Survivors reported clinical improvement compared to baseline:  $\Delta$ WOMAC+29.9 points (95% CI +16.9 to +42.9; p=0.001; figure 1C),  $\Delta$ VAS -46.8 mm (95% CI -31.6 to -61.9; p<0.001). In addition, a significant increase of the minimum JSW (+0.62 mm; 95% CI +0.13 to +1.11; p=0.020; figure 1D) was found after 7 years. No significant changes were found for the mean JSW (+0.36 mm; 95% CI -0.85 to +1.57; p=0.505). In patients whose treatment failed over time, last reported clinical scores were still improved compared to baseline:  $\Delta$ WOMAC+20.5 points (95% CI -1.8 to +42.8; p=0.067; figure 1C),  $\Delta$ VAS -25.4 mm (95% CI -3.2 to -47.7; p=0.030). In contrast, the minimum JSW (+0.22 mm; 95% CI -0.15 to 0.58; p=0.205) and mean JSW (+0.21 mm; 95% CI -1.08 to 1.51; p=0.712) at the last reported time points were no longer increased.

Gender and minimum JSW increase after 1 year predict survival of the native knee joint after 9 years (OR of 14 and 0.02; both p<0.046). The 1 year bone density decrease and mean cartilage thickness increase had a tendency to be predictive (OR of 1.38 and 0.01; both p<0.090).

**Abstract SAT0572 – Figure 1.** Long-term response after treatment with knee joint distraction. (A) Kaplan-Meier survival curves by gender, men (n=11) versus women (n=9), and (B) by increase in minimum joint space width one year after treatment, less than 0.5 mm increase (n = 7) versus more than 0.5 mm increase (n = 13). (C) Total WOMAC score change over nine years and (D) minimum joint space width change over seven years, separated by survivors and patients whose treatment failed within nine years. Mean values  $\pm$ SEM are given.

**Conclusions:** Joint distraction for end-stage knee OA shows long-lasting clinical and structural improvement with a survival of 48% at 9 years. Clinical scores in patients failing treatment were still improved compared to baseline and cannot

fully explain the subsequent TKA surgery. Positive predicting factors for survival of the native knee are male gender and a larger initial increase in minimum JSW (both, 70% survival at 9 years). Potentially, an initial decrease in bone density and an increase in mean cartilage thickness are predictive as well.

Overall, the initial structural response after KJD appears to be important for long-term success of the treatment.

SAT0573

### PROGRESSION OF PAIN, STIFFNESS, FUNCTION CHANGES, AND ULTRASOUND DETECTED SYNOVITIS AND OSTEOPHYTE FORMATION IN PATIENTS WITH HAND OSTEOARTHRITIS OVER THREE YEARS

O. Sleglova, O. Ruzickova, K. Pavelka, L. Senolt. Institute of Rheumatology, Prague, Czech Republic

**Background:** Hand osteoarthritis (HOA) is a common and frequent cause of pain. HOA is a heterogeneous group of disorders with two main subsets including non-erosive and erosive disease. Few studies demonstrated inflammatory ultrasound changes and more severe clinical symptoms in patients with erosive compared with non-erosive disease, however the results are inconsistent.

**Objectives:** The aim of this study was to evaluate progression of pain, stiffness, physical impairment and ultrasound features in patients with erosive and non-erosive HOA in a three years longitudinal study.

**Methods:** Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined, and erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes. Patients were examined at baseline and at the first, second and third year of follow up.

**Results:** Altogether, 97 patients (7 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2018. Out of these patients, 57 had erosive disease. The number of painful and clinically swollen joints (p<0.05) was significantly higher in patients with erosive compared with non-erosive disease at baseline. The number of painful and clinically swollen joints fluctuate over the second and third year of follow up, but it still remains statistically higher (p<0.01) at the third year of follow up in patients with erosive disease.

According to the AUSCAN, patients with erosive disease had more pain (p<0.05) and stiffness (p<0.01) at baseline. Pain and stiffness, but not function, worsened in patients with erosive compared with non-erosive disease after second year (p<0.01). Pain (p<0.01), stiffness (p<0.05) and also function (p<0.01) worsened in patients with erosive disease at the third year of follow up.

US-detected pathologies such as gray-scale synovitis (p<0.001), intensity of PDS (p<0.01) and number of osteophytes (p<0.01) were significantly higher in patients with erosive disease at baseline. There were improvements in gray-scale synovitis total score and intensity of PDS in patients with non-erosive disease while patients with erosive disease worsened after the second and third year of follow up (p<0.01). On the other hand, the progression of US-determined osteophyte formation was observed in both groups after the second year of follow up but were significantly higher in patients with erosive compared with non-erosive disease after the third year of follow up (p<0.05).

**Conclusions:** The findings of this study show that pain and number of clinically swollen joints associated with US-detected synovial changes and osteophyte formation is more severe in patients with erosive HOA than in patients with non-erosive disease. In addition, osteophyte formation is more likely to progress independent of synovial inflammation.

**SAT0574 SENSITISATION AND PAIN SEVERITY IN PATIENTS WITH HAND OSTEOARTHRITIS**

P. Steen Pøttersen<sup>1</sup>, T. Neogi<sup>2</sup>, K. Magnusson<sup>1</sup>, H.B. Hammer<sup>1</sup>, T. Uhlig<sup>1</sup>, T. K. Kvien<sup>1</sup>, I.K. Haugen<sup>1</sup>. <sup>1</sup>Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; <sup>2</sup>Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, USA

**Background:** Sensitisation, a hyperexcitability of nociceptive pathways, contributes to pain severity in patients with knee osteoarthritis, but this association has not yet been examined in patients with hand osteoarthritis (HOA).

**Objectives:** This study explored the occurrence of central and peripheral sensitisation in patients with HOA and the relationship between sensitisation and hand pain severity.

**Methods:** Three hundred subjects (89% women) with clinical and/or ultrasound-verified HOA were included in this cross-sectional study. Hand pain severity was assessed with the numeric rating scale (0–10 NRS) of hand pain during the last 24 hours, the pain subscale (0–20) of the Australian/Canadian (AUSCAN) hand index and a modified version (0–42 scale) of the Intermittent and Constant Osteoarthritis Pain (ICOAP) questionnaire.

Pressure pain thresholds (PPT) were measured with an algometer at two sites: dorsum of the OA finger joint reported to be most painful to test peripheral sensitisation, and at a remote site (mid-portion of tibialis anterior) to test widespread hyperalgesia. Temporal summation (TS), the increase in perceived pain to repetitive noxious stimuli reflecting central sensitisation, was assessed with a mechanical probe at the right wrist. First, probes with increasing weight (32, 64, 128, 256 or 512 mN) were applied at the wrist until the patients reported pain of at least 4/10. The selected probe was applied to the wrist ten times at 1 Hz. Subjects reported NRS pain on the first, fifth and tenth touch. The magnitude of enhanced TS was defined as TS-Δ: highest pain value of fifth or tenth touch minus the first pain value.

Subjects were categorised into sex-specific PPT tertiles. We then used linear regression to analyse whether PPT tertiles and TS-Δ were associated with pain severity with and without adjustments for age, sex, BMI, use of analgesics (NSAIDs, acetaminophen and opioid-like drugs) and several psychosocial factors (highest degree of completed education (1–7 scale), sleep disturbance (0–4 scale), the Pain Catastrophizing Scale (PCS) and the Hospital Anxiety and Depression Scale (HADS)).

**Results:** Median age was 61 (IQR 57, 67) years, symptom duration 6 (IQR 3, 13) years, and mean body mass index (BMI) was 26.5 (SD 4.9) kg/m<sup>2</sup>. Median TS-Δ among the participants was 1 (IQR 0, 2) and TS-Δ of 2 or more was found in 41%. Subjects in the lowest PPT tertile of their painful OA joint and tibialis anterior reported more hand pain than subjects in the highest PPT tertile. Unadjusted, the relation of PPT to NRS and ICOAP were statistically significant, and for the tibialis anterior only, it was also significantly associated with AUSCAN. After adjusting for potential confounders, the relationships were only statistically significant for NRS (Table).

We found positive adjusted associations between increasing TS-Δ and NRS (beta 0.18, 95% CI 0.04, 0.32) and ICOAP (beta 0.63, 95% CI –0.16, 0.3), but not for AUSCAN pain (beta 0.12, 95% CI 0.11, 1.16).

**Abstract SAT0574 – Table 1.** Pain severity across different levels of pressure pain thresholds.

	NRS	AUSCAN Pain	ICOAP
PPT- tertiles	Mean (SD)	Mean (SD)	Median (IQR)
Highest (ref.)			
Painful OA joint	3.48 (2.15)	7.87 (4.00)	9 (4, 17)
Tibialis anterior	3.06 (2.00)	7.31 (3.90)	9 (4, 14)
Middle			
Painful OA joint	3.49 (2.27)	8.08 (4.20)	10 (5, 15)
Tibialis anterior	3.59 (2.13)	8.01 (3.88)	11 (4, 15)
Lowest			
Painful OA joint	4.35 (2.32) *	8.72 (3.98)	14 (7, 22)
Tibialis anterior	4.65 (2.40) *	9.24 (4.21)	15 (8, 23)

Adjusted for age, sex, BMI, use of analgesics, education level, degree of sleep disturbance, PCS and HADS. \*Level of significance p<0.05.

**Conclusions:** In patients with HOA, sensitisation, as reflected by lower PPTs and enhanced TS, was significantly associated with greater pain severity. Future studies are needed to explore whether sensitisation is a result of OA pathology or traits of certain patients, and whether treatments aiming to reduce sensitisation might reduce pain in patients with HOA.

**Background:** Animal studies suggested that inhibiting IL-1α/β with lutikizumab (formerly, ABT-981) may reduce pain and slow structural progression in OA.

**Objectives:** This study (NCT02087904; ILLUSTRATE-K) assessed the safety and efficacy of lutikizumab in subjects with knee OA.

**Methods:** Subjects (n=350; 347 analysed) with Kellgren-Lawrence (KL) grade 2–3 knee OA, synovitis on MRI or US, and visual analogue scale knee pain score 4–8 (range, 0–10) were randomised to receive placebo (PBO) or lutikizumab 25, 100, or 200 mg subcutaneously (sc) every 2 wk (E2W) for 50 wk. The primary endpoints were change from baseline (BL) in WOMAC pain at wk 16 and change from BL in MRI synovitis at wk 26. Other endpoints included WOMAC function and OMERACT/OARSI response (wk 16, 26, and 52) MRI cartilage volume (wk 26 and 52), and x-ray joint space narrowing (JSN) (wk 52).

Data are least squares means unless otherwise noted. LOCF, last observation carried forward; PBO, placebo, sc, subcutaneous. \*P<0.05 vs PBO. Continuous variables compared with analysis of covariance (ANCOVA) with treatment, age, and KL grade as main factors and baseline as covariate. Categorical variables compared with Cochran-Mantel-Haenszel test with age group and KL grade as stratification factors. †Data missing for 1 subject.

**Results:** BL demographics and disease characteristics were balanced (KL grade 3, 36.0%–38.8%; mean WOMAC pain (scale 0–50), 26.2–28.4). The primary endpoint of WOMAC pain at wk 16 improved significantly, compared with PBO, with lutikizumab 100 mg (p=0.050), but not 25 mg (p=0.834) or 200 mg (p=0.415). WOMAC pain reduction in all lutikizumab groups was sustained from wk 16 to 52, but differences between lutikizumab and PBO for WOMAC pain and other key signs and symptoms were not significant (table 1). Synovitis-related imaging, cartilage volume endpoints, and JSN were similar between lutikizumab and PBO groups at wk 26 and 52. Lutikizumab was well tolerated; serious adverse events (SAEs), treatment-related SAEs, and infections and serious infections were similar with lutikizumab vs PBO. Injection site reactions, grade 2/3 neutropenia, and discontinuations due to neutropenia were more frequent with lutikizumab vs PBO. Lutikizumab exposures reached steady state after wk 6 and were stable

through wk 52. Pharmacodynamic responses (neutrophil and high-sensitivity CRP levels) plateaued at the 100 mg dose and data were similar at 200 mg. The low immunogenicity to lutikizumab did not meaningfully affect outcomes.

**Conclusions:** Lutikizumab was generally well tolerated and met the primary endpoint of reduction in WOMAC pain at wk 16 compared with placebo at a dose of 100 mg, but not at 25 mg or 200 mg; cartilage thickness, synovitis, and other structural endpoints were similar between lutikizumab and PBO.

SAT0576

#### BIOMARKERS PREDICTIVE OF PAIN IMPROVEMENT IN KNEE OSTEOARTHRITIS SUBJECTS TREATED WITH THE ANTI-IL-1 ALPHA/BETA DUAL VARIABLE DOMAIN IMMUNOGLOBULIN LUTIKIZUMAB (ABT-981)

S. Feng<sup>1</sup>, S. Chen<sup>1</sup>, L. Wang<sup>1</sup>, C. Peterfy<sup>2</sup>, V. Kraus<sup>3</sup>, R. Kamath<sup>1</sup>, L. Zhang<sup>1</sup>, Y. Luo<sup>1</sup>, L. Cui<sup>1</sup>, J. Medema<sup>1</sup>, M. Levesque<sup>1</sup>. <sup>1</sup>AbbVie Inc., North Chicago, <sup>2</sup>Spire Sciences, Inc., Boca Raton; <sup>3</sup>Duke University School of Medicine, Durham, USA

**Background:** Development of disease-modifying drugs for OA has been challenging, partly due to lack of predictive biomarkers.

**Objectives:** Our primary objective was to identify baseline (BL) biomarkers predicting greater treatment effects on WOMAC pain among knee OA subjects in the lutikizumab (formerly ABT-981) ILLUSTRATE-K trial (NCT02087904).

**Methods:** Subjects (n=347) with Kellgren-Lawrence (KL) grade 2-3 knee OA, synovitis on MRI or ultrasound, and knee pain score 4-8 (range, 0-10) were randomised to placebo (PBO) or lutikizumab 25, 100, or 200 mg subcutaneously every 2 wk for 52 wk. The primary endpoints were change from BL (CFB) in WOMAC pain at wk 16 and CFB in MRI synovitis at wk 26. Demographics, patient-reported outcomes (WOMAC, ICOAP, global assessment [PGA]), x-ray joint space width, and Whole Organ MRI Score (WORMS) were determined at BL. The Patient Rule Induction Method, Sequential Batching, and the Adaptive Index Model were used to identify BL predictive biomarkers and OA subsets with greater lutikizumab treatment effects. Continuous efficacy endpoints were assessed using ANCOVA with treatment, age group, and KL grade as main factors and BL measurements as covariates with LOCF imputation for WOMAC pain.

**Results:** WORMS Global Total Osteophyte Score (GTOS), which semi-quantitatively summates osteophyte severity from 14 regions of the knee, identified a subset of subjects with a greater lutikizumab treatment effect vs PBO; the optimal GTOS cutoff for discriminating treatment effects was 14 (figure 1). Among subjects with a GTOS  $\geq 14$ , the PBO WOMAC pain response was markedly reduced and only marginally improved for ABT-981. At wk 16, among subjects with GTOS  $\geq 14$ , the standardised mean difference (95% CI) of WOMAC pain for the lutikizumab 100 mg dose group vs PBO was  $-0.62$  ( $-0.16$  to  $-1.09$ ) vs  $-0.30$  ( $0$  to  $-0.61$ ) for all subjects. Compared with the total study population, the 41% of subjects with GTOS  $\geq 14$  not only had a greater ABT-981 treatment effect vs PBO on WOMAC pain, but also other measures of OA symptoms. BL systemic markers of synovitis (serum C1M and C3M) and potential markers of macrophage activation by IL-1 (serum alkaline phosphatase) were positively associated with greater lutikizumab treatment effects vs PBO but to a lesser extent than GTOS. Other data supported the robustness of the GTOS predictive marker because 1) a priori, KL grade was used to stratify subjects, 2) subject characteristics were balanced and 3) osteophyte formation is directly linked with synovial macrophage numbers in humans and OA synovial macrophages are the predominant source of IL-1, which is an important mediator of pain.

ABT-981	BL and LS Mean Change From BL (P Value) in WOMAC Pain at Weeks 16, 26, and 52 for ABT-981 vs PBO (LOCF)							
	All Subjects				BL MRI GTOS $\geq 14$			
	BL	Wk 16	Wk 26	Wk 52	BL	Wk 16	Wk 26	Wk 52
25 mg	27.1	-0.3 (0.834)	-0.6 (0.664)	-1.1 (0.500)	29.7	-2.2 (0.345)	-1.6 (0.521)	-4.6 (0.084)
100 mg	28.3	-2.9 (0.050)	-2.7 (0.075)	-2.2 (0.186)	28.2	-6.0 (0.010)	-5.4 (0.027)	-5.4 (0.013)
200 mg	27.1	-1.2 (0.415)	-2.4 (0.107)	-2.3 (0.157)	26.2	-4.6 (0.039)	-5.5 (0.024)	-6.6 (0.020)

Abstract SAT0576 – Figure 1

**Conclusions:** The GTOS biomarker predicted improvement of knee OA pain and other symptoms with lutikizumab treatment. We hypothesise that subjects with more severe osteophytes may have had more inflammation-dependent pain that was less responsive to PBO, suggesting that IL-1 inhibitors should be studied further as a treatment for knee OA symptoms in this subset of patients.

#### EVALUATION OF SARCOPENIA MULTIDimensionALLY IN PATIENTS WITH KNEE OSTEOARTHRITIS

S. Gümürük Aslan, M. Saraçoğlu, H. Genç, B. D.Çakıt, B. Nacir. *University of Health Science, Ankara Training and Research Hospital, Physical Medicine and Rehabilitation Clinic, ANKARA, Turkey*

**Background:** Osteoarthritis(OA) is a noninflammatory chronic degenerative disease.The rate of development of sarcopenia has been increased in patients with OA.

**Objectives:** In this study,we evaluated the presence of sarcopenia multidimensionally in patients with knee osteoarthritis (OA) using clinical,ultrasonographic and biochemical parameters,and in this respect, it was aimed to investigate the relation between OA and sarcopenia and to identify the most practical,easily accessible and inexpensive method for investigating sarcopenia.

**Methods:** 102 patients with clinical and radiological diagnosis of knee osteoarthritis and 33 healthy control subjects were included in the study.A total of 135 subjects were evaluated by the European Working Group on Sarcopenia in Older People (EWGSOP) for the diagnosis of sarcopenia.The first group consists of (OA) patients with sarcopenia, the second group consist of OA patients without sarcopenia and the third group is controls subjects.Dual-X-ray absorptiometry (DEXA) is used to measure Body composition parameters and muscle mass measurements, isometric muscle strength evaluations, hand grip strength and walking speeds for diagnosis of sarcopenia. Short form -36 (SF-36) The Nutritional Assessment-short form (MNA), the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), the International Physical Assessment Questionnaire Short Form (IPAQ-SF) and the Centre for Epidemiologic Studies Depression Scale (CES-D scale) were administered to every patients.

**Results:** The mean age of the group with sarcopenia was statistically higher than the other two groups ( $p < 0.001$ ). The weight, body mass index (BMI), waist circumference, upper mid-arm circumference, thigh and leg circumference of osteoarthritis (OA) patients with sarcopenia were statistically lower than those of non-sarcopenic and control group ( $p < 0.01$   $p < 0.001$ ).Body composition parameters results showed that sarcopenic patients had statistically lower values as fat mass, lean body mass and Skeletal Muscle Index ( $p < 0.001$ ,  $p = 0.001$ ,  $p < 0.001$ , respectively) than those of non-sarcopenic and control group.It was determined that body composition values measured with DEXA, ultrasonographic measures,

isokinetic muscle strength assessment, hand grip strength and gait speed had predictive values for sarcopenia.

**Abstract SAT0577 – Table 1.** Baseline features of the patients of knee Osteoarthritis and healthy controls

	Group 1	Group 2	Group 3	p
<b>Age</b>	67.08±2.02 (64-69) <sup>a</sup>	60.31±4.71 (50-70)	59.76±5.16 (52-69)	<0.001 <sup>c</sup>
<b>Body mass index</b>	23.24±3.34 (18.4-29.3) <sup>b</sup>	32.82±5.44 (20.8-61.6)	29.22±3.20 (22.6-35.9)	<0.001
<b>Mid-Upper Arm Circumference</b>	22.17±4.00 (18-32) <sup>b</sup>	33.37±5.04 (21-57)	32.18±4.33 (26-43)	<0.001
<b>Calf circumference</b>	31.92±2.68 (25-35) <sup>b</sup>	40.52±6.30 (32-63)	40.85±6.46 (32-57)	<0.001
<b>Gait speed</b>	09.36±0.1 (0.82-1.12) <sup>a</sup>	0.61±0.18 (0.36-1.5)	0.6±0.14 (0.36-0.9)	<0.001
<b>Hand grip strength (right)</b>	13.58±2.94 (7-17) <sup>a</sup>	20.69±5.38 (8-38)	21.94±5.72 (12-38)	<0.001

mean±standard deviation

<sup>a</sup> A statistically significant difference was found between the post-hoc bilateral comparative "sarcopenic" group (p < 0.017)

<sup>b</sup> A statistically significant difference was found between the post-hoc bilateral comparative "non sarcopenic" group (p < 0.017)

<sup>c</sup> A statistically significant difference was found between the post-hoc bilateral comparative "healthy control" group (p < 0.017)

**Conclusions:** We found that patients with sarcopenic OA were older, weaker, less powerful, undernourished, and restricted in their level of physical activity in the study in which we identified sarcopenia as approximately 12% in patients with osteoarthritis. Among the methods of determining sarcopenia, ultrasound becomes prominent with its practical, cheap and easily accessible features. We think that our results will increase the awareness of the presence of sarcopenia in OA patients.

#### SAT0578 PATELLAR TENDON ENTHESIS ABNORMALITIES AND THEIR ASSOCIATION WITH KNEE PAIN AND STRUCTURAL ABNORMALITIES IN OLDER ADULTS

S.M. Mattap<sup>1</sup>, D. Aitken<sup>1</sup>, K. Wills<sup>1</sup>, A. Halliday<sup>2</sup>, C. Ding<sup>1</sup>, W. Han<sup>1</sup>, F. Cicuttini<sup>3</sup>, G. Jones<sup>1</sup>, L. Laslett<sup>1</sup>. <sup>1</sup>Menzies Research Institute for Medical Research, University of Tasmania; <sup>2</sup>Department Of Medical Imaging, Royal Hobart Hospital, Hobart; <sup>3</sup>Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia

**Background:** The patellar tendon works together with the quadriceps tendon to enable knee flexion and straightening. Its attachment site (enthesis) is at risk of micro damage and degeneration. Recent studies suggest that enthesitis abnormalities are associated with development of osteoarthritis.<sup>1, 2</sup> However, no studies have assessed the presence of patellar enthesitis abnormalities in older adults and its association with osteoarthritis outcomes.

**Objectives:** To describe the associations of patellar tendon enthesitis (PTE) abnormalities visible on magnetic resonance (MR) images; and knee pain, physical function limitations, osteoarthritic structural abnormalities cross-sectionally and longitudinally over 10.7 years.

**Methods:** PTE abnormalities were defined as presence of abnormal bone signal and/or bone erosion. They were measured on T2-weighted fat suppressed fast spin echo MR images at baseline in 961 community-dwelling older adults and followed for 10.7 years. Knee pain and physical function limitation score were assessed using WOMAC. Bone marrow lesions (BMLs), cartilage volume and defects, tibial bone area, and infrapatellar fat pad (IPFP) area were assessed using validated methods. Associations were assessed using hurdle, log binomial, linear, and mixed models, after adjusting for confounders.

**Results:** 20% of participants had bone signal and/or erosion at PTE. Cross-sectionally, presence of PTE abnormalities were associated with greater intensity of pain while going up and down stairs ( $\beta=0.22$  (95% CI; 0.03, 0.41)), greater risk of having a femoral BML (RR=1.46 (1.22, 1.90)), greater lateral tibial bone area ( $\beta=25.95$  (1.00, 50.91)), smaller IPFP area ( $\beta=-0.26$  (-0.46, -0.05)), and a worse tibial cartilage defects cross sectionally (RR=1.70 (1.16, 2.47)), after adjustment of demographic and structural confounders. Longitudinally, PTE abnormalities at baseline predicted an increased risk of deleterious changes in tibial BML size (RR=1.52 (1.12, 2.05)) but not clinical symptoms, and other structural changes over 10.7 years.

**Conclusions:** Patellar tendon enthesitis abnormalities are common in the elderly. The presence of cross-sectional but not longitudinal associations suggests they commonly co-exist with other knee structural abnormalities, but that they are not be a major player in symptom development or structural changes, excepting tibial BMLs.

#### SAT0579 PRESENCE OF AUTOANTIBODIES IN EROSIIVE HAND OSTEOARTHRITIS AND ASSOCIATION WITH CLINICAL PRESENTATION

M.A. van Delft<sup>1</sup>, S. Van Beest<sup>1</sup>, M. Kloppenburg<sup>1,2</sup>, L.A. Trouw<sup>1,3</sup>, A. Ioan-Facsinay<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Clinical Epidemiology; <sup>3</sup>Immunohematology and Bloodtransfusion, Leiden University Medical Center, Leiden, Netherlands

**Background:** One of the most prevalent clinical phenotype of osteoarthritis (OA) is hand OA (HOA), which in some patients can evolve to erosive HOA. In erosive HOA central erosions and subchondral destruction are seen, and imaging studies have indicated that in erosive HOA hand joints display more inflammatory signs than in non-erosive HOA.

Autoantibodies directed against post-translationally modified proteins, such as citrullinated (ACPA) and carbamylated (anti-CarP antibodies) proteins, are a hallmark of rheumatoid arthritis (RA), and are associated with more severe joint damage and inflammation. Interestingly, these antibodies are present in a small subset of SLE patients as well, in which they associate with bone erosions. This suggests the possible involvement of autoantibodies in inflammation and joint damage in other conditions than RA. Therefore, we hypothesised that autoantibodies are present in HOA and associate with erosive disease.

**Objectives:** To investigate whether three RA-associated antibodies, Rheumatoid Factor (RF), ACPA and anti-CarP antibodies, are present in hand OA and associate with erosive OA.

**Methods:** Anti-CarP IgG, ACPA IgG and RF IgM were measured by ELISA in baseline sera of HOA patients from 3 cohorts: HOSTAS (n=510, mean age 61.0 years, 85.7% women, 27.2% EOA), ECHO (n=47, mean age 63.4 years, 89.4% women) and EHOA (n=23, mean age 57.1 years, 73.9% women), and in sera of healthy controls (HC; n=196, mean age 44.1 years, 51.0% women). The prevalence of autoantibodies was compared between HOA and HC and between erosive and non-erosive HOA. In HOSTAS, hand radiographs were scored (Kellgren-Lawrence, OARSI osteophyte and joint space narrowing scores) and C-reactive protein (CRP) levels, representing inflammation, were assessed. Groups were compared using non-parametric tests.

**Results:** In both ECHO and EHOA cohorts, only one patient was positive for RF IgM and none were positive for ACPA IgG. In all three cohorts, a low prevalence of anti-CarP IgG was detected and this was not different between HOA patients and HC (6.6% vs 3.6%, p=0.12). Moreover, in HOSTAS, the prevalence of all tested autoantibodies was low and not significantly different from HC (anti-CarP 7.1% vs 3.6%, p=0.08; ACPA 0.8% vs 1.5%, p=0.37; RF 6.1% vs 4.1%, p=0.30). Likewise, no difference was found between erosive and non-erosive HOA (anti-CarP 7.2% vs 7.1%, p=0.94; ACPA 0.7% vs 0.8%, p=0.92; RF 4.3% vs 6.5%, p=0.36). Radiographic damage and CRP levels were similar in anti-CarP positive vs negative, and RF positive vs negative HOSTAS patients.

**Conclusions:** The prevalence of autoantibodies is similar in HOA patients and healthy controls. Moreover, these autoantibodies are not associated with erosive disease, structural damage or inflammation in HOA patients, indicating that another mechanism is driving erosive disease.

SAT0580

#### ASSOCIATION OF CHILDHOOD AND ADULTHOOD ADIPOSITY MEASURES WITH KNEE CARTILAGE THICKNESS, CARTILAGE VOLUME AND BONE AREA IN YOUNG ADULTS

T. Meng<sup>1</sup>, A. Venn<sup>1</sup>, F. Eckstein<sup>2,3</sup>, W. Wirth<sup>2,3</sup>, F. Cicuttini<sup>4</sup>, L. March<sup>5</sup>, T. Dwyer<sup>1,6</sup>, M. Cross<sup>5</sup>, L.L. Laslett<sup>1</sup>, G. Jones<sup>1</sup>, C. Ding<sup>1,4,7</sup>, B. Antony<sup>1</sup>. <sup>1</sup>Menzies Institute for Medical Research, Hobart, Australia; <sup>2</sup>Institute of Anatomy, Paracelsus Medical University Salzburg and Nuremberg, Salzburg, Austria; <sup>3</sup>Chondrometrics GmbH, Ainning, Germany; <sup>4</sup>Department of Epidemiology and Preventive Medicine, Monash University, Melbourne; <sup>5</sup>Institute of Bone and Joint Research, University of Sydney, Sydney, Australia; <sup>6</sup>The George Institute for Global Health, Nuffield Department of Obstetrics and Gynaecology, University of Oxford, Oxford, UK; <sup>7</sup>Clinical Research Centre, Zhujiang Hospital, Southern Medical University, Guangzhou, China

**Background:** Adiposity is associated with increased risk of knee osteoarthritis (OA); cartilage thickness, cartilage volume and subchondral bone area are established biomarkers in knee OA. However, there are no studies describing the effects of adiposity during early life on knee cartilage and bone morphology in adulthood.

**Objectives:** To describe the longitudinal associations between adiposity measures in childhood and adulthood and knee cartilage thickness, cartilage volume and subchondral bone area in young adults.

**Methods:** 186 participants from the Australian Schools Health and Fitness Survey of 1985 (aged 7–15 years) were followed up 25 years later (aged 31–40 years). Childhood measures (weight, height, waist circumference and hip circumference) were collected in 1985, and corresponding adulthood measures were collected during 2004–2006. Body mass index (BMI) and waist-hip ratio (WHR) were calculated. Participants underwent knee magnetic resonance imaging (MRI) during 2008–2010, and cartilage thickness, cartilage volume and subchondral bone area were measured using a quantitative approach (Chondrometrics 3.0, Germany). Multivariable linear regressions were used to examine the above associations.

**Results:** Among 186 participants (48.4% females), 7.6% were overweight in childhood, and 42.1% in adulthood. There were no significant associations between childhood adiposity measures and adulthood knee cartilage and bone morphological measures; the same applied to adulthood BMI and overweight. However, adulthood WHR was negatively associated with cartilage thickness in the patella ( $\beta$   $-0.009$  mm/0.01 unit, 95% confidence interval (CI)  $-0.019$  to  $0.001$ ,  $p=0.065$ ), the medial femorotibial compartment (MFTC) ( $-0.011$ ,  $-0.022$  to  $0.000$ ,  $p=0.048$ ) and the lateral femorotibial compartment (LFTC) ( $-0.013$ ,  $-0.025$  to  $-0.002$ ,  $p=0.027$ ), with cartilage volume in the patella ( $\beta$   $-21.85$  mm<sup>3</sup>/0.01 unit, 95% CI  $-37.77$  to  $-5.93$ ,  $p=0.007$ ), the MFTC ( $-14.17$ ,  $-29.53$  to  $1.19$ ,  $p=0.070$ ) and the LFTC ( $-23.87$ ,  $-42.18$  to  $-5.57$ ,  $p=0.011$ ), and with subchondral bone area in the patella ( $\beta$   $-4.69$  mm<sup>2</sup>/0.01 unit, 95% CI  $-8.26$  to  $-1.12$ ,  $p=0.010$ ) and the LFTC ( $-4.76$ ,  $-9.47$  to  $-0.06$ ,  $p=0.047$ ), but not the MFTC.

**Abstract SAT0580 – Figure 1.** Scatter plots and linear regression lines for associations between adulthood WHR and knee cartilage thickness (A: patella; B: MFTC; C: LFTC).

Linear regression lines are from models adjusted for adulthood age, duration of follow-up, gender and adulthood knee injury. WHR, waist-hip ratio; MFTC, medial femorotibial compartment; LFTC, lateral femorotibial compartment.

**Conclusions:** Childhood adiposity measures did not predict adulthood knee cartilage and bone morphological measures. However, adulthood WHR, but not BMI or overweight status, was negatively associated with cartilage thickness, cartilage volume and subchondral bone area, suggesting central obesity may affect knee structures in young adults.

SAT0581

#### PREDICTIVE FACTORS OF RESPONSE TO A SINGLE INJECTION OF MANNITOL-MODIFIED CROSS-LINKED HYALURONIC ACID (HANOX-M-XL) IN PATIENTS WITH TRAPEZIOMETACARPAL OSTEOARTHRITIS. RESULTS OF A MULTICENTRE PROSPECTIVE OPEN-LABEL PILOT STUDY (INSTINCT TRIAL)

J. Dauvissat<sup>1</sup>, T. Conrozier<sup>1</sup>, H. Lellouche<sup>2</sup>, B. Maillet<sup>3</sup>, C. Rizzo<sup>4</sup>, V. Travers<sup>5</sup>, V. Locquet<sup>6</sup>, S. Mellac-Ducamp<sup>7</sup>. <sup>1</sup>Rheumatology, Nord Franche Comté Hospital, Trevenans; <sup>2</sup>Rheumatology, Institut Nolle, Paris; <sup>3</sup>Rheumatology, Clinique St Odilon, Moulins; <sup>4</sup>Orthoedics, Clinique du Parc; <sup>5</sup>Orthoedics, Clinique St Charles, Lyon; <sup>6</sup>Orthoedics, Inst. Chirurgical de la Main et du Membre Supérieur, Villeurbanne; <sup>7</sup>Rheumatology, Centre hospitalier, Nevers, France

**Background:** Viscosupplementation is likely effective to alleviate pain and improve function in patients suffering from rhizarthrosis. However no study has been focused on the predictors of efficacy of the treatment.

**Objectives:** To search predictive factors of success or failure 3 months after a single intra-articular injection of a mannitol-modified hyaluronic acid (HA) viscosupplement, in patients suffering from trapeziometacarpal (TMC) osteoarthritis (OA).

**Methods:** Patients with symptomatic TMC OA were included in a 3 month prospective multicentre open-label trial. To be included in the study patients must have symptomatic TMC OA, not adequately relieved by analgesics/NSAIDs therapy and/or by the use of a thumb splint. Before treatment all patients must have had plain radiographs with the Kapandji incidences, for the Dell radiological grade assessment. (1 to 4). Primary endpoints were the variation between injection (D0) and day 90 (D90) of the thumb pain measured on 11 point-Likert scale (0 to 10) and the patient's self-assessment of efficacy (0 to 3). Treatment consisted in a single injection of 0.6 to 1 ml of HANOX-M-XL, a viscosupplement made of a cross-linked HA of high molecular weight, from biofermentative origin, combined with mannitol. All injections were performed under fluoroscopic or ultrasound guidance. Predictive factors of pain decrease were studied in univariate and multivariate analysis. All statistical tests were carried out two tailed at the 5% level of significance.

**Results:** 122 patients (76% females, mean age 60, mean disease duration 36 months) were included and 120 (98%) were assessed at 3 months. 23% of the TMC OA were grade 1 according to Dell classification, 36.8% grade 2, 36.8% grade 3 and 3.5% grade 4. At D0, the average (SD) pain level was  $6.5 \pm 1.6$  without significant difference between Dell groups ( $p=0.21$ ). At day 90, pain decreased from  $6.5 \pm 1.6$  to  $3.9 \pm 2.5$  (Difference  $-2.7 \pm 2.5$ ;  $-42\%$ ;  $p<0.0001$ ) without significant difference depending on the Dell grade ( $p=0.055$ ), despite a seemingly smaller number of responders in stage 2 patients. The average analgesic consumption decreased in more than one out of two patients. In univariate analysis, the clinical response was significantly worse in patients taking NSAIDs at baseline ( $p=0.012$ ), but this difference no longer reached the significance threshold in the multivariate analysis. In multivariate analysis no predictor of response was identified. There was no safety issue. All AEs (11%) were transient increase of pain during or following HA administration and resolved without sequel within 1 to 7 days.

**Conclusions:** This study, of the largest cohort of patients treated with viscosupplementation in TMC OA, suggests that a single course of HANOX-M-XL injection is effective in relieving pain, without safety concern. Interestingly patients with the more advanced stages of OA seemed to benefit the treatment as well as those with less advanced OA.

**SAT0582 BONE MARROW LESION TYPE AND PAIN IN KNEE OSTEOARTHRITIS**

T.A. Perry<sup>1</sup>, T.W. O'Neill<sup>1,2</sup>, M.J. Parkes<sup>1</sup>, D.T. Felson<sup>1,3</sup>, R. Hodgson<sup>4</sup>, N. K. Arden<sup>5</sup>. <sup>1</sup>Arthritis Research UK Centre for Epidemiology, Division of Musculoskeletal and Dermatological Sciences, The University of Manchester, Manchester; <sup>2</sup>Department of Rheumatology, Salford Royal NHS Foundation Trust, Salford, UK; <sup>3</sup>Boston University, Boston, USA; <sup>4</sup>Centre for Imaging Sciences, Institute of Population Health, The University of Manchester, Manchester; <sup>5</sup>The University of Oxford, Oxford, UK

**Background:** Bone marrow lesions (BMLs) have been associated with pain in observational studies of knee OA. The aim of this study was to determine whether type of BML (subchondral, with and without regions of well-defined high post-contrast signal, and ligament-based) were associated with knee symptoms.

**Objectives:** To assess the association between bone marrow lesion volume, including sub-types, and pain in symptomatic knee OA.

**Methods:** Data were collected on a sub-sample of participants who were part of the UK VIDEO study<sup>1</sup>; a 3 year multicentre randomised placebo-controlled trial of vitamin D therapy in patients with symptomatic knee OA. Those recruited to one of the participating centres (Southampton) had contrast enhanced MR imaging (CE-MRI) of the index knee performed at one or more annual visits. BML volume was assessed by segmentation of sagittal T1-weighted fat-suppressed post-contrast scans. BMLs were categorised by type (subchondral/ligament-based) and by the presence/absence of regions of well-defined high post-contrast signal (for the subchondral BMLs only). As part of the trial, subjects completed the WOMAC questionnaire which included questions on pain, function and stiffness. We used random-effects multiple linear panel regression, adjusting for variance between follow-up visits to explore the relationship between BML volume and the WOMAC pain and function subscales. This approach is preferred over cross-sectional analyses, as it makes use of all available observations from study visits, and controls for within-patient correlations appropriately.

**Results:** In this analysis, we included 50 subjects who had had a baseline MRI and at least one other MRI performed. The mean age of the subjects was 63.3 (SD  $\pm$ 6.5) years and 74% were female. After adjusting for variation between visits, there was no significant association between total BML volume and WOMAC pain when the BMLs were stratified by type; total subchondral BML volume ( $b=41.5$  mm<sup>3</sup>; 95% CI  $-19.35$  to  $102.37$ ) or total ligament-based BML volume ( $b=9.1$  mm<sup>3</sup>; 95% CI  $-6.39$  to  $24.59$ ). Further, we did not observe an association between pain and volume of subchondral BMLs with or without regions of well-defined high post-contrast signal; (i) total mixed subchondral oedema-like BMLs containing regions of well-defined high signal ( $b=39.45$  mm<sup>3</sup>; 95% CI  $-3.93$  to  $82.83$ ) or (ii) subchondral oedema-like BML volume ( $b=-4.16$  mm<sup>3</sup>; 95% CI  $-53.49$  to  $45.18$ ), after adjusting for variation between visits. There was, however, a significant association between the volume of subchondral regions of well-defined high signal and both WOMAC pain ( $b=2.19$  mm<sup>3</sup>; 95% CI  $0.88$  to  $3.49$ ) and function ( $b=1.61$  mm<sup>3</sup>;  $0.37$  to  $2.84$ ).

**Conclusions:** In this analysis, an increased volume of regions of well-defined high signal intensity on post-contrast scans within subchondral BMLs was associated with knee pain and function.

**SAT0583 THE IMMEDIATE EFFECT OF A SOFT KNEE BRACE ON DYNAMIC KNEE INSTABILITY IN PERSONS WITH KNEE OSTEOARTHRITIS**

T. Cudejko<sup>1</sup>, M. van der Esch<sup>2</sup>, J. Schrijvers<sup>1</sup>, R. Richards<sup>1</sup>, T. Wrigley<sup>3</sup>, J. van den Noort<sup>1</sup>, M. van der Leeden<sup>2</sup>, L.D. Roorda<sup>2</sup>, W. Lems<sup>1</sup>, J. Harlaar<sup>1</sup>, J. Dekker<sup>1</sup>. <sup>1</sup>VU University Medical Center, <sup>2</sup>Amsterdam Rehabilitation Research Center, Reade, Amsterdam, Netherlands; <sup>3</sup>University of Melbourne, Melbourne, Australia

**Background:** Wearing a soft knee brace has been shown to reduce self-reported knee instability in persons with knee osteoarthritis (OA).<sup>1</sup> There is a need to assess whether a soft knee brace has a beneficial effect on objectively assessed dynamic knee instability as well.

**Objectives:** The aims of the study were: (i) to evaluate the immediate effect of a soft knee brace on dynamic knee instability, and (ii) to assess the difference in effect between a tight and a non-tight knee brace in persons with knee OA.

**Methods:** A within-subject cross-over design was used, comparing wearing a soft knee brace with not wearing a soft knee brace, and comparing wearing a tight

brace (standard fit) with wearing a non-tight brace (one size larger). The order of brace type was randomised. Participants walked, both without and with the brace, on a treadmill, which is integrated in the GRAIL system, placed in a virtual reality environment (GRAIL system, MOTeKForce Link, The Netherlands). Participants were subjected to two tasks: (i) level walking and (ii) walking with mechanical perturbations on the treadmill. Mechanical perturbations on the treadmill comprised five lateral and five medial translations (2 cm displacements) of the treadmill belts occurring during 20%–50% of the gait cycle. During the walking trials, 3D movement of the lower legs, pelvis and trunk were captured via markers on anatomical landmarks at 100 Hz using a motion-capture system (Vicon, Oxford, United Kingdom). The outcome measure was dynamic knee instability, expressed by the Perturbation Response (PR), i.e. a biomechanics based measure reflecting deviation in the mean knee varus-valgus angle after a controlled mechanical perturbation, standardised to the mean (standard deviation) varus-valgus angle during level walking. Lower PR values indicate less deviation in the mean varus/valgus angle. Linear mixed-effect model analysis was used to evaluate the effect of a brace on dynamic knee instability.

**Results:** Thirty-eight persons with knee OA and self-reported knee instability from the Amsterdam Osteoarthritis Cohort participated in the study. Wearing a brace significantly reduced the PR compared to not wearing a brace ( $p<0.05$ ). The PR value reduced from 0.48 when not wearing a brace to 0.32 when wearing a brace. This means that wearing a brace resulted in a reduction of 33% in dynamic knee instability compared to not wearing a brace. There was no difference between a non-tight and a tight brace ( $p>0.05$ ).

**Conclusions:** This study is the first to report that wearing a soft brace results in an improvement of objectively assessed dynamic knee instability, beyond the previously reported subjective improvement.

**SAT0584 CLINICAL VALIDATION OF TWO PANELS OF BIOMARKERS TO PREDICT SYMPTOMATIC DRUGS RESPONSE IN KNEE OA**

V. Calamia<sup>1</sup>, F. Picchi<sup>1</sup>, I. Rego<sup>1</sup>, M. Camacho<sup>1</sup>, L. González<sup>1</sup>, P. Fernández-Puente<sup>1</sup>, M. Herrero<sup>2</sup>, H. Martínez<sup>2</sup>, J. Vergés<sup>3</sup>, C. Ruiz-Romero<sup>1</sup>, F.J. Blanco<sup>1</sup>. <sup>1</sup>INIBIC, La Coruña; <sup>2</sup>Bioiberica S.A.U.; <sup>3</sup>OAFI Foundation, Barcelona, Spain

**Background:** The prediction of drug responses based on the analysis of multiple clinical variables and *omics* data is mandatory for accomplishing the promise of precision medicine in rheumatology.

**Objectives:** Integrating clinical-radiological-analytical variables and proteomics data for predicting patient's response to different treatments, in order to optimise therapeutic outcomes in OA.

**Methods:** A panel of 10 serum proteins potentially useful to predict OA patient's response was qualified using ELISA Kits in the whole Multicentre Osteoarthritis interVENTion trial with Sysadoa (MOVES) cohort. Patients were classified as responders (R) and non-responders (NR), either to Chondroitin sulfate/Glucosamine hydrochloride (CS+GH; Droglican, Bioiberica, Spain) or Celecoxib, after 6 months of treatment. Logistic regression analyses, adjusted by confounder variables previously reported as significant in bivariate approaches, were used to analyse the contribution of the measured proteins to our prediction models of drug response in knee OA. Appropriate receiver-operating-characteristics (ROC) curves were also calculated.

**Results:** In the *discovery phase* of the study, two different panels of putative predictive biomarkers useful to stratify OA patients according to their unique protein profiles was identified by shotgun proteomics ( $n=80$ ). In the *verification phase*, the panel of 6 proteins specific for Droglican treatment (APOA2, APOA4, APOH, ITIH1, C4BPa and ORM2), and the panel of 4 proteins specific for Celecoxib treatment ( $\alpha$ 2HS, SHBG, CD5L and TSP1) were verified in a larger cohort of OA patients ( $n=262$  for CS+GH group and  $n=244$  for Celecoxib group) by ELISA assays. In the *qualification phase*, the sensitivity and specificity of a panel of 4 validated proteins (ORM2, APOA2, ITIH1, and TSP1) were tested in blind in the whole MOVES cohort at baseline ( $n=506$ ). In CS+GH group, only ORM2 levels were significantly lower in responders compared to non-responders (R: 192.8 ug/mL vs NR: 261.6 ug/mL;  $p=0.042$ ), while no statistically significant differences were found in the Celecoxib group. Five clinical and two analytical parameters recorded at baseline significantly influence patients' response regardless of treatment. Notably, if we include ORM2 as covariate, we found a specific interaction

between response to CS+GH and baseline protein levels ( $p=0.007$ ) thus increasing the power of our prediction model (ROC up to 0,843). In the Celecoxib group, non parametric analysis showed increased levels only of TSP1 at baseline in responders compared to non-responders (R: 363,03±104,83 ng/mL vs NR: 331,95 ±92,59 ng/mL;  $p=0.041$ ), while no statistically significant differences were found for this protein in the CS+GH group. When we include in the regression model 4 predictive variables (2 clinical and 2 analytical) and TSP1 as covariate, we found a specific interaction between response to Celecoxib and baseline protein levels ( $p=0.045$ ) thus increasing the predictive power of this model (ROC up to 0,749).

**Conclusions:** Combining clinical and analytical parameters, we clinically validated (qualified) 2 panels of biomarkers that could efficiently predict OA patients' response to CS+GH with an accuracy of 84,3% or to Celecoxib with an accuracy of 74,9%.

### SAT0585 DECREASED SYNOVIAL LEVELS OF DICKKOPF-1 ARE ASSOCIATED WITH RADIOLOGICAL PROGRESSION IN KNEE OSTEOARTHRITIS PATIENTS

W.A. Hassan<sup>1</sup>, E.G. Behiry<sup>2</sup>. <sup>1</sup>Rheumatology and Rehabilitation; <sup>2</sup>Clinical and Chemical Pathology Department, Benha University Hospital, Benha, Egypt

**Background:** Dickkopf-1 (Dkk-1) is a direct inhibitory ligand of Wnt  $\beta$ -catenin signalling pathway that act through binding to low-density lipoprotein (LDL) related proteins (LRP5/6) receptors. Dkk-1 is considered an important mediator of cartilage homeostasis and skeletal remodelling.<sup>1</sup>

**Objectives:** This study aimed to measure serum and synovial fluid (SF) levels of Dkk-1 in patients with early primary knee osteoarthritis (KOA) and to examine the relationship between these levels and the clinical and functional parameters as well as radiological progression of KOA

**Methods:** We measured Dkk-1 in the serum ( $n=48$ ) and SF samples ( $n=22$ ) from 48 early KOA patients and in the serum from healthy control ( $n=30$ ). Body mass index (BMI), numerical rating scale of pain (NRS) and The Western Ontario Mc Master scale (WOMAC) were recorded. Plain radiographs using Osteoarthritis Research Society International (OARSi) atlas to assess joint space narrowing (JSN)<sup>2</sup> and musculoskeletal ultrasound examination (MSUS) were performed at baseline and after 24 months to assess radiological progression. Radiological progression was considered if there is more than 2 points increase in JSN score or transition to higher grade in MSUS examination<sup>3</sup> at the 24 months follow up period compared to baseline grade.

**Results:** SF Dkk-1 levels were significantly decreased (mean  $\pm$ SD 115.05  $\pm$ 34.2 pg/ml) compared to their paired serum levels (mean  $\pm$ SD 969.82  $\pm$ 365.72 pg/ml),  $p<0.001$  in KOA patients. There was no significant difference in serum Dkk-1 levels between KOA patients and healthy controls (mean  $\pm$ SD 988.77 $\pm$ 385.19 pg/ml and 1084.73 $\pm$ 408.38 pg/ml respectively), the SF concentrations of Dkk-1 significantly correlated with the baseline thickness of the cartilage on the medial condyle (0.53,  $p<0.05$ ) but not on the lateral condyle of the femur ( $r=0.11$ ,  $p>0.05$ ), there was no significant correlation between serum Dkk-1 and baseline cartilage thickness on medial and lateral condyles ( $r=-0.13$  and  $-0.09$  respectively,  $p<0.05$ ). Patients in the least quartile of SF Dkk-1 had an increased risk of radiological progression with plain radiography and MSUS (age, sex and BMI adjusted RR 2.1 and 3.4, 95% CI respectively).

**Conclusions:** Osteoarthritis patients have significantly lower synovial levels than serum levels of Dickkopf-1 that were obviously associated with radiological progression on plain radiography and MSUS suggesting that it could be a useful marker to reflect OA severity and implies a possible role in the pathogenesis of OA.

### SAT0586 RESULTS FROM A 52 WEEK RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE 2 STUDY OF A NOVEL, WNT PATHWAY INHIBITOR (SM04690) FOR KNEE OSTEOARTHRITIS TREATMENT

Y. Yazici<sup>1</sup>, T. McAlindon<sup>2</sup>, A. Gibofsky<sup>3</sup>, N. Lane<sup>4</sup>, D. Clauw<sup>5</sup>, C. Swearingen<sup>1</sup>, A. DiFrancesco<sup>1</sup>, J. Tambiah<sup>1</sup>, M. Hochberg<sup>6</sup>. <sup>1</sup>Samumed, LLC, San Diego; <sup>2</sup>Tufts Medical Center, Boston; <sup>3</sup>Hospital for Special Surgery, New York; <sup>4</sup>UC Davis Medical Center, Davis; <sup>5</sup>University of Michigan Medical School, Ann Arbor; <sup>6</sup>University of Maryland School of Medicine, Baltimore, USA

**Background:** Knee osteoarthritis (OA) is characterised by pain, disability and joint deformity due to articular cartilage degradation and bone remodelling. Wnt signalling is involved in these cellular processes. SM04690, a small molecule Wnt pathway inhibitor, is in development as a potential disease modifying OA drug (DMOAD) for knee OA.

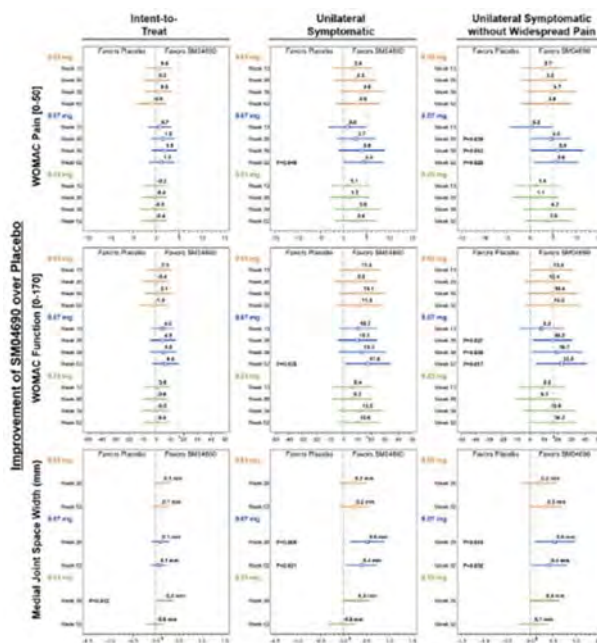

**Objectives:** A phase 2, multicenter, 52 week, placebo-controlled (PBO) trial was conducted to identify a target population, determine optimal dose and assess safety.

**Methods:** Knee OA subjects, Kellgren-Lawrence (KL) grades 2–3, received a single 2 mL injection of SM04690 0.03 mg, 0.07 mg, 0.23 mg or PBO in target (most painful) knee. WOMAC Pain and Function were assessed (Weeks 0, 4, 13, 26, 39, 52) and fixed flexion radiographs (QuAP positioned; Weeks 0, 26, 52) assessed medial joint space width (mJSW). Analysis of covariance adjusted for baseline was conducted using multiple imputation for missing data. Exploratory subgroups included: 1) unilateral symptomatic subjects (pre-specified; determined by history and examination) and 2) unilateral symptomatic subjects without comorbid pain (post-hoc; Widespread Pain Index  $\leq 4$ , Symptom Severity  $\leq 2$  [WP-]).

**Results:** 455 subjects (mean age 60.3 [ $\pm 8.7$ ] years, BMI 29.9 [ $\pm 4.6$ ] kg/m<sup>2</sup>, female 58.9%, KL grade 3 [64.4%], unilateral symptomatic OA [36.0%]) were enrolled, 91% with radiographic bilateral OA. Seventeen serious adverse events, all unrelated to SM04690, were reported.

The primary endpoint of Week 13 change from baseline in WOMAC Pain was not met. In ITT, at all timepoints, minimal clinically important differences ( $>10\%$  full range) in WOMAC Pain and Function compared to baseline were seen in all groups. In 0.07 mg unilateral symptomatic subjects, at 52 weeks, WOMAC Pain (4.4,  $p=0.049$ ), and Function (17.5,  $p=0.035$ ) were significantly improved compared to PBO. In 0.07 mg unilateral symptomatic WP- subjects at Weeks 26, 39, and 52, WOMAC Pain (4.6,  $p=0.039$ ; 5.9,  $p=0.042$ ; and 5.6,  $p=0.025$ , respectively) and Function (16.3,  $p=0.027$ ; 19.7,  $p=0.035$ ; and 22.8,  $p=0.017$ , respectively) were significantly improved compared to PBO (**Abstract SAT0586 – figure 1**).

At 26 and 52 weeks, 0.07 mg unilateral symptomatic (0.5 mm,  $p=0.006$  and 0.4 mm,  $p=0.021$ , respectively) and 0.07 mg unilateral symptomatic WP- (0.5 mm,  $p=0.016$  and 0.4 mm,  $p=0.032$ , respectively) subgroups demonstrated significant increases from baseline in mJSW compared to PBO (figure 1).

**Abstract SAT0586 – Figure 1.** Ladder plots depicting mean improvement (and 95% confidence intervals) of SMO4690 over placebo adjusted for baseline.

**Conclusions:** A target subgroup of unilateral symptomatic knee OA subjects and potential optimal dose (0.07 mg) of SM04690 were identified. Clinical and radiographic outcomes suggested that SM04690 has potential as a DMOAD, especially in subjects with unilateral symptomatic WP- knee OA. Further studies are ongoing.

### SAT0587 MAJOR SALIVARY GLANDS ULTRASONOGRAPHY IN DIFFERENTIAL DIAGNOSIS OF IGG4-RELATED DISEASE AND PRIMARY SJOGREN'S SYNDROME

E. Sokol, E. Rodionova, V. Vasilyev, S. Palshina, M. Burtseva. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** IgG4-related disease (IgG4-RD) is a group of fibro-inflammatory immunomediated conditions with IgG4 overexpression in the serum and affected tissues in the majority of patients. Major salivary and lacrimal glands are the most frequently affected sites in IgG-RD. Moderate sicca symptoms can be present as well thus requiring differential diagnosis with primary Sjogren's syndrome (pSS). Major salivary glands ultrasonography (sUS) has been reported as an effective diagnostic tool in pSS.

**Objectives:** To evaluate the difference in sUS score in pSS and IgG4-RD patients

**Methods:** 15 patients with IgG4-related sialoadenitis consecutively admitted to our clinic and 28 with pSS underwent sUS. Parenchymal echogenicity, homogeneity, hypoechogenic and hyperechogenic areas and clearness of salivary gland border were scored according to the Hocevar scoring system (cut-off – 15 points). Statistical analyses were performed using MEDCALC program. Median values of the sUS score and Mann-Whitney U-test were used to evaluate differences in total ultrasound score between patients in two groups.

**Results:** All patients with IgG4-related sialadenitis and pSS had some sUS abnormalities. The most frequent feature in IgG4-RD were: the presence of hypoechotic lesions in major salivary glands (53% of patients) or diffuse salivary gland parenchyma hypoechogenicity (27% of patients) and multiple intraglandular lymph nodes (66.7% of patients). Median value of sUS score in IgG4-RD group was 12 points and in pSS group – 22 points. The difference was significant (Mann-Whitney U-test 60.5,  $p < 0.05$ ).

**Conclusions:** Although different US-changes are frequently seen in IgG4-RD patients, sUS Hocevar score seems to be a rather reliable tool to differentiate IgG 4-related sialoadenitis and pSS.

### SAT0588 RHEUMATOLOGIC IMMUNE-RELATED ADVERSE EFFECTS OF CHECKPOINT INHIBITOR THERAPY: A SINGLE CENTRE COHORT OF 29 PATIENTS

M.D. Richter<sup>1</sup>, C.S. Crowson<sup>2</sup>, L.A. Kottschade<sup>2</sup>, H.D. Finnes<sup>2</sup>, S.N. Markovic<sup>2</sup>, U. Thanarajasingam<sup>2</sup>. <sup>1</sup>Graduate Medical Education; <sup>2</sup>Mayo Clinic, Rochester, USA

**Background:** Immune checkpoint inhibitors for advanced malignancy are associated with a wide range of autoimmune phenomena known as immune-related

adverse effects (irAEs).<sup>1</sup> Knowledge of irAEs resembling rheumatologic diseases is limited to case reports and small case series, and there are currently no specific guidelines on how to diagnose or manage these patients.

**Objectives:** To describe the prevalence, clinical presentation, and management of patients with rheumatologic irAEs from checkpoint inhibitor therapy.

**Methods:** We retrospectively studied all patients who received a checkpoint inhibitor for any malignancy at Mayo Clinic Rochester, Minnesota between January 1 st, 2011 and November 1 st, 2017. From these patients we identified those with possible rheumatologic irAEs using diagnostic codes, search terms, and the presence of specific laboratory testing.

**Results:** Of the 1216 patients who received any checkpoint inhibitor, we identified 29 who were clinically diagnosed with a rheumatologic irAE. The diagnosis was confirmed by a rheumatologist in all but 3 cases. Mean follow up time from irAE diagnosis was 1.5 years ( $\pm 1.1$ ). Seven patients had a pre-existing autoimmune disease with one of these being a rheumatologic disease (Giant-cell arteritis). irAEs included inflammatory arthritis,<sup>15</sup> sicca syndrome,<sup>3</sup> systemic sclerosis,<sup>3</sup> myositis,<sup>3</sup> vasculitis,<sup>3</sup> spondylitis,<sup>1</sup> and polymyalgia rheumatica.<sup>1</sup> Only one irAE represented a disease flare. Mean time from initiation of checkpoint inhibitor therapy to onset of irAE symptoms was 15.0 weeks ( $\pm 10.8$ ). 24 patients (83%) were treated with corticosteroids and 8 patients (28%) received additional therapy with disease modifying drugs. Mean treatment duration for these 24 patients was 19.5 weeks ( $\pm 21.7$ ), and 8 patients (33%) had complete symptom resolution within the study period. Rheumatologic irAEs resulted in discontinuation of checkpoint inhibitor therapy in 7 patients (24%).

Abstract SAT0588 – Table 1. Clinical Features

Rheumatologic irAEs	29 total
Inflammatory arthritis	15
Sicca syndrome	3
Systemic sclerosis	3
Myositis	3
Vasculitis	3
Spondylitis	1
Polymyalgia rheumatica	1
Treatment	
Prednisone only	16
Prednisone plus biologics	8
No treatment	5
Starting prednisone dose, MG, mean (St. Dev)	47 (26)
Weeks on prednisone, mean (St. Dev)	15 (11)
Weeks to symptom onset, mean (St. Dev)	15 (11)
Sedimentation rate, mean (St. Dev)	39 (30)
C-reactive protein, mean (St. Dev)	49 (57)
Diagnosed by rheumatologist	26 (90%)
Positive autoimmune serologies	4 (14%)
Flare of existing autoimmune disease	2 (7%)
Comorbid non-rheumatologic irAEs	19 (66%)

**Conclusions:** Our study represents one of the largest cohorts of rheumatologic irAEs to date. Most patients required long courses of treatment with only a minority achieving complete symptom resolution. Prospective, multicenter studies are necessary to determine the optimal management of these emerging disorders.

Kawakami<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Unit of Translational Medicine, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki; <sup>2</sup>Department of Infection and Host Defense, Graduate School of Medicine, Matsumoto; <sup>3</sup>Department of Pediatrics, School of Medicine, Kanazawa University, Kanazawa; <sup>4</sup>Proteo-Science Center, Ehime University, Matsuyama; <sup>5</sup>Department of Rheumatology, Fukushima Medical University School of Medicine, Fukushima, Japan

**Background:** Our previous nation-wide survey showed the clinical manifestations and prevalence of Japanese Familial Mediterranean Fever (FMF) patients. However, the clinical differences between young-onset FMF (YOFMF), adult-onset FMF (AOFMF), and late-onset FMF (LOFMF) have not been yet clarified.

**Objectives:** We sought to compare between the clinical profile of patients with AOFMF, LOFMF and YOFMF and to determine the clinical characteristics of them.

**Methods:** We enrolled consecutively 395 patients in 2006–2017. Mutation detection in exons 1, 2, 3, and 10 of the *MEFV* gene was performed. We defined YOFMF, AOFMF and LOFMF as the onset of FMF <20, 20–39 and ≥40 years of age, respectively. We compared clinical manifestations and mutations in *MEFV* gene among these three groups.

**Results:** The median age at the onset of YOFMF, AOFMF and LOFMF were 12.5, 28 and 51 years old respectively. A family history of FMF and a mutation in exon 10 of the *MEFV* gene were significantly more frequent in groups with younger onset ([YOFMF 28%, AOFMF 17%, LOFMF 12%; p<0.01], [YOFMF 51%, AOFMF 33%, LOFMF 19%; p<0.001], respectively). In the accompanying manifestations during the attacks, abdominal pain and chest pain were significantly more frequent in groups with younger onset ([YOFMF 64%, AOFMF 56%, LOFMF 30%; p<0.001], [YOFMF 45%, AOFMF 33%, LOFMF 24%; p<0.01], respectively), whereas arthritis and muscle pain were significantly more frequent in groups with older onset ([YOFMF 32%, AOFMF 48%, LOFMF 62%; p<0.001], [YOFMF 8%, AOFMF 18%, LOFMF 26%; p<0.01], respectively). There was no significant difference in the response to colchicine among the three groups.

	YOFMF (n=182)	AOFMF (n=115)	LOFMF (n=90)	P value		
				YOFMF vs AOFMF vs LOFMF	YOFMF vs Others	Others vs LOFMF
Thoracic pain	82/182(45%)	38/115(33%)	22/90(24%)	0.0025	0.0015	0.0060
Abdominal pain	117/182(64%)	64/115(56%)	27/90(30%)	<0.0001	0.0001	<0.0001
Arthritis	58/182(32%)	55/115(48%)	56/90(62%)	<0.0001	<0.0001	<0.0001
Myalgia	13/161(8%)	16/91(18%)	17/65(26%)	0.0014	0.0012	0.0051
Erysipelas-like erythema	18/182(10%)	16/115(14%)	17/90(19%)	0.11	0.10	0.08
Headache	25/161(16%)	18/91(20%)	10/65(15%)	0.65	0.65	0.85

**Conclusions:** Our results suggest that older onset FMF had a lower percentage of mutations in exon10 of the *MEFV* gene and predominantly presented arthritis and muscle pain during the attacks. It is thus important to distinguish them from other inflammatory diseases such as gout, adult Still's disease, and infectious arthritis.

### LONG-TERM EFFICACY AND SAFETY OF ADALIMUMAB BY AETIOLOGY IN PATIENTS WITH NON-INFECTIOUS UVEITIS IN THE VISUAL III TRIAL

P.T. Merrill<sup>1</sup>, A. Vitale<sup>2</sup>, M. Zierhut<sup>3</sup>, E. Fortin<sup>4</sup>, H. Goto<sup>5</sup>, M. Kron<sup>6</sup>, A. Song<sup>7</sup>, K. Douglas<sup>7</sup>, S. Pathal<sup>8</sup>. <sup>1</sup>Rush University Medical Center, Chicago; <sup>2</sup>University of Utah, Salt Lake City, USA; <sup>3</sup>University of Tuebingen, Center of Ophthalmology, Tuebingen, Germany; <sup>4</sup>University of Montreal, Montreal, Canada; <sup>5</sup>Tokyo Medical University, Tokyo, Japan; <sup>6</sup>AbbVie Deutschland GmbH and Co KG, Ludwigshafen, Germany; <sup>7</sup>AbbVie Inc., North Chicago, USA; <sup>8</sup>AbbVie Ltd, Maidenhead, UK

**Objectives:** To evaluate the long-term safety and efficacy of adalimumab in patients with non-infectious intermediate, posterior, or panuveitis, across different disease etiologies.

**Methods:** Adult patients in the Phase III VISUAL I/II trials, who met treatment failure (TF) criteria or who completed the study without TF, were eligible to enter the Phase III open-label extension study, VISUAL III, wherein patients received adalimumab 40 mg every other week. In this exploratory analysis, endpoints were analysed by six uveitis etiologies: i) idiopathic/other (IO), ii) birdshot chorioretinopathy (BCR), iii) multifocal choroiditis and panuveitis (MCP), iv) Vogt-Koyanagi-Harada syndrome (VKH), v) sarcoidosis, vi) Behçet's disease (BD). Endpoints assessed through Week 78 of treatment were proportion of patients with: no active inflammatory lesions in both eyes; anterior chamber (AC) cell grade ≤0.5 +in both eyes; vitreous haze (VH) grade ≤0.5 +in both eyes; and quiescence (defined as no active inflammatory lesions AND AC cell grade ≤0.5 + AND VH grade ≤0.5+). Mean best corrected visual acuity (BCVA) was also assessed. Missing data were reported using non-responder imputation for categorical endpoints and last observation carried forward for continuous variables. Adverse events (AEs) were collected from the first adalimumab dose in VISUAL III through the interim cut-off date of Oct 31, 2016.

**Results:** Of 371 patients included in the intent-to-treat analysis, disease etiology subgroups were (n[%]): IO (155 [41.8]); BCR (51 [13.7]); MCP (14 [3.8]); VKH (72 [19.4]); Sarcoidosis (52 [14.0]); BD (27 [7.3]). The proportion of patients achieving quiescence improved over time in all uveitis etiologic subgroups: IO 28.4%/63.9% (Week 0/Week 78), BCR 43.1%/64.7%, MCP 35.7%/50.0%, VKH 37.5%/63.9%, sarcoidosis 32.7%/69.2%, and BD 44.4%/74.1%. The proportions of patients with no active inflammatory lesions, AC cell grade ≤0.5+, or VH grade ≤0.5+, showed moderate increases or decreases between Weeks 0 and 78 within specific etiology subgroups; percentage ranges across all subgroups at Weeks 0/78, were 60.8–87.5/57.1–78.8% (no active inflammatory lesions), 47.2–92.2/50.0–77.8% (AC cell grade ≤0.5+), and 42.9–72.2/57.1–77.8% (VH grade ≤0.5+), respectively. Improvement or maintenance of mean BCVA was observed over time across the etiologic subgroups. AE rates were consistent with the VISUAL I and II trials.

**Conclusions:** Adalimumab increased the percentage of patients achieving quiescence and improved or maintained visual acuity at Week 78 of the VISUAL III study, with consistent results across uveitis etiologic subgroups. No new safety signals were detected with long-term adalimumab treatment.

SAT0591

### DEMOGRAPHIC AND CLINICAL FEATURES OF FAMILIAL MEDITERRANEAN FEVER PATIENTS

O. Ozdemir Isik<sup>1</sup>, B. Gonul<sup>2</sup>, A. Erof<sup>2</sup>, S. Tekeoglu<sup>1</sup>, D. Temiz Karadag<sup>1</sup>, A. Yazici<sup>1</sup>, A. Cefle<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Internal Medicine, Kocaeli University School of Medicine, Kocaeli, Turkey

**Background:** Familial Mediterranean Fever (FMF) is an autosomal recessive genetic disorder that causes recurrent episodes of fever, polyserositis, arthritis, skin eruptions.

**Objectives:** In this study, we aim to present clinical and demographic features of FMF patients followed up in our clinic.

**Methods:** The clinical, demographic, genetic features and managements of 402 FMF patients (fulfilling Tel-Hashomer Diagnostic Criteria) were analysed.

