after stimulation with PMA ionomycin. IL-17A ELISPOT assay was used to detect IL-17A-secreting cells.

**Results:** Analysis revealed that ILCs, and particularly NKp44-positive ILC3s, are expanded in the inflamed arthritic joint. Single cell expression analysis revealed that ST ILCs are clearly distinguishable from ST T cells and from their PB counterparts. We detected expression of Th17 signature transcripts *RORC*, *AHR* and *IL-23R* in the notable fraction of ST ILC3s. Furthermore these cells were capable to induce *IL-22*, but not *IL-17A* expression in response to *in vitro* re-stimulation

**Conclusions:** We demonstrate in this study that ILC3s are absolutely and relatively enriched in the synovial joint of patients with SpA, however these cells are not a significant source of IL-17A cytokine in this pathology.

**Disclosure of Interest:** None declared

#### SAT0022 MIR-15A/16 SUPPRESS INFLAMMATORY RESPONSE AND CELL INVASION AND MIGRATION IN FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS VIA TARGETING SOX5

W. Tan, Q. WU, A. Luo, Y. Wei, F. Wang, M. Zhang. *Rheumatology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

**Background:** Aberrant expressions of miRNAs play a critical role in the inflammatory and immune response in rheumatoid arthritis (RA). The microRNA cluster which encodes for miR-15a and miR-16, located at 13q14.3. Both these microRNAs have been implicated in the pathogenesis of many diseases, but little is known of their role in RA.

**Objectives:** In this study, we aim to investigate the underlying molecular mechanisms of MiR-15a/16 in RA, which will provide new insight into understanding the pathogenesis of RA and identifying novel therapeutic targets for this disease.

**Methods:** The expression of MiR-15a/16 in the peripheral blood mononuclear cell (PBMC) and synovium from RA, osteoarthritis (OA) and healthy controls (HC) was determined by RT-qPCR and Western blotting. Mimics of MiR-15a/16 were

transfected into the human rheumatoid fibroblast-like synoviocytes (FLS) MH7A cell line. The effect of MiR-15a/16 on proinflammatory cytokines expression, migration and invasion of FLS was detected by RT-qPCR, transwell and F-actin staining. The potentially target gene of miR-15a/16 was predicted by bioinformatics analysis. The 3'UTR of Sox5 containing wild-type or mutated miR-15a/16 binding sites was cloned to the downstream of a luciferase vector and transfected into MH7A, respectively.

**Results:** There is no significant difference of MiR-15a/16 expression in PBMC in RA and HC at baseline. However, the MiR-15a/16 expression is lower in PBMC from non-responders (defined DAS28 changes<1.2 after 3 months DMARDs therapy) than those in responders after 3 months DMARDs therapy. The levels of MiR-15a/16 expression were significant decreased in the synovium from RA patients, as compared with OA patients. Transfection of MH7A with MiR-15a and 16 mimic suppressed IL-1b, TNFa, IL-17 expression, decreased cell migration and invasion and affected the cytoskeletal reorganisation in RA-FLS. We co-transfected MH7A with luciferase-reporter constructs with either wild-type or mutated miR-132 or miR-15a/16 mimics. Luciferase assay showed that either miR-15a or 16 reduced the luciferase intensity of Sox5 3'UTR. However, mutated miR-15a/16 alleviated the inhibitory effect of miR-15a/16 on the intensity of Sox5 3'UTR. To determine whether Sox5 mediates the roles of miR-15a/16 in cell migration and invasion, we constructed recombinant Adenovirus SOX5 recombinant Adenovirus SOX5 overexpressing vector. We then found that overexpression of Sox5 restored the cell invasion, and migration in MH7A that were inhibited by and miR-15a/16.

**Conclusions:** In conclusion, our data indicate that MiR-15a/16 play an important role in inflammatory response and cell invasion and migration in RA-FLS by directly targeting Sox5, and imply that these miRNAs have potential as therapeutic targets for RA.

**Disclosure of Interest:** None declared

#### SAT0023 CONTROL OF CYTOKINE MRNA DEGRADATION BY THE HISTONE DEACETYLASE INHIBITOR ITF2357 IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES

C. Angiolini<sup>1,2</sup>, P. Kabala<sup>1,2</sup>, A. Grabcic<sup>2,3</sup>, M. Rossato<sup>1</sup>, W. Lai<sup>4</sup>, P. Blakeshear<sup>4</sup>, K. Reedquist<sup>1,2</sup>, D. Baeten<sup>2</sup>, T. Radstake<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht; <sup>2</sup>Department of Clinical Immunology and Rheumatology and Department of Experimental Immunology, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; <sup>3</sup>Department of Microbiology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Kraków, Poland; <sup>4</sup>Signal Transduction Laboratory, National Institute of Environmental Health Sciences, Research Triangle Park, NC, USA

**Background:** Control of cytokine mRNA degradation acts as an essential checkpoint to limit the overproduction of inflammatory proteins.<sup>1</sup> In rheumatoid arthritis (RA), altered expression of the mRNA-degrading protein TTP (tristetraprolin, *ZFP36*) has been recently reported in synovial tissue, possibly contributing to the perpetuating inflammatory loop in the synovium.<sup>2</sup> Histone deacetylase inhibitors (HDACi) are small molecule drugs suppressing cytokine production *in vitro* and *in vivo* and displaying initial safety and efficacy in the treatment of systemic onset juvenile idiopathic arthritis.<sup>3,4</sup> However, their transcriptional and post-transcriptional mechanisms of action are not yet completely characterised.

**Objectives:** We aimed to investigate the mRNA degrading properties of the HDACi ITF2357 on a panel of inflammatory mediators in RA fibroblast-like synoviocytes (FLS).

**Methods:** The effects of ITF2357 on the expression and mRNA stability of IL-1 $\beta$ -inducible genes in FLS were analysed using array-based qPCRs and Luminex. The expression of primary and mature cytokines transcripts, the mRNA levels of TTP and other AU-rich element binding proteins (ARE-BP) and the cytokine profile of fibroblasts derived from *ZFP36*<sup>+/+</sup> and *ZFP36*<sup>-/-</sup> mice was measured by qPCR. ARE-BP silencing was performed by siRNA-mediated knockdown, and TTP post-translational modifications analysed by immunoblotting.

**Results:** ITF2357 reduced the expression of 85% of the analysed IL-1 $\beta$ -inducible transcripts, including cytokines (*IL6*, *IL8*), chemokines (*CXCL2*, *CXCL5*, *CXCL6*, *CXCL10*), matrix-degrading enzymes (*MMP1*, *ADAMTS1*) and other inflammatory mediators. Analyses of mRNA stability demonstrated that ITF2357 accelerates *IL6*, *IL8*, *PTGS2*, and *CXCL2* mRNA degradation, a phenomenon associated with the enhanced transcription of TTP, but not other ARE-BP, and the altered post-translational status of TTP protein. TTP knockdown potentiated cytokine production in RA FLS and murine fibroblasts.

**Conclusions:** Our study identifies that regulation of cytokine mRNA stability is a predominant mechanism underlying ITF2357 anti-inflammatory properties, occurring via regulation of TTP. These results highlight the therapeutic potential of ITF2357 in the treatment of RA.

### DIFFERENTIAL LEVELS OF IL-7 EXPRESSION IN ADVENTITIA OF NON-RA AND RA PATIENTS WITH CORONARY ARTERY DISEASE

A.N. Burska<sup>1</sup>, K. Sime<sup>2</sup>, A. Williams<sup>2</sup>, K. Mikkelsen<sup>3</sup>, K. Saatvedt<sup>4</sup>, S.M. Almdahl<sup>5</sup>, I. Risnes<sup>6</sup>, C. Goodyear<sup>7</sup>, I. Hollan<sup>8,9</sup>, F. Ponchel<sup>1</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds; <sup>2</sup>Division of Infection and immunity, Cardiff University School of Medicine, Cardiff, UK; <sup>3</sup>Lillehammer Hospital for Rheumatic Diseases, Lillehammer; <sup>4</sup>Dep. of cardiothoracic surgery, Oslo University Hospital, Oslo; <sup>5</sup>Dep. of cardiothoracic surgery, University Hospital of North-Norway, Tromsø; <sup>6</sup>Dep. of cardiothoracic surgery, Feiring Heart Clinic, Feiring, Norway; <sup>7</sup>Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, UK; <sup>8</sup>Department of Medicine, Brigham and Women's Hospital, Boston, USA; <sup>9</sup>Department of Research, Innlandet Hospital Trust, Brumunddal, Norway

**Background:** Rheumatoid Arthritis (RA) patients have increased cardiovascular risk due to accelerated atherosclerosis (ATS), which significantly contributes to excess mortality in RA<sup>1</sup>. The increased cardiovascular risk cannot be fully explained by traditional risk factors and systemic chronic inflammation appears to play a crucial role. Interestingly, IL-7, a proinflammatory cytokine involved in RA pathogenesis, appears to play a role also in atherosclerosis<sup>2</sup> but its effect on cardiovascular disease (CVD) in RA has not been studied yet.

**Objectives:** To examine serum IL-7 levels and expression of IL-7, IL-7R, CD3 and CD20 in aortic adventitia of RA and non-RA patients with coronary artery disease (CAD) and to search for relationships between systemic IL-7 levels and expression of vascular markers, cardiovascular risk factors including metabolic and inflammatory markers.

**Methods:** We examined 19 RA patients and 20 non-RA patients undergoing coronary artery bypass graft surgery included in the Feiring Heart Biopsy Study. Serum IL-7 levels were measured by chemiluminescence (MSD). Biopsies from the adventitia of thoracic aorta from a subset of patients (12 RA and 14 non-RA) were stained for IL-7, IL-7R, CD3 and CD20 by immunohistochemistry and scored per mm<sup>2</sup> of tissue.

**Results:** Non-RA patients had lower IL-7 serum levels than RA (3.4±3.3 vs. 6.7±3.5, p<0.05). Independently of RA diagnosis, IL-7 significantly correlated with CRP (rho=0.450, p=0.008), triglycerides (TG, rho=0.566, p=0.005), glucose (rho=0.642, p=0.001) and hypertension (p=0.036). Levels of IL-7 were associated with New York Heart Association class (rho=0.429, p=0.014) and this was stronger in non-RA patients (rho=0.577, p=0.010). No associations were found with smoking or markers of CVD severity (i.e. numbers of arteries with significant stenosis or number of previous myocardial infarcts (MI)).

The number of IL-7+ and IL-7R+cells/mm<sup>2</sup> in adventitia were significantly higher in RA (134.2±45.5 and 144±49.9 respectively) than non-RA patients (46.9±22.8 and 54.4±20.2, p<0.005) and were associated with serum IL-7 levels (rho=0.551 and rho=0.588, p<0.01). Both IL-7+ and IL-7R+cells were associated with a positive history of MI (p=0.047 and p=0.005) and IL-7R+cells with the number of previous MIs (rho=0.408, p=0.038). Only in RA patients, IL-7R+cells showed a trend for correlation with TG (rho=0.771, p=0.072). IL-7+ and IL-7R+cells correlated with CD3 (rho=0.688, p=0.013 and rho=0.630 p=0.028), but no correlation was found with CD20. Cholesterol and HDL levels were associated with IL-7+ cells only in non-RA patients (rho=0.729 p=0.04 and rho=0.733, p=0.038).

**Conclusions:** Among patients with CAD, those with RA had higher serum IL-7 and a greater expression of both IL-7/IL-7R in aortic adventitia. Systemic levels of IL-7 were related to its vascular expression. Thus, the IL-7/IL-7R axis may play a role in the accelerated atherogenesis observed in RA; further studies are needed to elucidate the precise role of IL-7 and impact of potential IL-7R blockade in CV risk in RA.

### CO-EXPRESSION OF RECEPTORS TO TNFA AMONG NAIVE T-CELLS AND MEMORY T-CELLS IS ALTERED IN RHEUMATOID ARTHRITIS AND THE CHANGES CORRELATE WITH DISEASE ACTIVITY

A.A. Alshevskaya<sup>1,2</sup>, J. Lopatnikova<sup>1</sup>, O. Chumasova<sup>1</sup>, N. Shkaruba<sup>1</sup>, A. Sizikov<sup>1</sup>, V. Gladkikh<sup>2,3</sup>, S. Sennikov<sup>1</sup>. <sup>1</sup>Federal State Budgetary Scientific Institution "Research Institute of Fundamental and Clinical Immunology"; <sup>2</sup>Biostatistics and Clinical Trials Center; <sup>3</sup>Institute of Computational Mathematics and Mathematical Geophysics SB RAS, Novosibirsk, Russian Federation

**Background:** Changing the ratio of TNF $\alpha$  receptors of different types can lead to shift in the balance between pro-apoptotic and proliferative signalling pathways which is crucial for rheumatoid arthritis (RA) inflammatory processes.

**Objectives:** To study the level of expression of type 1 and 2 receptors for TNF $\alpha$  (TNFR1/TNFR2) on individual subpopulations of peripheral blood actively involved in immunopathological processes in RA

**Methods:** The study included 20 healthy donors aged 18–60 years (11 men (55%)) and 36 RA patients with high (n=14), medium (n=15) and low (n=7) disease activity at the age of 22–77 years (31 women (86, 1%)). Co-expression and number of type 1 and 2 receptors for TNF $\alpha$  were calculated for monocytes, B-cells, T-cells, as well as among: cytotoxic T-cells (CD8+), T-helper cells (CD4+), activated CD8+ cells, activated CD4+ cells, memory T-cells (CD45RO+) and naive T-cells (CD45RA+) from cytotoxic and T-helper cells, and T-regulatory cells (CD4+CD25highCD127low) by flow cytometry analysis (BD FACSVerse, USA).

**Results:** Seven indicators of receptor expression were revealed, which differed in patients with RA with high disease activity in comparison with HD, and didn't differ between HD and patients with low disease activity. These were 4 indicators on the number of receptors on cells and 3 cell percentages with specific combinations of expressed. The association between disease severity and activity indexes (DAS-28 index, disease duration, X-ray stage, activity stage, RF level, ASCP and C-RB, systemic manifestations and erosive arthritis) and parameters of TNF $\alpha$  receptor expression on immunocompetent cell subpopulations were studied. The following associations were revealed: RF level positively correlated with the percentage of double-positive TNFR1+TNFR2+ cells among naive and memory T-cells for both T-helpers and cytotoxic T-cells (r levels from 0.62 to 0.68 with p<0.05); the level of C-reactive protein positively correlated with the percentage of cells carrying only receptor type 1 among all the T-lymphocyte subpopulations studied (r levels from 0.73 to 0.9 with p<0.05); the presence of systemic manifestations is negatively correlated with the number of receptors of both types 1 and 2 on naive T-helper and cytotoxic cells (r levels from -0.63 to -0.74 with p<0.05).

**Conclusions:** The active inflammatory process in rheumatoid arthritis with DAS28 >5.1 is accompanied by a change in the ratio of cells with different variants of co-expression of receptors to TNF $\alpha$  among populations actively involved in the pathological process (naive T-cells and memory T-cells among T-helpers and cytotoxic T-cells). The selected parameters will be used to construct and verify the predictive models of response to therapy of different subclasses

**SAT0028 THE IMPORTANCE OF PROPER HANDLING OF HUMAN SYNOVIAL FLUID FOR ARTHRITIS RESEARCH**

H. Brouwers<sup>1</sup>, J.H. von Hegedus<sup>1</sup>, R.E.M. Toes<sup>1</sup>, T.W.J. Huizinga<sup>1</sup>, M.A. Giera<sup>2</sup>, M. Kloppenburg<sup>1</sup>, A. Ioan-Facsinay<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Center for Proteomics and Metabolomics, Leiden University medical Center, Leiden, Netherlands

**Background:** Synovial fluid (SF) is commonly used for diagnostic and research purposes since it is easily obtained and is thought to represent the local inflammatory environment. Common practice to obtain insight in the disease pathogenesis of arthritic diseases is the characterisation and quantification of synovial fluid cells and the measurement of inflammatory mediators. SF has a complex composition, containing hyaluronic acid which makes the fluid viscous and non-homogeneous, hampering subsequent analyses. Hyaluronic acid can be broken down by the addition of hyaluronidase, however, this is not commonly used in arthritic research.

**Objectives:** To determine the effect of hyaluronidase treatment on quantification and identification of SF cells and soluble mediators.

**Methods:** SF was obtained from twelve arthritis patients after knee aspirations as part of standard clinical care. Nine patients were diagnosed with rheumatoid arthritis, two with osteoarthritis and one with juvenile idiopathic arthritis. For cell analysis, synovial fluid was first centrifuged and the pellet was separated from the fluid. The fluid was subsequently treated with hyaluronidase and centrifuged again to isolate remaining cells. Cell numbers and phenotype were determined using flow cytometry. For soluble mediator measurements, 6–10 aliquots were taken and treated as represented in figure 1 resulting in set 1 and set 2. Set 1 contains replicates taken from SF before hyaluronidase treatment while set 2 mimics replicates which are taken after hyaluronidase treatment. Interleukin (IL)-8 was measured by ELISA and a total of seven fatty acid and oxidised fatty acid levels were determined using LC-MS/MS in all aliquots.

**Results:** Between 0.8%–70% of immune cells (median 5%) are lost when the SF is not treated with hyaluronidase. This percentage is higher for T and B cells: 7%–85% (median 22%) and 7%–88% (median 23%), respectively. To assess the variation between the soluble mediator concentrations in set 1 and set 2, the coefficients of variation (CV) of the replicate measurements were compared. Aliquots in set 2 showed a lower CV for the oxidised lipids 17-HDHA, leukotriene B<sub>4</sub> and prostaglandin E<sub>2</sub> for all patients tested. For IL-8, the oxidised lipid 15-HETE, and fatty acids arachidonic acid (AA), eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), it did not matter whether the aliquots were taken before or after hyaluronidase treatment. While in general the average levels of the soluble mediators tested were comparable between set 1 and set 2, we did observe large differences in IL-8 and AA levels in two independent patients.

**Conclusions:** Up to 70% of the synovial fluid cells are missed in analysis when the SF is not treated with hyaluronidase before cell isolation, leading to erroneous conclusion especially when investigating rare cells populations like antigen specific B or T cells, when searching for novel cell populations, or when correlations are made between clinical parameters and cell numbers. In addition, some cytokine as well as lipid levels determined in SF without hyaluronidase treatment might not accurately reflect their actual concentrations in SF.

**SAT0029 IMPACT OF GLUCOCORTICOIDS ON SIRTIUIN 1 EXPRESSION AND PROINFLAMMATORY CYTOKINE PRODUCTION IN RATS WITH ADJUVANT-INDUCED ARTHRITIS**

D. Wendling<sup>1</sup>, W. Abbas<sup>2</sup>, A. Kumar<sup>2</sup>, S. Pasquereau<sup>2</sup>, F. Verhoeven<sup>1</sup>, C. Prati<sup>1</sup>, C. Demougeot<sup>3</sup>, G. Herbein<sup>2</sup>. <sup>1</sup>Rheumatology, CHRU Besançon; <sup>2</sup>EA4266 EPILAB; <sup>3</sup>EA4267 Pepite, University BFC, Besançon, France

**Background:** Sirtuin 1 (SIRT1) is a class III histone deacetylase which could play a critical role in several biological functions including lifespan, stress, and inflammation.

**Objectives:** Our main objective was to evaluate SIRT1 expression in peripheral blood mononuclear cells (PBMCs) isolated from rats with adjuvant induced arthritis (AIA) treated or not with low and high doses of glucocorticoids (GCs). Our second aim was to determine the production of proinflammatory cytokines such as tumour necrosis factor alpha (TNF), interleukin-1 beta (IL-1) and interleukin-6 (IL-6) in tissues (liver and spleen) of these rats, and to assess a potential correlation between SIRT1 expression and the production of cytokines in tissues of rats with AIA treated or not with low and high doses of glucocorticoids.

**Methods:** We performed a study on rats with AIA treated with low and high doses of prednisolone or left untreated. The SIRT1 expression was quantified in PBMCs using western blotting. Levels of proinflammatory cytokines TNF, IL-1 and IL-6 were assessed in liver and spleen from rats with AIA treated with GCs or left untreated using an ELISA assay.

**Results:** SIRT1 expression was increased in PBMCs isolated from rats with AIA treated with LD-GCs and HD-GCs compared to untreated animals. In culture, resveratrol enhanced the SIRT1 expression in PBMCs isolated from rats with AIA in a dose-dependent manner. We observed increased levels of TNF alpha in liver (correlated with SIRT1 expression) and decreased IL-6 levels in spleens (negatively correlated with SIRT1 expression) from rats with AIA treated with LD-GCs and HD-GCs compared to controls.

**Conclusions:** SIRT1 expression is increased in PBMCs isolated from rats with AIA and treated with GCs parallel to decreased levels of IL-6 in spleen and increased levels of TNF in liver. This study shows that the SIRT 1 expression is measurable in circulating PBMCs of rats with AIA and is increased under GC treatment. The potential epigenetic effect of GCs on production of proinflammatory cytokines in tissues, namely liver and spleen, is also studied.

**SAT0030 VISFATIN DOWN-REGULATES GROWTH PROMOTING LINC RNA H19 IN OSTEOGENIC DIFFERENTIATION OF MESENCHYMAL STROMAL CELLS**

D.M. Küppers<sup>1</sup>, L. Tsiklauri<sup>1</sup>, M.-L. Hülser<sup>1</sup>, K. Frommer<sup>1</sup>, S. Rehart<sup>2</sup>, U. Müller-Ladner<sup>1</sup>, E. Neumann<sup>1</sup>. <sup>1</sup>Dept. of Rheumatology and Clinical Immunology, Justus-Liebig-University Gießen, Campus Kerckhoff, Giessen; <sup>2</sup>Dept. of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital, Frankfurt/Main, Germany

**Background:** Destructive bone diseases like osteoarthritis and osteoporosis are causes of chronic pain and disability. Mesenchymal stromal cells (MSC) are key regulators for bone homeostasis due to their potential for osteogenic differentiation, preventing bone loss and promoting tissue repair. Pro-inflammatory factors including adipokines such as visfatin alter the osteogenic potential of MSCs and may contribute to the shift towards adipogenic differentiation observed in osteoporosis. Long non-coding RNA H19 is one of the first lncRNAs discovered and best understood e.g. in embryonic growth and tumour formation. lncRNAs interact directly with DNA, RNA as well as proteins and fill a regulatory gap between the ribonucleic and protein world. H19 upregulation was shown in osteogenic differentiation of MSCs<sup>1</sup>. H19 increases the osteogenic potential by acting as a sponge for miRNA 675, 141 and 22, influencing TGFβ1 and Wnt/β-catenin pathways<sup>2,3</sup>. H19 may hence be involved in MSC mediated bone homeostasis.

**Objectives:** To analyse the link between adipokines and bone remodelling in destructive bone disease. To investigate the influence of adipokines on MSCs and on the expression of lncRNA H19 during osteogenesis.

**Methods:** Commercial human MSCs (hMSC) and primary human MSCs (phMSC) from osteoarthritis patients after knee replacement surgery were treated with differentiation medium to induce osteogenic differentiation (OD). Matrix mineralization was quantified after 21 days of OD by Alizarin Red. Expression of H19

and IL-6 protein production were measured using realtime PCR and ELISA at day 2/7/14 of OD.

**Results:** H19 up-regulation in MSCs during OD could be confirmed in a time dependent manner. Visfatin-stimulation of MSC during OD increased matrix mineralization over time as well as IL-6 production (day 7, 14, 21: 46-, 93-, 78-fold). Visfatin stimulation down-regulated H19 expression up to 10-fold over the course of OD compared to non-stimulated control. The effect was significant in pHMSCs in 2/3 measured time points (day 7,  $p=0.03$ ; day 14,  $p=0.002$ ,  $n=3$ ) and in hMSCs on day 14 ( $p=0.0003$ ,  $n=4$ ).

**Conclusions:** During osteogenic differentiation of MSCs, visfatin showed pro-inflammatory and mineralization promoting effects. However, H19 was significantly down-regulated by visfatin during osteogenic differentiation. This may contribute to the loss of osteogenic potency of MSCs in inflamed tissues with increased visfatin concentration as observed in affected areas of destructive bone disease. Further research to understand the H19 effector mechanisms on osteogenic differentiation and osteogenic potency of MSCs are in progress.

#### SAT0031 INTERLEUKIN 29 INHIBITS OSTEOCLAST DIFFERENTIATION AND FUNCTION IN RANKL-INDUCED OSTEOCLASTOGENESIS

F. Wang, A. Luo, Q. Wu, Z. Zhou, Q. Peng, W. Xuan, W. Tan. *The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

**Background:** Interleukin-29 (IL-29) is a new member of the recently discovered interferon (IFN)  $\lambda$  family and known to modulate immune functions of monocyte or macrophage. We have demonstrated that IL-29 is dysregulated in patients with rheumatoid arthritis (RA) and contributes to RA pathogenesis via inducing pro-inflammatory cytokines, chemokines or matrix metalloproteinases production in synovial fibroblasts,<sup>1,2</sup> as well as stimulating inflammation and cartilage degradation in osteoarthritis disease.<sup>3</sup> However, the role of IL-29 in bone resorption is unclear.

**Objectives:** Bone erosion in RA is associated with increased production of pro-inflammatory cytokines and accelerated osteoclastogenesis in affected joints.<sup>4</sup> IL-29 is an important proinflammatory cytokine in RA. We investigated the effect of IL-29 on receptor activator of nuclear factor  $\kappa$ B ligand (RANKL)-induced osteoclastogenesis *in vitro* to determine whether IL-29 can stimulate or attenuate osteoclast-mediated bone resorption that is a hallmark of RA.

**Methods:** The viability and apoptosis of RAW264.7 cells after IL-29 different treatment were assessed by Cell Counting Kit-8 and flow cytometry, respectively. Osteoclasts were generated from RAW264.7 cells, bone-marrow-derived monocyte/macrophage precursor cells (BMMs) and blood-derived human PBMC cells. The effects of IL-29 on osteoclast formation were evaluated by tartrate-resistant acid phosphatase (TRAP) staining and counting the number of TRAP + multinucleated cells. Bone resorption experiment was assessed by pit formation. The expression of key molecules implicated in osteoclastogenesis (TRAP, CTSK, MMP-9, NFATC1 and c-Fos) was measured by real time RT-PCR.

**Results:** Although IL-29 did not show significant effect on the viability and apoptosis of RAW264.7 cells, it inhibited multinucleated cells in the differentiation of murine and human osteoclastogenesis, the bone-resorbing activity of mature osteoclasts. In addition, IL-29 downregulated osteoclast specific genes expression of TRAP, CTSK, MMP-9, NFATC1 and c-Fos.

**Conclusions:** IL-29 inhibits murine and human osteoclastogenesis by a direct mechanism suppressing responses of osteoclast precursors to RANKL. Our findings suggest that IL-29 may play a previously unrecognised role in the osteoclast formation.

#### SAT0032 MESENCHYMAL STEM CELLS ALLEVIATE EXPERIMENTAL AUTOIMMUNE CHOLANGITIS THROUGH IMMUNOSUPPRESSION MEDIATED BY GALECTIN-9

J. Fan, X. Tang, H. Chen, L. Sun, Q. Wang. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, nanjing, China*

**Background:** Mesenchymal stem cells (MSCs) play anti-inflammatory role by secreting some kinds of bioactive molecules. However, the effect of MSCs on chronic autoimmune liver disease, such as primary biliary cholangitis (PBC) and its underlying mechanism remains elusive.

**Objectives:** The aim of this study was to assess the efficacy of UC-MSCs treatment (UC-MSCT) in 2OA-BSA-induced murine autoimmune cholangitis and explore its underlying mechanisms.

**Methods:** UC-MSCs were transplanted into experimental autoimmune cholangitis mice. Biochemical and histological analysis were performed based on the blood and liver tissues. The immunomodulatory effects of UC-MSCs and its cytoprotective function were also investigated.

**Results:** We found that UC-MSCT significantly ameliorated liver inflammation in 2OA-BSA induced autoimmune cholangitis mice, primarily by diminishing Th1 and Th17 responses, and modifying liver chemokine activity. We also found that UC-MSCs significantly repressed the proliferation of CD4 +T cells and suppressed the differentiation of Th1 and Th17 cells, both of which were dependent on galectin-9 (Gal-9). Furthermore, we determined the signal transducer and activator of transcription (STAT) and c-Jun N-terminal kinase (JNK) signalling pathways were involved in the production of Gal-9 in MSCs.

**Conclusions:** The present study shows that UC-MSCs exert profound inhibitory effects on inflammatory responses and that they ultimately alleviate the liver injury in experimental autoimmune cholangitis mice. Further, we demonstrate that UC-MSCs inhibit Th1 and Th17 cell responses as well as aberrant chemokine activity through Gal-9 mediated immunosuppression. Additionally, our research reveals that the induction of Gal-9 in MSCs is mediated by the involvement of the STAT and JNK signalling pathways. These findings may help in the development of stem cell therapies for the treatment of PBC.

#### SAT0033 TIME-DEPENDENT RELATIONSHIPS BETWEEN BIOLOGICAL PARAMETERS AND DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

K. Connelly<sup>1</sup>, H. Nim<sup>2</sup>, F. Vincent<sup>1</sup>, F. Petitjean<sup>2</sup>, A. Hoi<sup>1</sup>, R. Kohlmeyer<sup>1</sup>, S. Boyd<sup>2</sup>, E. Morand<sup>1</sup>. <sup>1</sup>Centre for Inflammatory Diseases; <sup>2</sup>Faculty of Information Technology, Monash University, Clayton, Australia

**Background:** Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease characterised by high inter-patient variability of clinical features, pathology, and disease time-course. Relationships between biomarkers and disease remission/relapse cycles are especially complex and poorly understood.

**Objectives:** To investigate the relationship between disease activity and biomarker expression in a longitudinally-followed SLE cohort.

**Methods:** We measured 4 candidate protein biomarkers implicated in SLE (MIF, CCL2, CCL19 and CXCL10) and 13 routinely collected serum and urine biological parameters, and assessed disease activity (SLEDAI-2k) on each clinic visit. We analysed these data by first focusing on the magnitude of expression levels of the 17 biological markers and then on the temporal dimension, to untangle their relationship to disease activity.

**Results:** Data from 843 visits in 110 SLE patients (median age 47, 83% female, 49% Asian ethnicity) were analysed. We demonstrated highly heterogeneous time-dependent relationships between disease activity and the measured

biological markers. Using unbiased magnitude-based hierarchical clustering of biomarker expression levels, we isolated a patient subset (n=9) with distinctively heterogeneous patterns of expression of the 17 biological parameters, compared to the other (n=101) patients who were more homogeneous. The smaller subgroup had significantly higher levels of MIF, CCL2, CCL19 and CXCL10, but the larger subgroup had stronger associations between biological parameters and SLEDAI-2k, based on leave-one-out cross-validated regression analysis. In this subgroup, when we constructed a time-dependent regression model, compared to the equivalent time-agnostic regression model, the biological parameters had significantly stronger predictive power for disease activity, suggesting a time-dependent relationship. To disentangle the effect of magnitude versus temporal correlation, we used dynamic time-warping analysis to align longitudinal clinical and laboratory profiles. This revealed a further subset (n=69) in whom a time-dependent regression model showed significantly stronger associations between biological parameters and disease activity, despite no significant difference in simple magnitude. This subgroup was characterised by lower rates of flare, lower disease activity and lower damage scores, suggesting that this patient cluster is highly clinically meaningful.

**Conclusions:** Using aggregated longitudinal clinical data and samples, we demonstrated significant subgroups of time-dependent relationships between disease activity and biological markers among patients with SLE. These results imply the association between biological parameters and disease activity may exist in a multi-dimensional time-dependent pattern. Longitudinal SLE data presents potential opportunities to identify patient-stratifying biomarker patterns that are concealed when time is not considered. This finding has significant implications for the design of SLE biomarker studies.