**Results:** The mean age was 36.8±11.2 years, mean diagnosis age was 28±11.9 years, and mean disease duration was 189.2±124.5 months, mean duration between onset of disease and onset of treatment was 93.6±104 months. Consanguineous marriage was detected in 7%<sup>29</sup> patients. Fever and abdominal pain both were initial symptoms in 72% of the patients, while 7% of them had chest pain, 4% had only fever, 15% had arthritis, 1% had erysipelas-like erythema and 1.5% had inflammatory back pain as the first symptom of FMF (table 1).

Eight patients (2%) were suffered from chronic kidney disease and 2 of them were on dialysis programme. Amyloidosis were identified in 14 patients (3.5%) with biopsy.

At least one mutation of *MEFV* gene was detected in 78% patients There was no mutation in 8% patients. In 15% patients, *MEFV* gene analysis could not be done. The most frequent mutation was M694V mutation and its allel frequency was 54%; the frequency of V726A, M680I, E148Q, R761H and A744S allels mutation

were 11%, 7%, 7%, 2%, 1%, respectively. The frequency of compound mutation was 38%, and the most common compound mutation was M694V+R202Q (11%). There was significantly relationship between M694V mutation and arthritis, erysipel-like erythema, proteinuria, sacroiliitis (table 2). Amyloidosis was more frequent in patients who had M694 homozygous mutation. Mean age of disease onset was lower in patient who had M694V homozygous mutation than M694V heterozygous mutation ( $p < 0.001$ ).

**Abstract SAT0591 – Table 1.** Demographical and Clinical Features of FMF Patients

n=402	n(%)
Gender Female	241 (60)
Male	161 (40)
Fever	299 (75.5)
Abdominal Pain	347 (86)
Erysipel-like erythema	54 <sup>13</sup>
Chest pain	83 (21)
Positive family history	174 (43)
Appendectomy	96 <sup>24</sup>
Amyloidosis	14 (3.5)
Chronic kidney disease	8 (2)
Inflammatory back pain	63 <sup>16</sup>
Arthritis	129 (32)
Hip pain	27 (7)
Heel pain	30 (7.5)
Uveitis	4 (1)
Sacroiliitis	44 <sup>11</sup>
Biological treatment	16 <sup>4</sup>

**Abstract SAT0591 – Table 2.** Relationship between M694V mutation and clinical findings

N(%)	Negative	Heterozygous	Homozygous	P
Fever	75 (60)	80 (62)	67 (75)	0,0503
Abdominal pain	107 (85,6)	107 (82,9)	79 (88,8)	0,487
Erysipel-like erythema	5 (4)	13 (10,1)	19 (21,3)	<b>0,0003</b>
Chest pain	21 (16,8)	24 (18,6)	20 (22,5)	0,0575
Myalgia	2 (1,6)	5 (3,9)	3 (3,4)	0,535
Arthritis	32 (25,6)	34 (26,4)	41 (46,1)	<b>0,002</b>
Sacroiliitis	11 (8,8)	12 (9,3)	19 (21,3)	<b>0,0096</b>
Amyloidosis	4 (3,2)	0 (0)	10 (11,2)	N/A
Proteinuria	7 (5,6)	5 (3,9)	18 (20,2)	<b>0,000</b>

**Conclusions:** Tight control and sustained management are important in FMF to protection from amyloidosis. Similar to literature, the most frequent mutation was M694V mutation, and there was significantly relationship between M694V mutation and arthritis, erysipel-like erythema<sup>(1)</sup>, proteinuria, sacroiliitis<sup>(2)</sup> in our study.

#### SAT0592 HRCT PULMONARY MANIFESTATIONS IN PATIENTS WITH SYNOVITIS, ACNE, PUSTULOSIS, HYPEROSTOSIS, AND OSTEITIS (SAPHO) SYNDROME

S. Liu<sup>1</sup>, C. Li<sup>2</sup>, W. Song<sup>3</sup>, W. Xu<sup>4</sup>, K. Xu<sup>4</sup>, W. Zhang<sup>5</sup>, X. Tian<sup>4</sup>. <sup>1</sup>Peking Union Medical College; <sup>2</sup>Traditional Chinese Medicine; <sup>3</sup>Radiology; <sup>4</sup>Respiratory medicine; <sup>5</sup>Rheumatology, Peking Union Medical College Hospital, Beijing, China

**Background:** Synovitis, acne, palmoplantar pustulosis, hyperostosis and osteitis syndrome (SAPHO) is a rare syndrome that affects the skin, bones and joints.<sup>1</sup> SAPHO syndrome shares a variety of features with the seronegative spondyloarthropathies (SpAs), such as psoriatic arthritis (PsA).<sup>1</sup> While the extra-articular manifestations of PsA are well defined, the systemic involvements of SAPHO syndrome are only reported occasionally.<sup>2</sup> Previous cases of accompanied pleural effusion<sup>3, 4</sup> and organising pneumonia<sup>5</sup> were reported. In clinical work, we observed that pulmonary lesions progressed when diseases aggravated.

However, the relationship between pulmonary manifestations and diseases activity remains unclear.

**Objectives:** This study is to explore the pulmonary comorbidity with SAPHO syndrome.

**Methods:** Pulmonary HRCT images were reconstructed from whole-spine CT images in 67 SAPHO patients. HRCT images of 58 healthy controls were obtained and reviewed. Pneumonia and tuberculosis were excluded. We investigated the presence of different HRCT images findings with detailed examinations.

**Results:** In detailed HRCT evaluations, abnormalities were identified in 45 of all patients. We found stripe in 29 (43.3%) cases, patchy shadows in 22 (32.8%), ground-glass opacity in 11 (16.4%), pleural thickening in 9 (13.4%), solitary nodule in 6 (9%), bronchiectasis in 3 (4.5%), pulmonary bulla in 2 (3%), multiple nodules in 1 (1.5%), and interstitial change in 1 (1.5%). Compared with healthy controls, SAPHO patients have significantly higher rate of patchy shadows while significantly lower percentage of nodules (especially multiple nodules), although the overall rates of abnormal HRCT findings are similar.

**Abstract SAT0592 – Figure 1.** HRCT images in 3 SAPHO patients. A: Ground glass opacities (arrows); B: Solitary nodule (arrow); C: Interstitial change (arrow).

**Conclusions:** Our study was the first to study HRCT pulmonary changes in SAPHO patients. SAPHO patients have significantly higher percentage of patchy shadows and significantly lower rate of pulmonary nodules than healthy controls. BASDAI and age are possible good predictors for abnormal HRCT pulmonary findings.

#### SAT0593 PROGRESSIVE FIBROSING INTERSTITIAL LUNG DISEASE (PF-ILD) IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES

A. Fischer<sup>1</sup>, M. Wijsenbeek<sup>2</sup>, M. Kreuter<sup>3</sup>, B. Mounir<sup>4</sup>, L. Zouad-Lejour<sup>4</sup>, V. Acciai<sup>4</sup>, C.D. Wells<sup>5</sup>, M. Quaresma<sup>4</sup>, C. Denton<sup>6</sup>. <sup>1</sup>University of Colorado Hospital, Aurora, USA; <sup>2</sup>University Medical Center Rotterdam, Gravendijkwal, Netherlands; <sup>3</sup>Universitätsklinikum Heidelberg, Heidelberg; <sup>4</sup>Boehringer Ingelheim International, Ingelheim, Germany; <sup>5</sup>Decision Resources Group, Burlington, USA; <sup>6</sup>University College London, London, UK

**Background:** Interstitial lung disease (ILD) associated with autoimmune conditions is among the most challenging aspect of care for patients with rheumatic diseases. While idiopathic pulmonary fibrosis (IPF) is the classic fibrosing ILD, some patients with differing clinical ILD diagnoses including autoimmune associated-ILD can develop a progressive fibrosing phenotype. This phenotype is characterised by progressive pulmonary fibrosis, worsening respiratory symptoms, declining lung function, resistance to immunomodulatory therapies and early mortality. There are limited data available on current practice in diagnosis, management and treatment of PF-ILD in patients with autoimmune rheumatic diseases.

**Objectives:** To investigate the patient journey in patients with autoimmune rheumatic diseases and PF-ILD.

**Methods:** Twenty-two ILD experts from Germany, Japan, UK and the US participated in a 1 hour interview. Physicians who spend  $\geq 75\%$  of their professional time managing patients and in whose caseload  $\geq 10$  patients had PF-ILD in the

past year completed an online survey. Physicians (243 pulmonologists, 203 rheumatologists, 40 internal medicine physicians) from the US, Japan, Germany, France, Italy, Spain and UK participated. ILD prevalence and treatment patterns in the US were analysed based on insurance claims from patients with  $\geq 2$  claims with an ILD diagnosis between 2014 and 2016 (ICD-9/10 codes) and  $\geq 1$  visit to a pulmonologist in the 3 years.

**Results:** Analysis of US claims identified 21 592 patients with autoimmune ILD. Rheumatoid arthritis ILD (RA-ILD) and systemic sclerosis ILD (SSc-ILD) were the most prevalent ILDs across all autoimmune rheumatic diseases. The course of the patient journey is summarised (figure 1). Most patients with autoimmune-associated ILD initially present to a rheumatologist or a primary care doctor. Both pulmonologists and rheumatologists play a key role in detection and diagnosis of ILD; however US claims data suggest that the former are more likely to make the diagnosis. Although there is significant inter-patient variation, diagnosis of ILD is estimated to take approximately 9–12 months after symptoms develop. In general ILD is diagnosed earlier in SSc. Management of patients with autoimmune-associated ILD is typically multidisciplinary, involving both a rheumatologist and a pulmonologist. The physician survey suggested that 24%–31% of patients with autoimmune-associated ILD develop PF-ILD; detection can take up to 1 year. The majority of physicians use corticosteroids as a first line treatment across autoimmune rheumatic diseases; cyclophosphamide and mycophenolate mofetil were the second and third first line option for SSc-ILD. Physicians estimate the total disease course in patients with autoimmune-associated PF-ILD to be approximately 5–7 years.

**Abstract SAT0593 – Figure 1.** Physician\* Estimated PF-ILD Disease Course in patients with autoimmune rheumatic diseases

**Conclusions:** Physicians who manage patients with autoimmune diseases estimate that 24%–31% develop PF-ILD. Delayed referral to a pulmonologist or rheumatologist is likely to delay diagnosis and management of PF-ILD. Life expectancy for these patients is believed to be similar to patients with IPF. There is an unmet need for treatments that slow or stabilise disease progression of PF-ILD.

**SAT0594 WHICH ONE IS MORE VALUABLE FOR DIAGNOSIS OF ADULT ONSET STILL'S DISEASE? SOLELY NEUTROPHILIA OR LEUKOCYTOSIS WITH NEUTROPHILIA?**

E. Bilgin<sup>1</sup>, A. Erden<sup>2</sup>, B. Armagan<sup>2</sup>, L. Kılıç<sup>2</sup>, A. Sari<sup>2</sup>, G. Yardımcı<sup>2</sup>, E. Bilgin<sup>3</sup>, A. Akdoğan<sup>1</sup>, Ö. Karadağ<sup>2</sup>, S. Apraş Bilgen<sup>2</sup>, I. Ertenli<sup>2</sup>, S. Kiraz<sup>2</sup>, U. Kalyoncu<sup>2</sup>.  
<sup>1</sup>Internal Medicine, <sup>2</sup>Internal Medicine, Division of Rheumatology, <sup>3</sup>Physical Medicine and Rehabilitation, Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background:** Adult onset Still's disease (AOSD) is a rare, auto-inflammatory disease that has unknown etiology and poorly defined pathogenesis. To date, there are several classification criteria, available for AOSD, but most commonly used one is proposed by Yamaguchi et al.<sup>1</sup> One of the major items of this set of criteria is leukocytosis with neutrophilia.

**Objectives:** To usefulness of solely neutrophilia instead of leukocytosis with neutrophilia for the Yamaguchi criteria.

**Methods:** Sixty-one AOSD patients followed at Hacettepe University department of rheumatology were included to analysis. Diagnosis of AOSD was based on physicians' decision, but Yamaguchi criteria was applied for all patients, as well. Complete blood test with differential was noted at the time of diagnosis of AOSD. One of the major criteria of Yamaguchi criteria was "leukocytosis with neutrophilia (defined as more than 80% of leukocytes would be granulocyte)". Leukocytosis [ $>10000/\text{mm}^3$  x1000] and neutrophilia [(6400/ $\text{mm}^3$ ) x1000] were defined according to normal upper limits of our laboratory. To compare with Yamaguchi criteria, neutrophil/leukocyte ratio for all patients were calculated. Descriptive statistics for non-normally distributed countable data were given as median and interquartile range (Med [IQR]).  $p < 0,05$  was considered as statistically significant.

**Results:** Total 61 patients (46 (75%) female) were recruited. Prevalence of major and minor Yamaguchi criteria were as follow: fever in all patients, arthralgia in 58 (95%) patients, rash in 43 (71%) patients, sore throat in 48 (79%) patients, lymphadenopathy and/or splenomegaly in 23 (38%) patients, absence of RF and ANA in 58 (96%) patients, elevated liver enzymes in 47 (77%) patients. Median leukocyte and neutrophil count were 13.5 (IQR;10.1–18,9) x 1000/ $\text{mm}^3$ , 12 (IQR;7.2–17.6) x 1000/ $\text{mm}^3$ , respectively. "Neutrophilia >UNL" was significantly more prevalent than "leukocytosis with neutrophilia >80%" (51 (83,6%) vs. 37 (60,6%),  $p < 0,001$ ). Overall, 14 (23%) patients would have one more positive major criteria if "neutrophilia >UNL" would be used instead of "leukocytosis with neutrophilia >80%". When current Yamaguchi criteria (including leukocytosis with neutrophilia >80%) applied to patients with AOSD, 57 (93,5%) of 61 patients were met the criteria. However, when "neutrophilia >UNL" was used instead of "leukocytosis with neutrophilia >80%", all patients were met the revised criteria.

**Conclusions:** As all patients who had leukocytosis also had neutrophilia but it was not vice versa. In other words, choosing "leukocytosis with neutrophilia >80%" instead of "neutrophilia >UNL" can underdiagnose AOSD approximately in 7% of patients according to Yamaguchi criteria. Moreover, Physicians should be keep in mind that reactive hemophagocytosis may influence the count of leukocyte. Consequently, using "neutrophilia >UNL" as a criteria instead of "leukocytosis with neutrophilia >80" may be more appropriate for the diagnosis of AOSD in real life.

**SAT0595 ANALYSIS OF RECURRENCES AFTER SUSPENSION OF IMMUNOSUPPRESSIVE TREATMENT IN NON-INFECTIOUS UVEITIS**

M. Uriarte<sup>1</sup>, C. Martín<sup>2</sup>, J. Gonzalez<sup>2</sup>, R. García de Vicuña<sup>1</sup>, E. Pato<sup>3</sup>, M. Gorroño<sup>4</sup>, Á. M. Aparicio<sup>5</sup>, M. Cordero<sup>6</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Ophthalmology, Hospital Universitario La Princesa, <sup>3</sup>Rheumatology, Hospital Clínico San Carlos, <sup>4</sup>Ophthalmology, Hospital Príncipe de Asturias, Madrid, <sup>5</sup>Rheumatology, Hospital Virgen de la Salud, Toledo, <sup>6</sup>Ophthalmology, Hospital Universitario de León, León, Spain

**Background:** Uveitis is the most common ocular inflammatory disease. According to the classification, non-infectious uveitis 70% of the total, presenting a chronic course and with it, an increased risk of complications. The phased therapeutic approach in ophthalmology is well established and is based on the efficacy of synthetic and biological immunosuppressive therapy.<sup>1</sup> However, we do not have evidence-based protocols that allow us to know how long to maintain them, or when to interrupt them.

**Objectives:** The main objective is to evaluate the free time without ocular inflammatory activity after the withdrawal of the synthetic and/or biological immunosuppressive treatment in patients with non-infectious uveitis.

As secondary objectives are collected the epidemiological and clinical characteristics, the distribution of the different immunosuppressive drugs employed and

analysed the cases of recurrence after the interruption of treatment, and the need of reintroduction.

**Methods:** A retrospective cohort multicenter study was conducted in patients with a diagnosis of non-infectious uveitis followed in a multidisciplinary unit, that after two or more years of ocular and extraocular inactivity, the immunosuppressive treatment was suspended. It was defined inactive uveitis as cell Tyndall 0 in anterior and vitreous chamber, as well as the absence of other signs of active inflammation (retinal infiltrates, choroid and vasculitis and/or papillitis with angiographic leakage).

Demographic characteristics, anatomical location and laterality of the uveitis, visual acuity at the beginning and end of the study and the drugs used were recorded.

**Results:** We analysed 48 patients with an average age at the onset of immunosuppressive treatment of 39.3 years ( $\pm 16$  years). 85.4% of the uveitis were bilateral. The main diagnoses are described in table 1. In 56.3% of cases a single immunosuppressant was used. Cyclosporine was the most employed (72.9%) and methotrexate was the most used in monotherapy (83.3%). 83% of patients received corticosteroids and 12% treatment with Infliximab. The mean duration of immunosuppressive treatment was 6.9 years ( $\pm 5$ , 7 años). The percentage of total and ocular recurrence was 37.5% and 31.25% respectively. The mean duration of follow-up after treatment suspension was 4.3 years ( $\pm 4.5$  years), being more than 1 year in 77.1% of patients. We found that 75% of patients remained free of recurrence at least 27 months. The administration of two or more immunosuppressive drugs proved to be a risk factor for recurrence ( $p=0,048$ ) and reintroduction of treatment after it ( $p=0,008$ ), which was performed in 39% of the ocular recurrences. Visual acuity did not suffer variation in 78.6% of recurrences and 80.3% of those that did not recur.

Abstract SAT0595 – Table 1-. Main diagnoses

Diagnosis	Female (n=29)	Male (n=19)	All (n=48)
Idiopathic uveitis (n=13)	7 (53,8%)	6 (46,2%)	13/48 (27%)
Juvenil idiopathic arthritis (n=1)	1 (100%)	0 (0%)	1/48 (2,08%)
Multifocal Choroiditis with Panuveitis (n=1)	0 (0%)	1 (100%)	1/48 (2,08%)
Serpiginous choroiditis (n=3)	1 (33,3%)	2 (66,7%)	3/48 (6,25%)
Behçet disease (n=10)	4 (40%)	6 (60%)	10/48 (20,83%)
Birdshot Retinochoroidopathy (n=5)	3 (60%)	2 (40%)	5/48 (10,41%)
Inflammatory bowel disease (n=1)	1 (100%)	0 (0%)	1/48 (2,08%)
Multiple sclerosis (n=3)	3 (100%)	0 (0%)	3/48 (6,25%)
Ankylosing spondylitis (n=1)	0 (0%)	1 (100%)	1/48 (2,08%)
HLA27 positive (n=1)	1 (100%)	0 (0%)	1/48 (2,08%)
Pars planitis (n=2)	1 (50%)	1 (50%)	2/48 (4,16%)
Sarcoidosis (n=5)	5 (100%)	0 (0%)	5/48 (10,41%)
Vogt-Koyanagi-Harada (n=2)	2 (100%)	0 (0%)	2/48 (4,16%)

**Conclusions:** In our cohort, patients with no ocular inflammatory activity for at least two years could benefit from the suspension of immunosuppressive treatment without a visual risk. The use of one or more immunosuppressive drugs has been identified as a risk factor for recurrence.

**Objectives:** To analyse whether thoracic involvement at diagnosis is associated with a specific clinical presentation of sarcoidosis.

**Methods:** The SARCOGEAS-SEMI is a nationwide registry of patients with sarcoidosis. Radiographic stages at diagnosis were classified as stage 0 (normal), stage I (only bilateral hilar lymphadenopathy -BHL-), stage II (BHL +pulmonary infiltrates), stage III (only infiltrates) and stage IV (fibrosis).

**Results:** The cohort consisted of 1245 patients (722 women, 523 men, mean age at diagnosis 47 years). Pulmonary imaging data at diagnosis was available in 1230 patients including 395 (32%) with stage I, 500 (40%) with stage II, 195 (16%) with stage III and 42 (3%) with stage IV. Patients with no thoracic involvement (stage 0) were more frequently women (73% vs 56%,  $p=0.002$ ), older (52.1 vs 46.8 years,  $p=0.001$ ) and had a higher frequency of skin (54% vs 34%,  $p<0.001$ ) and neurological (14% vs 6%,  $p=0.004$ ) involvements in comparison with those with stages I-IV. Patients without ILD (stage I) were more frequently women (61% vs 54%,  $p=0.031$ ), had a higher frequency of fever (27% vs 19%,  $p=0.002$ ), skin (43% vs 29%,  $p<0.001$ ) and salivary gland involvement (8% vs 3%,  $p=0.001$ ), and a lower frequency of respiratory symptoms (37% vs 54%,  $p<0.001$ ) and liver involvement (9% vs 16%,  $p=0.001$ ) with respect to those with ILD (stages II-IV).

**Conclusions:** A specific clinical and epidemiological pattern of disease presentation was found in patients with no thoracic involvement and in those presenting with interstitial lung disease at diagnosis.

**Disclosure of Interest:** None declared

SAT0597

#### NEW AUTOINFLAMMATORY PHENOTYPE MANIFESTING AS HYPOCOMPLEMENTEMIC URTICARIAL VASCULITIS AND ASSOCIATED WITH HOMOZYGOUS AGBL3 VARIANT

A. Gül<sup>1</sup>, N. Abacı<sup>2</sup>, S. Sirma Ekmekci<sup>2</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine; <sup>2</sup>Department of Genetics, Istanbul University, Institute for Experimental Medicine, Istanbul, Turkey

**Background:** Autoinflammatory disorders are primarily associated with inborn errors of the innate immune system, but some of them are also developing autoimmune features.

**Objectives:** To define a new autoinflammatory phenotype in a patient with inflammatory attacks manifesting as hypocomplementemic urticarial vasculitis and to identify responsible gene/pathway.

**Methods:** Clinical manifestations of the index case and his family history were carefully searched and blood samples were collected from the index case and his both parents. Genomic variations were screened by whole exome sequencing,

and a systematic search was carried out specifically for identification of deleterious genetic variants in genes involved in novel inflammatory pathways.

**Results:** The index case was coming from a consanguineous family of Assyrian origin, who is now 22-year-old male. He presented to our outpatient clinic with recurrent attacks of fever, urticarial rash on the extremities and trunk, conjunctival injections and arthralgia, without a trigger or more frequently following an infection. His attacks started when he was 13, and two to three days lasting attacks recurred more frequently during warm weather conditions or following hot baths. He had highly elevated CRP and ESR during attacks, but his acute phase response did not return to normal values in between the flares. Low C3 and C4 values were also observed during asymptomatic periods. His ANA test became positive during the course of his disease, with an increasing titer in the last year. He responded partially to corticosteroids as well as canakinumab and anakinra treatments, and he is currently on low dose steroids and 100 to 200 mg/day anakinra. Whole exome sequencing revealed a deleterious homozygous c.769C>T mutation in AGLB3 (ATP/GTP binding protein-like 3) gene, which results in early termination of the protein (p.Gln257Ter) and deletion of the functional carboxypeptidase domain. This protein belongs to metalloproteinases that mediate both deglutamylation and deaspartylation of target proteins. AGLB3 is suggested to catalyse the deglutamylation of polyglutamate side chains, especially in proteins such as tubulins. Also, STRING search revealed the interaction of AGLB3 with complement regulatory proteins, such as CD46, CD55, and CD59, which are potent inhibitors of the complement membrane attack complex. We searched databases from Turkey and other sources including 1000 Genomes Project data, and we could not identify this variant in other individuals.

**Conclusions:** This study identifies the AGLB3 metalloproteinase gene as a potential autoinflammatory gene involved in a novel pathway and possibly associated with hypocomplementemic urticarial vasculitis phenotype. Previously, DNASE1L3 mutations have been associated with hypocomplementemic urticarial vasculitis and systemic lupus erythematosus phenotype. The loss of function mutation in the AGLB3 may result in a potent innate inflammatory response as well as autoimmunity through a new pathway, which is resulting in lower complement levels and ANA positivity along with recurrent inflammatory episodes. This complex phenotype explains a partial response to the IL-1 blockade, and further studies in patients/families with a similar phenotype are needed.

#### SYSTEMATIC LITERATURE REVIEW ON THE EFFICACY AND SAFETY OF IMMUNOMODULATORY DRUGS IN PATIENTS WITH NONINFECTIOUS INTERMEDIATE AND POSTERIOR UVEITIS, PANUVEITIS AND MACULAR OEDEMA

A. Gómez Gómez<sup>1,2</sup>, E. Loza<sup>3</sup>, M.P. Rosario<sup>3</sup>, G. Espinosa<sup>4</sup>, J. M<sup>5</sup>, J.M. Herrerías<sup>6</sup>, S. Muñoz<sup>7,8</sup>, M. Cordero-Coma<sup>9</sup>. <sup>1</sup>Rheumatology, Hospital Infanta Sofía; <sup>2</sup>Universidad Complutense de Madrid; <sup>3</sup>Instituto de Salud Musculosquelética (INMUSC), Madrid; <sup>4</sup>Department of Autoimmune Diseases, Institut Clinic de Medicina i Dermatologia, Hospital Clínic., Barcelona; <sup>5</sup>Unidad de Inmunología, Complejo Asistencial Universitario e Instituto de Biomedicina Universidad de León (IBIOMED), León; <sup>6</sup>IOBA, Universidad de Valladolid, CIBER-BBN, Hospital Clínico Universitario de Valladolid, Valladolid; <sup>7</sup>Universidad Europea de Madrid; <sup>8</sup>Rheumatology, Hospital Universitario Infanta Sofía, Madrid; <sup>9</sup>Unidad de Uveitis, Complejo Asistencial Universitario e Instituto de Biomedicina Universidad de León (IBIOMED), León, Spain

**Background:** Posterior segment uveitis (PSU) is a sight-threatening condition

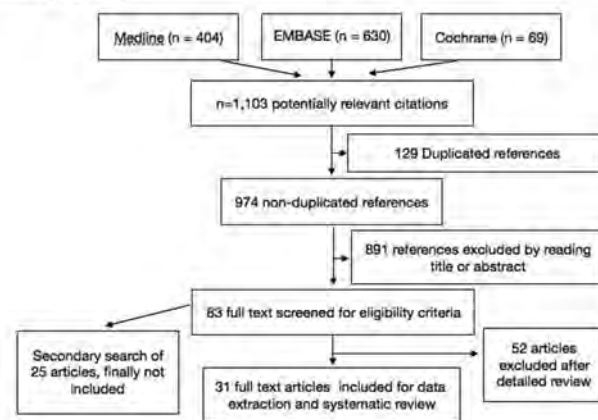

**Objectives:** To perform a systematic review of the literature on the use of immunomodulatory drugs in adult patients with non-infectious and non-malignant PSU including intermediate (IU) and posterior uveitis (PU), panuveitis (PanU) and macular oedema (ME).

**Methods:** Search strategies were designed for Medline, Embase, and Cochrane Library for articles with clinical, safety or cost-effectivity data up to, Jan 2017 followed by secondary search from their bibliography. Quality was assessed (Jadad/Oxford)

**Results:** From 1103 articles, 31 moderate quality clinical trials (CT) were selected, prospective/retrospective, with variability in mean duration, No. and patients' characteristics. PSU was treated with synthetic DMARDs methotrexate (MTX), azathioprine (AZA), cyclosporine A (CsA), cyclophosphamide (CyC), tacrolimus, sirolimus, micophenolate (MMF) and interferon  $\beta$ , and biologic DMARDs ranibizumab, daclizumab, rituximab (RTX), secukinumab, adalimumab (ADA), bevacizumab and infliximab (IFX) at usual dosages. Most common measures: visual acuity (VA), macular thickness and vitreous haze. MTX vs.MMF, was effective in IU, PU and PanU, with no differences in efficacy and adverse events (AEs), neither in Vogt-Koyanagi-Harada. MTX was effective with RTX, and SC was inferior to IFN $\beta$  with lower rate of AEs in IU with cistoid ME (CME). CsA did not show efficacy vs. placebo (pbo), with more neurological AEs. Tacrolimus vs. CsA was safer with similar efficacy, and CsA was useful with no differences vs.

prednisone (pred) or vs.CsG, and similar vs.CYC at 2 y in Behçet PSU. CsA +pred + ketoconazole combined showed additional benefits. CYC+AZA were effective in PU, except for VA and retinal vasculitis, with no differences vs. RTX +MTX. CYC was useful in serpinginoid vasculitis  $\pm$ dexamethasone. ADA was useful in IU, PU and PanU vs. pbo. IFX in Behçet PSU, was more effective vs. prednisolone +CsA + AZA/MTX. Intravitreal ADA and IFX did not show any benefit. Secukinumab vs. pbo did not prevent recurrences. In another RCT, IV route showed a higher response rate vs.SC for 30 mg/kg, with similar rate of EAs. Intravitreal bevacizumab was effective in multifocal choroiditis and CME. Intravitreal ranibizumab was useful in pigmentary retinitis +CME. Daclizumab in Behçet PSU did not show benefit vs. pbo. Tacrolimus as 2nd line in PU was effective  $\pm$ pred. Intravitreal and subconjunctival sirolimus were effective in IU, PU and PanU in vitreal haze but not VA and ME, improving functional scores

#### Studies flow chart

**Conclusions:** 1 Moderate quality of evidence

2 Variability in patients, definitions and outcomes

3 Systemic DMARDs MTX, MMF, CsA, CyC, tacrolimus, sirolimus, MMF and IFN $\beta$  were useful in PSU;AZA in combination

4 Biologic DMARDs ADA, IFX (systemic), ranibizumab, bevacizumab (intravitreal) were useful, daclizumab did not show efficacy. Possible efficacy of secukinumab

5 Intravitreal anti-TNF (ADA,IFX) were not useful

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3114

SAT0599

#### IDIOPATHIC GRANULOMATOUS MASTITIS MAY RESPOND WELL TO COMBINATION OF IMMUNOSUPPRESSIVES AND GLUCOCORTICOIDS

A. Sarı<sup>1</sup>, A. Konan<sup>2</sup>, M. Akpınar<sup>3</sup>, B. Armagan<sup>1</sup>, A. Erden<sup>1</sup>, L. Kilic<sup>1</sup>, O. Karadag<sup>1</sup>, A. Akdogan<sup>1</sup>, S. Apras Bilgen<sup>1</sup>, S. Kiraz<sup>1</sup>, I. Ertenli<sup>1</sup>, U. Kalyoncu<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>General Surgery, Hacettepe University Faculty of Medicine; <sup>3</sup>Radiology, Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background:** Idiopathic granulomatous mastitis (IGM) is a rare inflammatory disease of breast. Corticosteroids (CS) and immunosuppressive agents constitute treatment alternatives other than surgery.

**Objectives:** To evaluate the clinical characteristics and treatment responses of IGM patients followed up in our clinic.

**Methods:** The medical records of 70 IGM patients who were referred to Hacettepe University Rheumatology Clinic were examined. Forty-four patients who had at least one visit in the last 2 years were included in the analysis. Demographic, clinical and laboratory characteristics of the patients, treatments, clinical and/or ultrasonographically measured lesion sizes at the time of diagnosis and at the last follow-up were recorded. Complete and partial response in the last control visit were defined as  $\geq$ 50% and <50% decrease in the lesion size, respectively. Lesions which are stable or increasing in size was accepted as unresponsive. Increase in the drug dose by the clinician or increasing of the lesion size during follow-up were considered as relapse.

**Results:** Median age was 35.7 (24.3–57.2) years and median symptom duration was 2.5 (0.2–54.1) months at baseline. Palpable mass (90.9%) and breast pain (88.1%) were the most common symptoms. Skin fistules and axillary lymphadenopathy were present in 16 (37.2%) and 15 (34.1%) patients, respectively. Erythema nodosum was seen in 5 (11.4%) patients during follow-up. The median follow-up duration was 10.5 (1.05–99.6) months. CS monotherapy and combination of CS and immunosuppressive were used in 3 (7.8%) and 38 (86.4%) patients, respectively. Three patients were followed up without treatment. The first immunosuppressive agent was methotrexate (MTX) in 32 patients (84.2%) and

azathiopurine (AZA) in 6 patients (15.7%). In one patient, MTX was switched to AZA due to hepatotoxicity. Treatment regimens and responses of the patients are summarised in table 1. IGM lesions disappeared in 24 patients at the end of follow-up. In two patients who were on MTX and KS, surgical excision was required because of unresponsiveness. Among relapsed patients (n=5), 2 patients were on MTX and KS, 1 patient was on AZA and KS and 2 patients were on KS at the time of relapse. In one patient, relapse was observed 1 year after cessation of MTX and KS.

**Abstract SAT0599 – Table 1.** First line treatments and responses at last follow-up visit\*

	MTX+CS (n=32)	AZA+CS (n=6)	CS (n=3)	Observation (n=3)
Age <sup>a</sup> , years	36.1 (25.6-50.3)	33.8 (28.2-39.9)	28.9 (24.3-57.2)	29.4 (29.4-37.1)
Follow-up duration <sup>a</sup> , months	8.3 (1.5-54.4)	26.0 (13.8-99.5)	9.6 (3.0-35.8)	8.6 (1.0-13.4)
Duration of immunosuppressive treatment <sup>a</sup> , months	7.3 (0.9-28.2)	12.9 (8.2-27.3)	-	-
Immunosuppressive dose <sup>a</sup>	15 (10-15)	150 (100-150)	-	-
Duration of CS treatment <sup>a</sup> , months	7.0 (0.9-25.6)	13.7 (1.9-99.5)	2.5 (2.0-9.6)	-
Initial CS dose <sup>a</sup> , mg	30 (10-40)	20 (10-30)	20 (10-30)	-
CS dose at last control visit <sup>a</sup> , mg	7.5 (0-30)	0 (0-10)	10 (10-15)	-
Patients who discontinued CS, n (%)	12 (37.5)	3 (50.0)	-	-
Response to treatment				
Unresponsive, n (%)	5 (17.2)	1 (16.7)	-	-
Partial response, n (%)	1 (3.4)	-	1 (33.3)	-
Complete response, n (%)	23 (79.2)	5 (83.3)	2 (66.7)	2 (66.7)

\*Lesion size at last follow-up visit was available in 40 patients

<sup>a</sup>Values are given as median (min-max)

<sup>a</sup>Treatment doses are presented as mg/week for MTX and mg/day for AZA.

**Conclusions:** In a case series previously published by our study group, the efficacy of the combined use of KS and immunosuppressants in IGM treatment was retrospectively studied.<sup>1</sup> In this study, the efficacy of immunosuppressive therapy has been demonstrated with prospective approach.

#### SAT0600 MULTICENTRIC RETICULOHISTIOCYTOSIS (1980-2017): CLINICAL CORRELATES, TREATMENT OUTCOMES & ASSOCIATION WITH AUTOIMMUNITY & MALIGNANCY

A.S. Sandhu, C.S. Crowson, D.A. Wetter, G.A. McKenzie, A. Makol. *MAYO CLINIC, Rochester, USA*

**Background:** Multicentric reticulohistiocytosis (MRH) is a rare systemic disease characterised by papulo-nodular skin eruptions and a rapidly progressive, deforming arthritis. It can mimic rheumatic disorders such as rheumatoid arthritis or dermatomyositis. Immunosuppression is often helpful, but challenging due to the association of MRH with malignancy.

**Objectives:** To examine the clinical correlates and outcomes of MRH and its association with malignancy and other autoimmune conditions

**Methods:** A retrospective review of all patients with MRH treated at our institution between 01/01/1980 and 04/30/2017 was performed. Demographics, clinical features, laboratory tests, imaging findings, histopathology, treatments and outcomes were abstracted. Data on autoimmune disorders and malignancies before and after MRH diagnosis were collected.

**Results:** We identified 24 patients with MRH (58% female, 75% Caucasian, mean age at diagnosis 52 y). Median length of follow up was 2.3 y. All patients had confirmed diagnosis by histopathology (23 skin, 7 synovial). All patients had cutaneous and articular involvement. Nodular skin lesions were noted in 96% patients (periungual area and dorsal hand in 87%, periarticular 61% [around DIP 42%, PIP 25%, MCP 8%], face 54%, arms 42%, back 29%, neck 21%, legs 21%, ears 12%, scalp 12%). Mucosal nodules were noted in 30%. Regarding articular involvement, 22 (92%) had arthralgia, 21 (88%) patients had joint swelling, and 13 (54%) had synovitis. Frequency of joint involvement was upper extremity PIP (29%) > upper extremity DIPs, MCPs, wrist > MTPs, Toes > Knees > Elbows. Radiographic erosions were noted in 67% patients. Constitutional symptoms included fatigue,<sup>15</sup> unintentional weight loss,<sup>10</sup> lymphadenopathy<sup>4</sup> and pruritis.<sup>11</sup> Systemic features included dysphagia,<sup>5</sup> photosensitivity,<sup>4</sup> dry eyes,<sup>3</sup> pericarditis<sup>2</sup> and pleuritis.<sup>1</sup> Several patients had positive autoimmune serologies: ANA,<sup>8</sup> RF,<sup>5</sup> Anti-CCP,<sup>3</sup> SS-A,<sup>3</sup> SS-B,<sup>2</sup> Anti-DsDNA.<sup>1</sup> A third of patients had concomitant autoimmune disorders: inflammatory arthritis,<sup>3</sup> Sjögrens,<sup>1</sup> chronic focal glomerulonephritis,<sup>1</sup> JRA,<sup>1</sup> psoriasis,<sup>1</sup> myasthenia gravis and ITP.<sup>1</sup> A third of patients (8/24) had malignancy: malignant melanoma,<sup>3</sup> basal cell carcinoma,<sup>2</sup> and 1 each with ovarian carcinoma, squamous cell carcinoma lung, peritoneal

adenocarcinoma, and endometrial carcinoma. Most patients were treated with systemic glucocorticoids<sup>15</sup> and oral DMARDs<sup>13</sup>: methotrexate,<sup>8</sup> cyclophosphamide,<sup>10</sup> chlorambucil<sup>2</sup> and cyclosporine.<sup>1</sup> Biologics were used in 4 patients (1 infliximab, 2 etanercept, 1 adalimumab). Only 2 patients had complete resolution of their symptoms, while majority showed only partial improvement. 10 (44%) patients developed joint deformities involving: wrist,<sup>4</sup> MCP,<sup>4</sup> PIP,<sup>7</sup> DIP,<sup>4</sup> knee<sup>2</sup> and MTP.<sup>3</sup> None had arthritis mutilans. 75% patients were alive at last follow up.

**Conclusions:** To our knowledge, this is the largest series of MRH patients from a single institution, highlighting the rarity of the condition, and an unmet need for treatment options that can allow sustained disease remission. We emphasise the need for histopathology to distinguish it from mimicking rheumatic conditions and initiating early aggressive treatment to potentially prevent deforming joint disease. A high vigilance for malignancy and other autoimmune diseases is necessary.

**Objectives:** To assess the efficacy of Tocilizumab (TCZ) in refractory thyroid associated orbitopathy (TAO) due to Grave's disease.

**Methods:** Multicenter study of 29 patients with TAO refractory to conventional immunosuppressive therapy.

**Results:** We studied 29 patients (58 eyes) (23 women/6 men); mean age at diagnosis 48.79±12.39 years. Besides oral corticosteroids and before the onset of TCZ, patients had been treated with pulses of intravenous methylprednisolone (n=24), methotrexate (n=2) and other drugs (methimazole in 4 cases, leflunomide in 1, selenium in 9). Urgent decompressive surgery had to be performed in 2 patients.

According to the classification of severity of the EUGOGO group (European Group on Graves' Orbitopathy) using the clinical activity score (CAS), before TCZ onset patients whose data were available had severe (n=14 eyes) or moderate

(n=22 eyes) disease. Moreover, patients presented exophthalmos (n=30 eyes), strabismus (n=17 eyes), muscle fibrosis (n=15 eyes) and dysthyroid optic neuropathy (n=1).

TCZ was used in monotherapy (n=27) or combined with methotrexate (n=2) at 8 mg/kg/iv/4 weeks (n=24) or 162 mg/sc/week (n=5). TCZ yielded rapid and maintained improvement in all ocular parameters (TABLE).

After a mean follow-up of 8.96±7.55 months using TCZ, all patients experienced ocular improvement, with TCZ withdrawal in 16 cases due to complete remission (n=5) or stability of ocular inflammation (n=11). Only 4 adverse effects were observed (neutropenia, external otitis, otitis media, costal osteitis).

**TABLE.** Improvement of ocular parameters with TCZ therapy. Data are expressed as mean ±SD or median[IQR].

	BASAL	1 WEEK	2 WEEKS	1 MONTH	3 MONTHS	6 MONTHS	1 YEAR
<b>VA</b>	0.7 [0.5–1]	0.7 [0.6–1]	0.8 [0.7–1]	0.85 [0.7–1]	1 [0.9–1]	1 [0.7–1]	1 [0.8–1]
<b>IOP</b>	19.22 ±4.20	17.25 ±1.90	16.75 ±2.31	18.23 ±5.00	17.39±3.51	16.52±3.56	16.00 ±3.41
<b>CAS</b>	4.97 ±1.72	4.85 ±2.95	-	3.40±2.28	2.34±1.71	1.29±1.12	1.11 ±0.85

VA=visual acuity; IOP=intraocular pressure; CAS=clinical activity score (0/7 at baseline, 0/10 in the rest of time measures).

**Conclusions:** TCZ appears to be useful in TAO treatment.

SAT0602

#### CLINICAL SIGNIFICANCE OF AUTOANTIBODY POSITIVITY IN IDIOPATHIC PULMONARY FIBROSIS

B. Ghang<sup>1</sup>, J. Lee<sup>1</sup>, O.C. Kwon<sup>1</sup>, J.S. Oh<sup>1</sup>, W.J. Seo<sup>2</sup>, S. Hong<sup>1</sup>, Y.-G. Kim<sup>1</sup>, B. Yoo<sup>1</sup>, J.W. Song<sup>3</sup>, C.-K. Lee<sup>1</sup>. <sup>1</sup>Rheumatology, ASAN MEDICAL CENTER; <sup>2</sup>Rheumatology, Seoul Veterans Hospital; <sup>3</sup>Division of Pulmonary and Critical Care Medicine, Asan Medical Center, Seoul, Korea, Republic Of

**Background:** Recently, the concept of interstitial pneumonia with autoimmune features (IPAF) was proposed by the American Thoracic Society.<sup>1</sup> The serologic domain of IPAF is composed of antibodies to extractable nuclear antigens, cyclic citrullinated peptide antibody, a high titer of rheumatoid factor, and a high titer of antinuclear antibody. However, the clinical significance of the serologic domain of IPAF has not yet been evaluated in idiopathic pulmonary fibrosis (IPF).

**Objectives:** To investigate the clinical significance of autoantibody positivity in IPF.

**Methods:** We retrospectively reviewed the records of 528 patients who met the ATS/ERS/JRS/ALAT diagnostic criteria for IPF at a tertiary hospital from January 2007 through March 2014. Patients treated with pirfenidone or nintedanib, an established IPF treatment regimen, were excluded. All patients were divided into the following 3 groups: autoimmune IPF (n=153), patients with autoantibodies that met the criteria for the IPAF serologic domain; incomplete autoimmune IPF (n=68), patients who did not completely meet the criteria for the IPAF serologic domain; lone IPF (n=307), patients without autoantibodies. Multivariate Cox proportional hazards models with backward elimination were used to investigate the risk factors for mortality.

**Results:** The 5 year mortality rates were as follows: autoimmune IPF group, 54.9% (n=84, 3.4 years after diagnosis [median; IQR=1.9–5.0]); incomplete autoimmune IPF group, 64.7%; lone IPF group, 58.6% (n=180, 2.9 years after diagnosis [median; IQR=1.6–4.9]). Independent risk factors for mortality on multivariable analysis in the overall IPF patient population included age at diagnosis (adjusted hazard ratio (HR) 1.028, p=0.002), autoimmune IPF (adjusted HR 0.747, p=0.050), baseline SaO<sub>2</sub> in the 6 min walking test (6MWT, adjusted HR 0.973, p=0.012), baseline distance in the 6MWT (adjusted HR 0.998, p=0.001), baseline forced vital capacity (adjusted HR 0.977, p<0.001), and diffusing capacity of the lungs for carbon monoxide (DLCO) (adjusted HR 0.979, p<0.001). In the autoimmune IPF group, use of glucocorticoid (not for management of acute exacerbation, adjusted HR 1.971, p=0.029), use of immunosuppressants (adjusted HR 0.343, p=0.002), baseline distance in 6MWT (adjusted HR 0.998, p=0.032), and baseline DLCO (adjusted HR 0.975, p=0.003) were independent risk factors for mortality on multivariable analysis.

**Abstract SAT0602 – Table 1.** Risk factors associated with mortality in autoimmune IPF patients

Characteristics	Hazard Ratios	Multivariable analysis		P-value
		LB	UB	
Use of glucocorticoid (not for acute exacerbation management)	1.971	1.073	3.622	0.029
Use of immunosuppressants	0.343	0.175	0.674	0.002
Baseline distance in 6MWT	0.998	0.996	1.000	0.032
Baseline FVC	0.984	0.966	1.002	0.081
Baseline DLCO	0.975	0.959	0.991	0.003

6MWT = 6-minute walking test; FVC = forced vital capacity; DLCO = diffusing capacity of the lung for carbon monoxide.

**Conclusions:** Our results suggest that positive autoimmunity might be a favourable factor for 5 year mortality in IPF patients compared to those without autoimmunity, and the use of immunosuppressants could be associated with improved mortality in autoimmune IPF patients.

SAT0603

#### CAN HOMOZYGOUS OR HETEROZYGOUS MEFV MUTATIONS LEAD TO DIFFERENT PRESENTATION OF FAMILIAL MEDITERRANEAN FEVER?

A. Aktaş<sup>1</sup>, M. Karadavut<sup>1</sup>, D. Üsküdar Cansu<sup>2</sup>, C. Korkmaz<sup>2</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Internal Medicine, Rheumatology, Eskişehir Osmangazi University, Eskişehir, Turkey

**Background:** Although some patients with familial Mediterranean (FMF) have heterozygous mutations for MEFV gene, there is a debate about whether heterozygosity for MEFV mutations in FMF might be responsible for disease symptoms or not.

**Objectives:** To evaluate differences between the patients with FMF having homozygous (Hom) or heterozygous (Het) MEFV mutations in terms of clinical features and severity of the disease as well as concomitant disorders.

**Methods:** We included 259 unrelated patients (female: 143, male: 116; mean age: 33.5±12 years) who were clinically diagnosed as having FMF and who met the Tell-Hashomer's diagnostic criteria. The presence of MEFV mutations was investigated in exon 2,3,5 and 10 by multiplex-PCR reverse hybridization method. All clinical manifestations and their features were revised. All the patients were questioned for the presence of concurrent disorders, and the medical records of these patients were revised retrospectively. A previous diagnosis of a concomitant disease was taken into consideration if it met the relevant criteria.

**Results:** In 12 of 259 patient, MEFV mutation analysis was not performed. No mutation was not determined in 8 FMF patients (3.2%). Hom mutation was found in 79 patients with FMF (31.9%), Het plus compound heterozygotes (cHet) in 160 FMF patients (64.7%). Early onset and early diagnosis of FMF were found in Hom group compared to Het plus cHet group (8.4 years vs 13.6 years; 23.3 years vs 28.6 years, p<0.0001, respectively). The number of patients with a higher severity score was significantly higher in hom group than Het plus cHet group (p<0.001). No significant difference was found between Hom and Het plus cHet group in terms of clinical features except for erysipelas like erythema (ELE) (p<0.0001). Concomitant disorders were as follows: ankylosing spondylitis (AS) 24 (9.3%), amyloidosis 13 (5%), Behcet's disease 8 (3%). Amyloidosis (9 vs 4) was significantly higher in Hom group than Het plus cHet group (p<0.01).

**Conclusions:** The presence of homozygous MEFV mutations in contrast to Het mutations creates a tendency for early onset of the disease, early diagnosis, frequent ELE and amyloidosis and severe disease phenotype.

**SAT0604 SECONDARY HEMOPHAGOCYTIC SYNDROME: RETROSPECTIVE STUDY ACCORDING TO THE UNDERLYING DISEASE**

C.A. Egües Dubuc<sup>1</sup>, J.A. Valero<sup>1</sup>, A. De Diego<sup>1</sup>, J.R. Furundarena<sup>2</sup>, O. Maiz<sup>1</sup>, L. M. López<sup>1</sup>, J.J. Cancio<sup>1</sup>, E. Uriarte<sup>1</sup>, M.M. Yagüe<sup>1</sup>, J. Calvo Alen<sup>3</sup>, J. M. Belzunegui<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Hematology, Donostia University Hospital, San Sebastián; <sup>3</sup>Rheumatology, Araba University Hospital, Vitoria, Spain

**Background:** Secondary Hemophagocytic Syndrome (SHS) is associated with Hematologic (HO), Autoimmune (AI) diseases [such as Systemic Lupus Erythematosus (SLE) or Adult's Still Disease (ASD)] and in a lower frequency with Infections (Inf.) and Tumours (Tum.).

**Objectives:** Describe the demographic and underlying disorders during hospital admission of patients with SHS during the period December/2005-January/2018.

**Methods:** A retrospective search of patients diagnosed with SHS and bone marrow biopsy (B.M.O.) with hemophagocytosis was performed. Patients were grouped in: AI, HO, Inf, Tum. and SHS without cause (wc). The variables were: sex, age, diagnosis of the underlying disease, fever, organomegaly, laboratory findings, days of hospital stay, days from admission to B.M.O. and mortality.

**Results:** A total of 27 patients were found. table 1 shows the characteristics of the groups. AI □ diseases found were: 5 SLE, 2 ASD, 1 Rheumatoid Arthritis and 1 Sclerosing Disease Related to IgG4. The HOs were: 4 Myelodysplastic Syndrome, 3 Non-Hodgkins Lymphomas, 2 Acute Leukemias, 1 Extranodal Lymphoma of Natural Killer Cells (NKC) and 1 Gastric Plasmocytoma. Inf. were: 1 infection of *Pneumocystis* in the recent diagnosis of HIV and Gastroenteritis by *Campylobacter jejuni*. One Tum. in a patient with Glioblastoma multiforme who received temozolomide. During the follow-up no recurrence of SHS was observed. The sCD25 and cytolytic activity of the NKC were not done.

Abstract SAT0604 – Table 1

**SAT0605 THE PRESENCE OF UVEITIS PREDICTS THE RESPONSE TO THE INTERLEUKIN (IL)-1 INHIBITORS ANAKINRA AND CANAKINUMAB IN BEHÇET'S DISEASE**

C. Fabiani<sup>1</sup>, A. Vitale<sup>2</sup>, G. Emmi<sup>3</sup>, G. Lopalco<sup>4</sup>, D. Rigante<sup>5</sup>, J. Sota<sup>2</sup>, I. Orlando<sup>2</sup>, B. Frediani<sup>2</sup>, R. Franceschini<sup>2</sup>, M. Galeazzi<sup>2</sup>, F. Iannone<sup>4</sup>, G.M. Tosi<sup>2</sup>, L. Cantarini<sup>2</sup>. <sup>1</sup>Humanitas Clinical and Research Center, Milan; <sup>2</sup>University of Siena, Siena; <sup>3</sup>University of Florence, Florence; <sup>4</sup>University of Bari, Bari; <sup>5</sup>Università Cattolica Sacro Cuore, Rome, Italy

**Background:** In recent times IL-1 inhibition has been proposed as an intriguing therapeutic option in Behçet disease (BD) patients with multi-drug resistant manifestations.<sup>1</sup> However, despite the good clinical results obtained during the last years, cases of BD nonresponsive to anakinra (ANA) and canakinumab (CAN) have also been identified. This evidence has induced to suspect the existence of specific subsets of patients characterised by a more pronounced IL-1 driven pathogenesis.<sup>2,3</sup>

**Objectives:** To identify predictive factors of response to interleukin (IL)-1 inhibition among demographic, clinical and therapeutic data in patients with (BD).

**Methods:** BD patients treated with ANA or CAN were enrolled. Patients were divided into 2 groups according to the clinical response: group 1 included subjects showing a treatment duration of at least 52 weeks and no secondary inefficacy during the first follow-up year; the remaining patients were included in the group 2. Demographic, clinical and therapeutic data were analysed to identify significant differences between groups.

**Results:** Eighteen patients (50%) were included in group 1 and 18 (50%) in group 2. A better response to IL-1 inhibitors was significantly more common among patients with BD-related uveitis (p=0.006) and patients with a longer disease duration (p=0.03).

**Conclusions:** IL-1 blockade is effective in BD, especially in the subset of patients presenting ocular involvement and in those with long-lasting disease.

**SAT0606 DISEASE MODIFYING ANTI RHEUMATIC DRUGS IN THE TREATMENT OF SAPHO SYNDROME: SYSTEMATIC LITERATURE ANALYSIS**

M. Monet<sup>1</sup>, C. Prati<sup>1</sup>, X. Guillot<sup>1</sup>, M. Sondag<sup>1</sup>, F. Verhoeven<sup>1</sup>, F. Aubin<sup>2</sup>, D. Wendling<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Dermatology, CHRU Besançon, Besançon, France

**Background:** SAPHO (Synovitis Acne Pustulosis Hyperostosis Osteitis) Syndrome is a rare, heterogeneous clinical entity with cutaneous and osteoarticular expression. The therapeutic management is not codified and there is no validated evaluation tool for SAPHO syndrome.

**Objectives:** To perform a systematic analysis of the literature in order to evaluate the effects of DMARDs in SAPHO syndrome.

**Methods:** Bisphosphonates, conventional and targeted synthetic DMARDs, anti-TNF alpha, and other biologics have been subjected to advanced Pubmed research. Treatment was considered effective when the patient validated the response criteria defined in the study or if at least partial benefit was obtained for a minimum of three months. The different treatments were ranked according to their effectiveness rate in three interest groups and then grouped by therapeutic class to determine an overall response rate. These rates led to the calculation of an efficacy index weighted by the number of patients treated in the subgroup (molecule or therapeutic class) compared to the total number of patients in our study.

**Results:** Treatment efficacy was evaluable in 284 of the 292 patients analysed. The clinical presentation of cases was reported in 205 patients for osteoarticular

involvement, and 193 for cutaneous involvement. The group of treatments that most often induces a therapeutic response (in more than 75% of cases) includes lbandronate, Etanercept, Anakinra, Infliximab, Pamidronate and Adalimumab. Pamidronate, which represents the largest subpopulation in our study, has the highest weighted index of efficacy. Zoledronic acid, Leflunomide, Ustekinumab and Methotrexate have less often induced a therapeutic effect (efficacy between 50% and 75%) and Sulfasalazine and Secukinumab have response rates of less than 30%. In total, bisphosphonates and TNF alpha antagonists have efficacy rates of 87.77% and 85% respectively. The weighted index, more than twice as high for bisphosphonates (42.96 versus 17.96), reflects the predominant use of these in SAPHO syndrome, with most often a beneficial effect. Conventional and synthetic targeted DMARDs and other biological treatments are less often effective in our study, with response rates of 47% and 58% respectively. The frequencies of each clinical manifestation were in agreement with the data of the literature. There was no clear clinical profile of a good responder to a particular treatment.

Therapeutic class	Number of patients	Number of responders	Efficacy rate (%)	Weighted index
Bisphosphonates	139	122	87,77	42,96
Conventional DMARDs	68	32	47,06	11,27
Synthetic targeted drugs	0	NA	NA	NA
Anti TNF alpha	60	51	85	17,96
Other biologics	17	10	58,82	
TOTAL	284	215	75,82	NA

**Conclusions:** This work made it possible to rank the different DMARDs used in the SAPHO syndrome. Anti TNF alpha and Pamidronate are the treatments that seem to bring the higher benefit.

**Disclosure of Interest:** None declared

#### SAT0607 DRUGS USED OFF LABEL IN A RHEUMATOLOGY SERVICE OF A TERTIARY HOSPITAL

D. Martínez-Quintanilla Jiménez<sup>1</sup>, N. García Castañeda<sup>1</sup>, P. Moreno Fresneda<sup>1</sup>, M. Perez Abanades<sup>2</sup>, R. García De Vicuña<sup>1</sup>, I.G. Alvaro<sup>1</sup>, E. Tomero Muriel<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Hospital Pharmacy, Hospital La Princesa, Madrid, Spain

**Background:** The use of drugs off-label (DOL) is not uncommon in Rheumatology daily clinical practice for the treatment of patients with immune-mediated inflammatory diseases (IMID).

**Objectives:** To analyse the use of DOL requested by the Rheumatology Service.

**Methods:** We reviewed the medical records of all patients registered in the DOL database of the Hospital Pharmacy Service between July 2009 and March 2017. The following variables were collected: date of approval and start of the drug, physician, disease, reason for indication, sex and age of the patients, response to treatment according to the global assessment of the responsible physician, date and reason of withdrawal. A descriptive study of the variables collected through STATA 12 is carried out.

**Results:** 225 DOL were requested for a total of 174 patients. Women were 78.7%, with an average age of 56.5 years (sd 1.15). In most patients (77%) a single drug was requested. In 37 patients were requested between two (16.4%) and seven drugs (0.5%). The indications of the DOL in our database were: connective tissue diseases (CTD: 46.6%), vasculitis (23%), rheumatoid arthritis (RA: 5.2%) and spondyloarthritis (SPA:8%). Other diseases (17.2%) are included in two heterogeneous groups classified according to their etiology (autoimmune (8.6%) or not (8.6%).

39.5% of the drugs requested were conventional synthetic DMARDs (csDMARDs), 38.2% biological DMARDs (bDMARDs), 7.5% were antivirals, 2.6% vasodilators and 12% other drugs.

Conventional synthetic DMARDs (csDMARDs) represented 39.5% of request, biological DMARDs (bDMARDs) 38.2%, antiviral drugs 7.5%, vasodilator drugs 2.6% and other drugs 12%.

Tables 1 and 2 show csDMARDs and bDMARDs respectively, according to the indication.

The effectiveness of the DOL was variable, ranging between 0% and 76.5%. The most effective were antiviral drugs, used to treat viral infections in immunosuppressed patients (76.5%), tocilizumab (72.2%) and rituximab (61.1%). By contrast, the least effective were anakinra (0%) and TNF blockers (31.8%). The csDMARDs group had an effectiveness of 53.9% (Mycophenolate stands out with 75% effectiveness).

The disease groups that responded best to DOL therapy were connective tissue and vasculitis, with 58% and 53.7% of effectiveness.

**Abstract SAT0607 – Table 1**

	RA	CTD	SPA	VASCULITIS	OTHERS <sup>1</sup>
APREMILAST(%)	0	0	50	0	0
CYCLOPHOSPHAMIDE (%)	28.6	1.9	0	0	16.7
CYCLOSPORINE(%)	14.3	7.7	0	4.6	16.7
LEFLUNOMIDE(%)	0	1.9	50	45.5	16.7
MYCOPHENOLATE(%)	42.9	86.5	0	50	50
TACROLIMUS(%)	14.3	1.9	0	0	0

**Abstract SAT0607 – Table 2.**

	RA	CTD	SPA	VASCULITIS	OTHERS <sup>1</sup>
ABATACEPT (%)	0	0	7.7	3.9	16.7
ANAKINRA(%)	0	0	0	0	25
TNF blockers (%)	0	6	53.9	30.8	41.7
RITUXIMAB(%)	0	87.9	0	26.9	0
TOCILIZUMAB (%)	100	3	23.1	38.5	16.7
USTEKINUMAB (%)	0	0	15.4	0	0

<sup>1</sup>Others: other diseases mediated by immune mechanisms

**Conclusions:** Rheumatic diseases for which DOL is most commonly requested are connective tissue and vasculitis, as a consequence of the absence of specific indications for these pathologies. In our experience, rituximab is a good option in the treatment of connective tissue diseases, which contrasts with the results of some clinical trials. Tocilizumab is a good therapeutic option in the treatment of vasculitis, a group that includes Giant Cell Arteritis, as recently confirmed with its approval for this indication.

**Disclosure of Interest:** None declared

#### SAT0608 HOW TO DIFFERENTIATE ADULT ONSET STILL'S DISEASE FROM OVERALL OTHER CAUSES OF FEVER OF UNKNOWN ORIGIN: RESULTS OF A PROSPECTIVE STUDY FROM A TERTIARY REFERRAL CENTRE

E. Bilgin<sup>1</sup>, A. Erden<sup>2</sup>, B. Armagan<sup>2</sup>, L. Kılıç<sup>2</sup>, A. Sarı<sup>2</sup>, G. Yardımcı<sup>2</sup>, M.K. Hayran<sup>3</sup>, A. Akdoğan<sup>1</sup>, Ö. Karadağ<sup>2</sup>, S. Apraş Bilgen<sup>2</sup>, I. Ertenli<sup>2</sup>, S. Kiraz<sup>2</sup>, U. Kalyoncu<sup>2</sup>.

<sup>1</sup>Internal Medicine, <sup>2</sup>Internal Medicine, Division of Rheumatology, <sup>3</sup>Preventive Oncology, Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background:** Adult onset Still's disease (AOSD) is a rare, auto-inflammatory disease that commonly presents as fever of unknown origin (FUO), and most common rheumatologic cause of FUO. Clinical and/or laboratory parameters that can discriminate AOSD from other causes of FUO need to be clarified in current literature.

**Objectives:** To determine clinical and/or laboratory parameters that help to differentiate AOSD from other causes of FUO and demonstrating a clinician-friendly algorithm for this purpose.

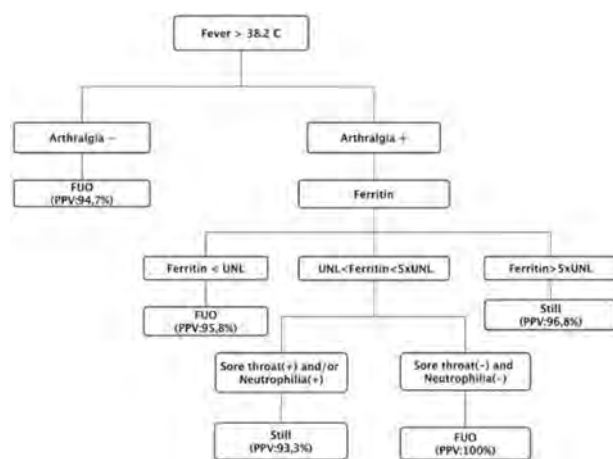

**Methods:** Data from patients who admitted to Hacettepe University Hospitals, inpatient sections of department of internal medicine with the complaint of FUO, who eventually had a certain diagnosis, collected prospectively during 30 months. AOSD patients followed at Hacettepe University department of rheumatology were included. Clinical and laboratory data were collected at the time of diagnosis of AOSD and time of admission of patients with FUO.

**Results:** Total 156 patients (n=69, for AOSD; n=87, for FUO) were included. FUO group were also divided into three subgroups: rheumatologic (n=31, 35.6%), infectious (n=28, 32.2%) and malignant (n=28, 32.2%) causes. While 51 (74%) patients were female in AOSD group, 43 (49.4%) patients were female in FUO group (p=0.03). Frequency of rash, arthralgia, arthritis, sore throat, fever at night (p<0.001 for each), history of hemophagocytosis (p=0.037) were significantly higher in AOSD group. Fever peak number equal and/or higher than 3, presence of lymphadenopathy (p=0.002 and p=0.001, respectively) were significantly higher in FUO group. While leukocytosis, neutrophilia, thrombocytosis, hyperferritinemia, higher lactate dehydrogenase and complement 3 levels (p<0.001 for each) were significantly more frequent in AOSD group, albumin levels lower than 3 g/dl and positive rheumatoid factor (p=0.009 and p=0.002, respectively) were significantly more frequent in FUO group. Results of univariate and multivariate analysis are given in table 1. Algorithm for discrimination of AOSD and FUO is given at **Abstract SAT0608 – figure 1.**

**Abstract SAT0608 – Table 1.** Results of univariate and multivariate analysis

Variables	Univariate Analysis			Multivariate Analysis

**SAT0609** **VENOUS VESSEL WALL THICKNESS IN LOWER EXTREMITY IS INCREASED IN MALE BEHCET'S DISEASE PATIENTS WITH AND WITHOUT VASCULAR INVOLVEMENT**

E. Alibaz-Oner<sup>1</sup>, R. Ergelen<sup>2</sup>, A. Mutis<sup>1</sup>, Z. Erturk<sup>1</sup>, R. Asadov<sup>2</sup>, T. Ergun<sup>3</sup>, H. Direskenel<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Radiology, <sup>3</sup>Dermatology, Marmara University, School of Medicine, Istanbul, Turkey

**Background:** Vascular involvement is seen in up to 40% of the patients with Behcet's Disease (BD), especially in young males and is one of the major causes of mortality and morbidity. Lower extremity vein thrombosis due to vascular inflammation is the most frequent form of vascular involvement in BD. Recently, assessment of vessel wall thickness (VWT) and venous dilatation by US is suggested to be valuable in patients with vascular inflammation.

**Objectives:** In this study, we investigated whether vessel wall thickness or dilatation is present in young male BD patients prone to venous vascular disease.

**Methods:** Thirty male patients with BD without major organ involvement and 29 male patients with Vascular BD (VBD) followed in Marmara University Behcet's Clinics, 24 healthy male controls and 27 male patients with Ankylosing Spondylitis (AS) were included the study. Bilateral lower extremity venous doppler ultrasonography (US) was performed by an experienced radiologist blinded to cases. No patients except VBD were under immunosuppressive treatment. Bilateral common femoral vein (CFV) wall thickness and great/small saphenous vein dilatations were examined. Behcet Syndrome Activity Score (BSAS) was used for the general assessment of disease activity. In 10 patients, CFV wall thickness was measured by 2 different radiologist (RE, RA) in the same day to calculate "inter-observer reliability". Correlation between radiologists was good. (r=0.765, p<0.001).

**Results:** The mean disease duration was 9.1±6 years in patients with BD. BSAS score was 24±17. All venous measurements were significantly higher in BD compared to AS and healthy controls (p<0.001 for all, table 1). When we compared mucocutaneous BD and VBD, all measurements of patients with VBD were higher than mucocutaneous BD. But only left CFV thickness and width of right great saphenous vein reached the statistical significance (p<0.001, an p=0.028, respectively, figure 1). There were no correlations between BSAS, acute phase reactants and venous wall measurements.

**Abstract SAT0609 – Table 1.** Venous wall measurements of lower extremity in study groups.

	Behçet's Disease (n=59)	Ankylosing Spondylitis (n=27)	Healthy Controls (n=24)	P Value

VWT: Venous wall thickness

**Abstract SAT0609 – Figure 1.** Venous Vessel Assessments of patients with Mucocutaneous Behçet and Vascular Behçet

**Conclusions:** In our study, an increased venous vessel wall thickness in lower extremity was shown in male BD patients with or without vascular involvement. As a similar change was not observed in controls, we think, increased VWT might be an early sign of venous inflammation in patients with BD rather than a result of non-specific systemic inflammation.

**SAT0610** **A DECLINING TREND IN FREQUENCY OF SECONDARY AMYLOIDOSIS IN BEHCET'S SYNDROME**

G. Karatemiz, S.N. Esatoglu, Y. Ozguler, S. Yurdakul, V. Hamuryudan, I. Fresco, M. Melikoglu, E. Seyahi, S. Ugurlu, H. Ozdogan, H. Yazici, G. Hatemi. Rheumatology, Istanbul University of Cerrahpasa Medical Faculty, Istanbul, Turkey

**Background:** A decline in the frequency of AA amyloidosis secondary to rheumatoid arthritis and infectious diseases has been reported. This is probably due to more effective treatment strategies. We had previously reported that although amyloidosis occurs in less than 0.5% of BS patients, it is one of the leading causes of death.<sup>1–3</sup> We had an impression that the frequency of amyloidosis is decreasing among our patients with BS.

**Objectives:** We aimed to determine the change in the frequency of AA amyloidosis over years in BS pts in addition to elaborating on clinical characteristics and outcomes.

**Methods:** We performed a chart review to identify all pts with amyloidosis in our BS centre since 1976. We noted demographic characteristics, BS manifestations, age at BS and amyloidosis diagnosis, treatment modalities of these pts. Our endpoints were death and end stage renal disease (ESRD) requiring renal replacement therapy. The prevalence of amyloidosis was calculated separately for two periods (pts registered between 1976–2000 and 2000–2017)

**Results:** Among our 9410 BS pts, 27 (0.29%) had amyloidosis. We identified 24 pts with amyloidosis among the 3820 pts in the earlier cohort and 3 additional amyloidosis among the 5590 pts in the recent cohort. The frequency of AA amyloidosis had declined from 0.62% to 0.054% in the recent cohort. M/F ratio was 22/5 and mean age at BS diagnosis was 29.5±7.4 years. Twenty-two (82%) of the pts with amyloidosis had major organ involvement (vascular involvement in 15, eye involvement in 13 and neurologic involvement in 2). Five (18%) of 27 pts had only mucocutaneous involvement. AA amyloidosis was diagnosed after a mean duration of 9.8±6.7 years (mean age at amyloidosis: 39.3±9.3 years) and was confirmed with renal biopsy in 14 pts and rectal biopsy in 13. Eight pts had non-nephrotic range proteinuria at amyloidosis diagnosis. After amyloidosis diagnosis, 24 pts continued their previous immunosuppressives and colchicine. Two of these 24 were on anti-TNFs at AA diagnosis. Biologics were initiated in 3 pts who were most recently diagnosed to have amyloidosis, anti-TNFs in 2 and tocilizumab in 1. Fourteen (52%) pts had died after a median follow-up of 3 (IQR:1–8.75) years, 3 were lost to follow-up just after amyloidosis diagnosis and 10 (37%) are still alive after a median follow up of 16 (IQR:10–23) years. The reasons for death were infections in 5, related to ESRD in 5, subarachnoid haemorrhage, gastric adenocarcinoma, liver cirrhosis and iatrogenic bowel perforation in 1 patient each. 10 (71%) of these 14 pts had developed ESRD before their deaths. Overall, 15/27 pts developed ESRD after a median follow-up of 3.5 (IQR:1.25–6.5) years after amyloidosis diagnosis. 5 of them had renal transplantation, all but 1 are still alive after 3, 4, 6, and 12 years.

**Conclusions:** AA amyloidosis appears to be a rare, but fatal complication of BS. Around 50% of patients died after a median follow-up of 3 years after amyloidosis. This study showed a decreasing trend of AA amyloidosis due to BS similar to that observed in other inflammatory and infectious causes. The shorter follow-up duration may be contributing for the lower prevalence of AA amyloidosis in the recent cohort.

SAT0611

#### CANAKINUMAB USE IN ADULT FAMILIAL MEDITERRANEAN FEVER PATIENTS: A LARGE SINGLE CENTRE EXPERIENCE

H. Babaoğlu<sup>1</sup>, O. Varan<sup>1</sup>, H. Kucuk<sup>2</sup>, N. Atas<sup>1</sup>, H. Satis<sup>1</sup>, R.B. Salman<sup>1</sup>, M. A. Ozturk<sup>1</sup>, B. Goker<sup>1</sup>, A. Tufan<sup>1</sup>, S. Haznedaroglu<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Gazi University Hospital, Ankara; <sup>2</sup>Department of Internal Medicine, Division of Rheumatology, Erzurum Research and Training Hospital, Erzurum, Turkey

**Background:** IL-1 blocking agents have been shown to be effective in the prevention of attacks in colchicine resistant FMF (crFMF) patients. Canakinumab is FDA approved long acting recombinant IL-1 receptor antagonist for use in crFMF patients which is available for off label use in Turkey. Herein, we aimed to share our real life single centre experience for use of canakinumab in adult crFMF patients.

**Methods:** Data was derived from Gazi FMF cohort which was established in year 2010. From that date patients with FMF who were diagnosed according to the Tel Hashomer criteria were registered. Co-morbidities, detailed attack characteristics, type, duration, severity, treatments, laboratory parameters and impact of FMF on their life in terms of quality of life and work productivity were recorded either by FMF diary or a mobile phone application (FMF AIDD free to download from App-Store and android market). A retrospective cohort analysis was made from records of patients who were treated with canakinumab.

**Results:** Eighteen adult crFMF patients (%61 female) treated with canakinumab were enrolled in this study. The median age was 31<sup>24–58</sup> years and the median disease duration was 28<sup>16–40</sup> years. All patients harbour homozygous or compound heterozygous exon 10 *MEFV* mutations. Treatment reasons for canakinumab were colchicine resistance (n=14) and amyloidosis (n=4). In three patients canakinumab was initiated directly, while in 15 it was switched from anakinra (seven was allergic to anakinra, one patient had significant leukopenia, in six fail to control attacks). The median duration of canakinumab use was 8 (min 1- max 22) months. In two patients canakinumab was used as 300 mg/monthly, and in

remaining as 150 mg/monthly. Pre- and post-canakinumab periods of patients were compared (Table). Patient reported attack severity (p<0.01), duration (p<0.01), frequency (p<0.01), C-reactive protein (CRP) (p<0.01) and erythrocyte sedimentation rates (p<0.01) were significantly improved while serum creatinine and alanine aminotransferase (ALT) levels remained same (p=0.2, p=0.35, respectively). Canakinumab achieved complete disease remission in 5 patients. Side effects requiring discontinuation of canakinumab were observed in none of patients.

**Table.** Comparison of attack characteristics of 18 Adult crFMF patients before and after canakinumab

	Colchicine	Colchicine +canakinumab	P
Attack severity, VAS	8,5 (5–10)	3,5 (0–10)	<0,01
Attack duration, hours	108 (48–144)	24 (0–96)	<0,01
Attack frequency*	6 (1–10)	1 (0–3)	<0,01
CRP, mg/L	35,8 (3,8–85,0)	4,2 (2,45–55)	<0,01
ESR, mm/h	38 (11–67)	12 (3–44)	<0,01
Serum creatinine	0,66 (0,40–3,00)	0,70 (0,43–3,00)	0,20
ALT	20 (10–55)	19 (9–70)	0,35
Treatment duration, months	204 (48–456)	8 (1–22)	

\*Attack frequencies adjusted for 3 months intervals. VAS: visual analogue scale, CRP: C-reactive protein, ALT: alanine aminotransferase, ESR: erythrocyte sedimentation rate

**Conclusions:** Canakinumab is effective in the prevention of attacks with a favourable safety profile.

SAT0612

#### THE EFFICACY OF CALCINEURIN INHIBITORS IN PATIENTS WITH ADULT-ONSET STILL'S DISEASE: SINGLE-CENTRE HISTORICAL COHORT STUDY

H. Nakamura, Y. Fujieda, M. Kato, K. Oku, T. Bohgaki, O. Amengual, S. Yasuda, T. Atsumi. Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan

**Background:** Adult-onset Still's disease (AOSD) is a systemic inflammatory disorder generally responsive to corticosteroid therapy, whereas refractory AOSD is often encountered that not controlled by corticosteroid monotherapy. In such cases, methotrexate and biologics including TNF- $\alpha$ , IL-1, or IL-6 inhibitors are used.<sup>1</sup> However, more treatment options are required for refractory AOSD patients who are intolerant to methotrexate or biologics. Calcineurin inhibitors downregulate T cell activation through inhibiting IL-2 transcription and signal transduction. Therefore, calcineurin inhibitors are reasonable therapeutic medication for AOSD since T cells and subsequently activated macrophages play a pathophysiological role in AOSD.<sup>2</sup> Nevertheless, only a few case series have indicated effects of calcineurin inhibitors in clinical practice.

**Objectives:** To evaluate the efficacy of calcineurin inhibitors in patients with AOSD.

**Methods:** This is a single-centre historical cohort study comprised of the consecutive patients with AOSD according to Yamaguchi classification criteria, who were attending our Rheumatology Department between January 2000 and December 2016. The primary endpoint was set as the time from the initiation of treatment to event defined as death of any causes, relapse of AOSD requiring an increase of corticosteroid dose, or serious adverse effects. Secondary endpoints were set as the minimum dose of corticosteroid, persistency rate of calcineurin inhibitors, and safety. Based on the recurrent event data analysis, these endpoints were evaluated for each event. We divided the events into two groups according to the treatment that included calcineurin inhibitors (CI+) or conventional therapy without calcineurin inhibitors (CI-), and compared them after adjustment using inverse probability of treatment weighting (IPTW) methods.

**Results:** Forty-two patients (31 female and 11 male) were enrolled in this study. Mean age was 41 year-old, and median follow-up period 38 months. Thirty-one events in 21 patients were treated with therapeutic regimen including calcineurin inhibitors (CI+, cyclosporine: 7, tacrolimus: 24), and 34 events in 25 patients were treated with the conventional therapy excluding calcineurin inhibitors (CI-). After adjustment, the CI +group had significantly longer event-free survival than the CI-group (figure 1). The weighted hazard ratio (HR) was 0.49 (95% CI, 0.25–0.93, p=0.03). In addition, the CI +group had lower doses of corticosteroid (3.5 vs 6.1 mg/day, p=0.03) when the events occurred. The persistency rate of

calcineurin inhibitors was 92% at 5th year. Serious infection occurred in four patients (19%) in the CI+ group, and one of them had a fatal course.

**Conclusions:** Our retrospective analysis suggested that calcineurin inhibitors could be an additional option for AOSD and further prospective studies were desired.

#### SAT0613 INCREASED SERUM LEVEL OF IL-36 RECEPTOR ANTAGONIST IS ASSOCIATED WITH ACTIVE DISEASE IN PATIENTS WITH ADULT-ONSET STILL'S DISEASE

H. Kim, J. Kang, B. Nam, J.S. Kim, D.-H. Yoo. *Division of Rheumatology, Hanyang University Medical Center, Seoul, Korea, Republic Of*

**Background:** Adult onset Still's disease (AOSD) is an inflammatory disorder which was associated with varying level of pro-inflammatory cytokines. However, the role of natural anti-inflammatory molecules has not been evaluated to date. Interleukin (IL) 1 cytokine family is closely related to clinical presentations, disease activity and thus is a target for treatment of AOSD. IL-36 receptor antagonist (Ra) is an anti-inflammatory molecule, but its clinical significance has not been studied in AOSD patients.

**Objectives:** To figure out the role of IL-36Ra in monitoring disease activity in patients with AOSD.

**Methods:** The number of 49 AOSD patients meeting Yamaguchi criteria were recruited. Each patient was serially monitored following clinical course of flare and remission, which presented at least 2 points of change in modified Pouchot's score. They were divided into two groups by clinical courses, which were predominant systemic symptoms or arthritis. We compared erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), ferritin as disease activity markers between flare and remission. Serum levels of inflammatory cytokines, IL-18, IL-37, and IL-36Ra were measured by enzyme-linked immunosorbent assay (ELISA) in each clinical state of AOSD patients.

**Results:** Forty-nine patients with AOSD were included in this study; 40 were women (81.6%) and 9 were men (18.3%), with mean age of  $49.08 \pm 14.17$  years old. The mean duration of follow-up was  $6.44 \pm 3.87$  years, and mean difference of modified Pouchot's score was  $5.37 \pm 1.98$  between remission and flare. The number of 33 (67.4%) patients had presented systemic symptoms predominantly, while 16 (32.7%) presented arthritis more frequently in their clinical course. In flare state of AOSD, overall inflammatory markers were elevated, including cytokines

of IL-18 and IL-37. The serum level of IL-36Ra was  $164.04 \pm 169.03$  pg/mL in active state, compared to  $125.36 \pm 452.0$  in inactive state of AOSD patients ( $p < 0.001$ ). IL-36Ra presented positive correlation with modified Pouchot's score and inflammatory markers, including CRP ( $r = 0.286$ ,  $p < 0.01$ ), ferritin ( $r = 0.225$ ,  $p < 0.05$ ) and IL-37 ( $r = 0.353$ ,  $p < 0.01$ ), but was not with level of IL-18 and ESR in active AOSD. Distribution of IL-36Ra level was analysed by each clinical course, however, there was no significant difference in level of IL-36Ra by clinical presentations stratified with predominance of arthritis.

**Abstract SAT0613 – Table 1.** Comparison of serum IL-36Ra levels in active AOSD patients with other markers for disease activity

	Modified Pouchot's score	ESR	CRP	Ferritin	IL-18	IL-37
IL-36Ra	0.295 <sup>a</sup>	0.086	0.286 <sup>b</sup>	0.225 <sup>a</sup>	0.095	0.353 <sup>a</sup>

Correlation coefficient was presented by each inflammatory markers; <sup>a</sup>  $p < 0.05$ , <sup>b</sup>  $p < 0.01$

**Conclusions:** Serum IL-36Ra level was significantly increased in active AOSD patients compared to inactive AOSD patients, presenting positive correlation with other inflammatory markers. In patients with AOSD, level of IL-36Ra might be another potential serologic marker to estimate disease activity, especially active state of the disease.

#### SAT0614 NEW VARIANT IN THE IL1RN-GENE ASSOCIATED WITH LATE ONSET AND ATYPICAL PRESENTATION OF DIRA

J.B. Kuemmerle-Deschner<sup>1</sup>, K. Hoertnagel<sup>2</sup>, S. Schlipf<sup>3</sup>, S. Hansmann<sup>4</sup>, A. Hospach<sup>5</sup>, X. Liu<sup>6</sup>, S.M. Benseler<sup>7</sup>, A.N. Weber<sup>6</sup>. <sup>1</sup>Department of Pediatrics, Division of Rheumatology, University Hospital Tuebingen; <sup>2</sup>Praxis für Humangenetik Tuebingen, Tuebingen; <sup>3</sup>Kinderarztpraxis Dr. Lakner, Schwäbisch Gmünd; <sup>4</sup>Department of Pediatrics, Division of Pediatric Rheumatology, UNIVERSITY HOSPITAL TUEBINGEN, Tuebingen; <sup>5</sup>Zentrum für Pädiatrische Rheumatologie, Klinikum Stuttgart, Olgahospital, Stuttgart; <sup>6</sup>Department of Immunology, University of Tuebingen, Tuebingen, Germany; <sup>7</sup>Rheumatology, Department of Paediatrics, Alberta Children's Hospital, University of Calgary, Alberta, Calgary, Alberta, Canada

**Background:** Deficiency of the interleukin-1 receptor antagonist (DIRA) is an autoinflammatory disease characterised by severe systemic inflammation with bone and skin involvement present in the first days of life.

**Objectives:** We report a novel variant in the *IL1RN*-gene associated an atypical phenotype of DIRA.

**Methods:** A 3 year-old Caucasian boy presented with recurrent monthly episodes of fever and fatigue, associated with lymphadenopathy, pericarditis, pleuritis, pancreatitis, and arthritis involving sacroiliac, hip, knee and ankle joints in the absence of any skin involvement. Symptoms had started at age one and had progressed over time to life-threatening episodes requiring intensive care therapy. Throughout, inflammatory parameters including ESR, CRP, SAA, S100A8/9, leukocytes, and platelets were highly elevated. Treatment with colchicine and steroids improved symptoms, however did not prevent flares. Immune deficiencies were ruled out; genetic testing for FMF, CAPS, TRAPS, HIDS and DITRA did not reveal variants in the associated genes.

**Results:** Whole exome sequencing detected a novel homozygous stop variant c.62C>G; p.Ser21\* in the *IL1RN* gene (NM\_173842.2). Mother, father and brother are heterozygous for the same variant. In addition, three variants of unknown significance were identified in the patient's *PCGF5*, *CPA1* and *SPTA1* genes. Functional studies revealed only marginal secretion of IL-1RA in the patient's unstimulated leucocytes and after stimulation with IL-1 $\beta$  and LPS, confirming the disease-causing nature of the variant. Subsequently, IL-1 inhibition with anakinra at 2 mg/kg/d was started resulting in complete resolution of clinical symptoms, normal inflammatory markers and dramatically improved energy levels. Intolerance to daily subcutaneous injections prompted a switch to canakinumab at 4 mg/kg/4 weeks. However patient's and mothers assessment of disease activity was inferior on canakinumab compared to anakinra. After four months a flare appeared and lead to return to anakinra.

**Conclusions:** This is the first report of the novel c.62C>G; p.Ser21\* variant in the *IL1RN*-gene primarily causing severe serositis in a homozygous carrier, while heterozygous family members were completely symptom free. Skin disease, one of the most prominent features in other patients with DIRA was not observed in this patient, while IL-1 inhibition was likewise effective.

Pathogenic variants in all reported DIRA patients so far affect all 4 isoforms of IL-1RA.<sup>1</sup> The different phenotype in the patient reported here, may be due to the selective loss of secreted IL1RN.

**SAT0615 SYMPATHETIC JOINT EFFUSION IN AN URBAN HOSPITAL**

J.L. Barlow<sup>1</sup>, I.J. Tan<sup>2</sup>. <sup>1</sup>Department of Internal Medicine; <sup>2</sup>Department of Internal Medicine; Section of Rheumatology, Temple University Hospital, Philadelphia, USA

**Background:** Sympathetic joint effusion (SJE) or sympathetic synovial effusion (SSE) is a rheumatologic entity that has not been well defined in the medical literature. It is a non-inflammatory synovial fluid collection that is associated with infection or inflammation of an adjacent anatomic structure.<sup>1</sup> The epidemiology and clinical characteristics of SJE/SSE are largely unknown. This knowledge gap has led to a lack of recognition and misdiagnosis by clinicians.

**Objectives:** Our study aimed to determine incidence, demographic information, and describe the clinical characteristics and potential triggering conditions for this presumptive reactive phenomenon.

**Methods:** We conducted a study of patients >18 years of age hospitalised at Temple University Hospital (TUH) between January 31, 2010 and December 10, 2016 who underwent diagnostic arthrocentesis for painful effusions. Individuals with synovial fluid white blood cell count (WBC) in the normal range of 200 WBC/mm<sup>3</sup> or less were included. Patients with both non-inflammatory and inflammatory range synovial fluid of greater than 200 WBC/mm<sup>3</sup> were excluded to limit confounders. Demographic and clinical data of 72 patients were included for detailed analysis.

**Results:** SJE/SSE was seen in 80/882 hospitalised patients (incidence of 9%). Seventy-two patients fulfilled inclusion criteria for detailed chart review. Demographic information revealed: male 46/72 (64%), female 26/72 (36%), African-American 38/72 (53%), Caucasian 16/72 (22%), Hispanic 10/72 (14%), undefined and other 8/72 (11%). Onset was typically acute, with 45/72 (63%) of patients developing symptoms within six days of arthrocentesis. All patients (100%) with SJE/SSE presented with painful effusion, and a minority had physical findings of warmth 23/72 (32%) or erythema 12/72 (17%). Interestingly, nearly a third of patients 21/72 (29%) were misdiagnosed with crystal or septic arthritis based solely on clinical exam, and empiric treatment was often administered prior to arthrocentesis. The most commonly affected joint was the knee 61/72 (85%), followed by the elbow 5/72 (7%), shoulder 3/72 (4%) and hip 3/72 (4%). Identifiable pathology in the affected limb was found in 29/72 (40%) of patients. Infection was the most common etiology, found in 17/29 (59%) of patients, and included cellulitis, abscess, osteomyelitis, septic bursitis, myositis, and necrotizing fasciitis. The majority of cases of SJE/SSE 23/29 (79%) were associated with concomitant infection, DVT or intramuscular hematoma in the affected limb which required specific therapeutic interventions.

**Conclusions:** Sympathetic joint effusion or sympathetic synovial effusion (SJE/SSE) is relatively common in hospitalised patients. SJE/SSE may be a sentinel sign for a more serious disorder affecting the same limb. Clinicians should maintain a heightened index of suspicion for SJE/SSE. A search for underlying infection, venous thrombosis, and intramuscular hematoma in the affected limb is warranted when encountering acute painful joint effusion with normal range synovial fluid WBC count.

**SAT0616 TEN-YEAR RETENTION RATE OF INFLIXIMAB IN PATIENTS WITH BEHÇET'S DISEASE-RELATED UVEITIS**

J. Sota<sup>1</sup>, C. Fabiani<sup>2</sup>, A. Vitale<sup>1</sup>, G. Emmi<sup>3</sup>, G. Lopalco<sup>4</sup>, V. Venerio<sup>4</sup>, I. Orlando<sup>1</sup>, R. Franceschini<sup>1</sup>, B. Frediani<sup>1</sup>, M. Galeazzi<sup>1</sup>, F. Iannone<sup>4</sup>, G.M. Tosi<sup>1</sup>, L. Cantarini<sup>1</sup>.  
<sup>1</sup>University of Siena, Siena; <sup>2</sup>Humanitas Clinical and Research Center, Milan; <sup>3</sup>University of Florence, Florence; <sup>4</sup>University of Bari, Bari, Italy

**Background:** To date, a few studies have reported the long-term efficacy of Infliximab (IFX) in Behçet's disease (BD)-related uveitis.<sup>1,2</sup> Nevertheless, it is known that TNF- $\alpha$  inhibitor drugs may lose their efficacy over time due to the formation of anti-drug antibodies, causing secondary failure and influencing the retention rate of these agents.<sup>3</sup> In this regard no previous study has specifically investigated IFX retention-rate in BD-related uveitis.

**Objectives:** To evaluate the 10 year drug retention rate of IFX in BD-related uveitis, the effect of a concomitant use of disease modifying anti-rheumatic drugs (DMARDs) on drug survival and differences according to the lines of biologic treatment.

**Methods:** Cumulative survival rates were studied using the Kaplan-Meier plot, while the Log-rank (Mantel-Cox) test was used to compare survival curves.

**Results:** Forty patients (70 eyes) were eligible for analysis. The drug retention rates at 12-, 24-, 60- and 120 month follow-up were 89.03%, 86.16%, 75.66% and 47.11% respectively. No differences were identified according to the use of concomitant DMARDs ( $p=0.20$ ), while a statistically significant difference was observed in relation to the different lines of IFX treatment ( $p=0.014$ ). Visual acuity improved from baseline to the last follow-up visit ( $p=0.047$ ) and corticosteroids-sparing effect was observed ( $p<0.0001$ )

**Conclusions:** IFX retention rate in BD-uveitis is excellent and is not affected by concomitant DMARDs

**SAT0617 COMORBIDITY IN PATIENTS AFFECTED BY AVASCULAR NECROSIS OF THE FEMORAL HEAD AND IMPACT OF COEXISTENT DISEASES ON CONTRALATERAL JOINT INVOLVEMENT**

K. Gudkevich<sup>1</sup>, N. Martusevich<sup>1</sup>, A. Murzich<sup>2</sup>. <sup>1</sup>Belarusian State Medical University; <sup>2</sup>RSPC for Traumatology and Orthopedics, Minsk, Belarus

**Background:** Avascular necrosis (AN) represents a significant problem of modern rheumatology. The highest incidence of this disease is in able-bodied men. The risk of disability among patients with avascular necrosis of the femoral head (ANFH) is high, especially in case of bilateral process, as AN tends to progress steadily and results in osteoarthritis due to untimely diagnosis. Patients with AN can be affected by other coexistent diseases, that can influence the disease presentation and management.

**Objectives:** This study aimed to analyse the prevalence and pattern of comorbidities in patients affected by ANFH and to determine if there is a differential pattern of comorbidities in patients with bilateral and unilateral ANFH.

**Methods:** This was a cross-sectional study, comprising 102 adult patients, aged 48,<sup>38–58</sup> with a diagnosis of ANFH according to Ficat and Arlet criteria. Sociodemographic, anthropometric, clinical parameters of interest were collected from medical records. In order to characterise the burden of coexisting diseases or conditions Charlson Comorbidity Index was calculated. The data obtained were processed with STATISTICA 10.0 using descriptive and nonparametric statistics.

**Results:** Among a total of 102 patients, a significant prevalence of comorbidities (86,27%) was found. 78,85% of all patients suffered from 2 or more coexistent conditions. The most prevalent comorbidities were: cardiovascular diseases

(CVD) (53,92%), including hypertension (50,0%) and atherosclerosis (34,31%), endocrine and metabolic disorders (66,67%), including hypercholesterolemia (65,70%) and obesity (32,35%), diseases of the digestive system (30,39%), dorsopathies (22,55%). The number of comorbidities was associated with age ( $p=0,42$ ,  $p<0,001$ ) and body mass index ( $p=0,29$ ,  $p<0,001$ ).

In patients with bilateral ( $n=44$ ), compared with those affected by unilateral ANFH ( $n=58$ ), prevalence of younger age (43,5 (36–51) vs. 54,<sup>43–62</sup>  $p<0,01$ ) and male gender (odds ratio (OR) 2,99 (95% confidence interval (CI) 1,28–6,99),  $p<0,05$ ) were detected. A history of (CVD) was more frequent in patients with unilateral ANFH (63,79% vs. 40,91%, OR 3,62 (95%CI 1,67–7,88),  $p<0,05$ ), as well as hypertension (62,07% vs. 34,09%, OR 3,16 (95%CI 1,40–7,17),  $p<0,01$ ). Patients with unilateral ANFH were more likely to have higher number of comorbidities (3,80<sup>1,17–6,43</sup> vs. 2,89 (0,73–5,05)) and Charlson Comorbidity Index (0,72 (0,43–1,47) vs. 0,52 (0,43–1,87)).

**Conclusions:** ANFH is associated with high prevalence of comorbidities, especially CVD.

CVD, including hypertension, were more likely to be found in patients with unilateral ANFH, as well as higher comorbidity burden. It can be explained by the fact that patients with CVD received treatment according to national guidelines, including antihypertensive drugs, anticoagulants, statins, etc. This indicates that performing secondary prevention of CVD can be important in both CVD and ANFH, as such treatment can influence on intraosseous blood circulation in the contralateral joint.

#### SAT0618 RELATIONSHIP BETWEEN ARTERIAL STIFFNESS AND DISEASE DURATION IN BEHCET'S DISEASE

K. Ayar<sup>1</sup>, B. Sensoy<sup>2</sup>, M.E. Aslançi<sup>3</sup>, T. Tekeç<sup>4</sup>, S. Cekiç<sup>4</sup>. <sup>1</sup>Rheumatology, University of Health Sciences, Bursa Yüksek İhtisas Training and Research Hospital; <sup>2</sup>Cardiology; <sup>3</sup>Ophthalmology; <sup>4</sup>Internal Medicine, University of Health Sciences, Bursa Yüksek İhtisas Training and Research Hospital, BURSA, Turkey

**Background:** There are few studies in the literature investigating arterial stiffness in Behcet's Disease (BD). The association of arterial stiffness with duration of disease is unknown.

**Objectives:** The aim of this study is to compare arterial stiffness by assessing pulse wave velocity (PWV) and augmentation index (AI) measurements in healthy controls (HC) and patients diagnosed as BD with low and high disease duration.

**Methods:** Seventy BD patients and 40 HC without diabetes mellitus, Hypertension or chronic renal failure were included in the study. Patients with BD who were diagnosed within 12 months were taken to the group with low disease duration (LDD) and the others to the group with high disease duration (HDD). Demographic data and lipid parameters of all participants were recorded and PWV and AI measurements were made from brachial artery. The clinical characteristics of the patients with BD were recorded and the Behcet's Syndrome Activity Scale (BSAS) questionnaire was filled in for all patients with BD. Findings were compared between LDD, HDD and HC groups.

**Results:** Age, gender and body mass indexes were not statistically different between groups ( $p=0.134$ ,  $p=0.948$ ,  $p=0.929$  respectively). Augmentation index and PWV measurements were different between groups ( $p=0.014$ ,  $p=0.024$  respectively). In the HDD group, both PWV and AI were significantly higher than HC ( $p=0.013$ ,  $p=0.006$  respectively). In LDD group AI was significantly higher than HC however PWV was not ( $p=0.047$ ,  $p=0.919$  respectively). There was moderate correlation between PWV and disease duration (Rho:0.393;  $p<0.001$ ) and there was no correlation between AI and disease duration ( $p=0.287$ )

**Abstract SAT0618 – Table 1.** Demographic data, parameters of arterial stiffness, lipid parameters in all participants and disease duration, BSAS scores in patients with BD.

	Healthy controls (n=40)	The time since the diagnosis of BD		P
		LDD <sup>1</sup> (12 months ≤) (n=32)	HDD <sup>2</sup> (12 months <) (n=38)	
Age (year)	38.35±8.99	37.16±8.89	41.37±9.38	0.134
Gender (f/m)	23/17	20/12	19/19	0.948
BMI <sup>3</sup> (kg/m <sup>2</sup> )	26.55±5.65	26.33±3.68	26.22±4.38	0.929
BSAS <sup>4</sup> (0-100)		42.97±21.59	42.87±22.83	0.985
Disease duration (month)		0 (0-6.7)	120 (36-186)	<0.001
Augmentation index (%)	22.53±7.80	26.63±9.72	28.87±11.24	0.014
Pulse wave velocity (m/s)	5.75 (5.3-6.4)	5.8 (5.3-6.5)	6.6 (5.6-7.0)	0.024
LDL (mg/dl)	124.25±29.99	114.89±29.41	115.80±27.78	0.593
T. Cholesterol (mg/dl)	204.25±36.80	191.82±42.66	188.80±29.62	0.426
Triglycerides (mg/dl)	105.62±35.46	127.82±77.22	125.40±58.38	0.507
HDL (mg/dl)	54.75±10.34	52.35±13.62	47.65±10.71	0.182

LDD: Low disease duration, HDD: High disease duration, BMI: Body mass index, BSAS: Behcet Syndrome Activity Scale, BD: Behcet Disease

**Conclusions:** The augmentation index is higher in patients with BD than HC regardless of the duration of the disease. Pulse wave velocity does not increase in the early period of the disease in patients with BD but increases with prolonged disease duration.

#### SAT0619 ASSOCIATIONS BETWEEN CLINICAL MANIFESTATIONS OF BEHCET'S SYNDROME AND WORK OUTCOMES: RESULTS FROM A UK CROSS-SECTIONAL ANALYSIS

L. Chadwick<sup>1,2</sup>, N.J. Goodson<sup>1,2</sup>, R.J. Moots<sup>1,2</sup>. <sup>1</sup>Department of Rheumatology, Aintree University Hospital; <sup>2</sup>Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, UK

**Background:** Behcet's syndrome (BS) is a multi-systemic auto-inflammatory disease which exhibits significant heterogeneity in clinical manifestations, including orogenital ulceration, skin rash, arthralgia and ocular, venous, gastro-intestinal and neurological involvement. BS affects adults of working age, usually presenting between 20–40 years,<sup>1</sup> and can therefore have a significant impact on work. The association between individual and cumulative clinical manifestations of BS on employment status has not previously been assessed.

**Objectives:** To 1) describe demographics, clinical manifestations, work outcomes and use of unemployment benefits in a UK BS cohort and 2) to explore the relationship between individual and cumulative manifestations of BS and work outcomes.

**Methods:** A cross sectional analysis was performed using the Liverpool Behcet's Centre of Excellence clinical database. Inclusion criteria were clinical characteristics meeting International Criteria for Behcet's Disease (ICBD) diagnostic criteria and recorded employment data. Patients meeting ICBD but thought unlikely to have BS on clinical review by our multi-disciplinary team were excluded. Demographics, clinical manifestations, work outcomes and use of employment related benefits were described. A binomial variable 'Out of work' was generated and defined as unemployment, sickness absence, or patients marked as retired but of working age, a carer or a homemaker if the patient had to stop work due to BS. Associations between Out of work and: 1) individual clinical manifestations of BS, and 2) number of clinical BS manifestations, were explored using multivariate logistic regression adjusted for age, gender, mean EQ5D score and socio-economic status. Odds ratios (OR) and 95% confidence intervals were calculated.

**Results:** 120 patients met inclusion criteria. Mean age was 41.1 years and 33 patients (28%) were male. The minimum number of clinical manifestations were two in order to meet ICBD; the frequencies were 100% oral ulceration, 94% genital ulceration, 71% arthralgia, 43% skin rash and 20% ocular, 7% neurological, 6%

vascular and 5% gastro-intestinal involvement. 37 patients (31%) were out of work with 44 patients (37%) claiming employment related benefits. With regard to individual clinical manifestations, ocular disease had a statistically significant increased risk for being out of work when assessed alone with OR 2.84 (95% CI 1.13, 7.13) but lost statistical significance when analysed in the multivariate model: OR 2.45 (95% CI 0.70, 8.60). With regard to cumulative clinical manifestations, patients with four or more clinical manifestations of BS had a statistically significant increased risk of being out of work with OR 5.57 (95% CI 1.33, 23.27) in comparison to patients with two manifestations in the multivariate model.

**Conclusions:** This study has highlighted the significant burden of BS on work outcomes in this UK cohort. In particular, four or more cumulative BS manifestations were independently associated with being out of work in this young cohort. Further work is required to identify whether education or intervention in the workplace can help prevent disease related job loss in BS.

SAT0620

#### FURTHER EVIDENCES OF SECONDARY AMYLOIDOSIS IN ALKAPTONURIA

B. Frediani<sup>1</sup>, L. Millucci<sup>2</sup>, G. Bernardini<sup>2</sup>, D. Braconi<sup>2</sup>, M. Bardelli<sup>1</sup>, B. Marzocchi<sup>2</sup>, O. Spiga<sup>2</sup>, M. Orlandini<sup>2</sup>, S. Sestini<sup>3</sup>, M. Galeazzi<sup>1</sup>, A. Santucci<sup>2</sup>. <sup>1</sup>Departement of Medical Sciences, Surgery and Neurosciences, A.O.U Siena, Departement of Medical Sciences, Surgery and Neurosciences, A.O.U Siena; <sup>2</sup>Department of Biotechnology, chemistry and pharmacy, Siena, Department of Biotechnology, chemistry and pharmacy, Siena; <sup>3</sup>Italian Association Alkaptonuria Patients, AIMAKU, Italian Association Alkaptonuria Patients, AIMAKU, Siena, Italy

**Background:** Alkaptonuria (AKU) is an ultra-rare inborn error of metabolism due to a deficient activity of homogentisate 1,2-dioxygenase. Patients suffer from a severe arthropathy. Evidence was provided on the presence of a secondary serum amyloid A (SAA)-based amyloidosis. Here a complete microscopic and ultrastructural analysis of different AKU tissues, taken from six differently aged patients, is presented.

**Objectives:** SAA amyloidosis is a complication in AKU, making the detection of amyloid deposits at an early phase, important for treatment. We present a study of tissues from patients of different age and relevance of symptoms, providing a detailed overview of AKU amyloidosis.

**Methods:** Different tissues were obtained from a cohort of 6 AKU patients: 4 M (63,68,42,44 y) and 2 F (66,71 y) with different severity of symptoms. Histology and amyloid were investigated. A complete microscopic and ultrastructural analysis is presented and patient features as radiological examination, mild-to-severe degenerative changes as joint space narrowing, cartilage irregularities, sub-chondral sclerosis or peripheral osteophytes and linear intervertebral disk calcifications were reported. SAAserum levels and other serological markers were measured too. Specimens were analysed by Congo Red, Immunofluorescence, Transmission Electron Microscopy.

**Results:** The analysis of all AKU specimens confirmed the massive presence of amyloid fibrils even in young patients. Alterations in collagen composition, strictly associated to amyloid bundles deposition, were observed especially in labial salivary gland, cartilage, tendons and infrapatellar fat pad. Histological analysis showed depletion of glycosaminoglycans in young patients, whereas, at light microscopy, calcification and fibrillation were observed only in elderly patients. Immunofluorescence assessed undoubtedly the presence of SAA in amyloid deposits in AKU, and we reported for the first time the finding of amyloid deposition in young AKU patients and in less common regions.

**Conclusions:** We provide the first detailed overview of amyloidosis in AKU. Overall, our findings depicted a novel biological framework underlining the pathological role of amyloidosis in several AKU tissues. Furthermore, we found that degradation of extra-cellular matrix AKU is not limited to elderly. The clinical burden of AKU may notably increase, since amyloidosis was found even in young AKU patients, whereas degeneration of cartilage and tendons was limited to older subjects.

SAT0621

#### CLINICAL SIGNIFICANCE OF INTERLEUKIN-18 AND INTERLEUKIN -6 ON DISEASE COURSE OF ADULT-ONSET STILL'S DISEASE

M.G. Ahmed. *Rheumatology, Alazhar University, Cairo, Egypt*

**Background:** Innate pro inflammatory cytokines interleukin (IL)–6 and IL-18 are critical for perpetuating the inflammatory processes in adult-onset Still's disease (AOSD),<sup>1</sup> and macrophage activation syndrome (MAS).<sup>2</sup>

**Objectives:** To assess the role of IL-6 and IL-18 in the pathogenesis of (AOSD) and MAS, and to investigate the clinical significance of serum cytokine profile with IL-6 and IL-18 in (AOSD) and MAS,

**Methods:** we analysed the serum IL-6 and IL-18 in patients with (AOSD) and compared them with the clinical features of (AOSD) 51 patients with (AOSD) including 17 patients with MAS were analysed. Levels of IL-6 and IL-18 were quantified in serum by enzyme linked immune sorbent assay. Results were compared with clinical features of (AOSD).

**Results:** Two distinct Adult Still's disease patient subsets based on their serum IL-6 and IL-18 levels were identified: an IL-18 dominant (IL-18/IL-6 1000) and an IL-6 dominant (IL-18/IL-6 1000). The IL-6 dominant subset had a significantly greater number of joints with active disease and higher serum levels of matrix metalloproteinase-3, whereas the IL-18-dominant subset was more likely to develop MAS. The cut off value of serum IL-18 to predict the development of MAS was 52000 pg/ml with 87.3% of sensitivity and 79.3% of specificity. The patients with IL-18 dominant pattern were likely to have monophasic or polycyclic disease course, whereas the patients with IL-6 dominant pattern were likely to have persistent disease course. Serum IL-18 levels in patients achieved remission decreased to the levels <1,000 pg/mL in inactive phase and normalised in remission phase. In contrast, serum IL-18 levels in patients experienced relapse during withdrawal of steroid within 12 months after disease onset demonstrated a sustained elevation of serum IL-18 levels >1,000 pg/mL during the inactive phase

**Conclusions:** Two subsets of patients with (AOSD), one which is prone for arthritis and another with prone for MAS, can be identified on the basis of their serum IL-6 and IL-18 levels. These two subsets appear to be characterised by certain distinct clinical features. Monitoring the cytokine profile with IL-18 and IL-6 might be useful to predict disease course. Furthermore, serum IL-18 levels reflect the biological activities of the immune system in (AOSD) and may predict the development of MAS and the prognosis of Adult Still's disease

SAT0622

#### HIGH DOSE INTRAVENOUS METHYLPREDNISOLONE INDUCES RAPID IMPROVEMENT IN SEVERE UVEITIS: A MULTICENTER STUDY OF 129 PATIENTS

N. Vegas-Revenga<sup>1</sup>, V. Calvo-Río<sup>1</sup>, I. González-Mazón<sup>1</sup>, L. Sánchez-Bilbao<sup>1</sup>, E. Beltrán<sup>2</sup>, A. Follonosa<sup>3</sup>, O. Maiz<sup>4</sup>, A. Blanco<sup>5</sup>, M. Cordero<sup>5</sup>, I. Ortego<sup>6</sup>, I. Torre<sup>7</sup>, F. Hernández<sup>8</sup>, S. Muñoz<sup>9</sup>, M. Esteban<sup>9</sup>, M. Diaz-Llopis<sup>10</sup>, J. Cañal<sup>1</sup>, J. A. Ventosa<sup>1</sup>, R. Demetrio<sup>1</sup>, M. Agudo<sup>1</sup>, L. Dominguez-Casas<sup>1</sup>, M.A. González-Gay<sup>1</sup>, R. Blanco<sup>1</sup>. <sup>1</sup>HUMV, Santander; <sup>2</sup>H. Peset, Valencia; <sup>3</sup>H. Cruces, Barakaldo; <sup>4</sup>H. Donostia, Donostia; <sup>5</sup>H. de León, León; <sup>6</sup>H. San Cecilio, Granada; <sup>7</sup>H. Basurto, Bilbao; <sup>8</sup>H. Negrín, Gran Canaria; <sup>9</sup>H. Infanta Sofía, Madrid; <sup>10</sup>H. La Fe, Valencia, Spain

**Background:** In uveitis rapid and effective remission-inducing therapy is mandatory to avoid irreversible damage.

**Objectives:** To evaluate the efficacy and safety of high-dose intravenous methylprednisolone (IVMP) pulse therapy in uveitis.

**Methods:** Multicentre study of 129 patients (203 eyes) with uveitis who received IVMP. The underlying diseases were: Idiopathic (n=30), Vogt Koyanagi Harada,<sup>29</sup> Behçet disease,<sup>19</sup> Sarcoidosis,<sup>6</sup> Multifocal Choroidopathy,<sup>4</sup> Birdshot chorioretinopathy,<sup>2</sup> Acute posterior multifocal placoid pigment epitheliopathy,<sup>1</sup> Granulomatosis with polyangiitis,<sup>2</sup> Aortitis,<sup>1</sup> Immune thrombocytopenic purpura,<sup>1</sup> Rheumatoid arthritis,<sup>2</sup> Axial Spondylitis,<sup>6</sup> Psoriatic arthritis,<sup>2</sup> Juvenile Idiopathic Arthritis,<sup>1</sup> Thrombophilia synd.,<sup>1</sup> Eales Disease,<sup>2</sup> Sympathetic Ophthalmia,<sup>2</sup> Multiple Sclerosis,<sup>2</sup> Relapsing Polychondritis,<sup>1</sup> Cogan's synd.,<sup>1</sup> Sjögren synd.,<sup>2</sup> Crohn's disease,<sup>1</sup> Reactive arthritis,<sup>1</sup> Toxic oil synd. and brain ischemia,<sup>1</sup> Raynaud's Disease and brain ischemia,<sup>1</sup> Pseudotumor,<sup>1</sup> Cataract surgery,<sup>1</sup> Herpes Simplex,<sup>1</sup> Varicella Zoster-associated acute retinal necrosis,<sup>1</sup> *T.pallidum*<sup>2</sup> and *M.*

*tuberculosis*.<sup>1</sup> The inflammatory ocular patterns were: panuveitis (66), posterior uveitis (PU),<sup>31</sup> intermediate uveitis (IU),<sup>5</sup> anterior uveitis (AU),<sup>12</sup> AU and PU,<sup>2</sup> AU and IU,<sup>1</sup> IU and PU,<sup>1</sup> exudative retinal detachment,<sup>3</sup> vasculitis,<sup>4</sup> pseudotumor,<sup>1</sup> scleritis<sup>2</sup> and sclero-uveitis.<sup>1</sup> Bilateral ocular involvement was observed in 74 cases. Patients were assessed at basal visit and day 2–5, 7, 15 and 30 after IVMP. The main outcome variable was best corrected visual acuity (BCVA), the degree of inflammation of the anterior chamber and vitreous, and macular thickness (macular oedema defined by OCT >300  $\mu$ m). The results are expressed as mean  $\pm$ SD for normally distributed variables, or as median [interquartile range] when are not. Comparison of continuous variables was performed using the Wilcoxon test.

**Results:** We studied 74 ♀/55 ♂; mean age 42 $\pm$ 14.3 years. IVMP dose ranged from 40–1000 mg/day for 3–5 consecutive days. Prior to IVMP, cycloplegic and corticosteroid eye drops were used in all cases. Improvement was faster among patients with inflammation in anterior chamber and vitritis than in BCVA, CME, retinitis and retinal vasculitis (TABLE). Total remission was achieved in 19.4% of the 129 patients after IVMP. In 126 of the patients continued with oral corticosteroids and 4 received an intraocular dose of steroids. These immunosuppressive drugs were added: Methotrexate (52), Cyclosporine A,<sup>48</sup> Azathioprine<sup>40</sup> and others.<sup>5</sup> In a few cases biological therapy (64) was administered afterwards. In general, acute respiratory infection was the side-effect most frequent.

Abstract SAT0622 – Table 1

	Affected eyes	Affected eyes after high-dose IVMP (%)				
	baseline	Day 2.3	Day 7	Day 15	Day 30	
BCVA, mean $\pm$ SD	0.47 $\pm$ 0.35	0.56 $\pm$ 0.34*	0.61 $\pm$ 0.33*	0.68 $\pm$ 0.31*	0.75 $\pm$ 0.3*	
Anterior chamber cells (median [IQR])	0.75 [0-4]	0 [0-4]*	0 [0-4]*	0 [0-3]*	0 [0-2]*	
Vitritis (median [IQR])	0 [0-5]	0 [0-5]*	0 [0-4]*	0 [0-3]*	0 [0-3]*	
OCT (microns) mean $\pm$ SD	465.36 $\pm$ 189.1	366.49 $\pm$ 159.7*	346.49 $\pm$ 150.9*	308.2 $\pm$ 120.06*	281.79 $\pm$ 107.6*	
Choroiditis/Chorioretinitis n. (%)	59 (23%)	51 (20%)	33 (13%)	23 (9%)	16 (6%)	
Retinitis n. (%)	86 (34%)	74 (29%)	70 (27%)	46 (18%)	21 (8%)	
Retinal vasculitis n. (%)	66 (26%)	58 (23%)	52 (20%)	36 (14%)	16 (6%)	
Synechiae n. (%)	39 (15%)	32 (12%)	30 (12%)	30 (12%)	33 (13%)	
Cystoid macular edema (CME) n. (%)	83 (33%)	68 (27%)	57 (22%)	41 (16%)	20 (8%)	

\*p < 0.05 compared with basal

**Conclusions:** High-dose IVMP pulse therapy is beneficial in the prompt control of severe uveitis and it is well tolerated.

## SAT0623 CLINICAL FEATURES AND TREATMENT OF IDIOPATHIC RECURRENT ACUTE PLEURO-PERICARDITIS

K. Dietz, H.-M. Lorenz, N. Blank. *Rheumatology, Internal Medicine 5, University Hospital Heidelberg, Heidelberg, Germany*

**Background:** Idiopathic recurrent acute pleuro-pericarditis (IRAP) is an increasingly recognised autoinflammatory disease comprising post-pericardiotomy-syndrome, recurrent pericarditis and post-myocardial-infarction-syndrome. Different autoimmune mechanisms were discussed in the past. Recently, IRAP is considered as an autoinflammatory disease. Therapeutic options comprise colchicine, prednisolone and interleukin (IL)–1beta blockingagents.

**Objectives:** to investigate whether idiopathic and post-interventional pleuro-pericarditis represent a clinical spectrum and to identify treatment options.

**Methods:** This study analyses demographic, clinical and laboratory features of post-interventional and idiopathic pleuro-pericarditis and adult onset Still's disease (AOSD) as a reference. Patients with infectious disease, connective tissue disease, chronic heart failure, renal failure and other non-exsudative effusions were excluded from this analysis. Patients with IRAP were treated with colchicine, prednisolone and IL1 $\beta$  blocking agents.

**Results:** Between 2005 and 2017 66 cases of idiopathic and post-interventional pleuro-pericarditis were identified and compared to 83 cases of AOSD. Clinical and laboratory features suggest that idiopathic and post-interventional pleuro-pericarditis represent a clinical spectrum which is identical with IRAP.

Prednisolone was started with 25 mg to 125 mg and tapered to less than 7 mg or discontinued if not effective. 47 of 66 patients (71%) were treated with prednisolone and 10/47 (21%) were in remission with no need of any further therapeutically escalation.

Colchicine was given to 44/66 patients (67%) and 29/44 (66%) were in complete remission.

Four of 66 patients (6%) did not respond or had contraindications against colchicine or prednisolone and were treated with anakinra. Of these patients 4/4 (100%)

were in remission. During the follow-up period of 20 patient\*months 2 of 4 patients maintained the remission with anakinra every 2nd day and two patients discontinued anakinra and remained in remission.

**Conclusions:** 1. post-pericardectomy-syndrome, post-myocardial-infarction-syndrome and idiopathic recurrent pericarditis represent a clinical spectrum of autoinflammatory diseases.

2. treatment options comprise colchicine as a first-line therapy, prednisolone and anti-IL1 blocking agents.

**Acknowledgements:** none.

**Disclosure of Interest:** None declared

## SAT0624 INCIDENCE AND BASELINE CHARACTERISTICS OF RELAPSE OR EXACERBATION IN PATIENTS WITH PULMONARY SARCOIDOSIS: A SINGLE CENTRE LONG-TERM OBSERVATIONAL COHORT STUDY

O. Murata<sup>1,2</sup>, A. Kudo<sup>2</sup>, K. Suzuki<sup>3</sup>. <sup>1</sup>Division of Pulmonary Medicine, Allergy, and Rheumatology, Department of Internal Medicine, School of Medicine, Iwate Medical University, Morioka; <sup>2</sup>Department of Pulmonary Medicine, Hachinohe Red Cross Hospital, Hachinohe; <sup>3</sup>Division of Rheumatology, Department of Internal Medicine, School of Medicine, Keio University, Tokyo, Japan

**Background:** Sarcoidosis is a systemic granulomatous disease that can affect multiple organs. Lung involvement is particularly common, occurring in more than 90% of patients.<sup>1</sup> However, spontaneous remission of pulmonary sarcoidosis is often observed within 2 years.<sup>2</sup> Factors reported to indicate a poor prognosis in pulmonary sarcoidosis include chest radiographic stage, skin involvement, age over 40 years and smoking history.<sup>3, 4</sup> To date, however, no study has comprehensively described factors of relapse and exacerbation and characteristics of untreated patients with favourable outcomes over a long-term period of more than 2 years.

**Objectives:** The aim of study was to identify the incidence and baseline characteristics of relapse and exacerbation in patients with pulmonary sarcoidosis over a long-term period.

**Methods:** One hundred- and three patients who visited our division of Hachinohe Red Cross Hospital between January 2007 and December 2016 and were clinically diagnosed as having pulmonary sarcoidosis were enrolled. The incidence and characteristics of relapse or exacerbation were prospectively calculated and statistically analysed using clinical, laboratory and imaging data collected from medical records.

**Results:** Of 103 patients, 79% were women and mean age at diagnosis was 50.1  $\pm$  16.4 years. Mean observation period was 9.8 $\pm$ 8.6 years. The number of patients with previously reported short-term prognostic factors were as follows: chest radiographic stage (Stage 0, n=7; Stage I, n=32; Stage II, n=36; Stage III, n=18; Stage IV, n=10), skin involvement (n=9), age over 40 years old (n=73), and smoking history (n=38). Overall relapse or exacerbation was 22.3% (n=23) and mean period to relapse or exacerbation was 8.7 $\pm$ 8.3 years. We then analysed the 69 patients who were observed for more than 5 years, and identified relapse or exacerbation within 5 years in 9 patients. Comparison of characteristics at diagnosis between the relapse or exacerbation group and spontaneous group showed that the relapse or exacerbation group had a significantly elevated frequency of bilateral hilar lymphadenopathy, disease duration, ocular involvement, cardiac involvement, and oral glucocorticoid use at diagnosis (p=0.014, 0.027, 0.019, 0.035, and 0.0043, respectively). On stratification, the number of risk factors was positively and significantly associated with the cumulative ratio of relapse or exacerbation (p=0.048).

**Conclusions:** Our long-term observational cohort study newly identified the incidence and baseline characteristics of relapse or exacerbation in patients with pulmonary sarcoidosis over a long-term period. Scoring the number of the factors at baseline may facilitate the prediction of relapse or exacerbation.

**SAT0625 SARCOIDOSIS IS ASSOCIATED WITH AN INCREASED RISK OF GASTROINTESTINAL EVENTS: A POPULATION-BASED RETROSPECTIVE COHORT STUDY 1976–2013**

P. Ungprasert<sup>1</sup>, C.S. Crowson<sup>2</sup>, E.L. Matteson<sup>2</sup>. <sup>1</sup>Research and development, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; <sup>2</sup>Rheumatology, Mayo Clinic, Rochester, USA

**Background:** An increased risk of gastrointestinal (GI) diseases has been observed in several chronic inflammatory disorders but the risk in patients with sarcoidosis is not known.

**Objectives:** This study was undertaken to characterise the risk of GI diseases in patients with sarcoidosis.

**Methods:** A population-based cohort of 345 incident cases of sarcoidosis among Olmsted County, Minnesota residents in 1976–2013 was identified from a comprehensive medical record-linkage system. Diagnosis was confirmed by individual medical record review. A cohort of 345 sex and age-matched comparators was also identified from the same underlying population. Medical records of both groups were reviewed for GI diseases. Cox models adjusted for age, sex and calendar year were used to compare the rate of development of GI diseases between the groups.

**Results:** GI events occurred in 101 cases and 63 comparators, corresponding to an adjusted hazard ratio (HR) of 1.90 (95% confidence interval [CI] 1.38–2.61). Patients with sarcoidosis had an increased risk for both upper (HR 1.90; 95% CI 1.27–2.83) and lower GI events (HR 1.97; 95% CI 1.27–3.05) relative to comparators. By disease type, patients with sarcoidosis had a significantly elevated risk of upper GI ulcer, upper GI haemorrhage and diverticulitis (**table 1**).

Comorbidity	Number of events prior to index date	p-value	Number of events after index date	Cumulative incidence at 10 years for non-sarcoidosis subjects (±SE)	Cumulative incidence at 10 years for sarcoidosis patients (±SE)	Hazard ratio (95% CI)	p-value
<b>Upper GI diagnoses</b>							
Upper ulcer	21/19	0.87	11/27	1.9 (0.2, 3.6)	4.5 (2.0, 6.8)	2.56 (1.27, 5.17)	0.009
Upper bleed	6/14	0.11	14/29	0.9 (0.0, 2.0)	4.4 (1.9, 6.9)	2.36 (1.24, 4.47)	0.009

**SAT0626 ANAKINRA TREATMENT IN REFRACTORY CASES OF ADULT-ONSET STILL DISEASE: CASE SERIES**

S. Ugurlu, B. Yurttas, G. Guzelant, B. Ergezen, H. Ozdogan. Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University Of Istanbul, Istanbul, Turkey

**Background:** Despite methotrexate and steroid treatment, in cases of Adult-onset Still's disease (AOSD) it is usually difficult to maintain clinic stability. In refractory cases, Anakinra treatment has been reported to be efficacious.<sup>1</sup>

**Objectives:** In this retrospective review, it is aimed to evaluate the AOSD cases treated with anakinra in our centre.

**Methods:** Fourteen AOSD patients (11 female, 3 male) who were being followed in our outpatient clinic were reviewed retrospectively. The demographic characteristics, pre- and post-treatment clinical findings were reported.

**Results:** The mean follow-up period of the patient population was 33.5±30.07 months (mean ±SD). Initial prednisolone dose was 37.3 mg/day. Except for one, all of our patients were exposed to methotrexate before being treated with anakinra. This patient was being treated with cyclosporine instead, since she had concomitant Macrophage Activation Syndrome. The other medications, the patients were previously treated with, were Etanercept (n=2), Tocilizumab (n=3), Infliximab (n=1) and Adalimumab (n=1).

All patients were on 100 mgs of Anakinra, daily, except for the one treated with 200 mg/day. The mean duration of Anakinra therapy was 11.4 months. Among 7 patients in whom anakinra therapy was terminated, 1 had drug induced urticaria, 1 was primary irresponsive, 4 were secondary irresponsive and the other had severe pneumonia. Primary irresponsiveness is the lack of response to the therapy since the drug was first introduced, whereas in secondary irresponsiveness the case responds to the medication for a while and starts to flare again after asymptomatic-free period on the medication. Among 14, 7 of our patients are still on 100 mg/d Anakinra.

The mean level of C reactive protein (CRP) measures was reduced from 64.38 ±61.95 mg/L to 34.3±24.3 mg/L with Anakinra therapy (p=0.003). Similarly, mean Erythrocyte Sedimentation Rate (ESR) was dropped to 33±22 mm/h from 59 ±35 mm/h by the help of the therapy (p<0.001). Among patients who primarily responded Anakinra therapy the mean Ferritin measures dropped to 427.25 ng/ml from 910 ng/ml (p=0.006). On the other hand, the Ferritin level was not significantly reduced in patients who did not respond Anakinra. The mean Patient reported Global Visual Analogue Scale (PG-VAS) score was also decreased to 3.83±4.7 from 9.5±0.07 following the therapy (p<0.001). Unfortunately, one of our 7 patients who were followed in remission under Anakinra died of an unknown etiology.

**Conclusions:** Adult-onset Still's disease is a challenging disorder, lacking a sufficient long-time clinical control. In order to obtain a full remission, various efforts have been spent so far. One of these approaches is to treat refractory cases with Anakinra, an IL-1 blocking agent. According to our clinical experience we state that, anakinra has a relatively high efficacy in controlling refractory cases.

**SAT0627 FABRY DISEASE: DIAGNOSTIC ERRORS IN RHEUMATOLOGY PRACTICE**

S. Moiseev<sup>1,2</sup>, P. Novikov<sup>1</sup>, N. Bulanov<sup>1</sup>, E. Karovaiquina<sup>1</sup>, A. Moiseev<sup>2</sup>, V. Fomin<sup>1</sup>. <sup>1</sup>Sechenov First Moscow State Medical University (Sechenov University); <sup>2</sup>Lomonosov Moscow State University, Moscow, Russian Federation

**Background:** Fabry disease (FD) is a rare X-linked storage disease resulting from the deficient activity of the lysosomal α-galactosidase A (AGAL) and leading to a progressive accumulation of glycosphingolipids in a wide range of cell types throughout the body, including kidney, heart and nervous system. Certain manifestations of FD can mimic those of rheumatic diseases.

**Objectives:** To evaluate the occurrence and the possible causes of diagnostic errors in patients with FD in rheumatology practice.

**Methods:** We retrospectively studied the medical records of 82 adult patients with definite FD (low or absent AGAL activity, pathogenic mutation in the GLA gene, typical clinical symptoms in patient and/or his relatives, results of kidney biopsy). There were 55 males and 27 females aged of 18 to 69 years (median 38<sup>29</sup>, 48<sup>48</sup> years).

**Results:** Seventy two of 82 patients (87.8%) had a history of classic phenotype of FD from childhood or adolescence. The typical manifestations included neuropathic pain that was related to heat and fever (65/82; 79%), angiokeratoma (37/

82; 45%), anhidrosis/hypohidrosis (44/82; 53.6%), and cornea verticillata (40/62; 64.5%). However, there was a significant delay to diagnosis of up to 51 years (median 18<sup>9</sup>; 27 years). Moreover, diagnosis was established by nationwide screening in dialysis units in 22/82 (26.8%) patients or by family screening in 34/82 (41.4%) patients. At the time of diagnosis, patients usually presented with a clinical picture of systemic disease with mild to moderate proteinuria with or without impairment of kidney function (70/82; 85.4%), left ventricular hypertrophy (56/82; 68.3%), white matter lesions on brain MRI (38/72; 52.8%), and/or a history of stroke (15/82; 18.3%). Twenty six of 82 patients (31.7%) previously had at least one diagnosis of rheumatic disease (Table 1). The common causes for referral to rheumatologist were skin rash and neuropathic pain. In 6 of 26 patients (23.1%), the latter was initially misdiagnosed as joint pain. The possible causes of diagnostic errors included also 'genuine' arthralgia (6/26; 23.1%), episodes of unexplained fever (13/26; 50%), Raynaud phenomenon (2/26; 7.7%), and the laboratory markers of inflammation (11/26; 42.3%).

**Abstract SAT0627 – Table 1.** 'Rheumatic' diagnoses in Fabry patients

Misdiagnoses	Number of patients
Vasculitis*	6 (7.3%)
Arthritis**	5 (6.1%)
Osler-Weber-Rendu disease	4 (4.9%)
Rheumatic fever	4 (4.9%)
Systemic lupus erythematosus	3 (3.7%)
Familial Mediterranean fever	1 (1.2%)

Note: \*Vasculitides included IgA-vasculitis, Behcet disease, etc. \*\*Arthritides included rheumatoid arthritis, juvenile rheumatoid arthritis and osteoarthritis.

**Conclusions:** Practicing rheumatologists should be aware of FD, given a high occurrence of diagnostic errors. The clues to correct diagnosis include a history of typical symptoms (i.e. neuropathic pain, angiokeratoma, hypohidrosis) from childhood or adolescence and/or the presence of typical manifestations in family members. Notably, FD can initially present as an autoinflammatory disorder with episodes of joint pain and unexplained fever associated with the laboratory markers of inflammation.

#### SAT0628 A RETROSPECTIVE OBSERVATIONAL STUDY OF AZATHIOPRINE MAINTENANCE THERAPY ON BEHCET'S DISEASE WITH VASCULAR INVOLVEMENT

S. Girgin<sup>1</sup>, S. Yurumez<sup>2</sup>, A. Omma<sup>2</sup>, C. Bes<sup>1</sup>, S. Celik<sup>1</sup>, N. Alpay Kanitez<sup>1</sup>.  
<sup>1</sup>Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul; <sup>2</sup>Ankara Numune Training and Research Hospital, Ankara, Turkey

**Background:** Vascular disease which has potential to involve both arteries and veins of all size is one of the major causes of mortality and morbidity in Behçet's disease (BD). There is no controlled studies for the immunosuppressive (IS) therapy in vascular involvement of BD. For the induction and/or maintenance therapy, azathioprine (AZA) is widely used as a corticosteroid tapering IS agent in vascular BD although there are many different clinical presentation.

**Objectives:** The purpose of this study to investigate relapse rate and the clinical factors affecting it during AZA maintenance therapy.

**Methods:** Consecutive BD patients with a documentation for arterial or venous involvement were evaluated from two rheumatology centre between January-September 2017. Patients who have been treated for at least 3 months after the complete or partial remission were included to study. The baseline clinical and laboratory findings, treatment protocol, first vascular relapse time and adverse events were obtained medical records. Long-term outcome and factor associated with vascular relapse were assessed.

**Results:** Totally 78 patients were included to the study and majority of them [59 (%75.6)] was male. The mean age  $\pm$ SD of the patients was 37.5 $\pm$ 9 years. Clinical characteristics of patients are seen in table 1. The median duration of maintenance therapy with AZA was 25 (min 3- max 144) months and the mean dose  $\pm$ SD of AZA was found as 1.7 $\pm$ 0.3 mg/kg/day. AZA was withdrawn in 4 (% 5.1) patients because of adverse events. Twenty patients (%25.6) were receiving anti-coagulant therapy. Vascular relapse was observed in 14 (%17.9) patients. In relapsing group, arterial involvement and uveitis was higher statistically ( $p=0.014$  and  $0.045$  respectively). In regression analysis, arterial involvement was independent risk factor for relapse ( $p=0.016$ ). The percentage of relapses

was calculated as %39 (7/18) in patient subgroup with arterial involvement. Relapse free survival rates according to involving vessel were seen in figure 1.

**Abstract SAT0628 – Table 1.** Clinical characteristics of vascular Behçet's Disease (n=78)

The mean age $\pm$ SD	37.5 $\pm$ 9.2
Male gender n (%)	59 (76)
Genital ulcer n (%)	49 (63)
Skin lesions n (%)	44 (57)
Paterji positivity n (%)	29 (38)
Uveitis n (%)	17 (22)
Musculoskeletal involvement n (%)	15 (20)
CNS involvement n (%)	1 (1.2)
GIS involvement n (%)	1 (1.2)
Venous involvement n (%)	67 (86)
Arterial involvement n (%)	18 (24)

SD: Standart deviation, CNS: Central nervous system, GIS: Gastrointestinal system

**Abstract SAT0628 – Figure 1.** Relapse free survival rates according to involving vessels in patients with Behçet's disease (BD) by using Kaplan-Meier method (BDVI: Behçet's disease with venous involvement, BDAI: Behçet's disease with arterial involvement,  $p=0.001$  by log-rank test).

**Conclusions:** According to our study, AZA is seen as safe in maintenance therapy of BD with vascular involvement, however it can be said that the relapse rate is not favourable especially in patients with arterial involvement. Vascular involvement is considered as related to endotel inflammation resulting BD activity and the effect of anti-coagulant therapy is still controversial. TNF inhibitors or other immunosuppressant may be alternative to AZA for maintenance therapy with the support of randomized-controlled studies.

**Disclosure of Interest:** None declared

#### SAT0629 IGG4 RELATED CASTLEMAN'S DISEASE OR "SECONDARY" IGG4 RELATED DISEASE OF MULTICENTER CASTLEMAN'S DISEASE?

X. Zhang, P. zhang, L. peng, Y. fei, W. zhang, R. feng, W. zhang. *Rheumatology*, Peking Union Medical College, Beijing, China

**Background:** It's widely accepted that a diagnosis of IgG4-related disease (IgG4-RD) can be made under a premise of rule out a series of disease including Castleman's disease (CD). Clinically, the two diseases may share similar clinical manifestations, such as multiple organ involvement. Pathologically, in some cases with CD, IgG4 positive plasma cell infiltrations are also evident. Otherwise, IgG4-RD may pathologically exhibits CD-like feature.<sup>1-3</sup>

**Objectives:** When the histopathology coincides with the diagnosis of both IgG4-RD and CD, it is hard to depart the two disease entity utterly. It's unknown whether it is IgG4 related CD or "secondary" IgG4-RD of multicentric CD, here we call it IgG4-CD provisionally. To our knowledge, no comparative study of IgG4-CD and IgG4-RD has yet been published. In this study, we aim to review the clinical feature of IgG4-CD.

**Methods:** This study is based on a retrospective analysis of a prospectively acquired database. IgG4-CD were defined histopathologically in patients who fulfilled the diagnosis of both IgG4-RD and CD. Forty five definite IgG4-RD patients were recruited as control. Clinical features including organ involvement, serum IgG4, IgG, IgE, ESR and CRP levels of all the participants were collected and analysed statistically.

**Results:** Fifteen patients (2.8%) out of 534 patients with IgG4-RD in China's largest prospective IgG4-RD and Mimicry cohort fulfilled the definition of IgG4-CD. There were 14 males and 1 female, mean age was 47±18 years, and the median disease duration before diagnosis was 12 (1–132) months. Eight patients have allergic history. IgG4-CD patients had more lymph node involvement (100% vs 57.8%,  $p<0.01$ ), while IgG4-RD patients had more submandibular (33.3% vs 77.1%,  $p<0.01$ ) and parotid gland (13.3% vs 40.9%,  $p<0.05$ ) affected. IgG4-CD patients had significantly higher levels of ESR (mm/h), CRP (mg/L), IgG (g/L), IgG1 (g/L), IgG3(g/L), IgG4(mg/dL), and IgE (g/L) [76.50 (5.00–129.00) vs 17.00 (2.00–89.00), 5.39 (0.54–134.00) vs 1.6 (0.08–113.74), 35.28 (9.76–69.00) vs 19.36 (7.46–61.00), 11.2 (6.84–41.00) vs 8.07 (4.08–16.70), 1.55 (0.19–3.20) vs 0.53 (0.09–2.00), 1590.00 (133.00–6420.00) vs 1070.00 (152.0–6100.00), 807.5 (215.00–2967.00) vs 214.00 (20.40–2437.00), respectively.  $p<0.05$ ). Except for one patient refused to receive drug therapy untreated, the remaining patients with IgG4-CD all received glucocorticoid (GC) treatment. Patients with multi-organ involvement or in severe inflammatory condition were treated with both GC and immunosuppressive agents, those who with active disease but resistant to above regimen accepted biologics such as rituximab. All patients with IgG4-CD exhibited favourable outcomes.

**Conclusions:** Both IgG4-RD and CD can involve multiple organs. There are a small group of patients who had clinical and pathological characteristics of both CD and IgG4-RD showed better clinical outcome. Long-term prognosis of these patients, the relationship of CD and IgG4-RD are waiting to be further elucidated.

## Diagnostics and imaging procedures

SAT0630

### AGREEMENT BETWEEN PATIENT-REPORTED SWOLLEN AND TENDER JOINTS, CLINICAL EXAMINATION AND SYNOVITIS DETECTED BY ULTRASONOGRAPHY IN RHEUMATOID ARTHRITIS PATIENTS AT THE TIME OF PATIENT-REPORTED FLARE

D. Kuettel<sup>1,2</sup>, L. Terslev<sup>3</sup>, U. Weber<sup>1,2</sup>, M. Østergaard<sup>3</sup>, J. Primdahl<sup>1,2</sup>, R. Petersen<sup>1</sup>, M.A. Danielsen<sup>3</sup>, K. Hørslev-Petersen<sup>1,2</sup>. <sup>1</sup>King Christian X's Hospital for Rheumatic Diseases, Graasten; <sup>2</sup>Institute for Regional Health Research, University of Southern Denmark; <sup>3</sup>Copenhagen Center for Arthritis Research (COPE CARE), Copenhagen, Denmark

**Background:** In Rheumatoid Arthritis (RA), patient-reported tender joints (PrTJ) correlate better with clinical examination than patient-reported swollen joints (PrSJ).<sup>1</sup> Clinical examination has inferior sensitivity to detect synovitis compared to ultrasonography (US).<sup>2</sup> However, data is sparse about these findings at the time of patient-reported flare (PRFI).

**Objectives:** To investigate agreement between PrSJ, PrTJ, clinically detected swollen and tender joints (cSJ and cTJ), and inflammation by Colour Doppler (CD) US in RA patients at the time of PRFI.

**Methods:** 80 consecutive rheumatoid-factor and/or anti-cyclic citrullinated peptide antibody positive RA patients with DAS28-CRP<3.2 and no swollen joints at baseline were during a one-year follow-up period requested to contact the hospital in case of a hand flare according to patients' perspective. At the flare visit, patients indicated PrSJ and PrTJ, and underwent examination for cSJ and cTJ, and US of

bilateral wrists (wrist joints and six extensor tendon compartments), 1–5 metacarpophalangeal joints (MCP) and 1–5 proximal interphalangeal joints (PIP). CD synovitis and tenosynovitis were graded 0–3 according to EULAR/OMERACT scoring system<sup>3</sup> and joints and tendon sheaths with CD ≥ 1 were considered positive. Percentage agreement and Cohen's kappa were calculated between PrSJ, PrTJ, cSJ, cTJ and CD in joints and tendon sheaths.

**Results:** Thirty-six percent (29/80) of the RA patients reported a hand flare (69% female, mean age 65 years, median DAS28-CRP 1.8, at baseline). At flare, mean (±SD) number of PrSJ, cSJ, PrTJ, cTJ and CD positive joints were 2.7 (2.86), 1.5 (1.02), 4 (3.04), 4 (3.46) and 1.8 (1.31), respectively. For swelling, there was slightly superior agreement with CD for cSJ than for PrSJ, except for wrist tenosynovitis where patients agreed more frequently with CD than clinical examination did (table 1). Highest percentage agreement was seen for PIP, followed by MCP. Agreement, as assessed by kappa, was poor to fair, ranging from –0.009 to 0.33. Swelling in MCP and PIP joints, by patients and clinicians, and swelling in the wrist by clinician showed better agreement with CD than tenderness did.

**Abstract SAT0630 – Table 1.** Concordance between patient-reported and clinically examined swollen and tender joints versus CD at the time of patient-reported flare

Joint	No of joints examined	Comparison between	++	+/+	+/-	-/-	% agreement
Wrist	n=58	Clinical swelling vs CD synovitis	6	10	11	31	64
		Clinical swelling vs CD tenosynovitis	4	12	4	38	72
		Patient-reported swelling vs CD synovitis	5	13	12	28	57
		Patient-reported swelling vs CD tenosynovitis	6	12	2	38	76
		Clinical tenderness vs CD synovitis	5	11	12	30	60
		Clinical tenderness vs CD tenosynovitis	4	12	4	38	72
		Patient-reported tenderness vs CD synovitis	5	11	12	30	60
		Patient-reported tenderness vs CD tenosynovitis	5	11	3	39	76
MCP	n=290	Clinical swelling vs CD synovitis	0	18	27	245	85
		Patient-reported swelling vs CD synovitis	3	34	24	229	80
		Clinical tenderness vs CD synovitis	7	47	20	216	77
		Patient-reported tenderness vs CD synovitis	4	45	25	218	77
PIP	n=290	Clinical swelling vs CD synovitis	0	8	9	273	94
		Patient-reported swelling vs CD synovitis	0	19	9	262	90
		Clinical tenderness vs CD synovitis	3	30	6	251	88
		Patient-reported tenderness vs CD synovitis	1	38	8	243	84

CD: Colour Doppler; MCP: metacarpophalangeal joint; PIP: proximal interphalangeal joint.