SAT0034

#### POSSIBLE INVOLVEMENT OF BAFF AND MATRIXMETALLOPROTEINASE-9 IN THE ACTIVATION OF MONOCYTES OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

K. Yoshimoto, K. Suzuki, T. Takeuchi. *Keio University School of Medicine, Tokyo, Japan*

**Background:** B cell activating factor belonging to TNF family (BAFF) is well known as a factor which regulates proliferation, differentiation and survival of B cells, and plays a pivotal role in the pathogenesis of primary Sjögren's syndrome (pSS). In our previous study, we found that BAFF significantly enhanced IL-6 production by pSS monocytes and the amount of IL-6 produced by BAFF-stimulated monocytes was positively and significantly correlated with the expression level of a BAFF receptor (BR3). These data collectively suggest that the BAFF signalling through BR3 is involved in activation of monocytes to promote production of inflammatory cytokines, such as IL-6. Matrix metalloproteinase-9 (MMP-9) is well known as one of the enzymes involved in degradation of extracellular matrix (ECM) and mainly produced by activated T cells and monocytes. It has been reported that the concentration of MMP-9 in saliva was significantly higher in pSS patients as compared to healthy controls (HC). Therefore, it is conceivable that MMP-9 is involved in the pathogenesis of pSS through degradation of ECM of salivary glands, which consequently results in decrease in saliva, one of the clinical manifestations of pSS.

**Objectives:** To explore the relationship between BAFF and MMP-9 in the pathogenesis of pSS.

**Methods:** Peripheral monocytes from pSS patients (n=37) and HC (n=19) were prepared by using CD14 +microbeads and cultured *in vitro* in the presence or absence of recombinant human soluble BAFF (rhsBAFF) for 96 hours. The amounts of IL-6 and MMP-9 in the culture supernatants were measured by ELISA. Signal transduction pathways were investigated by exposing rhsBAFF-stimulated pSS monocytes to several inhibitors against NF- $\kappa$ B (BAY11-7082 and BAY11-7085) and PI3 kinase (LY294002). FACS analysis of whole blood samples was performed to investigate the expression levels of BR3 and MMP-9 in monocytes. The expression level of MMP-9 was also analysed by quantitative RT-PCR (qPCR). Serum levels of BAFF and MMP-9 were measured by an electrochemiluminescence assay.

**Results:** Serum levels of BAFF and MMP-9 in pSS patients were significantly higher than those of HC, and the levels showed positive and significant correlation. FACS analysis of whole blood samples demonstrated that MMP-9 was mainly expressed in monocytes and that the expression level was significantly higher in pSS than in HC. ELISA and qPCR revealed that stimulation of pSS monocytes with rhsBAFF drastically enhanced the expression of MMP-9 as compared to normal monocytes. Remarkably, the amount of MMP-9 produced by the cells was positively and significantly correlated with the expression level of BR3 in pSS monocytes, suggesting that BAFF-signalling is involved in the production of MMP-9 by the cells. Moreover, the elevated production of MMP-9 was significantly

suppressed by specific inhibitors against NF- $\kappa$ B and PI3 kinase in a dose dependent manner.

**Conclusions:** The present study suggests that BAFF stimulates monocytes through BR3 to promote MMP9 production and may contribute to ECM degradation. Our study also suggests that NF- $\kappa$ B and PI3 kinase are involved in the pathway.

#### THE EFFECTS OF VISFATIN, RESISTIN AND IL-17 ON SYNOVIAL FIBROBLASTS FROM DIFFERENT RHEUMATIC DISEASE BACKGROUNDS

K. Frommer<sup>1</sup>, S. Rehart<sup>2</sup>, M. Sauerbier<sup>3</sup>, U. Müller-Ladner<sup>1</sup>, E. Neumann<sup>1</sup>. <sup>1</sup>*Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff-Klinik, Justus-Liebig-University Giessen, Bad Nauheim;* <sup>2</sup>*Dept. of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital;* <sup>3</sup>*Dept. of Plastic, Hand and Reconstructive Surgery, BGU Frankfurt, Frankfurt, Germany*

**Background:** Although rheumatoid arthritis (RA) and psoriatic arthritis (PsA) have several features in common, they also possess distinct differences. We hypothesised that RA and PsA synovial fibroblasts (SF), known key effector cells in the pathophysiology of inflammatory arthritis, differentially respond to various stimuli including adipokines and cytokines and that this may contribute to those differences. For example, IL-17 (also found in synovial tissue) is of particular therapeutic significance in PsA but not as effective in RA. Thus far, IL-17 in its isoform IL-17A has been the major therapeutic target in PsA but IL-17F also plays a role in the IL-23/IL-17 axis of inflammatory diseases.

**Objectives:** Therefore, we analysed the responses of SF from patients with PsA, RA or no rheumatic disease to IL-17A/F $\pm$ TNF- $\alpha$  and the adipokines visfatin and resistin, which show strong expression in the synovium of inflammatory arthritis.

**Methods:** SF were isolated from patients with PsA, RA or non-rheumatic disease controls (N), each undergoing joint surgery. PsASF, RASF and NSF were stimulated with human recombinant IL-17A/F, TNF- $\alpha$ , visfatin, and resistin. A neutralising anti-IL-17A antibody was used to verify specificity of the IL-17A effects. Secretion of the proinflammatory cytokine IL-6 was used as the initial readout parameter and was quantified using a commercial immunoassay.

**Results:** Stimulation with visfatin caused a strong increase in IL-6 secretion in all SF types (n=3 each), while resistin had no effect. Differences in responses were not statistically significant between the SF types studied. IL-17A at concentrations found in serum or synovial fluid did not induce IL-6 secretion in any of the SF. Dose-response curve analysis showed that considerably higher concentrations of IL-17A, which may occur locally in tissue, are required for the induction of IL-6 secretion. An anti-IL-17A antibody abolished the effect, thus showing that the effect is specific for IL-17A. The effects of IL-17A and IL-17F on IL-6 secretion by PsASF could be strongly amplified by a co-stimulation with TNF- $\alpha$  (IL-17A: 5-fold vs 113-fold; IL-17F: 1.7-fold vs 39-fold; TNF- $\alpha$  alone: 12-fold). The effects were stronger for IL-17A than for IL-17F with or without TNF co-stimulation. No effect of IL-17F alone was observed on NSF (n=1).

**Conclusions:** SF from RA and PsA patients were not differentially affected by the adipokines visfatin and resistin or IL-17A when used at serum or synovial fluid concentrations suggesting inflammatory cells to be the primary target of anti-IL-17 therapy. In its use as a therapeutic target, the attribute of IL-17F affecting PsASF would potentially increase the beneficial effects.

#### NICOTINE PROMOTES MMP-3 AND RANKL SECRETION THROUGH OVEREXPRESSED NICOTINIC ACETYLCHOLINE RECEPTOR A7 IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES

J.-D. Ma<sup>1</sup>, Y.-S. Mou<sup>2</sup>, T. Yan<sup>2</sup>, J. Jing<sup>1</sup>, Y.-Q. Mo<sup>1</sup>, Y.-L. Chen<sup>1</sup>, L. Dai<sup>1</sup>. <sup>1</sup>*Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University;* <sup>2</sup>*Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou, China*

**Background:** Smoking has been reported not only an established environmental risk factor for developing rheumatoid arthritis (RA), but also a predictor of radiographic progression. Nicotine, the major constituent of cigarette smoke, has been demonstrated inhibitory effect on proinflammatory cytokines through its receptor nicotinic acetylcholine receptor  $\alpha 7$  (AChR $\alpha 7$ ) in RA fibroblast-like synoviocytes (FLS). However, its effects on other function of RA-FLS remain elusive.

**Objectives:** To explore the effect of nicotine on matrix metalloproteinases (MMPs) and RANKL expression from RA-FLS and its possible intracellular signalling mechanism.

**Methods:** Synovial tissues were obtained from 45 patients with active RA as well as 11 osteoarthritis (OA) and 11 noninflammatory orthopaedic arthropathies (Orth.A) patients for control. The expression of AChR $\alpha$ 7 in synovial membrane and cultured FLS were detected by immunohistochemistry staining and Western blot. RA-FLS were treated *in vitro* with different concentration of nicotine and its effect on RA-FLS viability was evaluated by cell counting kit-8. After nicotine pretreatment on TNF- $\alpha$  stimulated RA-FLS, the expression of MMP-2, MMP-3, MMP-9, TIMP-1, TIMP-2, RANKL, and OPG in culture supernatant were measured by ELISA, while the change of AP-1 pathway including c-Fos and c-Jun were detected by quantitative real-time PCR and Western blot.

**Results:** Immunohistochemical analyses showed intense endochylema staining for AChR $\alpha$ 7 mainly in lining layer. The percentage of both lining and sublining AChR $\alpha$ 7 positive cells were significantly higher in RA than that in OA or Orth.A (figure 1A). Further western blot showed significantly higher expression of AChR $\alpha$ 7 in RA-FLS than that in Orth.A-FLS ( $p=0.003$ , figure 1B). Nicotine (0.1  $\mu$ M~50  $\mu$ M) showed no cytotoxicity on RA-FLS proliferation. Pretreatment with 50  $\mu$ M nicotine for 24 hours significantly promoted the secretion of MMP-3 and RANKL but inhibited TIMP-1 secretion in TNF- $\alpha$  stimulated RA-FLS (all  $p<0.05$ , figure 1C). Further, 25  $\mu$ M and 50  $\mu$ M nicotine treatment for 24 hours upregulated both mRNA and protein expression of c-Fos but not c-Jun which indicated that nicotine might activate AP-1 signalling pathway by c-Fos (all  $p<0.05$ , figure 1D).

**Abstract SAT0036 – Figure 1.** Effects of nicotine on the secretion of MMPs, RANKL and OPG as well as AP-1 signalling pathway activation in RA-FLS. A Immunohistochemistry staining for AChR $\alpha$ 7 in RA synovium. The data were representative as median and interquartile range from 45 RA, 11 OA and 11 Orth. A patients. B The expression of AChR $\alpha$ 7 in RA-FLS was measured by Western blot. C After nicotine treatment for 24 hours, the levels of MMP-3, TIMP-1 and RANKL in culture supernatant of TNF- $\alpha$  stimulated RA-FLS were measured by ELISA. D After nicotine treatment for 24 hours, the expression of c-Fos and c-Jun in RA-FLS was measured by quantitative real-time PCR and Western blot. The data were representative as means $\pm$ SD from six different RA patients, \* $P<0.05$ , \*\* $P<0.01$ , \*\*\* $P<0.001$ .

**Conclusions:** Nicotine can promote MMP-3 and RANKL expression through overexpressed AChR $\alpha$ 7 in RA-FLS which might be involved in the pathogenesis of osteogenesis and bone destruction in RA.

#### IGURATIMOD AMELIORATES BLEOMYCIN-INDUCED ALVEOLAR INFLAMMATION AND PULMONARY FIBROSIS IN MICE BY SUPPRESSING EXPRESSION OF MMP-9

L. Zhao, B. Mu, R. Zhou, C. Huang. *Department of Rheumatology, Beijing Hospital, National Center of Gerontology, Beijing, China*

**Background:** Interstitial lung disease (ILD) occurs in 15% of patients with connective tissue diseases (CTD) It contributes significantly to morbidity and mortality, and is difficult to manage<sup>(1)</sup>. Despite advances in management strategies, CTD-ILD have a significant adverse effect on quality of life and is still a leading cause of mortality, highlighting an urgent need for optimal treatment regimens. It is known that inflammatory cytokines played an important role in alveolitis and the development of pulmonary fibrosis<sup>(2)</sup>. Iguratimod (IGU) has a reported effect on

preventing the inflammatory processes by inhibiting the production of various inflammatory cytokines<sup>(3)</sup>.

**Objectives:** To investigate the potential therapeutic efficacy of IGU on mouse model of bleomycin (BLM) induced pulmonary fibrosis.

**Methods:** A total of 75 C57BL/6 mice were randomly and evenly divided into control group, BLM (5 mg/kg) group, BLM +IGU (90 mg/kg) group, BLM +methylprednisolone (MP, 10 mg/kg) group and BLM +pirfenidone (PF, 100 mg/kg) group. The mice were sacrificed on day7, day 14, day 28 respectively. The lung tissue was examined by Hematoxylin and eosin staining and Masson staining to evaluate the degree of alveolitis and fibrosis, and plasma cytokines were measured.

**Results:** Histopathological results showed that IGU attenuated BLM-induced alveolar inflammation and decreased collagen deposition in lung tissue from day 7 till day 28. Both the pathological alveolitis scores and fibrosis scores in drug treated group (IGU group, MP group and PF group) were decreased dramatically compared with BLM group on day7, day 14 and day 28 respectively ( $p<0.05$ ). There were no statistical significances among those three groups. Cytokine profile showed that IGU decreased the level of tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin (IL)-1, IL-6 and matrix metalloproteinase (MMP)-9 which were up-regulated by BLM on day 7, day 14 and day 28 respectively ( $p<0.05$ ). Furthermore, there is a strong correlation between the severity of the pulmonary fibrosis and the plasma MMP-9 levels ( $r=0.836$ ,  $p<0.001$ ).

**Conclusions:** IGU was effective in suppressing BLM-induced alveolar inflammation and pulmonary fibrosis, and it has the equal anti-inflammatory and anti-fibrotic effects as MP or PF. The therapeutic effects by IGU may be attributed to the inhibition of MMP-9 either directly or indirectly. Therefore, IGU presents as a promising agent for pulmonary fibrosis treatment.

#### MEMBRANE-ASSOCIATED AMPD2, A NOVEL REGULATOR IN SHIFTING THE BALANCE BETWEEN EXTRACELLULAR ATP AND ADENOSINE?

L. Ehlers, A. Kuppe, A. Damerau, Y. Chen, F. Buttgerit, T. Gaber. *Department of Rheumatology and Clinical Immunology, Charité – Universitat Tsmedizin Berlin, Berlin, Germany*

**Background:** Extracellular ATP and adenosine are potent immunomodulatory molecules that accumulate in states of inflammation. ATP/ADP are released from damaged or stressed cells and sequentially catabolized to AMP which is then catabolized to adenosine by the action of the ectonucleotidases CD39 and CD73, which drives a shift from an ATP-driven proinflammatory environment to an anti-inflammatory milieu induced by adenosine. Intracellularly, AMPD2 which encodes one of three known AMP deaminase homologs executes AMP deamination to IMP thereby reducing the formation of adenosine. Here, we postulate that this mode of action is also present on the cell surface of immune cells, which may lead to an increased state of inflammation such as found in chronic inflammatory diseases.

**Objectives:** Therefore, we analysed surface AMPD2 expression and its modulation on distinct human cell lines and primary human immune cells.

**Methods:** To this end, surface AMPD2 expression was evaluated on cell lines (THP1, Jurkat, HMEC1, and HEK293), human PBMCs and isolated monocytes by flow cytometry. Moreover, co-expression of surface AMPD2, CD73 and CD39 has been analysed on PBMCs and isolated monocytes. Association of surface AMPD2 and cell death was visualised using annexin V and 7-AAD staining and examined by flow cytometry. In addition, expression of AMPD2 was analysed by immunoblot of precipitated AMPD2 from membrane fractions and by mass spectrometry after precipitation from membrane fractions and from biotinylated surface-molecules using the surface AMPD2 positive cell line HEK293.

**Results:** Here, we demonstrate that (i) surface AMPD2 is present on T cells and monocytes in PBMCs from healthy donors, (ii) that LPS enhances surface expression of AMPD2 in PBMCs on both cell populations after 24 hour, (iii) that LPS also enhances surface expression of AMPD2 in isolated monocytes, (iv) that surface AMPD2 does not correlate to the expression of the ectonucleotidases CD39 and CD73 and (v) that all cell lines analysed are capable of expressing surface

AMPD2. Using HEK293, surface AMPD2 expression was reduced after Golgi transport inhibition. AMPD2 surface expression was not accompanied by enhanced cell death. Expression of AMPD2 could be confirmed in membrane fractions of HEK293 using immunoblot of precipitated AMPD2 and mass spectrometry, respectively.

**Conclusions:** Here, we demonstrate for the first-time surface expression of AMPD2 on immune cells enabling these cells to extracellularly convert AMP into IMP constituting a shunt-like mechanism to control the levels of adenosine and extracellular ATP formed from adenine nucleotides thereby controlling immunomodulation.

**Background:** The antimicrobial peptide LL37 plays a pathogenic role in psoriasis (Pso) due to its adjuvant and auto-antigenic properties. At least a third of Pso patients develop psoriatic arthritis (PsA) but mechanisms that lead PsA development in Pso patients remain elusive.

**Objectives:** To understand the role of LL37 in PsA pathogenesis and its relationship with inflammatory molecules IFN $\alpha$ , GMCSF, C5a.

**Methods:** Blood samples were collected from 32 biologic-naïve PsA, 12 active Pso (without PsA) patients and 8 healthy donors (HD). Synovial fluids (SF) were collected from 17 PsA and 12 osteoarthritis (OA) patients. Synovial biopsies from 3 biologic-naïve PsA patients were studied by confocal microscopy. Native-LL37 was synthesised and carbamylated LL37 (LL37carb) produced by incubating LL37 with 1 M potassium cyanate and verified by dot-blot assay. Antibodies to native-LL37/LL37carb and levels of LL37, GMCSF, IFN $\alpha$  and complement C5a were measured by in-house and commercial ELISA tests, respectively, in SF and plasma.

**Results:** High LL37 levels were detectable in SF of PsA compared to OA. Anti-LL37 [24% in SF (4/17)] and anti-LL37carb antibodies [47% in SF (8/17), 46% in plasma (15/32)] were present in PsA but not in OA and HD. Anti-LL37carb antibodies [41% (5/12)] were also detectable in Pso plasma. IFN $\alpha$  was present in 37% of SF PsA (7/16; not detectable in OA) and correlated with C-reactive Protein (CRP); GMCSF and C5a levels were significantly higher in SF PsA than in SF OA. Notably, GMCSF was also detectable in 40% and 30% of PsA and Pso plasma, respectively, but not in HD; Plasma C5a levels were comparable between PsA and Pso and significantly higher than in HD. SF GMCSF correlated with anti-LL37carb autoantibodies. Anti-LL37carb antibodies correlated with levels of C5a in Pso and PsA plasma. In synovial tissues of PsA the expression of the IFN-related gene MX1 was highly up-regulated in close proximity of neutrophil markers myeloperoxidase and LL37.

**Conclusions:** LL37 and, in particular, LL37carb is the target of autoantibodies that correlate with pro-inflammatory GMCSF and C5a in both Pso and PsA, suggesting immunological pathways in common between psoriasis and psoriatic arthritis.

### SAFETY, TOLERABILITY, PHARMACOKINETICS AND PHARMACODYNAMICS OF BCD-089, NOVEL MONOCLONAL ANTI-IL-6 RECEPTOR ANTIBODY: RESULTS FROM THE FIRST-IN-HUMAN SINGLE DOSE ESCALATION STUDY IN HEALTHY VOLUNTEERS

P. Khlyabova<sup>1</sup>, A. Ereemeeva<sup>2</sup>, A. Lutskii<sup>2</sup>, E. Dokukina<sup>2</sup>, E. Chemyaeva<sup>2</sup>, R. Ivanov<sup>2</sup>. <sup>1</sup>«BioEq» Ltd; <sup>2</sup>JCS Biocad, Saint-Petersburg, Russian Federation

**Background:** BCD-089 is a fully human monoclonal antibody targeting membrane-bound and soluble forms of IL-6R $\alpha$ , thereby blocking of IL-6 classic and trans- signalling. IL-6, a proinflammatory cytokine, plays a central role in the pathogenesis of many chronic inflammatory and autoimmune diseases. Thereby inhibition of IL-6 signalling is a promising approach in the treatment of immune-mediated pathology.

**Objectives:** To assess safety, immunogenicity, pharmacokinetics and pharmacodynamics of a single administration of BCD-089.

**Methods:** This was a phase I, open label, single ascending dose clinical study in healthy male volunteers, aged 22–37 years (n=19). In 1 st cohort, one «sentinel» volunteer received 0.006 mg/kg of BCD-089. Volunteers in cohorts 2–7 received single doses of BCD-089 0.3, 0.625, 1.0, 1.6, 2.2 and 2.9 mg/kg, respectively. Every next cohort was included after completed safety evaluation for the previous one. Safety, PK/PD and immunogenicity were assessed during 71 days follow up.

**Results:** All enrolled subjects have completed follow up period of 71 days. No withdrawals occurred. Single SC administration of BCD-089 was well tolerated and showed good safety profile at all tested doses: no grade 3/4 AEs, SAEs, DLTs or allergic reactions were reported in any cohort. None of the volunteers developed ADA to BCD-089. The only AEs reported were grade 1 or 2 laboratory abnormalities.

**Abstract SAT0040 – Table 1.** Subjects with abnormal test results, n (%). Table shows only cohorts where at least one abnormal test result was reported.

Adverse events	0.3 mg/kg (n=3)	0.625 mg/kg (n=3)	1.0 mg/kg (n=3)	2.2 mg/kg (n=3)	2.9 mg/kg (n=3)
Grade 1 WBC decrease	-	-	1 (33.3%)	2 (66.6%)	1 (33.3%)
Grade 1 neutropenia	-	-	1 (33.3%)	1 (33.3%)	-
Grade 2 neutropenia	-	-	-	1 (33.3%)	1 (33.3%)
Grade 2 t.bilirubin increase	-	1 (33.3%)	-	-	-
Grade 1 AST decrease	1 (33.3%)	-	-	-	-
Grade 1 Creatinine decrease	-	1 (33.3%)	-	-	-

Single SC administration of BCD-089 had a dose-dependent PK: the drug became detectable in the serum within the first 12 hour after injection for all tested doses (2–8 hour for doses>1.0 mg/kg). Serum concentration dose-proportionally increased and reached maximum at day 3 after administration, then gradually decreased. Elimination half-life showed significant inter-personal variability and dose-dependency, reflecting non-linear PK typical for drugs with target-mediated disposition.

**Abstract SAT0040 – Figure 1.** BCD-089(A), sIL6R(B), IL6(C) and CRP(D) serum concentration (Median and IQR).

The concentration of soluble IL-6 receptor increased after BCD-089 administration in a dose-dependent manner. A raise in the concentration of IL-6 was seen at doses >1.0 mg/kg. Membrane IL-6R saturation of 90%>100% was seen at doses  $\geq$ 0.6 mg/kg. Regardless to the dose, serum CRP decreased below the limit of detection in most volunteers within the first week after injection. All tested PD markers returned to baseline at the end of the follow-up.

**Conclusions:** Single SC administration of BCD-089 was well tolerated, showed favourable safety profile and low immunogenicity at all tested doses in healthy volunteers. PK/PD assessment revealed non-linear PK and significant capacity to inhibit the IL-6 signalling pathway. These findings support further clinical development of BCD-089.

SAT0024

### IL-36 AXIS IS AN EMERGING THERAPEUTIC TARGET IN PSORIATIC ARTHRITIS SYNOVIAL TISSUE

M.-A. Boutet, A. Nerviani, G. Liso-Ribera, K. Goldmann, M. Lewis, C. Pitzalis. Centre for Experimental Medicine and Rheumatology, Queen Mary University, London, UK

**Background:** The IL-36 family of cytokines includes three agonists, IL-36 $\alpha$ , IL-36 $\beta$  and IL-36 $\gamma$ , and two established or hypothetical antagonists, respectively IL-36Ra and IL-38. IL-36 agonists are pro-inflammatory cytokines highly expressed in skin and involved in the pathogenesis of psoriasis. A recent study demonstrated that only a subset of patients with rheumatoid arthritis (RA) had an elevated IL-36 agonists/antagonists ratio within the synovium and could potentially respond to IL-36 inhibition strategies but little is known about the expression and biologic functions of the IL-36 axis in synovial tissue of psoriatic arthritis (PsA) so far hardly been studied.

**Objectives:** In this study, we aimed to comparatively investigate the expression and role of IL-36 cytokines in synovial tissue of early RA and PsA patients.

**Methods:** Synovial tissue samples were collected from patients with early RA and PsA (disease duration <12 months) DMARDs (Disease Modifying Anti-Rheumatic Drugs) and steroids-naïve. All patients underwent an ultrasound-guided synovial biopsy before starting the treatment; the procedure was repeated following six months of treatment with conventional DMARDs. The expression of IL-36 family members was investigated in synovial tissue at gene level by RNA-Sequencing (87 RA, 15 PsA), at protein level by immunohistochemistry (IHC) and immunofluorescence (IF) (20 RA, 26 PsA) and in plasma by ELISA (22 RA, 38 PsA). RA and PsA-fibroblasts-like-synoviocytes (FLS) and peripheral blood mononuclear cells (PBMCs) were treated *in vitro* to assess their response to IL-36 stimulation.

**Results:** Gene and protein expression of IL-36 agonists was comparable between RA and PsA synovial tissue; conversely, the antagonists IL-36Ra and IL-38 were significantly lower in PsA compared to RA. Accordingly, the agonists/antagonists ratio was considerably higher in PsA synovium, suggesting an activation of the IL36 pro-inflammatory pathway. Among the immune cells infiltrating the PsA synovium, macrophages (CD68+), T lymphocytes (CD3+) and plasma cells (CD138+) were the primary IL36 $\alpha$ -expressing cells. At baseline, the synovial expression of IL-36 $\alpha$  was significantly higher in PsA patients who did not respond to DMARDs treatment at 12 months; this differential synovial expression of IL-36 $\alpha$  between responders and non-responders was also maintained at six months. In keeping with this observation, we showed that treatment with methotrexate or sulfasalazine did not reduce the expression of IL-36 in PsA cells *in vitro*. Finally, we observed that PsA-FLS and PsA-PBMCs produced significantly higher levels of IL-8 upon stimulation with IL-36 $\alpha$  in comparison with cells isolated from RA patients.

**Conclusions:** The expression of the anti-inflammatory IL-36 cytokines antagonists are differently regulated in early RA and PsA, being significantly lower in the latter. Moreover, the pro-inflammatory IL-36 $\alpha$  is up-regulated in synovial tissue of PsA non-responders to conventional DMARDs. The impaired balance between agonists and antagonists might contribute to the persistent inflammation characterising the diseased tissue. The exogenous replacement of the IL-36 antagonists may be a novel promising therapeutic target for PsA patients.

### CXCL4 ALTERS TRANSCRIPTOMIC AND EPIGENETIC IMPRINTING OF DENDRITIC CELLS THEREBY DRIVING FIBROSIS THROUGH EXTRACELLULAR MATRIX FORMATION

S.C. Silva-Cardoso<sup>1</sup>, W. Tao<sup>1</sup>, C. Angiolilli<sup>1</sup>, A. P.P. Lopes<sup>1</sup>, C. Bekker<sup>1</sup>, J. van Laar<sup>2</sup>, E. Hack<sup>3</sup>, M. Boes<sup>4</sup>, A. Pandit<sup>1</sup>, T.R.D.J. Radstake<sup>1</sup>. <sup>1</sup>Laboratory of Translational Immunology And Department of Rheumatology and Clinical Immunology; <sup>2</sup>Department of Rheumatology and Clinical Immunology; <sup>3</sup>Laboratory of Translational Immunology; <sup>4</sup>Department of Pediatrics, University Medical Center, Utrecht, Utrecht, Netherlands

**Background:** Aberrant accumulation of extracellular matrix (ECM) in multiple organs or fibrosis is one of the three hallmarks that characterises the pathogenesis of systemic sclerosis (SSc), together with immune dysregulation and small vessel vasculopathy. Recent studies have shown that CXCL4 (Chemokine CXC motif ligand 4) levels are increased in patients with SSc and correlated with skin and lung fibrosis.<sup>1</sup> CXCL4 plays key role in physiological processes, although it has been also implicated in several pathological conditions such as autoimmune diseases and cancer. We and others have shown that CXCL4 modulates the phenotype and function of immune cells<sup>2</sup>, suggesting a critical role of this chemokine in innate and adaptive immune responses. However, how CXCL4 exactly modulates immune cell responses remains unclear.

**Objectives:** Here we investigated the impact of CXCL4 exposure on the transcriptome and DNA methylation of monocyte-derived dendritic cells (moDCs), and the consequence on their function.

**Methods:** We differentiated human moDCs in the presence of CXCL4. After 6 days differentiation, cells were stimulated with a TLR3 ligand (polyI:C) as described in our previous study.<sup>2</sup> RNA sequencing and DNA methylation profiling was performed at various time points during differentiation and stimulation.

**Results:** Integration of high-throughput analyses of RNA sequencing and DNA methylation reveals that CXCL4 drives to dramatic changes on the transcriptome and epigenome levels. This is reflected in the dysregulation of critical innate and adaptive immune pathways, like antigen presentation, and cytokine signalling. For the first time, we show that CXCL4 potentiates a novel function to dendritic cells, namely, the production of ECM molecules, such as fibronectin (FN1) and osteopontin (OPN). Furthermore, we also found that CXCL4 exposure results in epigenetic imprinting during moDC differentiation. Using novel bioinformatic methods, we have found that CXCL4 mediates the altered cell function via key transcriptional regulators.

**Conclusions:** This study provides better understanding how CXCL4 affects moDCs through several immune and non-immune pathways and shows for the first time the direct implication of CXCL4 on the production of ECM by inflammatory cells, thereby underscoring the pivotal role of CXCL4 in inflammatory and fibrotic conditions such as SSc.

### COMPARISON OF DIFFERENT TYPE 1 IFN SIGNATURES DEMONSTRATES CONCORDANCE IN A REAL WORLD, HOME MONITORED SYSTEMIC LUPUS ERYTHEMATOSUS COHORT

M. Abedi, F. Flores, P. Naranatt, J. Spangler, L. Pan, R. Terbruggen. *Dxterity, Rancho Dominguez, USA*

**Background:** Type 1 Interferon (IFN) expression has been shown to correlate with disease severity in systemic lupus erythematosus (SLE) patients<sup>1</sup> and anti-IFN biologics are being evaluated in a clinical setting.<sup>2</sup> The 4-gene IFN response signature of IFI27, IFI44, IFI44L and RSAD2<sup>2</sup> is frequently used to determine IFN expression. However, numerous studies have reported on the use of different gene signatures.<sup>3, 4, 5</sup> The impact of using different IFN gene signatures to stratify SLE patients is unclear.

**Objectives:** The present study compares the relative performance of 4 IFN gene signatures in a cohort of 687 participants with self-reported SLE.

**Methods:** A centralised site, IRB-approved, SLE cohort was recruited using social media. Qualified participants with self-reported SLE were consented electronically and asked to provide medical record review consent, complete an online questionnaire regarding their disease as well as provide 3 fingerstick blood samples over approximately a 6 week period. Blood samples from 687 participants were tested using a multi-modular gene expression assay containing 11 IFN response genes (primarily from the IFN- $\alpha$  response pathway). Normalised gene expression values were calculated, and the resulting data analysed to determine concordance between IFN gene signatures.

**Results:** 10 of the 11 IFN response genes were highly correlated with one another ( $\rho \geq 0.80$ ). The 4-gene signature of IFI27, IFI44, IFI44L, and RSAD2<sup>2</sup> identified 36.5% of the participants as IFN high. Three other literature reported IFN signatures<sup>3, 4, 5</sup> provided similar classification results with participants being assigned to the same IFN sub-group over 90% of the time, and nearly identical patient distributions.

Abstract SAT0041 – Table 1

Signature	Genes	IFN High (%)	IFN Low (%)	% Agreement (95% CI) to Furie et al.
Furie et al. <sup>2</sup>	IFI27, IFI44, IFI44L, RSAD2	36.5	63.5	N/A
Niewold et al. <sup>3</sup>	EIF2AK2, IFIT1, MX1	36.3	63.7	94.8% (93.4–95.9)
Kirou et al. <sup>4</sup>	EIK2AK2, IFIT1, IFI44	36.0	64.0	95.1% (93.7–96.2)
Westra et al. <sup>5</sup>	IFI6, HERC5, IFIT1, MX1	36.0	64.0	94.8% (93.4–95.9)

**Conclusions:** The study demonstrated that commonly used IFN gene signatures provide similar IFN subtyping to the 90th percentile. The use of social media to engage patients directly along with self-collection of blood samples provides new opportunity for testing clinical study participants and potentially patients without requiring an office visit.