**Conclusions:** Thirty-six percent of the RA patients reported flares in the hand during one year follow-up. Numbers of joints affected by swelling, tenderness or positive CD sign were low. Limited concordance between US, patient-reports and clinical examination suggests that these domains reflect different and potentially complementary aspects of inflammation in patient-reported flare.

SAT0631

**LACK OF ASSOCIATION BETWEEN CLINICAL AND ULTRASOUND MEASURES OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS/CLINICAL REMISSION: A CROSS-SECTIONAL ANALYSIS**

K.F. Baker, B. Thompson, D. Lendrem, A.G. Pratt, J.D. Isaacs. *Musculoskeletal Research Group, Newcastle NIHR Biomedical Research Centre, Newcastle University and Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, UK*

**Background:** Ultrasound (US) measures of synovitis and tenosynovitis have been shown to persist in patients with rheumatoid arthritis (RA) who achieve clinical remission.

**Objectives:** To assess the prevalence of such US findings in RA clinical remission, and analyse whether the US abnormalities found in this group of patients could be predicted by their clinical parameters.

**Methods:** Patients with established RA (1987 or 2010 diagnostic criteria) in clinical remission (DAS28-CRP<2.4) on conventional synthetic disease-modifying anti-rheumatic drugs (DMARDs) were recruited as part of the Biomarkers of Remission in Rheumatoid Arthritis (BioRRA) Study. Patients who had received systemic glucocorticoids in the past 3 months were excluded. All patients underwent baseline clinical assessment followed by a 7-joint US scan (Backhaus et al). US assessment was performed by the same operator (KB) blinded to disease activity score. Synovial Power Doppler (SPD) and greyscale (SGS) change were measured using a 4-point semi-quantitative scale (0–3); tendon GS (TGS) and erosions were classified as either present<sup>1</sup> or absent (0). Intra- and inter-rater scoring agreement was good (Cohen’s kappa 0.72 and 0.61 respectively). The association between individual dependent variables (SPD, SGS, TGS, and erosions) and clinical parameters was assessed by multivariate ordinal logistic regression, with Benjamini-Hochberg adjustment for multiple testing.

**Results:** 66 patients with RA in remission (median disease duration 6 years, median age 66 years) were included in the analysis. US abnormalities were common in both DAS28-CRP and ACR<sup>EULAR 2011</sup> Boolean remission (table 1). Seven associations were significant at the unadjusted p<0.05 level (figure 1). Only two associations remained statistically significant after multiple test correction, namely those of disease duration and TJC with higher and lower erosion scores respectively (table 2).

Abstract SAT0631 – Table 1.

Criterion	US parameter	Remission Definition		p (χ <sup>2</sup> )
		DAS28-CRP<2.4 (n=66)	ACR/EULAR Boolean (n=40)	
n (%) patients with total score ≥1	SPD	17 (26)	10 (25)	0.931
	SGS	66 (100)	40 (100)	n/a
	TGS	29 (44)	17 (43)	0.885
	Erosions	45 (68)	25 (63)	0.549
n (%) patients with any joint score ≥2	SPD	8 (12)	6 (15)	0.671
	SGS	48 (73)	27 (68)	0.566

Abstract SAT0631 – Table 2.

US score	Clinical parameter	Odds ratio (OR) increase in US score	95% CI	Unadjusted multivariate p value	Adjusted multivariate p value
SGS	Male sex	5.04	1.47–17.26	0.010	0.139
	ESR (mm/hr)	1.05	1.00–1.09	0.038	0.245
TGS	SJC28	5.37	1.46–19.72	0.011	0.159
	Alcohol intake (units/week)	0.88	0.77–1.00	0.044	0.307
Erosion	Disease duration (years)	1.16	1.06–1.27	0.002	<b>0.024</b>
	TJC28	0.17	0.05–0.56	0.004	<b>0.025</b>
	ESR (mm/hr)	0.92	0.85–0.99	0.022	0.101

Multivariate p < 0.005: \* Unadjusted, \*\* Adjusted

**Conclusions:** We demonstrate considerable subclinical US findings in RA patients in clinical remission, even when remission is defined using the more stringent ACR/EULAR Boolean criteria. Patients with longer disease duration and fewer tender joints had more joint erosions, though no other significant associations were seen after multiple test correction. Most strikingly SPD, which portends a poor prognosis, failed to show significant association with any of the clinical parameters. Our results suggest that clinical and ultrasound examinations may serve complementary, rather than duplicative, roles in the assessment of RA remission.

**ULTRASOUND IN THE MANAGEMENT OF RHEUMATOID ARTHRITIS USING A NOVEL PRAGMATIC ALGORITHM: A MULTICENTRIC OBSERVATIONAL STUDY**

K.R. Bonfiglioli<sup>1</sup>, R. Chakr<sup>2</sup>, R. Lima<sup>3</sup>, E. Paiva<sup>4</sup>, I. Moss<sup>5</sup>, R. Giorgi<sup>6</sup>, M. Rassi<sup>3</sup>, R. Cardoso<sup>3</sup>, F. Nadaf<sup>3</sup>, R. Santos<sup>3</sup>, D. Ribeiro<sup>3</sup>, L. Arruda<sup>3</sup>, E. Melo<sup>5</sup>, D. Furtado<sup>5</sup>, A. Funke<sup>4</sup>, N. Andrade<sup>2</sup>, M. Fantinel<sup>2</sup>, L. Rossi<sup>2</sup>, M. Resmini<sup>2</sup>, N. Sacilotto<sup>6</sup>, J. A. Mendonça<sup>7</sup>, I. Laurindo<sup>8</sup>. <sup>1</sup>Reumatology, Hospital das Clínicas da Universidade de São Paulo, São Paulo; <sup>2</sup>Hospital de Clínicas de Porto Alegre, Porto Alegre; <sup>3</sup>Hospital de Base do Distrito Federal, Brasília; <sup>4</sup>Hospital de Clínicas de Curitiba, Curitiba; <sup>5</sup>Hospital Universitário Clementino Fraga Filho, Rio de Janeiro; <sup>6</sup>Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo; <sup>7</sup>PUC- Campinas, Campinas; <sup>8</sup>Universidade Nove de Julho, São Paulo, Brazil

**Background:** Recently, novel algorithms for the pragmatic use of US in the management of RA patients were published in order to guide US use in various clinical scenarios.

**Objectives:** To evaluate the performance of the 2016 algorithm<sup>1</sup> proposed for evaluation of therapeutic response and its potential to contribute in decision-making.

**Methods:** Multicentric (5 centres), cross-sectional and observational study. Inclusion criteria: Patients older than 18 years old, RA diagnosis (ACR/EULAR criteria), receiving stable doses of conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) for the last six months. Exclusion criteria: use of biological DMARDs, severe articular deformities. Patients were submitted to clinical examination, CDAI (Clinical Disease Activity Index) was recorded and US examination performed by trained rheumatologists blinded to CDAI results. The following joints were examined: wrists, metacarpophalangeal (2 and 3), proximal interphalangeal (2 and 3) and metatarsophalangeal (2 and 5), in addition to any symptomatic joint. Synovitis was determined according to OMERACT. Joint distension (grey scale, GS) and Power Doppler (PD) graded on semiquantitative scale: absent=0, mild=1, moderate=2, intense=3. Total individual GS and PD scores were calculated by the sum of each joint scores. Therefore, each participant had two separate scores (GS and PD).

**Results:** 139 patients were included: 93% women, RF positive in 66%, age=57 ±11 [mean ±SD]yr, disease duration=10±8 year. Almost half (47.5%, n=66) of the patients had moderate/high disease activity, CDAl=20.65±10.66[mean ±SD]; while 52.5%(n=73) were in low activity/remission, CDAl=4.43±3.24.**US:** of the 66 patients with moderate/high disease activity, 26 patients (39.3%) presented negative PD and lowGS score: 5.11±2.67[mean ±SD]vs.40 patients with positive PD(PD=4.93±4.9)and a higher GS score (11.6±6.29, p<0.0001). CDAl in positive and negative PD subgroups was similar: mean (SD) values 21.81±11.32 vs. 18.86±9.02, p=0.13.Regarding CDAl low activity/remission group, 74% had negative PD, GS=4.5±3.6 and 5 (6.85%) were in US remission. Of these 5 patients, only one was in CDAl remission. From 26 patients in clinical remission, 4 (15.4%) patients had positive PD and GS score greater than 5, one was in US remission and the remaining (80.8%)presented negative PD but mild GS score.

**Conclusions:** Our study confirms that patients in CDAl remission may present active synovitis upon US exam. Likewise, patients with US remission may present falsely elevated clinical metrics possible due to the influence of other non-inflammatory comorbidities. Similarly in patients with moderate/high disease activity, US can alert to the possibility of other factors adding to high clinical scores. The US contributed to differentiate both clinical scenarios, with potential to optimise the therapeutic approach.

#### SAT0633 ULTRASOUND PREDICTIVE VALUE IN PREARTHRTIS. A PROSPECTIVE LONGITUDINAL STUDY

D. Peiteado, I. Monjo, L. Nuño, A. Villalba, M.E. Miranda, P. Fortea, E. De Miguel, A. Balsa. RHEUMATOLOGY, HOSPITAL UNIVERSITARIO LA PAZ, Madrid, Spain

**Background:** Inflammatory arthritis have a period of subclinical disease before the development of synovitis. It is necessary to know adequately the characteristics of this period to identify serological/imaging markers that recognise patients at risk of developing inflammatory arthritis.

**Objectives:** To describe the clinical characteristics and ultrasound (US) findings in "pre-arthritis" phases. To investigate the association of the US parameters with clinical or laboratory parameters.

**Methods:** Prospective longitudinal study of a cohort of patients with suspicious joint pain (predominance in nights or mornings, improving at day or with movement, or with morning stiffness >30') of less than 1 year of evolution and involvement of at least one small joint of hands or feet. Patients with clear synovitis, previously treated with DMARDs/steroids, or those with a diagnosis of fibromyalgia or osteoarthritis were excluded. The number of painful and swollen joints (PJC, SJC) and laboratory parameters were evaluated. A blind and extensive ultrasound examination (US) was performed with a MyLabTwice (Esaote) equip with a 5–13 MHz probe for grayscale (GS) and Power Doppler (PD). We assess the presence of synovitis in GS, PD (0–3) and erosions in 36 joints (radio- Carpal, Inter-carpal, 1 st –5th MCP and IPP, 2nd –5th MTP, elbow, shoulder and knee bilaterally) and 14 tendon compartments (2nd, 4th, 6th wrist extensor tendon compartments, 3rd and 4th finger flexor tendons, posterior tibial and fibularis tendons). In addition, an overall score of EG and PD in the cohort is calculated. Statistics analysis was made by mean ±SD or median (IQR), and comparison was made by t- Student test (quantitative parameters) and non parametric test (qualitative) (p<0.05).

**Results:** 20 patients were included, 95% women (60% non-smokers). Symptoms duration was 8±3 months. PJC median was 6 (RIC 2–9), without swollen joints in any case. ACPA and/or RF were positive in 6 patients (30%). ESR and/or RCP were elevated in 6 patients (30%). In the following 12 months, 45% of patients improved clinically, and 6 patients (30%) developed rheumatoid arthritis (RA). US results are exposed in the table 1, showing the number and percentage of patients with presence [≥1] of synovitis in GS, PD and erosions at different locations. The mean overall PD score was significantly higher in patients who will evolve to RA (9.1±2.8 vs 2.7±1.9, p<0.01) and in those with US erosions (10±1.4 vs 4.3±3.5, p<0.05). In addition, the mean overall GE score was higher in the RA group (9.1 ±2.8 vs 2.7±1.9, p<0.01) No significant differences were found between patients with or without acute phase reactants or positive RF/ACPA.

	GE=1 (n;% patients)	PD=1 (n;% patients)	Us erosion (n;% patients)
Wrist	17 (85%)	17 (85%)	0
MCP	15 (75%)	9 (45%)	0
IFP	13 (65%)	8 (40%)	0
Elbow	0	1 (5.5%)	0
Shoulder	0	0	0
MTP	13 (65%)	4 (20%)	2 (16.6%)
Knee	7 (37%)	4 (20%)	0
Wrist extensor tendons (n=18)	7 (39%)	3 (17%)	-
Finger flexor tendons (n=18)	3 (17%)	3 (17%)	-
Posterior tibial tendon	5 (28%)	2 (11%)	-
Fibularis tendons	0	1 (5.5%)	-
Global score*	9.2±4.9	5.3±3.8	0.1±0.3
*mean±DS			
Patients affected%	20 (100%)	19 (95%)	2 (10%)

**Conclusions:** In patients with pre-arthritis, Doppler scores were significantly higher among those with US erosions and those who evolve to RA. This results demonstrate the usefulness of US to predict the development of clinical arthritis in patients with inflammatory pain without synovitis

#### SAT0634 DOES THE PRESENCE OF MRI-DETECTED OSTEITIS AT DIAGNOSIS WITH RHEUMATOID ARTHRITIS LOWERS THE RISK FOR ACHIEVING DMARD-FREE SUSTAINED REMISSION? – RESULTS OF A LONGITUDINAL STUDY

L.E. Burgers<sup>1</sup>, D.M. Boeters<sup>1</sup>, M. Reijnen<sup>2</sup>, A.H.M. van der Helm-van Mil<sup>1</sup>.

<sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Leiden University Medical Centre, Leiden, Netherlands

**Background:** Although infrequent, some rheumatoid arthritis (RA)-patients achieve disease-modifying antirheumatic drug (DMARD)-free sustained remission. Absence of RA-specific auto-antibodies, such as anticitrullinated protein antibodies (ACPA) are known to be associated with this outcome, but furthermore mechanisms underlying the chronic nature of RA are largely unknown.

**Objectives:** Magnetic resonance imaging (MRI)-detected bone marrow oedema (BME, osteitis) strongly predicts erosive progression and is associated with ACPA-positivity. Therefore, we hypothesised that presence of MRI-detected osteitis is also predictive of not achieving DMARD-free sustained remission and that the presence of osteitis mediates the association between ACPA and DMARD-free sustained remission.

**Methods:** A 1.5T unilateral hand and foot MRI was performed at disease presentation in 238 RA-patients, evaluating BME, synovitis and tenosynovitis (summed in MRI-inflammation score). The median follow-up duration was 3.8 years. DMARD-free sustained remission, defined as the absence of clinical synovitis after DMARD-cessation that persisted during the total follow-up, was assessed. Associations between the different MRI-detected inflammatory features and this outcome were studied. A mediation analysis was performed to study whether the presence of BME mediated the association between ACPA and DMARD-free sustained remission. Finally, patterns of MRI-detected inflammation (including type, severity and location) with regard to DMARD-free sustained remission were studied using partial least squares (PLS) regression.

**Results:** Forty-six (19.3%) patients achieved DMARD-free sustained remission. ACPA-positivity associated independently with remission (HR 0.16, 95% CI 0.06–0.39). In contrast, no associations were observed between MRI-detected BME (HR 0.99, 95% CI 0.94–1.03), or other MRI-inflammatory features, and achieving DMARD-free sustained remission. Thus, the presence of BME did not mediate the association between ACPA and DMARD-free sustained remission. Furthermore, PLS regression revealed that patients who did or did not achieve remission could not be distinguished by patterns of MRI-detected inflammation.

**Conclusions:** At disease presentation, osteitis, as well as other MRI-detected inflammatory features, were not associated with achieving DMARD-free sustained remission over time. The data indicate that imaging predictors for joint damage and disease persistence differ. The processes mediating RA chronicity remain largely unsolved.

SAT0635

### MAGNETIC RESONANCE IMAGING OF THE CERVICAL SPINE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS PRESENTING WITH CHRONIC NECK PAIN – A SYSTEMATIC COMPARISON OF CLINICAL ASSESSMENTS

X. Baraliakos, M. Soltani, U. Kiltz, J. Braun. *Rheumazentrum Ruhrgebiet, Herne, Germany*

**Background:** Despite the differences in pathogenesis, neck pain associated with functional limitation and impaired mobility of the cervical spine is a frequent clinical symptom of patients with rheumatoid arthritis (RA) and ankylosing spondylitis (AS).

**Objectives:** To directly compare inflammatory and structural findings obtained by magnetic resonance imaging (MRI) in patients with RA and AS who present with chronic neck pain, and to correlate MRI findings with clinical measurements.

**Methods:** A total of 120 patients (60 RA and 60 AS) were consecutively included in the study if they had chronic neck pain (duration >3 months). All patients had clinical examinations for neck function and mobility and were asked to fill in disease specific questionnaires. They also had laboratory examinations (CRP, ESR) and MRI of the cervical spine (CS) using contrast-enhanced MRI sequences (T1 pre- and post-Gadolinium, sagittal and axial images). A total of 107 patients (59 RA with 295 and 48 AS with 240 vertebral segments) could be finally evaluated. An experienced rheumatologist examined all patients blinded to diagnosis and MR images. In addition, two experienced readers blinded to patients' diagnosis and clinical assessments evaluated the MRIs by describing the anatomical structures of the CS (vertebral body, intervertebral disc, facet joints) and the pattern of inflammatory activity in the bone marrow (vertebral edges vs. vertebral endplates).

**Results:** The RA group included more females (66.1%) and older patients (58.6 ±11.4 years) in comparison to AS (68.8% males, mean age 47.9±13.1 years), while there were no differences in the duration of neck pain. AS patients reported higher mean levels of neck pain on a 0–10 numerical rating scale (5.0±3.6) as compared to RA patients (3.0±3.1) (p=0.003), while the Northwick pain questionnaire didn't reveal any differences. There were numerically more patients with AS (n=11, 22.9%) than RA (n=9, 15.3%) (p=0.166) with bone marrow oedema (BME) at the vertebral edges. The majority of lesions was located in the lower CS. In contrast, more patients with RA (n=18, 30.5%) than AS (n=3, 6.3%) had erosive osteochondrosis with endplate BME (p=0.002). Atlantoaxial synovitis was found in only 1 patient with RA (1.7%), while inflammatory changes around the dens axis were found in 2 (3.4%) and atlantodental synovitis in 5 (8.5%) RA patients but not in AS patients. In comparison, erosive changes in the dens axis region were found in 3 RA (5.1%) vs. 2 AS (4.1%) patients. No major differences related to the presence of facet joint osteoarthritis was found (78% in RA vs. 65% in AS). The prevalence of facet joint osteoarthritis was the only imaging finding correlating with clinical symptoms: r=0.259 (p=0.049) for RA and r=0.416 (p=0.003) for AS, respectively. Similarly, only facet joint osteoarthritis correlated with restriction of cervical rotation in patients with AS (r=0.471, p=0.001).

**Conclusions:** Both BME and chronic changes of the lower part of the CS but not of the atlantoaxial region are seen in patients with RA and AS who present with chronic neck pain. The pattern of BME involvement in patients with RA vs. AS was different. Facet joint osteoarthritis was the only imaging finding that correlated with the magnitude of neck pain, in AS it also correlated with impaired cervical rotation.

SAT0636

### REPEATABILITY OF MRI DIFFUSION WEIGHTED IMAGING OF SACROILIAC JOINTS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND HEALTHY SUBJECTS

J.M. Møller<sup>1</sup>, M. Østergaard<sup>2</sup>, H.S. Thomsen<sup>1</sup>, I.J. Sørensen<sup>2</sup>, O.R. Madsen<sup>2</sup>, S. J. Pedersen<sup>2</sup>. <sup>1</sup>Radiology, Herlev Hospital, Herlev; <sup>2</sup>COPECARE, Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen, Denmark

**Background:** Bone marrow oedema (BME) localised in sacroiliac joints (SIJ) as assessed by Short Tau Inversion Recovery (STIR) or T2 weighted fat saturated (T2w FS) sequences is one of the two cornerstones in the classification criterion for axial spondyloarthritis (SpA). Since Diffusion Weighted Imaging (DWI) can quantify water diffusion by measuring the Apparent Diffusion Coefficient (ADC), DWI may potentially be an alternative or supplementary imaging method to STIR or T2w FS.<sup>1</sup>

**Objectives:** The purpose was to measure the repeatability of (ADC) in a standardised Region-of-Interest (ROI) setting in healthy subjects and in active and chronic SpA patients and to compare the subjects.

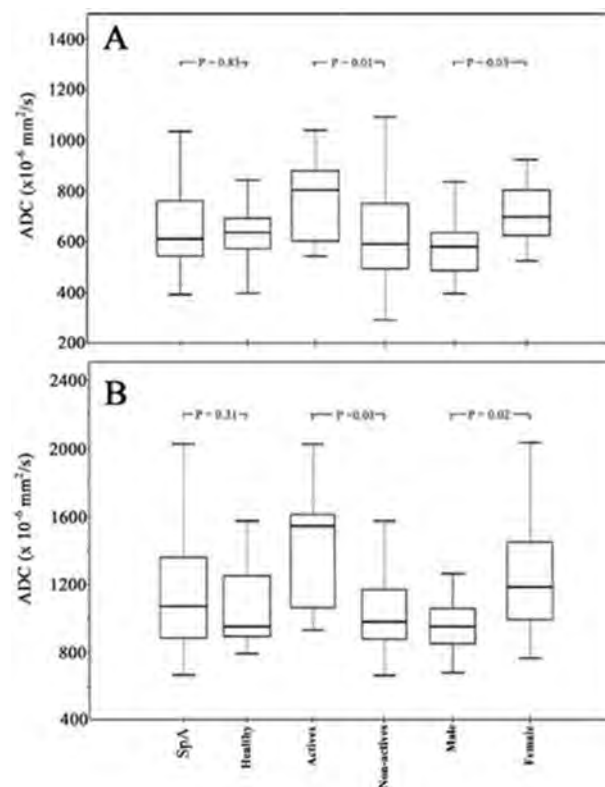

**Methods:** SpA patients and sex- and age- matched healthy subjects were examined twice within 7±2 days in the same MRI unit. Short Tau Inversion Recovery (STIR), T1 weighted and DWI sequences were performed in the semi-coronal plane. ADC map was calculated on basis of 4 b values: 0; 50; 500; 800. On each

consecutive slice in the cartilaginous compartment the SIJ was divided into four quadrants. From the joint surface a 5 mm deep ROI was drawn. In all ROIs median and 95th percentile ADC values were measured. Intraclass Correlation Coefficients (ICC) were measured to assess repeatability, and unpaired T tests to compare subgroups. Actives were defined as BME on STIR and non-actives as no BME on STIR.

**Results:** 25 SpA patients and 24 healthy subjects were enrolled. For all subjects inter-reader ICC was 0.66 and intra-reader ICC 0.92 for the median ADC and 0.57 and 0.74 for the 95th percentile ADC. In SpA patients, healthy subjects, females, males, actives and non-actives Inter-reader ICC was 0.79, 0.27, 0.42, 0.72, 0.78 and 0.52 for the median ADC and 0.74; 0.73, 0.68, 0.60, 0.88, 0.64, and 0.64 for the 95th percentile. Intrareader ICC was excellent for median ADC and good to excellent for 95th percentile ADC (table 1). Significant differences in median (figure 1A) and 95th percentile (fig 1B) ADC were measured between females versus males (p=0.03; p=0.02) and actives versus non-actives (p=0.01; p=0.01) but not in patients versus healthy controls.

**Abstract SAT0636 – Table 1.** Intraclass correlation coefficient (ICC) for median ADC and 95th percentile ADC measurements in subgroups.

	Inter Reader ICC	Inter Reader ICC	Intra Reader ICC	Intra Reader ICC
	(95% CI) Median ADC	(95% CI) 95th percentile ADC	(95% CI) Median ADC	(95% CI) 95th percentile ADC
All subjects	0.66 (0.46;0.80)	0.57 (0.33;0.73)	0.92 (0.86;0.95)	0.74 (0.58;0.85)
SpA	0.79 (0.58;0.90)	0.69 (0.40;0.85)	0.92 (0.82;0.96)	0.73 (0.47;0.87)
Healthy	0.27 (-0.17;0.61)	0.13 (-0.30;0.51)	0.95 (0.88;0.98)	0.68 (0.39;0.85)
Female	0.42 (0.01;0.71)	0.45 (0.04;0.73)	0.87 (0.72;0.94)	0.60 (0.24;0.81)
Male	0.72 (0.45;0.87)	0.63 (0.31;0.82)	0.93 (0.86;0.97)	0.88 (0.75;0.94)
BME on STIR	0.78 (0.16;0.96)	0.75 (0.08;0.95)	0.92 (0.59;0.99)	0.64 (-0.12;0.93)
No BME on STIR	0.52 (0.24;0.71)	0.29 (-0.03;0.55)	0.93 (0.87;0.96)	0.69 (0.48;0.82)

**Conclusions:** ADC seems a reliable parameter in SpA patients but not in healthy subjects. Our data encourage further studies of ADC measurements for discrimination of SpA patients with or without active inflammation.

### RADIOGRAPHIC AND MRI DETECTED SACROILIITIS IS MORE OFTEN OBSERVED IN PATIENTS WITH LUMBOSACRAL TRANSITIONAL VERTEBRA IN THE DESIR COHORT

G. Carvajal Alegria<sup>1</sup>, M. Voirin-Hertz<sup>1</sup>, F. Garrigues<sup>2</sup>, A. Simon<sup>3</sup>, A. Feydy<sup>4</sup>, D. van der Heijde<sup>5</sup>, M. Rejniersse<sup>6</sup>, D. Loeuille<sup>7</sup>, P. Claudepiere<sup>8</sup>, T. Marhadour<sup>1</sup>, A. Saraux<sup>1</sup> on behalf of In behalf of the DESIR cohort. <sup>1</sup>Rheumatology, <sup>2</sup>Radiology, <sup>3</sup>Neurosurgery, CHRU Cavale Blanche, Brest; <sup>4</sup>Radiology B, APHP Cochin, Paris, France; <sup>5</sup>Rheumatology, <sup>6</sup>Radiology, Leiden UMC, Leiden, Netherlands; <sup>7</sup>Rheumatology, CHRU Nancy, Nancy; <sup>8</sup>Rheumatology, APHP Henri Mondor, Créteil, France

**Background:** Lumbosacral transitional vertebra (LSTV) is a congenital anomaly of the lumbosacral transition reported in 16% to 36% of the general population. One study reported low clinical relevance of LSTV in the early diagnosis of axial spondyloarthritis (axSpA), but data remains scarce.

**Objectives:** Our objectives were to evaluate the association of LSTV with sacroiliitis on conventional radiographs (CR) and magnetic resonance imaging (MRI) in a population with inflammatory back pain (IBP) suspected of axSpA.

**Methods:** Baseline pelvic and lumbar CR of DESIR cohort patients (18–50 years, IBP ≥ 3 months but < 3 years and suspicion of axSpA) were analysed by readers blinded to clinical and other radiologic information. Baseline sacroiliac joint MRI had been read for sacroiliitis according to the ASAS definition. Radiographic sacroiliitis was defined according to the modified New York classification (mNYC). Unilateral sacroiliitis was defined as at least grade 2 according to the mNYC. LSTV were defined on radiographs, according to Castellvi classification: 0 normal; 1 enlarged transverse processes (a=unilateral, b=bilateral); 2 pseudo-articulation with the sacral bone (a=unilateral, b=bilateral); 3 fusion with the sacral bone (a=unilateral, b=bilateral); 4 pseudo-articulation on one side and fusion on the other. Imaging data collected at inclusion were compared in patients with LSTV versus patients without using Chi-square test or exact Fischer's test when appropriate.

**Results:** 688 patients with available CR enabling LSTV analysis were studied, 47% were men, mean age was 33 years, 64% fulfilled ASAS criteria. Among the 688 patients 29.1% presented LSTV. Number and percentages of patients with different classes of LSTV are presented in Table I. Patients with LSTV had more often sacroiliitis on CR than patients without, respectively 27% and 19% (p=0.013). Patients with LSTV had more often sacroiliitis on MRI (figure 1) than patients without, respectively 39% and 29% (p=0.019). Presence of fusion on the right transverse process was associated with both right (p=0.001) and left (p=0.001) sacroiliitis on CR. Presence of fusion on the left transverse process was associated with sacroiliitis in CR on both right (p=0.006) and left (p=0.001) sides.

Table I: Prevalence of LSTV in the DESIR cohort (for stage 4, laterality is for the fusion)

Castellvi	Laterality	Number (%)
I a (Mega-apophysis)	Right	26 (3.8)
	Left	28 (4.1)
I b		76 (11.0)
II a (New articulation)	Right	13 (1.9)
	Left	7 (1.0)
II b		12 (1.7)
III a (Fusion)	Right	3 (0.4)
	Left	4 (0.6)
III b		21 (3.0)
IV (New articulation and fusion)	Right	3 (0.4)
	Left	7 (1.0)

**Abstract SAT0637 – Figure 1.** A case of LSTV (class 4 from Castellvi classification) associated to CR (A) and MRI. T1 weighted sequence is shown in B and STIR weighted sequence in C and D.

**Conclusions:** LSTV is observed in 29.1% of patients from the DESIR cohort, as reported in the literature and is associated with sacroiliitis on conventional radiography and MRI. Further study is mandatory to understand if this is based on mechanical stress or AxSpA and to assess the potential bias of LSTV in axSpA diagnosis.

### ULTRASONOGRAPHY THE PREVALENCE OF MONOSIDIUM URATE CRYSTAL DEPOSITION IN PATIENTS WITH CALCIUM PYROPHOSPHATE DEPOSITION DISEASE: ASSOCIATION WITH LABORATORY, RADIOGRAPHIC PARAMETERS AND MICROSCOPY OF SYNOVIAL FLUID

M. Eliseev<sup>1</sup>, R. Osipiants<sup>2</sup>, S. Vladimirov<sup>1</sup>, K. Ilinykh<sup>1</sup>, A. Smirnov<sup>1</sup>. <sup>1</sup>V.A. Nasonova Research Institute of Rheumatology, <sup>2</sup>RUDN University, Moscow, Russian Federation

**Background:** An association between gout and chondrocalcinosis is well known. Our objectives were to first, to determine by ultrasonography (US) the prevalence of monosodium urate (MSU) crystal deposition in patients (pts) with calcium pyrophosphate deposition disease (CPPD) and second, to investigate the relationship between serum urate (SU), synovial fluid (SF) examination, radiographic and US findings.

**Methods:** Eighty five pts (52% – men) with CPPD disease [McCarty criteria; median age 58.5 (range 50.5–65) years] were enrolled. SU levels were obtained during the follow-up period. US examination (Logiq 9, GE, 9 MHz probe) was performed by one sonographer, blind to clinical and laboratory data. Hyaline cartilages of the knees, II-V metacarpophalangeal and I metatarsophalangeal joints were evaluated for the “double contour” (DC) sign as evidence of MSU crystal deposition.<sup>1,2</sup> SF analyses under polarised microscopy were obtained at each time of US assessment. X-ray of knee joints was performed in all pts. We assessed joint space narrowing, osteophytes, presence of osteosclerosis and cyst in the tibiofemoral (TF) and patellofemoral (PF) compartments, radiographic evidence of knee osteoarthritis (OA, Kellgren and Lawrence (KL) criteria grade ≥ 2 in the medial and/or lateral TF compartment).

**Results:** 44% (38/85) pts had PFOA, 19% (16/85) had TFOA and combined PFOA and TFOA in 10.5% (9/85). Thirty-five of 85 (41%) pts had a SU level of > 6 mg/dl [7.9 (7.7–8.3) mg/dl]. Among them 60% (21/35) were performed US assessment of the joints. The prevalence of the DC sign was found in at least one articular site in 17 of 21 (81%) cases. SU levels were positively correlated with presence of the DC sign in joints (Spearman's r=0.532, p<0.05), PFOA (r=0.291, p<0.05). The MSU crystals from SF aspirates were received in 4 of 17 (23.5%) cases.

**Conclusions:** This study confirmed that the US DC sign in joints significantly correlate with a SU level and may be of use as a non-invasive tool in reflecting changes of uricemia in pts with crystal-associated synovitis. Hyperuricemia in pts with CPPD was associated with PFOA disease pattern.

SAT0639

### INTEROBSERVER AGREEMENT OF THE OMERACT ULTRASONOGRAPHIC CRITERIA FOR THE DIAGNOSIS OF CALCIUM PYROPHOSPHATE DEPOSITION DISEASE AT THE WRIST, AMONG PANEL OF RADIOLOGISTS AND RHEUMATOLOGISTS

P. Zufferey<sup>1</sup>, G. Filippou<sup>2</sup>, F. Becce<sup>3</sup>, M. Nissen<sup>4</sup>, L. Brulhart<sup>5</sup>, S. Revaz<sup>6</sup>, R. Valcov<sup>3</sup>, F. Gianinazzi<sup>3</sup>, C. Benaim<sup>3</sup>, P. Omoumi<sup>3</sup>. <sup>1</sup>DAL, CHUV, Lausanne, Switzerland; <sup>2</sup>Rheumatology Department, University of Ferrara, Ferrara, Italy; <sup>3</sup>CHUV, Lausanne; <sup>4</sup>HUG, Geneva; <sup>5</sup>Hôpital neuchâtelois, La Chaux de Fond; <sup>6</sup>SUVA, Sion, Switzerland

**Background:** The OMERACT ultrasound (US) task force subdivision “US in CPPD” has created definitions for US identification of crystal deposits in joints and

tested interobserver agreement for several joints<sup>1</sup>. The knee and the wrist were the most reliable sites for assessing CPPD.

**Objectives:** To assess whether the high level of inter-observer agreement of US for the detection of Calcium Pyrophosphate Deposition Disease (CPPD) in the triangular fibrocartilage complex (TFCC) of the wrist found by the experienced rheumatologists of the OMERACT group<sup>2</sup> could be reproduced in real life

**Methods:** The OMERACT US criteria for identification of CPPD were utilised for this exercise on pre-recorded static images using a dichotomous score among several radiologists (n=2) and rheumatologists (n=5) with varying level of experience in musculoskeletal ultrasonography (range: 2–10 years). Firstly, the same 15 US images of the wrist that had been evaluated by the OMERACT panel were sent for evaluation to the local participants in order to calculate the inter-observer agreement. Secondly, 22 additional wrist US images extracted from locally performed examinations, in patients with a high suspicion of CPPD arthritis were evaluated. These local US examinations were performed in real life conditions, by different operators, on different machines and without prior standardisation of the procedure. For comparison, interobserver of wrist radiographs was also evaluated for all local patients

**Results:** The mean overall agreement and kappa values on the OMERACT panel US images were 0.89 and 0.78 respectively. These values are similar to those obtained previously by the OMERACT panel during the web exercise with the same images (0.80 and 0.68 respectively). The interobserver agreement was lower with the local US images (0.70 and 0.49 respectively), probably due primarily to the absence of strict standardisation of US procedure and inferior image quality. For comparison, the performance on the local radiographs was similar (0.70 and 0.47 respectively).

**Conclusions:** Our results confirm that the new OMERACT US definitions for assessing wrist CPPD are reliable when applied to pre-recorded static images. Scanning technique and standardisation of the procedure appear to be an important aspect with regards to the assessment of CPP deposition at the wrist.

#### SAT0640 WHOLE BODY-MRI IN AXIAL SPONDYLOARTHRITIS (AXSPA): DIFFUSION WEIGHTED IMAGING (DWI) OUTPERFORMS THE STIR SEQUENCE

A. Nzeusseu Toukap<sup>1</sup>, N. Vander Maren<sup>2</sup>, L. Collette<sup>3</sup>, N. Michoux<sup>2</sup>, P. Triqueneaux<sup>2</sup>, M.S. Stoeniou<sup>1</sup>, F. Houssiau<sup>1</sup>, J. Malghem<sup>2</sup>, F.E. Lecouvet<sup>2</sup>.  
<sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Cliniques Universitaires St-luc; <sup>3</sup>Eortc, Eortc Headquarters, Brussels, Belgium

**Background:** None

**Objectives:** To compare the diagnostic value of DWI and STIR sequences as part of WB-MRI studies in AxSpA patients.

**Methods:** 20 consecutive patients (P) with confirmed diagnosis of active AxSpA and 20 controls (C) referred for metastatic cancer screening were investigated with identical WB-MRI protocols including DWI and STIR images. Two independent observers recorded the presence of "lesions" (high signal intensity foci on STIR and high b-value DWI images) in 17 anatomic areas; making a 17-point "area score" and a calculated 40-point "lesion score". Both were tested for correlation with clinical and biological parameters.

**Results:** In P, the "lesion score" was significantly higher with DWI than with STIR (p<0.025). The most experienced observer had higher DWI lesion scores, suggesting a learning effect. The lesion score and some anatomic areas could discriminate P from C. For this purpose, DWI had a higher AUC than STIR (AUC=99.9, CI: 99.5–1.00 vs AUC=95.8, CI: 90.9–1.00). For a trained MRI observer using DWI, a lesion score threshold of >4 had 100% sensitivity and 95% specificity. With STIR, a threshold of >3 had 85% sensitivity and 90% specificity. The area score AUC was significantly lower with STIR than with DWI (p=0.0233), but no satisfactory area score threshold was identified. The most frequently involved areas were the spine and hip entheses in C, the spine and SIJ in P. Manubrio- and chondro-sternal joint involvement was specific for AxSpA. The lesion score was positively correlated with ASDAS-CRP and (log) CRP.

**Conclusions:** DWI is a promising alternative to STIR in WB-MRI studies for the detection of active lesions in AxSpA. Training may be necessary. The involvement of specific anatomic areas could distinguish P from C.

#### SAT0641 PERFORMANCE AND AGREEMENT OF DIFFERENT OPERATORS AND HISTOLOGICAL TECHNIQUES FOR THE ASSESSMENT OF GERMINAL CENTRES IN MINOR SALIVARY GLANDS IN PRIMARY SJÖGREN'S SYNDROME

A. Alunno<sup>1</sup>, P. Cipriani<sup>2</sup>, G. Coletti<sup>3</sup>, B. Bigerna<sup>4</sup>, M. Manetti<sup>5</sup>, P. Di Benedetto<sup>2</sup>, O. Bistoni<sup>1</sup>, G. Cipolloni<sup>3</sup>, V. Liakouli<sup>2</sup>, P. Ruscitti<sup>2</sup>, R. Gerli<sup>1</sup>, R. Giacomelli<sup>2</sup>, F. Carubbi<sup>2,6</sup>.  
<sup>1</sup>Department of Medicine, Rheumatology Unit, University of Perugia, Perugia; <sup>2</sup>Department of Biotechnological and Applied Clinical Science, Rheumatology Unit, School of Medicine, University of L'Aquila; <sup>3</sup>Biomedical Department, Pathology Unit, ASL1 Avezzano-Sulmona-L'Aquila, L'Aquila; <sup>4</sup>Department of Medicine, Institute of Haematology, University of Perugia, Perugia; <sup>5</sup>Department of Experimental and Clinical Medicine, Section of Anatomy and Histology, University of Florence, Florence; <sup>6</sup>Department of Medicine, ASL1 Avezzano-Sulmona-L'Aquila, L'Aquila, Italy

**Background:** A standardisation of minor salivary gland (MSG) histopathology in primary Sjögren's syndrome (pSS) has been recently proposed by the EULAR study group on Sjögren's syndrome. Although there is strong agreement that germinal centres (GCs) should be routinely identified, due to their prognostic value, a consensus regarding the best protocol is still lacking.

**Objectives:** Aim of this study was to compare the performance of different histological techniques and operators with variable experience in MSG histopathology to identify GCs in pSS MSGs.

**Methods:** MSG biopsies from 50 pSS patients were studied. Three blinded operators (expert rheumatologist, expert pathologist and rheumatologist with scarce experience on MSG histopathology) scored one slide stained with haematoxylin and eosin (H and E). Consecutive slides were processed by immunofluorescence and immunohistochemistry to assess CD3/CD20, CD21 and Bcl-6 expression.

**Results:** Overall, the prevalence of GC in MSG specimens (namely the presence of at least one focus positive for at least one operator or histological technique) ranged between 26% and 52%. By separate assessment of 225 foci, the best agreement was between H and E-stained sections evaluated by the expert rheumatologist and CD3/CD20 segregation (Cohen's kappa=0.72). In the foci with CD21 positivity, the agreement with the expert rheumatologist further increased (Cohen's kappa=0.75). Among the 3 methods employed, the best agreement was observed between B/T-cell segregation and the positivity for CD21 staining (0.84). The absence of Bcl-6 in a focus does not necessarily rule out the presence of the GC detected with other stainings.

**Conclusions:** GC assessment on H and E-stained sections should be performed with caution, as it is dependent on the background and expertise of the operator. The combination of H and E with CD3/CD20 and CD21 staining should be recommended as it is reliable, feasible, able to overcome the bias of operator experience and easily transferrable into routine practice.

#### SAT0642 A CAD SYSTEM IN HEP-2 IIF READING: A MULTICENTRE STUDY

A. Rigon<sup>1</sup>, M. Infantino<sup>2</sup>, M. Merone<sup>3</sup>, G. Iannello<sup>3</sup>, C. Sansone<sup>4</sup>, A. Tincani<sup>5</sup>, I. Cavazzana<sup>5</sup>, M. Manfredi<sup>2</sup>, A. Radice<sup>6</sup>, P. Soda<sup>3</sup>, A. Afeltra<sup>1</sup>.  
<sup>1</sup>Immunorheumatology, University Campus Biomedico-Rome, Rome; <sup>2</sup>Immunology and Allergy laboratory, S. Giovanni di Dio Hospital, Florence; <sup>3</sup>Unit of Computer Systems and Bioinformatics, University Campus Biomedico-Rome, Rome; <sup>4</sup>Dipartimento di Ingegneria Elettrica e delle Tecnologie dell'Informazione, Università degli Studi di Napoli Federico II, Napoli; <sup>5</sup>Rheumatology Unit, AST Spedali Civili, Brescia; <sup>6</sup>Microbiology and Virology Department, San Carlo Borromeo Hospital, Milan, Italy

**Background:** The indirect immunofluorescence (IIF) on HEP-2 cells is the recommended technique for anti-nuclear antibodies (ANA) detection. Automation of IIF image reading can provide a reliable basis for cost-effective serological diagnostics. Computer-aided diagnosis (CAD) tools based on digital imaging reading can help us to overcome the reader subjectivity. In a recent work<sup>1</sup> we assessed the inter-observer variability using digital images showing the 74.1% of agreement. It improved using "ground truth" as gold standard.

**Objectives:** To compare classification accuracy between readings provided by expert readers belonging to three different laboratories and those automatically returned by CAD.

**Methods:** We acquired 1771 images from 583 consecutive sample with an acquisition unit using HEp-2 cells (MBL) at 1:80 screening dilution. Each image was blindly classified as positive, negative, or weak positive by two experienced physicians, with more than ten years of experience in IIF, for each of the three laboratories. We obtained gold standard on the basis of annotations provided by expert physicians. We described a CAD system for HEp-2 classification that relies upon features provided by a deep neural network architecture, namely an Invariant Scattering Convolutional Network (Scatnet). We therefore compared human readings with automatic classification provided by a CAD.

**Results:** The dataset contains 215 positive samples, 136 weak positive, 219 negative. The CAD-system classification and experts showed a sensitivity of 93% vs 92.9%, 79.4% vs 74.5%, and 92.2% vs. 92.8% on positive, negative and weak positive, respectively (Fig 1). The CAD-system obtained an accuracy of 89.5%, slightly better than average experts' classification (88.5%) and, interestingly, it better recognised the weak positive samples.

Fig1

Sensitivity	CAD	Experts
Positive	0.930	0.929
Weak positive	0.794	0.745
Negative	0.922	0.928
<b>Positive Predictive Value</b>		
Positive	0.939	0.933
Weak positive	0.777	0.779
Negative	0.927	0.913

**Conclusions:** Solid gold standard is essential for use CAD systems in routine work lab. The CAD-system classification and the 3 experts have provided comparable results. Laboratories' agreement improves using digital images and comparing each single human evaluation to a potential reference data and for this reason nowadays the CAD system should be considered a reliable tool of standardisation reducing the inter-laboratory variability.

#### ULTRASOUND ABNORMALITIES IN WRIST, MCP2 AND MTP5 ARE MOST DISCRIMINATIVE IN PREDICTING ARTHRITIS DEVELOPMENT IN SEROPOSITIVE ARTHRALGIA PATIENTS

A. Blanken<sup>1</sup>, M. van Beers-Tas<sup>1</sup>, M. Nielen<sup>2</sup>, M. Meursing Reynders<sup>1</sup>, F. Turkstra<sup>1</sup>, C. van der Laken<sup>1</sup>, D. van Schaardenburg<sup>1</sup>. <sup>1</sup>Amsterdam Rheumatology and immunology Center, Reade, VUmc and AMC, Amsterdam; <sup>2</sup>Netherlands Institute for Health Services Research, NIVEL, Utrecht, Netherlands

**Background:** Seropositive arthralgia patients are at risk of developing rheumatoid arthritis (RA). Ultrasound (US) might be used to further predict which seropositive individuals will progress to RA. However, the value of US in the prediction of RA is still a point of debate, mainly due to the use of different scoring systems and compositions of joints in US protocols in literature.

**Objectives:** To investigate which joints are most discriminative in predicting arthritis development in seropositive arthralgia patients.

**Methods:** We included 174 seropositive patients with arthralgia, but without clinical arthritis. US was performed at baseline in 16 joints: bilateral metacarpal phalangeal (MCP) 2 and 3, proximal interphalangeal (PIP) 2 and 3, wrist and metatarsal phalangeal (MTP) joints 2, 3 and 5. Images were scored for grey-scale (GS) synovitis and Power Doppler (PD) on a scale of 0–3. Grades  $\geq 2$  for GS synovitis and grades  $\geq 1$  for PD were regarded as abnormal. Clinical arthritis development was assessed in any of 44 joints during yearly follow-up or during an

unscheduled visit in case of progression of symptoms. Patients were followed until clinical arthritis development or for a maximum of 5 years.

**Results:** In a total of 2784 joints that were imaged, 112 showed GS synovitis and 14 PD. The majority of GS synovitis was present in MTP2 and MTP3 joints (56 (50%) and 32 (29%), respectively), followed by wrists (15 (13%)), MCP3 (4 (4%)), MTP5 (3 (3%)), MCP2 (2 (2%)) and none in PIPs. Out of 14 joints with PD, 7 were wrists, 3 MTP5, 2 MCP2 and 2 PIP3. Fifty-one (29%) of the patients developed clinical arthritis in at least one joint after a median follow-up of 12 (interquartile range 6–23) months. For GS synovitis, the wrist, MCP2 and MTP5 were most discriminative in predicting clinical arthritis development (12/15 (80%) of patients with GS synovitis in wrist developed clinical arthritis, 3/3 (100%) in MTP5 and 2/2 (100%) in MCP2). MTP2 and 3 were least discriminative (<27%). No substantial differences were found between left and right joints. No clear association with clinical arthritis development was found in the limited number of joints that had positive PD.

**Conclusions:** Wrist, MCP2 and MTP5 joints (although numbers were small) showed the highest predictive value for development of clinical arthritis in any of 44 joints. Although most GS synovitis was observed in MTP2 and 3, predictive value of MTP2 and 3 joints for development of clinical arthritis was low. These results indicate that the choice of joints in the US protocol may influence the predictive value of ultrasound in predicting clinical arthritis development in seropositive arthralgia patients.

#### T1RHO MAPPING IN THE ASSESSMENT OF ARTICULAR CARTILAGE INTEGRITY OF THE KNEE IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

A.M. Barendregt<sup>1</sup>, V. Mazzoli<sup>2</sup>, C. van Gulik<sup>2</sup>, M. van den Berg<sup>3</sup>, A. Nassar Sheikh Rashid<sup>4</sup>, K.M. Dolman<sup>5</sup>, D. Schonenberg-Meinema<sup>4</sup>, T.W. Kuijpers<sup>5</sup>, M. Maas<sup>6</sup>, A. J. Nederveen<sup>6</sup>, R. Hemke<sup>6</sup>. <sup>1</sup>Department of Radiology and Nuclear Medicine; <sup>2</sup>Radiology and Nuclear Medicine, University of Amsterdam; <sup>3</sup>Department of Pediatric Hematology, Immunology, Rheumatology and Infectious Disease, Emma Children's Hospital; <sup>4</sup>Department of Pediatric Hematology, Immunology, Rheumatology and Infectious Disease, Emma Children's Hospital; <sup>5</sup>Pediatrics, OLVG; <sup>6</sup>Department of Radiology and Nuclear Medicine, Academic Medical Center, Amsterdam, Netherlands

**Background:** Early detection of microstructural damage to cartilage of patients with juvenile idiopathic arthritis (JIA) might prevent irreversible cartilage damage by timely treatment and follow-up of cartilage microstructure. New, quantitative MRI sequences such as T1 $\rho$  are possibly able to detect pre-erosive cartilage damage by quantifying proteoglycan (PG) loss of cartilage<sup>1-4</sup>.

**Objectives:** To study feasibility of T1 $\rho$  mapping for assessment of articular cartilage integrity in children with JIA and study correlation between T1 $\rho$  relaxation time and the Juvenile Arthritis MRI score (JAMRIS)<sup>5</sup> for disease activity.

**Methods:** After IRB approval and informed consent, the knee of patients with JIA or suspected JIA was imaged at 3T MRI using T2, pre and post contrast T1 and a sagittal T1 $\rho$  sequence with 400 Hz and spin lock time of 5, 10, 20, 40 and 50 ms. A region of interest (ROI) was drawn in articular cartilage of the knee on the T1 $\rho$  images, resulting in a mean T1 $\rho$  value of articular cartilage per patient. Using regular T2W and T1W pre and post contrast scans, JAMRIS was assigned to discriminate inflamed knees (JAMRIS  $\geq 1$ ) from non-inflamed knees (JAMRIS 0). In SPSS, Mann-Whitney U test and Spearman correlation coefficient were used to compare the mean T1 $\rho$  value between patients with and without arthritis on MRI and to correlate T1 $\rho$  values with JAMRIS score. ROI drawing was performed twice in 5 subjects. Intraclass correlation coefficient (ICC) was used to study intra-reader reliability.

**Results:** Of all 13 patients (median age 13.7 years), 7 patients had inflammation in the knee. No cartilage lesions were observed on standard MRI sequences. Acquisition of the T1 $\rho$  was successful and without artefacts in 100% of the children. Patients with inflammation in the knee showed a significantly longer T1 $\rho$  value than patients without inflammation in the knee: 36.3 ms (IQR 29.0–40.4) versus 27.7 ms (IQR 25.8–30.2),  $p=0.02$ . Correlation between T1 $\rho$  value and JAMRIS score was 0.76 ( $p=0.003$ ). Repeatability of ROI drawing was characterised by ICCs  $>0.99$ ,  $p<0.05$ .

**Conclusions:** This pilot study indicates that, even in the absence of cartilage erosions, significant differences are seen in cartilage integrity with higher  $T1\rho$  relaxation times in patients with knee arthritis. This might indicate loss of glycosaminoglycan content in active synovitis of the knee. Thus, our pilot data suggest that  $T1\rho$  could serve as an imaging biomarker for cartilage integrity, ultimately aiming to prevent irreversible cartilage damage and long-term disability in this young JIA population.

#### DIAGNOSTIC ACCURACY OF SERUM AUTOANTIBODIES MULTI-TESTING IN RHEUMATOID ARTHRITIS AND ECONOMIC CONSEQUENCES ACROSS EUROPE

B. Mascialino<sup>1</sup>, S. Swinarski<sup>2</sup>, I. Gehring<sup>2</sup>, M. Poorafshar<sup>1</sup>. <sup>1</sup>*ImmunoDiagnostics, Thermo Fisher Scientific, Uppsala, Sweden*; <sup>2</sup>*ImmunoDiagnostics, Thermo Fisher Scientific, Freiburg, Germany*

**Background:** Rheumatoid arthritis (RA) diagnosis requires interpretation of a combination of clinical, laboratory and imaging investigations. In RA, the consequences of incorrect serology test results are particularly important: patients with False Positive results (FPs) are initially managed as RA patients, bringing about extra costs until a correct diagnosis is made.

**Objectives:** The first aim of the study was to evaluate the diagnostic performance of RF-IgA, RF-IgM, and CCP, used alone or in multi-testing parallel or sequential combinations. The secondary goal focused on the economic consequences of serology FPs in selected European countries.

**Methods:** 190 established RA patients and 197 controls (either affected by other conditions or healthy donors) were used to assess the diagnostic performance of mono- and multi-serology testing in PC; both testing in Primary Care (PC) and in Secondary Care (SC) settings were considered.

For the secondary objective, a 12 month Markov model simulated, from the National Health Services perspective, 1.000 RA-suspected individuals tested in PC and SC with mono- or multi-testing. Costs come from the published literature. The European countries included in the analysis were the United Kingdom, Austria, Belgium, Denmark, France, Germany, Italy, the Netherlands, Portugal, Spain and Sweden. Uncertainty was addressed with sensitivity analysis.

**Results:** The mono-testing diagnostic performance was:

- RF-IgA: sensitivity [95% CI]=40.5% [33.5%, 47.9%], specificity=92.4% [87.8%, 95.7%];
- RF-IgM: sensitivity=59.0% [51.6%, 66.0%], specificity=89.3% [84.2%, 93.3%];
- CCP: sensitivity=59.5% [52.1%, 66.5%], specificity=96.5% [92.8%, 98.6%].

In multi-testing, defining a “positive result” as “positivity to at least one test” increased sensitivity; “positivity to all the tests” increased specificity. In a PC scenario:

- parallel testing:
  - o using CCP and RF-IgM increased specificity to 99.5% [97.2%, 100.0%];
  - o the three tests used simultaneously maximised specificity (100.0% [98.1%, 100.0%]), but reduced sensitivity to 35.8% [29.0%, 43.1%];
- sequential testing: testing positive to both RF-IgA and RF-IgM followed by CCP testing led to 90.7% [81.7%, 96.2%] sensitivity and to 100.0% [54.1%, 100.0%] specificity.

With respect to mono-testing, multi-testing options reduced the number of FPs. Therefore, in each of the countries considered, multi-testing allowed for important cost savings due to reduced clinical procedures and resource utilisation of FPs.

**Conclusions:** Multi-serology testing improve the diagnostic accuracy of the individual RF-IgA, RF-IgM and CCP tests. Optimal multi-testing combinations minimise the number of FPs, thus reducing avoidable costs to the National Health Services. Consequently, multi-testing for RA demonstrates superior value from patient and payer perspective.

#### DEVELOPMENT AND VALIDATION OF A DEEP LEARNING ALGORITHM FOR CLASSIFYING ANTINUCLEAR ANTIBODY PATTERNS IN INDIRECT IMMUNOFLUORESCENCE IMAGES

C.-H. Lin<sup>1</sup>, C.-F. Kuo<sup>1,2</sup>, Y.-F. Fang<sup>3</sup>, P.-H. Tsai<sup>3</sup>, Y.-F. Chen<sup>3</sup>. <sup>1</sup>*Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*; <sup>2</sup>*Academic Rheumatology, University of Nottingham, Nottingham, UK*; <sup>3</sup>*No 5, Fu-Hsing Road, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

**Background:** Antinuclear antibody (ANA) is a valuable test in the evaluate for a variety of autoimmune diseases. It can be detected using immunofluorescence (IIF) which yield both serum titers and also staining patterns. The manual titration of ANA is laborious and evaluation of staining patterns by a microscope requires experts to make correct classification. Deep learning is a collection of computational methods that enable an algorithm to ‘learn’ from a large set of data to acquire ‘skills’ that are characteristic of human intelligence, for example, complex pattern recognition. Application of these methods to ANA pattern classification requires further assessment and validation.

**Objectives:** To train a deep convoluted neural network to create an algorithm for automated classification of ANA patterns in images of indirect immunofluorescence.

**Methods:** We construct a deep convoluted neural network based on inception V3. The model adopted a deep learning architecture with 21 layers and ANA images were used to train to detect speckled, homogenous, nucleolar, centromere, dense fine speckled, cytoplasmic and mitochondrial patterns. The data were collected from rheumatology patients from June 2016 to October 2017. We validate the performance of the model using a separate set of images.

**Results:** Our data set consisted of 81822 ANA images from 8839 patients. The overall accuracy was 99.46% after 200 epochs of iteration using the training dataset (65 458 images) and the accuracy was 96.33% using the validation dataset (16.64 images). The sensitivity was 97.1% for speckled pattern, 91.4% for homogenous pattern, 97.1% for nucleolar pattern, 97.1% for centromere pattern, 97.2% for cytoplasmic pattern, and 100% for both dense fine speckled and mitochondrial patterns. The specificity was also good, ranged between 97.1% and 100%.

**Conclusions:** In this study, an algorithm based on deep convoluted neural network had high sensitivity and specific for detecting specific ANA patterns. Further research is needed to determine the feasibility to deploy the technology in routine clinical works to assist rheumatologists to interpret ANA.

**Disclosure of Interest:** None declared

SAT0647

### PREDICTIVE FACTORS OF POSITIVE POSITRON EMISSION TOMOGRAPHY FOR DIAGNOSING AORTITIS IN PATIENTS WITH POLYMYALGIC SYNDROME

D. Prieto-Peña<sup>1,1</sup>, J. Loricera<sup>1</sup>, I. Martínez-Rodríguez<sup>2</sup>, J. Banzo<sup>2</sup>, M. Calderón-Goercke<sup>1</sup>, V. Calvo-Río<sup>1</sup>, C. González-Vela<sup>3</sup>, M. González-Gay<sup>1</sup>, R. Blanco<sup>1</sup>, J. Hernández<sup>4</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Nuclear Medicine; <sup>3</sup>Pathology; <sup>4</sup>Internal Medicine, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

**Background:** Isolated non-infectious aortitis is a potentially serious condition whose diagnosis is often delayed due to the non-specific nature of its symptoms. Most of the patients initially present with polymyalgic syndrome associated with atypical symptoms. Nowadays, <sup>18</sup>F-FDG PET/CT scan is the best tool for early detection of aortitis. However, it is a complex and expensive technique. Thus, we should make an effort to select those patients who will benefit the most from this procedure. Unfortunately, we have no data about which factors may improve the probability of a positive diagnosis of aortitis using this imaging technique.

**Objectives:** Our aim was to evaluate, in patients with polymyalgia rheumatica (PMR), the predictive factors for a positive <sup>18</sup>F-FDG PET/CT scan, in order to make an early diagnosis of aortitis and optimise the use of this technique.

**Methods:** Retrospective study on 97 patients with PMR who had undergone an <sup>18</sup>F-FDG PET/CT scan between January 2010 and August 2017 with a high clinical suspicion of aortitis. Only patients with polymyalgic syndrome without any other underlying disease were included. We considered two groups: **a)** Classic PMR: patients who fulfilled the 2012 EULAR/ACR criteria; and **b)** Atypical PMR: patients with symptoms resembling PMR but did not fulfil the 2012 EULAR/ACR criteria. Distribution of categorical variables was compared by the Pearson Chi-squared test or Fisher exact test. Quantitative variables were analysed using the Student t test or MannWhitney U test as appropriate. An adjusted logistic regression model was built to assess the best set of predictive factors for a positive PET scan in both groups of patients.

**Results:** <sup>18</sup>F-FDG PET/CT scans were performed in 97 patients due to clinical suspicion of aortitis, being positive in 60 (61.9%). Patients (60 women/37 men) had a mean age of 68.4±10.7 years. Fifty-one (52.6%) had classic PMR and 46 (47.4%) atypical PMR. In patients with classic PMR, the best set of predictors for a positive PET/CT scan were lower limb pain (OR=8.4, 95% CI 2.0–35.1; p=0.004) and low back pain (OR=7.6, 95% CI 1.3–45.5, p=0.027), once adjusted for age, sex and current tobacco use. In atypical PMR patients, only the pelvic girdle affection (OR: 5.0, 95% CI 1.3–19.5; p=0.002) was significantly associated with a positive PET/CT scan, in the logistic adjusted model.

Abstract SAT0647 – Table 1

	PMR (n=97)					
	Classic PMR (n=51)			Atypical PMR (n=46)		
	Positive PET/CT (n=29)	Negative PET/CT (n=22)	P	Positive PET/CT (n=31)	Negative PET/CT (n=15)	P
Sex (women), n (%)	20 (69.0)	13 (59.1)	0.47	18 (58.1)	9 (60.0)	0.80
Age (years), mean ±SD	72.8 ± 8.8	75.2 ± 8.0	0.32	62.5 ± 9.1	62.4 ± 11.8	0.97
Recurrence of polymyalgic symptoms						
Neck pain, n (%)	6 (20.7)	4 (18.2)	0.99	3 (9.7)	2 (13.3)	0.71
Shoulder girdle, n (%)	17 (58.7)	15 (68.2)	0.45	12 (38.7)	10 (66.7)	0.076
Pelvic girdle, n (%)	19 (65.5)	11 (50.0)	0.27	29 (94.5)	4 (26.7)	0.016
Morning stiffness, n (%)	4 (13.4)	6 (27.3)	0.06	3 (9.7)	2 (13.3)	0.99
Atypical symptoms						
Inflammatory low back pain, n (%)	10 (34.5)	3 (13.6)	0.09	11 (35.5)	3 (20.0)	0.33
Diffuse lower limb pain, n (%)	17 (58.0)	8 (36.4)	0.004	17 (54.8)	8 (53.3)	0.35
Asthenia, n (%)	9 (31.0)	6 (27.3)	0.77	3 (9.7)	4 (26.7)	0.19
Hyporexia, n (%)	2 (6.9)	6 (27.3)	0.05	3 (9.7)	3 (20.0)	0.38
Weight loss, n (%)	4 (13.0)	6 (27.3)	0.30	5 (16.1)	4 (26.7)	0.45
Laboratory abnormalities						
Anemia, n (%)	11 (37.1)	12 (54.5)	0.24	8 (25.8)	5 (33.3)	0.73
CRP > 6 mg/l, n (%)	3 (10.3)	4 (18.2)	0.35	5 (16.1)	2 (13.3)	0.77
ESR > 40 mm, n (%)	12 (41.4)	12 (54.5)	0.57	16 (51.6)	8 (53.3)	0.81
Treatment response						
Lack of improvement with 15 mg of PD, n (%)	5 (17.2)	4 (18.2)	0.99	5 (16.1)	3 (20.0)	0.95

**Conclusions:** We have found that, in patients with classic PMR, the presence of diffuse lower limb pain and inflammatory low back may have clinical relevance when requesting a PET/CT scan due to aortitis suspicion. On the other hand, in patients with atypical PMR, only the presence of pain in the pelvic girdle seems to be a predictive factor for a positive result in PET/CT scan.

### COXALGIA IN HEMOPHILIC PATIENTS. SONOGRAPHIC EVALUATION OF A NOT TARGET JOINT

D. Melchiorre<sup>1</sup>, G. Castaman<sup>2</sup>, S. Linari<sup>2</sup>, M. Matucci-Cerinic<sup>1</sup>. <sup>1</sup>Department of Experimental and Clinical Medicine, University of Florence; <sup>2</sup>Centre for Bleeding Disorders, Azienda Ospedaliero Universitaria Careggi, Florence, Italy

**Background:** Spontaneous bleeding in haemophilia shows a predilection for joints, and repeated hemarthrosis induce synovial inflammation, cartilage degeneration and bone damage, leading to hemophilic arthropathy. The hip is not a target joint and its involvement is not easy to be distinguished from other conditions which may provoke pain referred to the hip.

**Objectives:** Aim of the study was to analyse the different sonographic findings related to different pain producing conditions.

**Methods:** Thirty patients with haemophilia A and monolateral coxalgia were examined. Sonographic exam (US) was performed in all patients by Esaote equipment My Lab 70 with linear probe 4–13 MHz and power Doppler. The iliopsoas muscle and its bursa, the greater trochanteric bursa, and the hip joint were analysed. Sonographic findings in the joint were scored (score ranging from 0 to 21) for effusion, bone remodelling, cartilage damage, synovial hypertrophy, hemosiderin, osteophytes, hemarthrosis, erosion and fibrotic septa. The World Federation of Haemophilia (WFH) orthopaedic joint scale score and the radiologic Pattersson score were evaluated in all patients.

**Results:** US showed effusion in 20 hip joints (67%), bone remodelling in 18 (60%), cartilage damage in 10 (33%), synovial hypertrophy in 12 (40%), hemosiderin in 4 (13%), osteophytes in 7 (23%), hemarthrosis in 10 (33%) with power Doppler activity (>3 flags). In no patient erosion or fibrotic septa were observed. Fifteen out of 30 joints showed US score ≤5, and 15 US score >5. In 8 patients a hematoma of iliopsoas muscle was present, in two patients great trochanteric bursitis was detected. WFH mean score value was 39.5 (range 12–57) and the mean Pattersson score value was 10.4 (range 6–12).

**Conclusions:** Surprisingly, in most cases (67%) coxalgia was not related to trochanteric bursitis or iliopsoas muscle involvement but was due to hemophilic arthropathy of the hip which is not a target joint. Moreover, power Doppler allowed to detect hemarthrosis in 33% of patients, supporting the hypothesis that vascular changes and remodelling in haemophilia are associated with bleeding and joint damage<sup>1</sup>.

SAT0649

### CORRELATION BETWEEN CLINICAL MANIFESTATIONS AND <sup>18</sup>F-FDG UPTAKE IN PATIENTS WITH POLYMYALGIA RHEUMATICA

D. Prieto-Peña<sup>1</sup>, J. Loricera<sup>1</sup>, I. Martínez-Rodríguez<sup>2</sup>, J. Banzo<sup>2</sup>, M. Calderón-Goercke<sup>1</sup>, V. Calvo-Río<sup>1</sup>, C. González-Vela<sup>3</sup>, M. González-Gay<sup>1</sup>, J. Hernández<sup>4</sup>, R. Blanco<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Nuclear Medicine; <sup>3</sup>Pathology; <sup>4</sup>Internal Medicine, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

**Background:** Polymyalgia rheumatica (PMR) is an inflammatory disease characterised by pain and stiffness of the neck, shoulder and pelvic girdles. It can also be accompanied by other non-specific symptoms such as inflammatory low back pain, diffuse lower limb pain and constitutional syndrome. The role of <sup>18</sup>F-FDG PET/CT is increasing in the diagnosis of PMR but it remains unknown if there is a correlation between clinical symptoms and <sup>18</sup>F-FDG uptake.

**Objectives:** Our aim was to assess if the localization of pain of patients with PMR correlates with <sup>18</sup>F-FDG uptake in the corresponding region of interest.

**Methods:** Retrospective study of 75 patients with PMR and their respective PET/CT scans from a referral centre. PMR diagnosis was based on 2012 EULAR/ACR criteria.

**Results:** We evaluated 75 patients (27 men and 48 women) with a mean age ±SD of 68.2±10.7 years. A PET/CT was performed in all of them. Pattern of <sup>18</sup>F-FDG uptake in patients with different clinical manifestations were summarised in the TABLE. Twenty-two out of thirty-three patients (66.7%) with <sup>18</sup>F-FDG uptake in sternoclavicular joints had shoulder girdle pain. In all patients with morning

stiffness (n=11) an increase of  $^{18}\text{F}$ -FDG uptake in shoulders was observed. Twenty-three patients of thirty-two patients (71.8%) with  $^{18}\text{F}$ -FDG uptake in hips had pelvic girdle pain. The remaining localizations of  $^{18}\text{F}$ -FDG uptake in PET/CT scans did not show significant correlations with clinical symptoms.

Clinical manifestation/location of FDG uptake	F-FDG uptake		
	Positive, n/N (%)	Negative, n/N (%)	P
<b>Shoulder girdle pain (n=40)</b>			
Shoulder	27/45 (60.0)	13/30 (43.3)	0.16
Sternoclavicular joints	22/33 (66.7)	18/42 (42.9)	<b>0.04</b>
Cervical interspinous bursae	6/9 (66.7)	34/66 (51.5)	0.49
<b>Neck pain (n=12)</b>			
Shoulder	8/45 (17.8)	4/30 (13.3)	0.61
Cervical interspinous bursae	2/9 (22.2)	10/66 (15.5)	0.63
<b>Morning stiffness (n=11)</b>			
Shoulder	11/45 (24.4)	0/30 (0.0)	<b>0.002</b>
Sternoclavicular joints	7/33 (21.2)	4/42 (9.5)	0.20
Cervical interspinous bursae	3/9 (33.3)	8/66 (12.1)	0.12
<b>Pelvic girdle pain (n=42)</b>			
Hips	23/32 (71.8)	19/43 (44.2)	<b>0.02</b>
Lumbar interspinous bursae	18/29 (62.1)	24/46 (52.2)	0.40
Subtrochanteric bursae	11/20 (55.0)	31/55 (56.4)	0.92
Ischial tuberosities	10/19 (52.6)	32/58 (57.1)	0.73
Pubic symphysis	3/4 (75.0)	30/71 (54.9)	0.63
<b>Inflammatory low back pain (n=20)</b>			
Hips	10/32 (31.3)	10/43 (23.3)	0.44
Lumbar interspinous bursae	10/29 (34.5)	10/46 (21.7)	0.22
Ischial tuberosities	3/19 (15.8)	17/56 (30.4)	0.26
Subtrochanteric bursae	7/20 (35.0)	13/55 (23.6)	0.33
Pubic symphysis	3/4 (75.0)	17/71 (23.9)	0.06
<b>Diffuse lower limb pain (n=35)</b>			
Knees	16/33 (48.5)	19/42 (45.2)	0.78
Subtrochanteric bursae	8/20 (40.0)	27/55 (49.1)	0.49
Ischial tuberosities	9/19 (47.4)	26/56 (46.4)	0.94
Hips	15/32 (46.9)	20/43 (46.5)	0.98

**Conclusions:** In patients with PMR, the presence of shoulder girdle pain seems to correlate with  $^{18}\text{F}$ -FDG uptake in sternoclavicular joints, morning stiffness with  $^{18}\text{F}$ -FDG uptake in shoulders and pelvic girdle pain with  $^{18}\text{F}$ -FDG uptake in hips. No other significant correlations were found between any other symptom and  $^{18}\text{F}$ -FDG uptake.