#### SAT0042 EVIDENCE OF NETOSIS IN CIRCULATING NEUTROPHILS AND SKIN LESIONS WITH VASCULITIS AND PANNICULITIS IN BEHÇET'S DISEASE

R. Kallas<sup>1</sup>, R. Safi<sup>2</sup>, R. Hamam<sup>3</sup>, I. Uthman<sup>4</sup>, D. Nassar<sup>2,5</sup>. <sup>1</sup>Internal Medicine, American University of Beirut Medical; <sup>2</sup>Anatomy, Cell Biology and Physiological Science, American University of Beirut; <sup>3</sup>Ophthalmology; <sup>4</sup>Internal Medicine; <sup>5</sup>Dermatology, American University of Beirut Medical Center, Beirut, Lebanon

**Background:** Behcet's disease (BD) pathophysiology is poorly understood. It is characterised by recurrent episodes of acute inflammation consisting of neutrophil infiltration in affected organs and around blood vessels. Recently, NETosis, trapping and killing pathogens by activated neutrophils, has been described. These Neutrophil Extracellular Traps (NETs) were shown to promote inflammation in a number of autoimmune diseases such as Systemic Lupus Erythematosus, ANCA-Associated Vasculitis and Rheumatoid Arthritis. We hypothesise that in BD, neutrophils trigger inflammation and vasculitis via NETosis.

**Objectives:** The aim of this study is to demonstrate the implication of NETosis in the pathophysiology of this disease.

**Methods:** Blood specimens from BD patients and matched healthy volunteers were collected at the American University of Beirut Medical Centre. Circulating neutrophils were isolated and cultured in Roswell Park Memorial Institute (RPMI) 1640 medium. Cultured cells were treated with colchicine, dexamethasone or corresponding vehicle, and stimulated with serum from BD patients, controls or left unstimulated. The kinetic and amount of NET formation was assessed by cell counting using Hoechst 33 342 and Sytox green staining and fluorescent microscopy. Moreover, previously described NET-bound proteins (elastase, myeloperoxidase, citrullinated histone-3 and PR-3) were identified by immunolabeling and mRNA expression levels of PAD4, a key enzyme that promotes citrullination of arginine residues on chromatin, was evaluated in neutrophils from BD compared to controls. Finally, evidence of NETosis *in vivo* was assessed on paraffin embedded specimens from damaged organs of BD patients using immunolabeling and confocal microscopy.

**Results:** The percentage of unstimulated neutrophils undergoing NETosis *in vitro* was significantly higher in BD patients compared to controls. Treatment of unstimulated BD neutrophils with colchicine and dexamethasone resulted in significant decrease in NETs formation compared to controls. Interestingly, the percentage of NETs increased upon exposure of neutrophils to serum from BD patients. Moreover, PAD4 mRNA expression was 3 times higher in BD patients compared to controls. Immunolabeling assay demonstrated that NET-bound proteins were present in NETs scaffold of unstimulated neutrophils from BD patients *in vitro*. Additionally, NETs were detected in skin tissues of BD patients focally distributed in proximity to small vessels in vasculitis patients and to inflamed adipose tissue in panniculitis patients. These were associated with elastase and citrullinated histone-3 proteins.

**Conclusions:** We show here for the first time that circulating neutrophils from BD patients are prone to NETosis *in vitro*. NET formation was inhibited by the addition of colchicine and dexamethasone reflecting their therapeutic benefits in BD. The increase of NETosis upon serum stimulation suggests the presence of soluble factors and cytokines triggering NETs in BD. Combined, these results suggest a major role of NETs in the pathophysiology of BD.

#### SAT0043 IL-33/ST2-MEDIATED INFLAMMATION IN ENDOTHELIAL CELL IS DIRECTLY AGGRAVATED BY IL-6 DURING LUPUS NEPHRITIS

S.L. Yu<sup>1</sup>, Y.B. Huo<sup>1</sup>, C.H. Huang<sup>1</sup>, Y. Tao<sup>1</sup>, W.H. Huang<sup>1</sup>, C.K. Wong<sup>2</sup>, L.S. Tam<sup>3</sup>, H.N. Qiu<sup>4</sup>, R.L. Chen<sup>1</sup>, C.H. Huang<sup>1</sup>, L. Zhong<sup>5</sup>. <sup>1</sup>Rheumatology, The Second Affiliated Hospital of Guangzhou Medical University, Guangzhou Medical University, Guangzhou; <sup>2</sup>Chemical Pathology; <sup>3</sup>Medicine and Therapeutics, Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong; <sup>4</sup>Pathogenic Biology and Immunology, Guangzhou Medical University; <sup>5</sup>Pathology, The Second Affiliated Hospital of Guangzhou Medical University, Guangzhou Medical University, Guangzhou, China

**Background:** "Alarmins" are prototypic endogenous pro-inflammatory factors as they are released from necrotic cells and provoke local damage or systemic inflammation. Evidences are accumulating to support the inclusion of "Alarmins" as targets of autoreactivity as well as inducers in the pathogenesis of Systemic Lupus Erythematosus (SLE). Interleukin (IL)-33 is a novel member of the family of "Alarmins" because of its characteristics and functions in mediating host immune responses. On this background, we sought to determine the role of IL-33/ST2 axis in lupus pathogenesis. The role of IL-33/ST2 axis has not previously been described in lupus nephritis.

**Objectives:** This project will study the followings:<sup>1</sup> To determine whether IL-33 was present in renal glomerular endothelial cells;<sup>2</sup> To assess the functional and intracellular signal transduction mechanisms regulating the link between IL-33/ST2-mediated innate immunity and inflammation in human umbilical vein endothelial cells (HUVECs).

**Results:** This study, for the first time, showed that IL-33 was pathologically expressed in the kidney tissue of patients with lupus nephritis and not in that of subjects with relative normal renal tissues from atrophy. However, no significant difference was observed between patients with lupus nephritis and kidney cancer. Immunofluorescence (IF) for IL-33 in kidney was performed in lupus patients. IL-33 was clearly seen in glomeruli and also in peritubular areas. To determine whether the IL-33 staining in glomeruli area was in endothelium, multiple staining for IL-33, CD34 (a marker for endothelial cells) and 4',6-diamidino-2-phenylindole

(DAPI) stained for cell nuclei was performed. Co-localization of IL-33 and DAPI in CD34 positive cells demonstrates IL-33 staining in the nucleus of glomerular endothelial cell of lupus kidney. Expression of intracellular but not surface ST2 was increased in plasmacytoid dendritic cells/pDC (CD16-CD14-CD85k+CD123+) of lupus patients when compared with healthy controls. Incubation of HUVECs with IL-33 and/or IL-12 increased the production of IL-6, but IL-4, IL-5, IL-6, IL-13 and TNF- $\alpha$  was not produced.

**Conclusions:** As a result of external stimuli or infection, renal glomerular endothelial cells undergo cellular death and release the "Alarmin", IL-33, to alert the lupus immune system. Released IL-33 interact with their target cells, pDC via their specific receptor ST2 to subsequently induce innate and adaptive responses, activate inflammatory pathways in the pathogenesis of lupus nephritis.

SAT0044

#### LIN28A IS OVEREXPRESSED IN OSTEOARTHRITIS AND IS ESSENTIAL FOR THE STABILITY AND HIGH LEVEL EXPRESSION OF IL-6 AND COX-2 IN HUMAN CHONDROCYTES

I. Ahmad, M.Y. Ansari, M.N. Khan, T.M. Haqqi. *Anatomy and Neurobiology, North East Ohio Medical University, Rootstown, USA*

**Background:** Osteoarthritis (OA), the most common type of joint disease, is characterised by progressive and irreversible degradation of articular cartilage. Dysregulated gene expression has also been linked to disease pathogenesis. Lin28A is an evolutionarily conserved RNA binding protein and known to play a critical role in development, metabolism and tumorigenesis. However, the role of Lin28A in osteoarthritis is not yet explored.

**Objectives:** To study the role of Lin28A in the regulation of genes associated with OA pathogenesis in human chondrocytes.

**Methods:** Primary human chondrocytes were isolated from the undamaged portion of the knee OA cartilage by enzymatic digestion and were cultured in DMEM/F12% and 10% FCS. Total RNA from cartilage explants or chondrocytes was prepared using Trizol and was made DNA-free by on-column digestion method. mRNA expression levels of Lin28A, Lin28B, MMP-13, IL-6, COX2 and iNOS were quantified by TaqMan assays. Protein expression was analysed by immunoblotting using validated antibodies. Nucleofection was used for the siRNA mediated depletion or plasmid mediated overexpression of Lin28A gene was used to study its role in chondrocyte function under pathological conditions. RNA immunoprecipitation (RIP) with anti-Lin28A antibody was performed to identify the interacting mRNA partners. Stability of the mRNAs was determined by Actinomycin-D chase experiments.

**Results:** Human OA cartilage samples (n=6) analysed were found to express Lin28A but not Lin28B transcripts. Lin28A mRNA expression was significantly high in the damaged OA cartilage compared to the smooth cartilage from the same patient (n=3, p<0.05). Stimulation with IL-1 $\beta$  induced the high levels of Lin28A mRNA and protein expression in OA chondrocytes in a time dependent as

well as dose dependent manner. siRNA mediated depletion of Lin28A expression in OA chondrocytes inhibited the IL-1 $\beta$ -induced expression of MMP-13, IL-6, COX2 and iNOS mRNAs. Importantly, the overexpression of Lin28A induced the expression of MMP-13, IL-6, COX-2 and iNOS mRNA and protein in OA chondrocytes. Immunoblotting analysis showed that the Lin28A depleted OA chondrocytes treated with IL-1 $\beta$  also produced significantly low levels of IL-6, MMP-13 and COX-2 protein compared to chondrocytes transfected with scrambled siRNAs (n=3, p<0.05). RIP analyses in IL-1 $\beta$  treated OA chondrocytes with anti-Lin28A antibody revealed that the MMP-13, IL-6 and COX2 mRNAs were pulled down with anti-Lin28A and were highly enriched when compared with the mRNA population pulled down by isotype control antibody. siRNA mediated depletion of Lin28A expression resulted in decreased half-life of IL-6 and COX-2 mRNAs, while the overexpression of Lin28A had the opposite effect in IL-1 $\beta$  stimulated OA chondrocytes. This indicated that Lin28A contributes towards the stability of IL-6 and COX-2 mRNAs.

**Conclusions:** Our data for the first time demonstrate that Lin28A plays a key role in OA pathogenesis by stabilising the expression of catabolic gene transcripts in human chondrocytes under pathological conditions. These data revealed a previously unidentified role of Lin28A in chondrocytes and identify it as a potential therapeutic target for the treatment of OA.

SAT0045

#### DNA METHYLATION OF SOCS3 AS A POSSIBLE MECHANISM FOR PERSISTENT URATE INDUCED INFLAMMATION

V. Klück<sup>1</sup>, T. Crisan<sup>2</sup>, M. Cleophas<sup>1</sup>, S. Keating<sup>1</sup>, B. Novakovic<sup>3</sup>, N. Dalbeth<sup>4</sup>, L. Stamp<sup>5</sup>, A. Phipps-Green<sup>6</sup>, M. Black<sup>6</sup>, D. Macartney-Coxson<sup>7</sup>, T. Merriman<sup>6</sup>, L. Joosten<sup>1</sup>. <sup>1</sup>Experimental Internal Medicine, Radboudumc, Nijmegen, Netherlands; <sup>2</sup>Department of Medical Genetics, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; <sup>3</sup>Department of Molecular Biology, Radboud University, Nijmegen, Netherlands; <sup>4</sup>Department of Medicine, University of Auckland, Auckland; <sup>5</sup>Department of Medicine, University of Otago, Christchurch; <sup>6</sup>Department of Biochemistry, University of Otago, Dunedin; <sup>7</sup>Environmental and Scientific Research, Wellington, New Zealand

**Background:** Hyperuricemia is a metabolic condition associated with cardiovascular diseases.<sup>1</sup> However, mechanisms for a causal relation have not been fully elucidated yet. Previously, we showed that monocytes primed with urate show a shift in the balance of cytokine production: increased proinflammatory cytokines and decreased levels of IL-1 receptor antagonist.<sup>2</sup>

**Objectives:** In this study we investigate if these changes to urate exposure are persistent and whether changes in DNA methylation serve as a molecular substrate for these effects of hyperuricemia.

**Methods:** DNA methylation was assessed in whole blood of 80 individuals of Maori ancestry with varying serumurate levels. Human PBMCs and monocytes from Dutch healthy volunteers were isolated and pretreated for 24 hour with urate. Cells were either directly stimulated with LPS or LPS/MSU or subjected to increasing resting days before restimulation. Cytokine levels were determined in supernatants by ELISA. SOCS3 mRNA levels were determined by qPCR after 24 hour urate priming. Phosphorylation of STAT3 was assessed after stimulation by flow cytometry with intracellular staining for pSTAT3.

**Results:** Human PBMCs primed with urate demonstrated increased IL-1 $\beta$  and IL-6 responses and decreased IL-1Ra production compared to controls. Although IL-1 $\beta$  production was diminished after increasing resting days, persistent effects were observed for the reduction of IL-1Ra and induction of IL-6. To investigate whether these persistent changes were mediated by epigenetic changes, differences in DNA methylation between normouricemic and hyperuricemic individuals were assessed. SOCS3 gene was higher methylated at 3 neighbouring SOCS3 intragenic positions in hyperuricemic individuals. *In vitro*, SOCS3 mRNA levels were significantly increased in monocytes after 24 hour urate treatment. Moreover, urate dose-dependently suppressed the phosphorylation of STAT3 after stimulation.

**Conclusions:** In this study we demonstrated that urate has persistent proinflammatory effects on human monocytes. Higher SOCS3 DNA methylation is observed in hyperuricemic individuals. *In vitro*, urate priming leads to increased levels of SOCS3 mRNA and consequently suppression of STAT3 phosphorylation. Interestingly, STAT3 inhibition has been reported to mediate IL-1Ra downregulation.<sup>3</sup> Therefore, we hypothesize urate induced inflammation is at least partly mediated by changes in methylation of the SOCS3 gene. However, further validation of this pathway is needed to elucidate possible targets for therapy.

SAT0046

### TRANSCRIPT-PROTEIN ASSOCIATIONS IN EARLY RA PATIENTS ACHIEVING SUSTAINED DRUG-FREE REMISSION AFTER TREATMENT WITH TOCILIZUMAB

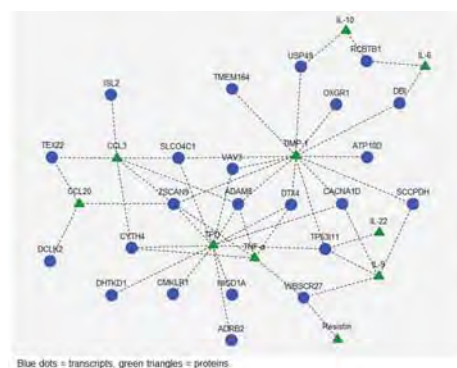

X.M. Teitsma<sup>1</sup>, J.W. Jacobs<sup>1</sup>, A.N. Concepcion<sup>1</sup>, A. Pethö-Schramm<sup>2</sup>, M.E. Borm<sup>3</sup>, J.M. van Laar<sup>1</sup>, J.W. Bijlsma<sup>1</sup>, F.P. Lafeber<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands; <sup>2</sup>F Hoffmann-La Roche, Basel, Switzerland; <sup>3</sup>Roche Nederland BV, Woerden, Netherlands

**Background:** In disease modifying anti-rheumatic drug (DMARD)-naïve early rheumatoid arthritis (RA) patients, we previously identified networks of differentially co-expressed genes associated with achieving sustained drug-free remission (sDFR).<sup>1</sup> A better understanding of processes involved with translation of mRNA into proteins might be used to develop personalised treatment for early RA patients.

**Objectives:** To identify inflammatory proteins associated with achieving sDFR by performing multi-analyte profiling in pre-treatment serum and subsequently to study significantly enriched biological pathways and compare these with the pathways previously found in the transcriptomic analyses.

**Methods:** In this exploratory study, baseline serum was analysed of 24 patients (n=13 achieved sDFR, n=11 controls) treated-to-target with tocilizumab (TCZ) therapy in the U-Act-Early trial. TCZ (intravenously, 8 mg/kg) was given every 4 weeks; if no remission, hydroxychloroquine (HCQ) was added and if subsequently remission was still not achieved, HCQ was replaced by (oral) methotrexate. Thereafter, if the target, remission, still was not achieved, patients switched to standard of care (e.g. tumour necrosis factor inhibitor). Provided remission persisted, therapy was tapered and subsequently discontinued. sDFR was reached when patients remained  $\geq 3$  months in remission while being drug-free until the end of the study period; those not able to discontinue therapy were selected as controls. Luminex<sup>®</sup> multi-analyte profiling (xMAP<sup>®</sup>) was used to measure 85 inflammatory proteins; partial least square discriminant analyses (PLS-DA) was applied to identify relevant proteins associated with achieving sDFR.

**Results:** No significant differences in clinical baseline characteristics were found between those achieving sDFR vs controls ( $p > 0.05$ ). PLS-DA identified 14 proteins of which 6/14 (n/N) were associated with a decreased chance of achieving sDFR. The protein considered most important (i.e. highest variable on importance (VIP) score) was chemokine (C-C motif) ligand 20 (CCL20, VIP 1.49). In total, 88 significantly enriched Gene Ontology (GO) terms were identified analysing the proteins; 5 terms, of which "positive regulation of leukocyte migration" ( $p < 3.41 \times 10^{-2}$ ) and "leukocyte chemotaxis" ( $p < 3.49 \times 10^{-3}$ ) were found in both proteomic and transcriptomic analyses. Significant transcript-protein correlations are shown in figure 1; the TIMP metalloproteinase inhibitor 1 (TIMP-1) protein showed the highest number (n=12) of correlations.

**Abstract SAT0046 – Figure 1.** Network visualisation of significant transcript-protein correlations.

Blue dots=transcripts, green triangles=proteins.

**Conclusions:** Several relevant proteins were found associated with achieving sDFR after treatment with TCZ. When performing pathway analyses, several enriched pathways within the protein biomarkers were also previously identified in the transcriptomic analyses, providing further insight into gene expression and translation of inflammatory proteins in early RA patients.

SAT0047

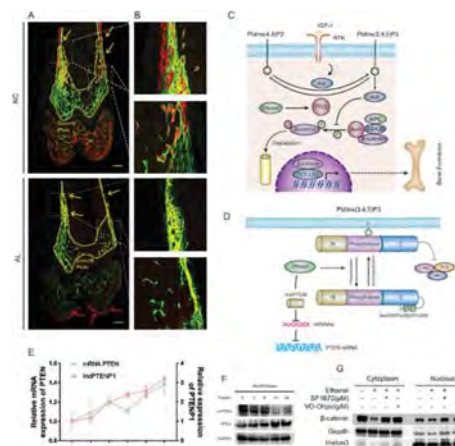

### PTEN REGULATION ALLEVIATES THE ALCOHOL-INDUCED OSTEOPENIA IN RAT VIA AKT/GSK-3B/B-CATENIN PATHWAY IN BMSCS

Y. Chen, Y. Gao, C. Zhang. Orthopedic, Shanghai Sixth People hospital, Shanghai, China

**Background:** Alcohol is regarded as a leading risk factor of osteopenia. Our previous works indicated Akt/GSK-3 $\beta$ / $\beta$ -catenin pathway plays crucial role in the ethanol-induced anti-osteogenic effect in bone mesenchymal stem cells (BMSCs). It was acknowledged that PI3K/Akt is negatively regulated by the phosphatase and tensin homologue (PTEN) phosphatase. PTEN expression was reported to be upregulated in ethanol-administrated animals.

**Objectives:** In this study, we explored the molecular mechanisms underlying alcohol-induced osteopenia and investigated the role of PTEN and Akt/GSK-3 $\beta$ / $\beta$ -catenin axis in this pathological process.

**Methods:** *In vitro*, Western blotting, separation of nucleus and cytosolic extracts, confocal scanning, RT-PCR were used to investigate the inhibition of ethanol on Akt/GSK3 $\beta$ / $\beta$ -catenin signalling pathway via upregulation of PTEN in hBMSCs. *In vivo*, micro-computerised tomography, hematoxylin and eosin (H and E) staining, Van Gieson staining, Masson's trichrome and fluorochrome labelling were employed to reveal that PTEN inhibition provided protective effects against ethanol on bone tissue.

**Results:** We found that ethanol increased PTEN expression both in BMSCs and in bone tissue of ethanol-administrated rats. PTEN upregulation impaired the recruitment of Akt to the plasma membrane, and suppressed Akt phosphorylation at Ser473, there by inhibiting the Akt/GSK3 $\beta$ / $\beta$ -catenin signalling pathway in BMSCs and inhibited the expression of osteogenic genes *COL1* and *OCN* both *in vitro* and *in vivo*. To counteract the inhibitory effect of ethanol, two selective PTEN inhibitors were introduced. The result of micro-computerised tomography,

hematoxylin and eosin (H and E) staining, Van Gieson staining, Masson's trichrome and fluorochrome labelling indicated PTEN inhibition provided protective effects against ethanol on bone tissue. Interestingly, our data revealed that the mRNA of PETN, paralleled with PTENP1, was increased in a time-dependent manner upon ethanol stimulation, which resulted in increasing PTEN protein level. In addition, ethanol increased PTEN expression while decreased p-PTEN expression in a time-dependent manner, which indicated the generation of more functional PTEN.

**Conclusions:** Taken together, dual regulations of PTEN by ethanol via transcriptional and post-transcriptional process impaired the downstream signalling of Akt/GSK3 $\beta$ / $\beta$ -catenin and osteogenic differentiation of hBMSC. Therefore, we propose that PTEN inhibition treatment for Akt/GSK3 $\beta$ / $\beta$ -catenin activation could be tested in the clinic as a potential therapeutic approach to preventing the development of alcohol-induced osteopenia.

## Cartilage, synovium and bone

### SAT0048 ANALYSIS OF DIFFERENT THERAPEUTIC REGIMES IN PATIENTS WITH HEMOPHILIC ARTHROPATHY

L. Mendez Diaz<sup>1</sup>, C. aguiler a cros<sup>1</sup>, M.D. Arcila Duran<sup>1</sup>, A. Ruiz Roman<sup>1</sup>, N. Garrido Puñal<sup>1</sup>, M. Lisbona Muñoz<sup>1</sup>, R.J. Nuñez Vazquez<sup>2</sup>, J. Povedano Gomez<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Hematology, Hospital Universitario Virgen del Rocío, Sevilla, Spain

**Background:** The greater morbidity of the patient with haemophilia is due to hemarthrosis. The treatment is based on the administration of deficient coagulation factor (FC). The treatment is divided into prophylactic (TP) and on demand (AD). Prophylaxis consists in the administration of FC in order to maintain adequate levels of factor to prevent or reduce spontaneous bleeding and AD is the application of the factor when there is clinical evidence of bleeding. The TP is the recommended treatment in severe haemophilia, plasma and recombinant concentrates are used, safe and effective, but with a short half-life, which requires frequent intravenous infusions, being a barrier to compliance. Another drawback of the current treatment in haemophilia A (HA) is that up to 30% develop inhibitor (antibodies that neutralise the activity of a CF).

New subcutaneous drugs (NSD) have begun to be used in clinical trials, such as:

- Emicizumab: Bispecific anti-IXa/X monoclonal antibody.
- Concizumab: Anti-TFPI antibody.

This new therapeutic strategy can have implications both from a clinical and economic point of view.

**Objectives:** To analyse the different treatment regimens and their economic implications in a cohort of patients with hemophilic arthropathy (HA).

Evolution of hemarthroses in patients with AH after starting treatment with NSD in the clinical trial phase.

**Methods:** Retrospective descriptive study, in the Haemophilia Unit of our hospital (regional reference), in patients with AH (Haemophilia A and moderate-severe B), followed in consultation with episodes of joint bleeding, from January 2007 to October 2017. Gravity of the haemophilia determined by the percentage of FC activity (VIII and IX), moderate from 1% to 5%, severe <1%. The number of joint bleeds was analysed 6 months before and after the start of treatment with the NFS in patients who have participated in a multicenter phase III study and continue with the treatment

**Results:** We included 89 patients (88 men and 1 carrier woman), mean age 31 ±17 years, HA (severe 56%, moderate 26%), HB (severe 15%, moderate 1%). 17% develop inhibitor (10 severe HA, 3 moderate HA, 3 severe HB). Treatment on demand 44% and prophylaxis 38%. Replacement therapy: FC VIII (44% severe HA, 22% moderate HA), FC IX (11% severe HB, 1% moderate HB), recombinant active factor VII (rFVIIa) (2 patients with severe HB with inhibitor).

In treatment with monoclonal antibody (patients currently in Clinical Trial): 15% Emicizumab, of these 4 are with inhibitor (2 severe HA, 1 moderate HA, 1 severe HB and 1% Concizumab (severe 1HB with inhibitor).

The number of hemarthroses was analysed 1 year before the administration of NFS until now, achieving a statistically significant reduction in the rate of joint bleeding of 86% (p<0.005) compared to conventional pre-treatment.

**Conclusions:** The majority of patients with severe and moderate haemophilia are on demand treatment, despite existing recommendations.

It can also be said that there are drugs in the research phase that may involve a paradigm shift in the therapeutic approach of patients with haemophilia, which will allow more personalised treatment, to achieve better joint protection and a better quality of life.

**Disclosure of Interest:** None declared

### SAT0049 11BETA-HYDROXYSTEROID DEHYDROGENASE TYPE 1 REGULATES CHRONIC SYNOVITIS WITH LOCAL AND SYSTEMIC COMPLICATIONS

B.S. Hardy<sup>1</sup>, C. Fenton<sup>1</sup>, A. Croft<sup>1</sup>, A. Naylor<sup>1</sup>, C.D. Buckley<sup>1</sup>, G.G. Lavery<sup>2</sup>, M. S. Cooper<sup>2</sup>, K. Raza<sup>1</sup>. <sup>1</sup>Institute of Inflammation and Aging; <sup>2</sup>Institute for Metabolism and Systems Research, The University of Birmingham, Birmingham, UK; <sup>3</sup>ANZAC Research Institute, University of Sydney, Sydney, Australia

**Background:** Inflammation, local joint destruction and systemic bone loss are common complications in patients with rheumatoid arthritis (RA). We have identified that localised pre-receptor activation of glucocorticoids (GC) by the enzyme 11beta-hydroxysteroid dehydrogenase type 1 (11 $\beta$ -HSD1) is increased within sites of inflammation and surrounding tissues, such as synovium and bone. Whilst this greatly increases local bioavailability of cortisol, which supports resolution of inflammation, in chronic disease, GCs drive may drive catabolic pathways that contribute to joint destruction and systemic bone loss.

**Objectives:** To determine the contribution of 11 $\beta$ -HSD1 activated glucocorticoids to joint destruction and inflammatory bone loss, we crossed an 11 $\beta$ -HSD1 null mouse onto a transgenic murine model of chronic polyarthritis (TNF-Tg) to generate TNF-tg<sup>11 $\beta$ KO</sup> mice.

**Methods:** Clinical measures of joint inflammation, mobility and behaviour were collected between 4 and 9 weeks of age. Paw swelling was determined using calliper measurements. Histology was assessed in formalin fixed sections following staining with haematoxylin and eosin, safranin O or TRAP staining. Juxta articular and systemic bone losses were measured by micro-Ct. synovitis was determined by Image J analysis of histology sections.

**Results:** 11 $\beta$ -HSD1 was completely knocked out within sites of inflammation in the TNF-tg<sup>11 $\beta$ KO</sup> mouse. At 9 weeks, both clinical and inflammation scores were markedly exacerbated in TNF-tg<sup>11 $\beta$ KO</sup> animals relative to TNF-tg counterparts (inflammation score; TNF-tg, 4.3±2.26 versus TNF-tg<sup>11 $\beta$ KO</sup>, 11.08±0.86; p<0.001). This was supported by marked increases in joint swelling and juxta articular bone loss from these animals (erosion scores, TNFtg, 5.2±0.61 versus TNF-tg<sup>11 $\beta$ KO</sup>, 9.0±0.66; p<0.005). Closer examination of joint destruction revealed that the pannus was larger and more extensive within subchondral bone, whilst evidence of cartilage degradation was significantly worse in the TNF-tg<sup>11 $\beta$ KO</sup> mouse (synovitis size, TNFtg, 26 763 (AU) ±3200 versus TNF-tg<sup>11 $\beta$ KO</sup>, 530276 ±3225; p<0.005). Systemic bone loss determined by bone volume to tissue volume (BV/TV), trabecular thickness (TT) and trabecular number (TN) was also greatly exacerbated within the TNF-tg<sup>11 $\beta$ KO</sup> mouse (TNF-tg, BV/TV 5.7±0.75, TT 73.5±6.4, TN 0.00077±0.00004 versus TNF-tg<sup>11 $\beta$ KO</sup> BV/TV 1.8±0.36, TT 7359.77 ±3.7, TN 0.0003±0.00005; p<0.001, p<0.005, p<0.001 respectively).

**Conclusions:** This study demonstrates that rather than contributing to catabolic pathways of tissue destruction, local GC activation by 11 $\beta$ -HSD1 is critical in mediating the suppression inflammation, joint destruction, synovitis and inflammatory bone loss in this murine model of chronic polyarthritis.

**Acknowledgements:** We would like to thank Professor George Kollias (Hellenic Pasteur Institute, Athens, Greece) for providing the hTNFtg mice. This research was supported by the Arthritis Research UK grants (Reference: 19859 and 20843).

**SAT0050 STANDARDISATION OF SYNOVIAL BIOPSIES ANALYSIS: A EULAR SYNOVITIS STUDY GROUP INITIATIVE USING A DELPHI SURVEY.**

A. Najm<sup>1</sup>, B. Le Goff<sup>1</sup>, C. Orr<sup>2</sup>, J. Fonseca<sup>3</sup>, B. Lauwerys<sup>4</sup>, D. Veale<sup>2</sup> on behalf of EULAR Synovitis Study Group. <sup>1</sup>Rheumatology, Nantes University Hospital, NANTES, France, <sup>2</sup>Centre for Arthritis and Rheumatic Disease, University College Dublin, Dublin Academic Medical Centre, St. Vincent's University Hospital., Dublin, Ireland, <sup>3</sup>Hospital de Santa Maria & Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, <sup>4</sup>Université catholique de Louvain and Department of Rheumatology, Cliniques Universitaires Saint-Luc, Louvain, Belgium

**Background:** Synovial biopsies are increasingly performed in both clinical setting and translational research.<sup>1</sup> An unmet need in the field is the standardisation of synovial biopsies handling and analysis procedures.

**Objectives:** The aim of this collaborative work was to create a consensual set of points to consider for handling and analysis of synovial biopsies in clinical practice and translational research through EULAR Synovitis Study Group (ESSG).

**Methods:** The items were identified and formulated based on a comprehensive literature review.<sup>1</sup> A task force (TF) of EULAR Synovitis Study Group (ESSG) members were constituted and TF members were consulted through a 2-stage eDelphi process. The 2 sequential rounds occurred in 9 months. The first written round occurred in June 2016. Members were sent a written questionnaire containing items divided in 2 parts. The items were identified and formulated based on a comprehensive literature review. The first part of the questionnaire referred to clinical practice containing 5 subsections: biopsy sampling, biopsy handling, histological analysis, staining and immunohistochemistry (IHC), biopsy analysis and pathologist's report. The second part referred to translational research and contained 6 subsections (same 5 plus RNA analysis). Every participant was asked to score each item with a 5 points Likert (0: strongly disagree, 5: strongly agree), comments were allowed for each item. Items with a median score above 3.5 on 5 and a percentage of agreement above 70% were for the next round. Items with lower score were either suppressed or modified according to participants' comments. Anonymized detailed results were circulating through participants between each round. The face to face meeting occurred at ESSG meeting in June 2017.

**Results:** 27 ESSG members from 19 centres were contacted by email. 20 participants from 17 centres answered (response rate of 74%). Response rates for next rounds were 100%. First questionnaire contained 44 items for Part 1 Clinical practice. 52.3% (23items/44) were selected for the second round based on their score and agreement percentage. 83% (19items/23) were selected for the third round. First questionnaire contained 43 items for the second part about translational research. 44% (19 items/43) were selected for second round based on their score and agreement percentage. 95% (18 items/19) were selected for third round (figure 1). Third oral round allowed to obtain a final set of items unanimously (table 1).