### SAT0650 MUSCULOSKELETAL ULTRASOUND IN FIRST DEGREE RELATIVES OF RHEUMATOID ARTHRITIS PATIENTS

E. Soliman<sup>1,2</sup>. <sup>1</sup>Internal Medicine, Rheumatology and Clinical Immunology, Faculty of Medicine, Alexandria, Egypt; <sup>2</sup>EULAR Certified MSUS Trainer. Rheumatology postgraduate diploma student, University of South Wales, South UK

**Background:** Preclinical phase of rheumatoid arthritis (RA) is characterised by a state of autoimmunity and inflammation. MSUS is known for its ability to detect subclinical synovitis, but changes in first degree relatives (FDR) are not yet defined.

**Objectives:** To investigate the presence of abnormal MSUS findings in FDR of RA who are free of clinical disease.

**Methods:** Study included 20 RA patients, and 25 of their FDR without evidence of arthritis. All were subjected to full history taking with special emphasis on joint symptoms, and joint examination. Measurements of ESR, CRP, RF and anti-CCP were performed in all and MSUS scan using the 7 joint ultrasonography (US7) score<sup>1</sup>

**Results:** Mean age in FDR 33.1±13.4 years, and in RA was 39.50±13.43 years with a mean disease duration of 11.95±8.36 years. All RA (100%) had symmetrical, polyarthralgia and/or arthritis, mostly involving small joints of hands and feet. 8/25 FDR (32%) had arthralgia that included different joints. While 17/25 FDR (68%) were asymptomatic. None of FDR had arthritis as it was an exclusion criteria. MSUS findings were detected in 16/20 (80%) RA and in 10/25 (40%) FDR. Of whom 3/10 FDR (12%) had arthralgia and 7/10 (28%) were asymptomatic. Synovitis was the commonest MSUS finding in RA (n=16, 80%), and in their FDR (n=10, 40%). Tenosynovitis was present in 5 (25%) RA and only one (4%) FDR. Erosions were detected in 9 (45%) of RA and one (4%) FDR in the 2nd MCP. In RA the wrist was most common joint to be involved on MSUS (n=14, 70%), followed by 2nd MCP and 2nd MTP joints in 11 (55%), 5th MTP joint in 8 (40%), 3rd MCP joint in 6 (30%), 2nd PIP joint in 4 (20%), with least involvement in the 3rd PIP joint in 3 (15%) of RA. In FDR the wrist was also the most commonly involved joint on MSUS and 2nd MTP joint in 6 (24%), followed by 2nd MCP joint in only 1 (4%). Whereas, the 3rd MCP, 2nd and 3rd PIPs and 5th MTP joints were spared.

US7 score in RA and FDR are shown in table 1. US7 erosion score correlated significantly with disease duration in RA. Anti-CCP significantly correlated with all parameters of US7 and RF with the tenosynovitis GS (grey scale) score. While, in FDR there was no statistical significant correlation between US7 score with any of the inflammatory or seromarkers.

**Abstract SAT0650 – Table 1.** US7 Joint score in RA and FDR

US7 score	RA (n=20)	FDR (n=25)	P
Synovitis GS	5.15±4.26	0.64±1.04	<0.001*
Synovitis PD	2.05±2.54	0.24±0.83	0.003*
Tenosynovitis GS	0.35±0.75	0.04±0.20	0.040*
Tenosynovitis PD	0.30±0.80	0.0±0.0	0.048*
Erosions	1.60±3.10	0.04±0.20	0.001*
Total score	9.45±7.21	0.96±2.01	<0.001*

Shown values are mean ±SD. p: p values for Mann Whitney test for comparing between the two groups\*. Statistically significant at p<0.05

**Conclusions:** This study confirms the presence of inflammatory synovial changes in FDR of RA who are free of clinical disease. This strengthens the concept of FDR as pre-RA. US7 score is a useful screening tool to identify subclinical synovitis in at-risk individuals. While in RA, US7 score is significantly correlated to disease duration and autoantibodies. More long term studies on FDR are needed for establishing the predictive value of abnormal MSUS findings for the development of persistent arthritis.

### SAT0651 CAROTID ULTRASOUND IN PATIENTS WITH ARTHRITIS: ¿IN WHICH PATIENTS DOES IT RE-STRATIFY CV RISK?

F. Sivera, N. Martinez-Alberola, R. Martin-Domenech, G. Albert-Espi, C. Fernandez-Carballido, T. Pedraz-Penalva. *Dpt Rheumatology, Hospital General Universitario De Elda, Elda, Spain*

**Objectives:** To explore in which patients with inflammatory rheumatic disease, the findings in a carotid ultrasound result in a change in cardiovascular (CV) risk stratification as compared to the CV risk measured with the SCORE index.

**Methods:** Longitudinal prospective study in patients included in a program geared at CV risk factor screening followed by optimisation of their treatment. Patients with rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PsA) were included in the program. In a nurse-led single-visit, the existence and adequate control of classic CV risk factors were recorded. SCORE index was calculated and then modified according to EULAR recommendations. CV risks was stratified according to European guidelines. A carotid ultrasound was performed in patients with a low, intermediate or high-risk stratification in order to assess intimal-media thickness (IMT) and plaques. If plaques were detected, CV risk was re-stratified to very high risk.

From this program, patients who had completed the baseline evaluation and the carotid ultrasound were selected. The characteristics of patients with findings in carotid ultrasound that allowed re-stratification to those without these findings were compared.

**Results:** A total of 181 patients have completed the baseline work-up, including the carotid ultrasound. 122 (67%) of the patients were women with a mean age of 55 (±11) years of age. Included patients had RA (n=96, 53%), SpA (n=37, 20%) or PsA (n=48, 27%).

A diagnosis of DM was performed in 19 (10%), hypertension in 78 (43%) and hypercholesterolemia in 92 (51%); 38 (21%) were active smokers and 63 (35%) were obese (BMI >30). Mean SCORE index (modified according to EULAR recommendations) was 2.4 (±1.7). Risk stratification before ultrasound was 145 (80%) patients with intermediate risk and 36 (20%) with high risk.

Carotid ultrasound imaging showed plaques in 43 patients (bilaterally in 14). In these, risk was re-stratified as very high risk. Overall, 11 patients showed a thickening of IMT; all presented plaques as well. Final risk stratification after including

the carotid ultrasound findings showed 110 patients with intermediate risk, 28 with high risk and 43 with a very high risk.

In table 1, the characteristics of the 43 patients whose carotid ultrasound findings resulted in a risk re-stratification vs the 138 with no risk modification.

	Risk modification due to pathologic carotid ultrasound (n=43)	No risk modification due to pathologic carotid ultrasound (n=138)
Sex (Woman)	32 (74%)	90 (65%)
Age (years)	58.1 (±9)	53.5 (±12)*
Disease	28 (65%)	68 (49%)
RA (n=96)	6 (14%)	31 (22%)
SpA (n=37)	9 (21%)	39 (28%)
PsA (n=48)		
DM	4 (9%)	15 (11%)
High blood pressure	24 (56%)	54 (39%)
Hypercholesterolemia	30 (70%)	59 (43%)*
Smoker	12 (28%)	26 (19%)
Obesity	31 (72%)	87 (63%)
Modified SCORE	2.7 (±1.6)	2.3 (±1.7)

\*p<0.05 between group comparison

**Conclusions:** Patients with risk modification due to carotid ultrasound findings were older and were more frequently hypercholesterolemic. Performing a carotid ultrasound in these patients seems to offer especially relevant information.

**Disclosure of Interest:** None declared

SAT0652

#### STUDY OF NAIL UNIT WITH ULTRASONOGRAPHY IN SEVERAL RHEUMATOLOGICAL CONDITIONS: A CROSS SECTIONAL STUDY OF DISTAL INTERPHALANGEAL JOINT AND NAIL

G. Adami, E. Vantaggiato, C. Benini, A. Fassio, A. Giollo, G. Orsolini, L. Idolazzi, D. Gatti. *Rheumatology Unit, University of Verona, Verona, Italy*

**Background:** The ultrasonography (US) is a feasible technique when you refer to the peripheral small joints and also to the nail.<sup>1</sup> DIP joints are not only affected by inflammatory disease and a more frequent condition is osteoarthritis (OA). The bone and synovial changes due to this condition are very similar to the ones of PSA especially regarding osteoproliferative lesions.

**Objectives:** The aim of our study was exploring through imaging the changes of nail and entheses of extensor tendon of the finger in inflammatory and degenerative conditions in order to find structural differences of nail and DIP.

**Methods:** This is an observational study on PSO, PSA, RA or OA patients. A control group of 50 healthy volunteers was used for comparison. Diagnosis was based on clinical or scientific criteria, such as CASPAR or EULAR/ACR were applicable. The study sample included 203 individual. The ultrasonographers were blind to clinical data and diagnosis of the patient. The ultrasound examination was done with a GE Logiq S8. The structural alterations of the plate were evaluated using a semiquantitative score for the magnitude of the alteration. The score provides values from 0 (no alteration) to 3 (severely altered). A semiquantitative approach was also used for evaluation of the power Doppler signal.

**Results:** The study sample was composed by 51 patients affected by PsA, 31 affected by PSO group, 37 subjects with RA, 34 with OA and 50 HC. The analysis of nail bed PDUS revealed an unusual trend for patients affected by OA who showed a prevalence of lesions of every grade but a lower rate of normal cases. The evaluation of the PDUS of the entheses revealed that patients affected by PsA have an increased rate of PDUS signal at the entheses of the extensor tendon. Considering nail plate HC showed a strong difference (p value<0.001) vs all groups except for patients affected by RA. Regarding nail bed thickness HC showed difference only if compared with PSA or OA group. P values are reported in table 1.

		PSO	PSA	RA	OA	HC
Nail plate Thickness	PSO	//	0.99	0.021	0.99	<0.001
	PSA	0.99	//	0.002	0.99	<0.001
	RA	0.021	0.002	//	0.06	0.06
	OA	0.99	0.99	0.06	//	<0.001
	HC	<0.001	<0.001	0.06	<0.001	//
Nail bed Thickness	PSO	//	0.99	0.003	<0.001	0.15
	PSA	0.99	//	<0.001	<0.001	0.002
	RA	0.003	<0.001	//	0.69	0.12
	OA	<0.001	<0.001	0.69	//	0.012
	HC	0.15	0.002	0.12	0.012	//

**Conclusions:** The data support the concept that nail entheses unit is in some way involved in different pathological conditions. No exclusive feature belongs only to one or another disease, but the data provided suggested that peculiar lesions might be found only in certain disease and in certain structures, like the entheses.

The US of the nail should be considered as one of the possible and promising approach in the study of these structures.

#### RELATIONSHIP BETWEEN CARDIAC VALVULAR CALCIFICATION, CAROTID ATHEROSCLEROSIS, AND CORONARY CALCIFICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. Udachkina, D. Novikova, T. Popkova, E. Markelova, I. Kirillova, E. Gerasimova, V.A. Nasonova *Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** The prevalence and relationship of VC with arterial atherosclerosis in patients with rheumatoid arthritis (RA) is under-investigated.

**Objectives:** investigate the prevalence of VC in patients with RA and its relationship with carotid atherosclerosis (CA) and coronary artery calcification (CAC).

**Methods:** Study population was consisted of 128 adult patients (65.6% women, age 55<sup>43</sup>;61 years) with RA according to ACR/EULAR criteria (disease duration 6<sup>5</sup>;18 month) with moderate/high RA activity (DAS28 5.3 [5.0; 6.1]). Arterial hypertension (AH) was found in 64%, ischaemic heart disease (IHD) – in 14%, dyslipidemia – in 54.7%, smoking – in 20.3%, diabetes mellitus type 2 – in 7%, myocardial infarction – in 1.6%, stroke – in 1.6%. Cardiac VC was evaluated by transthoracic echocardiography; CAC scoring was done with 32-row scanner by standard Agatston method; CA was evaluated with duplex ultrasound.

**Results:** Patients were divided on 3 groups depending on valve condition: normal (34.3%); leaves thickening (30.5%); VC (35.25%). The VC group consisted of isolated mitral VC – in 11%, isolated aortic VC – in 51%, calcification of both valve – in 38%. Mitral regurgitation (3 degree) was detected in 0.8% patient, mitral stenosis (mild) – 0.8%, aortic regurgitation (1 degree) – in 25%, aortic stenosis (mild) – in 0.8%. Age, BMI, SBP and frequency of AH, IHD, CA, CAC significant increased from 1 to 3 group (p<0.05). There was no significant difference in the sex, lipid levels, Rg-stage, RA duration and level of parameters of RA activity (DAS28, CRP, ESR) between investigated groups.

	Normal valve (n=44)	Thickening (n=39)	Calcification (n=45)
Age	39.5 <sup>29</sup> ;51	56.5 [51.5;62]	60 <sup>57</sup> ;67 *
BMI	23.4 [21.4;28.6]	26.3 [23.7;29.3]	27.2 <sup>25</sup> ;31 *
SBP	120 <sup>100</sup> ;130	120 <sup>110</sup> ;134	130 <sup>120</sup> ;140 *
AH	19 (43.2)	23 (59)	40 (88.9) *
IHD	1 (2.3)	6 (15.4)	11 (24.4) *
CA	12 (27.3)	30 (77)	39 (86.7) *
CAC	8 (18.2)	16 (41)	32 (71.1) *

Note: Data are expressed as median [25 percentile;75 percentile] for continuous variables and as a number (%) for the categorical variables. \* Difference for trend (p<0.05)

**Conclusions:** Among RA patients, more than half have a modified valve structure and in 1/3 of them VC. The presence of VC is correlated with traditional cardiovascular risk factors, but not with lipid levels, activity and severity of RA. The probability of CA and CAC presence is significantly increased when there is VC.

#### ASSOCIATION OF PREDNISONE AND ANTIMALARIALS AND ECHOCARDIOGRAPHIC FINDINGS IN ASYMPTOMATIC CARDIOVASCULAR PATIENTS WITH SLE

L. Jochims, L.M.H. Mota, L. Muniz, D.F. Vasconcelos, L.L. Santos-Neto. *UNIVERSITY OF BRASILIA, Brasilia, Brazil*

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disease that presents with increase of cardiovascular risk. Echocardiogram can detect morphofunctional cardiac changes and predict clinical outcomes in patients with SLE<sup>1</sup>.

**Objectives:** To evaluate echocardiographic morphofunctional parameters in women with SLE, using conventional echocardiogram and to relate the echocardiographic findings to disease-related factors and therapeutics.

**Methods:** We have selected 51 women with SLE, without cardiovascular symptoms, under regular medical follow-up. Patients who had limitations to do echocardiography, smokers, and those with a creatinine level higher than 1.5 mg/dL were

excluded. 51 patients were divided into two groups, patients with SLEDAI <6 (n=30) and with SLEDAI ≥6 (n=21). They were submitted to clinical evaluation, laboratory tests and a traditional echocardiogram.

**Results:** Patients presented an average age of 34.5 years and average time of diagnosis of SLE of 7.2 years. In the comparison between groups, patients with SLEDAI ≥6 had a higher daily dose of prednisone (p=0.0016), more hospitalizations in the last 12 months (p=0.0173), and a higher cumulative dose of pulse therapy with methylprednisolone (p=0.008). Patients with SLEDAI <6 had a longer average time of antimalarials (AM) use (p=0.0309). Regarding the echocardiographic parameters, group with SLEDAI ≥6 presented greater left ventricular mass (LVM, p=0.0156), thickness of ventricular septum (p=0.0106) and left ventricular posterior wall (LVPW, p=0.0273). In multivariate analysis the LVM presented a positive association with age (p=0.0160), current daily dose of prednisone (p=0.0009) and time of AM use (p=0.0026),  $r^2$  0.3625. Regarding the thickness of the interventricular septum, there was a positive association with age (p<0.0001), current dose of prednisone (p<0.0001), SLEDAI (p=0.02), SLICC (p=0.0093) and pulse with methylprednisolone (p=0.0062), with  $r^2$  0.6983. There is a positive association of daily dose of prednisone with the parameters LVPW, LVM and septum thickness and AM was a predictor of greater LVM.

**Conclusions:** Several factors may contribute to cardiac morphofunctional changes in SLE. Ventricular hypertrophy in asymptomatic cardiovascular patients was not related to the use of prednisone or time of AM use in other studies, however these factors should be taken into account. There are no adequate study designs in literature to evaluate the effect of high doses of corticosteroids and time of AM use on cardiac morphology and function. AM induced cardiomyopathy is a rare, probably under-recognised, complication of prolonged AM treatment, it presents as a hypertrophic, restrictive cardiomyopathy with or without conduction abnormalities. Early recognition and drug withdrawal are critical with a survival rate of almost 55%. Longitudinal studies are needed to determine the effect of prednisone and AM use in subclinical echocardiographic findings to avoid unfavourable cardiovascular outcomes.

#### MYOSITIS AND FASCIITIS BY MAGNETIC RESONANCE IMAGING IN RECENT-ONSET POLYMYALGIA RHEUMATICA AND EFFECT OF TOCILIZUMAB THERAPY

J.P. Laporte<sup>1</sup>, F. Garrigues<sup>1</sup>, A. Huwart<sup>1</sup>, S. Jousse-Joulin<sup>2</sup>, T. Marhadour<sup>3</sup>, D. Guellec<sup>3</sup>, D. Cornec<sup>2</sup>, V. Devauchelle-Pensec<sup>2</sup>, A. Sarau<sup>3</sup>. <sup>1</sup>Radiology, CHU Brest and Université Bretagne Occidentale; <sup>2</sup>Rheumatology, CHU Brest and UMR 1227 Université Bretagne Occidentale; <sup>3</sup>Rheumatology, CHU Brest and Université Bretagne Occidentale, Brest, France

**Background:** In everyday practice, myofascial lesions are not usually evaluated on MRIs obtained for patients with PMR.

**Objectives:** To assess the prevalence of myofascial inflammatory lesions visible by magnetic resonance imaging (MRI) and their changes after tocilizumab therapy in active polymyalgia rheumatica (PMR).

**Methods:** We conducted a post hoc analysis of data from the TENOR study of tocilizumab monotherapy in PMR.<sup>1</sup> The 18 patients each received tocilizumab injections at weeks 0, 4, and 8. The shoulder and pelvic girdles were assessed at baseline then at weeks 2 and 12 using T1- and T2-STIR-weighted MRI. Radiologists blinded to patient data assessed each muscle group for myositis and fasciitis on baseline, week-2, and week-12 MRIs. Reproducibility was estimated by having two radiologists assess the week-2 MRIs of 13 patients then computing the kappa coefficient.

**Results:** For myofascial lesion detection, intraobserver reproducibility was almost perfect ( $\kappa=0.890$ ) and interobserver reproducibility was substantial ( $\kappa=0.758$ ). At baseline, all patients had at least one inflammatory myofascial lesion (example on right shoulder fig 1); sites involved were the shoulder in 10 (71.4%) patients, hip in 13 (86.7%), ischial tuberosity in 9 (60.0%), and pubic symphysis in 12 (80.0%). Sites involved at week 12 were the shoulder in 8 (53.3%) patients, hip in 5 (33.3%), ischial tuberosity in 1, and pubic symphysis in 3 (20.0%). At week 12, of 103 muscle groups studied in all, 43 (41.7%) had no inflammatory lesions, compared to 33 at baseline (Mac Nemar; p<0.001) but some areas seemed to be more responsive to tocilizumab compared to other areas. Improvements were noted in 66 (64.1%) muscle groups, worsening in 2 (1.9%), no change in 35 (34.0%).

**Conclusions:** Myositis and fasciitis are common in recent-onset PMR and improve during tocilizumab therapy. They could be used for the diagnosis in routine practice and as criteria of outcome evaluation.

#### CIRCULATING MIR-99B-5P IS A MARKER OF INFLAMMATION AND STRUCTURAL DAMAGE ON MRI IN EARLY RHEUMATOID ARTHRITIS

J. Yue<sup>1</sup>, F. Xiao<sup>2</sup>, J. Xu<sup>3</sup>, P.C. Wong<sup>1</sup>, E.K. Li<sup>1</sup>, L.P. Tam<sup>1</sup>, M. Li<sup>1</sup>, L. Qin<sup>3</sup>, J. F. Griffith<sup>2</sup>, L.-S. Tam<sup>1</sup>. <sup>1</sup>The department of Rheumatology; <sup>2</sup>Department of Imaging and Interventional Radiology; <sup>3</sup>Department of Orthopedics and Traumatology, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hongkong, Hong Kong

**Background:** Expression of several miRNAs occurs in the plasma and synovial fluid of patients with established rheumatoid arthritis (RA). We found that microRNA-143-3 p (miR-143-3 p), miR-145-5 p, and miR-99b-5p expression was associated with greater erosion volume in early RA (ERA)<sup>EULAR 2018</sup>-abstract no 1980). Whether these miRNAs are associated with bone erosion and joint inflammation on magnetic resonance imaging (MRI) is unknown.

**Objectives:** To determine whether plasma cell-free circulating miRNAs are associated with (a) bone erosion and (b) inflammation severity on MRI in patients with ERA.

**Methods:** 66 ERA patients were recruited at presentation for this cross-sectional study. 60 of these 66 patients (90.9%) were treatment naïve. MRI of the most severely affected wrist was performed in all patients. The degree of bone damage (i.e. erosions), bone inflammation (osteitis) and soft tissue inflammation (synovitis/tenosynovitis) was scored on MRI (a) semi-quantitatively using the Rheumatoid Arthritis MRI score (RAMRIS) for scoring the severity of erosions, bone marrow oedema, synovitis and tenosynovitis; and (b) quantitatively by measuring synovial and tenosynovial volume (mm<sup>3</sup>). The three most dysregulated miRNAs (miR-143-3 p, miR-145-5 p, and miR-99b-5p) identified in our previous ERA study were validated by TaqMan<sup>®</sup> qRT-PCR in all patients.

**Results:** Expression of miR-99b-5p was higher in ERA patients with erosions (1.28±0.61) on MRI than those without erosions (0.23±0.43, p<0.05). Subdivided according to mean RAMRIS synovitis score (5.69), miR-99b-5p expression was higher in ERA patients with relatively more synovitis (0.75±1.24) on MRI than those with relatively less synovitis (0.34±1.14, p<0.05). Bone marrow oedema or tenosynovitis on MRI were not found to be associated with specific miRNA expression. Expression of miR-99b-5p did, however, correlate with synovial (r=0.443, p=0.018) and tenosynovial volume (r=0.423, p=0.025) on MRI. Linear regression analysis revealed miR-99b-5p expression to be independently associated with both increased synovial volume (B=15.65, 95% CI 3.42–27.89,

p=0.014) and increased tenosynovial volume (B=7.39, 95% CI 0.41~14.38, p=0.039) (Table).

Table 1 Univariate and multivariate analysis for factors associated with synovial volume and tenosynovitis volume at baseline in all ERA patients

Table Univariate and multivariate analysis for factors associated with synovial volume and tenosynovitis volume at baseline in all ERA patients

Tj: Tender joint count; DAS 28: Disease Activity Score 28

**Conclusions:** Increased cell-free circulating miR-99b-5p is associated with increased synovial and tenosynovial volume as well as more severe bone erosion in ERA patients at presentation. Whether it may serve as a biomarker for monitoring the progression of synovitis and damage would need to be addressed in prospective studies.

#### SAT0657 MICROWAVE RADIOMETRY-DERIVED THERMAL CHANGES OF SACROILIAC JOINTS AS A BIOMARKER OF SACROILIITIS IN PATIENTS WITH SPONDYLOARTHRITIS

K. Laskari, D.A. Pitsilka, G. Pentazos, E. Siores, M.G. Tektonidou, P.P. Sfikakis. *Rheumatology Unit, 1st Dept. Of Propaedeutic Internal Medicine, Athens University Medical School, Athens, Greece*

**Background:** Microwave Radiometry (MR) is a rapid, easy-to-perform, non-invasive method that detects in-depth tissue temperatures. In a proof-of-concept study we found that an increased knee joint temperature detected by MR reflects the presence of subclinical synovial inflammation in patients with rheumatoid arthritis.<sup>1</sup>

**Objectives:** To test the hypothesis that MR-derived increased temperature of sacroiliac (SI) joints is a biomarker of local inflammation in patients with axial spondyloarthritis (SpA) in a cross-sectional study.

**Methods:** Sixty patients with SpA (32 with ankylosing spondylitis, 24 with psoriatic arthritis, 4 with enteropathic arthritis) underwent clinical and laboratory assessments, magnetic resonance, X-ray imaging, and MR measurements of SI joints. All MR measurements were performed by a physician who was blinded to the clinical evaluations. Patients were classified as having active sacroiliitis (pain and/or tenderness and/or bone marrow oedema on magnetic resonance, n=23), inactive sacroiliitis (n=19), whereas signs/symptoms of a present/past SI joint involvement were absent in the remaining 18 patients. Twenty five age-matched healthy individuals served as controls. Three MR measurements were performed along each SI joint and a number was calculated for each patient denoting the difference ( $\Delta T$ ) in temperature between the warmest point in either SI joint and a control point, which was the iliac bone.

**Results:** A lower  $\Delta T$ , indicative of a warmer joint, was found in patients with either active or inactive sacroiliitis compared to patients without sacroiliitis [mean (SD)  $\Delta T$  of 0.1 (0.5) vs. 0.6 (0.5), respectively, p=0.001] or healthy controls [mean (SD)

$\Delta T$  of 0.60 (0.55), p=0.003]. A warmer SI joint was not significantly associated with the presence of local tenderness or pain, the patient visualised analogue pain scale for SI joints, the BASDAI score, the New York radiological grading of SI lesions, or C-reactive protein levels. Notably, all 20 patients with increased SI joint temperature ( $\Delta T < 0.05$ , which was the mean  $\Delta T$  value minus one SD in healthy controls) had either symptoms/signs of sacroiliitis or imaging confirmed sacroiliitis even in the absence of clinical findings. Receiver operating analysis showed that a  $\Delta T$  cut-off of 0.35 could discriminate with a sensitivity of 78% and specificity of 74% patients with sacroiliitis from those without, or from healthy controls (both p=0.001); sensitivity reached 100% for  $\Delta T$  values equal or lower than 0.05.

**Conclusions:** MR-derived increased in-depth temperature indicative of local inflammation of SI joints may serve as an additional diagnostic marker in axial SpA

#### QUANTITATIVE ANALYSIS OF JOINT STRUCTURE BY HR-pQCT IN PATIENTS WITH RHEUMATOID ARTHRITIS: CORRELATION BETWEEN CARTILAGE LOSS AND BONE DETERIORATION

K. Chiba<sup>1</sup>, N. Iwamoto<sup>2</sup>, N. Oki<sup>3</sup>, K. Watanabe<sup>1</sup>, M. Osaki<sup>1</sup>, A. Kawakami<sup>2</sup>.

<sup>1</sup>Department of Orthopedic Surgery, <sup>2</sup>Department of Immunology and Rheumatology, <sup>3</sup>Department of Radiological Sciences, Nagasaki University, Nagasaki, Japan

**Background:** HR-pQCT is a high-resolution CT dedicated to human extremities. It has been used for the study of rheumatoid arthritis (RA) in recent years, enabling quantitative analysis of bone erosion, bone microstructure, and joint space.

**Objectives:** The purpose of this study is to investigate a correlation between cartilage loss and bone deterioration (juxta-articular osteoporosis and erosion) in patients with RA by HR-pQCT.

**Methods:** Twenty patients with RA (70±8 years, 15 female, 5 male) participated in this study. The second and third MCP joints were scanned by second-generation HR-pQCT (XtremeCT II, Scanco Medical, Switzerland) at the voxel size of 61  $\mu\text{m}$ .

The following parameters were measured semiautomatically using dedicated software (TRI/3D-BON, Ratoc System Engineering, Tokyo) based on previous studies<sup>1-3</sup>. 1) Average joint space width (ave-JSW) of MCP joints, 2) bone microstructure of metacarpal head: volumetric bone mineral density (vBMD), trabecular thickness (Tb.Th), trabecular number (Tb.N), and structure model index (SMI), 3) total volume of erosions (ER-volume) on the metacarpal head.

**Results:** Ave-JSW of MCP joints was 1.47 (1.00-1.89) mm. vBMD of the metacarpal head was 131.4 (54.3-263.5)  $\text{mg}/\text{cm}^3$ , Tb.Th was 213.1 (166-329.3)  $\mu\text{m}$ , Tb.N was 0.95 (0.69-1.50)/mm, and SMI was 1.68 (0.65-2.52). The total number of erosions was 31, and an average number of erosions on each metacarpal head was 0.9 (0-4). Total ER-volume on the metacarpal head was 1.96 (0-16.7)  $\text{mm}^3$ . Ave-JSW had significant correlations with vBMD, SMI and ER-volume (R=0.37, -0.40, -0.42, p<0.05).

**Conclusions:** Cartilage loss was correlated with juxta-articular osteoporosis and bone erosion in RA patients. Quantitative evaluation of total joint structure (joint space, bone microstructure, and erosion) by HR-pQCT would be useful for the pathophysiological research and drug development of RA.

### IS SYNOVIAL HYPERTROPHY WITHOUT DOPPLER ACTIVITY IN RHEUMATOID ARTHRITIS JOINTS SENSITIVE TO CHANGE? – RESULTS OF A LONGITUDINAL ULTRASOUND STUDY

L. Terslev<sup>1</sup>, M. Østergaard<sup>1</sup>, J. Sexton<sup>2</sup>, H.B. Hammer<sup>2</sup>. <sup>1</sup>Center for Rheumatology and Spine Disease, Rigshospitalet-Glostrup, Glostrup, Denmark; <sup>2</sup>Rheumatology, Diakonhjemmet, Oslo, Norway

**Background:** Ultrasound (US) is used to assess diseases activity in rheumatoid arthritis (RA). Grey scale (GS) US shows the synovial hypertrophy (SH) and Doppler the amount of hyperemia which is believed to reflect disease activity. Some joints with SH may have no Doppler activity despite the use of high-end US equipment and these joints are generally believed to be inactive without potential to change.

**Objectives:** The aim was to investigate if joints with SH but no Doppler activity is sensitive to change during treatment with biological DMARD (bDMARD) in RA patients.

**Methods:** RA patients initiating or changing bDMARD treatment were included. US examination was performed at baseline, 3 and 6 months using Siemens Antares US equipment with Doppler settings for slow flow.

36 joints were evaluated at each visit. SH and Doppler activity was graded from 0–3 according to the US atlas by Hammer et al.<sup>(1)</sup> The GS score for SH in joints without Doppler activity was registered for the individual joints using GS SH  $\geq 1$  as threshold. The changes were compared to changes in SH in joints with Doppler activity.

**Results:** 151 patients (82.8% women, 80.1% seropositive for anti-CCP) were included, with a mean (SD) age 51.4 (13.2) years, disease duration 9.9 (7.9) years. At baseline, 50.7% used prednisolone (mean (SD) 5 mg (4.68)).

The patients had a mean (SD) baseline DAS28 of 4.5 (1.5). At baseline 23% of the joints had SH without Doppler activity and 23% of the joints had SH with Doppler activity.

Doppler-negative joints had overall lower grades of SH (mean 1.2) than Doppler-positive joints (mean 2.2) at baseline using GS SH  $>1$  as cut-off. The improvement in SH was similar in Doppler-positive and Doppler-negative joints but when adjusting for the baseline score of SH, Doppler-negative joints had a higher tendency towards decrease than Doppler-positive joints for all grades (3 months:  $p < 0.0001$ ; 6 months = 0.0006).

A weak correlation was found to changes in DAS 28(crp) (Doppler-negative joints: 0.27 ( $p = 0.001$ ) and 0.18 ( $p = 0.03$ ) at 3 and 6 months respectively – Doppler-positive joints: 0.25 ( $p = 0.004$ ) and 0.33 ( $p = 0.0002$ ) at 3 and 6 months respectively).

**Conclusions:** SH in joints without Doppler activity improves during bDMARD, i.e. is sensitive to change. Thus, SH without Doppler activity is not a sign of inactive disease. These findings document that both Doppler and SH should be evaluated when assessing disease activity by US.

### CLINICAL SIGNIFICANCE OF ANTI-RA33 AUTOANTIBODIES IN RHEUMATOID ARTHRITIS

M. Volkava, A. Kundzer. *BelMAPGE, Minsk, Belarus*

**Background:** Recently heterogeneous nuclear ribonucleoproteins (hnRNPs) were identified as antigenic targets for autoantibodies in RA. Autoantibodies to RNP B1, B2 and heterogeneous complex A2/b are the most studied and are referred to as "antigen RA33". Clinical value of anti-RA33 in RA continues to be studied, so the question is about the diagnostic and pathogenetic significance of these autoantibodies in patients with RA remains open.

**Objectives:** The aim of this study was to investigate the frequency of occurrence of anti – RA33y patients with RA and compare them with clinical manifestations and immunological parameters of disease.

**Methods:** The study included 139 patients with RA. The diagnosis was verified according to the classification criteria of ACR/<sup>EULAR 2010</sup> Autoantibodies to RNP B1 IgG was assessed in samples of blood serum by enzyme immunoassay (ELISA; Medipan AG, Germany). Anti-CCP, RF and antibodies to Sa-antigen (anti-Sa) was evaluated by ELISA according to the manufacturer's instructions (Euroimmun AG company, Germany). The results were expressed in relative units (U/ml). Statistical data processing was carried out using the software Statistica 7.0 (StatSoft, USA) and Medcalc 12.5.0.0 (USA), including standard methods of parametric and nonparametric analysis. Differences were considered significant at  $p < 0.05$ .

**Results:** In our cohort of patients with RA, the incidence rate of RF IgM was 96.02%, anti-CCP – 81.75%, anti-Sa – 69.88%, anti-RA33 – 35.97% of patients. For further analysis of the clinical significance of anti-RA33 patients were divided into 2 groups: anti-RA33 positive and anti-RA33negative.

Positive and negative for anti-RA33 patients did not differ ( $p > 0.05$ ) by key characteristics, such as age, gender, duration of disease, and indicators of disease activity (CRP levels, DAS28, SDAI, CDAI). In contrast to the data obtained Maslyansky A. L. and co-authors the correlation relationship between the levels of anti-RA33 and indicators of disease activity as well as duration of disease has not been established. At the same time seronegative for anti-RA33 patients demonstrated a higher frequency of extraarticular manifestations ( $p < 0.05$ ).

When analysing the frequency of occurrence of anti-CCP, RF IgM, anti-Sa and anti-RA33 autoantibodies, there were no differences between the groups of seropositive and seronegative for anti-RA33. Correlation relationship between the levels of the investigated autoantibodies is not established.

**Conclusions:** Thus anti-RA33 is a perspective independent biomarker of RA, which has its own potential. The possible pathogenic significance of anti-RA33 as a biomarker of a more favourable course of the RA should be considered.

To clarify the diagnostic and pathogenic value of anti-RA33 further research with a large sample size, comparison of immunological data with genetic factors, the results of other laboratory and instrumental studies, clinical manifestations of the disease are required. The obtained data will allow us to more thoroughly study the pathogenesis of RA and contribute to the search for new therapeutic options.

Grassi<sup>2</sup>. <sup>1</sup>Instituto Médico Platense, La Plata, Argentina; <sup>2</sup>Clinica Reumatologica, Università Politecnica delle Marche, Jesi (Ancona), Italy; <sup>3</sup>Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal

**Background:** The "halo sign" is considered the well known qualitative ultrasound (US) finding for the diagnosis of giant cell arteritis (GCA). Recently, the measurement of the intima-media thickness (IMT) of temporal and axillary arteries has been proposed as a potential complementary US biomarker. A cut-off for IMT of 0.42, 0.29, 0.34 and 1.0 mm for superficial temporal arteries, parietal and frontal branches and axillary arteries, respectively, has been suggested. In fact, other conditions, such as atherosclerosis, may determine an increase of the IMT.

**Objectives:** To measure the IMT of the temporal and axillary arteries in subjects with different risks of cardiovascular (CV) disease and to investigate the prevalence of IMT values greater than the reference cut-off values.

**Methods:** Consecutive patients older than 50 years without signs or symptoms and without a previous history of GCA or polymyalgia rheumatica, were included. The European Guidelines of CV disease prevention were used to define different categories of CV risk. The subjects were divided in two groups: a first group made up of subjects with very high or high risk of CV disease and a second group made up of subjects with moderate or low risk of CV disease. The US examination was performed with a My Lab Twice (Esaote S.p.A. Genoa, Italy). The temporal arteries (superficial temporal arteries, parietal and frontal branches) were evaluated using a 18–22 MHz probe, whereas the axillary arteries were studied using a 6–18 MHz probe.

**Results:** Eight hundred and eight arteries were evaluated in 101 subjects (mean age 66.1 SD 8.5, 73.3% females). Thirty-one subjects (30.7%) were classified with very high risk of CV disease, 7 (6.9%) with high risk, 34 (33.7%) with moderate risk and 29 (28.7%) with low risk. The IMT of the superficial temporal and axillary arteries were significantly higher in the group made up of subjects with very high or high risk of CV disease than in the group made up of subjects with moderate or low risk of CV disease (0.21 SD 0.82 vs 0.19 SD 0.86  $p < 0.013$ ; 0.54 SD 0.17 vs 0.48 SD 0.10  $p < 0.20$ ). The value of the IMT was higher than the reference cut-off in 13 out of 808 (1.61%) of the studied arteries (2 superficial temporal artery, 6 parietal branch, 4 frontal branch and 1 axillary artery), in at least one artery in 10 out 101 patients (10.1%). Of these 10 patients, 8 (98%) were classified as having very high or high risk of CV disease.

**Conclusions:** These preliminary results suggest that an increased value of IMT may be observed in patients with very high or high risk of CV disease. However, the IMT value was higher than the reference cut-off only in a limited number of the studied arteries.

#### SAT0662 SCREENING RESEARCH OF ULTRASONOGRAPHIC PERIPHERAL ARTHRITIS AND ENTHESITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. Uematsu<sup>1,2</sup>, T. Okano<sup>1</sup>, K. Inui<sup>1</sup>, Y. Yamada<sup>1</sup>, K. Mandai<sup>1</sup>, Y. Sugikoka<sup>3</sup>, K. Mamoto<sup>1</sup>, T. Koike<sup>3,4</sup>, H. Nakamura<sup>1</sup>. <sup>1</sup>Department of Orthopedic surgery, Osaka City University Graduate School of Medicine; <sup>2</sup>Department of Orthopedic surgery, Higashiumiyoshi morimoto hospital; <sup>3</sup>Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka; <sup>4</sup>Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama, Japan

**Background:** Some patients with inflammatory bowel diseases (IBD) such as ulcerative colitis (UC) and Crohn's disease (CD) develop spondyloarthritis (SpA). Conventionally, the assessment of affected joint count in patients with SpA was relied for the detection of swelling and tenderness in the joints and entheses by clinical physical examination. To date, high quality ultrasonography (US) can detect inflammatory condition in the joint and entheses more sensitively than clinical assessment.

**Objectives:** The aim of this study was to research the utility of US screening for detection of peripheral arthritis in patients with IBD.

**Methods:** Total 42 patients including 27 patients with UC and 15 patients with CD were consecutively included. HI VISION Ascendus (HitachiAloka Medical, Tokyo, Japan) was used with an 18 MHz linear array transducer. US examination was performed in MCP, PIP, DIP and wrist joints in both hand. Greyscale (GS) and power Doppler (PD) US were scored on a 0–3 semiquantitative scale for each joint. Moreover, the US assessment of entheses was performed. Lateral epicondyle, triceps entheses, the proximal and distal patella tendon entheses, Achilles tendon and fascia plantaris tendon entheses was scanned in both GS and PD assessment. Abnormal findings of entheses was defined structure, thickness, bur-sitis, erosion, calcification in GS and power Doppler signal.

**Results:** In the joint clinical assessment, 12 patients with UC and 7 patients with CD had joint symptoms. US active synovitis (GS Grade $\geq$ 2 · PD Grade $\geq$ 1) was found in 8 patients with UC and 6 patients with CD. The concordance rate between clinical findings and US findings was relatively low in UC and high in CD patients. In the enthesial clinical assessment, 9 patients with UC and 7 patients with CD had tenderness in any entheses. Active enthesitis in US was found in 16 patients with UC and 8 patients with CD. The concordance rate between clinical findings and US findings was relatively high and subclinical enthesitis was also found in many patients.

	UC (n=27)	CD (n=15)
Male (%)	9 (33.3%)	7 (46.7%)
Age (years)	46.1 $\pm$ 14.2	39.4 $\pm$ 11.6
Height (cm)	161.2 $\pm$ 8.4	163.1 $\pm$ 5.8
Weight (kg)	56.4 $\pm$ 17.4	56.0 $\pm$ 9.16
BMI	21.3 $\pm$ 4.9	21.0 $\pm$ 3.0
Duration of IBD (years)	13.3 $\pm$ 12.5	12.3 $\pm$ 9.7
Clinical peripheral joint symptom	12 (44.4%)	7 (46.7%)
Active US synovitis (GS $\geq$ 2, PD $\geq$ 1)	8 (29.6%)	6 (40.0%)
Clinical enthesial symptom	9 (33.3%)	7 (46.7%)
US enthesitis (any pathological findings)	16 (59.3%)	8 (53.3%)
Inflammatory back pain	12 (44.4%)	9 (60.0%)

**Conclusions:** The peripheral arthritis and enthesitis findings in patients with IBD was compared between clinical and US examination. The prevalence rate of sub-clinical synovitis was not high, thus US screening might not be useful in patients with IBD without arthritis symptom. However, the subclinical enthesitis was found in patients without any enthesial symptoms. US screening might be useful to detect subclinical enthesitis than clinical examination in patients with IBD.

#### SAT0663 A NEW OPERATOR INDEPENDENT AUTOMATIC TOOL FOR ACCURATE IDENTIFICATION OF VERTEBRAL FRAGILITY FRACTURES

F. Conversano<sup>1</sup>, R. Franchini<sup>1</sup>, E. Quarta<sup>2</sup>, P. Pisani<sup>1</sup>, E. Casciaro<sup>1</sup>, D. Lobbreglio<sup>2</sup>, M. Muratore<sup>2</sup>. <sup>1</sup>National Research Council, Institute of Clinical Physiology, Lecce; <sup>2</sup>O.U. of Rheumatology, Galateo Hospital, ASL-LE, San Cesario di Lecce, Italy

**Background:** Osteoporosis is a systemic skeletal disease characterised by a compromised bone resistance that predisposes a subject to an increased risk of fracture. In particular, vertebral fractures are the most common of all osteoporotic fractures. A common clinically-used method for vertebral fracture detection is vertebral morphometry, which is based on measurements of front (Ha), middle (Hm), and rear (Hp) heights of vertebral bodies in radiographic images. This method is quantitative and does not require specific operator skills, but its actual accuracy is affected by errors made during the time-consuming manual measurements.

**Objectives:** In this work we propose a fully automatic algorithm for morphometric measurement, whose final goal is to reduce errors due to manual and semi-automatic processes. Our automatic method identifies the vertebrae and their edges. Then, the algorithm measures the characteristic vertebra heights (Ha, Hm, Hp) and determines possible vertebral deformities.

**Methods:** The vertebral morphometry uses lateral X-ray images and it is based on height measurements of vertebral bodies:

$$Hp = ||P1 - P2||_2,$$

$$Ha = ||A1 - A2||_2,$$

$$Hm = ||M1 - M2||_2.$$

**Where:** Pi: rear vertebral corners;

Mi: middle vertebral points;

Ai: front vertebral corners.

The vertebral deformities can be determined as follows:

biconcave deformity:  $Hm/Hp < 0.80$ , crushing deformity:  $Hp/Hp(\pm 1) < 0.80$ , wedge deformity:  $Ha/Hp < 0.80$ .

The main problem in implementing our fully automatic algorithm was the correct placement of the six reference points for each detected vertebra. Our approach first combined literature-reported methods for the identification of vertebrae in X-Ray images, subsequent emphasise the vertebral borders. The four corners of the vertebra (Pi and Ai) were localised on the borders detected vertebra. While, the middle points Mi were positioned at equal distance from Pi and Ai.

**Results:** The performance tests were based on the comparison between the results coming from our automatic approach and those obtained from the manual measurements by an experienced radiologist. We analysed 100 conventional lateral radiographs. The following metrics were used: sensitivity and specificity in vertebra detection; errors in the localization of characteristic points and in the measurement of diagnostic parameters; correlation between manual and automatic measurements. The results of our method showed a sensitivity of 90.8% and a specificity of 99.0%. Average errors in the localisation of vertebral characteristic points were always smaller than 3 mm. Bland-Altman analysis documented a mean error in automatic measurements of diagnostic ratios of 0.01  $\pm$  0.15 (bias  $\pm$  2 SDs), while Pearson's correlation coefficient resulted  $r=0.71$  ( $p < 0.001$ ).

**Conclusions:** Obtained results of our method compared to the results obtained by a trained radiologist showed an acceptable low error rate, a very good performance in vertebra detection and the same diagnosis (normal, biconcave deformity, crushing deformity, and wedge deformity). Overall, the adopted method has a strong potential for an effective employment in clinical routine for fast and accurate diagnosis of vertebral fractures.

**SAT0664** **CARTILAGE DAMAGE QUANTITATIVELY ASSESSED BY MRI USING T2 MAPPING IN CCP-POSITIVE RA PATIENTS**

N. Renner<sup>1</sup>, A. Kleyer<sup>2</sup>, G. Krönke<sup>2</sup>, D. Simon<sup>2</sup>, J. Rech<sup>3</sup>, G. Schett<sup>2</sup>, G. Welsch<sup>4</sup>, M.L. Pachowsky<sup>1</sup>. <sup>1</sup>Trauma and Orthopaedic Surgery; <sup>2</sup>Department of Internal Medicine 3, Rheumatology and Immunology; <sup>3</sup>Department of Internal Medicine 3, Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Erlangen; <sup>4</sup>UKE Athleticum, University Hospital Hamburg-Eppendorf, Hamburg, Germany

**Background:** T2 mapping is a non-invasive quantitative MRI approach which reflects cartilage hydration and collagen integrity without using contrast enhancement. It is a sensitive tool to determine cartilage damage and is currently spreading into broader clinical application.<sup>1</sup>

**Objectives:** This study aimed to analyse biochemical changes in cartilage of Metacarpophalangeal (MCP) joints in patients with rheumatoid arthritis (RA) using T2 mapping in a 3 T MRI setting.

**Methods:** Thirty RA patients fulfilling the 2010 ACR/EULAR criteria were recruited. Image acquisition was performed using two surface coils in a 3 T MRI whole body scanner (VERIO; SIEMENS Healthcare).<sup>2</sup> We obtained high-resolution images of the 2nd and 3rd MCP joint. T2 maps were calculated using a pixel-wise, mono-exponential, non-negative least-squares-fit analysis. Region-of-interest (ROI) analysis was performed by dividing the cartilage into medial, central and lateral phalangeal (med, cent, lat P) and metacarpal (MC) area. ACPA positive patients were compared to ACPA negative patients. Statistical evaluation was performed by means of univariate ANOVA testing with random factors. A p-value < 0.05 was considered statistically significant. The study protocol was approved by the local ethics commission. Written informed consent was obtained from all patients

**Results:** Fourteen ACPA positive (3 male/11 female) and 16 ACPA negative patients (6 male/10 female) were included. Mean age, sex distribution and disease duration were comparable (age: 49.0±15.1 years (ACPA+) vs. 56.1±10.9 years (ACPA-), t=1.494, p=0.146; sex distribution:  $\chi^2$  (1)=0.918, p=0.338, disease duration: 7.9±7.3 years (ACPA+) vs. 3.9±3.8 years (ACPA-), U=69.0, Z=-1.799, p=0.072).

T2 values were significantly higher in the majority of the ROIs in ACPA-positive (+) RA patients compared to ACPA negative (-) patients with a statistical significance in five of the six ROIs.

T2 values in ms: MC med (+) 41.3±15.3 vs. (-) 29.6±7.4 p=0.010, cent (+) 43.8±14.6 vs. (-) 28.4±10.9, p=0.001, lat (+) 45.6±13.8 vs. (-) 32.0±8.6, p=0.008.

P: med (+) 30.3±14.6 vs. (-) 25.7±14.0, p=0.169, cent (+) 29.9±13.0 vs. (-) 22.5±10.1, p=0.014, lat (+) 37.0±15.9 vs. (-) 28.8±12.6, p=0.039.

**Conclusions:** T2 mapping is a clinically feasible non-invasive MR tool for cartilage evaluation of RA patients' MC joints. ACPA positive RA patients showed significantly increased T2 values compared to ACPA negative patients reflecting a more severe cartilage alteration despite comparable disease duration.

**SAT0665** **SYNOVITIS AS A PREDICTOR OF EROSIONS IN THE HAND OSTEOARTHRITIS**

O. Balueva<sup>1</sup>, A. Sarapulova<sup>2</sup>, O. Teplyakova<sup>2</sup>. <sup>1</sup>Ultrasound Diagnosis, Medical Association "New hospital"; <sup>2</sup>Urals state Medical University, Yekaterinburg, Russian Federation

**Background:** The formation of bone erosions in hand osteoarthritis (HOA) is the result of the association of destructive and inflammatory changes in the joint and leads to a more aggressive course of the disease. X-ray examination assesses destructive bone changes, but there is no possibility to assess the condition of periarticular tissues and inflammatory changes objectively. Visualisation of both

erosions and synovitis is possible during ultrasound examination of the hands. On the basis of this results it is possible to predict the further development of the disease.

**Objectives:** To determine the risk of erosion appearance and the features of progression in patients with hand osteoarthritis in a prospective study.

**Methods:** The study included 45 women which were 45–75 years old with the diagnosis of HOA, defined by criteria of the American College of Rheumatologists (ACR). 22 joints were examined at each patient by ultrasound: distal interphalangeal joints (DIP), proximal interphalangeal joints (PIP), joints of the thumb and 1 st carpo-metacarpal joint (1 st CMC). Ultrasound examination included multiplane gray-scale investigation of the listed above groups of joints. The presence and severity of synovial hypertrophy and effusion followed by evaluation of the degree of synovitis was determined in the B-mode; the quantity and the sizes of osteophytes and bone erosions were evaluated in a similar way. The vascularisation of synovial hypertrophy was estimated in the power Doppler ultrasound. The study was started in 2013. In 3 years the study was repeated. The results were processed with STATISTICA 10.0 software (StatSoft Inc. USA) using the methods of nonparametric statistics. For the description of communication of qualitative signs we used coefficient "odds ratio" OR and  $\chi^2$ . The results were recognised statistically reliable at value p < 0.05.

**Results:** The total number of hand joints was evaluated using ultrasound 990. In the primary examination 391 joints had synovitis, 46 joints had synovitis and erosion. In 3 years the number of joints with synovitis and the number of joints with synovitis and erosion increased up to 443 and 73 respectively. In 2016 among 73 joints with synovitis and erosion, 40 joints were with erosion against the background of synovitis 3 years ago, and only in the 8 joints erosion were revealed where was no synovitis. Thus the frequency of erosion detection in hand joints at repeated examination was higher in the cases the synovitis was detected at primary examination:  $\chi^2$  2=16.38 p=0.0001; OR 4.373, CI 95% 2.01–9.47.

**Conclusions:** The synovitis in hand joints is a prognostic adverse factor of erosions appearance and transformation in the erosive subtype of osteoarthritis. The possibility one-time visualisation of inflammatory and destructive changes allows using ultrasound investigation at primary and differential diagnostics, and dynamic evaluation.

**SAT0666** **INFLAMMATION BEYOND CLINICAL REMISSION: ULTRASOUND AS A TOOL TO GUIDE US TO REMISSION**

P. Estrada<sup>1</sup>, C. Diaz-Tomé<sup>2</sup>, V. Torrente<sup>3</sup>, P. Moya<sup>2</sup>, C. Moragues<sup>4</sup>, D. De La Fuente<sup>5</sup>, S. Ros<sup>5</sup>, J. Ramirez<sup>6</sup>, M. Moreno<sup>7</sup>, E. García<sup>8</sup>, M. Puyol<sup>9</sup>, N. Busquets<sup>10</sup>, A. Ponce<sup>10</sup>, J. De Agustín<sup>11</sup> on behalf of Ecocat on behalf of ECOCAT. <sup>1</sup>Hospital Moisès Broggi-CSI; <sup>2</sup>Hospital de la Santa Creu i Sant Pau; <sup>3</sup>Hospital General de L'Hospitalet; <sup>4</sup>Hospital Plató; <sup>5</sup>Hospital Viladecans; <sup>6</sup>Hospital Clínic; <sup>7</sup>Hospital Parc Taulí; <sup>8</sup>Hospital Mollet; <sup>9</sup>Mútua de Terrassa; <sup>10</sup>Hospital Granollers; <sup>11</sup>Hospital de la Vall d'Hebron, Barcelona, Spain

**Background:** Among patients with RA in remission, subclinical synovitis (SS) has a prevalence of 45% and is associated with an increased risk of clinical relapse and progression to structural damage. US is a sensitive and accessible tool for evaluating SS<sup>1,2,3</sup>.

**Objectives:** To analyse US as a tool for evaluating SS in RA patients treated with tocilizumab (TCZ), in order to assess remission, and from there on propose therapeutic tapering.

**Methods:** Multicenter, 1 year follow up study in 45 patients with RA treated with TCZ. The project was approved by Ethics Committees and all the patients gave their informed consent. At each visit: DAS28, SDAI, CDAI, mHAQ, US grey scale (GS) and Power Doppler (PD) parameters for 32 joints (J) and 28 tendons (T), with a semiquantitative scale from 0–3 points. A quantitative index was obtained for J and T in GS and PD and overall (EG + PD) for each patient/visit. SS was considered as the presence of synovitis with PD(+) ≥ 2. Our intra and interobserver kappa index was 0.8.

**Results:** A significant reduction of all clinical indexes and US variables was observed in all patients. Patients were divided into two groups: remission (R) and no remission (NR) according to whether they achieved DAS28 ≤ 2.6 at 12 months. Group R achieved DAS28 ≤ 2.6 after mo 3, whereas US showed SS (GS+, PD > 2) until mo 12. The final overall PD value in the R group was 0.6 (± 0.9).

**Conclusions:** A significant number of patients achieve clinical remission within a few months of starting TCZ. The R group, achieved a good EULAR response since mo 3; a progressive improvement in PD, persisted until mo 12. We consider that these findings refer to SS. From our data we consider that dose tapering should not be initiated until at least 9 months from the start of remission.

#### SAT0667 IMPLEMENTATION AND ROLE OF MODERN MUSCULOSKELETAL IMAGING IN RHEUMATOLOGICAL PRACTICE IN EUROPE

P. Mandl<sup>1</sup>, A. Ciechomska<sup>2</sup>, X. Baraliakos<sup>3</sup>, P.G. Conaghan<sup>4</sup>, M.-A. D'Agostino<sup>5</sup>, A. Iagnocco<sup>6</sup>, C.J. van der Laken<sup>7</sup>, M. Ostergaard<sup>8</sup>, L. Terslev<sup>9</sup>, E. Naredo<sup>9</sup>.  
<sup>1</sup>Rheumatology, Medical University Vienna, Vienna, Austria; <sup>2</sup>Rheumatology, University Hospital Wishaw, Wishaw, UK; <sup>3</sup>Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany; <sup>4</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; <sup>5</sup>Rheumatology, APHP, Hôpital Ambroise Paré, Boulogne-Billancourt, France; <sup>6</sup>Dipartimento di Scienze Cliniche e Biologiche, Università degli Studi di Torino, Turin, Italy; <sup>7</sup>Rheumatology, VU University Medical Center, Amsterdam, Netherlands; <sup>8</sup>Center for Rheumatology and Spine Diseases, Copenhagen University Hospital Glostrup, Copenhagen, Denmark; <sup>9</sup>Rheumatology, Joint and Bone Research Unit, Hospital Universitario Fundación Jiménez Díaz and Autónoma University, Madrid, Spain

**Background:** Modern non-X-ray imaging methods are increasingly utilised by rheumatologists though the uptake and use of these techniques has developed very differently across Europe and there is limited data on their present impact in rheumatology for individual countries.

**Objectives:** To document the current implementation, role and training in modern musculoskeletal imaging techniques: musculoskeletal ultrasound (MSUS), magnetic resonance imaging (MRI), computed tomography (CT), and positron emission tomography (PET) among rheumatologists in the member countries of the European League Against Rheumatism (EULAR).

**Methods:** A EULAR Taskforce comprised of 9 rheumatologist experts in imaging developed English-language questionnaires for each imaging modality (CT, MRI, MSUS, PET) which were sent out to: national rheumatology societies of EULAR, national societies of the European Federation of Societies for Ultrasound in Medicine and Biology, the European Society for Magnetic Resonance Ultrasound in Medicine and Biology, as well as identified experts in the given modalities involved in research and/or training. The surveys were distributed via an online survey tool (SurveyMonkey). Simple descriptive and summary statistics were calculated from the responses.

**Results:** A total of 205 out of 395 experts replied to the surveys. More than 90% of MSUS experts had an MSUS unit in their department. The majority of responders reported having easy access to MRI, CT or PET (56%, 78% and 50% respectively). Suspicion of rheumatoid arthritis and peripheral spondyloarthritis were the main clinical indications for performing MSUS for diagnostic purposes. Suspicion of sacroiliitis and degenerative spine disease were the most common indications to perform MRI or CT for diagnostic purposes, while PET was mainly performed to

diagnose large vessel vasculitis and investigation of fever of unknown origin. When asked about the percentage of rheumatologists performing MSUS in their country 37% of experts reported less than 20%, 33% reported values between 20%–40% and 24% reported more than 40% (6%: unknown). The overwhelming majority (99%) of experts were certified in MSUS, while only 22% and 26% of experts in MRI and CT were certified in their techniques. Seventy-seven percent of responders reported that their national rheumatology societies organise MSUS courses, while courses in MRI or CT organised by the national rheumatology societies were less commonly reported (38% and 16% respectively).

**Conclusions:** Rheumatologists in Europe utilise modern imaging techniques, however access among the techniques and training offered is varied.

**Disclosure of Interest:** None declared

#### SAT0668 ARTICULAR INVOLVEMENT IN CHRONIC HEPATITIS C INFECTION – A PRELIMINARY ULTRASOUND STUDY

R.A. Ionescu<sup>1,2</sup>, L.M. Pana<sup>3</sup>, V.M. Pompilian<sup>1</sup>, A. Voicu<sup>4</sup>, S. Caraiola<sup>1</sup>, D. Ramba<sup>3</sup>, C.R. Baicus<sup>5</sup>, A. Dan<sup>5</sup>. <sup>1</sup>3rd Internal Medicine Dept, "Carol Davila" University of Medicine and Pharmacy; <sup>2</sup>Colentina Clinical Hospital, Bucharest, Romania; <sup>3</sup>3rd Internal Medicine Dept, Colentina Clinical Hospital; <sup>4</sup>"Alexandru Obregia" Clinical Hospital; <sup>5</sup>Internal Medicine Clinic, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

**Background:** Chronic hepatitis C is a public health issue. Extra-hepatic manifestations of this infection also include articular involvement, that sometimes mimics rheumatoid arthritis.

**Objectives:** Evaluation of potential articular involvement in patients diagnosed with chronic hepatitis C infection and possible correlations with biological abnormalities.

**Methods:** We evaluated 31 patients with chronic hepatitis C infection, using ultrasound (US) examination of both wrists and the second and fifth interphalangeal joints of the fingers. Then, we looked for possible correlations with various laboratory findings.

**Results:** 29% of patients were symptomatic (pain) at the time of the US examination.

10% of our patients had tenosynovitis of the extensor tendons, another 10% had active synovial hypertrophy (Doppler positive), 31.14% had inactive synovial hypertrophy, 20.9% had erosions and in 20% of them the US examination of the above mentioned joints was normal.

61.29% of patients having US abnormalities, where rheumatoid factor positive.

All patients with erosions and inactive synovial hypertrophy, 83.3% of those with active synovial hypertrophy and 67% of those with tenosynovitis where cryoglobulins positive.

We found low levels of C3 fraction of complement in 92.3 patients with erosions, 83.3 patients with active synovial hypertrophy, 84.2 patients with inactive synovial hypertrophy and 50% of patients with tenosynovitis.

In 85.7% of patients with active synovial hypertrophy, and 53.8% of patients with erosions, the C-reactive protein (CRP) levels were elevated.

No patient was diagnosed as also having rheumatoid arthritis

**Conclusions:** Even in asymptomatic patients with chronic hepatitis C infection, US examination of the wrists and of the second and fifth interphalangeal joints may reveal abnormalities. Certain types of these are probably correlated with the presence of cryoglobulins and possibly associated with CRP levels, C3 levels and rheumatoid factors positivity.

Further studies are needed to verify our finding

**Disclosure of Interest:** None declared

#### SAT0669 99mTc-HDP SPECT/CT – A NEW METHOD IN EARLY DIAGNOSIS OF SACROILEITIS

R.A. Hemelein<sup>1</sup>, Z. Besenyi<sup>2</sup>, A. Bakos<sup>2</sup>, L. Kovács<sup>1</sup>, L. Pávics<sup>2</sup>. <sup>1</sup>Department of Rheumatology and Immunology; <sup>2</sup>Department of Nuclear Medicine, University of Szeged, Szeged, Hungary

**Background:** 99Tc hydroxyl-diphosphonate SPECT-CT (HDP SPECT-CT) is a hybrid imaging technology, which is a new modality in the examination of the sacroiliac joint. It is a high resolution, low dose structural computer tomography scan fused with a functional metabolism recording. Our aim was to investigate whether it is comparable in sensitivity with MRI, to analyse quantitatively the radioisotope uptake, to assess its potential in the assessment of inflammatory activity, and in the diagnosis of spondylarthritis (SpA).

**Objectives:** Seventeen patients (9 women, 8 men, mean age 35 years) were involved into the study from July 2016. The patients were selected according the following clinical features: inflammatory type low back pain raising the suspicion of axial SpA,<sup>17</sup> elevated CRP level,<sup>6</sup> HLA-B27 positivity,<sup>8</sup> associated oligo- or

polyarthritis,<sup>5</sup> dactylitis,<sup>1</sup> enthesitis,<sup>1</sup> psoriasis,<sup>1</sup> uveitis<sup>1</sup> and inflammatory bowel disease.<sup>1</sup> All patients were therapeutic-naïve for glucocorticosteroids, DMARDs or TNF- $\alpha$  inhibitors.

**Methods:** First, we performed examination of the sacroiliac joint with X-ray, to exclude those patients, who already had radiographic lesions. Then an MRI was performed in the following sequences: T2-weighted STIR for the bone marrow oedema (BME) and T1-weighted sequence for the fat metaplasia (FM). The HDP SPECT/CT was used within one week to examine the sacroiliac joint. Thereafter, the MRI images were fused with HDP SPECT/CT images. On the MRI images the BME (active lesion) and FM (chronic lesion), on the CT scans the sclerotic lesions (SCL, chronic lesion) were drawn manually as volume of interest (VOI). Uninvolved cortical areas were drawn on the different modality slices as reference region (ref). Then, we determined the isotope (99mTc-labelled HDP) uptake of the different lesions and areas.

**Results:** Four active sacroileitis and five chronic sacroileitis without active lesions were diagnosed according to the MRI results. On the other 8 patient's sacroiliac joints images (MRI, scintigraphy, CT scans), no inflammation-related lesions were observed. The MRI and HDP SPECT-CT findings were 100% concordant. The isotope uptake of BME was the highest, the radioisotope uptake of sclerotic lesions was moderate, whereas the isotope uptake of FM lesions was not different from the HDP uptake of reference regions.

**Conclusions:** According to the initial results, the different MRI lesions have different isotope uptake, which suggests, that the HDP SPECT/CT can distinguish the early and chronic stage of axial SpA from chronic lesions. Thank to whole body imaging technique we can have further information about disease activity and extent. The presented data are the first of our prospective study, and examinations of new patients are still in progress and we plan to investigate our SpA patients in remission to explore the utility of this new method in subclinical activity assessment. We also plan to investigate the corner lesions of the spine to find other potential uses of the HDP SPECT-CT imaging in SpA.

#### SAT0670 DYNAMIC THIOL/DISULFIDE HOMEOSTASIS AS A NOVEL OXIDATIVE MARKER IN BEHÇET'S DISEASE

S. Can Sandıkcı<sup>1</sup>, S. Colak<sup>2</sup>, A. Omma<sup>2</sup>, M.E. Enecik<sup>3</sup>, Z. Ozbalkan<sup>2</sup>, S. Neselioglu<sup>4</sup>, O. Erel<sup>4</sup>. <sup>1</sup>Rheumatology, Ankara Diskapi Yildirim Beyazit Training And Research Hospital; <sup>2</sup>Rheumatology, Ankara Numune Training and Research Hospital, Ankara; <sup>3</sup>rheumatology, Mersin City Hospital, Mersin; <sup>4</sup>Biochemistry, Yildirim Beyazit University, Ankara, Turkey

**Background:** Behçet's disease (BD) is a relapsing systemic inflammatory disorder of unknown etiology.<sup>1</sup>

**Objectives:** In this study, we aimed to evaluate the relationship between the thiol-disulfide balance and disease activity and organ involvement in BD.

**Methods:** One hundred fifty (150) patients with BD and 100 age-gender matched healthy controls were included in the study. Disease activity was assessed with the BD Current Activity Form (BDCAF) score. Serum levels of native thiol (NT), total thiol (TT), and disulfide were measured and the disulfide/native thiol, disulfide/total thiol and native thiol/total thiol levels were calculated for the patient and control groups.

**Results:** NT, TT, NT/TT values of the BD patients were significantly lower than those of the control group. The disulfide/NT, disulfide/TT values of BD patients were higher compared to the control group and the disulfide value of the BD group was slightly higher compared to the control group (table 1). No correlation was determined between thiol levels and disease activity and organ involvement in BD.

**Abstract SAT0670 – Table 1.** Laboratory results of the BD and the control group

	BD	HC	p
<b>Native Thiol (SH)(<math>\mu</math>mol/l)</b>	357.93 $\pm$ 76.65	453.01 $\pm$ 60.8	<b>0.000*</b>
<b>Total Thiol (<math>\mu</math>mol/l)</b>	398.57 $\pm$ 78.33	490.29 $\pm$ 58.48	<b>0.000*</b>
<b>Disulfide (<math>\mu</math>mol/l) (SS)</b>	20.32 $\pm$ 8.19	18.64 $\pm$ 7.87	<b>0.109</b>
<b>Disulfide/native thiol x100</b>	5.93 $\pm$ 2.76	4.25 $\pm$ 1.99	<b>0.000*</b>
<b>Disulfide/total thiol x100</b>	5.2 $\pm$ 2.13	3.86 $\pm$ 1.69	<b>0.000*</b>
<b>Native thiol/total thiol x100</b>	89.6 $\pm$ 4.26	92.28 $\pm$ 3.38	<b>0.000*</b>

\*p<0,05

**Conclusions:** In patients with Behçet's disease, the dynamic thiol-disulfide homeostasis balance shifted towards disulfide formation due to thiol oxidation. It may be used as a novel marker in BD because it is easy, practical, fully automated and relatively inexpensive.

**Acknowledgements:** The authors thank staff of Ankara Numune Training and Research Hospital, Department of Rheumatology for their generous friendly assistance in every step of this study.

**Background:** Magnetic resonance imaging (MRI) allows objective assessment of inflammation in peripheral joints and entheses. MRI scoring systems have until now focused on assessing specific parts of the musculoskeletal system in detail, e.g. the Rheumatoid Arthritis MRI Scoring System (RAMRIS), which is applied to wrist and metacarpophalangeal joints and adjacent tendon sheaths. The interest in a whole-body MRI approach is growing as modern MRI scanners now permit whole-body scanning within an acceptable time frame, and future improvements in MRI hardware and pulse sequences are expected to improve scan time and image resolution further.

**Objectives:** To develop a whole-body MRI scoring system for inflammation of peripheral joints and entheses and to investigate its feasibility and reliability.

**Methods:** Definitions of the key pathologies and locations for assessment have been agreed upon in the OMERACT MRI Working Group<sup>1</sup>. In a first round in June 2017, 9 readers (AJM/DG/FG/IE/MØ/PB/SJP/SK/WPM) scored MR images of 2 patients with spondyloarthritis using a draft web-based scoring system. Results were discussed and the scoring system was slightly modified. Hereafter, in a second round in October 2017, 14 MRI readers (3 musculoskeletal radiologist (IE/JLJ/RGL) and 11 rheumatologists with varying exposure to MRI (AJM/DG/FG/MS/MØ/PB/RP/SJP/SK/VF/WPM), scored 5 similar patients by the modified scoring system. Using a semiquantitative scale 0–3 (none/mild/moderate/severe), synovitis and osteitis were scored separately for 83 joints, and soft tissue inflammation and osteitis were scored separately for 33 entheses. Discrepancies between readers were discussed during an online meeting to obtain consensus, to train inexperienced readers, and to identify potential pitfalls when applying the scoring system.

**Results:** Inter-reader reliability was overall moderate for joint scores and poor for enthesis scores; however, among the 3 musculoskeletal radiologists, enthesis scores were as reliable as joint scores (Table). Reliability did not improve between the first and second round, possibly because patients with several very conspicuous inflammatory lesions were selected as cases in the first round.