Item	Consensus Points	Median score	% Agreement	Median score	% Agreement
<b>1. Biopsy sampling</b>					
A minimum of 3 synovial biopsies needs to be collected in each patient	100.00	5	100.00	5	100.00
A minimum of 3 synovial biopsies needs to be collected in each joint	92.31	5	92.31	5	92.31
Biopsies shall be removed in different areas of the joint, if possible	94.50	5	94.50	5	94.50
If it is clinically relevant, bacteriological, fungal and mycobacteriological assessment should be performed	75.00	5	75.00	5	75.00
Microscopic chain reaction analysis for ANA, ANCA, IgG4 should be performed if clinically relevant. Specialized laboratory facilities have been started	71.43	5	71.43	5	71.43
If it is clinically relevant, immunogenetic analysis for Lyme and HLA-B*27:05 should be performed	71.43	5	71.43	5	71.43
<b>2. Biopsy processing</b>					
The biopsies should be stored at -80°C in formalin-free	100.00	5	100.00	5	100.00
At least 2 biopsies should be formalin-fixed and paraffin-embedded	76.92	5	76.92	5	76.92
<b>3. Histological criteria</b>					
Synovial histology should be assessed on 3 biopsies	100.00	5	100.00	5	100.00
A scoring system should be used	94.50	5	94.50	5	94.50
Morphology of the synovial tissue should be preserved	94.50	5	94.50	5	94.50
<b>4. Staining and immunohistochemistry (IHC)</b>					
IHC staining should always be performed	100.00	5	100.00	5	100.00
CD68 staining should be performed	75.00	5	75.00	5	75.00
CD3, CD59 or CD38 staining should be performed	66.67	5	66.67	5	66.67
Additional CD 31 or P401, CD34, CD38 staining might be performed depending on the question	66.67	5	66.67	5	66.67
In particular clinically relevant cases, additional staining should be performed (CD3, CD38, CD31, CD34 or P401)	66.67	5	66.67	5	66.67
If performed, IHC results can be given using a semi-quantitative score	100.00	5	100.00	5	100.00
In formalin, IHC results can be given using a semi-quantitative score	66.67	5	66.67	5	66.67
In formalin, IHC results can be given using a semi-quantitative score	66.67	5	66.67	5	66.67
<b>5. Biopsy interpretation and pathologist report</b>					
A systematic report should be performed, including: lining layer hyperplasia, inflammatory infiltrate and resident cell activation (if relevant)	100.00	5	100.00	5	100.00
Microscopy should be included	100.00	5	100.00	5	100.00
The distribution of resident cells per field or per high-power field should be assessed	100.00	5	100.00	5	100.00
Lining layer hyperplasia should be assessed	100.00	5	100.00	5	100.00
Resident cell activation should be assessed	100.00	5	100.00	5	100.00
Presence or absence of lymphoid follicles within the membrane should be described	83.33	5	83.33	5	83.33
Analysis can be semi-quantitative or quantitative depending on the question	100.00	5	100.00	5	100.00
If semi-quantitative or quantitative analysis is performed for multiple biopsies, an average score should be calculated and given for the analysis of inflammation and activation	75.00	5	75.00	5	75.00
The pathologist should mention the presence of all granulomas	66.67	5	66.67	5	66.67
In granulomas and giant cells, the presence of all granulomas	66.67	5	66.67	5	66.67
<b>6. RNA Analysis</b>					
Biopsies can be stored for RNA extraction if needed	100.00	5	100.00	5	100.00

**Conclusions:** We hereby propose a set of consensual points to consider on analysis of synovial biopsies in clinical practice and translational research. This standardisation initiative was conducted through ESSG members using a validated consensus method.

**SAT0051 EXAMINING THE ROLE OF TRPC5 IN OSTEOARTHRITIS PAIN**

J. Sousa-Valente, F. Ayaz, X. Kodji, S.D. Brain. *Vascular Biology and Inflammation Section, King's College London, London, UK*

**Background:** Transient receptor potential canonical 5 (TRPC5) is a cation channel that putatively acts as a sensor of one or more chemical factors but the exact biology is not fully known. It was recently found to be expressed in fibroblast-like synoviocytes where TRPC5 activation by endogenous thioredoxin – which has been shown to be elevated in synovial fluid of patients with rheumatoid arthritis – results in the suppression of matrix metalloproteinases secretion.<sup>1</sup> Genetic deletion or pharmacological blockade of TRPC5 receptor in arthritic mice resulted in marked exacerbation of hyperalgesia and critically increased localised inflammation in the synovium, characterised by increased cellular infiltration, secretion of early response cytokines and enhanced synovial vascularisation.<sup>2</sup> Interestingly, in this study, mRNA expression of TRPC5 was reduced in inflamed human arthritis samples particularly in the synovium from patients with osteoarthritis (OA), highlighting a potential role for TRPC5 in OA.

**Objectives:** With the aim to investigate putative mechanisms mediated by TRPC5 signalling in OA pain, we have examined the development of monoiodoacetate (MIA)-referred mechanical hypersensitivity and joint pathology in wild type and mice carrying a TRPC5 deletion.

**Methods:** Wild type and TRPC5 knock-out (TRPC5) mice were intra-articularly injected with 0.75 mg of MIA, and hind-paw mechanical thresholds and weight bearing changes were assessed at regular intervals up to 28 days. Knee joint histochemical analysis of cartilage degradation using toluidine blue staining and synovial inflammation using haematoxylin and eosin staining was also performed.

**Results:** Both TRPC5 KO and WT mice developed referred mechanical hypersensitivity following MIA injection, however the onset was faster (day 3 vs day 10) in TRPC5 KO mice. By the end of the study, at 28 days after MIA injection, mechanical hypersensitivity had reached similar levels in TRPC5 KO and WT mice. Moreover, at a 0.7 mg MIA dose administered, TRPC5 KO, but not WT mice developed weight bearing asymmetries over the course of the study and most significantly from 14 to 28 days after MIA injection. In paraformaldehyde-fixed joints obtained 28 days post MIA injection from TRPC5 KO and WT mice no significant differences in cartilage degradation or inflammatory content were observed.

**Conclusions:** This study suggests that deletion of the TRPC5 receptor signalling is associated with a faster onset of referred allodynia and increased guarding/on-going pain like behaviour in a model of OA.

**SAT0052 THE COLL2-1 PEPTIDE OF COLLAGEN TYPE II: A NEW ACTOR OF SYNOVITIS IN OSTEOARTHRITIS**

C. Lambert<sup>1</sup>, D. Borderie<sup>2</sup>, F. Rannou<sup>2</sup>, Y. Henrotin<sup>1</sup>. <sup>1</sup>Bone and cartilage research unit, University of Liège, Liège, Belgium, <sup>2</sup>Inserm umr 1124, Laboratory of pharmacology, toxicology and cell signaling, University Paris Descartes, Paris, France

**Background:** Osteoarthritis (OA) is characterised by degradation of the extracellular matrix associated with inadequate repair responses including pro-inflammatory pathways of nonspecific natural immune response.

**Objectives:** We evaluated the inflammatory effect of Coll2-1 peptide in osteoarthritic synoviocytes and rats by comparing peptide-induced inflammatory reaction with the one induced by bovine type II collagen or streptococcal cell wall.

**Methods:** Human synoviocytes from knee OA patients (n=10) were pre-treated with AS0619 or CLI-095 (500 nM, 1 and 2.5 µM) before a 24 hours treatment with Coll2-1 peptide (<sup>108</sup>HRGYPGLDG<sup>116</sup>; 0.45 or 4.5 nmol). Expression of Interleukin (IL)-8, Vascular Endothelium Growth Factor (VEGF) and phosphorylation of the IκB-α and p65 were evaluated. Either Coll2-1 peptide, bovine type II collagen (CIA), streptococcal cell wall (SCW) or saline solution (100 µl SC or 50 µl IA) were injected into Lewis rats (n=108). The Coll2-1 peptide was subcutaneously injected (SC; 20 and 200 µg/100 µl/animal) or intra-articular (IA; 0.5 and 5 µg/50 µl/animal). The bovine type II collagen was SC injected (200 µg/100 µl/

animal), streptococcal cell wall in IA (5 µg/50 µl/animal). The animals were injected on day 10 and monitored for 21 or 28 days. Visual evaluation of the severity of arthritis and histological lesions were performed.

**Results:** Coll2-1 at 0.45 nmol (\*\* $p<0.01$ ) and 4.5 nmol (\*\* $p<0.05$ ) significantly increased IL-8 gene expression and tended to increase VEGF expression by synovocytes. With AS0619, a specific antiserum for Coll2-1 peptide, IL-8 expression significantly decreased (\*\* $p<0.05$ ). Coll2-1 also induced both translocation of p65 and IκB-α degradation. The latter being reduced with oxidative stress inhibitors. With CLI-095, we observed a decrease of IL-8 expression. *In vivo*, bovine type II collagen injection and Coll2-1 peptide injection resulted in an increase in visual arthritis score from D7. The global histological score was also increased by bovine type II collagen on D21 ( $p=0.0005$ ) and on D28 ( $p<0.0001$ ) and by the peptide Coll2-1 on D21 at the concentration of 200 µg ( $p=0.0252$ ) and on D28 at the concentration of 20 µg ( $p=0.0025$ ). Compared to control, all the components of the histological score were similarly modified by bovine type II collagen and the peptide Coll2-1 at both on D21 and on D28: increase in the inflammatory parameter (D21 200 µg  $p=0.0217$  and D28 20 µg  $p=0.0021$ ), reduction of proteoglycan contents (D28 200 µg  $p=0.0072$  and 20 µg  $p=0.0024$ ), increased cartilage degradation (J28 200 µg  $p=0.0070$  and 20 µg  $p=0.0024$ ) and modification of the subchondral bone (D21 200 µg  $p=0.0025$  and D28 20 µg  $p=0.0065$ ). Similarly, both the injection of SCW and that of Coll2-1 peptide induced an increase in the visual score from D10. The effect of Coll2-1 peptide on this score was identical to that of the SCW. Compared to control, SCW and Coll2-1 peptide increased the global histological score (D21  $p=0.0119$  and D28  $p=0.0045$ ). Like SCW, the injection of Coll2-1 peptide caused both inflammatory reaction, loss of proteoglycan, appearance of cartilage structural lesions (D28 0.5 µg  $p=0.0201$ ) and subchondral bone modification.

**Conclusions:** Coll2-1 peptide is able to induce an inflammatory reaction and structural changes in articular cartilage and subchondral bone comparable to those induced by SCW and bovine type II collagen. In conclusion, Coll2-1 may initiate nonspecific natural immunity and therefore be a therapeutic target for biotherapy.

#### SAT0053 IDENTIFICATION OF NOVEL DRUGS WITH SENOLYTIC ACTIVITY AS OSTEOARTHRITIS THERAPEUTICS

U. Nogueira-Recalde<sup>1</sup>, F.J. Blanco<sup>1</sup>, M.I. Loza<sup>2</sup>, D. Grassi<sup>3</sup>, P. Robbins<sup>3</sup>, E. Dominguez<sup>2</sup>, B. Carames<sup>1</sup>. <sup>1</sup>Rheumatology Division, Cartilage Biology Group, The Institute of Biomedical Research of A Coruña (INIBIC), A Coruña; <sup>2</sup>Biofarm Research Group, Center for Research in Molecular Medicine and Chronic Diseases (CIMUS), University of Santiago de Compostela, Santiago, Spain; <sup>3</sup>Department of Metabolism and Aging, The Scripps Research Institute, Jupiter, FL, USA

**Background:** Disease-modifying treatments for Osteoarthritis (OA) are not available. Aging-related features such as failure of cellular homeostasis mechanisms, including autophagy, cause extracellular matrix damage, chondrocyte senescence and death, which leads to articular cartilage degeneration as well as loss of joint function.

**Objectives:** The objective of this study was to identify senolytics and activators of autophagy by cell-based imaging of approved drugs in human chondrocytes.

**Methods:** To induce cellular senescence and reduced autophagy, High Content Screening system. Validation assays with readouts for senescence, autophagic flux, inflammation and apoptosis in primary human chondrocytes were performed. The anabolic effect on human cartilage and chondrocytes was evaluated by Safranin O staining and Nitric oxide production. To define the effects on senescence (senomorphic or senolytic), TC28a2 chondrocytes and human lung fibroblasts (IMR90) were employed. Senescence was induced in TC28a2 and IMR90 by treatment with IL-6 (20 ng/ml) for 72 hours and Etoposide (20 µM) for 48 hours, respectively, and treated with serial dilutions of identified compounds. The number of senescence cells and the number of total cells were determined with Cell Analyzer 6000 Confocal Imaging System. Navitoclax (2,5 µM) and Rapamycin (10 µM) were employed as reference controls for senolytic and senomorphic effects, respectively.

**Results:** Our primary screen yielded 279 senotherapeutic compounds. The effects of hits at inducing the autophagic flux were evaluated. 37 compounds with both senotherapeutic and pro-autophagy effects were selected. An approved drug with a defined molecular mechanism of action was selected for further validation. The compound reduced senescence ( $p<0.001$ ) and increased autophagic flux ( $p<0.0001$ ). Furthermore, we found that it protects against defective autophagy and inflammation in response to IL-6 and IL-1b. This protective effect was

confirmed in human cartilage explants by a reduction of proteoglycans loss ( $p<0.05$ ) and in primary human chondrocytes by a reduction of NO production and chondrocyte death by apoptosis ( $p<0.0001$ ). Moreover, a significant senolytic effect of the selected compound was observed in both chondrocytes and fibroblasts ( $p<0.05$ ). This effect was also observed for structurally different compounds sharing the same mechanism of action, suggesting that pharmacological modulation of this mechanism may provide therapeutic benefits in OA.

**Conclusions:** Our imaging screening methodology provides a unique opportunity to identify drugs and mechanisms to prevent cartilage pathology. Autophagy activation and disruption of senescence may provide benefits for delaying cartilage degeneration.

#### SAT0054 SIGNIFICANT DECREASE OF T-CELLS BUT NOT MACROPHAGES IN THE SYNOVIUM OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AFTER TREATMENT WITH TOCILIZUMAB

K. Chatzidionysiou, M. Engström, E. af Klint, A. Hensvold, A.I. Catrina. Department of Rheumatology, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden

**Background:** Tocilizumab (TCZ) is an anti-IL6R monoclonal antibody approved for the treatment of Rheumatoid Arthritis (RA). There is limited data on synovial tissue histology changes.

**Objectives:** The aim of this study was to evaluate the effect of TCZ on synovial cell populations and on citrullination.

**Methods:** 15 patients with RA, according to ACR 1987 criteria, independent of disease duration, were included. Synovial biopsies were obtained before and after 8 weeks of treatment. We evaluated by immunohistochemistry (IHC) expression of citrullinated proteins (CP) and protein arginine deiminase (PAD) enzymes in synovial tissue before and after treatment (1325:C03, 1325:B09, PAD2, PAD4). Negative controls were used for each antibody. Expression of CD68, CD3, CD20 and CD55 was also evaluated. Evaluation of all IHC variables was performed by two blinded independent observers using a semiquantitative score on a 0–3 scale (0, no staining; 1, low amounts of staining; 2, moderate amounts of staining; 3, high amounts of staining). Paired-wised Wilcoxon Signed Ranks Test was used to compare the median values.

**Results:** The median (IQR) age, disease duration, N. prior biologic DMARDs and DAS28 at baseline was 66, 58–79, 4 (1–13), 1 (0–2), 6 (5–7), respectively. 93% were female, 53% were RF + and 60% ACPA+, 53% had concomitant glucocorticoids and only 27% had concomitant conventional synthetic DMARDs. Significant reductions in DAS28, swollen and tender joint count (SJC and TJC, respectively), and acute phase reactants (ESR and CRP) were observed between baseline and 8 weeks (table 1). By IHC, TCZ induced significant decrease in the number of CD3, C03 and CD55, but not in the number of the other CP, PAD2, PAD4 and CD68 (table 1).

#### Abstract Sat0054 – Table 1

##### Baseline 8 weeks p-value (Wilcoxon Signed Ranks Test)

DAS28 BL	5.9 (4.7–6.8)	2.98 (2.0–3.8)	0.028
SJC BL	9 (3–14)	1 (0–4.25)	0.009
TJC BL	10 <sup>4–15</sup>	1 (0–2.25)	0.017
ESR BL	34 <sup>15–69</sup>	6 (5–16)	0.001
CRP BL	11 <sup>5–27</sup>	1 (1–2)	0.005
CD68 2	(1–3)	2 (0.75–3)	0.41
CD3 2	(1–3)	1 (0–2)	0.046
CD55 2	(2–3)	1.5 (1–2)	0.05
C03 (cit)	1 (0–1)	0 (0–1)	0.025
B09 (cit)	2 (1–2)	2 (1–2)	0.20
PAD2 3	(2–3)	2 (1.5–3)	0.16
PAD4 2	(2–3)	2 (2–3)	0.37

**Conclusions:** Treatment with tocilizumab reduced the number of synovial tissue T cells. This was observed in the responders but not in non-responders. Significant reduction in citrullination as assessed by expression of 1325:C03 but not 1325:B09. No significant reduction in macrophages was observed.

**Acknowledgements:** This study was funded by Roche.

**Disclosure of Interest:** None declared

**SAT0055 SIMULATING THE PATHOGENESIS OF ARTHRITIS IN VITRO BY DEVELOPING A HUMAN-BASED MULTICOMPONENT 3D JOINT MODEL**

A. Damerou<sup>1</sup>, Y. Chen<sup>1</sup>, A. Lang<sup>1</sup>, I. Ponomarev<sup>2</sup>, M. Pfeifferberger<sup>1</sup>, F. Buttgerit<sup>1</sup>, T. Gaber<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin Berlin, Berlin; <sup>2</sup>fzmb GmbH, Bad Langensalza, Germany

**Background:** Our ultimate goal is to develop a valid human *in vitro* 3D joint model to simulate the pathogenesis of arthritis. The *in vitro* 3D joint model consists of different components including an<sup>1</sup> osteogenic and<sup>2</sup> chondrogenic part,<sup>3</sup> the synovial fluid and<sup>4</sup> the synovial membrane and contains all involved cell types and thus, to allow interactions between cells by cell contacts and signalling molecules. As an alternative experimental setup for animal models, our *in vitro* 3D joint model will enable us to study the influence and efficacy of drug treatment. Currently, there is no valid 3D model which is able to mimic an arthritic joint.

**Objectives:** Here, we aim to mimic the<sup>1</sup> osteogenic and<sup>2</sup> chondrogenic part,<sup>3</sup> the joint space with synovial fluid and<sup>4</sup> the synovial membrane.

**Methods:** For the osteogenic component of the 3D joint model, we populated  $\beta$ -tricalcium phosphate (TCP) – mimicking the mineral bony part – with osteogenic pre-differentiated human bone marrow-derived mesenchymal stromal cells (hMSC) and coated the particles with an hMSC monolayer cell-sheet to get a compact bony component. Survival, adhesion and structural integrity of the cells were evaluated by Scanning Electron Microscopy (SEM), LIVE/DEAD staining and cellular release of LDH. Osteogenic differentiation was analysed by  $\mu$ CT for mineralization and on gene expression level using qRT-PCR. To mimic the chondrogenic part, a scaffold-free 3D cartilage construct was generated by chondrogenic differentiation of hMSC under hypoxia with intermittent mechanical stimulation. Constructs were analysed by histology and qRT-PCR. Simulating the synovial fluid, hyaluronic acid was applied to the osteochondral model. To model the synovial membrane, a confluent monolayer of hMSC was formed on a polycarbonate membrane and visualised by hemacolor staining.

**Results:** We developed an *in vitro* 3D bone model by successfully seeding pre-differentiated hMSC on a  $\beta$ -TCP scaffold. Cells consistently adhere onto the scaffold for up to 3 weeks as observed by SEM. The analysis of cell viability via LDH detection and LIVE/DEAD staining showed no toxic effects on the cells even after 3 weeks of incubation as compared to the corresponding control. mRNA expression of bone-related genes such as *RUNX2*, *SPP1* and *COL1A1* as well as  $\mu$ CT analysis confirmed the osteogenic phenotypic of hMSC grown in 3D. Mimicking the articular cartilage component, we verified its chondrogenic phenotype by HE and Alcian Blue staining as well as by the reduced mRNA expression of *COL1A1* and an abundant expression of *COL2A1*. Interestingly, co-cultivation of the osteogenic and chondrogenic part for up to 3 weeks demonstrated successful colonisation, connectivity and initial calcification implying a functional transitional bridging area. Modelling the synovial membrane, we successfully and reproducibly created a confluent monolayer of hMSC, which is easily transferable to the model.

**Conclusions:** First steps towards the *in vitro* simulation of an arthritic joint based on a multi-component model confirm good cell vitality and phenotypic stability which indicates successful progression. To finalise the development of healthy joint model, we will combine the established parts to provide a suitable 3D multi-component joint model which enables us to study the efficacy of drug treatment *in vitro*.

**SAT0056 OSTEOARTHRITIS SEVERITY IS REDUCED BY INTRA-ARTICULAR ADMINISTRATION OF HYDROGEN SULFIDE**

E.F. Burguera<sup>1,2</sup>, Á. Vela-Anero<sup>3</sup>, T. Hermida-Gómez<sup>1</sup>, P. Filgueira-Fernández<sup>1,2</sup>, L. Gato-Calvo<sup>1</sup>, R. Mejjide-Failde<sup>3</sup>, F.J. Blanco<sup>1</sup>. <sup>1</sup>Rheumatology Research Group, Instituto de Investigación Biomédica de A Coruña, A Coruña; <sup>2</sup>CIBER-BBN, Madrid; <sup>3</sup>Cell Therapy and Regenerative Medicine Group, Dep. of Medicine, University of A Coruña, A Coruña, Spain

**Background:** Osteoarthritis (OA) is a chronic inflammatory disease leading to cartilage loss and eventual joint destruction. Exogenous supplementation of hydrogen sulphide ( $H_2S$ ) with synthetic salts in *in vitro* models of OA has been shown to exert anti-inflammatory effects and to result in reduced cartilage degradation<sup>1</sup>

**Objectives:** To evaluate the effects of administering an  $H_2S$ -producing compound intra-articularly in an experimental model of OA.

**Methods:** Experimental OA was induced in Wistar rats by transecting the medial collateral ligament and removing the medial meniscus of the left knee. Right knees were used as control. Animals were randomised into 3 groups (3 rats per group). Group 1 (intra-articular sulphide, IS): A single intra-articular injection of GYY4137

(200 mM in saline, 50 ml) at day 7. Group 2 (intra-articular control, IC): A single intra-articularly injection of vehicle (saline, 50 ml) at day 7. Group 3 (Surgical control, C): No treatment.

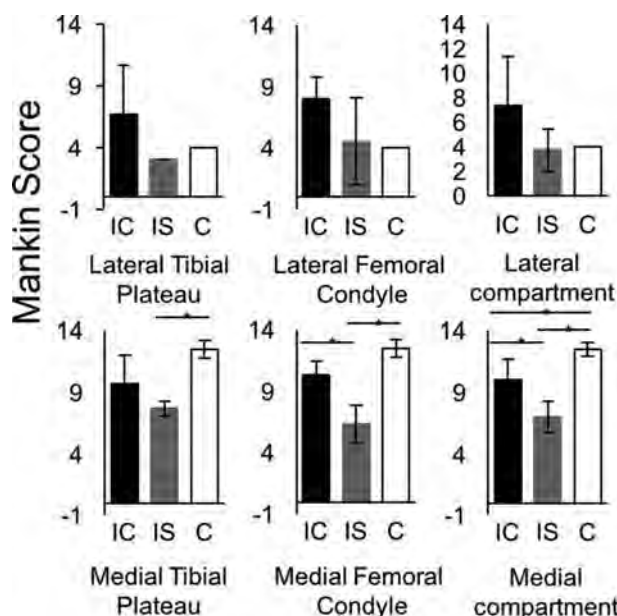

Gross evaluation of the animals at days 0 (before surgery), 7, 15 and 40 (euthanasia) included indirect evaluation of pain in a Rotarod performance test. Histopathological changes in articular cartilage and synovium were evaluated with the Mankin Score (MS) and the Krenn Score (KS), respectively.

**Results:** All 3 groups showed worse performance in the Rotarod test at day 7 after surgery. Number of falls was significantly increased (except in IC) and time to 1 st fall was reduced (table 1). At day 40, there was no significant improvement in either of these parameters in group C, while in IC the n# of falls had returned to pre-surgical levels. In IS there were significant improvements with respect to day 0 and both C and IC groups (table 1). Times to 1 st fall were also significantly better in the IS group vs. C and IC both at days 15 and 40.

Histology showed no significant differences among groups in the lateral tibial plateau (TP) or femoral condyle (FC) separately or in the compartment as a whole. Conversely, MS in the medial compartment were significantly better in the IS group vs the C group, both when considering TP or FC separately, and for the whole compartment (figure 1). No significant differences were found among groups on the Krenn Scores.

**Abstract SAT0056 – Table 1.** Number of falls (n±sd) and time to first fall (s) in a Rotarod. C: control group; IC: intra-articular control; IS: intra-articular sulphide (n=3/group). #p<0.05 vs. T0; \*p<0.05 vs. C. §p<0.05 vs. IC.

	Falls (n±sd)				Time to 1 st fall (s)			
	T0	T7	T15	T40	T0	T7	T15	T40
C	0.8 ±0.7	4.0 ±0.9#	4.0 ±0.9#	3.7±1.7#	233.7 ±77.8	57.2 ±35.2#	90.3±67.5#	77.8 ±40.2#
IC	1.7 ±1.0	3.3 ±1.7	2.2±1.0	2.0±0.9	209.2 ±78.2	31.7 ±11.7#	90.8±20.9#	143.3 ±50.3
IS	1.3 ±0.8	4.0 ±1.5#	2.5 ±1.1	0.0 ±0.0#§	265.3 ±58.8	78.5 ±65.9#	196.3 ±81.3*§	300.0 ±0.0*§

**Conclusions:** Exogenous  $H_2S$  administered intra-articularly (200 mM GYY4137 in 50 ml saline) can reduce the severity of cartilage destruction in an *in vivo* model of OA as compared to no treatment or a vehicle control.  $H_2S$  also led to a reduction in pain levels as demonstrated by a performance test. Therefore, hydrogen sulphide is a viable pharmacological candidate for OA treatment and should be further tested, including human clinical trials.

**SAT0057 THE EFFECT OF EXOSOMES FROM BONE MARROW MESENCHYMAL STEM CELLS ON OSTEOARTHRITIS**

H. Zhu, J. Ji, T. Fu, J. Yang, Z. Gu. *Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China*

**Background:** Mesenchymal stem cells (MSCs) exert chondroprotective effects in clinical models of osteoarthritis (OA), but the exact mechanisms were still unclear. Exosomes that serve as carriers of genetic information have been implicated in many diseases and are known to participate in many physiological processes.

**Objectives:** Here, we investigate the therapeutic potential of exosomes from human bone marrow MSCs in alleviating OA and explore the mechanism.

**Methods:** Exosomes were harvested from conditioned culture media of BM-MSCs by a sequential centrifugation process. The anterior cruciate ligament transection and destabilisation of the medial meniscus (DMM) surgery were performed on the knee joints of SD female rat as an OA model. After four weeks, the animals were followed by intra-articular injection of either BM-MSCs or their exosomes every week for four weeks. Cartilage destruction, matrix degradation and subchondral bone changes were evaluated with histological staining and micro-CT at the post-surgery 8 weeks. Primary human chondrocytes treated with IL-1 $\beta$  were used as an *in vitro* model to evaluate the effects of exosomes for 24 hours.

**Results:** We found that intra-articular injection of BM-MSCs and BM-MSCs derived exosomes improve cartilage destruction and subchondral bone remodelling in ACLT+DMM model. BM-MSCs and exosomes equally protected rat from joint damage. These exosomes maintained the chondrocyte matrix by increasing collagen type II synthesis and decreasing ADAMTS5, MMP13 and Col II expression in the presence of IL-1 $\beta$  *in vitro*. In addition, BM-MSCs derived exosomes were also shown to protect chondrocytes from apoptosis and senescence.

**Conclusions:** The exosomes from BM-MSCs exert a beneficial therapeutic effect on OA by not only repairing the degenerative cartilage, but also improving subchondral bone remodelling, which in turn provides a new target for OA drug and drug-delivery system development.

**SAT0058 ADALIMUMAB:TNF COMPLEXES ARE CLEARED MORE EFFICIENTLY BY HUMAN OSTEOCLASTS THAN THOSE WITH ETANERCEPT THROUGH FCG-RECEPTOR BINDING AND INTERNALISATION**

B.P. Harvey, J. Cohen-Solal, Z. Kaymakcalan. *Biologics, Abbvie Bioresearch Center, Worcester, USA*

**Background:** TNF-alpha (TNF $\alpha$ ) has been shown to contribute to osteoclastogenesis (OCgenesis) independently and in conjunction with M-CSF or RANKL, two key cytokines involved in osteoclast (OC) development. We have previously demonstrated that TNF enhances the kinetics of RANKL-induced human OCgenesis and that its effects are mitigated more effectively by the anti-TNF biologic adalimumab (ADA) as compared to etanercept (ETN).

**Objectives:** To determine whether Fc-gamma receptor (Fc $\gamma$ R)-mediated internalisation of the biologic:TNF complexes is a contributing mechanism responsible for the difference in effectiveness between ADA and ETN in preventing TNF-enhanced OCgenesis.

**Methods:** TNF biologics [ADA and ETN] alone or in preformed complexes with TNF $\alpha$  at 50:1 molar ratio were tested for Fc $\gamma$ R binding by flow cytometry using CHO stably transfected with human Fc $\gamma$ Rs (Fc $\gamma$ RI, Fc $\gamma$ RIIA, -RIIB, -RIIC, Fc $\gamma$ RIIIA and -RIIIB). Fc $\gamma$ R expression and binding of preformed biologic:TNF complexes at 10:1 ratio  $\pm$ Fc $\gamma$ R blocking antibodies to primary human OC precursors (OCP) was evaluated by flow cytometry. Fc $\gamma$ R-mediated internalisation was

assessed by monitoring a reduction in OC survival in response to preformed biologic:TNF complexes (25:1 ratio) bound with saporin (ZAP), a ribosome-inactivating toxin, as anti-human Fc IgG Fab conjugate  $\pm$ Fc $\gamma$ R blocking antibodies.

**Results:** The binding study to CHO (human Fc $\gamma$ Rs) cell lines showed that monomeric ADA and ETN bind similarly to Fc $\gamma$ R (highly on high affinity Fc $\gamma$ R and loosely on low affinity Fc $\gamma$ Rs) while preformed biologics: TNF complexes bind differently. ADA:TNF complexes bind to low affinity Fc $\gamma$ R, whereas ETN:TNF keep a monomeric binding profile with no gain of binding to low affinity Fc $\gamma$ R. OCP were found to express mostly Fc $\gamma$ RII early in development with predominant binding of only ADA:TNF, not ETN:TNF, to this Fc $\gamma$ R with additional binding to undefined receptor(s). Despite subsequent increases in Fc $\gamma$ RI and RIII later on, ADA:TNF still preferentially bound to Fc $\gamma$ RII on the matured OCP with minimal binding to RIII, whereas ETN:TNF binding was observed only to Fc $\gamma$ RI. Exposure of OCP to ADA:TNF:ZAP(toxin) complexes led to a significant reduction (4-fold) in mature OC due to complex internalisation as compared to human IgG:ZAP +TNF conditions that was partially rescued only with the addition of Fc $\gamma$ RII blocking antibody. Interestingly, a 1.5-fold reduction in mature OC was observed with ETN:TNF:ZAP.

**Conclusions:** Our *in vitro* findings demonstrate that human OCP can bind and internalise ADA:TNF complexes more efficiently than ETN:TNF complexes. In addition, this process is partially mediated through Fc $\gamma$ RII. Clearance of the ADA:TNF complexes may help reduce exposure of the OCP to localised TNF by removing TNF more effectively in the joint environment. Additional *in vivo* analysis need to be done to verify these *in vitro* findings.

**SAT0059 IMPAIRMENT IN HYDROGEN SULFIDE SYNTHESIS IN OSTEOARTHRITIC CHONDROCYTES FROM DIABETIC PATIENT AND UNDER A HIGH GLUCOSE STRESS**

C. Vaamonde-Garcia<sup>1,2</sup>, F. Blanco<sup>2</sup>, R. Meijide-Falide<sup>1</sup>. <sup>1</sup>*Biological science, Medicine and Physiotherapy, University of A Coruña;* <sup>2</sup>*Rheumatology, INIBIC-CHUAC, A Coruña, Spain*

**Background:** A growing number of findings support the hypothesis that type 2 diabetes is an independent risk factor of osteoarthritis (OA). However, the mechanisms underlying the connexion between both diseases remain unclear. Hydrogen sulfide (H<sub>2</sub>S) plays an important role in the pathogenesis of diabetes and its complications. In relation, we and other authors have observed a protective impact of H<sub>2</sub>S induction on activation of pathological pathways in the chondrocyte.<sup>1</sup>

**Objectives:** In this study we examined the modulation of H<sub>2</sub>S levels in osteoarthritic chondrocytes from diabetic (DB) or non-diabetic (non-DB) patients subjected or under glucose stress, in order to elucidate whether impairment in H<sub>2</sub>S-mediated signalling could participate in the establishment of diabetes-related OA.

**Methods:** Chondrocytes were isolated from OA cartilage of diabetic (DB) or non diabetic (non-DB) patients. T/C28a2 and primary human chondrocytes were stimulated w/o IL-1 $\beta$  (5 ng/mL) under a normal (5.5 mM; NG) or a high (25 mM; HG) glucose environment. Gene and protein expression of enzymes involved in H<sub>2</sub>S synthesis (cystathionine  $\gamma$ -lyase [CSE], cystathionine  $\beta$ -synthase [CBS], and 3-mercaptopyruvate sulfurtransferase [3-MT]) and HO-1 were assessed by RT-qPCR and WB, respectively. To determine the involvement of H<sub>2</sub>S in catabolic pathways activated by HG in chondrocytes, NaSH and GYY 4137 (500  $\mu$ M), a fast and slow-releasing H<sub>2</sub>S donor respectively, were employed.

**Results:** Fresh isolated chondrocytes from OA cartilage of diabetic patients showed lower levels of H<sub>2</sub>S synthesising enzymes (CSE, CBS and 3-MT) than those of non-DB patients (figure 1). In relation, chondrocytes T/C28a2 exposed to HG stress expressed lower mRNA and protein levels of these 3 enzymes after 3 days of incubation compared to those incubated in NG conditions (0.41-fold and 0.83-fold [CSE], 0.42-fold and 0.66-fold [CBS], and 0.52-fold and 0.79-fold [3-MT] for mRNA and protein expression, respectively; n=6, p<0.05). IL-1 $\beta$  also attenuated the gene and protein expression of CBS elicited by chondrocytes incubated in NG (0.47-fold and 0.86-fold, respectively; n=6, p<0.05). Additionally, the expression of pro-inflammatory chemokine IL-8 induced by IL-1 $\beta$  was significantly higher in chondrocytes under HG than NG condition (6-fold; n=5, p<0.05); whereas protein levels of heme oxygenase 1, an anti-inflammatory enzyme, were reduced in HG exposed chondrocytes (0.77-fold; n=6, p<0.05). GYY 4137 and NaSH co-treatment recovered HO-1 expression and reduced IL-8 levels in chondrocytes under IL-1 $\beta$ +HG conditions. Furthermore, similar results were registered in primary human chondrocytes from OA cartilage.

**Conclusions:** The results indicate a reduction of H<sub>2</sub>S synthesis as a critical feature involved in hyperglucidic-mediated dysregulation of articular chondrocytes. The impairment of H<sub>2</sub>S signalling could participate in the mechanisms underlying the predisposition to OA development in diabetic individuals and may open new opportunities for treating patients with a diabetes-related OA phenotype.

#### SAT0060 PROTEOMIC ANALYSIS OF OSTEOBLASTS SECRETOME PROVIDES NEW INSIGHTS IN MECHANISMS UNDERLYING OSTEOARTHRITIS SUBCHONDRAL BONE SCLEROSIS

C. Sanchez, G. Mazzucchelli, F. Comblain, C. Lambert, E. DePauw, Y. Henrotin. *University of Liège, Liège, Belgium*

**Background:** Osteoarthritis (OA) is characterised by cartilage degradation but also by other joint tissues modification like subchondral bone sclerosis

**Objectives:** In this study, we used a proteomic approach to compare secretome of osteoblasts isolated from sclerotic (SC) or non sclerotic (NSC) area of OA subchondral bone

**Methods:** Secretome was analysed using differential quantitative and relative label free analysis on nanoUPLC G2 HDMS system. mRNA of the more differentially secreted proteins were then quantified by RT-PCR and the most relevant proteins identified using western-blotting and immunoassays

**Results:** 175 proteins were identified in NSC osteoblasts secretome. Compared to NSC osteoblasts secretome, 13 proteins were significantly less secreted (Osteomodulin, CSF-1, IGFBP5, VCAM-1, IGF2, 78 kDa glucose-regulated

protein, versican, calumenin, IGFBP2, thrombospondin-4, periostin, reticulocalbin 1 and osteonectin), and 12 proteins significantly more secreted by SC osteoblasts (CHI3L1, fibulin-3, SERPINE2, IGFBP6, SH3BGRL3, SERPINE1, reticulocalbin3, alpha-2-HS-glycoprotein, TIMP-2, IGFBP3, TIMP-1, SERPINF1). Similar changes in periostin, osteomodulin, SERPINE1, IGFBP6, fibulin-3 and CHI3L1 mRNA levels were observed. Finally, osteomodulin and fibulin-3 specific sequences were quantified by western blot and immunoassays in serum and osteoblasts conditioned culture supernatants.

**Conclusions:** We highlighted some proteins differentially secreted by NSC and SC osteoblasts of OA subchondral bone sclerosis. These changes contribute to explain some features observed in OA subchondral bone, like the increase of bone remodelling or abnormalities in bone matrix mineralization. Among identified proteins, osteomodulin was found decreased and fibulin-3 increased in serum of OA patients. These findings suggest that osteomodulin and fibulin-3 fragments could be biomarkers to monitor early changes in subchondral bone metabolism in OA.

#### SAT0061 TARGETING ACTIVATED SYNOVIAL FIBROBLASTS USING PHOTODYNAMIC THERAPY IN RHEUMATOID ARTHRITIS

D.N. Dorst<sup>1</sup>, M. Rijpkema<sup>1</sup>, M. Buitinga<sup>2</sup>, M. Brom<sup>1</sup>, D.L. Bos<sup>1</sup>, A. Freimoser<sup>3</sup>, C. Klein<sup>3</sup>, B. Walgreen<sup>1</sup>, P. van der Kraan<sup>1</sup>, M. Gotthardt<sup>1</sup>, M.I. Koenders<sup>1</sup>. <sup>1</sup>RADBOUDUMC, Nijmegen, Netherlands; <sup>2</sup>KU Leuven, Leuven, Belgium; <sup>3</sup>Roche innovation center, Zurich, Switzerland

**Background:** Activated synovial fibroblasts (SF) play an important role in the pathogenesis of rheumatoid arthritis (RA). They contribute to the pro-inflammatory environment in the joint as well as to the degradation of cartilage. Depleting SF could ameliorate both the symptoms of joint inflammation and degradation in RA. SF are characterised by the expression of Fibroblast Activation Protein (FAP). Here, we investigated the potential of photodynamic therapy (PDT) targeting FAP to selectively induce cell death in these cells as well as in synovial tissue from RA patients. In PDT, a light-sensitive molecule is delivered to a target cell and activated with light of a specific wavelength. This causes cell death through the production of reactive oxygen species.

**Methods:** The anti-FAP antibody 28 H1 was conjugated with the photosensitizer IRDye700DX (28 H1–700DX). *In vitro* PDT assays were performed with 3 T3 fibroblasts stably transfected with FAP. 3T3-FAP cells were incubated with 28 H1–700DX or a control conjugate for 4 hours, and exposed to varying 690 nm light exposures. Subsequently, cell viability was measured using the CellTiter-Glo assay. For *ex vivo* evaluation of PDT efficiency, human RA synovial tissue obtained after joint replacement surgery was processed into standardised 6 mm biopsies and used for FAP-based PDT. The biopsies were incubated with 28 H1–700DX for 4 hours, subjected to 52 J/cm<sup>2</sup> light exposure and fixed in formalin after 1 hour. Tissue was then embedded in paraffin and stained for the presence of gH2AX and caspase 3 as indicators of DNA double-strand breaks and early apoptosis on sequential slides. The presence of FAP was also determined on subsequent slides.

**Results:** The effect of PDT was optimal at 13.7 J/cm<sup>2</sup> light exposure to 3T3-FAP cells incubated with 6.67 pM 28 H1–700DX, which dramatically reduced cell viability with 89.27%±2.48 compared to control (p<0.001). No cell death was observed with the control 700DX-conjugate (p=0.16).

In the PDT experiment on human RA synovial biopsies, the groups incubated with 28 H1-700DX and exposed to light showed apparent cell death in the synovial tissue as evidenced by the positive staining of both the gH2AX and caspase 3 markers (figure J and K). Staining of these markers co-localised with areas of high FAP staining (figure L). This was not the case in the control samples that were not exposed to either 28 H1-700DX and/or light (figure A – I). All biopsies did show FAP staining indicating that the cell death was only achieved when the biopsies were exposed to both the antibody and the light.

**Conclusions:** We have demonstrated fibroblast-specific cell death by targeted PDT using 700DX-conjugated 28 H1. Furthermore, we demonstrated that PDT also induces cell death of FAP-positive cells in synovial tissue from RA patients, suggesting FAP-targeted PDT as a promising new tool in treating RA.

SAT0062

### METABOLOMICS AND METABOLIC FUNCTION ANALYSIS OF THE SECRETOME OF ARTICULAR CARTILAGE AND CHONDROCYTES IN RESPONSE TO PRO-INFLAMMATORY CYTOKINES

C. Fellows<sup>1,2</sup>, H. Quasnichka<sup>1,2</sup>, N.R. Chowdhury<sup>3</sup>, E. Budd<sup>1,2</sup>, D.J. Skene<sup>3</sup>, A. Mobasher<sup>1,2</sup>. <sup>1</sup>Veterinary Pre-Clinical Studies; <sup>2</sup>The D-BOARD European Consortium for Biomarker Discovery; <sup>3</sup>Chronobiology, University of Surrey, Guildford, UK

**Background:** Chondrocytes rely primarily on glycolysis to meet their energy requirements, but can support cell survival and matrix synthesis during periods of nutrient stress by enhancing glycolysis with mitochondrial respiration. Accessing this 'spare respiratory capacity' requires optimal mitochondrial function. Impaired mitochondrial function is implicated in osteoarthritis (OA). Metabolic adaptation is evident in early-stage OA, however cartilage from late-stage disease does not seem to have this flexibility. A deeper understanding of these complex metabolic pathways may identify new markers of disease stage, and support therapeutic strategies for treating OA.

**Objectives:** Metabolomics has the potential to reveal pathological pathways and identify novel biomarkers. The aim was to identify metabolic processes involved in early stage disease by analysis of metabolites and metabolic function in pro-inflammatory models of cartilage degradation.

**Methods:** Macroscopically normal articular cartilage was obtained from equine and bovine metacarpophalangeal joints. Equine cartilage explants (n=6), and primary chondrocytes seeded at 105,000/cm<sup>2</sup> (n=4), were cultured for 7 days in serum-free DMEM (Gibco) with or without 10 ng/ml equine interleukin-1 $\beta$  (IL-1 $\beta$ ) and 10 ng/ml tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ). Secretome metabolite levels were measured using AbsoluteIDQ p180 targeted metabolomics kit (Biocrates), with Waters Xevo TQ-S mass spectrometer coupled to an Acquity UPLC system. PCA and OPLS-DA were performed using SIMCA-P v12.0 software. Metabolic function of primary equine (n=9) and bovine chondrocytes (n=3) was determined using Seahorse XFp and XF24 analyzers. Cells were treated with species-specific 10 ng/ml IL-1 $\beta$  and/or 10 ng/ml TNF- $\alpha$  for 18 hour, and metabolically challenged with the Mito Stress Test. Metabolite levels, and oxygen consumption rates, were normalised to total cell protein, and values analysed by ANOVA with Tukey's multiple comparison post-tests.

**Results:** Cytokine treatment decreased proline, ornithine and alpha-aminoadipic acid (p<0.0001) in explant secretome. Citrulline increased with cytokine treatment (p<0.0001) and glutamate, present in DMEM, was also elevated (p<0.0001). Metabolomic analysis of chondrocyte secretome showed that glutamine decreased (p<0.02) with cytokine treatment whereas citrulline was elevated (p<0.003). Metabolic analysis showed that cytokine treatment reduced basal respiration and negated spare respiratory capacity in chondrocytes (p<0.01), and the effect was due to IL-1 $\beta$  alone.

**Conclusions:** Explant metabolites which decreased with cytokine treatment are all downstream of glutamate. With elevated glutamate, this suggests that cytokines inhibit glutamate uptake and metabolism. Elevated citrulline in cell and explant models may be attributed to disruption of the urea cycle via induction of nitric oxide synthase. IL-1 $\beta$  alone negated spare respiratory capacity, and chondrocytes remained glycolytic. In conclusion, cytokines disrupt glutamate and citrulline metabolism, normally tightly regulated mitochondrial pathways, and IL-1 $\beta$  alone is responsible for the metabolic switch. These metabolic pathways could provide markers of early-stage inflammatory disease.

SAT0063

### EFFECTS OF INTRA-ARTICULAR INJECTED DIACEREIN-LOADED NANOPARTICLES ON JOINT IN RAT MODEL OF OSTEOARTHRITIS

J.H. Jung, G.G. Song, S.J. Choi, J.D. Ji, Y.H. Lee, J.-H. Kim. *Internal Medicine, Korea University Medical Center, Seoul, Korea, Republic Of*

**Background:** Osteoarthritis (OA) is a major health problem in recent years, but the current medical treatment is mainly symptom control and joint disability improvement. Diacerein (DIA) reduces the level of interleukin (IL)-1 receptor on the surface of chondrocytes, alleviates the pain, and prevents the structural degradation of the joint tissue. However, DIA has the side effects such as diarrhoea and urine discoloration when taken orally. To increase bioavailability and reduce systemic side effects, it is preferable to inject DIA directly into the joints. Nanoparticulate drug carriers have been attempted with the advances in drug delivery systems.

**Objectives:** We investigated that DIA-loaded nanoparticles (DIA/NPs) can efficiently inhibit the inflammatory reaction in synoviocytes stimulated by lipopolysaccharide *in vitro* and alleviate both inflammation and cartilage degeneration in monosodium iodoacetate (MIA)-induced OA rat model *in vivo*.

**Methods:** DIA/NPs were fabricated by water/oil/water emulsion method. *In vitro*, the mRNA levels of pro-inflammatory cytokines (IL-1, IL-6, MMP-3, MMP-13, COX-2, ADAMTS-5, and TNF- $\alpha$ ) were measured at 1 st and 3rd day after the administration of NPs only and DIA/NPs to synoviocytes using real-time PCR. MIA was intra-articular injected through the infrapatellar ligament of the rats' knee to induce OA. The rats were randomly divided into the six treatment groups: <sup>1</sup> control, <sup>2</sup> MIA, <sup>3</sup> MIA and NPs, <sup>4</sup> MIA and DIA(1%)/NPs, <sup>5</sup> MIA and DIA(5%)/NPs, and <sup>6</sup> MIA and DIA(5%) solution injection. After NPs, DIA(1%)/NPs, DIA(5%)/NPs, and DIA(5%) solution were injected, at 8th week, the rats were sacrificed to evaluate the plain radiographic and micro-computed tomography (micro-CT), histological study, and pro-inflammatory cytokines expression.

**Results:** The mRNA expression levels for pro-inflammatory cytokines in cells seeded with DIA(5%)/NPs and DIA(5%) solution were significantly lower than those in cells seeded with NPs at 1 st and 3rd day. Moreover, the mRNA levels of pro-inflammatory cytokines in cells injected with DIA(5%) solution decreased much greater than in cells injected with DIA(5%)/NPs. The rats injected DIA(5%)/NPs showed the least amount of cartilage and bone damage on plain radiography and micro-CT and had the less cartilage loss and the bony erosions on microscopic observation. The pro-inflammatory cytokines expression was lowest in the rats injected DIA(5%)/NPs, followed by NPs, DIA(1%)/NPs, and DIA(5%) solution.

**Abstract SAT0063 – Figure 1.** The macroscopic observations for 9 weeks after the MIA injection and for 8 weeks after treated with NPs, DIA (1%)/NPs, DIA (5%)/NPs, or DIA (5%) solution injections (arrows indicate erosions).

**Conclusions:** DIA(5%)/NPs are a promising therapeutic material to control the symptoms and prevent the progression of OA.

**SAT0064** **CD14+CD16+ MONOCYTE SUBPOPULATION IS DOMINANT IN THE INFLAMMATION OF OSTEOARTHRITIS SYNOVIAL FLUID**

J. Kim<sup>1</sup>, S.-J. Yoo<sup>1</sup>, Y. Kim<sup>2</sup>, S.W. Kang<sup>1</sup>, S.C. Shim<sup>1</sup>, S.M. Kim<sup>3</sup>. <sup>1</sup>Internal Medicine, Chungnam National University College of Medicine; <sup>2</sup>Internal Medicine, Daejeon Veterans Hospital, Daejeon; <sup>3</sup>Internal Medicine, Chungbuk National University Hospital, Cheong-ju, Korea, Republic Of

**Background:** In osteoarthritis (OA), the activation of inflammation response involving the interaction of cartilage and synovial hyperplasia may contribute to disease progression. However, inflammatory cells in OA synovial fluid (OASF) have been rarely studied.

**Objectives:** To investigate the phenotype of CD14 +cells and the secretion of proinflammatory cytokines by these cells

**Methods:** Immunohistochemistry staining in OA synovium was performed using anti-CD14, anti-CD16 and anti-CD56 antibody. The OASF was obtained through arthrocentesis. Mononuclear cells from OASFs were stained with anti-CD3, anti-CD4, anti-CD14, anti-CD16, anti-CD16 and anti-CD16 or anti-CD16 and analysed using flow cytometry. CD14 +CD16+ and CD14+CD16 mononuclear cells in OASF were selected with magnetic microbeads. In the supernatant of these cells culture, the concentration of IL-1 $\beta$ , IL-6, IL-8, TNF $\alpha$ , MMP-1, -3 were measured by Luminex.

**Results:** In OA synovium, CD14 or CD16 was stained, but CD56 was not expressed. In OASF, there was a substantial number of CD14 +cells (36.6%  $\pm$  25.2%), CD3 +cells (37.4%  $\pm$  12.9%), with a rarity of CD90 +cells (1.7%  $\pm$  1.3%). The proportion of CD14 +cells was increased significantly in recurrent synovial fluid, compared with the proportion in initial synovial fluid. Among CD14 +cells in OASF, CD14 +CD16+ monocyte subpopulation (21.2%  $\pm$  21.8%) was more abundant than CD14 +CD16- monocyte subpopulation (10.9%  $\pm$  10.0%). TLR4 and TLR2 expressions were higher in CD14 +CD16+ cells than in CD14 +CD16- cells. The concentration of IL-8 and MMP-3 was more increased in the supernatant of CD14 +CD16+ cells than in that of CD14 +CD16- cells.

**Conclusions:** In OASF, the proportion of CD14 +cells was increased in recurrent synovial effusion. Compared to CD14 +CD16- monocyte subpopulation, CD14 +CD16+ monocyte subpopulation released more cytokine such as IL-8 and MMP-3, and had higher expressions of TLR4 and TLR2.

**SAT0065** **CHONDROCYTES UNDER PATHOLOGICAL CONDITIONS PREFERENTIALLY DEGRADES SELECTED tRNAs TO INHIBIT PROTEIN SYNTHESIS**

J. Green, T. Haqqi. North East Ohio Medical University, Rootstown, USA

**Background:** Oxidative and ER stress play an important role in the pathogenesis of osteoarthritis (OA). These stress conditions can induce the cleavage of transfer RNA (tRNA) via angiogenin. This cleavage at the anticodon loop of the tRNA produces 5'-tRNA and 3'-tRNA halves known as tiRNAs.

**Objectives:** We aim to identify specific tRNA to tiRNA isotype fragments that occur during oxidative or ER stress in human OA chondrocytes.

**Methods:** Primary human articular chondrocytes were enzymatically isolated from OA cartilage. Cells were cultured *in vitro* for 72 hour and then treated with tert-butyl hydroperoxide (TBHP) over a 12 hour time course or with Interleukin-1b (IL1b) over a 24 hour time course. RNA was collected for mRNA expression analysis (qRT-PCR). Protein was harvested for western blot analysis. A tRF and tiRNA PCR Array that profiles 55 known tiRNAs was used to perform an unbiased dissection of the formation of tiRNAs in OA chondrocytes. Total RNA was adapted using a First-Strand cDNA Synthesis Kit designed to create cDNA libraries from small RNAs for qPCR detection to identify ten novel tiRNAs associated with cell stress in OA chondrocytes.

**Results:** Using qRT-PCR RNase gene expression was measured. Of these RNases 250  $\mu$ M TBHP treatment at 12 hour induced KIAA0430 ( $p < 0.05$ ), RNase7 ( $p < 0.0001$ ) and ZC3H12A ( $p < 0.0001$ ) but not angiogenin or SND1. 10 ng/ml IL1 $\beta$  treatment at 6 hour induced SND1 ( $p < 0.0001$ ), RNase 7 ( $p < 0.01$ ), ZC3H12A ( $p < 0.01$ ) but not angiogenin or KIAA0430. Chondrocytes undergoing oxidative or ER stress produced tiRNA halves in a time dependent manner, tiRNA formation was highest at 6 hour of IL1 $\beta$  treatment and after 12 hour of TBHP treatment. tiRNA fragments of tRNAs specific for arginine, glutamic acid, glycine, histidine, lysine and valine were increased after TBHP or IL1 $\beta$  treatment. Ten tiRNAs that were induced by IL1 $\beta$  and TBHP were selected for further study. Primer sets for these tiRNA and the parent tRNAs were designed and screened across a wider time course, and with higher patient numbers.

**Conclusions:** The expression of several RNases was increased in a time dependent manner in stressed OA chondrocytes and may be involved in the cleavage of tiRNA fragments. tiRNA halves were grouped together based on their parent tRNA amino acid target. We hypothesised that an increase in fold change in these grouped tiRNAs may result in less production of proteins that contain a high percentage of that specific amino acid. These changes in amino acid distribution may account for decreases seen in amino acid rich proteins such as Type II collagen (a glycine rich protein) in stressed chondrocytes. By designing tiRNA and parent tRNA primers we will discover if tiRNA formation effects total levels of parent tRNAs. The outcomes from this research will provide us with an increased understanding of tRNA to tiRNA formation in human chondrocytes and may allow us to identify therapeutic targets for the treatment of OA and provide insights into novel stress signalling pathways.

**SAT0066** **THE LONG NONCODING RNA (LNCRNA) HOTTIP IS A MASTER REGULATOR OF CELL CYCLE IN HAND SYNOVIAL FIBROBLASTS IN ARTHRITIS**

M. Frank Bertonecchi<sup>1</sup>, T. Masterson<sup>1</sup>, E. Karouzakis<sup>1</sup>, C. Kolling<sup>2</sup>, A. Filer<sup>3</sup>, C. D. Buckley<sup>3</sup>, S. Gay<sup>1</sup>, O. Distler<sup>1</sup>, C. Ospelt<sup>1</sup>. <sup>1</sup>Center of Experimental Rheumatology Zurich, University Hospital Zurich, Schlieren; <sup>2</sup>Schulthess Klinik, Zurich, Switzerland; <sup>3</sup>Institute of Inflammation and Ageing (IIA), University of Birmingham, Queen Elizabeth Hospital, Birmingham, UK

**Background:** Rheumatoid arthritis (RA) and other types of inflammatory arthritis follow a characteristic anatomical pattern of joint involvement. We have recently shown that local synovial stromal cells, specifically synovial fibroblasts, exhibit joint-specific transcriptomes and functions. In particular, hand SF exhibited prominent proliferative and chemotactic activities. Density of stroma and leukocyte infiltration were increased in hand synovium.

**Objectives:** To explore the role of hand/feet-specific lncRNA HOTTIP in shaping the function of hand synovial fibroblasts in arthritis.

**Methods:** We studied transcriptomes and epigenomes of hand, shoulder and knee SF from patients with RA or osteoarthritis and from knees of non-arthritic subjects using RNA-seq (Illumina HiSeq 2000 n=21), histone ChIP-seq (Illumina HiSeq 2500, n=7) and Infinium HumanMethylation450 BeadChip (n=12). qPCR was used to confirm RNA-seq data in a larger cohort of SF from different joints. We silenced the lncRNA HOTTIP in hand SF using LNA GapmeRs, followed by RNA-seq, qPCR, protein-protein interaction analysis of RNA-seq data (STRING), and *in vitro* assays for proliferation (BrdU assay) and apoptosis (Annexin V/PI staining).

**Results:** Genome-wide DNA methylation patterns and histone marks at actively transcribed DNA regions (H3K27ac) and enhancers (H3K4me1) defined joint-specific origin of SF. SF from hands and feet specifically expressed the lncRNA HOTTIP. This distal-specific HOTTIP expression coincided with the enrichment of H3K4me3 and H3K27ac and a decrease in repressive marks (H3K27me3, DNA methylation) at the HOTTIP promoter in hand SF. In contrast, the HOTTIP promoter displayed scarce activating, but abundant repressive epigenetic marks in shoulder and knee SF. Silencing of HOTTIP in hand SF altered the expression of 447 protein-coding genes (log ratio  $> 2$ , FDR  $< 0.05$ ). These genes were strongly enriched in the mitotic cell cycle protein interaction network (n=48 genes,  $p = 3.3 \times 10^{-7}$ ). Several of the enriched mitotic cell cycle genes, including NCAPG, CENPO, ZWILCH and BUB1 were confirmed as downregulated by HOTTIP silencing in a larger cohort of hand SF (n=6). The basal expression of 36 out of the 48 enriched cell cycle genes correlated with the basal HOTTIP expression in hand SF (n=6, RNA-seq,  $R > 0.06$ ). We further measured these correlations in a larger cohort of hand SF (n=21) for a subset of the 36 genes using qPCR. Among the measured genes, TADA 3 and CDC27 were confirmed to correlate with HOTTIP expression in hand SF ( $R = 0.5$ ,  $p < 0.05$ ). Silencing of HOTTIP for 24 hour, 48 hour and 72 hour decreased the incorporation of BrdU into DNA of

hand SF as measured by BrdU proliferation assay ( $p < 0.05$ ,  $n = 3$ ). Apoptosis of hand SF increased at 48 hour of HOTTIP silencing ( $p < 0.05$ ,  $n = 3$ ).

**Conclusions:** The lncRNA HOTTIP, which is specifically expressed in hand joints via epigenetic mechanisms, is a master regulator of mitotic cell cycle genes and proliferation in hand SF. Distal-specific expression of HOTTIP might imprint hand SF with enhanced proliferative potential, thereby shaping the location-specific joint pathology, e.g. prominent synovial hyperplasia and increased severity of hand arthritis in RA.

#### SAT0067 ROLE OF NOX2-DERIVED REACTIVE OXYGEN SPECIES IN S100A8/A9-DRIVEN INFLAMMATORY OSTEOARTHRITIS

N. Kruisbergen, S. van Dalen, M. van den Bosch, A. Blom, P. van Lent. *Experimental Rheumatology, Radboudumc, Nijmegen, Netherlands*

**Background:** Synovitis in inflammatory osteoarthritis (OA) is driven by locally released DAMPs like S100A8/A9 proteins that have been shown to enhance joint destruction. S100A8/A9 induce ROS (reactive oxygen species) release by phagocytes in OA synovium via the NADPH-oxidase 2 (NOX2)-complex. Assembly of this complex is dependent on the neutrophils cytosolic factor (Ncf1). In this complex, the NOX2 protein is responsible for ROS production.

**Objectives:** In the present study we investigated whether NOX2-derived ROS are involved in joint pathology during collagenase-induced OA (CiOA).

**Methods:** CiOA was induced in knee joints of wild type (WT) and Ncf1-deficient (Ncf1<sup>-/-</sup>) mice. Synovial gene expression of NOX2-subunits was measured with qRT-PCR. Joint pathology was assessed using histology and antibodies against aggrecan neo-epitope VDIPEN. Levels of inflammatory proteins were measured with Luminex or ELISA. Phagocytes present in synovium, blood, bone marrow and spleen were analysed with flow cytometry. Extracellular ROS production by bone marrow-derived phagocytes was measured using an Amplex Red ROS detection assay.

**Results:** CiOA induction in knee joints of WT mice caused significantly increased synovial gene expression of NOX2 subunits. On day 7 of CiOA, synovial thickening, synovial S100A8/A9 levels and synovial percentages of inflammatory macrophages, PMNs, and monocytes were comparable between WT and Ncf1<sup>-/-</sup> mice. Cartilage damage and MMP activity, as measured by VDIPEN staining, were comparable, as well as levels of inflammatory mediators in serum and phagocyte percentages in blood, bone marrow and spleen. On day 42 of CiOA, synovitis, cartilage damage, and osteophyte formation in Ncf1<sup>-/-</sup> mice were unaltered when compared to WT mice. ROS production by Ncf1<sup>-/-</sup> PMNs was completely absent but Ncf1<sup>-/-</sup> macrophages, the more predominant phagocyte involved in development of pathology during CiOA, produced ROS in similar amounts as WT macrophages. Ncf1 deficiency thus seems to exclusively affect PMNs, this surprising finding might explain the lack of differences observed between CiOA development in WT and Ncf1<sup>-/-</sup> mice. ROS production by WT and Ncf1<sup>-/-</sup> macrophages was strongly upregulated by S100A8 and almost completely inhibited by the pan-NOX inhibitor diphenyleneiodonium chloride (DPI). In order to determine whether NOX1 complexes caused the compensation responsible for Ncf1 independent ROS production, we co-stimulated Ncf1<sup>-/-</sup> macrophages with NOX1-specific inhibitor ML171. However, no ML171-induced inhibition of ROS production was observed.

**Conclusions:** Absence of PMN-derived ROS does not alter synovitis and joint pathology in S100A8/A9-driven experimental inflammatory OA. The mechanism that enables Ncf1-independent ROS production by macrophages should be further investigated.

#### SAT0068 BILIRUBIN PROMOTES DOWN-REGULATION OF RUNX2 AND UP-REGULATION OF RANKL GENE EXPRESSION IN BONE EXPLANTS AND IN OSTEOBLASTIC AND OSTEOCYTIC CELL LINES

S. Ruiz-Gaspà, A. Parés, A. Combalia, P. Peris, A. Monegal, N. Guañabens. *Metabolic Bone Diseases and Liver Units, Hospital Clínic, Idibaps, Ciberehd, University of Barcelona, Barcelona, Spain, Barcelona, Spain*

**Background:** *In vitro* studies have shown that the retained substances of cholestasis have deleterious effects in human osteoblasts and osteocytic cells. Bilirubin (BIL) and lithocholic acid (LCA) induce alterations in the proliferation, differentiation and apoptosis of osteoblastic and osteocytic cells. However, their effects in human bone tissue and in bone cell lines have not been deeply analysed.

**Objectives:** To investigate the effects of BIL, LCA and ursodeoxycholic acid (UDCA) in gene expression of human trabecular bone explants as well as in osteoblastic (SAOS2) and osteocytic cells (MLO-Y4/MLO-A5).

**Methods:** Bone tissue harvested from trabecular bone fragments, SAOS2 and MLO-Y4/MLO-A5 cells were cultured and treated with BIL (50  $\mu$ M), LCA (10  $\mu$ M) and UDCA (10/100  $\mu$ M) for 24 hour. Gene expression of osteocalcin (*BGLAP*), *Cbfa1* (*RUNX2*)/*Osterix* (*OSX*) and *RANKL* (*TNFRSF11B*) were quantified by real time PCR.

**Results:** BIL diminishes *RUNX2* gene expression in bone tissue (-37%), SAOS2 (-75%), MLO-Y4 (-56%) and MLO-A5 (-77%), and increases *RANKL* expression in 60%, 27%, 72% and 60%, respectively ( $p \leq 0.02$ ). In bone tissue and in osteoblastic and osteocytic cells, LCA increases gene expression of *BGLAP* (NS) and *RANKL* ( $p \leq 0.03$ ). UDCA 100  $\mu$ M increases *RUNX2* and *OSX* expression in bone tissue (78% and 82%), MLO-Y4 (72% and 80%) and SAOS2 (75% and 70%) ( $p \leq 0.03$ ). In addition, UDCA 100  $\mu$ M significantly increases expression of *BGLAP*, *OPG* and *RANKL* in bone tissue and in osteocytic lines. UDCA 10/100  $\mu$ M counteracts the decrease in *RUNX2* induced by BIL in bone tissue, SAOS2, MLO-A5 and MLO-Y4 cells.