**Abstract SAT0671 – Table 1.** Inter-reader reliability of scoring inflammation of peripheral joints and entheses (Cohen's kappa with squared weights for individual scores, ICC(3,1), agreement, for sum scores). All values are median (IQR; range) of all reader pairs (36 reader pairs for 9 readers, 91 reader pairs for 14 readers, 3 reader pairs for 3 readers [values for 3 reader pairs provided]).

	Kappa for osteitis scores (joints)	Kappa for synovitis scores (joints)	Kappa for osteitis scores (entheses)	Kappa for soft tissue inflamm. (entheses)	Kappa for all sites combined	ICC
First round (9 readers)	0.86 (0.81-0.90; 0.67-0.98)	0.63 (0.43-0.84; 0.26-0.94)	0.51 (0.27-0.63; 0.03-0.84)	0.36 (0.17-0.74; -0.08-0.92)	0.67 (0.62-0.75; 0.47-0.90)	0.64 (0.28-0.89; -0.26-1.00)
Second round (9 readers that had participated in first round)	0.61 (0.52-0.67; 0.36-0.80)	0.66 (0.61-0.70; 0.53-0.82)	0.33 (0.26-0.42; 0.02-0.69)	0.21 (0.12-0.31; -0.01-0.62)	0.53 (0.50-0.58; 0.42-0.70)	0.68 (0.60-0.82; 0.47-0.99)
Second round (all 14 readers)	0.48 (0.36-0.60; 0.10-0.80)	0.57 (0.45-0.66; 0.24-0.82)	0.32 (0.18-0.44; -0.06-0.80)	0.22 (0.12-0.35; -0.06-0.62)	0.47 (0.40-0.54; 0.25-0.72)	0.60 (0.30-0.75; -0.02-0.99)
Second round (3 musculoskeletal radiologists)	0.50 / 0.32 / 0.26	0.68 / 0.58 / 0.54	0.53 / 0.67 / 0.68	0.51 / 0.58 / 0.45	0.57 / 0.54 / 0.49	0.70 / 0.52 / 0.23

**Conclusions:** It is feasible to perform online multi-reader scoring exercises of whole-body MRI using a web-based scoring interface. MRI readers need to be further trained and calibrated in the semiquantitative scoring approach used to increase inter-reader reliability.

#### SAT0672 IS ULTRASOUND REMISSION ACHIEVABLE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS?

T. Serban<sup>1,2</sup>, I. Azzolin<sup>1</sup>, I. Satulu<sup>3</sup>, C.M. Mihai<sup>2</sup>, G. Massazza<sup>1</sup>, M. Bojinca<sup>2</sup>, A. Iagnocco<sup>1</sup>. <sup>1</sup>Università degli Studi di Torino, Turin, Italy; <sup>2</sup>Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; <sup>3</sup>Kalmar County Hospital, Kalmar, Sweden

**Background:** In rheumatoid arthritis (RA) the "window of opportunity" has a crucial role for better long-term outcomes.<sup>1</sup> The ACR/EULAR remission criteria for RA are mostly represented by clinical parameters, while ultrasound (US) is not included.<sup>2</sup> However, in early diagnosed and early treated patients, who fulfil the remission criteria, residual US modifications can be identified.<sup>3</sup>

**Objectives:** The aim of this study was to investigate whether significant US-detectable differences between early RA (ERA) patients treated for one year and healthy controls (HC) are present.

**Methods:** We enrolled in this cross-sectional study consecutive patients with ERA at 1 year after having initiated RA disease-modifying (DMARD) therapy and who had received treatment following RA recommendations. Only patients who had fulfilled EULAR/ACR 2010 criteria for RA<sup>4</sup> and with symptoms duration of less than 1 year at treatment initiation were included. US exams were performed in 10 joints bilaterally (wrist, MCP II-V) by using both gray-scale and Doppler for evaluating synovitis was graded according to a semi-quantitative 4-point scale (0–3). A total US score for synovitis was calculated by adding the values recorded at each joint site. The presence of erosions was also recorded. Finally, US results obtained in patients were compared to those detected in HC.

**Results:** 84 subjects were enrolled – 45 ERA patients and 39 HC. In ERA patients the mean duration of symptoms prior to diagnosis was 3.5±3.5 months. The demographic, clinical and US data are reported in table 1.

**Abstract SAT0672 – Table 1.** Demographic, clinical and US data for ERA patients and HC [n (%), mean±SD or median (IQR)]

Parameters	ERA (n=45)	HC (n=39)	p
Gender (Female)	28 (62.2%)	25 (64.1%)	0.859
Age	56.16±19.91	46.59 ±12.93	0.003
VAS pain	19 (10.25–30)	0 (0–2)	<0.001
US score	4 (1.5–6.5)	1 (0–3)	<0.001
Erosions	23 (51.11%)	0 (0%)	<0.001

As expected, the values of visual analogue scale (VAS) for pain and of the total US score and the incidence of erosions were significantly higher in ERA patients than in HC. The values of the US score correlated with the presence of erosions ( $r_s=0.427$ ,  $p<0.001$ ) as well as with the values of acute phase reactants (CRP:  $r_s=0.539$ ,  $p=0.412$  and ESR:  $r_s=0.412$ ,  $p=0.005$ ), VAS of disease activity reported by patients ( $r_s=0.473$ ,  $p<0.001$ ) and physician ( $r_s=0.412$ ,  $p<0.001$ ).

**Conclusions:** Patients with RA, who had been early diagnosed and early treated, after 1 year of tight control had still US inflammatory and erosive changes compared to HC. US assessment gives an added value to clinical evaluation in ERA, for its capacity to detect residual inflammatory abnormalities, even under optimised treatment and consequent structural lesions.

#### SAT0673 MAGNETIC RESONANCE IMAGING IN THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

T.J. Bray<sup>1</sup>, A. Jones<sup>1</sup>, P. Mandl<sup>2</sup>, H. Marzo-Ortega<sup>3</sup>, M.A. Hall-Craggs<sup>1</sup>, P. M. Machado<sup>1</sup> on behalf of British Society of Spondyloarthritis (BRISpA). <sup>1</sup>UCL, London, UK; <sup>2</sup>Rheumatology, Medical University of Vienna, Vienna, Austria; <sup>3</sup>NIHR LBRC, Leeds Teaching Hospitals Trust and LRMM, University of Leeds, Leeds, UK

**Background:** Magnetic resonance imaging (MRI) is an essential tool in the diagnosis and management of axial spondyloarthritis (axSpA). However, a recent survey showed variable practices in the use of MRI across the UK.<sup>1</sup> To inform a joint rheumatology and radiology consensus exercise aimed at standardising practice, we systematically reviewed the literature regarding the use of MRI in the diagnosis of axSpA.

**Objectives:** We aimed to answer three research questions:

1. How does the choice of anatomical region influence diagnostic performance?
2. How do MRI acquisition parameters influence diagnostic performance?
3. Which lesion, or combination of lesions, is most sensitive and specific for the diagnosis of axSpA?

**Methods:** MEDLINE (via Pubmed) and EMBASE (via Ovid) databases were searched using previously-reported terms.<sup>2</sup> These terms identified studies including adult patients with clinically suspected axSpA undergoing MRI, where a diagnosis of axSpA was used as an outcome and where patients with a negative test for SpA were used as controls. We included studies performed between January 2013 and March 2017, in addition to those included in a previous systematic literature review, which included all studies up to January 2013.<sup>2</sup> Search results were screened by title and abstract, and the included studies were subject to detailed review and quality assessment using the QUADAS-2 tool.<sup>3</sup>

**Results:** The combined search resulted in a total of 8114 studies; 34 of these were finally selected for inclusion.

Five studies evaluated the added value of spinal MRI over SIJ MRI alone, with variable results depending on the cohort.

Three studies addressed the effect of sequence choice on diagnostic accuracy, demonstrating comparable utility of fat-saturated T2-weighted (T2w) sequences and STIR imaging, and suggesting T2w Dixon imaging as a potential alternative

method for fat suppression. Three studies investigated the role of gadolinium in the SIJs, and overall found minimal added value.

Bone marrow oedema of the sacroiliac joint (SIJ) was found to be the most sensitive and specific lesion in the diagnosis of axSpA in seven studies. Sensitivity and specificity were increased by including other structural lesions, particularly bone marrow fat or erosions. Four studies addressed the utility of SIJ fat infiltration, demonstrating good sensitivity but relatively poor specificity. A number of studies addressing erosions, high T1 signal in the SIJ, fluid signal in the SIJ, ankylosis, sclerosis, capsulitis, backfill and vacuum phenomenon reported low to moderate diagnostic performance for these features. In the spine, four studies reported moderate sensitivity and specificity for corner inflammatory lesions, and four reported poor sensitivity and specificity for spinal fatty lesions.

Three studies evaluated agreement between observers for inflammatory and structural features. Agreement was best for the presence of oedema in the SIJs, but was poor for structural features. Agreement was weak to moderate for global diagnosis.

**Conclusions:** These results have informed the recommendations of a consensus group aiming to standardise practice around the use of MRI scans in the UK.

#### SAT0674 THE USE OF QUANTITATIVE MUSCLE ULTRASOUND AS A FOLLOW-UP TOOL IN INFLAMMATORY MYOSITIS AND DUCHENNE MUSCULAR DYSTROPHY IN CHILDREN

W.A. Hassan<sup>1</sup>, A.E.S. Elbrashy<sup>1</sup>, S.S. Ganab<sup>1</sup>, D.R. Lasheen<sup>1</sup>, E.A. Mohammady<sup>2</sup>.  
<sup>1</sup>Rheumatology and Rehabilitation; <sup>2</sup>Pediatric, Benha University Hospital, Benha, Egypt

**Background:** Ultrasound (US) can provide a painless and noninvasive tool for evaluation and follow up of muscle diseases especially in young children who may have restrictions in execution of muscle strength tests and functional scales.

**Objectives:** This study aimed to assess skeletal muscle structural status in children with Juvenile dermatomyositis (JDM) and Duchenne muscular dystrophy (DMD) using quantitative muscle US and to perform a longitudinal follow up of these changes over time and correlate these findings with clinical parameters, functional scales, biochemical and electromyographic tests.

**Methods:** This is a longitudinal study conducted on 35 subjects: 20 JDM patients and 15 DMD patients at baseline and after 12 months of follow-up. In all patients, Quantitative MSUS measurements was performed to the biceps brachii muscle (BB), the forearm flexors (FF), the rectus femoris muscle (RF), the tibialis anterior muscle (TA) according to a standard protocol.<sup>1</sup> The captured images were analysed offline for muscle thickness and echo intensity (EI) by means of computer-assisted grayscale histogram analysis. Manual muscle testing (MMT) was assessed and serum creatine kinase (CK) levels were measured. Also, Quantitative electromyography (QEMG) assessment was performed as BB and RF were studied on the most affected side with emphasis on motor unit potential (MUP) duration, area to amplitude ratio (AAR).

**Results:** In JDM patients, EI of the proximal muscles (BB and RF) at 12 months follow up (75.32±29.84 and 74.73±25.58 respectively) were highly significantly decreased compared to their baseline EI (127.18±50.62 and 100.68±33.65 respectively) (p<0.05). Also, EI of BB and RF at 12 months follow up showed statistically significant correlation with their MMT (r=-0.51, p<0.05), CK levels (r=0.42, p<0.05) and MUP duration (p<0.05). In DMD patients, EI of BB, RF and TA muscles at 12 months follow up (122.3±41.29, 132.55±41.38 and 136.75±38.02 respectively) were significantly increased compared to their baseline EI (116.7±42.65, 124±43.33 and 133.3±39.57 respectively, p<0.05). Also, EI of BB, RF and TA at 12 months follow up showed statistically significant correlation with their MMT (r=-0.67, -0.68 and -0.68 respectively, p<0.05), CK levels (r=0.77, 0.76 and 0.7 respectively, p<0.05), MUP duration (r=-0.73, -0.58 and -0.53 respectively, p<0.05) and AAR ratio (r=-0.79, -0.81 and -0.62 respectively, p<0.05). Logistic regression analysis showed that baseline EI were predictive of follow up MMT score in both JDM and DMD patients (p=0.03 and 0.01 respectively).

**Conclusions:** Quantitative muscle US is a sensitive, objective technique for measuring the presence and severity of muscle pathology in both JDM and DMD patients. EI is remarkably correlated with MMT, muscle enzymes and quantitative EMG suggesting that it could be a useful follow up tool to reflect disease severity and residual muscle damage.

#### SAT0675 SOLUBLE VASCULAR ADHESION MOLECULE-1 IS OVEREXPRESSED IN PATIENTS WITH VASCULITIS, RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS

W. Laaraj<sup>1</sup>, M.F. Seidel<sup>2</sup>. <sup>1</sup>University Hospital Bonn, Bonn, Germany; <sup>2</sup>Rheumatology, Schmerzklinik Basel, Basel, Switzerland

**Background:** Markers in rheumatology are in great demand in order to objectively diagnose the presence and activity of disease. CRP or ESR frequently are normal in many conditions. Vascular cell adhesion molecules mediate transendothelial migration. Several soluble isoforms can be measured in serum as marker for endothelial activation, for example in synovitis or vasculitis. We have recently shown that soluble vascular cell adhesion molecule-1 (sVCAM-1) is elevated in patients with positive antinuclear antibodies.<sup>1</sup>

**Objectives:** The objective of this study was to analyse sVCAM-1 in a set of several rheumatic diseases and compare them to age- and gender-matched healthy controls.

**Methods:** Cross sectional study with 223 patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA) and different vasculitides. Patients were treated with routine immunosuppressive agents, where indicated. CRP (mean mg/l±SD, normal <5), ESR (mean mm/h±SD), standard clinical disease activity scores (mean ±SD) and sVCAM-1 (ng/ml±SEM) in serum, determined by ELISA, was analysed.

**Results:** Patients with RA (n=136) had a DAS28 of 2.54±0.83, a close to normal CRP of 6.43±10.52, ESR of 16.9±12.6 and sVCAM-1 levels of 225.40±20.35 vs. 158.90±7.32 (p=0.0025). Patients with vasculitis (n=20) had a mean BVAS of 24.85±10.68, CRP was 5.86±7.77 mg/dl, ESR 14.5±11.5 and sVCAM-1 levels were also significantly different as compared to HC with 358.20±68.91 vs. 122.60±14.62 (p=0.0013). Patients with AS (n=33) had a mean BASDAI of 4.16±2.40, a CRP of 4.06±4.67, ESR 12.0±8.8 and had sVCAM-1 levels of 291.30±51.91 vs. 144.60±34.01 (p=0.021). Patients with PsA (n=34) did not show significant changes.

**Conclusions:** sVCAM-1 might be an objective disease marker in patients with RA, vasculitis and AS. It might be more reliable than standard CRP, especially in vasculitis. Prospective studies are needed to determine if sVCAM-1 is a predictive marker of disease activity and perhaps specific for biologic treatment regimens.

#### SAT0676 ULTRASOUND DETECTED INFLAMMATION IN RHEUMATOID ARTHRITIS: ELUCIDATING THE RELATIONSHIP WITH CLINICAL MANIFESTATIONS AT THE WRIST

Y.K. Tan<sup>1,2,3</sup>, R.B. Moorakonda<sup>4,5</sup>, J.C. Allen Jr<sup>5</sup>, P.G. Conaghan<sup>6,7</sup>, L. C. Chew<sup>1,2,3</sup>, J. Thumboo<sup>1,2,3</sup>. <sup>1</sup>Department of Rheumatology and Immunology, Singapore General Hospital; <sup>2</sup>Duke-NUS Medical School; <sup>3</sup>Yong Loo Lin School of Medicine, National University of Singapore; <sup>4</sup>Biostatistics, Singapore Clinical Research Institute; <sup>5</sup>Centre for Quantitative Medicine, Duke-NUS Medical School, Singapore, Singapore; <sup>6</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>7</sup>NIHR Leeds Biomedical Research Unit, Leeds, UK

**Background:** Tender and swollen joint counts are part of rheumatoid arthritis (RA) disease activity assessments. While subclinical synovitis is now a well-known entity, the relationship between tender and swollen joints and ultrasound (US) detected inflammation has not been well explored.

**Objectives:** To compare US detected inflammation (synovitis and/or tenosynovitis) with joint swelling and/or tenderness of the wrist, an important joint in RA. Tendons are included as tenosynovitis on US can be mistaken for joint involvement clinically.

**Methods:** Wrist outcome groups (Groups) 1–4 were identified: 1=S0 T0 (not swollen, not tender); 2=S0 T1 (not swollen but tender); 3=S1 T0 (swollen but not tender); 4=S1 T1 (swollen and tender). Power Doppler (PD) and grey-scale (GS) US were used to grade (a) synovitis semi-quantitatively (0–3) at the following joint recesses: dorsal radiocarpal and intercarpal, dorsal ulnocarpal and volar radiocarpal, and (b) tenosynovitis dichotomously (0=no, 1=yes) at the following tendon sites: extensor digitorum, extensor carpi ulnaris, and flexor digitorum. Scores on each wrist consisted of a PD score, a GS score and a combined (PD +GS) US (CUS) score. Positivity (+ve) for PD, GS and CUS scores was analysed using a generalised linear repeated measures mixed model with binary distribution and logit link. Scores were analysed using a general linear repeated measures mixed model assuming Gaussian errors. In both analyses, patients were modelled as random effects, and wrist (R/L) and follow up visit (baseline, 3 months) as fixed effects. Pairwise comparisons on +ve and scores were carried out among the 4 groups in the context of the models. P-values were not adjusted for multiple comparisons.

**Results:** 122 wrist assessments resulted from 32 RA subjects (87.5% female; 78.1% Chinese; mean (SD) disease duration of 42.8 (52.9) months) who either started or escalated on systemic corticosteroids and DMARDs. All subjects were assessed at baseline and 29 at 3 months. Significant differences among Group scores were: 4 vs 1 (PD, p=0.0031; GS, p=0.0159; CUS, p=0.0045), 4 vs 2 (PD, p=0.0176; GS, p=0.0160; CUS, p=0.0074), and 4 vs 3 (CUS, p=0.0374). Significant differences among +ve were: 4 vs 1 (PD, p=0.0007), 4 vs 2 (PD, p=0.0234), and 3 vs 1 (PD, p=0.0202). No significant Group differences were found for 2 vs 1 (for +ve and scores) and when comparing the 4 groups for GS +ve and CUS +ve. Table 2 shows the frequency distribution of patients by wrist and follow up. There were no significant effects attributable to differences in wrists or follow up visit (p-values all >0.05).

**Abstract SAT0676 – Table 1.** Analysis summary of ultrasound scores and positivity in the wrist.

**Epidemiology, risk factors for disease or disease progression**

**SAT0677 PREVOTELLA COPRI IN INDIVIDUALS AT RISK FOR RHEUMATOID ARTHRITIS**

D. Alpizar-Rodriguez<sup>1</sup>, T.R. Lesker<sup>2</sup>, A. Gronow<sup>2</sup>, E. Raemy<sup>1</sup>, C. Lamacchia<sup>1</sup>, D. Courvoisier<sup>1</sup>, C. Gabay<sup>1</sup>, A. Finckh<sup>1</sup>, T. Strowig<sup>2</sup>. <sup>1</sup>HUG, Geneva, Switzerland; <sup>2</sup>Helmholtz Centre for Infection Research, Braunschweig, Germany

**Background:** *Prevotella spp.* have been identified as highly enriched in the intestinal microbiota of patients newly diagnosed with rheumatoid arthritis (RA), suggesting a role in the development of the disease.<sup>1</sup> Sequence homology between RA-specific autoantigens and proteins of *Prevotella copri* have been reported.<sup>2</sup> However, the role of these bacteria in the pathogenesis of the disease is not yet established.

**Objectives:** To determine the microbiome composition and prevalence of *Prevotella spp.* in different pre-clinical phases of RA, in a group of individuals at risk for RA, namely first degree relatives of patients with RA (RA-FDR).

**Methods:** In an ongoing cohort study of RA-FDR, enrolling individuals without clinical evidence of RA at inclusion, we categorised individuals in the following groups: 'healthy controls': asymptomatic RA-FDR without any autoantibodies or symptoms associated with possible RA; 'pre-clinical RA': individuals with 'systemic autoimmunity associated with RA' defined by the presence of anti-citrullinated peptide antibodies (ACPA) or rheumatoid factor (RF) and/or symptomatic individuals with clinically suspect arthralgias or unclassified arthritis. Participants provided stool samples for microbiome analysis. We excluded subjects who had undergone antibiotic therapy within the last 3 months, with known history of inflammatory bowel disease and/or gastrointestinal tract surgery ever. Stool samples processing and microbial diversity culture-independent analyses were performed. After DNA extraction, the V4 region of the 16S rRNA gene was amplified using barcoded primers and sequencing was done on an Illumina MiSeq. Statistical analyses of community structures were performed.<sup>3</sup>

**Results:** Of the 134 participants enrolled, 51 were categorised as 'healthy controls' and 83 as 'pre-clinical RA'. table 1 shows the general characteristics of the two groups. The microbiota of 'pre-clinical RA' individuals was significantly altered compared to 'healthy controls', with abundance of specific bacteria, particularly an enrichment of *Prevotella spp.* (figure 1).

**Abstract SAT0677 – Table 1.** General characteristics of participants

Characteristics	Healthy controls n=51	Pre-clinical RA** n=83
Age, median (IQR)	55 (47–62)	58 (50–66)
Female sex, n (%)	39 (76)	74 (89)
Current Smoking, n (%)	12 (23)	16 (19)
Current Alcohol, n (%)	22 (46)	29 <sup>††</sup>
Body mass index, median (IQR)	24 (22–27)	24 (22–27)
Obesity, BMI≥30, n (%)	5 (10)	9 (11)
ACPA positivity, n (%)	0 (0)	38 (46)*
RF positivity, n (%)	0 (0)	28 (34)*
Shared epitope (1 or 2 copies), n (%)	32 (65)	42 (52)

\*p-value<0.05, Kruskal-Wallis test for continuous variables and Fisher's exact test for categorical variables. \*\*Pre-clinical RA group includes individuals with ACPA or RF positivity and/or with arthralgia or unclassified arthritis.

**Abstract SAT0677 – Figure 1.** Linear discriminant analysis (LDA) effect size (LEfSe) estimates the different relative abundance of bacteria in Healthy controls and Pre-clinical RA participants

**Conclusions:** Individuals at risk of RA who have developed systemic autoimmunity associated with RA and/or symptoms, have enrichment of *Prevotella spp* in comparison with healthy controls. Our findings support the hypothesis of a causal role of *Prevotella spp* in the development of RA, which could lead to future attempts to interfere with its intestinal colonisation during the preclinical stages of disease.

**SAT0678 SEASONALITY OF NEW EARLY INFLAMMATORY ARTHRITIS CASES: PRELIMINARY RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT**

E. Kudaeva<sup>1</sup>, M. Speechley<sup>1</sup>, N. Klar<sup>1</sup>, O. Schieir<sup>2</sup>, S. Bartlett<sup>3</sup>, C. Hitchon<sup>4</sup>, G. Boire<sup>5</sup>, B. Haraoui<sup>6</sup>, E. Keystone<sup>7</sup>, D. Tin<sup>8</sup>, C. Thorne<sup>9</sup>, V. Bykerk<sup>10</sup>, J. Pope<sup>11</sup> on behalf of CATCH investigators. <sup>1</sup>Epidemiology and Biostatistics, Schulich School of Medicine and Dentistry, Western University, London; <sup>2</sup>Department of Epidemiology, University of Toronto Dalla Lana School of Public Health, Toronto; <sup>3</sup>Department of Medicine, McGill University, Montreal; <sup>4</sup>Department of Medicine, University of Manitoba, Winnipeg; <sup>5</sup>Department of Medicine, Universite de Sherbrooke, Sherbrooke; <sup>6</sup>Rheumatic Disease Unit, Institut de Rheumatologie, Montreal; <sup>7</sup>Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto; <sup>8</sup>Allied Health Professional Association; <sup>9</sup>Division of Rheumatology, Southlake Regional Health Centre, Newmarket; <sup>10</sup>Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto; <sup>11</sup>Division of Rheumatology, St. Joseph Health Care, Schulich School of Medicine and Dentistry, London, Canada

**Background:** Disease clustering suggests a possible environmental cause. However, confirming the causes of time-place clustering is challenging. Rheumatoid arthritis (RA) is an autoimmune disease that may be triggered by environmental factors: viral or bacterial infections can lead to RA via molecular mimicry, epitope spreading, B-cell-mediated pathway, bystander activation and via superantigens. Putative infections may also cluster.

**Objectives:** To study the seasonal distribution of early inflammatory arthritis (IA) onsets in a Canadian sample, and potential relationships with influenza (flu) outbreaks.

**Methods:** Data from an incidence cohort of adults (>18 years) with early IA with <13 months symptom duration from the Canadian Early Arthritis Cohort (CATCH) enrolled between January 2007 – January 2017. Patient-reported date of symptom onset and physician-reported date of IA onset were used to estimate the monthly frequency of early inflammatory arthritis onsets. Monthly flu case frequencies from September 2010 – December 2016 were retrieved from the Public Health Agency of Canada’s FluWatch national surveillance system of confirmed influenza A and B cases. Time-series Poisson regression analyses were performed to assess the non-random covariance of IA and flu with different hypothesised time lags.

**Results:** A total of 2262 with early IA were included. Patient-reported IA onset was more frequent in winter months compared to other seasons (p=0.002), with peaks in January (figure 1). The ten-year aggregated data also showed January peaks of IA onset. There was a positive linear correlation between the number of IA and influenza A onsets (r=0.23, p=0.045), and almost no relationship between the number of IA and influenza B cases (p=0.87) (figure 2).

**Abstract SAT0678 – Figure 1**

**Abstract SAT0678 – Figure 2**

**Conclusions:** Our study provides novel information on the increased onset of IA in relation to seasonal influenza patterns in a Canadian population and adds to the existing literature supporting viral infections as a possible trigger to RA onset.

**SAT0679 CIGARETTE SMOKING AND RISK OF BEHCET’S DISEASE: A CASE-CONTROL STUDY**

A. Khabbazi, A. Malekmahdavi. Internal medicine, Connective Tissue Diseases Research Center, Tabriz university of medical sciences, Tabriz, Iran, Islamic Republic Of

**Background:** Behcet’s disease (BD) is a chronic inflammatory multisystem disease characterised by recurrent oral and genital aphthous ulcers, uveitis and skin lesions. Smoking play an important role in the development of inflammatory diseases.<sup>1</sup>

**Objectives:** BD is an inflammatory disease and smoking may have a role in its triggering. Although few studies reported association between smoking and clinical manifestations of BD, to the best of our knowledge, there is no research on the risk of developing BD in smokers.<sup>2–4</sup> This case-control study was conducted to investigate the association between smoking and the risk of BD.

**Methods:** We included 192 patients with BD and 822 healthy siblings of patient with BD and 373 age and sex matched healthy unrelated persons as control groups (table 1). Written informed consent was obtained from all the participants. Demographic data and smoking history of patients and their siblings were obtained by direct and in some cases by telephone interview with the participants. Demographic data and smoking history of healthy controls were obtained by direct interview. Current and former smokers were classified together as ever smokers for the purposes of this analysis. We carried out multivariate analyses with a logistic regression model with BD as the main outcome variable and smoking history as the main predictor variable. Models were adjusted for age, gender, marital status, educational status and pack-years.

**Results:** The patients with BD were more often ever smokers than healthy siblings of patients and healthy unrelated controls (table 1). However, pack-years of smoking in control groups were significantly more than the BD group. By multivariate logistic regression and after adjustment for age, sex, marital status and educational status (model 1), ever smoking was significantly associated with an increased risk of BD compared with never smoking. In comparison with healthy siblings and healthy unrelated persons who never smoked, the relative risk (RR) of developing BD was 1.43 and 1.51, respectively. After including pack year in multivariate analysis (model 2), the RR of developing BD in ever smokers increased to 2.23 and 2.01, respectively.

**Abstract SAT0679 – Table 1.** Demographic characteristics of participants

Variables	BD group (n=192)	Healthy sibling group (n=822)	P-value	Healthy unrelated control group (n=373)	P-value
Age (years)	38.9±10.6	39.3±11.3	NS	37.9±9.7	NS
Gender:			0.001		NS
Male	118 (61.5)	399 (48.5)		228 (61.1)	
Female	74 (38.5)	423 (51.5)		145 (38.9)	
Smoke status			0.01		0.025
Never-smoker	141 (73.4)	673 (81.9)		302 (81)	
Current smokers	43 (22.4)	138 (16.8)		58 (15.5)	
Past smokers	8 (4.2)	11 (1.3)		13 (3.5)	
Ever smokers	51 (26.6)	149 (18.1)		71 (19)	
Pack-years of smoking	11.19±8.8	17.79±11.4	0.003	14.19±10.7	0.007

Qualitative and quantitative variables were displayed as numbers (percentages) and means ±SD, respectively.

BD: Behcet’s disease; NS: non-significant

No significant differences were observed in the clinical manifestations of BD patients in ever smokers and never smokers. However, disease activity, at disease presentation and last visit in ever smokers was significantly more than never smokers.

**Conclusions:** Our data suggest that smoking is a significant risk factor for BD and genetic factors may play an important role in the developing of BD in smokers. We also show a particularly strong relationship between smoking with BD activity and response to treatment.

**Conflict of interest:** We have no potential conflict of interest.

### SAT0680 THE DEVELOPMENT AND VALIDATION OF INTERSTITIAL LUNG DISEASE PREDICTION MODELS IN THREE INTERNATIONAL MIXED CONNECTIVE TISSUE DISEASE COHORTS: THE NORWEGIAN MCTD COHORT, THE HUNGARIAN MCTD COHORT AND THE MCTD COHORT FROM MINNESOTA, US

S. Reiserter<sup>1</sup>, P. Ungprasert<sup>2</sup>, R. Gunnarsson<sup>1</sup>, Ø. Molberg<sup>1</sup>, M.B. Lund<sup>3</sup>, T. M. Aaløkken<sup>4</sup>, P. Szodoray<sup>5</sup>, E. Bodolay<sup>6</sup>. <sup>1</sup>Rheumatology, Oslo University Hospital, Oslo, Norway; <sup>2</sup>Rheumatology, Mayo Foundation for Medical Education and Research, Rochester, USA; <sup>3</sup>Respiratory Medicine; <sup>4</sup>Radiology, Oslo University Hospital; <sup>5</sup>Centre for Immune Regulation, University of Oslo, Oslo, Norway; <sup>6</sup>Clinical Immunology, University of Debrecen, Debrecen, Hungary

**Background:** Mixed Connective Tissue Disease (MCTD) is characterised by the presence of anti-RNP antibodies with clinical features also found in SSc, SLE and IIM. There is an ongoing debate of MCTD's position as a CTD. A substantial proportion of MCTD patients develop Interstitial Lung Disease (ILD).

**Objectives:** This study was conducted with the aims to explore the value of MCTD diagnosis and risk assessment by developing and validating ILD prediction models.

**Methods:** Multivariable logistic regression analyses were performed in 3 international MCTD cohorts. ILD prediction model development from clinical and laboratory parameters was performed in the Norwegian MCTD cohort (n=119). External validation of the models were performed in the Hungarian MCTD cohort (n=196) and the MCTD cohort from Minnesota, US (n=50). ILD was diagnosed by chest CT examination.

**Results:** The cohort characteristics are presented in table 1. An ILD prediction model including Pulmonary Function Test (PFT) results (table 2) and excluding PFT results was developed. The Hosmer-Lemeshow goodness of fit test (HL test) was. 31 and. 71 and the ROC was. 83 and. 78 respectively. The ILD prediction model including DLCO <60% was validated in the Hungarian MCTD cohort and showed good calibration and discrimination (HL test=0.95 and ROC=0.82). The ILD prediction model excluding PFT results showed good calibration and discrimination in both the Hungarian MCTD cohort (HL test=0.72 and ROC=0.80) and the MCTD cohort from Minnesota (HL test=0.96 and ROC=0.67).

**Abstract SAT0680 – Table 1.** Characteristics of the three MCTD cohorts

Characteristics	Norwegian MCTD cohort (n=119)	Hungarian MCTD cohort (n=196)	Minnesota MCTD cohort (n=50)	P- value

<b>Never arthritis</b>	<b>5.4</b>	<b>2.1–13.6</b>	<b>&lt;0.001</b>	<b>4.1</b>	<b>1.4–11.6</b>	<b>0.008</b>
<b>Pericarditis</b>	<b>2.2</b>	<b>0.8–6.1</b>	<b>0.117</b>			
<b>Agegroup at CT</b>						
<25 years						
26–35 years	1.0	0.2–4.5	0.953	1.8	0.3–9.8	0.504
36–45 years	2.6	0.6–	0.213	4.8	0.9–25.5	0.065
46–55 years	1.7	11.7.	0.513	2.9	0.5–14.7	0.210
56–65 years	2.3	4–7.4.	0.289	3.7	0.6–23.9	0.167
>65 years	6.0	5–10.8	0.048	13.0	1.6–	0.017
		1.0–35.4			107.3	

**Conclusions:** The cohorts have different characteristics. Despite these differences the ILD prediction models developed in the Norwegian MCTD cohort have shown external validity when assessed in the Hungarian MCTD cohort and the MCTD cohort from Minnesota. Risk factors of ILD in MCTD patients are high levels of anti-U1 RNP antibodies, absence of arthritis and increasing age. The successive ILD prediction across different MCTD cohorts strengthens the value of MCTD diagnosis and anti-RNP antibody detection in clinical practice.

### SAT0681 THE CAUSAL ASSOCIATION BETWEEN CHILDHOOD AND ADULTHOOD BODY MASS INDEX AND OSTEOARTHRITIS: A MENDELIAN RANDOMIZATIONSTUDY

A. Prats-Uribel<sup>1,2</sup>, S. Sayols-Baixeras<sup>2,3</sup>, A. Fernández-Sanlés<sup>2,3</sup>, T. Duarte-Salles<sup>4</sup>, J. Logue<sup>5</sup>, R. Elosua<sup>2,6,7</sup>, D. Prieto-Alhambra<sup>8</sup>. <sup>1</sup>UDMPiSP PSMAR-UPF-ISGLOBAL; <sup>2</sup>Cardiovascular Epidemiology and Genetics Research Group, REGICOR, IMIM; <sup>3</sup>Universitat Pompeu Fabra; <sup>4</sup>Idiap Jordi Gol, Barcelona, Spain; <sup>5</sup>Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, UK; <sup>6</sup>CIBERCV, Barcelona; <sup>7</sup>Medical School, UVic-UCC, Vic, Spain; <sup>8</sup>Centre for Statistics in Medicine, NDORMS, University of Oxford, Oxford, UK

**Background:** Childhood obesity is a strong predictor of adult obesity. Body mass index (BMI) has been associated with a dose-response increase in risk of osteoarthritis. However, studying causality in this association is difficult due to confounding factors

**Objectives:** To study the causal association of childhood and adult BMI on the risk of developing osteoarthritis using Mendelian Randomization (MR) methods

**Methods:** A two-step MR analysis was conducted. Exposures were determined by reviewing data from two genome-wide association study (GWAS) from >47,000 children describing 15 SNPs associated with childhood BMI, and another GWAS describing 97 SNPs related to BMI within 3 39 224 adults. For the

outcomes, data gathered from a GWAS analysing 3 37 000 unrelated individuals in the UK BioBank was used to assess the association between the SNPs of interest and self-reported osteoarthritis and ICD10 linked hospital data: knee, hip and first carpo-metacarpal joint osteoarthritis. Traumatic eye injury from the same cohort was used as a negative control. An inverse variance weighted meta-analysis estimator was used to test for association. In presence of heterogeneity, a weighted median approach was used and, when necessary, pleiotropy was controlled for using the MR Egger method. All analyses were performed using the TwoSampleMR package in R

**Results:** 14 and 91 SNPs associated with BMI in the childhood and adulthood were identified in the UK BioBank GWAS respectively. Association between childhood BMI and adult OA was seen for self-reported and hip and knee OA. Adult BMI also appeared associated with them [figure 1]. Conversely, no associations were found between BMI (either childhood or adult) and Hand OA risk. Finally, no relationship was seen between BMI and traumatic eye injury (negative control)

	Adult BMI		Child BMI	
	OR	95% CI	OR	95% CI
S-R OA	1.027	1.019–1.036	1.017	1.011–1.023
Hip OA	1.005	1.002–1.007	1.006	1.002–1.010
Knee OA	1.012	1.010–1.015	1.006	1.003–1.009
Hand OA	1.001	0.999–1.001	1.000	0.999–1.001
Eye Injury	0.999	0.994–1.003	0.999	0.993–1.004

**Conclusions:** Higher BMI in both childhood and adulthood overweight/obesity cause an excess in risk of knee and hip osteoarthritis. Whilst the effect of adult BMI seems stronger on knees, childhood BMI might impact both knee and hip osteoarthritis risk similarly. Age-specific associations should be treated with caution given significant overlap between loci associated with BMI across age ranges. In contrast, our findings contradict previous cohorts that found an association between overweight/obesity and hand osteoarthritis, which could be explained by confounding factors such as manual work or related socio-economic factors. The association between increased BMI and knee or hip osteoarthritis adds further impetus to strategies for the prevention of childhood and adult obesity in order to reduce subsequent disability.

**“INCIDENCE AND REGIONAL VARIATION OF ANKYLOSING SPONDYLITIS AND SPONDYLOARTHRITIS 2000–2013: A NATIONWIDE COHORT STUDY”**

A. Nygaard<sup>1</sup>, P.M. Ljungdahl<sup>2</sup>, M. Iachina<sup>2</sup>, B. Schiøtz-Christensen<sup>1</sup>. <sup>1</sup>Spinecentre of Southern Denmark, Middelfart; <sup>2</sup>Center for Clinical Epidemiology, Odense University Hospital, and Research Unit of Clinical Epidemiology, University of Southern Denmark, Odense, Denmark

**Background:** Spondyloarthritis is a group of inflammatory rheumatic diseases with Ankylosing Spondylitis (AS) as the major subgroup. Only a few studies worldwide have reported incidences of AS and their trend over time.

**Objectives:** To describe the incidences of Ankylosing Spondylitis (AS) and spondyloarthritis (SpA) in the Danish population in 2000–2013, at both national and regional level. To establish if there is a trend in incident cases over time and test if such a trend may be explained by use of MRI scans for diagnostic evaluation.

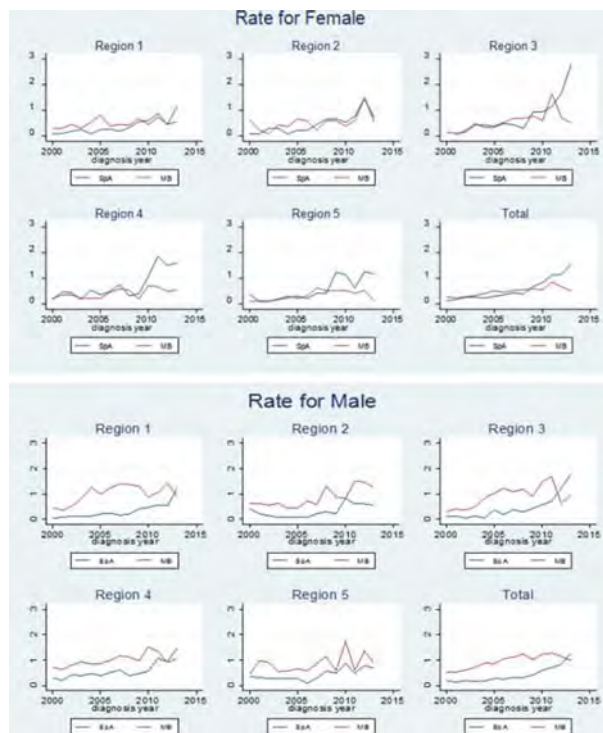

**Methods:** In the Danish National Patient Registry, we identified all patients with a valid Danish civil registration number who received an AS (ICD10:DM45) or SpA (ICD10:DM46) diagnosis during the time period from 1 January 2000 until 31 December 2013. Incident cases were identified and incidence rates described as rates per 1/100.000 of AS and SpA were calculated for each year. Variation among the five Danish regions were evaluated and correlated to the diagnostic use of MRI.

**Results:** We identified 3620 incident cases (AS: 2116, SpA: 1504). Males are overrepresented among AS incidents (58%–80%), both nationwide and regionally. The percentages of males with an AS diagnosis are stable throughout the time period (65%–69%). Females are overrepresented among SpA incidents nationwide and in most regions. In the Region of Southern Denmark, there is a small overrepresentation of males for both SpA and AS diagnoses (58%).

The number of nationwide AS incident cases increases between 2005 and 2009 from 534 (rate: 0.52) to 828 cases (0.82). During 2010–2013 the AS incidence decreased to 754 (0.94).

The number of SpA incident cases increased from 220 (0.21) in 2009 to 430 (0.43) in 2009 with an additional increase in incidence to 854 (1.06) in 2010–2013. The trend is the same throughout the five regions.

MRI was used for diagnostic purposes in only 10%–15% of the patients in 2002. In 2013 the number had increased to 95.0% of male patients and 94.3% of female patients diagnosed with AS and 98.5/98.1% of patients diagnosed with SpA.

**Conclusions:** In this Danish nationwide cohort, the incidence of AS increased during the years 2000–2004 and stabilised in 2005–2013 which is in line with previous studies exploring the trends of AS incidence.

The SpA incidence increased significantly during the years 2000 to 2013. This might be caused by the implementation of the ASA criteria in 2009, which included the “imaging arm”, and by increased access to MRI for diagnostic evaluation in patients with low back pain. This might lead to overestimation and/or misdiagnosis

of SpA because signs of inflammatory changes in the sacroiliac joint are a common finding in MRIs of low back pain patients.

**Objectives:** To analyse the influence of geolocation on the clinical systemic presentation of primary Sjögren syndrome (SjS) at diagnosis.

**Methods:** The Big Data Sjögren Project Consortium is an international, multi-centre registry created in 2014. Centres were classified by continent, with an additional north-south sub-classification according to latitude (>or<50°N in Europe, equator >or<in America and >or<30°N in Asia). Systemic involvement at diagnosis was retrospectively scored using the ESSDAI.

**Results:** The highest baseline ESSDAI scores were reported from Southern vs Northern countries in Europe (7.2 vs 4.6, p<0.001), America (5.3 vs 3.5, p<0.001) and Asia (6.3 vs 3.9, p<0.001). In Europe, the frequency of activity in each domain was higher in Southern countries (in all domains except constitutional, p<0.001). In America, Southern countries had the highest frequencies of active patients in constitutional, articular, cutaneous, pulmonary, PNS and CNS domains (p<0.001 in all) and the lowest frequencies in lymphadenopathy (p=0.018) and biological (p<0.001) domains. In Asia, patients from China had the highest frequency of activity in glandular, articular, pulmonary, muscular, haematological and biological and those from India in lymphadenopathy, cutaneous, renal and PNS.

**Conclusions:** This study provides the first evidence for a strong influence of geolocation on the systemic phenotype of primary SjS at diagnosis. Geographical determinants should be considered as key variables when systemic disease is scored.

#### APPENDICITIS AND THE RISK OF NEWLY DIAGNOSED SYSTEMIC SCLEROSIS: A NATIONWIDE, POPULATION-BASED, CASE-CONTROL STUDY IN TAIWAN

H.-H. Chen<sup>1,1,1</sup>, K.-L. Lai<sup>2</sup>, D.-Y. Chen<sup>3</sup>. <sup>1</sup>Department of Medical Research; <sup>2</sup>Division of Allergy, Immunology and Rheumatology; <sup>3</sup>Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China

**Background:** Previous studies suggested that patients with systemic sclerosis (SSc) had specific alterations in the gastrointestinal microbiota, including increased levels of pathobiont genera, such as Fusobacterium. Local expansion of Fusobacterium was also found in children with acute appendicitis. However, no prior study had explored the association between incident SSc and prior appendicitis.

**Objectives:** To explore the association between appendicitis and the risk of incident systemic sclerosis (SSc).

**Methods:** Using the 2003–2012 claims data of the entire population in Taiwan, we identified 1595 patients with a new diagnosis SSc (ICD-9-CM 710.1) validated by a thorough review of the original medical record from 2006 to 2012 as SSc cases. We also selected 15 950 individuals who never had a diagnosis of SSc during 2003–2012 matching SSc cases (1:10) for age, sex, and the year of index date from claims data of a one million representative Taiwanese population as non-SSc controls. The index date was defined the first date of SSc diagnosis in the SSc group and the first date of ambulatory visit for any reason in the control group. Using conditional logistic regression analysis, The association between appendicitis (ICD-9-CM 540–543) and the risk of incident SSc was tested by estimating odds ratios (ORs) with 95% confidence intervals (CIs) controlling for potential confounders, including Charlson comorbidity index, a history of periodontal disease (ICD-9-CM 523), salmonella infection (ICD-9-CM 003), and intestinal infection (ICD-9-CM 009). We also performed sensitivity analyses by varying the definition of appendicitis according to the status of receiving primary appendectomy.

**Results:** The mean ±SD age was 51±15 years in both cases and controls. The proportion of women was 77.5%. Appendicitis was identified in 17 (1.1%) of 1595 SSc cases and 81 (0.5%) of 15 950 non-SSc controls before the index date had a history of appendicitis. A significant association between appendicitis and the risk of SSc was demonstrated (OR, 2.03; 95% CI, 1.14–3.60) after adjustment for potential confounders. The association between appendicitis and SSc risk was still statistically significant using various definitions of tonsillitis based on the status of primary appendectomy.

	Univariate	Multivariate
	OR (95% CI)	OR (95% CI)
Appendicitis	2.11 (1.25–3.57)	2.03 (1.14–3.60)
Primary appendectomy	2.04 (1.17–3.57)	1.93 (1.06–3.54)
Appendicitis with primary appendectomy	2.07 (1.18–3.62)	1.97 (1.07–3.61)
Appendicitis or primary appendectomy	2.09 (1.23–3.53)	1.99 (1.13–3.53)

**Conclusions:** The present study reveals an association between SSc risk and a history of appendicitis.

### TEMPERATURE AND SMALL PARTICULATE MATTER POLLUTION ARE ASSOCIATED WITH ORGAN SPECIFIC LUPUS FLARES: A SPATIO-TEMPORAL ANALYSIS

G. Stojan<sup>1</sup>, A. Kvit<sup>2</sup>, F. Curriero<sup>2</sup>, M. Petri<sup>1</sup>. <sup>1</sup>Rheumatology, Johns Hopkins University; <sup>2</sup>Epidemiology, Bloomberg School of Public Health, Baltimore, USA

**Background:** Understanding the role of environmental exposures in the development of SLE and their association with SLE activity may help identify modifiable risk factors and potential etiological mechanisms. Cluster detection is an essential tool in public health which has the goal of detecting anomalous clusters of disease cases.

**Objectives:** We performed a spatial-time cluster analysis of the Johns Hopkins Lupus cohort with the goal of identifying potential spatial-time clusters of SLE organ specific disease activity related to temperature changes and fine particulate matter pollution (PM2.5).

**Methods:** 1261 patients who fulfil 4 of the 11 American College of Rheumatology classification criteria for SLE and who had recorded home addresses were included in the analysis. Disease activity was expressed as Physician Global Estimate (PGA), and included rash, joint, serological, neural, renal, pulmonary, and haematological flare-ups. The area utilised in this analysis was a 350 kilometre radial buffer around the Johns Hopkins Lupus Centre. This area was considered due to the high and consistent density of study participants. The data ranged from January 1999 to February 2009. Average temperature and PM2.5 exposure over a period of 10 days prior to patient visit was obtained from the United States Environmental Protection Agency, and county level demographics were obtained from the US census. Univariate, multivariate, and multilevel models were built in order to study the association of these variables with lupus flare-ups. The models were adjusted for age, sex, income, racial distribution, and rural vs. urban patient residence.

**Results:** Rash (OR=1.0075 for 1 degree Fahrenheit(F) increase), neurologic (OR=1.0096 for 1 degree F increase), and joint (OR=1.011 for 1 degree F increase) flares were statistically significantly associated with an increase in temperature in univariate and multivariate analysis. Renal flares were negatively associated with increases in temperature (OR=0.996 for 1 degree F increase) in both univariate and multivariate analysis. Serositis flares were found to be associated in both univariate and multivariate analysis with increases in PM2.5 concentration (OR=1.024 for an increase of 1 ug/m<sup>3</sup>), as were hematologic flares (OR=1.019 for an increase of 1 ug/m<sup>3</sup>), and joint flares (OR=1.011 for an increase of 1 ug/m<sup>3</sup>). Maps were generated highlighting the study area and the flares. After adjusting for temperature and PM2.5, rash, neurologic, and renal flare-up clusters changed spatially and temporally, suggesting that the adjustment variables could be contributing causes to the original clusters of these kinds of flare-ups.

**Conclusions:** An increase in temperature was found to be significantly associated with skin, joint, and neurologic flares and inversely associated with renal flares, while increase in fine particulate matter pollution was significantly associated with serositis and hematologic flares. Spatiotemporal cluster adjustment for PM2.5 and temperature changed the neurologic, renal, and rash flare up clusters both spatially and temporally further supporting that these variables could be contributing causes to the original flare clusters. The clusters that remained unchanged indicate areas of unexplained variation that requires further study.

SAT0686

### ARE MRI-DETECTED EROSIONS IN PATIENTS WITH UNDIFFERENTIATED ARTHRITIS PREDICTIVE FOR THE DEVELOPMENT OF RHEUMATOID ARTHRITIS? A LARGE LONGITUDINAL STUDY

D.M. Boeters<sup>1</sup>, A.C. Boer<sup>1</sup>, A.H. van der Helm – van Mil<sup>1,2</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden; <sup>2</sup>Rheumatology, Erasmus University Medical Center, Rotterdam, Netherlands

**Background:** Radiographic erosions are a clear hallmark of rheumatoid arthritis (RA) and the presence of radiographic erosions according to the EULAR definition is sufficient to classify patients as RA. Recently, the use of MRI has been recommended to detect erosions since it is more sensitive than radiography. To determine the specificity of MRI-detected erosions, we recently compared hand and foot MRI of patients presenting with RA with those of symptom-free persons and

patients presenting with other arthritides. This revealed that many MRI-detected erosions were not specific for RA but a few erosion features were identified as specific for RA. These were grade  $\geq 2$  erosions (defined as  $>10\%$  of bone eroded), erosions located in MTP5, and erosions located in MTP1 in persons aged  $<40$ . These results were derived by comparing patients that already received their final diagnosis. A clinically relevant question is whether MRI-detected erosions in patients presenting with undifferentiating arthritis (UA) are valuable in predicting future progression to RA.

**Objectives:** To determine whether MRI-detected erosions in patients presenting with UA are valuable in predicting future progression to RA.

**Methods:** 302 patients consecutively presenting with UA (not fulfilling the 2010-criteria) between 2010 and 2016 were studied. At baseline 1.5T MRI of the 2nd –5th metacarpophalangeal(MCP)- and 1st –5th metatarsophalangeal(MTP)-joints was performed. Erosions were scored according to the RAMRIS system by 2 readers (ICC  $>0.93$ ); an erosion was considered present if both readers scored  $\geq 1$ . First the presence of any MRI-detected erosion was evaluated. Then the presence of RA-specific erosions, defined as grade  $\geq 2$  erosions, erosions in MTP5 and erosions in MTP1 in persons aged  $<40$ , was evaluated. Patients were followed up for 1 year on the development of RA (according to the 2010-criteria) and/or on the start of DMARDs.

**Results:** Of the 302 UA-patients 144 (48%) developed RA and/or started DMARDs. MRI-detected erosions were observed in 57% of the 2010 UA-patients but their presence was not predictive for the development of RA (OR 1.3, 95% CI 0.8–2.0, PPV 50%). RA-specific erosions (either a grade  $\geq 2$  erosion, erosion in MTP5 and/or erosion in MTP1 in persons aged  $<40$ ) were present in only 8% of the 2010 UA patients and were also not associated with RA-development (OR 0.9 95% CI 0.4–1.9, PPV 44%). The observed PPVs were comparable to the prior risk of 48%. Similar findings were obtained when studying the individual RA-specific erosions separately.

**Conclusions:** MRI-detected erosions were frequently present in UA-patients. In contrast, RA-specific MRI-detected erosions were rare in UA. Since MRI-detected erosions were not associated with an increased risk on progression to RA, the present data indicate that evaluation of MRI-detected erosions is not prognostically relevant in UA-patients.

### SILICONE BREAST IMPLANTS AND THE RISK OF AUTOIMMUNE DISEASES: REAL WORLD ANALYSIS

A. Watad<sup>1</sup>, V. Rosenberg<sup>2</sup>, S. Tiosano<sup>1</sup>, J.W. Cohen Tervaert<sup>3</sup>, Y. Yavne<sup>4</sup>, Y. Shoenfeld<sup>5</sup>, V. Shalev<sup>6</sup>, G. Chodick<sup>2</sup>, H. Amital<sup>4</sup>. <sup>1</sup>Internal Medicine B, Sheba Medical Center; <sup>2</sup>Epidemiology, Maccabi Healthcare Services, Tel-Aviv, Israel; <sup>3</sup>Medicine and Immunology, Maastricht University, Maastricht, Netherlands; <sup>4</sup>Sheba Medical Center, Tel-Aviv, Israel; <sup>5</sup>The Zabudowicz Center for Autoimmune Diseases, Sheba Medical Center; <sup>6</sup>Maccabi Healthcare Services, Tel-Aviv, Israel

**Background:** Previous reports have suggested an association between silicone breast implants (SBIs) and connective tissue disorders. However, several epidemiological studies have produced inconsistent results.

**Objectives:** To evaluate the association between SBIs and the most clinically relevant auto-immune diseases (ADs) using a large, population based database.

**Methods:** In this cross-sectional study, we used the computerised databases of Maccabi Healthcare Services (MHS) which include up to 20 years of data on 2 million members. Women with SBIs were identified by procedure and diagnosis codes, clinical breast examinations and mammography referrals. ADs were identified using the International Classification of Diseases 9th revision (ICD-9) codes. SBIs-free women were matched by age group and socio-economic status (SES) in a ratio of 1:4. Multivariable logistic regression and Cox's proportional hazards models were performed.

**Results:** We included 24,651 SBI recipients and 98 604 matched SBIs free women in our study. The association between SBIs and AD was significant ( $p<0.05$ ) (adjusted OR 1.21, 95% CI 1.17–1.26). The strongest association with SBIs (OR  $>1.5$ ,  $p<0.001$ ) was recorded for systemic sclerosis (SSc) and sarcoidosis (OR of 1.99 and 1.67, respectively). Similar results were calculated when analysis was limited to cancer free women. Multivariable Cox regression model yielded a HR of 1.45 (95% CI 1.21–1.73) for being diagnosed with at least one AD in women with SBI compared to those without.

Proportions and OR for ADs among SBI recipients in comparison to SBI-free women				
	SBI free women n=98,604 n (%)	SBI recipients n=24,651 n (%)	Unadjusted OR (95% CI)	Adjusted OR* (95% CI)
Any auto-immune disease	22 634 (22.95)	6510 (26.41)	1.20 (1.17–1.24)	1.21 (1.17–1.25)

**SAT0688 PROGRESSIVE DRIFT OF PATIENT POPULATIONS IN RHEUMATOID ARTHRITIS CLINICAL TRIALS OVER TIME**

A. Kerschbaumer<sup>1</sup>, B. Bierbaumer<sup>2</sup>, J.S. Smolen<sup>1</sup>, D. Aletaha<sup>1</sup>. <sup>1</sup>Department of Medicine III (Chairman: Prof. Josef Smolen, MD), Medical University of Vienna, Vienna, Austria; <sup>2</sup>Independent, Munich, Germany

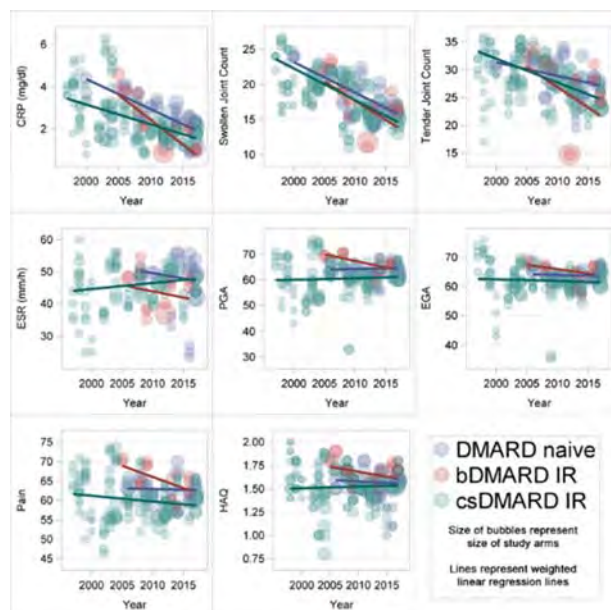

**Background:** Rheumatoid arthritis (RA) is among the most intensively studied chronic inflammatory musculoskeletal diseases. Over the past two decades numerous new compounds have been tested in RA. Although the results from any new clinical trial in RA is usually interpreted in the context of existing data from previous trials, it is not clear whether trial populations are necessarily historically comparable.

**Objectives:** To understand secular trends and drifts in characteristics of patient populations enrolled in RA clinical trials.

**Methods:** We performed a systematic literature review of randomised, controlled, double-blind trials, investigating biological therapies in RA. Reports were identified using PUBMED, EMBASE and the Cochrane Library. Populations were stratified into conventional disease modifying anti-rheumatic drug (cDMARD) naïve, cDMARD inadequate responders (IR), and biological DMARD IR. The following variables at baseline were extracted from reports: swollen and tender joint counts (SJC, TJC), pain, patient and evaluator global (PGA, EGA), acute phase measures (erythrocyte sedimentation rate, ESR and C-reactive protein, CRP), as well as the Health Assessment Questionnaire Disability Index (HAQ). In addition, we obtained the year of publication and the inclusion criteria of each trial. We then performed a mixed model meta-regression of year of publication on each of the mentioned baseline variables.

**Results:** Out of 697 abstracts selected for screening, 73 studies were chosen as relevant; 3 studies with mixed populations were excluded, resulting in 70 studies included for analysis. Table 1 shows the observed medians and quartiles for the baseline characteristics. Meta-regression showed a significant decrease of SJC ( $\beta = -0.415; p \leq 0.001$ ), TJC ( $\beta = -0.378; p \leq 0.001$ ), and CRP ( $\beta = -0.123; p \leq 0.001$ ) over the years (figure 1); for all other core set measures, there was no trend or significance. Inclusion criteria showed similar trends over time for SJC ( $\beta = -0.154, p \leq 0.001$ ), TJC ( $\beta = -0.243, p \leq 0.001$ ), and CRP ( $\beta = -0.065, p \leq 0.001$ ).

<b>No of patients (n)</b>	8894	23 752	4584
<b>Year of publication (YYYY)</b>	2014 (2009–2016)	2008 (2003–2012)	2013 (2008–2016)
<b>CRP (mg/dL)</b>	2.59 (2.27–3.26)	2.08 (1.67–3)	2.1 (1.08–3.11)
<b>ESR (mm/h)</b>	49.4 (42–52.8)	45.95 (40.2–49.9)	46.85 (39.2–48.2)
<b>Swollen Joints (0–66)</b>	16.65 (16–20.3)	17.95 (15.59–20.4)	17.1 (16.2–19)
<b>Tender Joints (0–68)</b>	28.05 (25.5–31)	28.1 (25.88–31.7)	28.75 (25.6–31.2)
<b>Patient global assessment (0–100)</b>	63.9 (61.8–66)	61 (58–65)	66.5 (63–69.7)
<b>Evaluator global assessment (0–100)</b>	63.6 (62–65.6)	62.05 (59.7–65)	66.45 <sup>62–67</sup>
<b>Patients pain assessment (0–100)</b>	62.5 (60.9–64.6)	60.29 (56.66–65)	65 (62–69)
<b>Health assessment questionnaire (0–3)</b>	1.54 (1.5–1.63)	1.51 (1.41–1.66)	1.7 (1.6–1.74)

**Conclusions:** There is a progressive drift towards lower number of swollen and tender joints and lower CRP-levels at trial entry of time, which is at least partly related to a similar trend in inclusion criteria for RA. The constancy of patient-reported outcomes suggests that the baseline activity is still perceived as similarly high. Differences in overall baseline inflammatory activity may pose a challenge for comparing newer with older trial results.

SAT0689

#### THYMECTOMY IN PATIENTS WITH MYASTHENIA GRAVIS AND THE RISK OF AUTOIMMUNE RHEUMATIC DISEASES: A NATIONWIDE COHORT STUDY

C.C. Chang<sup>1,2</sup>, J.-H. Chen<sup>3</sup>. <sup>1</sup>Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, School of Medicine, College of Medicine, Taipei Medical University; <sup>2</sup>Division of Rheumatology, Immunology and Allergy, Department of Internal Medicine, Taipei Medical University Hospital; <sup>3</sup>Biostatistics Center and Graduate Institute of Data Science, College of Management, Taipei Medical University, Taipei, Taiwan, Province of China

**Background:** Previous studies have shown myasthenia gravis (MG) and autoimmune rheumatic diseases (ARDs) share common pathogenetic mechanisms.

**Objectives:** Therefore, the present study investigated the possible relationship between MG and ARDs.

**Methods:** We analysed Taiwanese medical data from the Registry of Catastrophic Illness and identified patients with MG. From the entire general population data of the National Health Insurance Research Database, we randomly selected a comparison cohort that was frequency-matched by age (in 5 year increments), sex, and index date. We analysed the risk of ARDs by using a Cox proportional hazards regression model stratified by sex, age, and treatment.

**Results:** We enrolled 6478 patients with MG (58.03% women; mean age, 50.55 years) and 25 912 age- and sex-matched controls in the present study. The risk of total ARDs was 6.25 times higher in the MG cohort than in the non-MG cohort after adjustment for age and sex. Furthermore, the MG cohort was associated with a significantly higher risk of primary SS (pSS), SLE, and other ARD types (adjusted hazard ratios [HRs]: 15.84 [95% CI: 8.39–23.91]; 11.32 [95% CI: 5.04–25.429]; and 4.07 [95% CI: 1.31–12.62], respectively). MG cohort who received thymectomy had an increased risk of RA, pSS, and SLE (adjusted HRs: 4.41; 15.06; and 23.68, respectively).

**Conclusions:** The present nationwide cohort study revealed an association between MG and incident ARDs. MG cohort who received thymectomy had an increased risk of RA, pSS, and SLE. Future studies are needed to elucidate the underlying pathogenesis and to translate them into clinical therapeutic options.

#### THE ASSOCIATION BETWEEN SARCOIDOSIS AND ISCHAEMIC HEART DISEASE – A BIG DATA ANALYSIS

D. Katz<sup>1,2</sup>, S. Tiosano<sup>3,4</sup>, D. Comanesther<sup>5</sup>, A.D. Cohen<sup>5,6</sup>, H. Amital<sup>7,8</sup>. <sup>1</sup>Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer, Ramat Gan; <sup>2</sup>Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem; <sup>3</sup>Department of Medicine 'B' and Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, Ramat Gan; <sup>4</sup>Sackler Faculty of Medicine, Tel-Aviv University; <sup>5</sup>Chief Physician's Office, Clalit Health Services, Tel Aviv; <sup>6</sup>Siala Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva; <sup>7</sup>Department of Medicine 'B' and Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, Ramat Gan; <sup>8</sup>Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel

**Background:** Sarcoidosis is an inflammatory disease characterised by the hallmark sign of non-caseating granulomas<sup>1,2</sup>. In the past decade a consensus has formed regarding the pivotal role of inflammation in atherosclerosis<sup>3</sup>. Since this discovery the association between chronic inflammatory states and ischaemic heart disease was confirmed in several rheumatic diseases<sup>4</sup>. Therefore, the constant state of inflammation to which sarcoidosis patients are exposed might pose as a risk factor for ischaemic heart disease.

**Objectives:** The aim of this study is to assess the relation between sarcoidosis and Ischaemic heart disease and its prognostic significance.

**Methods:** Based on data from Clalit Health Services (CHS), Israel's largest health maintenance organisation, the medical records of 3993 sarcoidosis patients and 19 856 controls were acquired. Controls were matched to sarcoidosis patients according to age and sex. Chi-square and student t-tests were used in order to compare variables distribution in the cohort. Variables associated with ischaemic heart disease were assessed by logistic regression model. Log-rank test was performed for survival analysis, while Cox proportional hazards method was utilised to evaluate variables related to increased risk of all-cause mortality.

**Results:** Matched by sex and age – both sarcoidosis group and the control group were composed from 63% females with mean age being 56 years. Compared to the control group, sarcoidosis patients had a higher proportion of ischaemic heart disease, presenting with 856 (21.4%) cases whereas the control group had only 2999 cases (15.1%, p<0.001). The association between sarcoidosis and ischaemic heart disease was demonstrated by a multivariate analysis, (adjusted OR 1.503, 95% CI 1.361–1.660). A 15 year follow up revealed increased mortality among sarcoidosis patients – as 710 (17.8%) of sarcoidosis patients had passed away while 2121 (10.7%) deaths were reported in the control group (p<0.001). In a multivariate model, sarcoidosis patients were found to be in increased risk for all-cause mortality compared to the control group (adjusted HR 1.95, 95% CI 1.75–2.14).

**Conclusions:** Sarcoidosis is associated with an increased risk for ischaemic heart disease and all-cause mortality. Patients with co-morbidity of sarcoidosis and ischaemic heart disease should be treated accordingly.

#### ADHERENCE TO DISEASE-MODIFYING DRUGS IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES: SEVERAL QUESTIONNAIRES, DIVERSE PATIENT CHARACTERISTICS AND SOME EFFICACIOUS INTERVENTIONS – A SYSTEMATIC LITERATURE REVIEW

D. Puyraimond-Zemmour, X. Romand, M. Lavielle, A. Molto, P. Gaudin, M. Soubrier, C. Beauvais, D. Wendling, E. Senbel, S. Pouplin, R.-M. Flipo, C. Richez, A. Sarau, L. Gutermann, M. Mézière, M. Dougados, L. Gossec. *Rencontres d'Experts 2017 Working Group, Paris, France*

**Background:** In chronic inflammatory rheumatic diseases (CIRDs), adherence to disease-modifying drugs (DMD) is only moderate. Non-adherence may lead to complications, unnecessary treatment switches and heightened costs. Physicians are often at a loss when faced with non-adherence.

**Objectives:** To obtain an overview of how to measure adherence, who to screen particularly (risk factors of non adherence) and interventions to enhance medication adherence to DMD in patients with CIRDs.

**Methods:** A systematic literature review was performed in Pubmed, Cochrane, Embase and websites in 2017. All english and french studies related to methods to measure non-adherence, risk factors regrouped in 5 domains according to World Health Organisation (patient characteristics, health status, treatments, socio-economic conditions and relations with caregivers and the health system) and interventions for non-adherence regrouped in 5 modalities (educational, behavioural, cognitive behavioural, multicomponent interventions or others) were selected. The scope was limited to CIRDs (i.e., rheumatoid arthritis (RA), spondyloarthritis (SpA), psoriatic arthritis (PsA), crystal-induced arthritis (CIA), connective tissue diseases (CTD), vasculitis and auto-inflammatory diseases), and to DMD (i.e., mainly conventional DMARDs, biologics and targeted synthetic DMARDs).

**Results:** After screening 1131 publications and 194 other documents, 231 relevant papers were analysed for measuring adherence (60% in RA, 8% in SpA, 6% in PsA, 11% in CIA and 15% in CTD), 117 for predicting non-adherence (55% in RA, 9% in SpA, 14% in gout and 22% in CTD) and 22 for improving adherence (72% in RA, 8% in SpA, 16% in systemic lupus and 4% in gout). Objective measurements of non-adherence included: delivery data (total number of use: n=92), pill counts (n=8), medication event monitoring system (n=9), blood level assessments (n=7). Subjective measurements included: patient global assessment (n=57), and 4 questionnaires. The most used questionnaire was the Morisky Medication Adherence Scale and the most widely validated in rheumatology were the Compliance Questionnaire on Rheumatology and the Medication Adherence Self-report Inventory. Around 100 predictive factors were identified. Polymedication, mood disorders, lack of information and poor physician-patient relationship were associated with lower adherence. Regarding management options for non-adherence, 13/22 studies were randomised controlled trials (1535 patients) and only 5 (38%) were positive (774 patients). Educational interventions were the most represented with the highest level of evidence: 8/13 trials (1017 patients) with 4/8 yielding positive results.

**Conclusions:** Despite the importance of medication adherence in CIRDs, this review revealed limitations in methods to measure non-adherence, a multiplicity of non-adherence risk factors and a relative lack of evidence on interventions to improve medication adherence. It's important to improve the assessment and optimisation of adherence in CIRDs.

#### BREASTFEEDING IS NOT ASSOCIATED WITH ANTI-CITRULLINATED ANTIBODIES DEVELOPMENT IN INDIVIDUALS AT RISK FOR RHEUMATOID ARTHRITIS

D. Alpizar-Rodriguez<sup>1</sup>, M. Ruediger<sup>2</sup>, B. Möller<sup>3</sup>, J. Dudler<sup>4</sup>, A. Ciurea<sup>5</sup>, P. Zufferey<sup>6</sup>, D. Kyburz<sup>7</sup>, U. Walker<sup>7</sup>, I. von Mühlentzen<sup>7</sup>, P. Roux-Lombard<sup>1</sup>, C. Lamacchia<sup>1</sup>, C. Gabay<sup>1</sup>, A. Finckh<sup>1</sup>. <sup>1</sup>HUG, Geneva; <sup>2</sup>KSSG, St Gallen; <sup>3</sup>Inselspital, Bern; <sup>4</sup>HFR, Fribourg; <sup>5</sup>USZ, Zurich; <sup>6</sup>CHUV, Lausanne; <sup>7</sup>USB, Basel, Switzerland

**Background:** 'Systemic autoimmunity associated with rheumatoid arthritis' (RA), is a pre-clinical stage preceding the onset of clinical RA, characterised by the presence of autoantibodies, such as anti-citrullinated protein antibodies (ACPA) or anti-carbamylated protein antibodies (antiCarP). Breastfeeding has been proposed as a protective factor for RA development,<sup>1</sup> but there are some controversies.<sup>2</sup> To establish the causal role of a putative risk factor, longitudinal studies are needed, in particular in the pre-stages of RA development.