**Conclusions:** The retained substances of cholestasis, particularly bilirubin, cause noxious effects on transcription factors of osteoblast differentiation and on osteoclastic activators in bone tissue and in osteoblastic and osteocytic cells. Ursodeoxycholic acid reverses the harmful effects of bilirubin. These results provide new insights into the low bone formation and at some stages, high resorption, associated with chronic cholestasis.

#### SAT0069 ABNORMAL BONE AND CARTILAGE METABOLISM COULD BE ANTAGONISED BY SLEED ELECTROMAGNETIC FIELDS (PEMFs) AND TNF-A AND IL-6 GENE KNOCKOUTS IN A SIMILAR MECHANISM

S.Z. Zhu<sup>1</sup>, H. He<sup>1</sup>, Q. Wang<sup>1</sup>, D. Wang<sup>2</sup>, H. Wang<sup>1</sup>, C. Gao<sup>1,3</sup>, C. Zhang<sup>1,4</sup>, X. Yu<sup>5</sup>, C. He<sup>1,3</sup>. <sup>1</sup>Rehabilitation Medicine, West China Hospital, Sichuan University; <sup>2</sup>School of Aeronautics and Astronautics, Sichuan University; <sup>3</sup>Institute for Disaster Management and Reconstruction, Sichuan University-The Hong Kong Polytechnic University, Chengdu; <sup>4</sup>Rehabilitation Medicine, Southwest Medical University, Luzhou; <sup>5</sup>Laboratory of Endocrinology and Metabolism, West China Hospital, Sichuan University, Chengdu, China

**Background:** Pulsed electromagnetic fields (PEMFs), as a safe and non-invasive method, could positively affect bone and cartilage metabolism. However, the effect and underlying mechanisms of PEMFs on osteoporosis and osteoarthritis remain poorly understood.

**Objectives:** The present study is designed to investigate the effect of PEMFs on osteoporotic bone and degenerative cartilage together with its potential molecular mechanisms in mice with different gene background.

**Methods:** Twenty 12 week male and Female wild-type (WT), *TNF $\alpha$*  knockout (*TNF $\alpha$ <sup>-/-</sup>*) or *IL6* knockout (*IL6<sup>-/-</sup>*) mice, respectively, were sham-operated (SHAM) or subjected to destabilisation of the medial meniscus (DMM) and ovariectomy (OVX) surgeries. After surgeries, WT mice were equally assigned to the non-treatment and PEMFs groups. Mice in PEMFs group were subjected to daily 1 hour PEMFs exposure with 8 Hz, 3.8 mT (peak value). Then all mice were euthanized after 4 weeks. Bone mass and subchondral microarchitecture were determined using micro-CT. Bone and cartilage metabolism was assessed by histological analysis, serum analyses, qRT-PCR and Western-Blot.

**Results:** The surgical models of osteoporosis and osteoarthritis were proved successful evidenced by the analysis of micro-CT data and histological analysis. The bone loss and damaged cartilage were largely repaired by *TNF $\alpha$*  and *IL6* gene knockout and partially inhibited by PEMFs exposure. Interestingly, no difference

in Micro-CT data analysis was found between PEMFs group and gene knockouts, although a slight increase could be observed in  $TNF\alpha^{-/-}$  mice when compared to the PEMFs group. Negative effects on bone and cartilage was proved by testing key cytokines in anabolism and catabolism. PEMFs treatment and gene knockouts corrected the negative effects by targeting mediators in molecular pathways like Wnt and RANK. The differences in mRNA and protein level changes between PEMFs and gene knockouts were minor.

### PEMFs exposure system (Version 1.0)

### PEMFs exposure system (Version 2.0)

**Conclusions:** PEMFs alleviated surgeries induced bone loss and cartilage degeneration by promoting anabolism and inhibiting catabolism possibly in a similar mechanism to  $TNF-\alpha$  and  $IL-6$  gene knockouts, which imply that  $TNF-\alpha$  and  $IL-6$  may become new potential targets for PEMFs in treating degenerative bone diseases.

### ROLE OF C/EBPβ IN 1,25D-INDUCED ACTIVATION OF RANKL EXPRESSION

S. Jo<sup>1</sup>, Y.L. Lee<sup>1</sup>, I.-H. Sung<sup>2</sup>, T.-H. Kim<sup>1</sup>. <sup>1</sup>Rheumatology, Hanyang University Hospital For Rheumatic Disease; <sup>2</sup>Orthopaedics, Hanyang University Seoul Hospital, Seoul, Korea, Republic Of

**Background:** 1 alpha 25-dihydroxyvitamin D3 (1,25D) is the active form of vitamin D3, which is responsible for osteoblast activation, subsequently bone formation. Although recent studies have shown that 1,25D stimulates RANKL expression in osteoblast differentiation<sup>1</sup>, its molecular mechanism of action is not fully understood.

**Objectives:** The aims of this study were to evaluate cellular response of human bone-derived cells to 1,25D treatment by observing expression during osteoblast differentiation

**Methods:** In this study, MG63, SaOS2, and primary bone-derived cells (BdCs) were cultured and isolated to further elucidate the effect of 1,25D on osteoblasts. Those were incubated in osteogenic medium (ascorbic acid, beta-glycerol phosphate, and dexamethasone) for 1, 3, and 7 days with or without 20 μM 1,25D. The

osteoblast activity and differentiation status were evaluated by intercellular Alkaline Phosphatase (ALP) activity, ALP staining, Alizarin Red S (ARS) staining, and hydroxyapatite staining. In this situation, C/EBPβ gene manipulation with siRNA or overexpression system were subjected to report assay of human RANKL promoter, quantitative PCR(qPCR), immunoblotting and immunostaining of osteoblastic gene expression (alkaline phosphatase, osteocalcin, vitamin D3 receptor, RANKL, and C/EBPβ etc.)

**Results:** 1,25D promotes osteoblast differentiation and expression of osteogenic markers in three different cells. Intriguingly, treatment of 1,25D to those cells are accompanied by stabilising C/EBPβ proteins and stimulating RANKL expression. Moreover, Overexpression of C/EBPβ significantly increases RANKL mRNA and protein. In contrast, suppression of C/EBPβ decreases RANKL expression. Thus, C/EBPβ is a key mediator involved in 1,25D induced RANKL expression.

**Conclusions:** our preliminary data indicated that human bone-derived cells response to vitamin D3 promoted RANKL expression via activation of C/EBPβ, and enhanced osteoblast activity and differentiation. This study provides insight into the molecular mechanism of RANKL expression and osteoblast activation in human bone-derived cells response to 1,25D.

SAT0071

### SUBCHONDRAL OSTEOGENESIS BUT NOT CARTILAGE DAMAGE IS PREVALENT IN KNEE JOINTS OF PREMATURELY AGEING MITOCHONDRIAL DNA MUTATOR MICE

J. Geurts<sup>1</sup>, S. Nasi<sup>2</sup>, T.A. Prolla<sup>3</sup>, G.C. Kujoth<sup>3</sup>, U.A. Walker<sup>4</sup>, T. Hügle<sup>2</sup>. <sup>1</sup>Spine and Surgery and Biomedical Engineering, University Hospital Basel, Basel; <sup>2</sup>Rheumatology, University Hospital Lausanne, Lausanne, Switzerland; <sup>3</sup>Medical Genetics, University of Wisconsin, Madison, USA; <sup>4</sup>Rheumatology, University Hospital Basel, Basel, Switzerland

**Background:** Mitochondrial dysfunction has been demonstrated in ageing and osteoarthritic tissues. However it remains unclear whether dysfunctional mitochondria are directly implied in the pathogenesis of osteoarthritis.

**Objectives:** We investigated knee joints of prematurely ageing mitochondrial DNA mutator mice (*Polg<sup>D275A</sup>*) to evaluate a causal relationship between mitochondrial dysfunction and different features of osteoarthritis.

**Methods:** Bone structural parameters and chondrocyte were evaluated in knee joints of mice displaying increased mtDNA mutations rates and accelerated ageing, due to expression of a proofreading-deficient mtDNA polymerase, using micro-computed tomography and histopathological analysis.

**Results:** Homozygous mutants displayed osteopenia of the epiphyseal trabecular bone and subchondral cortical plate in comparison to wild type controls and heterozygous mutants. Osteopenia was associated with a strong increase of osteoclast numbers (0.88±0.30/mm bone perimeter) compared to heterozygous (0.25±0.03/mm) and wild type mice (0.12±0.04/mm). New bone formation was not observed. Wild type mice displayed only low grade cartilage degeneration (OARSI grade ≤1) due to loss of cartilage proteoglycans. Increased tibio-femoral chondrocyte was not apparent in hetero- and homozygous mitochondrial DNA mutator mice.

**Conclusions:** Mitochondrial dysfunction and premature ageing in mice with somatically acquired mtDNA mutations predisposes to enhanced subchondral bone resorption as potential early step of osteoarthritis, but not to cartilage damage or new bone formation. This phenotype potentially corresponds to an osteoporotic osteoarthritis phenotype in humans.

**Disclosure of Interest:** None declared

SAT0072

### MIRNA-146A IS A KEY PLAYER IN BONE METABOLISM AND OSTEOPOROSIS

V. Saferding<sup>1</sup>, M. Hofmann<sup>1</sup>, J.S. Brunner<sup>1</sup>, M.F. Militar<sup>1</sup>, A. Puchner<sup>1</sup>, S. Hayer<sup>1</sup>, M. Timmen<sup>2</sup>, R. Stange<sup>2</sup>, J.S. Smolen<sup>1</sup>, S. Blüml<sup>1</sup>. <sup>1</sup>Medical University Of Vienna, Vienna, Austria; <sup>2</sup>University Muenster, Muenster, Germany

**Background:** Micro RNAs (miRNAs) play a crucial role in the regulation of bone metabolism. MiR-146a, an important anti-inflammatory miRNA, was found to negatively impact osteogenesis and bone regeneration *in vitro*, by controlling the differentiation of mesenchymal stem cells. But to date the role of miR-146a in bone

remodelling, its influence on bone stability and development of osteoporosis is not known.

**Objectives:** The objective of this project is the analysis of the role of miR-146a in bone metabolism.

**Methods:** Systemic bone, tibiae and femur, of wt and miR-146a deficient animals was assessed histologically and via  $\mu$ CT analysis, over a period of 3 to 18 months of age. Serum cytokine levels were analysed by Elisa. mRNA expression levels in bone were analysed by qPCR. To induce osteoporosis, ovariectomy (OVX) induced bone loss was performed.

**Results:** When we analysed bone volume of long bones histologically as well as with  $\mu$ CT analysis we detected significantly increased trabecular bone mass in miR-146a deficient compared to wt animals, starting at an age of 6 months. However, cortical thickness of systemic bones from miR-146a knock out animals was significantly reduced compared to control mice. Analysis of serum in aged miR-146a deficient animals displayed elevated activity of bone resorbing osteoclasts as amounts of CTX I in miR-146a<sup>-/-</sup> mice were significantly increased compared to wt animals. Q-PCR analysis of important osteoclast as well as osteoblast marker genes in bones *ex vivo* displayed elevated expression of signature molecules of both cell types in aged miR-146a deficient mice, suggesting a regulatory role of miR-146a in both osteoclasts as well as osteoblasts. When we induced osteoporosis using the OVX disease model, histological analysis of long bones showed significant trabecular bone loss in ovariectomized wt mice. In contrast, we detected no trabecular bone loss in ovariectomized miR-146a knock out animals, suggesting that loss of miR-146a deficiency protects bone loss induced by oestrogen deficiency.

**Conclusions:** MiR-146a seems to control bone turnover and miR-146a deficient mice accrue bone over time. Moreover this miRNA has a negative influence on bone loss occurring during oestrogen loss induced osteoporosis. Therefore miR-146a could be possibly used as a therapeutic target in the treatment of osteoporosis.

## Rheumatoid arthritis – prognosis, predictors and outcome

SAT0073

### ACPA AND RF AS PREDICTORS OF SUSTAINED CLINICAL REMISSION IN RHEUMATOID ARTHRITIS PATIENTS: RESULTS FROM THE ONTARIO BEST PRACTICES RESEARCH INITIATIVE (OBRI)

J.E. Pope<sup>1</sup>, M. Movahedi<sup>2,3</sup>, E. Rampakakis<sup>3</sup>, A. Cesta<sup>2</sup>, J.S. Sampalis<sup>4</sup>, C. Bombardier<sup>2,5,6</sup> on behalf of Other OBRI investigators. <sup>1</sup>Saint Joseph's Health Care, University of Western Ontario, London; <sup>2</sup>Ontario Best Practices Research Initiative, Toronto General Research Institute, University Health Network, Toronto; <sup>3</sup>JSS Medical Research, St-Laurent-QC; <sup>4</sup>McGill University, Montreal-QC; <sup>5</sup>Department of Medicine (DOM) and Institute of Health Policy, Management, and Evaluation (IHPE), University of Toronto; <sup>6</sup>Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada

**Background:** Positive anti-citrullinated protein antibody (ACPA) and rheumatoid factor (RF) are included among the 2010 ACR/EULAR classification criteria for rheumatoid arthritis (RA). Previous studies have shown that autoantibodies are positive predictors of response in RA patients treated with some biologics whereas other studies suggest worse prognosis if positive for ACPA and RF.

**Objectives:** The purpose of this study was to evaluate the interaction of RF and ACPA in predicting sustained clinical response in a large observational registry of RA patients followed in routine practice.

**Methods:** RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) registry, with active disease ( $\geq 1$  swollen joint), available autoantibody information, and at least 1 follow-up assessment were included in the analysis. Sustained clinical remission was defined as CDAI  $\leq 2.8$  in at least 2 sequential visits separated by at least 3 and maximum of 12 months. Time to sustained remission was assessed by plotting cumulative incidence curves and multivariate cox regression.

**Results:** A total of 970 (30%) out of 3251 patients in the registry were included, of whom 262 (27%) were anti-CCP<sup>neg</sup>/RF<sup>neg</sup>, 60 (6.2%) anti-CCP<sup>pos</sup>/RF<sup>neg</sup>, 117 (12.1%) anti-CCP<sup>neg</sup>/RF<sup>pos</sup>, and 531 (54.7%) anti-CCP<sup>pos</sup>/RF<sup>pos</sup>. At baseline, significant differences were observed between groups in age ( $p=0.02$ ), CDAI ( $p=0.03$ ), tender joint count ( $p=0.02$ ), and HAQ-DI ( $p=0.002$ ), with anti-CCP<sup>pos</sup>/RF<sup>pos</sup> and anti-CCP<sup>pos</sup>/RF<sup>neg</sup> patients being youngest and having the lowest disease activity and disability. No differences were observed in terms of biologic use (20.2% of patients).

Sustained remission was 10% more likely if anti-CCP<sup>pos</sup>, and was achieved by 43.5% of anti-CCP<sup>pos</sup>/RF<sup>pos</sup> patients, 43.3% of anti-CCP<sup>pos</sup>/RF<sup>neg</sup> patients, 31.6%

of anti-CCP<sup>neg</sup>/RF<sup>pos</sup> patients and 32.4% of anti-CCP<sup>neg</sup>/RF<sup>neg</sup> patients ( $p=0.01$ ). Significant differences were observed in the time to achieving sustained clinical response from enrolment in the OBRI based on anti-CCP status ( $p<0.001$ ), RF status ( $p=0.06$ ), and both ( $p=0.004$ ) (figure 1). ACPA<sup>pos</sup>/RF<sup>pos</sup> (median: 3.7 years; 95% CI: 3.0–4.3) and ACPA<sup>pos</sup>/RF<sup>neg</sup> (median: 3.4 years; 95% CI: 2.4–NE) patients achieved sustained remission earlier than ACPA<sup>neg</sup>/RF<sup>neg</sup> patients (median: 5.1 years; 95% CI: 3.7–6.2), respectively (figure 1).

Multivariate cox regression adjusting for baseline CDAI score, age and sex also showed differences between groups; statistically significance in anti-CCP<sup>pos</sup>/RF<sup>pos</sup> vs. anti-CCP<sup>neg</sup>/RF<sup>neg</sup> patients (HR [95% CI]: 1.30 [1.01–1.67];  $p=0.04$ ).

**Abstract SAT0073 – Figure 1.** Cumulative incidence of first sustained remission by ACPA/RF status

**Conclusions:** These results suggest that anti-CCP but not RF positivity may be associated with a higher chance of remission, possibly due to an improved treatment response.

Bessant<sup>3</sup>, C. Pitzalis<sup>2</sup>, F. J. Blanco<sup>1</sup>. <sup>1</sup>Unidad de Proteómica-ProteoRed/ISCIII, Grupo de Investigación en Reumatología, INIBIC – CHUAC, A Coruña, Spain; <sup>2</sup>Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London; <sup>3</sup>School of Biological and Chemical Sciences, Queen Mary University of London, London, UK

**Background:** The treatment of rheumatoid arthritis (RA) aims to control a patient's signs and symptoms, prevent joint damage, and maintain his/her quality of life. Among the best known disease-modifying antirheumatic drugs, Methotrexate (MTX) is one of the most effective and widely used medications. It is used as a general first-choice drug, although some patients will not respond to this treatment and it is not free from side effects.

**Objectives:** To identify circulating proteins that could be useful as predictors of the patient's response to MTX.

**Methods:** Serum samples from patients enrolled in the Pathobiology of Early Arthritis Cohort (PEAC) were collected before treatment with MTX. Response to therapy was determined after 6 months by calculating the initial and final DAS28 of the patients. Their classification was performed following the EULAR response criteria. Sixty samples at baseline from this cohort (30 good responders and 30 non-responders) were depleted from the 14 most abundant proteins by affinity chromatography to remove background. Then, they were analysed by reversed-phase nanoliquid chromatography coupled to mass spectrometry using a SWATH strategy in a tripleTOF MS (Sciex). The quantitative data obtained in this proteomic analysis were processed using the ProteinPilot 5.0.1 and PeakView 2.1 software (Sciex). Machine learning analyses were performed on a train set of 30 samples (15 responders and 15 non-responders) via support vector machine (SVM) using the Classyfire, e1071 and caret R packages. Results were verified in an independent set of 24 samples by a two-stage support vector machine (TSSVM) with RBF kernel and 10 cross-fold validation for each meta-model.

**Results:** The proteomic analysis led to the identification and quantification of 229 proteins that were common between the screening and validation sets. Independent screening and validation data sets were preprocessed by PCA for dimension reduction and analysed by machine learning tools, leading to the definition of a panel of 8 proteins (one of them involved in MTX metabolism) differentiating the groups of responders and non-responders to MTX with strong agreement (Kappa >0.80), very high accuracy and good relevant metrics (table 1).

**Abstract SAT0074 – Table 1.** Metrics of the classification performance of the 8-protein panel identified in this work to predict response of the patient to MTX. Cut-off for significance was p-value <0.05.

Train set							
Accuracy	95% CI	p-value	Kappa	Sensitivity	Specificity	Pos pred value	Neg pred value
0.9333	(0.7793 - 0.9918)	1.108e-05	0.8667	0.8824	1.0000	1.0000	0.8667
Validation set							
Accuracy	95% CI	p-value	Kappa	Sensitivity	Specificity	Pos pred value	Neg pred value
0.9583	(0.7888 - 0.9989)	0.0007722	0.9091	1.0000	0.9375	0.8889	1.0000

**Conclusions:** We have defined a panel of circulating proteins useful to predict the response to MTX therapy in rheumatoid arthritis patients.

### SAT0075 ADDITIONAL TARGET OF NORMAL SERUM MATRIX METALLOPROTEINASE-3 IS A POTENTIAL BIOMARKER FOR LESS ONE-YEAR RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS

L.-F. Chen, J.-D. Ma, Y.-Q. Mo, X.-Y. Du, D.-H. Zheng, L. Dai. *Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*

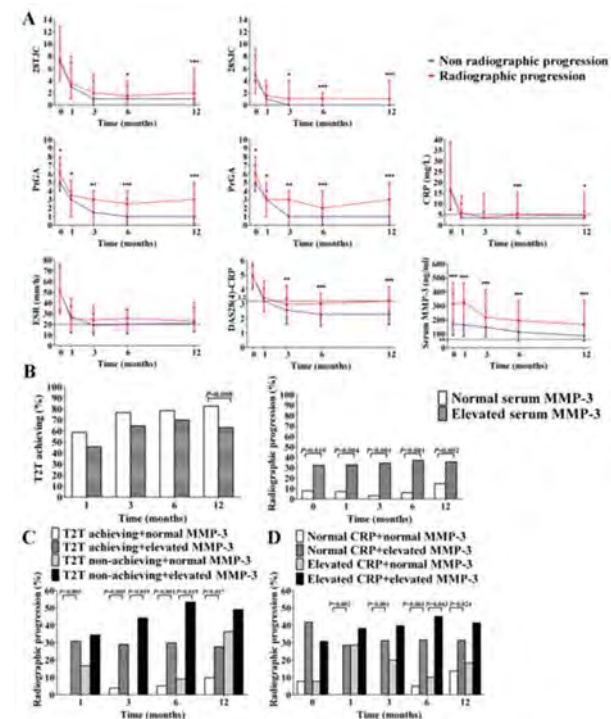

**Background:** Matrix metalloproteinase (MMP)-3 plays important roles in bone and cartilage destruction in rheumatoid arthritis (RA). Our previous study showed continuously elevated serum MMP-3 for 3–6 months predict one-year radiographic progression in RA (Arthritis Res Ther. 2015 17:289). However, whether serum MMP-3 normalisation is a biomarker for better outcome remains elusive.

**Objectives:** To explore the association of serum MMP-3 normalisation with clinical and radiographic outcome in RA.

**Methods:** RA patients with moderate to high disease activity (DAS28-CRP>3.2) were treated according to treat to target (T2T) strategy and followed up at regular intervals (0, 1 st, 3rd, 6th and 12th months). Demographic and clinical data were collected according to the 2017 EULAR recommendation and serum MMP-3 was detected by ELISA at each visit. X-ray assessment of hand/wrist was repeated at baseline and month 12 and radiographic progression was defined as a change of the Sharp/van der Heijde modified sharp score  $\geq 0.5$  units.

**Results:** (1) Among 200 RA patients recruited, there were 163 (81.5%) female, with median disease duration 24 (11–84) months, median DAS28-CRP 4.9 (4.2–5.7). There were 29% patients showed one-year radiographic progression. (2) The median MMP-3 was 209.7 (108.6–430.0) ng/ml. RA patients without radiographic progression had significant lower level of serum MMP-3 than those with radiographic progression at baseline and each visit (figure 1A, all p<0.001). (3) There were 13.0%, 14.5%, 17.0%, 25.5% and 31.0% patients having normal MMP-3 at baseline and 1 st, 3rd, 6th and 12th months, respectively. There were significantly

lower percentage of RA patients with normal MMP-3 at baseline and each visit showed radiographic progression than those with elevated MMP-3 (figure 1B, all p<0.05). (4) There were 8.5%, 13.0%, 20.0% and 25.5% patients who achieved therapeutic target and showed normal MMP-3 at 1 st, 3rd, 6th and 12th months, respectively. Among patients achieved therapeutic target, there were significantly lower percentage of normal MMP-3 patients showed radiographic progression than those with elevated MMP-3 (figure 1C, all p<0.05). (5) There were 6.5%, 11.0%, 14.5%, 20.5% and 25.5% patients who had normal CRP and normal MMP-3 at baseline and 1 st, 3rd, 6th and 12th months, respectively. Among patients with normal CRP, there were significantly lower percentage of normal MMP-3 patients at 1 st, 3rd, 6th and 12th months showed radiographic progression than those with elevated MMP-3 (figure 1D, all p<0.05).

**Abstract SAT0075 – Figure 1.** Dynamic change of serum MMP-3 and indicators of disease activity and radiographic progression in RA. **A** Comparison of disease activity and radiographic progression indicators between RA patients with and without radiographic progression. **B** Comparison of T2T achieving and the percentage of RA patients showing radiographic progression between normal and elevated serum MMP-3 groups at each visit. **C** Comparison of the percentage of RA patients showing radiographic progression among groups with or without T2T achieving and normal serum MMP-3. **D** Comparison of the percentage of RA patients showing radiographic progression among groups with or without normal CRP and normal serum MMP-3.

**Conclusions:** Additional target of normal serum MMP-3 may be a potential biomarker for less one-year radiographic progression.

### SAT0076 SYNOVIAL MAST CELLS AND RESPONSES TO SYNTHETIC AND BIOLOGIC DMARDS IN EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS

F. Rivellesse, A. Nerviani, D. Mauro, S. Pagani, F. Humby, C. Pitzalis. *Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, London, UK*

**Background:** Mast cells (MCs) are immune cells implicated in the pathogenesis of Rheumatoid Arthritis (RA), but their presence in synovia has not been assessed systematically and their association with disease progression and treatment response is unknown.

**Objectives:** To analyse MCs in the synovia of patients with early vs established RA in correlation with histological and clinical phenotype.

**Methods:** DMARDs-naïve patients with early (<12 months) RA (n=97) and patients with established RA failing synthetic DMARDs and candidate to biologic treatment (n=27) underwent ultrasound-guided synovial biopsy. Sections of paraffin embedded synovial tissue were stained with H and E to measure the degree of synovitis (Krenn Score). Sequentially cut sections were stained by immunohistochemistry to evaluate the presence of immune cells, including CD117 (c-kit) positive mast cells. Upon SQ scoring (0–4), patients were stratified into synovial pathotypes (Lymphoid, Fibroid, and Myeloid), as previously described

**Results:** In the cohort of DMARDs-naïve early RA (mean disease duration 6 months), MC+ve patients (67.7%) had significantly higher synovial inflammation (Krenn score), higher prevalence of the lymphoid pathotype, higher inflammatory markers and disease activity; however, they did not differ in terms of response to sDMARDs at 6 months (table 1, left). In established RA (mean disease duration 5 years), MC+ve patients (48.1%) had significantly higher synovial inflammatory scores and higher prevalence of the lymphoid pathotype, while systemic inflammatory markers or disease activity scores were not different. At 6 months follow-up, MC+ve patients had significantly higher rates of response to anti-TNF $\alpha$  (table 2, right).

Abstract SAT0076 – Table 1

	Early RA				Established RA			
	All (n=99)	MC- (n=32)	MC+ (n=67)	P value*	All (n=27)	MC- (n=14)	MC+ (n=13)	P value*

\*Mann-Whitney or Chi square as appropriate

**Conclusions:** We here show that early RA patients with MC+ve synovitis and high levels of local and systemic inflammation do not respond differently to synthetic DMARDs. In the context of established RA after sDMARDs failure, patients with MC+ve synovitis, despite having similar levels of systemic inflammatory markers and disease activity, had higher chances of responding to anti-TNF- $\alpha$ . Although the latter observation will need validation on larger cohorts, our data suggests that the analysis of synovial MCs might help defining synovial histopathology and possibly contribute to the prediction of treatment response.

SAT0077

#### CHANGE IN FREQUENCY OF ARTHROPLASTY SURGERY IN RHEUMATOID ARTHRITIS: A 13 YEAR POPULATION HEALTH STUDY

J.G. Hanly<sup>1</sup>, L. Lethbridge<sup>2</sup>, C. Skedgel<sup>3</sup>. <sup>1</sup>Rheumatology And Medicine; <sup>2</sup>Dalhousie University and Queen Elizabeth II Health Sciences Center; <sup>3</sup>Dalhousie University, Halifax, Canada

**Background:** Improvement in the medical management of rheumatoid arthritis (RA) over the past two decades may have reduced the need for arthroplasty surgery but the literature to date has reported inconsistent findings.

**Objectives:** To compare the annual frequency of hip, knee and other arthroplasty surgery in a prevalent cohort of RA cases and matched controls over 13 years.

**Methods:** A retrospective cohort study was performed utilising administrative healthcare data from approximately 1 million people with access to universal

healthcare between 1997 and 2010. RA cases were identified using a previously validated RA case definition in the same dataset.<sup>1</sup> Each case was matched by age and sex to 4 randomly selected controls. The annual frequency of arthroplasties in cases and controls was compared. In addition the frequency of coronary artery interventions (bypass grafting, angioplasty and stenting) was compared. Data included physician billings, hospital discharges and patient registry information using ICD-9 and ICD-10. Statistical analysis used least squares regression t-tests and 2-proportion z-tests.

**Results:** The number (prevalence) of RA cases increased from 3913 (0.42%) to 4911 (0.52%) over the study. The mean (SD) age changed from 56.7 (15.9) to 60.1 (14.9) years and the proportion of females from 70.8% to 73.9%. In both the first and last years of the study the frequency of all arthroplasty procedures was higher in cases than controls (p<0.001) (Table). Over time there was a gradual and significant reduction in arthroplasty surgery in RA cases by 51.9% (p<0.001). This was in contrast to controls in whom the frequency of procedures increased by 31.9% (p=0.002) with the exception of hip arthroplasty. For the latter procedure, the frequency decreased by 63% in RA cases (p<0.001) and 35% in controls (p=0.617). In contrast to arthroplasty procedures the frequency of cardiac procedures, which were higher in RA cases in both the first (p=0.013) and final (p=0.003) years of observation, increased in both cases and controls over time although did not reach statistical significance in either.

Abstract SAT0077 – Table 1. Demographics and surgical procedures in RA patients and controls

Demographics	1997		2010	
	RA cases	Controls	RA cases	Controls
Age (SD) in years	56.7 (15.9)	56.7 (15.9)	60.1 (14.9)	60.1 (14.9)
Female (%)	70.8	70.8	73.9	73.9
	% population undergoing procedure in 1997		% population undergoing procedure in 2010	
Surgical procedures	RA cases	Controls	RA cases	Controls
Total arthroplasties	4.78	0.47	2.30	0.62
Hip arthroplasty	1.43	0.20	0.53	0.13
Knee arthroplasty	1.74	0.13	0.81	0.27
Other arthroplasty	1.76	0.13	0.98	0.22
Cardiac procedures	0.36	0.16	0.57	0.29

**Conclusions:** There was a striking reduction in arthroplasty surgery in RA cases over 13 years of observation. Lack of similar changes in controls and sustained rates of cardiac procedures over the same time suggests that this was not due to limited surgical access for RA patients. Improvement in medical treatment of RA is likely responsible.

SAT0078

#### WHICH CDMAID STRATEGY IS MOST EFFECTIVE IN NEWLY DIAGNOSED SERONEGATIVE RHEUMATOID ARTHRITIS PATIENTS; POST-HOC ANALYSIS OF THE TREATCH STUDY

N. Luurssen-Masurel<sup>1</sup>, A. E. A. M. Weel<sup>1,2</sup>, J.M.W. Hazes<sup>1</sup>, P.H.P. de Jong<sup>1,2</sup>. <sup>1</sup>Rheumatology, Erasmus MC; <sup>2</sup>Rheumatology, Maastad Hospital, Rotterdam, Netherlands

**Background:** The disease spectrum of rheumatoid arthritis (RA) is heterogeneous. Literature suggests that these different disease subsets could be treated differently, with less aggressive treatment for rheumatoid factor and anti-citrullinated protein antibody negative RA patients ("seronegative RA"). Current treatment guidelines, however, do not take this into account since evidence is lacking. Especially, data about standardised treatment strategies in seronegative patients are needed.

**Objectives:** To compare 1 year clinical efficacy of 4 different initial treatment strategies in newly diagnosed, seronegative RA patients, according to the 2010 criteria.

**Methods:** For this post-hoc analysis data of the tREACH trial (stratified, single-blinded, randomised clinical trial) were used. Eligible patients, for the tREACH, were stratified into 3 probability tertiles (low, intermediate and high) according to their likelihood of progressing to persistent arthritis based upon the prediction model of Visser. For this analysis we selected all seronegative RA patients, of whom respectively 81% and 19% were in the intermediate and high stratum. Patients received 1 of the following 4 initial treatment strategies, which were

based upon the tREACH randomization within each stratum (figure 1): [A] triple DMARD combination therapy (MTX 25 mg/wk.+SASP 2 gr/day+HCQ 400 mg/day+GCs (intramuscular or an oral tapering scheme, starting with 15 mg/day), [B] MTX 25 mg/wk.±GCs orally starting with 15 mg/day, [C] HCQ 400 mg/day and [D] GCs orally starting with 15 mg/day. Treatment strategies were 'tightly controlled', with patients being examined every 3 months. Treatment decisions were based upon the original Disease Activity Score (DAS) threshold for low disease activity (DAS <2.4). Primary outcomes were DAS and functional ability, measured with the Health Assessment Questionnaire (HAQ), over time, using a linear mixed model (LMM). In our final model we corrected for baseline DAS and HAQ and visser score, which is a confounder by indication on forehead.

**Results:** 162 patients were grouped into treatment arms A (n=17), B (n=64), C (n=40) or D (n=41). Patients were mostly female (67%) with an average symptom duration of 161 days (95% CI: 146–175). At baseline the average visser score was 4 out of 13 (IQR 4–5). The difference in visser score was mainly due to the difference in erosions (figure 1A). Figure 1B and C show the DAS and HAQ over time per treatment arm. Our corrected LMM showed that there was no significant difference between treatment arms for DAS over time. After 3 months 56%, 38%, 35% and 69% respectively treated with A, B, C and D had an active disease (DAS ≥ 2.4), and thus needed a treatment intensification (P<0.003 for C versus D). However, after 1 year there was no difference between DAS over all treatment arms. HAQ over time did differ between treatment arms. Patients who received HCQ showed a better functional ability over time compared to patients receiving 1 of the other treatments (C versus respectively B ( $\beta = -0.18$ , p<0.000), D ( $\beta = -0.14$ , p<0.004) and A ( $\beta = -0.17$ , p<0.016)).

**Abstract SAT0078 – Figure 1.** (A) Baseline characteristics and clinical response after 12 months for each induction therapy group, according to intention-to-treat. (B) Mean DAS over time per treatment arm. (C) Mean HAQ over time per treatment arm. <sup>a</sup> Not everyone filled out a (complete) questionnaire and therefore n is different for HAQ. MTX 25 mg/wk, SASP 2 gr/day, HCQ 400 mg/day, GCs intramuscular or an oral tapering scheme starting with 15 mg/day for treatment A and only oral for treatment B+D. \* P<0.011 for C versus D. Abbreviations: DAS, Disease Activity Score; GCs, glucocorticoids; HAQ, Health Assessment Questionnaire; HCQ, hydroxychloroquine; MTX, methotrexate; RA, rheumatoid arthritis; SASP, sulfasalazine

**Conclusions:** This research supports current hypothesis that seronegative RA patients can be treated with less aggressive treatment with similar efficacy.

### SAT0079 TREATMENT EXPECTATIONS INFLUENCE BOTH SUBJECTIVE AND OBJECTIVE OUTCOME PARAMETERS IN PATIENTS WITH RHEUMATOID ARTHRITIS - A PROSPECTIVE COHORT STUDY

J. Mucke<sup>1</sup>, R. Brinks<sup>1</sup>, A. Dimitriou<sup>2</sup>, J. Richter<sup>1</sup>, M. Schneider<sup>1</sup>. <sup>1</sup>Policlinic for Rheumatology and Hiller-Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany; <sup>2</sup>Department of Rheumatology, Stadtspital Triemli, Zurich, Switzerland

**Background:** The prediction of individual response to treatment in rheumatoid arthritis (RA) is challenging and often limited. Here we evaluate the influence of patients' expectations and attitudes towards newly initiated disease-modifying anti-rheumatic drugs (DMARDs) on clinical outcome in RA.

**Methods:** 100 patients (74 female) with RA according to 2010 ACR/EULAR classification criteria with upcoming change in DMARD treatment were included. Patients' treatment beliefs, health related quality of life, treatment expectations, and pain-related cognitions were measured using *the beliefs about medicines*

*questionnaire* (BMQ), the SF-36, the *questionnaire about patient expectation* (PE), and the *pain-related self-statement scale* (PRSS), respectively before treatment initiation (T0) and their DAS28-CRP was calculated at T0 and after 4 months (T4). Associations between patients' beliefs, expectations and their attitude according to the questionnaires and changes in DAS28-CRP between T0 and T4 were explored by regression analyses using the Aikake information criterion.

**Results:** Regression analyses revealed that 42.2% of all variability in treatment response measured as a decline in DAS28-CRP ( $\Delta$ DAS28) could be explained by expectations, psychological factors and laboratory parameters assessed with the applied questionnaires. Among these we identified the expected *improvement rate* with 23.4% as well as the patients' *fear of side effects* with 22.0% as the main predictors of  $\Delta$ DAS28. The CRP-value at T0 accounted with 15% to the variability in  $\Delta$ DAS28. Other highly influential factors were PRSS *catastrophizing* scale (10.7%), the BMQ *concern* scale (8.1%), other BMQ scales (7.9%) and medications' route of administration (8.0%).

**Conclusions:** The present study indicates a high impact of patients' expectations and their attitude towards new therapies on clinical response effecting both objective and subjective outcome parameters. Integration of individual patient's preferences and their expectations in treatment decisions and management can significantly increase treatment response.

### SAT0080 SECULAR TRENDS PRIOR TO-AND AFTER DISSEMINATION OF BEST PRACTICE RECOMMENDATIONS SHOWED EARLIER INTENSIFIED MEDICATION STRATEGIES AND IMPROVED OUTCOMES IN CANADIANS WITH EARLY INFLAMMATORY ARTHRITIS

O. Schieir<sup>1</sup>, S.J. Bartlett<sup>2</sup>, M.-F. Valois<sup>3</sup>, J.E. Pope<sup>4</sup>, C. Thorne<sup>5</sup>, C. Hitchon<sup>6</sup>, B. Haraoui<sup>7</sup>, G. Boire<sup>8</sup>, D. Tin<sup>5</sup>, E.C. Keystone<sup>9</sup>, V.P. Bykerk<sup>9,10</sup> on behalf of the CATCH Investigators. <sup>1</sup>U Toronto, Toronto; <sup>2</sup>Epidemiology; <sup>3</sup>McGill University, Montreal; <sup>4</sup>U Western Ontario, London; <sup>5</sup>Southlake Regional Health Center, Newmarket; <sup>6</sup>U Winnipeg, Winnipeg; <sup>7</sup>Institute de Rhumatologie, Montreal; <sup>8</sup>U Sherbrooke, Sherbrooke; <sup>9</sup>Rheumatology, U Toronto, Toronto, Canada; <sup>10</sup>Rheumatology, Hospital for Special Surgery, New York, USA

**Background:** International and local best-practice recommendations released in 2010–11 aimed to improve outcomes in early RA via earlier diagnosis and a treat-to-target approach. These should be associated with improved outcomes.

**Objectives:** To examine secular trends in patient characteristics and treatment strategies at RA diagnosis and disease activity outcomes in the 1st year of follow-up comparing earlier (2007–2010) and later (2011–2016) time periods, prior to and following dissemination of 2011 guidelines in a large Canadian early inflammatory arthritis (EIA) cohort of RA patients.

**Methods:** Data were from patients with early classifiable (87%) or probable (13%) RA (<1 year of symptoms) enrolled each year in an ongoing prospective multi-centre cohort study between 2007–2016 with  $\geq 12$  M follow-up undergoing 3-monthly visits including clinical assessments, questionnaires, and laboratory tests in the 1st year. Treatment was decided by their rheumatologist. These were cohort investigators who met annually to discuss means to improve outcomes. Descriptive statistics compared patient characteristics, early treatment strategies with conventional synthetic(cs) and biologic(b) DMARDs and disease activity (DAS28) outcomes. Differences in DAS28 targets achieved per time period were compared using Chi-Squares and medication doses by Cochrane Hermitage trend tests.

**Results:** Of 2227 patients enrolled in CATCH (Canadian Early Arthritis Cohort), symptom duration was 6 (3) months. There was a slight increase in number recruited, education and income and slight decrease in baseline symptom duration from early to later time periods. Baseline smoking, obesity rates, comorbidities, positive serology, inflammatory markers and joint counts did not differ significantly between time periods. Baseline erosions were less frequent (17% vs. 24%, p<0.0001) and mean symptom duration decreased slightly (5.6 vs. 5.9 months, p=0.018) in earlier vs later periods. Most (87%) entered in moderate or high disease activity (MDA or HDA);disease activity at 3, 6 and 12 M markedly improved over calendar time (figure 1). Respective DAS28 REM/LDA rates at 12 M from early to late periods significantly increased (p<0.01), 20% (p<0.001) used higher doses of MTX ( $\geq 20$  mg); and more used subcutaneous (sc) MTX, MTX combo therapies sooner and more rapidly escalation to bDMARDs all p's<0.05).

Abstract SAT0080 – Figure 1. Earlier Use of High Doses of poMTX and scMTX in 2nd Time Period Resulted in More Reaching RA Treatment Targets

**Conclusions:** This 10 year Canadian prospective study of classifiable/probable RA patients, who were assessed for 1 year suggests that earlier, more intensified treatment promoted in practice recommendations were implemented and resulted in lower disease activity with a greater proportion of patients reaching targets of LDA and/or REM, although 25%–30% of patients still did not achieve LDA or REM by 12 M.

Kristensen<sup>3</sup>, L. Dreyer<sup>1,3,6</sup>. <sup>1</sup>Center for Rheumatology and Spine Diseases, Rigshospitalet- Gentofte, Copenhagen, Denmark; <sup>2</sup>Musculoskeletal Pharmaco- and Device Epidemiology, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, UK; <sup>3</sup>The Parker Institute, Bispebjerg and Frederiksberg Hospital, Frederiksberg; <sup>4</sup>Department of Orthopaedic Surgery, Copenhagen University Hospital Herlev- Gentofte, Copenhagen; <sup>5</sup>Department of Orthopaedic Surgery and Traumatology, University Hospital Odense, Odense; <sup>6</sup>Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark

**Background:** We have previously shown that the incidence rate of total knee replacements started to decrease among rheumatoid arthritis (RA) patients following the introduction of biological (b) DMARDs, but less is known on the impact of bDMARDs on the need for joint replacements (JR) of the upper limbs.

**Objectives:** To investigate the association between bDMARD introduction for the treatment of patients with RA on the trends of upper limb JR among newly diagnosed RA patients compared with a matched general population cohort (GPC) in Denmark.

**Methods:** Nationwide register-based interrupted time-series analysis using the Danish National Patient Register and Civil Registration System. **Study populations:** incident RA patients diagnosed at a rheumatology or general internal medicine clinic/department from 1996–2010. **Intervention:** introduction of bDMARDs

Abstract SAT0081 – Table 1. Changes in 5-year incidence rate of upper limb joint replacements (JR) in incident rheumatoid arthritis (RA) patients following introduction of biological DMARDs in 2002 compared with secular trends in a matched general population cohort (GPC).

Cohort	N	Mean age at start of follow-up	Females, n (%)	n JR	PYRS	Baseline incidence rate/1000 pyrs	Δ per year*	Δ in level 2003	Δ per year*	Absolute/relative Δ at midpoint in bDMARD era (mid-2006) compared with counterfactual value
RA	26 458	58.9 years	18 691 (71%)	295	1 23 814	2.65 (2.27–3.04)	-	-	-0.10 (-0.21+0.01)	-0.44 (-0.49 to -0.39)/-17%
GPC	2 57 505	58.4 years	1 82 192 (71%)	377	1,152,052	0.11 (0.04–0.17)	0.03 (0.02–0.03)	-	0.03 (0.02–0.03)	No change

in Denmark in 2002. **Comparison:** Each RA patient was matched on age, sex and municipality with up to 10 non-RA individuals (GPC). **Outcome:** Composite outcome of first shoulder, elbow, wrist, or finger replacement surgery (JR). **Statistical analyses:** 5 year age- and sex-standardised incidence rates of JR calculated for incident RA patients diagnosed biannually compared with GPCs. Outcome trends in the pre-bDMARD era (1996–2001) were compared with those in the bDMARD era (2003–2015) with a 1 year lag period in 2002.

**Results:** From 1996 to 2010, 26 458 incident RA patients were identified and compared with 257,505 GPCs (Table). The JR incidence rate was stable among RA patients in 1996–2001, but started to decrease from 2003 and onwards. Among GPCs, the incidence rate increased throughout the study period. Stepwise backward elimination to produce most parsimonious model: p-entry <0.05 and p-exit >0.2.

\* Δ per year based on biannual data. Abbreviations: pyrs, person years

**Conclusions:** Following the introduction of bDMARDs, the incidence rate of upper limb JR started to decrease among RA patients, whereas the incidence rate steadily increased from 1996–2015 among matched GPCs. The baseline incidence rate was 7-fold higher among RA patients than GPCs, but the absolute need for upper limb JR was low in both groups.

**SAT0082 OSTEOPOINTINE AND OSTEOPTROTEGRINE AS MARKERS OF ALTERED PRECLINICAL BONE METABOLISM IN RHEUMATOID FIRST DEGREE RELATIVES**

E. Soliman<sup>1</sup>, M. Zehairy<sup>2</sup>, A. Aly<sup>2</sup>, K. Mattarawy<sup>3</sup>, A. alhadiy<sup>2</sup>. <sup>1</sup>Internal Medicine, Rheumatology and Clinical Immunology; <sup>2</sup>Faculty of Medicine; <sup>3</sup>medical research, Alexandria, Egypt

**Background:** First degree relatives (FDR) of RA are known to have increased risk of developing the disease. The detection of altered bone metabolism in FDR could be a predictor of the preclinical phase of the disease.

**Objectives:** To study osteopontine (OPN) and osteoprotegrine (OPG) in FDR of RA patients as markers of altered bone metabolism in relation to clinical manifestations, inflammatory and RA seromarkers.

**Methods:** 55 persons were included, divided into 20 RA patients, 25 FDR of RA patients (without evidence of arthritis) and 10 healthy matched controls. Clinical evaluation, with emphasis on joint symptoms and signs was done for all, in addition to measurement of ESR, CRP, RF, anti-CCP, serum OPN and serum OPG.

**Results:** Mean ESR was significantly higher in RA ( $64.15 \pm 34.29$ ) than in FDR ( $15.6 \pm 11.04$ ,  $p \leq 0.001$ ) and controls ( $6.0 \pm 2.05$ ,  $p \leq 0.001$ ) and significantly higher in FDR than controls ( $p = 0.001$ ). Mean CRP was significantly higher in RA ( $26.38 \pm 29.14$ ) than FDR ( $5.99 \pm 5.08$ ,  $p \leq 0.001$ ) and controls ( $2.02 \pm 0.53$ ,  $p \leq 0.001$ ) and significantly higher in FDRs than in controls ( $p = 0.011$ ). Mean RF and anti-CCP were statistically higher in RA than in FDR and controls. Mean anti-CCP was higher in FDR than in controls but without reaching statistical significance while there was no difference regarding mean RF between FDR and controls. OPN was higher in RA ( $3.66 \pm 4.20$ ) than in FDR ( $1.97 \pm 1.04$ ) and controls ( $2.81 \pm 1.31$ ) without statistical significance ( $p = 0.102$ ). While OPG was significantly higher in RA ( $143.89 \pm 365.47$ ) than in both FDR ( $22.23 \pm 65.73$ ,  $p = 0.009$ ) and controls ( $6.20 \pm 12.43$ ,  $p = 0.003$ ). Mean serum OPN in RA was higher in RF and CCP positive ( $3.77 \pm 4.43$  and  $4.13 \pm 3.48$  respectively) than RF and CCP negative ( $2.65 \pm 0.35$  and  $3.58 \pm 2.58$  respectively) but without reaching statistical difference. Mean serum OPG in RA was higher in RF and CCP positive ( $153.15 \pm 384.64$  and  $161.78 \pm 394.67$  respectively) than RF and CCP negative ( $60.50 \pm 85.56$  and  $42.47 \pm 68.09$  respectively) but without reaching statistical difference. 8/25 (32%) FDR had arthralgia while 17/25 (68%) FDR were asymptomatic. FDRs with arthralgia had significantly higher ESR ( $27.88 \pm 11.22$ ) and CRP ( $10.36 \pm 5.21$ ) than asymptomatic FDR ( $9.82 \pm 4.13$ ,  $p = 0.003$ ) and ( $3.93 \pm 3.58$ ,  $p = 0.003$ ) respectively. OPG was higher in FDR than in controls and higher in those with arthralgia ( $51.55 \pm 114.68$ ) than those without ( $8.44 \pm 9.67$ ) but without reaching statistical difference ( $p = 0.314$ ). Similarly, serum OPN was higher in FDR with arthralgia ( $2.09 \pm 1.19$ ) than asymptomatic ( $1.70 \pm 0.55$ ) but also without significant difference ( $p = 0.620$ ). Furthermore, mean RF and anti-CCP were higher in FDR with arthralgia but didn't reach significant difference.

**Conclusions:** OPN and OPG are markers of altered bone metabolism in RA. Their elevation in FDR than controls denotes a state of altered bone metabolism. Moreover, FDR with arthralgia experience higher levels of OPN, OPG, ESR, CRP, RF, and anti-CCP than asymptomatic FDR. These findings reflect an ongoing disturbed bone metabolism and inflammation in FDR which could precede the clinical disease phase. Thus, OPN and OPG could serve as markers of altered preclinical bone metabolism in rheumatoid FDR. Results need to be confirmed on larger numbers of FDR.

Nishimura<sup>5</sup>, K. Misaki<sup>7</sup>, Y. Nobuhara<sup>3</sup>, S. Hatachi<sup>9</sup>, T. Nakazawa<sup>3</sup>, G. Tsujii<sup>2</sup>, S. Kumagai<sup>2,3</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine; <sup>2</sup>Center for Rheumatic diseases, Shinko Hospital; <sup>3</sup>Shinko Institute for Medical Research; <sup>4</sup>System Corporation, Kobe; <sup>5</sup>StaGen Co. Ltd., Tokyo; <sup>6</sup>Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Okayama; <sup>7</sup>Department of Rheumatology, Kita-Harima Medical Center, Hyogo; <sup>8</sup>Department of Rheumatology, Osaka saiseikai nakatsu hospital; <sup>9</sup>Clinical Immunology and Rheumatology, Kitano Hospital, Osaka, Japan

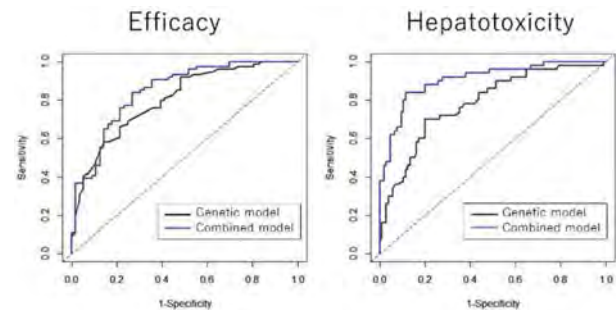

**Background:** The efficacy and toxicity of methotrexate (MTX) depend on individual patients with rheumatoid arthritis (RA) and are difficult to predict before treatment although MTX is the anchor drug and achieving the treatment target earlier is desirable to prevent progression of structural and functional damage. Our previous studies revealed high predictive accuracy of single nucleotide polymorphisms (SNPs) to predict the efficacy and toxicity of MTX, suggesting the influence of genetic variations in enzymes associated with MTX metabolism and folate metabolic pathway<sup>1,2</sup>. However, higher accuracy and replicability is demanded for clinical application.

**Objectives:** To develop combined genetic and clinical models to predict the efficacy and hepatotoxicity of MTX.

**Methods:** Patients with RA under the treatment of MTX according to Japanese guideline for the management of RA with MTX were enrolled. To predict the efficacy and hepatotoxicity, 1971 polymorphisms of 246 enzymes/transporters potentially relevant to pharmacokinetics and pharmacodynamics of MTX were measured by the DMET microarray (Affymetrix Inc.) and direct-sequencing method and clinical variables at baseline were collected. As for efficacy, the EULAR-CRP response criteria was chosen to classify patients with RA as responders (good response) and non-responders (moderate or no response). Hepatotoxicity was defined as either serum AST or ALT levels higher than 1.5 times the upper limit of the normal range. Among SNPs and clinical variables with significant association with outcomes using univariate analyses, stepwise model selection

was conducted by Akaike information criterion in logistic regression model and receiver operating characteristic (ROC) analyses were performed. Bootstrapping ( $n = 100,000$ ) was used to assess the robustness of the results.

**Results:** A total of 166 patients with RA was included. The median age was 61.5 years with 81.3% of women. For efficacy, genetic prediction model using 7 SNPs showed area under the curve of ROC (AUC) was 0.822 with sensitivity of 74.3% and specificity of 76.8%, while combined clinical and genetic model indicated AUC was 0.844 with sensitivity of 81.5% and specificity of 76.9%. By incorporating clinical variables into the genetic model, overall category-free net reclassification improvement (NRI) was 0.700 ( $p < 0.0001$ ) and overall integrated discrimination improvement (IDI) was 0.089 ( $p = 0.0005$ ). For hepatotoxicity, genetic prediction model using 7 SNPs showed AUC was 0.783 with sensitivity of 70.0% and specificity of 80.0%, while combined clinical and genetic model indicated AUC was 0.906 with sensitivity of 85.1% and specificity of 87.8%. Overall category-free NRI was 1.122 ( $p < 0.0001$ ) and overall IDI was 0.279 ( $p < 0.0001$ ).

**Conclusions:** Genetic and clinical models showed higher predictive accuracy for both efficacy and hepatotoxicity of MTX. These models should be validated with a larger scale of prospective study.

### ANTI-CARBAMYLATED PROTEIN ANTIBODIES AS POTENTIAL BIOMARKERS OF DISEASE ACTIVITY IN EARLY ARTHRITIS PATIENTS

A. Gonzalez<sup>1</sup>, C. Regueiro<sup>1</sup>, A.M. Ortiz<sup>2</sup>, L. Nuño<sup>3</sup>, D. Peiteado<sup>3</sup>, A. Villalba<sup>3</sup>, D. Pascual-Salcedo<sup>3</sup>, A. Martinez-Feito<sup>3</sup>, A. Balsa<sup>3</sup>, I. Gonzalez-Alvaro<sup>2</sup>. <sup>1</sup>Instituto Investigación Sanitaria- H. Clínico Universitario de Santiago, Santiago de Compostela; <sup>2</sup>Hospital Universitario La Princesa. IIS-IP; <sup>3</sup>Instituto de Investigación del Hospital de La Paz (IDIPAZ), Madrid, Spain

**Background:** It has become increasingly clear that appropriate initial management of rheumatoid arthritis (RA) increases the chances of success and improves long-term prognosis. Therefore, rheumatologists need prognostic biomarkers to select patients requiring aggressive management. It is possible that anti-carbamylated protein antibodies (anti-CarPA) may serve as such biomarkers because they are associated with erosions and their progression, and with mortality in some studies. Recently, the possibility that they are also associated with disease activity in early arthritis (EA) has been examined by several studies with discordant results.

**Objectives:** We aimed to explore the relationship between variation in disease activity and anti-CarPA in EA patients.

**Methods:** EA patients from two prospective clinics, Hospital Universitario La Paz ( $n = 492$ ) and Hospital Universitario La Princesa ( $n = 501$ ), were included. DAS28 was available at baseline and at months 6 (M6), 12 (M12) and 24 (M24) of follow-up. Anti-CarPA were determined in baseline serum samples by ELISA using *in vitro* carbamylated fetal calf serum. Student t test and main effects general linear regression were used for analysis.

**Results:** The 27.4% of EA patients that were positive for anti-CarPA showed higher DAS28 at baseline than the negative patients ( $4.93$  vs  $4.31$ ,  $p = 1.6 \times 10^{-5}$ ). The difference persisted at all visits during follow-up ( $3.60$  vs  $3.19$  at M6;  $3.47$  vs  $3.09$  at M12; and  $3.31$  vs  $2.79$  at M24; all with  $p \leq 0.001$ ). These differences were independent of patient sex and age, smoking, time since symptoms onset, the specific EA clinic and the year of onset. In addition, they persisted after accounting for the presence of RF or ACPA at baseline ( $p = 1.3 \times 10^{-5}$ , and  $p = 5.7 \times 10^{-5}$ , respectively) and at later visits ( $p < 0.05$  for all analyses). Analysis of the relation

between anti-CarPA and  $\Delta$ DAS28 showed association only with  $\Delta$ DAS28 from baseline to M6 ( $p=0.005$ ). In this period, the positive patients showed less decrease of DAS28 than the negative patients. This was independent of all the variables mentioned above and of the initial DAS28. As a result of this association, 20.5% of the anti-CarPA positive patients reached remission at M6, in comparison with 34.6% of the negative patients. In contrast,  $\Delta$ DAS28 from M6 to M12 and from M12 to M24 were small and not associated with anti-CarPA.

**Conclusions:** Anti-CarPA were associated with high disease activity at presentation and with less improvement in the first 6 months of follow-up in EA patients. These results reinforce the possibility that anti-CarPA could be useful in the clinic as prognostic biomarkers.

**SAT0085 RELATIONSHIP BETWEEN SERUM CALPROTECTIN, DISEASE ACTIVITY PARAMETERS AND THE 7-JOINT ULTRASOUND SCORE IN RHEUMATOID ARTHRITIS**

M. Torgutalp<sup>1</sup>, A.B. Kelesoglu Dincer<sup>1</sup>, E.M. Yayla<sup>1</sup>, E. Uslu Yurteri<sup>1</sup>, E.I. Okatan<sup>1</sup>, G.E. Aydemir Guloksuz<sup>1</sup>, S. Serdar<sup>1</sup>, U. Ebru<sup>2</sup>, G. Kiriikli<sup>1</sup>, M.T. Turgay<sup>1</sup>, A. Atas<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Microbiology, Ankara University Faculty of Medicine, Ankara, Turkey

**Background:** Calprotectin may be a sensitive biomarker of rheumatoid arthritis (RA) disease activity.

**Objectives:** In this study we aimed to investigate whether calprotectin is a better biomarker than known inflammation markers for predicting clinical activity and ultrasound parameters in patients with RA.

**Methods:** A total of 80 RA patients were underwent to clinical (swollen joint count, tender jointcount, disease activity score-DAS28, simplified disease activity index-SDAI and clinical disease activity index-CDAI) and ultrasound (German US7) examination. Correlation of clinical, laboratory and ultrasound measures were analyzed using Spearman's correlation coefficient. The RA patients were divided into two subgroups according to their DAS28-ESR (erythrocyte sedimentation rate) score; group 1 (DAS-28  $\leq$ 3.2 remission and low activity), group 2 (DAS28  $>$ 3.2 moderate and high activity), respectively. Thirty healthy controls were simultaneously studied.

**Results:** The serum calprotectin levels of the RA patients were significantly higher than those of healthy controls (96.3 $\pm$ 45.9, 54.7 $\pm$ 50.0, respectively;  $p<0.001$ ). Distribution of age (years; 57.2 $\pm$ 9.6, 53.9 $\pm$ 10.5, respectively;  $p=0.115$ ) and sex (female; 78.8%, 70%, respectively,  $p=0.336$ ) between these groups were similar. The clinical, laboratory and ultrasound characteristics of the patients are shown in table 1. The calprotectin levels were 74.8 $\pm$ 45.5 in group 1 ( $n=37$ ) and 114.7 $\pm$ 37.9 in group 2 ( $n=43$ ) ( $p<0.001$ ). The association between calprotectin and scores of DAS28-ESR are shown in figure 1A. Serum calprotectin was significantly associated with DAS28-ESR, DAS28-CRP (C-reactive protein), SDAI, CDAI, ESR, CRP and US7 parameters. We also found a moderate to strong correlation of US7 score with DAS28-ESR, DAS28-CRP, SDAI, CDAI, CRP and ESR (table 2). The correlation between calprotectin and US7 is shown in figure 1B.

**Abstract SAT0085 – Table 1.** Baseline characteristics of patients with RA

	Group 1 (n=37)	Group 2 (n=43)	p

**Abstract SAT0085 – Figure 1.** A Box plots between calprotectin and DAS28-ESR B. Correlation graph between calprotectin and US7 score

**Conclusions:** The results of our study support an additional role of calprotectin in assessing inflammatory activity in patients with RA. Therefore, the combination of serum calprotectin levels and the US7 score could be a simple and practical assessment approach for detection of RA disease activity.

**SAT0086 EVALUATION OF DIAGNOSTIC PERFORMANCE OF MAGNETIC RESONANCE IMAGING (MRI) AND ULTRASOUND (US) TOWARD EARLY RHEUMATOID ARTHRITIS FROM NAGASAKI EARLY ARTHRITIS COHORT**

A. Takatani<sup>1</sup>, M. Tamai<sup>1</sup>, N. Ohki<sup>2</sup>, Y. Nakashima<sup>1</sup>, Y. Endo<sup>1</sup>, S. Tsuji<sup>1</sup>, T. Shimizu<sup>1</sup>, M. Umeda<sup>1</sup>, S. Fukui<sup>1</sup>, R. Sumiyoshi<sup>1</sup>, A. Nishino<sup>1</sup>, T. Koga<sup>1</sup>, S.-Y. Kawashiri<sup>1</sup>, N. Iwamoto<sup>1</sup>, T. Igawa<sup>1</sup>, K. Ichinose<sup>1</sup>, K. Arima<sup>3</sup>, H. Nakamura<sup>1</sup>, T. Origuchi<sup>1</sup>, S. Sato<sup>4</sup>, M. Uetani<sup>2</sup>, A. Kawakami<sup>1</sup>.  
<sup>1</sup>Department of Immunology and Rheumatology; <sup>2</sup>Department of Radiological Sciences; <sup>3</sup>Department of Public Health, Nagasaki University Graduate School of Biomedical Sciences; <sup>4</sup>Clinical Research Center, Nagasaki University Hospital, Nagasaki, Japan

**Background:** We previously reported that the presence of autoantibodies, magnetic resonance imaging (MRI) bone oedema, ultrasound (US) power Doppler (PD)  $\geq$  grade 2 articular synovitis are indispensable markers to predict the development of RA from undifferentiated arthritis whereas combination analysis used by the above variables, focusing on very early phase of arthritis, remains to be done in our cohort.

**Objectives:** To investigate and re-confirm the diagnostic performance of autoantibodies, MRI findings and US findings toward early RA from NAGASAKI EARLY ARTHRITIS COHORT.

**Methods:** One hundred and three patients, suffering arthralgia less than 6 months and examined by both MRI and US of wrist and finger joints, were selected from NAGASAKI EARLY ARTHRITIS COHORT dating from September 2009 to August 2017. US were evaluated by synovitis score of semi-quantitative manner by gray-scale (GS) and power Doppler (PD) proposed from EULAR. In MRI, synovitis, bone oedema and bone erosion were assessed by the Rheumatoid Arthritis Magnetic Resonance Imaging Scoring system (RAMRIS). After univariate analysis, multivariate analysis was employed to clarify the diagnostic predictors of early RA.

	odds ratio	95% confidence interval	p-value
ACPA titer	1.05	1.01-1.08	0.0069
PD $\geq$ grade 2	17.43	5.15-59.06	0.00025

**Results:** Median of age was 60 years and that of symptomatic duration was 2 months. Female was 68.9%, positive rate of RF was 64.7% and that of ACPA was 47.1%. Total GS score was 4.0, total PD score 2.0, MRI synovitis score 3.0, MRI bone oedema score 0, MRI bone erosion score 0. Seventy patients were diagnosed as early RA during follow-up periods. A univariate analysis showed ACPA, CRP, MMP-3, fulfilment of 2010 ACR/EULAR criteria, MRI synovitis score, MRI bone oedema score, total GS score, total PD score and PD  $\geq$  grade 2 articular synovitis were associated with early RA. Multivariate analysis revealed ACPA and PD  $\geq$  grade 2 articular synovitis at any joints were independent predictors toward diagnosis of early RA.

**Conclusions:** Our present study re-confirms the importance of ACPA, PD  $\geq$  grade 2 articular synovitis and MRI bone oedema, especially the former two, to predict the development of early RA from undifferentiated arthritis patients.