**Objectives:** To study the association between breastfeeding and the development of systemic autoimmunity associated with RA.

**Methods:** This ongoing prospective study includes individuals genetically at risk of developing RA, namely first-degree relatives of RA patients (RA-FDR). Individuals without clinical evidence of RA were enrolled, and assessed yearly clinically and biologically. We included all RA-FDR women with available ACPA status (anti-CCP 2, 3.1 or 3.0) and information about breastfeeding. The primary outcome was ACPA positivity. The exposure of interest was breastfeeding and duration of breastfeeding (categorised as 0, 1–7 and ≥7 months). The presence of antiCarP was a secondary outcome. We used logistic regression to analyse univariable and multivariable associations.

**Results:** A total of 882 women were included, of which 57 (6%) were ACPA positive. The characteristics of ACPA positive and negative participants were balanced, except for an older age in ACPA positives (median 52 versus 45 years; table 1). In the univariable analysis, ACPA positivity was not significantly associated with breastfeeding (OR 1.5, p=0.16) or with breastfeeding duration (OR=1.8, p=0.14). In the multivariable analysis adjusted by age, smoking, number of pregnancies and years of education, there was a weak, but not significant, association between breastfeeding for more than 7 months and ACPA positivity (OR 2.16, p=0.10). Among 728 women with available antiCarP results, 70 (10%) were positive, of which 27 (40%) breastfed. Breastfeeding for more than 7 months was not significantly associated with antiCarP in univariable or multivariable analyses (OR 1.3, p=0.52 and OR 1.9, p=0.16, respectively).

**Abstract SAT0692 – Table 1.** General characteristics of RA-FDR women, n=882

Table 1. General characteristics of RA-FDR women, n=882

**SAT0693 GENETIC POLYMORPHISMS AND EFFICACY OF METHOTREXATE IN RHEUMATOID ARTHRITIS**

E. Chamizo<sup>1</sup>, E. González<sup>2</sup>, C. Carrasco<sup>1</sup>, S. Rojas<sup>1</sup>, J.J. Aznar<sup>1</sup>, P. Dorado<sup>2</sup>, A. Llerena<sup>2</sup>. <sup>1</sup>Rheumatology, Hospital Mérida and CHU Badajoz, Mérida; <sup>2</sup>CICAB, CHU de Badajoz, Badajoz, Spain

**Background:** Methotrexate (MTX) is the DMARD of choice in the treatment of rheumatoid arthritis (RA). There is important variability in its therapeutic response. The identification of genetic factors related to the absorption, metabolism and action of MTX may facilitate a more efficient use.

**Objectives:** To study the effect of clinical characteristics and different single nucleotide polymorphisms (SNPs), related to the transport and metabolic pathways of MTX, on the therapeutic response of MTX in monotherapy in RA patients.

**Methods:** Observational study. Outcome variable: response to MTX (DAS-PCR <3.2). Study factors: SNPs of transport (ABCB1 C3435T), glutamine (GGH T16C and FPG G2782A), transmethylation (MTHFR C677T and MTHFR A1298C) and adenosine (AMPD1 C34T, ADA A534G, ITPA C94A). The association between SNPs and therapeutic response was analysed by logistic regression, assessing the allele independence (Hardy-Weinberg equilibrium) and interaction by sex. Different models of SNPs inheritance were analysed. Models were adjusted by the characteristics of the patient, of disease and of treatment. The haplotypes of the MTHFR SNPs (C677T and A1298C) were also analysed.

**Results:** Bivariate analysis showed lower probability of response with smoking (OR=0.37), erosions (OR=0.26), Mantoux (OR=0.20), disease activity (OR=0.08), previous DMARDs (OR=0.46) and doses of folic acid (OR=0.97), MTX (OR=0.87) and prednisone (OR=0.93), with higher response at a higher age at diagnosis (OR=1.05). In relation to the SNPs, the C/A genotype of the ITPA\_C94A decreases the probability of response (OR=0.48) according to an overdominant inheritance model, and the C/C genotype of MTHFR\_A1298C is also associated with a lower response according to a model of recessive inheritance (OR=0.18). An interaction between the GGH\_T16C SNP and sex was observed, so that the C/C genotype increases the possibility of response in women (OR=2.95), but not in men.

In the adjusted models, only the effect of genotype C/C of MTHFR\_A1298C is maintained (OR=0.14), irrespective of age, sex, smoking, alcohol, RF, anti-CCP, erosions, extra-articular manifestations, Mantoux, DAS28-CRP, previous

DMARDs, time to MTX, doses of folic acid, prednisone, MTX and route of administration. On the contrary, the association between the ITPA-C94A polymorphism and the response was not maintained nor the interaction effect of the C/C genotype of GGH\_T16C observed in bivariate analysis. Finally, the CC haplotype of the combination MTHFR C677T and MTHFR A1298C is associated with a decrease in the response (OR=0.55) in the adjusted models, so it is an effect independent of the control variables. No interaction effects were observed by sex.

**Conclusions:** Genetic polymorphisms related to the transport and metabolism of MTX have little effect on the therapeutic response, or at least much lower than other patient (smoking), disease (activity, erosions), or treatment (number of previous DMARDs) characteristics.

**Disclosure of Interest:** None declared**DOI:** 10.1136/annrheumdis-2018-eular.3047
**SAT0694 DETERMINANTS OF TRAJECTORIES OF MULTI-SITE PAIN IN KNEE OSTEOARTHRITIS: A 10.7-YEAR PROSPECTIVE STUDY IN OLDER ADULTS**

E. Pan<sup>1</sup>, J. Tian<sup>1</sup>, F. Cicutini<sup>2</sup>, C. Ding<sup>1</sup>, G. Jones<sup>1</sup>. <sup>1</sup>Menzies Institute for Medical Research, University of Tasmania, Hobart; <sup>2</sup>Department of Epidemiology and Preventive Medicine, Monash University Medical School, Melbourne, Australia

**Background:** Pain in osteoarthritis (OA) is very common especially in elderly and commonly occurs at multiple sites. Multi-site pain (MSP) has been shown to be associated with more severe symptoms and worse health-related quality of life compared to single-site pain. Limited evidence exists about understanding the course of MSP and its determinants.

**Objectives:** To identify distinct trajectories of MSP over 10.7 years in an older population, and to examine risk factors for identified trajectories.

**Methods:** 1099 participants (mean age 63 years) from the population-based Tasmanian Older Adult Cohort study were recruited at baseline. 875, 768 and 563 participants attended years 2.6, 5.1 and 10.7 follow-up, respectively. Demographic, psychological, lifestyle and comorbidities data were obtained at baseline. Knee radiographic OA was assessed by X-ray at baseline. Group-based trajectory modelling was applied to identify distinct trajectories of MSP. Multi-nominal logistic regression was used for the analyses with adjustment for potential confounders.

**Results:** Three distinct MSP trajectories were identified: a group of participants with 'no MSP' (11%), a group with 'fluctuating MSP' (38%), and a group with 'persistent MSP' over time (51%). In multivariable analyses with the 'no MSP' trajectory as reference, emotional problems and comorbidity were significantly associated with both 'fluctuating MSP' and 'persistent MSP' trajectory. In addition, female sex, being obese and radiographic knee OA predicted the trajectory of 'persistent MSP' in the whole population. Results were similar with emotional problems (relative risk [RR]: 2.57 for 'fluctuating MSP' and 5.70 for 'persistent MSP', both p<0.05), being obese (RR: 3.80 for 'persistent MSP', p=0.007) and comorbidity (RR: 2.45, p=0.010) in either 'fluctuating MSP' or 'persistent MSP' trajectory in those with radiographic knee OA.

**Conclusions:** MSP trajectories appear stable once established and can be predicted by factors both peripheral and central in origin.

**SAT0695 HOSPITALISATION RATES AMONG PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME: A POPULATION-BASED STUDY, 1995–2016**

G. Maciel<sup>1</sup>, L. Servioli<sup>1</sup>, C. Nannini<sup>2</sup>, A. Berti<sup>3</sup>, C. Crowson<sup>4</sup>, S. Achenbach<sup>4</sup>, E. Matteson<sup>5</sup>, D. Cornec<sup>4</sup>. <sup>1</sup>Maciel Hospital, Montevideo, Uruguay; <sup>2</sup>Hospital of Prato, Prato; <sup>3</sup>San Raffaele Scientific Institute, Milan, Italy; <sup>4</sup>Mayo Clinic, Rochester, USA; <sup>5</sup>Mayo Clinic, Rochester, Uruguay

**Objectives:** To determine rates and primary discharge diagnoses of hospitalisation in a cohort of patients with incident primary Sjögren's syndrome (pSS) compared to the general population.

**Methods:** This was a retrospective population-based cohort study focused on Olmsted County, Minnesota. The pSS cohort consisted of patients with incident pSS in the 1976–2015 period and was compared with a cohort of individuals without pSS matched 3:1 for age, sex and calendar year, randomly selected from the same population. Hospitalizations in 1995–2016 were examined. Discharge diagnoses were categorised using the Clinical Classifications Software for ICD-9-CM.

**Results:** A total of 385 hospitalizations occurred in the 160 patients with pSS during 1592 person-years of follow-up. Among 466 comparators, there were 899 hospitalizations during 4660 person-years of follow-up, resulting in a significantly higher rate of hospitalizations in patients with pSS (rate ratio [RR]:1.25, 95% CI:1.11–1.41). Rates of hospitalisation were increased among patients with pSS for endocrine, nutritional and metabolic diseases and immunity disorders

(RR:1.82, 95% CI:1.08–2.98), diseases of the musculoskeletal system and connective tissue (RR:1.49, 95% CI:1.05–2.05), and for injuries and poisoning (RR:1.46, 95% CI:1.01–2.06). While not significantly increased overall, hospitalizations for diseases of the circulatory system were significantly increased in patients with pSS aged  $\geq 75$  years (RR:1.54, 95% CI: 1.11–2.11).

**Conclusions:** Patients with pSS experienced higher rates of hospitalisation than the general population. Hospitalizations for endocrine/metabolic disorders, diseases of the circulatory system, diseases of the musculoskeletal system and connective tissue disorders, and injuries were more common among patients with pSS than comparators.

SAT0696

#### ASSOCIATIONS BETWEEN ANTIBIOTICS FOR NON-TUBERCULOUS MYCOBACTERIAL INFECTION AND INCIDENT SJÖGREN'S SYNDROME: A NATIONWIDE, POPULATION-BASED CASE-CONTROL STUDY

H.-H. Chen, W.-C. Chao. *Department of Medical Research, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China*

**Background:** We recently reported an association between Sjögren's syndrome (SS) and prior nontuberculous mycobacterial (NTM) infection which was defined as having a diagnosis of NTM with concurrent combinational antibiotics therapy for NTM infection. However, whether the increased risk of SS was attributed to NTM infection or antibiotics used to treatment NTM infection was unknown.

**Objectives:** To address the association between use of antibiotics which can be used to treat NTM infection and the risk of newly diagnosed SS.

**Methods:** Using a nationwide, population-based, claims dataset, 5751 newly diagnosed SS were identified, and we further excluded those (n=198) having a history of confirmed or suspected mycobacterial infection to avoid the confounding effect of NTM infection-associated incident SS as we previously identified. A total of 5,553 SS cases were enrolled and compared them with 83 295 non-SS controls matched (1:15) for age, sex, and their year of first SS diagnosis date. The association between the risk of incident SS and antibiotics was determined by calculating odds ratios (ORs) with 95% confidence intervals (CIs) using conditional logistic regression analysis.

**Results:** After adjusting for potential confounders, the risk of SS was increased in patients treated with new macrolides (aOR 1.95, 95% CI 1.80–2.11), fluoroquinolones (aOR 1.52, 95% CI 1.41–1.64), and tetracyclines (aOR 1.69, 95% CI 1.59–1.79) compared with those in non-SS controls after adjusting for CCI, bronchiectasis and *Helicobacter pylori* infection. Notably, we found that the association was consistent among each antibiotic in these three groups of antibiotics. In contrast to these three groups of antibiotics, usage of amikacin was found to have a negative association with incident SS (aOR 0.68, 95% CI 0.53–0.87).

	Model A	Model B
	aOR (95% CI)	aOR (95% CI)
<b>New macrolide</b>		1.95 (1.80–2.11)
Clarithromycin	1.84 (1.69–2.01)	
Azithromycin	2.07 (1.71–2.51)	
<b>Aminoglycoside</b>		0.68 (0.53–0.87)
Amikacin	0.58 (0.41–0.81)	
Streptomycin		
Kanamycin	0.83 (0.58–1.19)	
<b>Fluoroquinolone</b>		1.52 (1.41–1.64)
Ofloxacin	1.15 (1.01–1.32)	
Ciprofloxacin	1.34 (1.17–1.54)	
Levofloxacin	1.50 (1.22–1.85)	
Moxifloxacin	1.43 (1.30–1.56)	
<b>Tetracycline</b>		1.69 (1.59–1.79)
Doxycycline	1.59 (1.49–1.70)	
Minocycline	1.48 (1.35–1.62)	

**Conclusions:** New macrolides, fluoroquinolones and tetracyclines were associated with a higher incidence of SS, whereas usage of amikacin had a negative correlation. These findings indicated the need for vigilance of SS in prescribing

these antibiotics to treat NTM and other infectious diseases and warrant further mechanistic studies.

#### ASSOCIATION BETWEEN TONSILLITIS AND NEWLY DIAGNOSED ANKYLOSING SPONDYLITIS: A NATIONWIDE, POPULATION-BASED, CASE-CONTROL STUDY

H.-H. Chen<sup>1,1,1</sup>, W.-C. Chao<sup>1</sup>, D.-Y. Chen<sup>2</sup>. <sup>1</sup>*Department of Medical Research;* <sup>2</sup>*Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China*

**Background:** To date, two most commonly proposed environmental risk factors for ankylosing spondylitis (AS) include mechanical stress at the enthesis and infections. A recent Swedish study showed that childhood tonsillitis was associated with future development of AS. However, no Asian study has reported this association.

**Objectives:** To investigate the association between tonsillitis and the risk of newly diagnosed AS.

**Methods:** We used 2003–2012 data from the Taiwanese National Health Insurance Database to perform a nationwide, population-based, case-control study. We identified AS patients newly diagnosed from 2005 to 2012 as the study group and selected sex, age and the year of index date matched (1:6) non-AS individuals as controls. Using conditional logistic regression analysis after adjustment for potential confounders, including a history of periodontitis, appendicitis, and Charlson comorbidity index (CCI), we measured the association of AS risk with prior tonsillitis by calculating odds ratios (ORs) with 95% confidence intervals (CIs). Sensitivity analyses for the association between AS risk and tonsillitis were conducted by varying the definition of tonsillitis.

**Results:** We identified 37 002 incident AS cases and 2 22 012 matched non-AS controls. The risk of AS was associated with tonsillitis (OR, 1.80; 95% CI, 1.55–2.10) after adjustment for potential confounders. The association between AS risk and a history of tonsillitis remained significant by using various definitions of tonsillitis based on ICD9-CM Codes. Such associations were consistent across various subgroups stratified by age, sex, and a history of periodontitis or appendicitis.

**Conclusions:** The present study reveals an association between AS risk and prior tonsillitis.

estimate excess mortality of diseased people compared to non-diseased people if prevalence and incidence are known.

**Objectives:** To compute the mortality in RA patients in comparison to the population without RA in Germany, utilising claims data from 60 million people.

**Methods:** We used a mathematical relation between the age-specific prevalence, incidence and mortality to estimate the age- and sex-specific hazard ratio (HR) of mortality rates for patients with diagnosed RA compared to patients without RA.<sup>2</sup> Standardised mortality ratios (SMRs) for men and women were calculated using the sex-specific age distributions in Germany in 2012. In addition, we calculated years of lost life (YLL) for men and women aged 40 and 60 years with diagnosed RA.

**Results:** Estimation of sex-specific HR in the age range of 40 to 95 years is possible from the data in.<sup>1</sup> The age-specific HRs are elevated in both male and female RA patients (figure 1, left panel and right panel, respectively) with a particular increase in the younger. SMRs in the age range of 40 to 95 are 1.93 and 2.15 for men and women, respectively. YLL at age 40 are 12.0 and 7.5 years for men and women with RA, respectively. The associated YLLs at age 60 are 5.2 and 4.7 years.

**Abstract SAT0698 – Figure 1.** Age-specific HR for men (left) and women (right) in Germany 2012. Grey regions indicate the range of possible values.

**Conclusions:** Despite the limitation of the data source (claims data), an estimation of excess mortality in terms of the HR is possible and yields plausible results. The obtained SMRs are similar to comparable populations.<sup>3</sup> At age 40 men with RA suffer more from reduced life expectancy than women with RA. At age 60 the difference in YLL between men and women with RA is virtually vanished.

#### SAT0699 PREDICTION OF CARDIOVASCULAR EVENTS IN RHEUMATOID ARTHRITIS PATIENTS USING A MULTI-BIOMARKER OF DISEASE ACTIVITY

F. Xie, L. Chen, H. Yun, J.R. Curtis. *University of Alabama at Birmingham, Birmingham, USA*

**Background:** The ACC/AHA recommends preventive strategies for patients with a high predicted risk of atherosclerotic cardiovascular disease (CVD). RA patients are at higher risk for CVD events, yet the role of systemic inflammation and the influence of traditional CVD risk factors is unclear with respect to risk prediction in RA.

**Objectives:** A simple and accurate algorithm for predicting CVD event risk that includes systemic inflammation might help risk assessment for RA patients and optimise preventive care.

**Methods:** We derived a U.S. cohort of RA patients with multi-biomarker disease activity (MBDA) test results linked to Medicare claims data. Patients had to have  $\geq 1$  year baseline with Medicare coverage prior to the first MBDA test. Exclusions were past MI, PCI/CABG, stroke, or cancer. Follow-up ended at the earliest of 1) CVD event; 2) other than CVD cause of death; 3) loss of coverage; or 4) 12/31/2014. The composite CVD event comprised of incident MI, stroke or fatal CVD event, using validated algorithms. MBDA scores were grouped as low ( $<30$ ), moderate,<sup>30–44</sup> and high ( $>44$ ). Other predictors included demographics, healthcare utilisation, and comorbidities. Three separate models were developed using Cox regression. Model 1 included age, sex and race. Model 2 included age, sex, race, 9 comorbidities and CVD medication classes, plus interaction terms. Model 3 included age, sex, and race plus categorised MBDA score. We calculated the net reclassification index (NRI) for model 2 and 3 compared to model 1. We also plotted the observed vs. predicted probability of CVD event for each model, with risk categorised as low ( $<7.5$ ), moderate (7.5– $<15$ ) and high ( $\geq 15$ ) per 1000 person-years based upon annualised ACC/AHA cutpoints.

**Results:** A total of 15,757 RA patients were included; mean (SD) age 68.6 (10.8) years, 80% female, 80% white. A total 209 CVD events occurred in 14 843 person years (1.41/100 py). The median (IQR) follow up time was 0.84 (0.41, 1.27) year. The maximum event time was at 2.7 year. All models had reasonable discrimination and calibration; model 3 was better than models 1 and 2 and observed vs predicted risk is shown (figure 1). The sum of the absolute difference between observed and predicted probability was 0.56, 0.57 and 0.33 for models 1, 2 and 3 respectively.

Compared to model 1, model 2 resulted in a positive overall NRI of 0.214 (non-event NRI=0.173, event NRI=0.041); model 3 resulted in positive overall NRI of 0.279

(non-event NRI=0.092, event NRI=0.187), consistent with more accurate CVD event classification.

**Abstract SAT0699 – Figure 1.** Observed vs. Predicted One-Year CVD Risk per 1000 person-years in RA Patients, using only Age, Sex, Race, and MBDA score (Model 3)

**Conclusions:** Preliminary results from this analysis suggest that a simple algorithm consisting only of age, sex and race plus a multi-biomarker score can provide an accurate method to predict short term CVD risk in RA. Further validation with more extended time frames should improve the utility of this approach.

#### THE RELATIONSHIP BETWEEN MUSCULOSKELETAL PAIN, INFLAMMATION AND DEPRESSION IN MEN

J. McBeth<sup>1</sup>, M.J. Cook<sup>1</sup>, G. Bartfai<sup>2</sup>, F. Casanueva<sup>3</sup>, M. Maggi<sup>4</sup>, A. Giwerzman<sup>5</sup>, D. Vanderschueren<sup>6</sup>, J. Slowikowska-Hilczek<sup>7</sup>, M. Punab<sup>8</sup>, T.W. O'Neill<sup>1,9,10</sup>. <sup>1</sup>The University of Manchester, Manchester, UK; <sup>2</sup>Medical University, Szeged, Hungary; <sup>3</sup>Santiago de Compostela University, Santiago de Compostela, Spain; <sup>4</sup>University of Florence, Florence, Italy; <sup>5</sup>Lund University, Malmö, Sweden; <sup>6</sup>Katholieke Universiteit Leuven, Leuven, Belgium; <sup>7</sup>Medical University of Lodz, Lodz, Poland; <sup>8</sup>United Laboratories of Tartu University Clinics, Tartu, Estonia; <sup>9</sup>NIHR Manchester Biomedical Research Centre, Central Manchester University Hospitals NHS Foundation Trust, Manchester; <sup>10</sup>Salford Royal NHS Foundation Trust, Salford, UK

**Background:** Up to 40% of persons with musculoskeletal (MSK) pain report depression. High sensitivity C-reactive protein (hsCRP), a sensitive marker of chronic low grade inflammation, is elevated in persons with MSK pain when compared to those who are pain free, and in those with MSK pain is positively associated with increasing pain severity. High levels of hsCRP are also associated with depression. Whether hsCRP is the mechanism linking MSK pain to depression has not been tested.

**Objectives:** To test the hypothesis that MSK pain predicts depression and the relationship would at least in part be explained by hsCRP.

**Methods:** 3309 men aged 40–79 in the multicentre European Male Ageing Study completed a postal questionnaire asking about MSK pain (classified as chronic widespread pain<sup>American College of Rheumatology 1990</sup> criteria) (CWP), some pain that was not CWP (SP), or no pain (NP) and depression (Beck Depression Inventory-II (BDI-II), score range 0–21). At a research clinic, fasting morning blood samples were shipped to one Centre where hsCRP was measured using a solid-phase, chemiluminescent immunometric assay with a sensitivity of 0.01 mg/dL. Covariates were date of birth, education level, body mass index (BMI), tobacco use, and frequency of alcohol consumption. Participants were followed up (mean 4.4 (SD 0.3) years) and completed the BDI-II. Linear regression tested the association between baseline pain and follow up BDI score (outcome), with adjustments for age, centre and baseline BDI. In a final model hsCRP and covariates were added and the impact on the relationship between pain and BDI-II examined. Results are expressed as  $\beta$  coefficients with 95% confidence intervals (CI).

**Results:** 2404 (72.7%) men had complete baseline and follow-up data. At baseline 1003 (41.7%) reported NP, 1205 (50.1%) SP, and 196 (8.2%) CWP. Mean (SD) age was 59.3 (10.6), CRP 0.41 (0.74) mg/l, and BDI 6.6 (6.2). Mean BMI was 27.8 (10.6), 30.1% were current smokers, 23.6% drank alcohol 5–7 days/week and 53.9% had gone on to further education. After adjusting for age, Centre and baseline BDI-II when compared to those with NP having SP ( $\beta=0.7$ , 95% CI (0.3, 1.1)) or CWP (1.3 (0.5, 2.0)) at baseline was associated with higher BDI-II scores at follow-up. Baseline hs-CRP did not predict follow up BDI-II (0.05 (-0.2, 0.3)). The relationship between SP (0.7 (0.2, 1.1)) or CWP (1.5 (0.7, 2.3)) and follow up BDI-II persisted after adjustment for hs-CRP and all covariates.

**Conclusions:** The excess rate of depression in men with MSK pain remains to be explained. A broader assessment of inflammatory markers (e.g. TNF- $\alpha$ , Interleukins, and IFN- $\gamma$ 1) may identify mechanisms linking MSK pain with subsequent depression.

SAT0701

#### PREGNANCY OUTCOME IS IMPROVED AND SIMILAR TO THAT OF THE GENERAL OBSTETRIC POPULATION IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO FOLLOW THE “IDEAL CLINICAL PATHWAY” BEFORE AND DURING PREGNANCY

L. Andreoli<sup>1</sup>, A. Bortoluzzi<sup>2</sup>, G. Carrara<sup>3</sup>, V. Ramoni<sup>4</sup>, M. Padovan<sup>2</sup>, M. Govoni<sup>2</sup>, A. Tincani<sup>1</sup> on behalf of Gender Medicine SIR, C.A. Scirè<sup>2</sup> on behalf of RECORD SIR. <sup>1</sup>Rheumatology, University of Brescia, Brescia; <sup>2</sup>Department of Medical Sciences, University of Ferrara, Ferrara; <sup>3</sup>Epidemiology Unit, Società Italiana di Reumatologia – SIR, Milano; <sup>4</sup>Rheumatology, University of Pavia, Pavia, Italy

**Background:** With the therapeutic advances of the last decades yielding to stable disease remission in the majority of patients, the goal of a successful pregnancy appears to be attainable for women affected by Rheumatoid Arthritis (RA). However, individual risk stratification and measures to minimise it (e.g. withdrawal and wash-out of teratogenic drugs) are essential for the management of pregnancy in RA.<sup>(1)</sup>

**Objectives:** This analysis aims to evaluate the adherence to a reference clinical pathway of diagnostic, pharmacological and follow-up management in women with RA, and the influence of the adherence to this pathway on the outcome of pregnancy.

**Methods:** Data were extracted from the Lombardy Region's (Italy) health databases for the period between 2004–2013. Patients with RA were identified through the chronic disease certification by rheumatologist (ICD9-CM code 714.0). Among these, women between the ages of 18 and 51 were selected. Data of controls from general population were also extracted. Conception has been approximated from the date of delivery or abortion. Seven healthcare quality indicators have been constructed: 1) screening of blood chemistry tests, 2) pre-conception musculoskeletal imaging, 3) pre-pregnancy antiphospholipid antibody tests, 4) ANA test and anti-ENA (antiRo/SSA) test, 5) no exposure or wash-out from teratogenic drugs (MTX/LEF); 6) no exposure to biological drugs; 7) rheumatological follow-up in outpatient visits. These 7 indicators were then summarised in 3 pathway indicators: 1) diagnostic pathway, 2) therapeutic pathway, 3) follow-up. The pregnancy outcome was defined on the basis of the DRG of complicated birth or abortion. Subanalysis on abortion was also done. The relationship between quality indicators and outcome variables was analysed using logistic models crude and adjusted for age and comorbidities, and the results presented as odds ratios (OR) and 95% confidence intervals (95% CI).

**Results:** 443 pregnancies of patients with RA were identified, with median age of 34 (IQR 31–37), median disease duration at conception of 3.8 years (IQR 1.83–6.19), 157 (35.4%) of which with unfavourable outcome pregnancy outcome, of which 115 pregnancy losses. The increase or decrease of risk for those who meet specific quality indicators and pathway indicators showed a better outcome for patients screened for autoantibodies and with no exposure or washout from MTX/LEF (Table). The comparisons of those who followed the ideal pathway or not compared to the general population showed a significant increase of risk only for patients not following the ideal pathway (Table).

Clinical pathway indicator	Overall Adjusted OR(95%CI)	Abortion Adjusted OR(95%CI)
Blood chemistry tests	0.99 (0.47-2.11)	0.78 (0.36-1.70)
Imaging	1.09 (0.72-1.65)	1.14 (0.72-1.81)
antiphospholipid antibody tests	0.56 (0.37-0.85)	0.34 (0.20-0.56)
ANA or anti-ENA	0.64 (0.42-0.96)	0.43 (0.27-0.68)
No exposure or wash out of MTX/LEF	0.52 (0.31-0.86)	0.44 (0.25-0.75)
No exposure to biological drugs	Not estimable	Not estimable
Rheumatological follow-up in outpatient visits	0.85 (0.56-1.28)	0.65 (0.40-1.04)
Diagnostic pathway	1.05 (0.46-2.38)	0.84 (0.36-1.98)
Therapeutic pathway	0.48 (0.29-0.80)	0.44 (0.25-0.75)
Follow-up	0.85 (0.56-1.28)	0.65 (0.40-1.04)
Ideal pathway	0.59 (0.37-0.95)	0.38 (0.21-0.67)
General population	Reference	Reference
Ideal pathway	0.89 (0.57-1.37)	0.70 (0.40-1.23)
No ideal pathway	1.48 (1.12-1.95)	1.81(1.31-2.49)

**Conclusions:** The optimal management of pregnancy (stratification of pre-conceptional obstetric risk, modulation of therapy) in women with RA is associated with a reduced risk of unfavourable pregnancy outcome, bringing back that risk to that expected for a general obstetric control population.

#### SAT0702 INFLUENCE OF OBESITY AND GENDER ON DRUG EFFECTIVENESS IN RHEUMATOID ARTHRITIS DEPENDS ON THE OUTCOME CONSIDERED

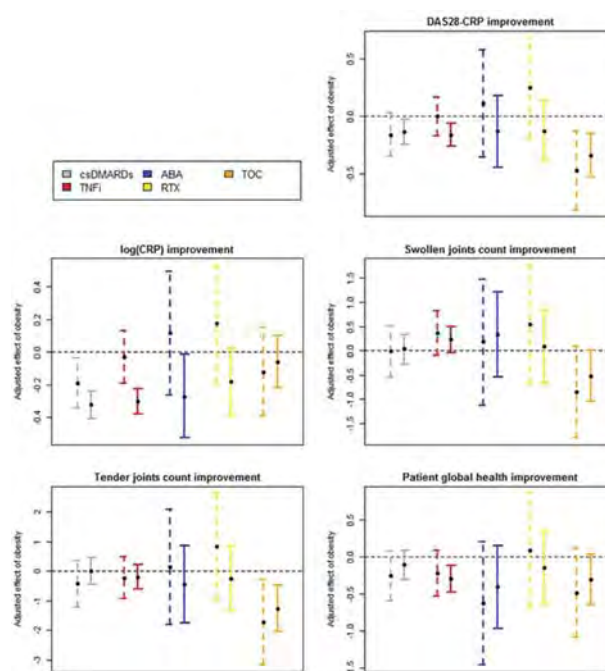

M. Schäfer<sup>1</sup>, Y. Meissner<sup>1</sup>, J. Kekow<sup>2</sup>, S. Berger<sup>3</sup>, S. Remstedt<sup>4</sup>, A. Strangfeld<sup>1</sup>, J. Listing<sup>1</sup>, A. Zink<sup>1,5</sup>. <sup>1</sup>Epidemiology Unit, German Rheumatism Research Centre, Berlin; <sup>2</sup>Scientific Advisory Board, Vogelsang-Gommern; <sup>3</sup>Rheumatologist, Naunhof; <sup>4</sup>Rheumatologist; <sup>5</sup>Charité University Medicine, Berlin, Germany

**Background:** While effectiveness of TNF inhibitors (TNFi) and, to some extent, tocilizumab (TOC), has been shown to be affected by obesity in patients with rheumatoid arthritis (RA), no such effect has been found for abatacept (ABA) and rituximab (RTX). Also, it remains unresolved whether gender is an effect modifier for obesity, e.g. due to different body fat distributions in men and women.

**Objectives:** Assess whether obesity affects drug effectiveness of common DMARDs, taking into account potential differences between sexes. As measures for effectiveness, the degree of improvement regarding DAS28-CRP as well as its components after 6 months of treatment were considered.

**Methods:** Data of 8,623 RA patients included since 2009 in the German observational cohort study RABBIT were analysed. Patients had to have a BMI  $\geq 18.5$  and at least 6 months of follow-up. Multiple imputation of missing values in outcomes was performed. The influence of obesity (BMI  $\geq 30$ ) on drug effectiveness was investigated by multiple linear regression, adjusting for age, baseline value of the outcome of interest, disease duration, prior bDMARD failure, glucocorticoid therapy, number of comorbidities, joint erosions, autoantibody status, and smoking habits.

**Results:** At baseline, obese patients were comparable to others in age (both mean 58 years) and gender (women: 75% vs. 74%). They were less likely to be seropositive (66% vs. 75%), had less erosions (40% vs. 52%) but more often  $\geq 3$  comorbidities (43% vs. 30%). With the exception of infliximab, around 90% of patients or more received the recommended drug dosage regardless of their weight (assuming a tolerance interval for norm in case of weight-dependent infliximab and tocilizumab dosages). For women treated with TNFi or csDMARDs as well as for patients treated with TOC, obesity had a negative influence on the improvement in DAS28-CRP after 6 months of treatment (figure 1). With the exception of patients treated with TOC, this influence seemed to be caused mostly by inflammation, while for joint swelling or pain no associations were observed. Men and women treated with TNFi differed significantly regarding the effect of obesity on the improvement of log(CRP) values.

**Abstract SAT0702 – Figure 1.** Influence of obesity on the RA disease course regarding the improvement in DAS28-CRP and its components after 6 months of treatment, as assessed by multiple linear regression. Shown are point estimates and 95% confidence intervals for obesity effects, separately for men (left, dashed line) and women (right, solid line) in five treatment groups.

**Conclusions:** The influence of obesity on drug effectiveness depends on the considered outcome and, to some extent, on gender. It may therefore be worthwhile to assess it separately for men and women.

M. Chen-Xu<sup>1</sup>, C. Yokose<sup>2</sup>, H.K. Choi<sup>2</sup>. <sup>1</sup>Department of Social and Behavioral Sciences, Harvard T.H. Chan School of Public Health; <sup>2</sup>Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, USA

**Background:** Although African-Americans (AAs) have a higher prevalence of risk factors for gout and hyperuricemia (e.g., hypertension, obesity, and chronic kidney disease [CKD]) than Whites, data on their disease burden of gout and hyperuricemia remains scarce.

**Objectives:** To examine potential racial/ethnic disparities in the prevalence of gout and hyperuricemia, using a nationally-representative sample of United States (US) adults over the past 10 years (The National Health and Nutrition Examination Survey [NHANES] 2007–16).

**Methods:** Using data from 26 332 participants aged  $\geq 20$  years (13 539 females and 12 793 males) from NHANES 2007–16, we calculated the age-standardised prevalence of gout and hyperuricemia by race/ethnicity. Gout was defined by report of a diagnosis by a health professional, and hyperuricemia as a serum urate  $>7.0$  mg/dL (0.42 mmol/L) from participants' blood samples. Logistic regression was used to adjust for covariates, while taking into account clusters and strata of the complex survey design of NHANES.

**Results:** The age-standardised prevalence of gout was 3.7% for Whites and 4.7% for AAs, with the age-standardised prevalence of hyperuricemia being 12.7% and 14.9% for Whites and AAs, respectively. Compared to Whites, AAs had a 65% higher odds of gout among females (age-adjusted OR, 1.65; 95% CI, 1.14 to 2.38) and a 31% higher odds of gout among males (age-adjusted OR,

1.31; 95% CI, 1.05 to 1.63). Further adjustment by body-mass index (BMI) attenuated these associations to non-significance for both sexes (table 1). AA females had a higher odds of hyperuricemia than White females (age-adjusted OR, 2.17; 95% CI, 1.72 to 2.73), but not males (age-adjusted OR, 1.08; 95% CI, 0.95 to 1.22; *P* for interaction=0.002) (table 1). Among females, this association attenuated after further adjustment for BMI, hypertension, CKD, type 2 diabetes mellitus, household income, and education, but remained significant (adjusted OR, 1.52; 95% CI, 1.19 to 1.95).

**Abstract SAT0703 – Table 1.** ORs of Gout and Hyperuricemia According Race/Ethnicity, NHANES 2007–16

	Gout		Hyperuricemia	
	Age-adjusted OR (95% CI)	Age and BMI-adjusted OR (95% CI)	Age-adjusted OR (95% CI)	Age and BMI-adjusted OR (95% CI)
<b>Female</b>				
White	1.00 (Referent)	1.00 (Referent)	1.00 (Referent)	1.00 (Referent)
African American	1.65 (1.14–2.38)	1.33 (0.92–1.92)	2.17 (1.72–2.73)	1.62 (1.27–2.05)
<b>Male</b>				
White	1.00 (Referent)	1.00 (Referent)	1.00 (Referent)	1.00 (Referent)
African American	1.31 (1.05–1.63)	1.24 (1.00–1.53)	1.08 (0.95–1.22)	1.02 (0.89–1.17)

**Conclusions:** These nationally-representative data indicate that AAs have a larger disease burden of gout and hyperuricemia than Whites, particularly among women. This burden appears to be at least partly due to a higher prevalence of risk factors for hyperuricemia in AAs.<sup>1</sup>

#### SAT0704 COLLECTION OF ANTI-RHEUMATIC MEDICATION DATA FROM BOTH PATIENTS AND RHEUMATOLOGISTS SHOWS STRONG AGREEMENT IN A REAL WORLD CLINICAL COHORT: RESULTS FROM THE ONTARIO BEST PRACTICES RESEARCH INITIATIVE (OBRI)

M. Movahedi<sup>1</sup>, A. Cesta<sup>1</sup>, X. Li<sup>1</sup>, C. Bombardier<sup>1,2,3</sup> on behalf of Other OBRI Investigators. <sup>1</sup>Ontario Best Practices Research Initiative, Toronto General Research Institute, University Health Network; <sup>2</sup>Department of Medicine (DOM) and Institute of Health Policy, Management, and Evaluation (IHPE), University of Toronto; <sup>3</sup>Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada

**Background:** Collection of Anti-Rheumatic Medication (ARM) information from both patients and rheumatologists is considered a strength for Rheumatoid Arthritis (RA) registries and cohorts. However, it is important to assess the agreement between these two data sources.

**Objectives:** We aimed to examine the agreement of ARM use, their administration routes, and start and stop dates between self-reports and rheumatologist reports in the Ontario Best Practices Research Initiative (OBRI).

**Methods:** Adult Patients enrolled in the OBRI who consented to both patient interviews and rheumatologist evaluations were included. Patients in the OBRI are interviewed every six months, while rheumatologist assessments are conducted as per routine care. For this analysis, we included patients who enrolled in OBRI on or after Sep 1 st 2010 and compared ARM use reports where rheumatologist visits and interviews occurred within 60 days of each other. ARM included conventional synthetic Disease-Modifying Antirheumatic Drugs (csDMARDs) and biologic DMARDs (bDMARDs). Cohens' Kappa statistics of agreement between the two data sources were calculated. Kappa values 0.61–0.80 were considered to represent good and 0.81–1.00 as very good agreement. To examine factors associated with agreement, a multivariate backward stepwise logistic regression was used to model the odds of agreement for ARM use. The agreement and absolute time gap (days) for starts and stops dates between self-reports and rheumatologist reports were also assessed and presented by median and interquartile range (IQR) in a subset analysis.

**Results:** 2154 patients (78.7% female) were included with a mean (SD) age at OBRI enrolment of 57.8 (12.6) year. Mean (SD) disease parameters were: disease duration: 8.4 years (9.9); DAS28: 4.2 (1.6); physician global: 4.0 (2.5); and health assessment questionnaire (HAQ) disability Index: 1.1 (0.8). For csDMARDs use, the prevalence was 74.2% based on self-reports and 76.6%

based on rheumatologist reports. The prevalence of bDMARDs use was approximately 20.0% based on both reports.

Overall agreement for ARM use between self-reports and rheumatologist reports was good. In the regression model, increased HAQ-pain index (OR: 0.66; 95% CI: 0.60–0.73) and physician global (OR: 0.95; 95% CI: 0.92–0.98) were significantly associated with the lower agreement. By contrast, post-secondary education (OR: 1.20; 95% CI: 1.02–1.40), and seeing an academic rheumatologist (OR: 1.47; 95% CI: 1.25–1.73) were significantly associated with the higher agreement between two data sources.

There was a good and very good agreement for reported administration route of bDMARDs and csDMARDs, respectively. The median absolute time gap (IQR) of start dates and stop dates for ARM use reported by two data sources was 7 days 1–27 and 19 days, 5–48 respectively.

**Conclusions:** The results of this analysis suggest that ARM reports from the two data sources have strong agreement in the OBRI. This agreement is even better for patients who have post-secondary education and are being treated by an academic rheumatologist.

#### SAT0705 ASSOCIATION BETWEEN FRACTURE SITES IN PATIENTS WITH A HISTORY OF PARENTAL FRACTURE

M. Dey, M. Bukhari. *Rheumatology, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, UK*

**Background:** Fragility fractures (FF) are fractures due to low energy force. Factors predisposing to FF in the general population include reduced bone mineral density (BMD), and family history of osteoporosis. FF most commonly occur in the vertebrae, proximal femur, and distal radius. Studies have demonstrated increased risk of FF in patients with decreased BMD and parental history of FF, particularly hip fracture.<sup>1,2</sup> Few data exist on the association between sites of fracture in patients with a history of parental fracture, especially whether they co-exist at several sites and if particular factors are associated with discrete sites.

**Objectives:** We aimed to find the correlation between sites of FF in patients with a history of parental fracture, and identify and examine the clinical association with any clusters of fractures.

**Methods:** 2094 patients with a history of parental FF and personal history of at least one FF, presenting for BMD estimation from their primary or secondary care practitioner, from 2006–2016, were included. Parameters recorded: height, weight, age at scan, average fat mass, site of fracture(s), smoking, alcohol, corticosteroid use, aromatase inhibitor use, Depo-Provera use, hormone replacement therapy (HRT), rheumatoid arthritis (RA), polymyalgia rheumatica (PMR), breast or prostate cancer, and coeliac disease.

Factor analyses with polychoric correlation matrices were applied to determine association between fracture sites. Any associations with Eigenvalues of more than one were then examined using a logistic model to analyse the effect of the above risk factors.

**Results:** Fracture sites with Eigenvalue of more than one (tibia/fibula, spine, ribs, pelvis) were compared to sites with least co-variability (humerus, forearm, femur). The two cohorts were significantly different in age; therefore, an age-adjusted model is reported below (table 1). Smoking, HRT, and increased age significantly impacted clustering of fractures in the tibia/fibula, spine, ribs, and pelvis, compared with clustering at the humerus, forearm, and femur.

**Abstract SAT0705 – Table 1.** Age-adjusted predictors of fracture for tibia/fibula/spine/ribs/pelvis vs. humerus/forearm/femur (\* denotes significance)

Variable/Fracture cluster	OR (95% CI)
Corticosteroid	0.878 [0.748–1.031]
Smoking	0.879 [0.779, 0.992] *
Alcohol	0.954 [0.808–1.127]
Rheumatoid arthritis	1.393 [0.928–2.092]
Polymyalgia rheumatica	0.907 [0.465–1.769]
HRT	0.635 [0.420, 0.961] *
Aromatase inhibitors	0.950 [0.772, 1.170]
Breast/prostate cancer	1.489 [0.610–3.636]
Gender	0.804 [0.589–1.096]
Age at scan (years)	1.011 [1.003, 1.019] *
Height (cm)	0.989 [0.978–1.000]
Weight (kg)	0.995 [0.989–1.000]

**Conclusions:** In this cohort of patients, there was overlap between all fracture sites, with significant clustering seen in fractures of the tibia/fibula, spine, ribs, and pelvis. After adjusting for age, predictors of fracture in this cluster were smoking, HRT and increased age. This indicates that risk factors for FF are different at different sites, and affects the association of fracture between sites. Further work validating this finding is currently underway.

#### SAT0706 INCIDENCE OF PSORIATIC ARTHRITIS IN GERMANY: ANALYSIS OF CLAIMS DATA FROM 65 MILLION PEOPLE FROM 2009 TO 2012

P. Sewerin, I. Haase, M. Schneider, B. Ostendorf, R. Brinks. *Department for Rheumatology, University Hospital Duesseldorf, Düsseldorf, Germany*

**Background:** Epidemiological studies are important for understanding the etiology and burden of psoriatic arthritis (PsA). Currently, there are no data available about the incidence of PsA in Germany.

**Objectives:** This study aims to estimate the age-standardised incidence of diagnosed PsA for German men and women during 2009 to 2012.

**Methods:** Estimation of the incidence of a chronic disease from prevalence data is possible if information about the general mortality and excess mortality of diseased compared to non-diseased people are available in terms of the hazard ratio (HR).<sup>1</sup> Prevalence was extracted from the complete diagnosis data (in- and outpatient) from about 80% of the overall German population during 2009 to 2012. Diagnoses are based on claims data from all insurances of the German statutory health insurance (SHI) system. After determining the age-standardised sex-specific prevalence of PsA for each of the four years, the age-standardised incidence for men and women has been estimated. General mortality was obtained from the Federal Statistical Office of Germany. Since the HR is unknown in Germany, we use different scenarios motivated from a systematic review<sup>2</sup> in the range from 1.3 to 1.6.

**Results:** For each of the years from 2009 to 2012, a total of 127, 138, 146 and 156 thousand patients with diagnosed PsA were identified in about 65 million people from the SHI, respectively. The age-standardised prevalence increases from 1.8 to 2.1 per mil in men, and from 2.1 to 2.5 per mil in women. The estimated age-standardised incidence over the study period is shown in the figure 1. Over the study period, the incidence rate of PsA decreases for both sexes and the rate of men is lower than the rate of women. The average incidence rates are 11.5 and 14.5 per 100'000 person-years for men and women, respectively. This means that about 4700 men and 5900 women contract PsA each year. The impact of the different scenarios in HR is small.

**Conclusions:** These data from about 65 million people insured in the German SHI for the first time allow an estimation of the incidence of PsA in Germany. A selection bias is likely to be present, because the roughly 20% of the overall German population who could not included in the analysis (mainly privately insured people) are known to have other health risks. However, the results refer to the vast majority of the German population. The analysis cannot be adjusted for potential confounders other than age and sex (e.g., socio-economic position or presence of co-morbidities).

#### SAT0707 TRENDS IN THE INCIDENCE OF RHEUMATOID ARTHRITIS IN DENMARK FROM 1995–2016: A NATIONWIDE REGISTER-BASED STUDY

R.L. Cordtz<sup>1</sup>, P. Højgaard<sup>1,2</sup>, K. Zobbe<sup>1,2</sup>, L. Dreyer<sup>1,2,3</sup>. <sup>1</sup>Center for Rheumatology and Spine Diseases, Rigshospitalet- Gentofte, Copenhagen; <sup>2</sup>The Parker Institute, Bispebjerg and Frederiksberg Hospital, Frederiksberg; <sup>3</sup>Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark

**Background:** Previous studies have shown conflicting results regarding temporal trends in the incidence of rheumatoid arthritis (RA).

**Objectives:** To investigate annual incidence rates of RA in Denmark from 1995–2016 using nationwide health care registers, and to explore how these are affected by different case definitions of RA.

**Methods:** The Danish National Patient Register captures all in- and outpatient (since 1977 and 1994, respectively) contacts at private and public hospitals. Excluding prevalent cases (ICD-8: 712), and using two different case-definitions, we identified all incident RA patients (ICD-10 codes M05.1;3;8;9 and M06.0;8;9) aged  $\geq 18$  in each year from 1995–2016, and calculated annual age-standardised incidence rates (per 1 00 000 person years). We used the NORDCAN population for direct standardisation, and the number of adults alive in Denmark at the beginning of each year as the denominator. We furthermore calculated the age- and sex specific incidence rates during the period. **Strict case definition:** incident patients were required to have at least two in- or outpatient visits at a rheumatology- or general internal medicine clinic/department within 90 days with RA listed as the main diagnosis. **Liberal case definition:** patients with at least two in- or outpatient contacts listing RA as a main- or contributory diagnosis within 1 year.<sup>1</sup>

**Results:** We identified 26 090 and 43 080 patients using the Strict and Liberal case definitions, respectively. Patient characteristics according to choice of definition are presented in the Table. The overall incidence rates were 23.7/100,000 person years (23.4–23.9) using the Strict and 39.7/100,000 person years (39.4–40.1) using the Liberal definition. As seen from the figure 1, a slightly increasing trend in RA was observed from 1995 to 2016 independent of choice of case definition, and this increase was more pronounced in 2010.

The age-specific incidence rates were highest in women (Strict: 75/100,000 person years; Liberal: 134/100,000 person years) as well as men (Strict: 47/100,000 person years; Liberal: 81/100,000 person years) aged 70–79 years.

Table. Demographics and characteristics of rheumatoid arthritis patients diagnosed at hospitals in Denmark 1995–2016 according to case definition.

	Strict case definition	Liberal case definition
N	26 090	43 820
Mean (s.d) age at diagnosis	58.1 (15.2)	59.3 (15.5)
Females, n (%)	18 238 (70)	30 749 (70)
% with COPD	3.1	3.7
% with DM	3.3	3.8
% with CVD	7.2	8.4

**Conclusions:** We found a slightly increasing trend in the incidence rate of RA from 1995–2016. Further, we found that using the Liberal case definition, the overall and age- and sex specific incidence rates were remarkably similar to those reported from Sweden<sup>1</sup>, whereas the Strict definition resulted in lower incidence rates than previously reported from other countries.

SAT0708

### WILLINGNESS TO PARTICIPATE IN RESEARCH AND REPRESENTATIVENESS OF AN ONLINE HEALTH COMMUNITY AND A PATIENT ORGANISATION POPULATION WITH RHEUMATOID ARTHRITIS

R. Costello, J. McBeth, W.G. Dixon. *Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, UK*

**Background:** Studies requiring large numbers of participants usually recruit from hospital clinics or general practice registers. These recruitment methods are expensive, time consuming and often fail to reach recruitment targets. One method to overcome these limitations is to recruit patients directly through the internet or patient organisations. However it is not known how willing people would be to take part in different types of research and how representative participants would be of the target population.

**Objectives:** To describe: 1) the willingness of users of an online health community (HealthUnlocked.com (HU)) with rheumatoid arthritis (RA) to participate in research, 2) the representativeness of HU users and patient organisation members (National Rheumatoid Arthritis Society (NRAS)) with RA compared to the general RA population identified from a UK primary care research database (the Clinical Practice Research Datalink (CPRD)).

**Methods:** A pop-up survey was embedded on HU to determine users' willingness to participate in different types of research, demographics (age, gender, employment, postcode and ethnicity) and disease duration. NRAS provided a dataset of their members' demographics and disease characteristics. People with RA were identified from the CPRD, to represent the general RA population. Willingness and characteristics of those willing to take part in research was tabulated. The characteristics of HU users and NRAS members were compared to the characteristics of the RA cohort from CPRD.

**Results:** The HU survey was live for 74 days between May and August 2016 and had 1 00 112 pop-ups. 2647 people clicked on the pop-up, 900 people agreed to take part, 750 respondents had RA, of whom 135 did not provide age and gender resulting in 615 responses available for analysis. Over 80% of users were willing to complete questionnaires of different lengths, from a single questionnaire taking up to 1 min to complete, to multiple questionnaires over a number of months. 74% were willing to wear an activity tracker and 63% to use an app. Just over half (53%) were willing to take part in trials that involved visits to clinics (figure 1). Younger users were more willing to take part in all types of research, with 2% to 17% difference between those aged less than 65 years and those 65 years or over. Compared to those 65 years or over, 2% more of those aged less than 65 years were willing to complete multiple questionnaires over a number of months and 17% more were willing to provide information via an app. HU users were younger than NRAS and the general RA population (Age <55 years HU: 49%, NRAS: 23%, CPRD: 23%). Both HU and NRAS had more females, 88% and 85%, respectively, compared to CPRD 70%. A total of 61% HU participants were diagnosed in the years 2010–2016 compared to 25% in NRAS and 37% in CPRD.

**Conclusions:** Participants surveyed online show high rates of willingness to participate in research studies. While broadly representative of the general RA, they

were younger and more recently diagnosed and these population differences should be considered during study design.

**Disclosure of Interest:** None declared

### SUBCLINICAL HEPATITIS C VIRUS INFECTION IN EGYPTIAN PATIENTS WITH RHEUMATOLOGIC DISEASES: A MULTI-CENTRE STUDY

S. Mahran<sup>1</sup>, M. Hassani<sup>2</sup>, D.A. Nigm<sup>3</sup>, A. Moshri<sup>4</sup>, M. Hasanein<sup>5</sup>, M.Z.A. Abu Rahma<sup>6</sup>, M.I. Risha<sup>7</sup>, M.A. Hanafy<sup>8</sup>, A.H. Shalaby<sup>8</sup>, M. Abdelkareem<sup>8</sup>, H. Hamoud<sup>8</sup>, S. Ghanem<sup>8</sup>, S. Abd-Elsalam<sup>9</sup>, F. El-Nouby<sup>10</sup>, A. fehr<sup>11</sup>, E. F. Kholef<sup>10</sup>, A. O. B.S. Osman<sup>10</sup>, D.G. Mahran<sup>12</sup>. <sup>1</sup>Rheumatology and Rehabilitation, Assiut University; <sup>2</sup>Rheumatology and Rehabilitation; <sup>3</sup>clinical pathology; <sup>4</sup>Al-Azhar University, Assiut University Hospital; <sup>5</sup>AL-Azhar University; <sup>6</sup>tropical medicine, Assiut University Hospital, Assiut; <sup>7</sup>Rheumatology and Rehabilitation; <sup>8</sup>AL-Azhar University, Cairo; <sup>9</sup>Tanta University, Tanta; <sup>10</sup>Aswan University, Aswan; <sup>11</sup>Helwan University, Cairo; <sup>12</sup>Public health, Assiut University Hospital, Assiut, Egypt

**Background:** Egypt has the highest prevalence of hepatitis C virus (HCV) in the world. In 2015, the prevalence of HCV RNA was found to be 7.0%.<sup>(1)</sup> The prevalence of HCV was studied in Rheumatoid arthritis in few studies,<sup>(2,3)</sup> but to our knowledge, no previous work studied it in other rheumatologic patients.

**Objectives:** This study aims at detecting the prevalence of subclinical HCV infection in different rheumatologic disease groups in Egypt.

**Methods:** Consecutive patients with different rheumatologic diseases from seven-geographically different- rheumatology departments were prospectively studied. None of the patients was known to have previous HCV infection. Patients' serum samples were screened for the presence of anti-HCV antibodies. Patients with positive serology were further evaluated for the presence of HCV ribonucleic acid by reverse transcriptase polymerase chain reaction (RT-PCR).

**Results:** 1454 rheumatic patients (1242 (85.4%) women, 212 (14.5%) men) with mean age[SD] of 43.7 [12.7] years were included in this study. Both anti-HCV serology and HCV RNA were positive in 124 patients (8.5%). Positive PCR for HCV was significantly higher in the age group of 40 to <60 years (p<0.0001) versus other age groups. No statistically significant difference in HCV PCR positivity was found in relation to gender, specific rheumatologic disease, comorbidities or disease duration among studied patients. AST and ALT serum levels were significantly higher in the HCV PCR positive patients (p<0.0001 and p=0.002 respectively).

Geographic area	Anti HCV PCR Positive No=124 (8.5%)	Total No. No=1454	P value P1
Assiut	48 (9.5%)	504 (34.7%)	0.947
Tanta	14 (6.9%)	202 (13.9%)	
AL-Behera	14 (9.6%)	146 (10.0%)	
Cairo	24 (6.9%)	346 (23.8%)	
Aswan	10 (8.2%)	122 (8.4%)	
Sharkeya	14 (10.4%)	134 (9.2%)	
<b>Diagnosed Diseases</b>			<b>P2</b>
-Rheumatoid arthritis	82 (8.4%)	974 (67.1%)	0.053
-Systemic Lupus erythrematosis	10 (5.1%)	196 (13.5%)	
-Scleroderma	0 (0.0%)	38 (2.6%)	
-Behcet's Disease	2 (3.7%)	54 (3.7%)	
-Crystal arthropathy	4 (8.7%)	46 (3.2%)	
-Others	26 (18.1%)	144 (9.9%)	
<b>Disease duration</b>			<b>P3</b>
<5 years	44 (8.1%)	546 (37.6%)	0.924
5–10 years	52 (9.0%)	578 (39.8%)	
>10 years	28 (8.5%)	330 (22.7%)	

Table (1): Number and percentage of positive HCV PCR and statistical significant differences among geographic areas (P1), among different diseases (P2), and between age groups(P3)

**Conclusions:** The detection of subclinical HCV infection in 8.5% of rheumatologic patients in Egypt with significant higher level in the middle age group, draws attention to the importance of screening for HCV in such population for early detection and intervention.

**SAT0710 RISK ASSOCIATION FOR ANKYLOSING SPONDYLITIS USING A GENETIC RISK SCORE COMBINING 110 SNPS OF GENOME-WIDE SIGNIFICANCE IN THE POPULATION-BASED HUNT STUDY**

S. Rostami<sup>1</sup>, M. Hoff<sup>1,2</sup>, M.A. Brown<sup>3</sup>, K. Hveem<sup>4</sup>, O.L. Holmen<sup>1</sup>, V. Videm<sup>1,2</sup>.  
<sup>1</sup>NTNU – Norwegian University of Science and Technology; <sup>2</sup>St Olavs University Hospital, Trondheim, Norway; <sup>3</sup>Queensland University of Technology, Brisbane, Australia; <sup>4</sup>KG Jebsen Center for Genetic Epidemiology, NTNU – Norwegian University of Science and Technology, Trondheim, Norway

**Background:** The genetic component of AS development is estimated to ~90%. About 20% of the known heritability for AS is attributed to *HLA-B27* and about 7.4% to 113 SNPs found in genome-wide association studies,<sup>1</sup> with a further ~60% of heritability determined by as yet unmapped variants.

**Objectives:** To evaluate whether a weighted genetic risk score (wGRS) developed based on the currently identified SNPs is predictive of AS in the Norwegian population-based Nord-Trøndelag Health Study (HUNT).

**Methods:** HUNT invited the entire adult population of Nord-Trøndelag county. We used data from HUNT2 (1995–97) and HUNT3 (2006–8). AS cases were diagnosed from hospital records using the Modified New York Criteria. Participants with other inflammatory arthritis were excluded, leaving 181 AS cases and 55 586 controls. Genotyping was performed with Illumina HumanCoreExome arrays. Imputation was performed with Minimac3 based on European ancestry data. Imputed or genotyped data were available for 110 (97%) of the 113 SNPs. We used rs4349859 to indicate *HLA-B27* carrier state (positive/negative). The wGRS was calculated by addition of risk alleles and weighting by the published OR from,<sup>1</sup> representing each person's carriage of all risk variants. Data were analysed using logistic regression. Four models were compared using AUC analysis: 1) the wGRS only; 2) *HLA-B27* only; 3) the wGRS and *HLA-B27*; 3) the wGRS, *HLA-B27*, age, gender, BMI, hypertension, and smoking (never/previous/present). HUNT had ethical approval and participants gave informed consent.

**Results:** At baseline, mean age for cases was 43 years, 61% were men and 87% were *HLA-B27* positive. The corresponding figures for controls were 46 years, 47% men and 12.7% *HLA-B27* positive. The mean wGRS was 14.37 (range: 10.93 to 17.41). The wGRS alone was associated with AS (OR=1.7 for one unit increase,  $p<0.001$ ), but had low discriminative ability (AUC: 0.62, 95% CI: 0.58–0.66). *HLA-B27* alone was also associated with AS (OR=48<sup>31-74</sup>),  $p<0.001$  and showed high discriminative ability (AUC: 0.88 (0.85–0.90)). AUC for the combined wGRS and *HLA-B27* model (0.89 (0.87–0.92)) was higher than for the univariate models ( $p<0.001$  vs. wGRS only;  $p<0.01$  vs. *HLA-B27* only). Further addition of age, gender, BMI, hypertension, and smoking to the combined model gave a small improvement (AUC: 0.91 (0.88–0.94),  $p=0.03$ ).

**Conclusions:** The wGRS was associated with AS, but had low predictive ability in a population-based setting. *HLA-B27* was a much better predictor. Addition of clinical variables only slightly improved prediction, in accordance with the high genetic component in AS pathophysiology. Discovery and inclusion of more genetic risk variants, epigenetic factors, other demographic factors, and interaction terms, in addition to more efficient statistical approaches such as genome-wide risk score development, could improve prediction. Study limitations are false positive- or -negative AS diagnoses and potential selection bias of participants in HUNT.

**SAT0711 SENSE OF COHERENCE PREDICTS DEVELOPMENT OF CHRONIC WIDESPREAD PAIN OVER TIME**

S. Hägerström<sup>1</sup>, S. Bergman<sup>1,2</sup>. <sup>1</sup>Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg; <sup>2</sup>RandD Spenshult, Halmstad, Sweden

**Background:** Chronic musculoskeletal pain is a common condition that has become a great challenge for those affected and for the society. Although much is known about factors that are associated with chronic pain, there is less of knowledge on the influence of salutogenetic factors as measured by sense of coherence (SOC) on pain, especially over time.

**Objectives:** To investigate the associations between SOC, health status and chronic musculoskeletal pain in a general population followed over 13 years.

**Methods:** A cross-sectional and longitudinal cohort study, based on a postal survey at baseline 2003 and a follow-up survey in 2016, including a sample of 1850 subjects from the general population. SOC was measured by a short three item

questionnaire, SOC-3. Subjects were divided into three levels of SOC (low, moderate, high). Health status was measured by SF-36. Pain was reported on a pain mannequin with 18 predefined regions, and was categorised into three pain groups; no chronic pain (NCP), chronic regional pain (CRP), and chronic widespread pain (CWP). CWP was defined according to the ACR<sup>1990</sup> criteria for fibromyalgia. The results were controlled for age and gender, and where appropriate also for pain group.

**Results:** Subjects with high SOC at baseline reported higher mean scores in all eight SF-36 dimensions than those with moderate or low SOC ( $p<0.001$  for all dimensions). Those with high SOC also reported a higher prevalence of NCP (66% vs. 34%) and a lower prevalence of CWP (8% vs. 33%) than subjects with low SOC ( $p<0.001$ ). In the long term follow-up a report of high SOC significantly ( $p<0.001$ ) predicted a better outcome with regard to development and persistence of CWP. Subjects with NCP and high SOC at baseline were less likely to report CWP in the thirteen-year follow-up than those with low SOC (3.6% vs. 10%). For those with CWP at baseline, subjects with high SOC more often reported less chronic pain (NCP or CRP) at follow-up compared to those with low SOC (43.5% vs. 20.5%). When controlled for age, gender and pain, there were no significant differences in SF-36 at follow-up for subjects with different level of SOC at baseline.

**Conclusions:** High level of SOC predicted a lower risk to develop CWP over time, and a better prognosis for those with CWP at baseline. The findings suggest that it would be beneficial to develop methods and make efforts to strengthen SOC, both when meeting patients in the clinic and when making interventions on a national level.

**SAT0712 EVALUATION OF STRUCTURAL DAMAGE IN PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW**

T. Gudul<sup>1</sup>, I. Janta<sup>2</sup>, R. Ionescu<sup>1</sup>. <sup>1</sup>Rheumatology, Sf Maria Hospital, UMF Carol Davila, Bucharest, Romania; <sup>2</sup>Rheumatology, Gregorio Marañon Hospital, Madrid, Spain

**Background:** Measuring structural damage in psoriatic arthritis (PsA) is important since it is the ultimate goal of treatment.<sup>1</sup> Similar to rheumatoid arthritis (RA), structural damage in PsA is evaluated mainly on x-rays, but there is no consensus about the radiologic scoring method to use in trials. Usually scores from RA are used and modified so they can capture PsA specific features, such as distal interphalangeal (DIP) joints involvement, bone proliferation, periostitis, osteolysis etc.<sup>2</sup>

**Objectives:** The objective of this study was to analyse existing data on the definition and scoring methods of structural damage in studies on PsA.

**Methods:** A systematic literature review was performed. Studies evaluating structural damage in PsA were identified in Pubmed/Medline and Embase on 10th December 2017. Several synonyms for the main components (i.e. psoriatic arthritis, structural damage, radiologic progression) were used. No search limits were applied. Studies not assessing structural damage or not providing enough information on the definition of damage were not included, nor reviews, case-reports, letters. Descriptive statistics were used.

**Results:** In all, 3321 abstracts were identified of which 61 full length articles were included in the final analysis. The majority were observational studies (59%). Only 3 studies were on axial PsA (axPsA) and around 10% of the studies also had a control population, e.g., RA, osteoarthritis, spondyloarthritis and healthy individuals. In total, a median of 220 (minimum-maximum: 12–1077) patients were included. Most of the studies used the CASPAR criteria (63.9%). A wide majority of studies (80.3%) assessed progression of structural damage.

Structural damage was defined mainly radiographically (77%), followed by the clinical definition (24.6%) and to a lesser extent by other investigations: magnetic resonance imaging (8.2%), computer tomography (4.9%) and ultrasound (3.3%), respectively.

Radiologic assessment of peripheral damage included radiographs of hands and feet, but was very heterogeneous, with most of the studies using the scores “borrowed” from RA and modified for PsA. Hence, 97.8% of the studies using the radiographic evaluation of damage have adapted the scoring method so that it includes the DIP joints of hands and feet. The following elements were included in the radiographic scores: space narrowing 42 studies (93.3%), erosions 44 (97.8%), osteolysis 24 (53.3%), proliferation 12 (26.7%), periostitis 9 (20%), tuft resorption 14 (31.1%), pencil in cup 17 (37.8%), juxta-articular osteopenia/osteoporosis 4 (8.9%), subluxation 6 (13.3%), and ankylosis 5 (11.1%) (table 1). In axPsA radiographic damage was defined by sacroiliitis grades and spine damage, i.e., presence of syndesmozytes and scores such as BASRI-spine, mSASSS, RASSS and PASRI.

**Abstract SAT0712 – Table 1.** Frequency of specific psoriatic arthritis radiographic features

	Randomized control trials	Observational studies	Total number of studies (out of N=61)
Erosions	24 (54.5%)	20 (45.5%)	44
Space narrowing	24 (57.1%)	18 (42.9%)	42
Osteolysis	14 (58.3%)	10 (41.7%)	24
Pencil in cup	10 (58.8%)	7 (41.2%)	17
Tuft resorption	6 (42.9%)	8 (57.1%)	14
Proliferation	6 (50%)	6 (50%)	12
Periostitis	5 (55.6%)	4 (44.4%)	9
Subluxation	3 (50%)	3 (50%)	6
Ankylosis	2 (40%)	3 (60%)	5
Juxta-articular osteopenia/osteoporosis	0 (0%)	4 (100%)	4

**Conclusions:** Damage in PsA is usually evaluated radiologically. Although radiographic scores are almost always adapted for PsA in order to include DIP joints, the other PsA specific radiographic elements are not so frequently assessed. A more specific but also a feasible radiographic score for PsA damage to be universally used in studies is still needed. Further research on other methods of evaluating PsA damage is also needed since data is scarce.

SAT0713

### INCIDENCE OF EROSIVE INTERPHALANGEAL OA IS STRONGLY ASSOCIATED WITH AGE, FEMALE GENDER, WHITE RACE, AND PRE-EXISTING HAND OA: DATA FROM THE OSTEOARTHRITIS INITIATIVE

T. McAlindon<sup>1</sup>, M. Roberts<sup>2</sup>, L. Schaefer<sup>3</sup>, J. Driban<sup>1</sup>, I.K. Haugen<sup>4</sup>, S.E. Smith<sup>3</sup>, J. Duryea<sup>3</sup>, C. Eaton<sup>2</sup>. <sup>1</sup>Rheumatology, Tufts Medical Center, Boston; <sup>2</sup>Center for Primary Care and Prevention, Alpert Medical School of Brown University, Pawtucket; <sup>3</sup>Radiology, Brigham and Women's Hospital and Harvard Medical School, Boston, USA; <sup>4</sup>Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

**Background:** Symptomatic erosive interphalangeal OA (SEIPOA) is differentiated from hand OA by the presence of central joint erosions and is more strongly associated with hand pain, disability and finger deformity. There are no specific treatments for SEIPOA and relatively little is known about its incidence and natural history.

**Methods:** We evaluated participants in the Osteoarthritis Initiative (OAI), a multicenter cohort study of 4796 adults with or at risk for symptomatic knee OA recruited at 4 clinical sites between February 2004 and May 2006, which included postero-anterior radiographs of one or both hands at baseline and at 48 months, as well as questions about joint pain including the hand (based on a homunculus where patients indicated left or right hand pain) and self-reported physician-diagnosed hand OA.

Trained readers scored the severity of OA in 16 joints of the dominant hand using the Kellgren Lawrence scale and classified presence of central erosions according to the OARS1 Atlas of radiographic features: 2nd-5th distal interphalangeal (DIP) joints, 2nd-5th proximal interphalangeal (PIP) joints, 1st-5th metacarpophalangeal (MCP) joints, thumb interphalangeal (IP) joint, thumb-base joints (i.e., first carpometacarpal (CMC-1) joint and the scaphotrapezium (ST) joint).

We classified erosive interphalangeal OA (EIPOA) based on presence of OA (KL  $\geq 2$ ) in at least one IP joint on two different fingers (excluding thumb base joints) with at least one with a central erosion and symptomatic erosive interphalangeal OA (SEIPOA) if there was also a report of hand pain.

Baseline characteristics were examined by incident SEIPOA and EIPOA using ANOVA for continuous variables and chi-square analysis for categorical variables. Odds ratios were calculated to estimate the strength of association with

incident SEIPOA. A p-value  $\leq 0.05$  was considered significant. All analyses were conducted with SAS 9.4.