SAT0089

### INITIATING TOFACITINIB IN A TREAT TO TARGET STRATEGY FOR RHEUMATOID ARTHRITIS LEADS TO BLUNTED MULTI-BIOMARKER DISEASE ACTIVITY SCORES AS COMPARED TO ANTI-TUMOUR NECROSIS FACTOR AGENTS

C. Wiesenhuber<sup>1,2</sup>, <sup>1</sup>School of Medicine, University Of Washington, Seattle; <sup>2</sup>Coeur d'Alene Arthritis Clinic, Coeur d'Alene, USA

**Background:** The use of a treat-to-target (T2T) strategy for the management of rheumatoid arthritis (RA) leads to better outcomes<sup>1</sup> but requires the regular use of disease activity measures (DAMs) to make clinical decisions. The optimal DAMs that should be used for this purpose have yet to be determined.

**Objectives:** To assess the utility of various DAMs for clinical decision making at a rheumatology clinic implementing a T2T strategy, following the initiation of Tofacitinib (tofc) and anti-tumour necrosis factor (anti-TNFs) agents.

**Methods:** Patients at a community based rheumatology clinic (authors) undergo DAM assessments on a routine basis as part of the implementation of a T2T strategy. These assessments include conventional clinical assessments, DAS28CRP, and the CDAI, as well as the ultrasound power Doppler joint count (UPDJC)<sup>2</sup> and multi-biomarker disease activity score (MBDA). Patients undergo regular assessments, and if found to be under inadequate control, changes are made in their clinical regimen, and then the patients are reassessed three to six months later. Clinical significance was determined by Paired-samples T tests.

**Results:**

	Before			After			
	N	DAS28CRP ±SD	Avg ±SD	DAS28CRP ±SD	Avg ±SD	% Change	Prob
Tofacitinib	39	4.90	±1.00	3.78	±1.20	23%	p<0.001
Anti-TNFs	40	5.07	±1.08	4.09	±1.01	19%	p<0.001
		CDAI		CDAI			
Tofacitinib	37	29.7	±11.1	17.6	±12.1	41%	p<0.001
Anti-TNFs	40	29.9	±11.8	21.4	±12.4	28%	p=0.001
		UPDJC		UPDJC			
Tofacitinib	37	8.9	±4.0	7.0	±3.9	21%	p=0.002
Anti-TNFs	38	9.3	±4.5	7.3	±3.1	22%	p=0.03
		MBDA		MBDA			
Tofacitinib	37	48.1	±12.2	44.3	±10.4	7%	NCS
Anti-TNFs	38	50.0	±11.0	39.3	±10.9	21%	p<0.001

Over the past four years, Thirty nine patients at this clinic were determined to be under inadequate control and were started on tofc. Also, the last forty patients started on anti-TNFs at the clinic were assessed for comparison. The two groups of patients had similar demographics with a combined average duration of clinical disease found to be >10 years. Sixty eight% of these patients were female, and 85% of patients were rheumatoid factor positive.

Table I shows that all of the DAMs listed resulted in significant clinical responses with the exception that following the institution of tofc, the MBDA did not result in clinically significant improvement. When individual biomarkers from the MBDA were analysed, anti-TNFs therapy lead to significant reduction in six of twelve biomarkers (IL-6, TNF-R1, TNF-R2, MMP-2, SSA and CRP) whereas treatment with tofc lead to significant reduction of two (VCAM and Resistin) and borderline reduction in two (IL-6 and TNF-R1) and a significant increase in one (Leptin).

**Conclusions:** Several DAMs performed well with the exception of the MBDA after tofc therapy. The MBDA showed a blunted response when compared to other DAMs in the tofc treated group, as well as when compared to patients treated with anti-TNFs. This finding is most likely due to tofc's unique mode of action, as reflected in the relatively small number of biomarkers that decreased following treatment, and the fact that leptin significantly increased.

### EVALUATION OF THE USE OF ULTRASOUND TO MANAGE PATIENTS WITH RHEUMATOID ARTHRITIS OVER TIME: RESULTS FROM THE CORRONA REGISTRY

D.A. Pappas<sup>1</sup>, K.C. Saunders<sup>2</sup>, C.J. Etzel<sup>2</sup>, D.W. Hua<sup>2</sup>, K. Deering<sup>3</sup>, P. Zueger<sup>4</sup>, V. Garg<sup>4</sup>, <sup>1</sup>Columbia University, New York; <sup>2</sup>Corrona, LLC, Waltham; <sup>3</sup>Epi-Q, Inc., Oak Brook; <sup>4</sup>AbbVie Inc., North Chicago, USA

**Background:** Musculoskeletal ultrasound (MSUS) imaging in patients with rheumatoid arthritis (RA) can detect synovial inflammation with higher sensitivity compared to physical examination alone.<sup>1</sup> Not all rheumatologists have adopted the use of MSUS in their daily practice.

**Objectives:** To compare clinical outcomes in patients whose physicians use MSUS to assess joint inflammation vs those who do not.

**Methods:** Data from patients  $\geq$ 18 years old with a confirmed diagnosis of RA who had an index visit in the Corrona RA Registry from 01/01/2012 to 12/31/2015 with  $\geq$ 12 months of follow-up were stratified into 2 groups: patients whose physicians use MSUS frequently—ie, in >50% of their patient encounters—(MSUS group) and patients whose physicians do not use MSUS at all (No-MSUS group). Frequency of MSUS can be recorded and updated by the rheumatologist in the registry questionnaires at every Corrona visit. The index visit was the first visit in which the physician reported the frequency of MSUS use. Outcomes included mean Clinical Disease Activity Index (CDAI) and the proportion of patients in low disease activity (LDA)/remission (CDAI  $\leq$ 10) at each time point and were evaluated at index and 1, 2, and 3 years post-index. Comparisons between groups were made using 2-sample *t*-tests for mean CDAI and Chi-square tests for achievement of LDA/remission.

**Results:** 21 physicians reported using MSUS frequently compared with 111 who did not use MSUS at all. 5446 of their patients met the criteria for analysis; 1018 (18.7%) were in the MSUS group and 4428 (81.3%) were in the No-MSUS group. At the index visit, the MSUS group was younger (mean age 57.7 years vs 59.8 years,  $p<0.01$ ) and had shorter disease duration (mean 8.7 years vs 11.0 years,  $p<0.01$ ) compared with the No-MSUS group. At the index visit, the MSUS group had lower mean CDAI (9.7 vs 12.6,  $p<0.01$ ) and a greater proportion of patients in LDA/remission (64.9% vs 56.8%,  $p<0.01$ ) compared with the No-MSUS group; these differences were also present at 1, 2, and 3 years post-index (figure 1).

**Conclusions:** A greater percentage of patients whose physicians use MSUS were in LDA/remission over time. Average disease activity of these patients was lower compared with patients whose physicians did not use MSUS. This pattern was observed at 4 different time points over a 3 year period.

SAT0091

### CLINICAL REMISSION PREDICTION USING BASELINE GENE EXPRESSION IN THE PERIPHERAL BLOOD OF DMARD-NAÏVE RHEUMATOID ARTHRITIS PATIENTS TREATED WITH METHOTREXATE

E.V. Tchetina<sup>1</sup>, N.V. Demidova<sup>2</sup>, G.A. Markova<sup>1</sup>. <sup>1</sup>Immunology and Molecular Biology; <sup>2</sup>Early Arthritis, Nasonova Research Institute Of Rheumatology, Moscow, Russian Federation

**Background:** Rheumatoid arthritis (RA) is an autoimmune disease of unknown etiology, which is characterised by erosive arthritis (synovitis) and systemic inflammation. Methotrexate (MTX) is a basic drug for RA treatment. However, presently it is not possible to predict MTX efficacy in every patient while some patients are non-responsive to MTX or the drug may induce adverse effects. Therefore, identification of patients sensitive to MTX before treatment could significantly improve therapy outcome.

**Objectives:** To investigate the importance of baseline expression of genes involved in the metabolic and energy generation pathways in RA patients, which could serve prognostic biomarkers of treatment response to methotrexate.

**Methods:** Peripheral blood of 40 DMARD-naïve RA patients aged 47.5±15.5 years old, disease duration 7.9±6.0 weeks treated with MTX (15 mg/week) during two years and 26 healthy age-matched control subjects were examined. Clinical response was assessed by disease activity score (DAS) 28, serum levels of ACPA antibodies, C-reactive protein (CRP), and rheumatoid factor (RF). Clinical remission was assessed according to ACR criteria and DAS28 (DAS28 <2.6). Bone erosion and joint space narrowing (JSN) scores were monitored by X-ray analysis. Protein concentrations were measured using ELISAs. Total RNA was isolated and used in gene expression studies performed with quantitative real-time RT-PCR.

**Results:** MTX treatment significantly decreased the disease activity according to DAS28. At the end of the study the majority of patients demonstrated moderate disease activity (DAS28 >3.2 <5.1), four patients retained high disease activity while 12, attained remission (DAS28 <2.6). Gene expression analysis has revealed that RA patients, which attained clinical remission after MTX treatment demonstrated significantly higher baseline expression of genes associated with glycolysis (Glut1, PKM), hypoxia (HIF1 $\alpha$ ), and cell cycle related cyclin D1 compared to other examined RA patients and healthy subjects. RA patients, which retained high disease activity after treatment had baseline expression of genes related to apoptosis (p21, caspase 3), tissue regeneration (TGF $\beta$ 1, RUNX2) and cyclin D1, significantly lower than that in the controls and other examined RA patients.

**Conclusions:** Clinical remission attainment in DMARD-naïve RA patients treated with methotrexate is associated with high baseline expression of genes associated with glycolysis, hypoxia and cyclin D1 compared to other examined patients. Non-responsiveness to MTX is accompanied by lower baseline expression of genes related to apoptosis, tissue regeneration, and cyclin D1 compared to controls. Increased baseline expression of cyclin D1 gene compared to healthy subjects could serve a positive prognostic marker of sensitivity to methotrexate therapy.

SAT0092

### PALINDROMIC RHEUMATISM (PR): EXPERIENCE IN A REAL WORLD SETTING – THE NOTTINGHAM CASEMIX REGISTER (NCR)

F. Kynaston-Pearson<sup>1,2</sup>, I. Pande<sup>2</sup>, I. Gaywood<sup>2</sup>. <sup>1</sup>Rheumatology, Royal Derby Hospital, Derby; <sup>2</sup>Rheumatology, Queens Medical Centre, Nottingham, UK

**Background:** PR is an unusual arthritis characterised by brief, self-limiting attacks of synovitis usually affecting one joint at a time with outcomes including transformation to persistent inflammatory rheumatic disease, usually rheumatoid arthritis (RA), continuation of PR and spontaneous remission. Seropositivity for rheumatoid factor (RF) or ACPA may predict transformation to RA. We examined the experience of PR in a large UK teaching hospital rheumatology department using data collected routinely at outpatient encounters. The NCR records a primary rheumatology diagnosis, demographic data, administrative details (type of consultation, grade of clinician and outcome) for every rheumatology consultation. Between March 2016 and February 2017 19 832 clinical encounters were logged forming the basis of this study.

**Objectives:** To identify the burden of PR in a large UK teaching hospital and its management in a real world setting.

**Methods:** PR patients were extracted from the NCR and their electronic record (Bloods/Radiology/Clinic letters) analysed for any change in diagnosis (prior to or following PR diagnosis), treatments prescribed, serological status and radiological findings. In the subgroup whose diagnosis changed, a separate analysis to look at predictive factors was carried out.

**Results:** 101 patients (149 attendances) were analysed (24 new patient appointments, 125 follow ups). The female:male ratio was 2.16, mean age 53.5. Over half were between 40–59. 31 new diagnoses of PR were made in the study period. The NCR prevalence of PR was 1%. Duration of PR in previously diagnosed patients was a mean of 4 years. The diagnosis was changed in 13 PR patients (to RA in 9). Serological status is shown below:

Status	RhF	ACPA	Dual Rhf/ACPA
Positive	53	48	43
Borderline	7	3	NA
Negative	37	39	27
Not known	4	11	13

Plain radiographs were available for 88 patients (hands- 69, feet- 54). Erosions were noted once (RA was then diagnosed). Synovitis was detected in 10 of 25 patients who underwent ultrasound and in 2 of 18 patients who underwent small joint MRI. 63 patients were on DMARDs, most often HCQ.<sup>4,3</sup> 9 received dual DMARD therapy. DMARD therapy was more frequent in sero-positive patients. PR patients later diagnosed as RA were older (64.9 vs 53.5 years) and more commonly seropositive (6 being dual antibody positive) with similar gender ratio (2:1 F:M). The duration of PR diagnosis ranged from 6 months to 10 years (average 4.2).

Duration of PR prior to new Diagnosis	Change to RA	Change to other diagnosis
Less than 1 year	1	2
1–2 years	2	1
2–5 years	3	1
>5 years	3	0

Abstract SAT0092 – Figure 1. PR patients by age

**Conclusions:** PR accounted for 1% of all patients on the NCR with 10% of patient's having their diagnosis changed in the study period. RA patients on the NCR numbered 2292, making the RA:PR ratio 22.7:1. Approximately half of PR patients were RF/ACPA positive or both with over half the PR population on DMARD treatment, most often HCQ. PR patients developing RA were older and ACPA/RF positivity was more common. Although a third PR patients who later developed RA did so within 2 years, the majority took longer with some diagnosed as RA over 5 years later suggesting PR patients, especially if seropositive, should be followed long term. Two year follow up will be available from March 2018.

### MALE SEX PREDICTS A FAVOURABLE OUTCOME IN SERONEGATIVE EARLY RHEUMATOID ARTHRITIS

G. Cagnotto<sup>1,2</sup>, E. Rydell<sup>2,3</sup>, L. Jacobsson<sup>4</sup>, C. Turesson<sup>2,3</sup>. <sup>1</sup>Rheumatology, Skåne University Hospital, Lund; <sup>2</sup>Rheumatology, Department of Clinical Sciences, Malmö, Lund University; <sup>3</sup>Rheumatology, Skåne University Hospital, Malmö; <sup>4</sup>Rheumatology and Inflammation Research, Sahlgrenska Academy at Gothenburg University, Gothenburg, Sweden

**Background:** Rheumatoid factor (RF) and anti-citrullinated peptides antibodies (anti-CCP) are universally recognised negative prognostic factors in rheumatoid arthritis (RA). The majority of studies of early RA have focused on RF and anti-

CCP positive patients. Much less is known about prognostic markers in seronegative RA. Several studies report worse drug survival and worse patient reported outcomes in women with RA. This affects outcomes such as the 28-joint disease activity score (DAS28) and the health assessment questionnaire (HAQ). How these differences relate to autoantibody status is unknown.

**Objectives:** To investigate if the relation between sex and clinical outcomes varies by autoantibody status in patients with early RA.

**Methods:** An inception cohort of patients with early RA (n=233; symptoms duration ≤12 months), recruited in 1995–2005, was studied. All the patients fulfilled the 1987 American College of Rheumatology criteria for RA. The patients were managed according to usual care, with no pre-specified protocol for pharmacotherapy or rehabilitation. In a structured follow-up program, all patients were examined by the same rheumatologist. In the present study we divided the patient population in three groups according to autoantibodies status: RF and anti-CCP seropositive (double positive), RF or anti-CCP seropositive, RF and anti-CCP seronegative (double negative). We examined the relation between sex and different outcomes at 12 months (EULAR good response, clinical remission (DAS28 <2.6), HAQ≤0.5 and low pain score (VAS pain 0–100 of <20) by means of logistic regression.

**Results:** Complete data on autoantibody status at baseline was available for 201 patients (mean age at inclusion 61 years, 72% female, 60% RF positive and 58% anti-CCP positive). Twenty-eight% of the patients were double negative, 27% were single positive and 45% were double positive. Mean baseline DAS28 was 4.53. All patients were treated with a conventional synthetic DMARD (48% with methotrexate). Oral glucocorticoids were prescribed in 38% of patients. At the 1 year follow up, 19% had a EULAR good response, 21% were in remission, 40% had low pain and 53% low HAQ. Male patients in the double negative group were more likely to reach remission (odds ratio (OR) 6.40; 95% confidence interval (CI) 1.6–26.2) and EULAR good response (OR 4.67; 95% CI 1.2–18.3) compared to females. There were no such associations among the double positive patients (Table). Results were similar in analyses adjusted for DAS28 at baseline (Table). There was a similar pattern among double negative patients for low pain at 1 year (OR for male vs female patients 2.25; 95% CI 0.58–8.67 – adjusted for baseline pain), but no association between male sex and low HAQ at 1 year in double negative patients (OR 0.99; 95% CI 0.23–4.22 – adjusted for baseline HAQ) or the other subgroups.

#### Abstract SAT0093 – Table 1

Impact of sex on the chance of EULAR good response and clinical remission at the 1-year follow-up in patients with early RA. Logistic regression analysis.

	Sex	EULAR good response OR (95% CI)		Clinical remission* OR (95% CI)	
		Crude	Adjusted for baseline DAS28	Crude	Adjusted for baseline DAS28
All	Female (n=144)	(reference)	(reference)	(reference)	(reference)
	Male (n=57)	1.9 (0.9-3.7)	1.9 (0.9-3.7)	2.0 (1.0-3.9)	2.1 (1.0-4.1)
RF and anti-CCP negative	Female (n=42)	(reference)	(reference)	(reference)	(reference)
	Male (n=14)	4.7 (1.2-18.3)	6.0 (1.3-26.4)	6.4 (1.6-26.2)	6.3 (1.5-25.9)
RF or anti-CCP positive	Female (n=41)	(reference)	(reference)	(reference)	(reference)
	Male (n=13)	3.2 (0.6-17.2)	3.4 (0.6-20.6)	3.8 (0.8-17.7)	2.1 (0.3-12.3)
RF and anti-CCP positive	Female (n=61)	(reference)	(reference)	(reference)	(reference)
	Male (n=30)	1.3 (0.4-4.5)	1.2 (0.3-4.2)	0.9 (0.3-2.9)	1.1 (0.3-3.7)

\*DAS28 <2.6

**Conclusions:** In the subgroup of patients with seronegative early RA, male patients are more likely than female patients to reach DAS28 remission and EULAR Good Response after treatment with conventional synthetic DMARDs.

#### SAT0087 ASSOCIATION OF BIOMETRICS WITH DISEASE CHARACTERISTICS AND SYNOVIAL PHENOTYPE IN INFLAMMATORY ARTHRITIS

C. Low, R. Conway, F. Young, K. Murray, H. Convery, M. Biniecka, U. Fearon, D. Veale. Centre for Arthritis and Rheumatic Disease, St. Vincent's University Hospital, Dublin Academic Medical Centre, Elm Park, Dublin 4, Ireland, Dublin, Ireland

**Background:** The potential importance of altered body composition in the development of and disease course in inflammatory arthritis is increasingly being recognised. Body composition in different types of inflammatory arthritis and its influence on synovial pathology remains to be fully characterised.

**Objectives:** To evaluate body composition in seropositive and seronegative rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients and assess associations with disease characteristics and baseline synovial arthroscopic findings.

**Methods:** We performed a prospective observational study of consecutive inflammatory arthritis patients seen in outpatient clinics. Demographic and clinical characteristics were collected on all patients. Synovial biopsy was performed by needle arthroscopy, and macroscopic and histologic features recorded. The degree of synovitis and vascularity were recorded on a 0–100 mm visual analogue scale, and chondropathy on a semi-quantitative scale from 0–3. Mann-Whitney U test was used to compare groups. Spearman's Rank Correlation Coefficient was used to assess for associations between biometrics and demographic and clinical markers. GraphPad Prism Version 7 and IBM SPSS Statistics Version 24 were used for data analysis.

**Results:** We included 58 patients, 32 with seropositive RA, 10 with seronegative RA, and 16 with PsA. 37 (64%) were female. Mean (SD) age was 52.8 (13.9) years. Mean (SD) BMI was 29.7 (6.3) kg/m<sup>2</sup>, waist circumference was 94.4 (20.3) cm, and hip circumference 104.3 (21) cm. Full demographic and clinical details are shown in table 1. Seronegative RA patients had significantly increased BMI (p=0.033) and waist circumference (p=0.017), but not hip circumference (p=0.248) compared to seropositive RA patients. PsA patients had significantly increased BMI (p<0.001), waist circumference (p=0.001), and hip circumference (p<0.001) compared to seropositive but not seronegative RA patients. There was a significant correlation between waist circumference and both synovitis (r=0.31, p=0.018) and vascularity (r=0.34, p=0.010) at arthroscopy. BMI and hip circumference did not correlate with arthroscopic findings.

	Seropositive RA	Seronegative RA	PsA
Female, n (%)	18 (56.3)	7 (70)	12 (75)
Age, mean (SD), years	55.9 (14.6)	46.7 (15.8)	50.6 (9.6)
Rheumatoid Factor+, n (%)	31 (96.9)	0 (0)	3 (18.8)
ACPA+, n (%)	24 (75)	0 (0)	2 (12.5)
BMI, mean (SD), kg/m <sup>2</sup>	26.9 (4.8)	31.9 (7.1)	34.0 (5.8)
Waist circumference, mean (SD), cm	86.4 (20.4)	101.3 (16.3)	105.9 (15.4)
Hip circumference, mean (SD), cm	98.4 (23.9)	105.8 (16.4)	115.4 (11.1)
CRP, mean (SD), mg/L	12.8 (17.8)	18.6 (27.1)	7.5 (6.0)
ESR, mean (SD), mm/hr	28.2 (24.5)	18.9 (19.7)	17.5 (8.8)
Swollen Joint Count, mean (SD)	4.1 (5.0)	2.4 (3.1)	3.2 (6.1)
Tender Joint Count, mean (SD)	6.2 (6.8)	7.5 (7.5)	4.4 (7.1)
VAS general health, mean (SD), mm	49.1 (31.0)	51.3 (21.3)	49.1 (25.2)
DAS28-CRP, mean (SD)	3.91 (1.54)	3.98 (0.94)	3.6 (1.4)
Synovitis, mean (SD), mm	65.3 (20.3)	60.0 (14.1)	75.0 (12.6)
Vascularity, mean (SD), mm	62.5 (19.8)	58.0 (17.5)	75.0 (13.2)
Chondropathy, mean (SD)	1.6 (0.7)	1.4 (0.6)	1.5 (0.7)

**Conclusions:** Different types of inflammatory arthritis have distinct body composition profiles. Waist circumference, but not other biometrics, correlates with baseline synovial inflammation and vascularity.

#### SAT0088 PREDICTIVE FACTORS FOR INTERSTITIAL LUNG DISEASE PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A ROLE FOR BIOLOGICAL INFLAMMATION AND DISEASE MODIFIED ANTI RHEUMATIC DRUGS (DMARDs)

C. Lucas<sup>1</sup>, S. Jouneau<sup>2</sup>, M. Lederlin<sup>3</sup>, S. Guillot<sup>4</sup>, C. Salliot<sup>5</sup>, L. Joffres<sup>6</sup>, E. Solau-Gervais<sup>9</sup>, M. Herbette<sup>7</sup>, A. Saraux<sup>7</sup>, J.-B. Cren<sup>8</sup>, B. Bouvard<sup>8</sup>, J.-D. Albert<sup>1</sup>, G. Coiffier<sup>1</sup>, P. Guggenbuhl<sup>1</sup>, A. Perdriger<sup>1</sup>. <sup>1</sup>Rheumatology department, University Hospital Center, <sup>2</sup>Pneumology department, University Hospital Center, <sup>3</sup>Radiology department, <sup>4</sup>Pneumology department, University Hospital Center, Rennes; <sup>5</sup>Rheumatology department, Hospital Center, Orléans; <sup>6</sup>Rheumatology department, University Hospital Center, Poitiers; <sup>7</sup>Rheumatology department, University Hospital Center, Brest; <sup>8</sup>Rheumatology department, University Hospital Center, Angers, France

**Background:** Interstitial Lung Disease (ILD) related to Rheumatoid Arthritis (RA) is frequent. ILD is associated with an increased mortality in RA patients. Predictive factors for ILD progression are not well studied.

**Objectives:** In RA patients with an ILD according to CT scan criteria, identify clinical and biological predictive factors for ILD progression.

**Methods:** It is a retrospective multicentric study. RA patients with ILD confirmed by a first thoracic CT scan (tCT at T0) were included if ILD progression could be studied with a second CT scan (Tx) done at least 6 months after T0. RA patients were classified in two groups after double tCT evaluation on a blind review of data: those with ILD progression (pILD) and those with a stable ILD (sILD). Predictive factors for tCT ILD progression were studied by comparing these two groups.

Studied data were ILD pattern, classified into typical UIP (Usual Interstitial Pneumonia) or not typical UIP, RA disease characteristics, biological parameters, and RA treatments, collected for each patient at T0 and Tx.

**Results:** Thirty-six RA patients with ILD confirmed by tCT were included. During an average follow-up of 3 years, 21 RA patients (58.1%) had ILD progression. Predictive factors for ILD progression at T0 are shown in table 1. In pILD group, we observed a significant higher value of the C Reactive Protein (CRP). A CRP rate superior to 20 mg/L was highly associated to ILD progression (Odds ratio=14.4; IC95%(1.36–15.2); p=0.02). Eight patients were treated at T0 by a DMARD different from Methotrexate (MTX). They all were in pILD group (p=0.01). Thirteen patients were treated with MTX at T0. Eight of them were in sILD group (61.5%) and only 5 patients in pILD group (38.5%). Eight patients continued MTX treatment after ILD diagnosis and for one patient, MTX was introduced between T0 and Tx. For these 9 patients exposed to MTX after ILD diagnosis, during 27 months on average, no significant ILD progression was observed.

**Abstract SAT0088 – Table 1.** Predictive factors for tCT ILD progression

Variable	pILD tCT (n=21)	sILD tCT (n=15)	P value
ACPA positivity – no. (%)	15 (70.4)	13 (86.7)	NS
DAS28CRP – pts	3.8±1.42	4.9±1.63	NS
<b>T0 CRP rate – mg/L</b>	<b>29.3±21.1</b>	<b>13.7±18.6</b>	<b>0.03</b>
<b>T0 CRP rate&gt;20 mg/L</b>	<b>OR=14.4; 95% CI (1.36–15.2)</b>		<b>0.02</b>
MTX at T0 – no. (%)	5 (23.8)	8 (53.3)	NS
<b>non-MTX DMARDs (LFN or SSZ) at T0 – no. (%)</b>	<b>8 (38.1)</b>	<b>0</b>	<b>0.01</b>
Biotherapy at T0 – no. (%)	10 (47.6)	6 (40.0)	NS
Corticosteroids at T0 – no. (%)	17 (81.0)	9 (60.0)	NS
MTX exposure between T0 and Tx – no. (%)	5 (55.6)	4 (44.4)	NS
Death – no. (%)	6 (28.6)	3 (20.0)	NS

CI: Confidence Interval; NS: Not Significant; ACPA: Anti-cyclic Citrullinated Peptide Antibody, +>10 U/mL; DAS: Disease Activity Score; LFN: Leflunomide; SSZ: Sulfasalazine; \*: p significant

**Conclusions:** Factors associated with ILD progression were biological inflammation and exposure to a DMARD different from MTX. Exposure to MTX before or after ILD diagnosis was not associated with ILD worsening during the follow up.

**Disclosure of Interest:** None declared

**SAT0094** **PHYSICAL FUNCTION AND HEALTH RELATED QUALITY OF LIFE IN EARLY RHEUMATOID ARTHRITIS PATIENTS WHO ACHIEVED ONLY LOW DISEASE ACTIVITY COMPARED WITH REMISSION**

H.M. Lam<sup>1</sup>, M.C. Wan<sup>2</sup>, L.S. Tam<sup>1</sup> on behalf of The Hong Kong CRYSTAL Study Group. <sup>1</sup>Department of Medicine and Therapeutics, The Chinese University Of Hong Kong, Sha Tin; <sup>2</sup>Department of Medicine, Ruttonjee Hospital, Wan Chai, Hong Kong

**Background:** Current treatment target for rheumatoid arthritis (RA) aims at reaching sustained remission or Low Disease Activity (LDA). It is unclear whether achieving clinical remission is necessary or achieving stable LDA is already sufficient to maintain physical function and Health Related Quality of Life (HRQoL) in patients with early RA.

**Objectives:** To compare physical function and health related quality of life in early RA patients who achieved sustained remission and those who achieved only sustained LDA.

**Methods:** Early RA patients with symptom onset <2 years were recruited. Disease activity over time was determined by the cumulative average of Disease Activity Score 28 (caDAS28) and Simple Disease Activity Index (caSDAI) measured at month 3, 6, 9 and 12. Physical function was measured by the Health Assessment Questionnaire Disability Index (HAQ-DI). HRQoL was assessed by the Physical Component Scale (PCS) and Mental Component Scale (MCS) of the 36-Item Short Form Survey (SF-36) and the Euro Quality of Life Five Dimensions Questionnaire (EQ-5D).

**Results:** A total of 308 (53±13 years old, 80 [26.0%] male) patients completed one year follow up (table 1). 132 (42.9%) and 87 (28.2%) patients achieved caDAS28 remission and caDAS28 LDA while 48 (15.6%) and 156 (50.6%) patients achieved caSDAI remission and caSDAI LDA. Patients who achieved caDAS28 remission have better SF-36 PCS, HAQ-DI and EQ5D at year 1 than patients who achieved only caDAS28 LDA or remained active after adjusting for

other potential confounders at baseline with multivariable regression analysis (Image 1). However, SF-36 PCS, HAQ-DI were not different between caSDAI remission and caSDAI LDA after adjustment for confounders.

SAT0095

### A PERCEIVED BIOLOGICAL CAUSE OF RHEUMATOID ARTHRITIS ONSET IS ASSOCIATED WITH LOWER LEVELS OF DEPRESSED AND ANXIOUS MOOD OVER ONE YEAR COMPARED TO PATIENTS WHO ATTRIBUTED ONSET TO OTHER CAUSES

J. Gwinnett<sup>1</sup>, S. Verstappen<sup>1,2</sup>, K. Hyrich<sup>1,2</sup>, M. Lunt<sup>1</sup>, A. Barton<sup>2,3</sup>, L. Cordingley<sup>1</sup> on behalf of RAMS coinvestigators. <sup>1</sup>Arthritis Research UK Centre for Epidemiology, The University of Manchester; <sup>2</sup>NHR Manchester Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust; <sup>3</sup>Arthritis Research UK Centre for Genetics and Genomics, The University of Manchester, Manchester, UK

**Background:** Patients with rheumatoid arthritis (RA) attribute onset of their condition to a range of causes including biological, psychological, work-related causes or stressful life events. Causal attributions are associated with a range of short- and long-term outcomes.

**Objectives:** To compare the 1 year outcomes of early RA patients who attribute a biological cause of onset of RA with patients who perceive non-biological causal attributions.

**Methods:** The Rheumatoid Arthritis Medication Study (RAMS) is a prospective cohort of patients with RA starting methotrexate for the first time in the United Kingdom. Demographic and clinical data (pain and fatigue visual analogue scales [VAS-pain/VAS-fatigue], disease activity [DAS28], the Hospital Anxiety and Depression Scale [HADS-A, HADS-D] and the Health Assessment Questionnaire [HAQ]) were collected at baseline and 1 year later. At baseline, patients completed the Brief Illness Perception Questionnaire (Brief IPQ), which assesses key beliefs about the impact, controllability, and chronicity of RA. The final item of the Brief IPQ asks patients to report the most important factor they believe caused their disease. These causal attributions were coded as either biological (e.g. age, genetics) or other causes (e.g. work related, stressful life event). Brief IPQ item response scores were compared between these groups using linear regression, adjusted for age and gender. HAQ, DAS28, VAS-pain, VAS-fatigue, HAD-A and HADS-D over follow-up were compared between the two groups using random effects models.

**Results:** Of 1171 patients, 483 (41.2%) reported a biological cause to be the most important factor in causing their arthritis and 688 (58.8%) reported a non-biological cause. Patients who believed in biological causes were younger (median 58 vs. 61 years;  $p=0.003$ ) and more likely to be women (72.1% vs. 59.2%;  $p<0.001$ ). Other baseline characteristics were similar (Table). Patients who perceived biological causes reported significantly lower concerns about their illness (median: 8 vs. 9;  $p=0.004$ ) and significantly lower emotional impact (median: 5 vs. 6;  $p<0.001$ ). Over follow-up, patients who attributed biological causes reported lower depression and anxiety HADS scores than those holding non-biological attributions (mean difference [95% CI]: HADS-D = -0.76 [-1.19, -0.33]; HADS-A = -0.94 [-1.41, -0.47]). Other outcomes over follow-up were similar.

**Abstract SAT0095 – Table 1.** Baseline and one year characteristics, stratified by perceived cause of patients' illness