**Results:** 3604 participants had hand radiographs at baseline and 48 months; 18 radiographs were not readable and 121 had prevalent SEIPOA at baseline, leaving 3465 individuals eligible for analysis. The average age was 60.8 years (sd=9.1), 56.1% were female, and 81.3% were white.

133 individuals (3.8%) developed incident SEIPOA over the 4 year observation period. They had greater burden of IP OA at baseline (1.9 vs. 6.2 joints, p<0.001) and were more likely to report a diagnosis of hand OA (13.0% vs. 42.9%, p<0.001) than those who did not develop SEIPOA. 97.7% of the incident SEIPOA occurred in hands with radiographic hand OA, vs. 2.3% in hands without radiographic OA. SEIPOA incidence was strongly associated with older age, female gender, white race, smoking, lower BMI and lower level of physical activity (Image 1). Results were similar for radiographic EIPOA with the exception of the association with hypertension.

	No SEIPOA (n=3332)	SEIPOA (n=133)	p-value	OR (95% CI)
Age, years (mean, sd)	60.6 (9.1)	66.6 (7.6)	<0.001	2.00 (1.66, 2.41)
Gender (n, %)			<0.001	
Female	1844 (55.3)	99 (74.4)		2.35 (1.58, 3.49)
Race/Ethnicity (n, %)			0.003	
White	2695 (80.9)	121 (91.0)		2.38 (1.31, 4.34)
Smoking Status (n, %)			0.007	
Ever smoked	1313 (39.4)	69 (51.1)		1.61 (1.14, 2.28)
BMI, kg/m <sup>2</sup> (mean, sd)	28.6 (4.8)	27.0 (4.2)	<0.001	0.69 (0.57, 0.84)
Waist Circumference > cut-point (n, %)	2404 (74.1)	110 (82.7)	0.025	1.68 (1.06, 2.64)
Diabetes (n, %)	219 (6.7)	11 (8.5)	0.436	1.29 (0.68, 2.42)
Hypertension (n, %)	1652 (49.6)	84 (63.2)	0.002	1.74 (1.22, 2.50)
PASE score (mean, sd)	166 (82.3)	137 (72.5)	<0.001	0.68 (0.56, 0.82)
# joints with OA sans TB (mean, sd)	1.9 (2.6)	6.2 (2.6)	<0.001	3.11 (2.67, 3.62)
MD diagnosed hand OA (n, %)	434 (13.0)	57 (42.9)	<0.001	5.01 (3.50, 7.16)

Note: OR's are calculated per SD for continuous variables

**Figure 1.** Comparison of baseline characteristics by incident SEIPOA group

**Conclusions:** Incidence of SEIPOA in older people is substantial and approximates that of rheumatoid arthritis. SEIPOA is strongly related to age, female gender, and white race, develops in the setting of pre-existing hand OA, and is somewhat associated with reduced BMI and lower level of physical activity.

### IMPACT OF PM10 ON THE BURDEN OF RAYNAUD'S PHENOMENON SECONDARY TO SYSTEMIC SCLEROSIS

T. Schioppa<sup>1</sup>, V. Bollati<sup>2,3</sup>, S. Iodice<sup>2,3</sup>, O. De Lucia<sup>1</sup>, A. Murgo<sup>1</sup>, F. Ingegnoli<sup>1,2</sup>. <sup>1</sup>Division of Rheumatology, ASST Pini-CTO; <sup>2</sup>Dept of Clinical Sciences and Community Health; <sup>3</sup>EPIGET Lab, Università degli Studi di Milano, Milano, Italy

**Background:** Raynaud's phenomenon (RP) is the most frequent manifestation of patients with systemic sclerosis (SSc) and it is responsible for significant morbidity. RP has been ranked by patients with SSc as the second most disturbing related-disease symptom.<sup>1</sup> It's well known that RP, defined as episodic digital ischemia characterised by pain, numbness and digital colour changes, is provoked by environmental factors such as cold temperature and smoking exposure.<sup>2</sup> No data are available on the impact of particulate matter (PM) exposure on SSc-RP severity.

**Objectives:** Our aim was to evaluate the association between PM with aerodynamic diameter  $\leq 10 \mu\text{m}$  (PM<sub>10</sub>) and SSc-RP severity.

**Methods:** We applied multivariable continuous ordinal regression model to evaluate the association between short-term exposure to PM<sub>10</sub> and a measure of RP severity (in terms of number and duration of RP attacks, numbness, pain, burning and tingling) as measured by a Visual Analogue Scale (VAS). The model was then adjusted by sex, intravenous prostacyclin therapy (alprostar or iloprost), SSc subtype, general health (GH) VAS and season. Daily PM<sub>10</sub> concentrations, from monitoring stations measured by Regional Environmental Protection Agency (ARPA Lombardia), were used to assign short-term exposure (mean of the 3 days preceding the evaluation) to each study subjects at his/her area of residence.

**Results:** We enrolled 87 consecutive patients with SSc-RP from September 2016 to February 2017. 88.5% were female, mean age was 61 years, median time from diagnosis was 14 years (q1-q3: 7–21 years), and 10% had diffuse cutaneous SSc. The median VAS severity was 5 mm (q1-q3: 2–7 mm). 43.7% were treated with prostacyclin therapy.

The model, performed as described above, estimated that for each 10  $\mu\text{g}/\text{m}^3$  increase in  $\text{PM}_{10}$  there is a worsening of 40% in RP VAS severity (OR 10  $\mu\text{g}/\text{m}^3 \approx 1.40$ ; 95% CI: 1.12–1.74).

**Conclusions:** To our knowledge a correlation between SSc-RP and air pollution as assessed by  $\text{PM}_{10}$  has never been published before. There is increasing evidence that a number of environmental factors are fundamental in the development and course of SSc.<sup>3</sup> These results support the need to perform exposome epidemiology studies, next to genomics, to fully reveal the underlying mechanisms of diseases.

#### RISK FACTORS OF IMMUNE-RELATED ADVERSE EVENTS IN PATIENTS TREATED WITH ANTI-PD-1 ANTIBODY PEMBROLIZUMAB

Y. Eun<sup>1</sup>, I.Y. Kim<sup>1</sup>, H. Kim<sup>1</sup>, J.K. Ahn<sup>2</sup>, E.-J. Park<sup>3</sup>, J. Hwang<sup>4</sup>, H. Jeong<sup>5</sup>, J. Y. Chai<sup>6</sup>, H.-S. Cha<sup>1</sup>, E.-M. Koh<sup>1</sup>, J. Lee<sup>1</sup>. <sup>1</sup>Department of Medicine, Samsung Medical Center; <sup>2</sup>Department of Medicine, Kangbuk Samsung Hospital; <sup>3</sup>Department of Medicine, National Medical Center; <sup>4</sup>Department of Medicine, National Police Hospital, Seoul; <sup>5</sup>Department of Medicine, Soonchunhyang University Hospital, Bucheon; <sup>6</sup>Department of Medicine, Bundang Jesaeng General Hospital, Seongnam, Korea, Republic Of

**Background:** Immune checkpoint inhibitors targeting cytotoxic T-lymphocyte-associated protein 4 and programmed cell death protein 1 (PD-1) have been

established as a novel standard treatment for various types of malignancies. However, these new class of drugs have led to increased immune-related adverse events (IrAEs) including rheumatic manifestations.

**Objectives:** To determine the risk factors of IrAEs in patients treated with anti-PD 1 antibody pembrolizumab.

**Methods:** A retrospective medical record review was performed to identify all patients who received at least one dose of pembrolizumab at Samsung Medical Centre, Seoul, Korea between June 2015 and December 2017. Three hundred and ninety two patients were identified. Multivariate logistic regression model was used to identify risk factors of IrAEs.

**Results:** The mean age was 59.7 $\pm$ 13.0 years (range, 18–95) and the median number of doses of pembrolizumab was 2 (IQR, 1.25–5). The primary malignancies included in the study were lung cancer (n=212, 54.1%), melanoma (n=74, 18.9%), lymphoma (n=53, 13.5%) and others (n=53, 13.5%). Sixty-seven (17.1%) patients experienced clinically significant IrAEs; most commonly dermatologic disorders (n=39, 9.9%), pneumonitis (n=11, 2.8%), musculoskeletal disorders (n=10, 2.6%), followed by endocrine disorders (n=7, 1.8%). Fourteen patients (3.6%) experienced serious IrAEs ( $\geq$ Grade 3). Most common serious IrAEs were pneumonitis (n=9, 2.3%). There were 4 deaths associated with IrAEs, all of which were due to pneumonitis. Multivariate logistic regression analysis showed that obesity was the risk factors of IrAEs in pembrolizumab-treated patients. Patients with a body mass index (BMI) of 25 or higher had a 3.65-fold higher risk of IrAEs compared with patients with a BMI between 18.5 and 22.9 (95% CI, 1.58 to 8.42).

**Conclusions:** To our knowledge, this is the first study to explore the risk factor for IrAE in patients undergoing modern cancer immunotherapy. Our study demonstrate that BMI is associated with an increased risk of IrAEs in patients treated with pembrolizumab. Further studies to investigate the potential mechanisms by which obesity raises IrAEs are needed.

### ASSOCIATION OF DICKKOPF1-1 POLYMORPHISMS WITH RADIOLOGICAL DAMAGE AND PERIODONTAL DISEASE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

A.D. Cardona-Rincón<sup>1,2</sup>, M. Acevedo-Godoy<sup>3</sup>, S. Perdomo-Lara<sup>3</sup>, L. Chila<sup>3</sup>, P. Chalem Ch<sup>4</sup>, W. Bautista-Molano<sup>2,3</sup>, R. Valle-Oñate<sup>1</sup>, J.M. Bello-Gualtero<sup>1,2</sup>, C. Romero-Sanchez<sup>1,2,3</sup>. <sup>1</sup>Rheumatology and immunology, Hospital Militar Central; <sup>2</sup>Clinical Immunology Group, Universidad Militar Nueva Granada; <sup>3</sup>Unit of Oral Basic Investigation, Universidad El Bosque; <sup>4</sup>Fundación Instituto de Reumatología Fernando Chalem, Bogotá D.C., Colombia

**Background:** Rheumatoid arthritis (RA) is an autoimmune disease that primarily affects the joints but also has extra-articular manifestations such as Periodontal Disease (PD). The Dickkopf-1 (DKK-1) may have an active role in the regulation of bone biology and patients with RA that carry genetic variants of DKK-1 have greater bone damage

**Objectives:** To investigate the polymorphisms of DKK-1 in patients with early RA (eRA) and its association with some rheumatic, radiological and periodontal variables.

**Methods:** A cross-sectional study in 63 patients with eRA according to the ACR/EULAR 2010 criteria and PD based on the AAP/CDC and Prevention criteria. Serum markers rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), C reactive protein (CRP) and anticitrullinated peptide antibodies (APCAs) were evaluated. Patients selected were over 18 and less than 65 years old and were on treatment with conventional disease modifying antirheumatic drugs. Rheumatic activity was assessed by scales disease activity score 28 and simplified disease activity index. Radiographs of hands and feet were evaluated using the Sharp-van der Heijde (SvH) and Simple Erosion Narrowing Scores (SENS). DKK-1 polymorphisms as rs1896368, rs1896367 and rs1528873 were determined using the High resolution Melting technique (Bio-Rad). A bivariate analysis was performed to determine the variables associated between polymorphism to the presence of radiological and activity scores, diagnosis and severity of PD. A regression model was performed to confirm these associations.

**Results:** The mean age was 48.57±11.35 years, and 76.7% were female. 11.7% had a body mass index >30 kg/m<sup>2</sup>. 35% had an ESR >20 mm/h, and 56.7% had elevated CRP. RF >20 was observed in 61.7% of patients as were APCAs >20 in 43.3% of them. 30%, 42% and 1.6% of patients were homozygous for polymorphism rs1896367, rs1896368 and rs1528873 respectively. Individuals heterozygous for polymorphism rs1896367 had more frequent erosions (p=0.026) and joint space narrowing (JSN) (p=0.005) in the feet, and consequently higher SHS scores (p=0.016). These patients also had higher SENS scores (p=0.001) and more frequent erosions (p=0.02). In contrast, patients homozygous for polymorphism rs1896368 had less frequent JSN in hands and feet as assessed by SHS, as well as less presence of erosions based on the SENS scale. These findings were validated in the regression model (OR: 0.04, 95% CI:0.00–0.93;p<0.05). Finally, the presence of PD was associated with the homozygous expression of polymorphism rs1896367 (p=0.009) and the heterozygous expression of polymorphism rs1696368 (p=0.033).

**Conclusions:** DKK-1 polymorphisms can be associated with the presence of bone damage in patients with eRA and it could affect periodontal outcomes. While polymorphism rs1696367 seems to be associated with greater radiological compromise, polymorphism rs1696368 confers protection against bone damage in Colombian eRA patients.

### EFFECT OF COMMON POLYMORPHISMS IN THE METHOTREXATE PHARMACOKINETIC PATHWAY ON EFFICACY/ADVERSE EFFECTS AND METHOTREXATE POLYGLUTAMATE LEVELS IN RA

A. Sandhu<sup>1</sup>, V. Dhir<sup>2</sup>, S. Ahmed<sup>3</sup>. <sup>1</sup>Internal Medicine, PGIMER, Chandigarh; <sup>2</sup>Internal Medicine, PGIMER; <sup>3</sup>Department of Biochemistry, Punjab university, Chandigarh, India

**Background:** Measurement of erythrocyte methotrexate polyglutamate levels (MTX-glu<sub>n</sub>) are widely used to predict response and adverse effects to methotrexate in rheumatoid arthritis patients, but there are very few studies in which these levels were correlated with common polymorphisms in genes involved in methotrexate (MTX) pharmacokinetics. This preliminary study evaluated their utility in Asian Indian patients in a prospective study over 24 weeks.

**Objectives:** The objective of this study is to investigate the impact of seven common polymorphisms in genes involved in methotrexate (MTX) pharmacokinetics on response, adverse effects and methotrexate polyglutamate (MTXPG) levels in rheumatoid arthritis.

**Methods:** This study enrolled 117 RA patients who were treated prospectively with MTX for 24 weeks. Patients were categorised on the EULAR criteria into responders (good and moderate) and non-responders. Adverse effects were ascertained using a questionnaire. The following polymorphisms were ascertained using hydrolysis probes – rs1045642 (ABCB1 3435C>T), rs1128503 (ABCB1 1236C>T), rs10106 (FPGS 1994A>G), rs1544105 (FPGS G>A), rs11545078 (GGH 452C>T), rs3758149 (GGH -401C>T) and rs1051266 (RFC1 80G>A). RBC MTXPG1–5 levels were determined using HPLC at 4, 8, 16 and 24 weeks.

**Results:** There was a significant association of the GGH 452C>T CC genotype (OR 9.5, 95% CI 1.2 to 76.0) with response to MTX. On logistic regression, higher DAS28<sup>3</sup> at baseline and GGH 452CC genotype were significantly associated with response (table 1); the accuracy of the model was 75%. The FPGS 1994A>G GG genotype was associated with a significantly lower risk of adverse effects to MTX (Odds Ratio 0.3 (95% CI 0.1 to 0.6)). On logistic regression, FPGS 1994GG genotype and lower BMI were significant predictors for adverse effects with an accuracy of 66%. The other polymorphisms were not associated with response or adverse effects. None of the polymorphisms were associated with change in MTXPG levels.

**Conclusions:** GGH 452 CC genotype was found to be associated with response to MTX and FPGS 1994 A>G GG with a lower risk of adverse effects; however, not by change in MTXPG levels.

### A GALNT3 GENE MUTATION IN TWO SIBS WITH CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS ASSOCIATED WITH HYPERPHOSPHATEMIC FAMILIAL TUMORAL CALCINOSIS

D. El Dessouki<sup>1</sup>, M.S. Abdel-Hamid<sup>2</sup>, M.I. Mehrez<sup>3</sup>, M.S. Aglan<sup>1</sup>, S.A. Temtamy<sup>1</sup>.<sup>1</sup>Clinical Genetics; <sup>2</sup>Medical Molecular Genetics; <sup>3</sup>Oro-dental Genetics, National Research Centre, Giza, Egypt

**Background:** Chronic recurrent multifocal osteomyelitis (CRMO) is an uncommon inflammatory disease mostly affects the metaphyses of long bones. It can be distinguished from osteomyelitis by multifocality and recurrence. Hyperphosphatemic familial tumoral calcinosis (HFTC) is a rare genetic disorder characterised by increased re-absorption of phosphate through the renal proximal tubule leading to increased phosphate concentration and deposition of calcified deposits in cutaneous and subcutaneous tissues, as well as some visceral organs. HFTC is inherited in an autosomal recessive manner and is caused by mutations in three different genes, *FGF23*, *GALNT3* and *KLOTHO*. CRMO has been associated with some chronic inflammatory diseases such as inflammatory bowel disease, palmoplantar pustulosis and SAPHO syndrome. The association of CRMO and HFTC is extremely rare and only three patients have been described so far in the literature.

**Objectives:** To report the clinical, radiological and molecular findings of two sibs with CRMO associated with HFTC.

**Methods:** In this report, we present two siblings; offspring of consanguineous parents. They presented with spontaneous bony pains not responding to NSAID and later on, that developed tender hard masses. There were no similarly affected family members, and they had a non-affected sibling. Clinical, laboratory, pathological and radiological examination was performed. Mutational analyses of the *FGF23*, *GALNT3* and *KLOTHO* genes was carried out by Sanger sequencing of the entire coding region of each gene.

**Results:** Laboratory results including blood cultures and sensitivities were normal, apart from mildly elevated ESR. Serum calcium, 25(OH) vitamin D, renal functions, albumin, alkaline phosphatase, parathormone hormone, and phosphorous were normal apart from hyperphosphatemia in both siblings.

Initial x-rays revealed lytic lesions with a sclerotic margin. Follow up x-rays showed healing with sclerosis and hyperostosis. After developing the hard masses, x-rays showed calcified masses. Resection pathological analysis revealed non-neoplastic inflammatory bone growth with prominent periosteal and bone proliferation, it was free from any granulomatous or malignant changes. We suggested a provisional diagnosis of CRMO associated with HFTC. Molecular studies confirmed the diagnosis by identifying a known pathogenic mutation in the donor splice site of exon 8 of the *GALNT3* gene, c.1524+1G>A. The mutation was found in the homozygous form in the two sibs and both parents were heterozygous.

**Conclusions:** This study documents the first Egyptian family clinically diagnosed with CRMO associated with HFTC and confirmed by molecular studies, with the identification of a splice mutation in the *GALNT3* gene.

### PHARMACOGENETIC ASPECT OF METHOTREXATE, IN A GROUP OF COLOMBIAN PATIENTS WITH RHEUMATOID ARTHRITIS

E.L. Saldarriaga<sup>1</sup>, C.A. González<sup>1</sup>, L.F. Restrepo<sup>1</sup>, R. Giraldo-Bustos<sup>1</sup>, J. G. Ballesteros-Muñoz<sup>1</sup>, A.Y. Vásquez<sup>1</sup>, S. Arias-Correal<sup>1</sup>, L. Valero<sup>1</sup>, M.-I. Ospina<sup>1</sup>, P. Lopez-Morales<sup>1</sup>, E. Couto-Luvie<sup>1</sup>, M.J. Soares-Santeguini<sup>1</sup>, J.-I. Angarita<sup>1</sup>, J.C. Rueda<sup>1</sup>, F.-M. Cuervo<sup>1</sup>, P. Santos-Moreno<sup>2</sup>, J. Londoño<sup>1</sup>, A. M. Santos<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Immunology—Group of spondyloarthropathies, Universidad de la Sabana; <sup>2</sup>BIOMAB, Centro de Artritis Reumatoide, bogota, Colombia

**Background:** Methotrexate (MTX) as monotherapy or in combination, is the most commonly Disease-Modifying-AntiRheumatic-Drug (DMARDs) used in rheumatoid arthritis (RA). About 40% of patients do not respond to treatment or have adverse effects. The genetic variability could be responsible for this phenomenon. Different studies suggest associations between polymorphisms in the enzymes involved in the metabolic pathway of MTX with alterations in the efficacy and toxicity.

**Objectives:** Determine the polymorphisms of the enzymes involved in MTX metabolism in a group of Colombian patients.

**Methods:** 400 patients with RA over 18 years old, diagnosed according to the ACR/EULAR classification criteria, who consecutively attended an outpatient RA clinic between March 2015 and December 2016 were included. MTX efficacy was defined by DAS28 score  $\geq 3.2$ , liver toxicity by elevation of transaminases above three times the normal value, Haematological toxicity by: leukocytes <4,000, Hb <9.5, platelets <150,000, renal toxicity: creatinine >1.5. The single nucleotide polymorphisms (SNPs) studied were MTHFR C677T, MTHFR A1298C, ATIC C347G,

RFC1 G80A, FPGS-AG and DHFR-CT and were identified by the technique of polymerase chain reaction in real time (RT-PCR).

**Results:** The mean age of patients was 60.7±13.9 years, the duration of the disease was 13.2±10.9 years and 76% were women. A significant increase in the frequency of MTHFR C677T and A1298C SNPs (p=0.05 and p=0.048) were found in the responding patients compared to non-responders. The DHFR-CT and the ATIC C347G SNPs were significantly increased in patients with any toxicity to MTX (p=0.0095 and p=0.005 respectively). We did not find a significant difference between the polymorphisms studied with any specific toxicity.

**Conclusions:** The Colombian population has similar statistical data compared to the global studies regarding the association of SPNs with the efficacy and toxicity of methotrexate, however the polymorphisms associated with inefficiency in the literature are not replicated in our data. These SNPs could be established as biomarkers to the methotrexate response in terms of efficacy and toxicity in our Colombian population with RA.

### HLA CLASS II IN PARAGUAYAN IMMUNE-MEDIATED INFLAMMATORY PATIENTS

L. Acosta-Colman<sup>1</sup>, S. Cabrera-Villalba<sup>1</sup>, G. Avila-Pedretti<sup>1</sup>, M.E. Acosta Hetter<sup>2</sup>, M. Vazquez<sup>1</sup>, A. Ayala Lugo<sup>2</sup>, V. Jolie<sup>2</sup>, L. Roman<sup>1</sup>, M. Melo<sup>1</sup>, M. González<sup>1</sup>, M. Duarte<sup>1</sup>, H. Torio<sup>3</sup>, M.T. Martínez de Filártiga<sup>3</sup>. <sup>1</sup>Departamento de Reumatología, Hospital de Clínicas de la Facultad de Medicina de la Universidad Nacional de Asunción; <sup>2</sup>Instituto de Investigación en Ciencias de la Salud; <sup>3</sup>Laboratorio Curie, Asunción, Paraguay

**Background:** Immune-mediated inflammatory disease (IMID) is a concept used to describe a group of conditions that share common inflammatory pathways leading to systemic inflammation. The best-known genetic factor for IMID susceptibility is the human leukocyte antigen (HLA) haplotypes. Nowadays, there is a lack of information about HLA profile in Paraguayan patients with IMIDs.

**Objectives:** To identify HLA alleles associated with susceptibility to develop an IMID in Paraguayan patients controlled in a reference centre.

**Methods:** Paraguayan IMID patients were recruited from the Rheumatology Department of Hospital de Clínicas, Paraguay. IMID *HLA II* frequencies were compared with a control group of 50 unrelated individuals without disease and from the same geographic origin. Genotyping for HLA was performed using LumineX PCR technology. The association analysis with the IMIDs risk was performed using the chi-square allelic test.

**Results:** 249 IMID patients (95 lupus, 104 rheumatoid arthritis and 50 systemic sclerosis) were included. Of these 84.4% were women with an average age of 43.4 ( $\pm 14$ ). Comparing the haplotypes profiles for the 5 HLA class II genes between the patients and the healthy controls, in the risk association analysis, the association of the known risk allele was corroborated HLADRB1\*03:01 ( $p=2e-06$ , OR:14.97). A significant association was identified between the allele HLADRB1\*08:02 ( $p=0.0271$ , OR:0.13) and HLADRB1\*08:07 ( $p=0.0133$ , OR: 0.08). In the gene *HLADQA1*, 1 allele associated with the IMIDs were found, the HLADQA1\*04:01 ( $p=1.4e-05$ , OR: 0.06). In the *HLADPB1* gene 3 alleles associated with the IMIDs were identified: HLADPB1\*02:01 ( $p=4.2e-05$ , OR: 82.91), HLADPB1\*03:01 ( $p=2e-06$ , OR: 14.97), HLADPB1\*04:01 ( $p=1.5e-05$  OR: 34.55). Different associations between IMIDs and alleles was identify (table 1).

**Abstract AB0005 – Table 1.** List of associated alleles stratified by disease

ALLELE (Systemic Lupus Erythematosus Cohort)	P-value	OR

HLADPB1*04:01	0.0001	29.69
HLADQA1*02:01	0.0467	0.24
HLADQA1*04:01	0.002	0.07
HLADPA1*02:01	0.0022	0.029
ALLELES (Scleroderma Cohort)		
	P-value	OR
HLADPB1*02:01	0.0003	82.33
HLADPB1*03:01	0.0094	8.44
HLADPB1*04:01	0.0001	47.50
HLADQA1*04:01	0.0013	0.06

**Conclusions:** In the genetic association analysis, already known associations have been replicated and new ones previously unpublished have been identified in Paraguayan IMIDs patients. This is the first genetic association study in IMID patients Paraguayan origin.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.5021

AB0006

#### MIR-26A POLYMORPHISM IS ASSOCIATED WITH SUSCEPTIBILITY OF RHEUMATOID AND PSORIATIC ARTHRITIS

J. Swierko<sup>1</sup>, R. Sokolik<sup>1</sup>, M. Kozłowski<sup>2</sup>, L. Korman<sup>1</sup>, P. Wiland<sup>1</sup>, K. Bogunia-Kubik<sup>2</sup>. <sup>1</sup>Department of Rheumatology and Internal Medicine, Medical University; <sup>2</sup>Laboratory of Clinical Immunogenetics and Pharmacogenetics, Hirsfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wrocław, Poland

**Background:** Serum levels of miR-26a has been reported to act as potential biomarker of rheumatic diseases.

**Objectives:** The aim of the study was to analyse the genetic variation and expression of miR-26a as potential diagnostic and/or prognostic markers of rheumatoid diseases.

**Methods:** The miR-26a polymorphism was examined in 111 patients with rheumatoid arthritis (RA), 86 patients with psoriatic arthritis (PsA) and 162 healthy blood donors that served as a control group. Genotyping for miR-26a rs7372209 was performed using a LightSNiP assay. For analysis of the miR-26a expression, RNA was isolated from sera of 15 RA patients (before and 3 months after anti-TNF treatment) and 10 controls (Nucleospin-miRNA Plasma; MACHEREY-NAGEL GmbH and Co. KG) followed by cDNA synthesis (TaqMan MicroRNA Reverse Transcription Kit; Applied BiosystemsTM by Life Technologies) and Real-time PCR amplifications with hsa-miR-26a TaqMan specific and U6 snRNA control primers for each probe. The results were analysed using the ( $\Delta\Delta C_t$ ) calculations.

**Results:** It was found that the presence of miR-26a TT genotype (rs7372209) more than 5 times increases the risk of RA (OR=5.28,  $p=0.003$ ) while the presence of CC homozygotes is associated with the risk of PsA (OR=1.77,  $p=0.037$ ).

There was no significant difference in the miR-26a serum levels between patients and controls. Also miR-26a serum levels did not significantly differed between RA patients before, 3 and 6 months after the implementation of biological therapy with TNF-alpha inhibitors.

**Conclusions:** These results imply that miR-26a rs7372209 allelic variants differentially affect the risk of rheumatoid and psoriatic arthritis while anti-TNF biological treatment seems not to affect the miR-26a expression in RA patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6673

AB0007

#### ASSOCIATION AT SYSTEMIC LEVELS OF CYTOKINE MRNAS AND PROTEIN QUANTITIES IN RHEUMATOID ARTHRITIS

I. Manolova<sup>1</sup>, M.G. Ivanova<sup>2</sup>, G. Vasilev<sup>3</sup>, R. Stoilov<sup>2</sup>, L. Miteva<sup>1</sup>, S. Stanilova<sup>1</sup>. <sup>1</sup>Department of Molecular Biology, Immunology and Medical Genetics, Medical Faculty, Trakia University, Stara Zagora; <sup>2</sup>Clinic of Rheumatology, University Hospital "St. Iv. Rilski", Medical Faculty, Medical University; <sup>3</sup>Laboratory of Clinical Immunology, University Hospital "St. Ivan Rilski", Medical Faculty, Medical University, Sofia, Bulgaria

**Background:** Rheumatoid arthritis (RA) is an autoimmune inflammatory disease, characterised by chronic synovitis, bone and cartilage destruction, as well as systemic manifestation. In accordance with the pivotal role of cytokines in autoimmunity and their impact as biomarkers, we analysed gene expression at both mRNA and protein levels of several cytokines in peripheral blood of RA patients.

**Objectives:** The aim of the present study was to investigate the gene expressions at mRNA and protein levels of main pro-inflammatory (TNF- $\alpha$ , IL18, IL-12p40; IL-23, IL-6) and immunosuppressive (TGF- $\beta$ 1 and IL10) cytokines and transcription factor Foxp3 in peripheral blood of RA patients.

**Methods:** Total RNA from peripheral blood was isolated from 32 patients matching the ACR/EULAR 2010 criteria for RA and 27 healthy controls. Quantitative real-time polymerase chain reaction was performed for the 8 genes of interests, using the TaqMan detection system. Relative quantitative evaluation of mRNAs was performed by the comparative  $\Delta\Delta C_t$  method and results were presented as n-fold mean difference (RQ-relative quantity) of target genes relative to calibrator (healthy controls) after normalisation to the reference genes (GAPDH and 18srRNA). Serum quantities of cytokines were measured by ELISA.

**Results:** From studied pro-inflammatory cytokine genes, we found down-regulation in the following order: IL6 >TNFA>IL12B; up regulation of IL23A and no change in IL18 gene expression in RA patients group compared to healthy controls. For anti-inflammatory genes we detected significantly increased quantity for IL10 mRNA and no change for TGF $\beta$ 1 mRNA. The most profound down-regulation (more than 7-fold) was observed for IL6 gene ( $p<0.001$ ), while the serum level of the same cytokine was significantly increased as compared to the same controls. The similar tendency was observed in the expression of TNFA, which gene expression was approximately 2-fold down-regulated, whereas serum levels were increased. IL12B mRNA were slightly but not significantly decreased (RQ=0.709;  $p=0.169$ ) in RA patients. An upregulation of IL-23 was detected for IL23A gene (RQ=2.422,  $p=0.002$ ) and serum level of IL-23 as well.

TGF $\beta$ 1 mRNA levels were approximately equal in patients and controls in contrast to IL-10, which was upregulated in both mRNA (RQ=1.6;  $p=0.034$ ) and serum levels (over 6.6 fold;  $p<0.05$ ). In addition, mRNA expression of FoxP3, a master transcription factor for Treg subset was also down-regulated over 4-fold in RA patients ( $p<0.001$ ). A positive correlation was found between gene expression of IL6 with Foxp3, TNFA and TGF $\beta$ 1 in RA ( $r=0.744$ ,  $p=0.004$ ;  $r=0.6$ ,  $p=0.03$ ;  $r=0.556$ ,  $p=0.048$ , respectively).

**Conclusions:** Our results demonstrated significant differences in the expression of mRNA encoded cytokines and their protein quantities at systemic level of RA patients, mostly on IL-23, IL-6 and TNF-alpha.

**Disclosure of Interest:** None declared

#### CROSS-TALK BETWEEN BONE TURNOVER AND CARDIOVASCULAR DISEASE. ASSOCIATION OF MICRORNAs EXPRESSION, FRACTURE AND ABDOMINAL AORTIC CALCIFICATIONS

M.-E. Pickering<sup>1,2</sup>, M. Croset<sup>1,2</sup>, M. Millet<sup>1,2</sup>, E. Somay-Rendu<sup>1,2</sup>, J.-C. Rousseau<sup>1,2</sup>, O. Borel<sup>1,2</sup>, P. Szulc<sup>1,2</sup>, R. Chapurlat<sup>1,2</sup>. <sup>1</sup>Hospices Civils de Lyon; <sup>2</sup>INSERM UMR 1033, Lyon, France

**Background:** MicroRNAs (miRs) have emerged as pivotal epigenetic key actors of gene regulation and several miRs have been shown to be at the crossroads of angiogenesis and of bone turnover, taking part in the calcification process by acting on osteoblasts and osteoclasts.<sup>1</sup> Calcification of the aortic media is highly

regulated and involves numerous factors, including calcium deposal and other bone remodelling factors.<sup>2</sup>

**Objectives:** The objective of this study was to find a signature of miRs linked both to osteoporotic fracture risk and abdominal aortic calcification (AAC).

The first outcome was the link between miRs levels at baseline and incident osteoporotic fractures (IOF) during 20 years; the second outcome was the link between miRs levels at baseline and the increase in AAC during 17 years.

**Methods:** Post-menopausal women older than 50 years from the OFELY cohort (Os des Femmes de LYon) were selected if they had available serums at inclusion, and available data for each outcome.

3 miRs selected after literature review because of their impact on vascular calcification and bone turnover (miRs 26a-5p, 34a-5p, and 223-5 p) were measured at baseline. Bioassays of miRs was conducted with miRCURY Biofluids (Exiqon) extraction kit, TaqMan Life Technologies protocol, and QuantStudio 7 flex (Applied Biosystems) for RNA quantification. Results are expressed by relative quantification of Cycle threshold (Ct).

**Results:** A sample of 434 age-matched women (63 [57–72] years old), 50% with incident osteoporotic fracture during the 20 years of follow-up, was included. 183 women had available data to explore AAC; 93 had an increase in Kauppila score in 17 years (58 [55–61] years old), 90 did not (55 [53–58] years old).

No significant link was underlined between miRs and IOF (miR-26: 1.06 [0.85–1.27] vs 0.99 [0.85–1.17],  $p=0.07$ ; miR-34: 1.15 [0.53–1.87] vs 1.26 [0.60–2.07],  $p=0.35$ ; miR-223: 1.01 [0.68–1.43] vs 1.05 [0.72–1.56],  $p=0.32$ ).

No miR was significantly linked to an increase in AAC (miR-26: 1.09 [0.94–1.28] vs 1.10 [0.89–1.30],  $p=0.95$ ; miR-34: 0.78 [0.46–1.21] vs 0.73 [0.38–1.50],  $p=0.90$ ; miR-223: 0.97 [0.69–1.22] vs 0.78 [0.56–1.22],  $p=0.11$ ).

**Conclusions:** No association was observed between the 3 tested miRs and IOF or increase in AAC. Larger studies are necessary to select interesting epigenetic pathways reproducible on wider population.

#### AB0009 GENETIC ASSOCIATION OF MITOCHONDRIAL DNA POLYMORPHISMS WITH BEHÇET'S DISEASE IN A KOREAN POPULATION

M.-H. Kwon<sup>1</sup>, C.-I. Joung<sup>1</sup>, S.-J. Yoo<sup>2</sup>, S.W. Kang<sup>2</sup>, I.S. Yoo<sup>2</sup>, J. Kim<sup>2</sup>, I.A. Choi<sup>3</sup>, M.-K. Lim<sup>4</sup>. <sup>1</sup>Internal medicine, Konyang university; <sup>2</sup>Internal medicine, Chungnam national university, Daejeon; <sup>3</sup>Internal medicine, Chungbuk national university, Chungju; <sup>4</sup>Internal medicine, Eulji university, Daejeon, Korea, Republic of Ireland

**Background:** Behcet's disease (BD) is an inflammatory multi-genetic disorder with unknown etiology. In the previous study, we sequenced whole mitochondrial nucleotides from blood of 20 BD patients and 10 sex-, age-matched healthy controls, m.248A>G, m.709G>A, m.3970C>T, m.6392T>C, m.6962G>A, m.10310G>A, m.10609T>C, m.12406G>A, m.12882C>T, m.13928G>C, m.16129G>A, and m.16304T>C were more frequently observed in patients group than healthy control without statistical significance. While, m.304C>A, m.3010G>A, m.4883C>T, m.5178C>A, and m.14668C>T were more frequent in control group ( $p=0.008$ , 0.026, 0.007, 0.007, and 0.026, respectively). m.16182A>C, m.16183A>C, m.16189T>C were associated with uveitis ( $p=0.041$ , 0.022, and 0.014, respectively).

**Objectives:** We performed a follow-up study to validate these possible associations in larger groups.

**Methods:** Whole blood or buffy coat were collected from 98 BD patients from four university hospitals located in Chung-Cheong district of Republic of Korea, 196 age-, sex-matched healthy controls from Konyang University Hospital. Above mentioned 20 targeted mitochondrial DNA (mtDNA) genomes were analysed using MassARRAY<sup>®</sup> system (Agena Bioscience, Inc., San Diego, CA, USA) for m.709, m.3010, m.4883, m.6392, m.6962, m.10310, m.10609, m.12406, m.12882, m.13928, and m.14668; Sanger sequencing for m.248, m.304, m.5178, m.16129, m.16182, m.16183, m.16189, and m.16304; and TaqMan-based genotyping assay (Applied Biosystems, Foster City, CA, USA) for m.3970. Results were compared with the revised Cambridge Reference Sequence (rCRS). Chi square or Fisher's exact test were used to analyse association of mtDNA

alterations between groups and between mtDNA alterations and clinical/laboratory characteristics.

**Results:** Presence of m.248A>G, m.304C>A, m.709G>A, m.3010G>A, m.3970C>T, m.4883C>T, m.5178C>A, m.6392T>C, m.6962G>A, m.10310G>A, m.10609T>C, m.12406G>A, m.12882C>T, m.13928G>C, m.14668C>T, m.16129G>A, and m.16304T>C were not differentiated by the groups. However, m.16812A>C was more frequently observed in the patient group than control [22 (22.4%) vs. 24 (12.2%),  $p=0.061$ ], and it was significantly associated with HLA-B51 positivity ( $p=0.011$ ), arthralgia ( $p=0.043$ ) and methotrexate use ( $p=0.02$ ), and was not associated with uveitis in the follow-up study. Among clinical and laboratory characteristics in BD patients, thrombosis was more frequently observed in male patients than female patients [7 (22.6%) vs. 0 (0%),  $p<0.001$ ], and WBC counts were lower in female patients [3642.3±3413.6 vs. 5200.8±3912.7,  $p=0.048$ ].

Abstract AB0009 – Table 1

RCRS position	Alteration	BD (n=98)	HC (n=196)	p-value	OR* (95% CI)
248	A del	12 (12.2%)	23 (11.7%)	1.000	1.050 (0.499–2.209)
304	C>A	0 (0%)	0 (0%)	NA	NA
709	G>A	24 (24.5%)	35 (17.9%)	0.236	1.492 (0.929–2.686)
3010	G>A	19 (19.4%)	50 (25.5%)	0.307	0.702 (0.387–1.273)

#### AB0010 EVALUATION OF SENSITIVITY TO DNA DAMAGING AGENTS AND EFFICIENCY OF DNA REPAIR IN HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS FROM PATIENTS WITH DERMATOMYOSITIS AND POLYMYOSITIS

O. Brzezinska<sup>1,2</sup>, A. Maciejka<sup>3</sup>, A. Lewandowska-Polak<sup>1</sup>, J. Sarnik<sup>3</sup>, M. Kubicka<sup>3</sup>, J. Makowska<sup>1</sup>, T. Poplawski<sup>3</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Department of Rheumatology, Immunology and Allergy, Medical University of Lodz; <sup>3</sup>Department of Molecular Genetics, University of Lodz, Łódź, Poland

**Background:** Idiopathic inflammatory myopathies (IIM) being one of the connective tissue diseases are a group of diseases with not fully understood pathology. The common features are production of autoantibodies, abnormal immune response against self-antigens and inflammatory process leading to destruction of muscle cells and internal organ involvement. Patients with inflammatory myopathies have higher risk of developing cancers. One of the processes that can

attribute to increased risk of cancers can be genomic instability and impaired DNA repair.

**Objectives:** The aim of the study was to assess the processes of endogenous and exogenous DNA damage and its repair in patients with IIM as compared to healthy controls.

**Methods:** The study included 10 patients (9 men and 1 woman, mean age 46.6 ± 16.5) with idiopathic inflammatory myopathies (dermatomyositis or polymyositis) as well as 7 healthy control individuals (4 men and 3 women, mean age 33.8 ± 9.8). DNA damage and repair were investigated by the comet assay. To perform the comet assay human peripheral blood mononuclear cells (PBMCs) were isolated and incubated with tert-butyl hydroperoxide (t-BOOH) or bleomycin. Both compounds are common DNA damaging agents – t-BOOH induces oxidative DNA lesions whereas bleomycin induces also DNA double strand breaks (DSBs). To test the DNA repair capability, PBMCs were allowed to recover for 2 hour. The level of endogenous DNA lesions was also investigated.

**Results:** The levels of endogenous DNA damage were not statistically significantly different between tested groups (IIM-3.3±3.6% vs 3.2±3.8% in control;  $p=0.648$ ). The extent of the DNA damage induced by bleomycin (IIM-23.3 ± 19.5% vs 9.8±5.9% in control) as well as oxidative stress (IIM-14.7±16.2% vs 10.4±7.4% in control) was significantly higher in PBMCs derived from IIM patients than in healthy counterparts ( $p<0.001$ ). Kinetic curves of DNA repair are different but the background mechanism underlying observed differences in the repair curve between healthy subjects and patients need to be evaluated further.

**Conclusions:** Understanding the etiology of this phenomena in these diseases may provide insight into disease pathogenesis and explain the increased susceptibility of patients to malignancies. Finding the patients with increased DNA instability could potentially serve as a biomarker and indicate the group of patients who should be carefully screened for neoplasms.

#### AB0011 EVALUATION OF SALIVARY MIRNAS IN PATIENTS AFFECTED BY SJÖGREN'S SYNDROME AND CORRELATION WITH CLINICAL AND ULTRASONOGRAPHIC OUTCOMES

R. Talotta<sup>1</sup>, M. Biasin<sup>2</sup>, S. Bongiovanni<sup>1</sup>, V. Mercurio<sup>2</sup>, C. Vittori<sup>2</sup>, L. Boccassini<sup>1</sup>, F. Rigamonti<sup>1</sup>, A. Batticciotto<sup>1</sup>, F. Atzeni<sup>3</sup>, D. Trabaton<sup>2</sup>, P. Sarzi-Puttini<sup>1</sup>.

<sup>1</sup>Rheumatology Unit, <sup>2</sup>Biomedical and Clinical Sciences, University Hospital "Luigi Sacco", Milan; <sup>3</sup>Rheumatology Unit, AOU "G.MARTINO", Messina, Italy

**Background:** It has been demonstrated that miRNAs expressed in PBMCs and salivary glands of patients affected by Sjögren's Syndrome (SS) could be involved in the epigenetic control of the disease.

**Objectives:** We aimed to compare the concentration of miRNA-146a/b, 16, 17–92 cluster and 181a in salivary and plasmatic samples collected from SS patients and healthy controls and to evaluate the associations with clinical, laboratory and ultrasound findings.

**Methods:** We collected plasmatic and salivary samples from 28 patients (27 females, mean age 64.4±10.1 years, mean disease duration 10.7±6.9 years) affected by primitive SS according to <sup>ACR</sup> 2012 and/or 2016 criteria and 23 matched healthy controls. In the group of patients, the following data were recorded: ESS-DAI and ESSPRI scores, anti-SSA and anti-SSB status and laboratory data, Schirmer's test, ultrasound scores of the four major salivary glands according to Cornec et al. and concomitant treatments. The following miRNA were extracted, retro-transcribed and quantified: miR16–5 p, miR17–5 p, miR18a–5p, miR19a–5p, miR19b–1–5 p, miR20a, miR92–5 p, miR146a–5p, miR146b–5p, miR181a–5p.

**Results:** The concentration of miRNAs evaluated in plasma and saliva did not significantly match both in patients and in controls, underlining a different modulation in their expression according to the corporeal district. In patients and controls miRNAs16, 17 and 20 were hyper-expressed and miRNA146b and 181 hypo-expressed in salivary samples compared to plasmatic ones. Salivary miRNAs 18a and 146a were hyper-expressed in patients and hypo-expressed in controls, when compared to plasmatic concentrations.

Comparing salivary and plasmatic patients' miRNAs concentrations to those of healthy subjects, plasmatic miRNA16 and 181a were significantly more expressed in patients than in controls (two-tailed Wilcoxon test and Student's T test for unpaired samples).

In SS patients, salivary miRNA 181 and 146a were significantly increased in older subjects ( $p=0.01$  and  $p=0.04$  respectively). Spearman's correlation revealed that salivary miRNA146b was significantly hyper-expressed in patients with worse ESSPRI scores ( $p=0.02$ ); on the contrary, salivary miRNA17, 146b and plasmatic miRNA17 were reduced in patients with higher scores at ultrasound evaluation ( $p=0.01$ ,  $p=0.01$  and  $p=0.04$  respectively). Plasmatic concentration of miRNA18a was increased in patients with less lachrymal production at Schirmer's test ( $p=0.01$ ) and plasmatic concentration of miRNA17 was reduced in patients with

higher ESR values ( $p=0.01$ ). Salivary miRNA18a was significantly increased in patients with anti-La/SSB ( $p=0.04$ ; Mann-Whitney U test for unpaired samples). Salivary and plasmatic miRNAs did not correlate with disease duration and concomitant therapies.

**Conclusions:** Our data show that the expression of salivary miRNAs 17, 18a and 146b may be altered in SS patients and associated with worse ultrasound and ESSPRI scores and anti-La/SSB positivity.

#### AB0012 ALLELE AND GENOTYPE FREQUENCY OF SOME GENE POLYMORPHISMS DIFFERS IN VARIOUS JUVENILE IDIOPATHIC ARTHRITIS SUBTYPES

H.A. Yatskiu<sup>1</sup>, N.V. Nikitchenko<sup>1</sup>, N.V. Savina<sup>1</sup>, T.D. Kuzhir<sup>1</sup>, A.M. Tchitchko<sup>2</sup>, I. D. Chyzheuskaya<sup>3</sup>, N.L. Bils kaya<sup>4</sup>, M.G. Myslivets<sup>5</sup>, A.V. Sukalo<sup>2</sup>, R. I. Goncharova<sup>1</sup>. <sup>1</sup>Institute of Genetics and Cytology of NAS of Belarus; <sup>2</sup>Belarusian State Medical University; <sup>3</sup>4th City Children's Clinical Hospital, Minsk; <sup>4</sup>Gomel Regional Children's Clinical Hospital, Gomel; <sup>5</sup>Grodno Regional Children's Clinical Hospital, Grodno, Belarus

**Background:** In spite of the fact that chronic arthritis has been the core of paediatric rheumatology, etiology and pathogenesis of juvenile idiopathic arthritis (JIA) are still unclear. It is important to ascertain genetic nature of such a heterogeneous disease.

**Objectives:** The aim of the study was to assess the role of some SNPs of six genes implicated in immune and inflammatory responses: *TNFA* (rs1800629, rs361525), *PTPN22* (rs2476601), *MIF* (rs755622, rs5844572), *TRAF/C5* (rs3761847), *CTLA4* (rs5742909, rs231775), *STAT4* (rs7574865); as well as homozygous deletions of xenobiotic biotransformation genes *GSTT1* and *GSTM1*.

**Methods:** 206 patients diagnosed with JIA (mean age 8.87±4.92), and 218 hospital controls with no signs of autoimmune or inflammatory diseases (mean age 13.88±2.72) were recruited for the study. The JIA patients were divided into subgroups according to IAR classification criteria; the majority of them (125 patients) had oligoarthritis, 42 children developed RF-negative polyarthritis and 27 patients were diagnosed with systemic arthritis. Genomic DNA was extracted from peripheral blood samples by means of the phenol-chloroform method. SNPs were genotyped using PCR-RFLP, Real-Time PCR or fragmental analysis.

**Results:** The allele frequencies for all SNPs in the hospital control group were similar to those in European populations. The allele and genotype frequency distribution for all SNPs was identical in patients and controls. However, when comparing distinct subtypes of JIA, *STAT4* polymorphism demonstrated higher frequencies of minor T allele (30.5% vs. 17.8%,  $p=0.01$ , OR=2.03, 95% CI [1.14–3.6] and G/T genotype (46.3% vs. 25.6%,  $p=0.03$ , OR=2.51, 95% [1.2–5.24]) in RF-negative polyarthritis than in oligoarthritis. On the contrary,  $\Delta$ *GSTT1* appeared to prevail in oligoarthritis (23.7% vs. 7.9% in RF-negative polyarthritis,  $p=0.03$ , OR=3.6, 95% CI [1.03–12.7]). As to systemic arthritis, it was shown, that minor G allele of *TRAF/C5* was more frequent in comparison with oligoarthritis ( $p=0.037$ , OR=2.43, 95% CI [1.05–5.6]).

**Conclusions:** The results obtained can be considered as evidence for distinct genetic nature of the different JIA subtypes.

#### AB0013 EXPRESSION LEVELS OF MIR-124 IN THE PLASMA OF RHEUMATOID ARTHRITIS PATIENTS

R. Shumnalieva<sup>1</sup>, D. Kachakova<sup>2</sup>, V. Shumnalieva-Ivanova<sup>3</sup>, P. Miteva<sup>4</sup>, R. Kaneva<sup>2</sup>, Z. Kolarov<sup>1</sup>, S. Monov<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Clinic of rheumatology, <sup>2</sup>Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Medical University – Sofia, <sup>3</sup>University Hospital "Alexandrovska", Medical University – Sofia, Bulgaria, <sup>4</sup>University Hospital "Prof. Ivan Mitev", Medical University – Sofia, Bulgaria, Sofia, Bulgaria

**Background:** Micro-ribonucleic acids (microRNAs) comprise a class of small non-coding RNAs that regulate gene expression on post transcriptional level. Levels of miR-124 have been found to be decreased in rheumatoid arthritis (RA) synoviocytes and *in vivo* studies have shown that treatment with pre-miR-124 suppresses the progression of joint damage<sup>1</sup>.

**Objectives:** To evaluate the expression levels of miR-124–3 p in plasma of RA patients and to determine its possible role as biomarker for diagnosis and disease activity.

**Methods:** 34 RA patients according to the 1987 ACR criteria were included in the study. Expression levels of miR-124–3 p in the plasma were determined by PCR

(SYBR Green technology).  $2^{-\Delta\Delta Ct}$  method was used for analysis. 10 healthy donors were used as controls.

**Results:** Expression levels of miR-124-3 p were upregulated in the plasma of 33 (97.06%) of the patients when compared to controls. Receiver operating characteristic curve analysis was conducted in order to evaluate the diagnostic accuracy of the expression levels of the studied miRNA in the plasma. Area under the curve for miR-124-3 p was 0.879 (95% CI=0.740–1.00),  $p=0.303 \times 10^{-3}$ . When the relative quantification (RQ) cut value was 2.89, the sensitivity was 91.2% and the specificity was 80%. Levels of miR-124-3 p in plasma correlated with the diagnosis ( $p=0.106 \times 10^{-3}$ ), with markers of inflammation – ESR ( $p=0.0497$ ) and CRP ( $p=0.047$ ) as well as with the immunological activity – the presence of RF ( $p=0.007$ ), RF IgM ( $p=0.004$ ), RF IgG ( $p=0.004$ ), RF IgA ( $p=0.005$ ) and anti-CCP antibodies in the serum ( $p=0.025$ ).

**Conclusions:** In contrary to the literature data that report levels of miR-124 to be decreased in RA synovial fibroblasts we found increased expression of miR-124-3 p in the plasma of RA patients which might reflect the pathophysiological response to the inflammation, the effect of the treatment regimen or the presence of miR-124a gene promoter hypermethylation in the synovial tissue which might downregulate miR-124 locally.<sup>1,2</sup> To our knowledge this is the first study to evaluate the diagnostic accuracy of plasma levels of miR-124 in RA patients as well as the possibility of using miR-124 as biomarker for disease activity but larger set is needed to confirm these results in the clinical practice.

#### AB0014 GENETIC INFLUENCE OF DIFFERENT MEASURE FOR TUMOUR NECROSIS FACTOR INHIBITORS RESPONSE IN RHEUMATOID ARTHRITIS

S. Bang<sup>1</sup>, Y. Park<sup>2</sup>, K. Kim<sup>3</sup>, Y.B. Joo<sup>4</sup>, S.-K. Cho<sup>2</sup>, C.-B. Choi<sup>2</sup>, Y.-K. Sung<sup>2</sup>, T.-H. Kim<sup>2</sup>, J.-B. Jun<sup>2</sup>, D.-H. Yoo<sup>2</sup>, H.-S. Lee<sup>1</sup>, S.-C. Bae<sup>2</sup>. <sup>1</sup>Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Guri; <sup>2</sup>Rheumatology, Hanyang University Hospital for Rheumatic Diseases; <sup>3</sup>Biology, Kyung Hee University, Seoul; <sup>4</sup>Rheumatology, St. Vincent's Hospital, Catholic University, Suwon, Korea, Republic of Ireland

**Background:** The genetic studies of tumour necrosis factor inhibitors (TNFi) response in patients with rheumatoid arthritis (RA) have largely relied on the changes in complex disease scores as a measure of treatment response. It is expected that genetic architecture of such complex score is heterogeneous and not very suitable for pharmacogenetic studies.

**Objectives:** We aimed to select the most optimal phenotype for TNFi response using heritability estimates using genome-wide association studies (GWAS) in the Korean population.

**Methods:** Disease Activity Scores based on 28 joint counts (DAS28) and Clinical Disease Activity Index (CDAI) were assessed at baseline, and after 6 months in 370 Korean RA patients who started TNFi due to moderate or high disease activity. Genotypes were generated on the Illumina HumanOmni2.5Exome array (2.5 million variants) in TNFi-treated Korean patients with RA. We estimated heritability using a linear mixed-modelling approach (GCTA) for the TNFi drug-response phenotype  $\Delta$ DAS28,  $\Delta$ CDAI and its separate components, such as  $\Delta$  swollen joint count (SJC),  $\Delta$  tender joint count (TJC),  $\Delta$  erythrocyte sedimentation rate (ESR),  $\Delta$  visual-analogue scale of general health (VAS-GH) and  $\Delta$  provider global assessment of disease activity (PrGA). Furthermore, a multivariate GWAS approach was implemented, analysing separate DAS28 and CDAI components simultaneously

**Results:** The highest heritability estimates were found for  $\Delta$ PrGA ( $h^2=0.76$ ) and  $\Delta$ TJC ( $h^2=0.73$ ); lower heritability was found for  $\Delta$ DAS28 ( $h^2=0.32$ ) with estimates for  $\Delta$ ESR ( $h^2=0.66$ ),  $\Delta$ SJC ( $h^2=0.62$ ),  $\Delta$ CDAI ( $h^2=0.60$ ) and  $\Delta$ VAS-GH ( $h^2=0.53$ ) (all  $p$ -value<0.005).

**Conclusions:** Our results indicate that multiple SNPs together explain a substantial portion of the variation in change in provider global assessment of disease

activity in TNFi-treated patients with RA. In conclusion, optimal phenotype based on heritability suggests the use of changes in clinical disease activity index (CDAI) including provider global assessment than DAS28 in pharmacogenetic study.

**Disclosure of Interest:** None declared

#### AB0015 THE EFFECT OF RARE CODING VARIANTS ON RESPONSE OF TNF INHIBITORS TREATMENT IN RHEUMATOID ARTHRITIS

S. Bang<sup>1</sup>, Y. Park<sup>2</sup>, H.-H. Kwon<sup>1</sup>, H. Yoo<sup>1</sup>, H.-S. Lee<sup>1</sup>, S.-C. Bae<sup>2</sup>. <sup>1</sup>Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Guri; <sup>2</sup>Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of Ireland

**Background:** Although pharmacogenetic studies of TNF inhibitors (TNFi) response presented the estimates of high heritability, only few loci with suggestive weak common association as biomarkers for TNFi response have been identified.

**Objectives:** We aimed to identify novel functional rare variants associated with response to etanercept using targeted exon sequencing in Korea.

**Methods:** Disease activity scores were assessed at baseline and after 6 months in 156 Korean RA patients who started etanercept due to moderate or high disease activity. We analysed targeted exon sequencing data of 399 genes selected from a multifaceted approach. We conducted a single-marker association test (MAF  $\geq 1\%$ ) and a gene-based analysis [optimal sequence kernel association test (SKAT-O)] of rare variants (MAF <1%). In addition, we performed gene set analyses of TNF pathway genes.

**Results:** We identified that clinical factors seem to influence the therapeutic good response of etanercept including male, high disease activity score at baseline, BMI. After stringent quality control, we analysed 14 024 variants of 399 genes in 156 RA patients. We identified two novel significant functional SNPs [rs16942564, rs61734378 (exon of AKAP13)] associated with response to etanercept, surpassing study-wide significant threshold ( $p < 3.0 \times 10^{-5}$ ) in single variant association tests. Using a gene-based approach, we found two genes with nominal burden signals ( $p < 0.001$ ) which did not reach study-wide significance. In the gene set enrichment test, we found no evidence for enrichment of association at genes involved in the TNF pathway.

**Conclusions:** We were unable to identify rare coding variants with large effect of 399 targeted genes. Our study suggests that rare coding variants of RA risk associated genes do not contribute to heritability of response to etanercept therapy.

**Disclosure of Interest:** None declared

#### AB0016 CHROMATIN LOCALIZATION OF SURVIVIN IN CD4+ T-CELLS OF PATIENTS WITH RHEUMATOID ARTHRITIS

S. Andres<sup>1</sup>, K.M. Andersson<sup>2</sup>, A. Damdimopoulos<sup>3</sup>, G. Katona<sup>1</sup>, M.I. Bokarewa<sup>2,4</sup>. <sup>1</sup>Department of Chemistry and Molecular Biology; <sup>2</sup>Department of Rheumatology and Inflammation Research, University of Gothenburg, Gothenburg; <sup>3</sup>Department of Biosciences and Nutrition, Karolinska Institutet, Solna; <sup>4</sup>Sahlgrenska University Hospital, Gothenburg, Sweden

**Background:** Oncoprotein survivin emerged as an important player in the pathogenesis of rheumatoid arthritis (RA). Results of genome-wide study suggest that survivin may take part in transcription stimulation of the RA-specific genes.

**Objectives:** To identify and describe survivin-dependent differences in transcription pattern between CD4<sup>+</sup> T-cells of RA patients and healthy subjects focusing in particular on a subset of genes involved in maturation of Th1 and Th17 cells.

**Methods:** CD4<sup>+</sup> T-cells were isolated from PBMC of 3 RA patients and 5 non-smoking and 2 smoking healthy controls using a positive selection and activated by Pam3cys+Concanavalin A+LPS. Chromatin immunoprecipitation (ChIP) was done using rabbit polyclonal anti-Survivin, purified DNA was prepared into libraries using ThruPLEX (Rubicon) and sequenced using Hiseq 2000 (Illumina). Resulting fastq sequencing files were mapped to the human reference genome (hg38) using the STAR aligner. Peaks were associated with the closest transcription start site. Enriched peak regions ( $p < 10^{-5}$ ) were identified in survivin-ChIP samples above background ("input") using the Homer software. The peaks were analysed using gene ontology (GO) technique as implemented in GOrilla and GSEA software. The genes, scored high in RA and not present/low in any controls or vice versa were identified. The enriched GO groups were searched for presence of Th1/Th17 regulating genes.

**Results:** We identified 11 145 survivin-bound chromatin sequences. Out of them, GO technique indicated 770 genes in RA samples (7.3%) and 766 genes in healthy controls (19.5%) which were annotated and enriched (>log-5) in GO

terms. In the screening for genes regulating maturation of Th1/Th17 cells, CBLB, IRF1, STAT3, SGK1 and TNFSF14 were identified among the genes enriched in RA samples, while EGR3 and ETS1 were enriched only in healthy controls. Additionally, transcription factors Ezh2, Rad21, Ctp2 and Suz12 were identified as common for both RA and healthy groups genes, associated with significant GO enrichment.

**Conclusions:** This study confirms the role of survivin as a transcription mediator in CD4 +T cells and is suggested to influence multiple genes involved in RA pathology.

#### AB0017 VITAMIN D LEVEL AND MIRNA 22 AND 125b GENE EXPRESSION IN BEHÇET'S DISEASE PATIENTS

R.M. Erfan<sup>1</sup>, Y.H. Nasser<sup>1</sup>, G.N. Morcos<sup>1</sup>, O.G. Shaker<sup>1</sup>, T.A. Gheita<sup>2</sup>. <sup>1</sup>Medical Biochemistry and Molecular Biology, <sup>2</sup>Rheumatology and Clinical Immunology, Faculty of Medicine, Kasr Al-Ainy School of Medicine, Cairo University, Cairo, Egypt

**Objectives:** To investigate serum levels of vitamin D and its effect on microRNA 22 and 125b gene expression in Behçet's disease (BD) patients and to evaluate their relation to clinical characteristics and disease activity.

**Methods:** Fifty-one BD patients and 45 matching controls were studied. Disease activity was assessed using BD Current Activity Form (BDCAF). Serum vitamin D3 was measured by ELISA. MicroRNAs were assayed by reverse transcription-quantitative polymerized chain reaction (RT-qPCR).

**Results:** Patients mean age was 34.3±8.6 years and disease duration 65.3±52.4 months. The BDCAF was 2.4±1.3. Vitamin D level was significantly lower (29.7 ±14.4 ng/ml) in patients than in control (40.1±17.8 ng/ml)(p<0.001) especially males (25.8±7.5 ng/ml) compared to females (48±23.7 ng/ml)(p<0.001). There was no relation between 25(OH)D levels and disease activity or with the presence of clinical manifestations. There was a 3.8±1.5 fold increase in miRNA125b while miR-22 showed no significant difference (0.38±0.46) but was significantly reduced in those receiving steroids (0.21±0.27) compared to those not (0.66±0.58) (p=0.003). There was no significant difference in the frequency of miR-22 or miR-125 expression according to the presence of clinical manifestations, medications received or disease activity. The fold change in miR-125b significantly correlated with vitamin D (r=0.54, p<0.001) but not with BDCAF (p=0.64).

**Conclusions:** Vitamin D level is decreased in BD patients and significantly correlated with the fold change of miR-125b especially in males thus representing a possible therapeutic target. The miR-22 expression did not change but was notably downregulated by steroids. Further longitudinal studies on a larger sample are recommended to validate the present results.

#### AB0018 CLINICAL STATUS AND GENE EXPRESSION IN CLASS IV LUPUS NEPHRITIS

L.A. Mas<sup>1,2</sup>, V. Sauri<sup>2,3</sup>, E. Palomino<sup>1,2</sup>, J.L. De la Fuente<sup>2,4</sup>, M. Angelina<sup>2,4</sup>, A. Alejandro<sup>2,3</sup>, T. Alvarcellos<sup>1,2</sup>. <sup>1</sup>Immunogenetics, Hospital Privado Universitario de Cordoba; <sup>2</sup>Instituto Universitario de Ciencias Biomedicas de Cordoba; <sup>3</sup>Rheumatology; <sup>4</sup>Nephrology, Hospital Privado Universitario de Cordoba, Cordoba, Argentina

**Background:** Lupus nephritis (LN) is one of the most frequent and serious complications in the patients with systemic lupus erythematosus. Several studies have identified risk factors for poor kidney prognosis in patients with SLE, including age, sex, hypertension, decreased estimated GFR (eGFR), proteinuria, and renal pathologic types.<sup>1</sup> Biopsy allows classifying the type of renal involvement, assessing its activity, and thus guiding the therapeutic behaviours. It has been shown that structural changes and inflammatory infiltrate associated with LN contribute to a hypoxic state which induces angiogenesis.<sup>2</sup> Herein, it was hypothesised that differential expression of angiogenic genes could classify Lupus

Nephritis Patients (LNP) with the same histological score but different "clinical status".

**Objectives:** To investigate if there is a differential angiogenic gene expression in biopsies of LNP under the same histological classification but different "clinical status" measured by eGFR.

**Methods:** Twenty four kidney biopsies samples classified according to ISN/RPS scoring system as Class IV from 24 LNP were divided into eGFR <60 ml/min (n=10, age: 31.00±10.93, range: 17–46) and eGFR >60 ml/min (n=14, age: 32.64 ±11.34, range: 21–64). RNA was isolated using TRIzol-Chloroform technique and then was reverse-transcribed using random primers. Gene expression level of pro-angiogenic factors: VCAM-1, VEGF, TGF-β and ANGPT-1 were evaluated using Quantitative Real Time PCR (QPCR). The threshold cycle (Ct) scores were averaged for calculations of relative expression values. The Ct scores were normalised by subtracting β2Microglobuline (β2M) control, or ΔCt=Ct<sub>gene</sub>-Ct<sub>β2M</sub>. To test for differential gene expression between groups, a two sample T-test was performed to compare the ΔCt in the two groups.

**Results:** ΔCt is inversely proportional to the gene expression level. Significant differences between groups was found in VEGF-A gene (p=0.0326), where the greatest expression corresponding to eGFR <60 ml/min group. However, there were not statistically significant differences in VCAM-1, ANGPT1 and TGF-β expression (table 1). Particularly TGF-β, a proangiogenic and profibrotic gene showed a uniform expression level in both groups.

**Abstract AB0018 – Table 1.** Levels of gene expression and laboratory parameters in eGFR <60 ml/min and eGFR >60 ml/min expressed as ΔCt values.

Gene	eGFR<60 ml/min	eGFR>60 ml/min	p value
	n=10	n=14	
VCAM-1	5,021±1768	6,248±3264	0,3165
VEGF-A	3,414±1161	4,651±1409	0,0326
TGF-β	6,168±1011	6,699±1351	0,3421
ANGPT1	10,330±2294	9,891±2113	0,5007

**Conclusions:** In the present cross-sectional study, increased levels of VEGF-A were observed in biopsies Class IV from LNP with eGFR <60 ml/min. These findings suggest a differential gene expression that may be associated with an impaired renal function, reflected by eGFR.

#### AB0019 THE ROLE OF THE IL2-IL21 RS6822844 POLYMORPHISM IN THE PREDISPOSITION TO THE ERYTHROCYTE SEDIMENTATION RATE ELEVATION IN JUVENILE IDIOPATHIC ARTHRITIS

L.S. Nazarova<sup>1</sup>, K.V. Danilko<sup>1</sup>, V.A. Malievsky<sup>1</sup>, T.V. Viktorova<sup>1,2</sup>. <sup>1</sup>Bashkir State Medical University; <sup>2</sup>Institute of Biochemistry and Genetics, Ufa, Russian Federation

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disorder in paediatrics.<sup>1</sup> The erythrocyte sedimentation rate (ESR) is one of the key measures of the JIA activity.<sup>2</sup> However, in some patients, even in the active disease period, the ESR is not elevated.<sup>3</sup>

**Objectives:** The aim of the study was to assess the relationship between the *IL2-IL21 rs6822844* locus polymorphic variants and a predisposition to the ESR elevation in JIA patients.

**Methods:** The study included 255 JIA patients from the Republic of Bashkortostan, Russia. The ESR was considered elevated if its value exceeded the upper limit of the normal range two or more times. Genotyping was performed by real-time PCR, statistical analysis – using the two-tailed Fisher exact test (p) and the odds ratio (OR) with a 95% confidence interval (CI).

**Results:** The girls/boys ratio was 65.88%/34.12%. The ESR elevation in the active disease period was seen in 70.98% of patients. When studying the *IL2-IL21 rs6822844* polymorphic locus, a marginal significance level was noted for the rarer occurrence of the GT genotype in patients with the elevated ESR (14.92%

vs. 25.68%,  $p=0.049$ , OR=0.508, 95% CI 0.258–0.985, compared with patients with the normal ESR, respectively). After stratification according to the sex, similar differences in the GT genotype frequencies were seen and even intensified only for female JIA patients (15.38% vs. 31.37%, respectively,  $p=0.022$ , OR=0.398, 95% CI 0.180–0.897). In addition, a significant increase in the GG genotype proportion and a tendency towards a decrease in the T allele proportion were observed in girls with the elevated ESR (GG: 83.76% vs. 68.63%,  $p=0.038$ , OR=2.358, 95% CI 1.058–5.110; T: 8.55% vs. 15.69%,  $p=0.057$ , compared with girls with the normal ESR, respectively).

**Conclusions:** In the present study, the association of the *IL2-IL21* rs6822844 locus polymorphic variants with a predisposition to the ESR elevation in female JIA patients was shown.

#### AB0020 DIFFERENTIALLY EXPRESSED GENES IN SJGREN'S SYNDROME MICROARRAY

L. Wei<sup>1</sup>, Z. Wenjia<sup>2</sup>, W. Yuanhao<sup>1</sup>, J. Yue<sup>1</sup>, Z. Lei<sup>1</sup>, L. Bin<sup>1</sup>, X. Bin<sup>1</sup>, Z. Bo<sup>1</sup>, D. Ran<sup>1</sup>, C. Yue<sup>1</sup>, W. Xiaoshuang<sup>1</sup>. <sup>1</sup>First Teaching Hospital of Tianjin University of Traditional Chinese Medicine; <sup>2</sup>Tianjin University of Traditional Chinese Medicine, Tianjin, China

**Background:** Sjogren's syndrome (SS) is a chronic autoimmune disease characterised by a decrease in the secretion of tears and saliva, and is considered to be a common rheumatic immunologic disease second only to rheumatoid arthritis. Patients with SS may have different prognosis or different reactions to the same treatment plan. Therefore, a more accurate and more practical predictor is needed to provide a basis for the individualised treatment of SS. Bioinformatics is a new approach. It applies bioinformatics methodology, tools, software and database to molecular mechanisms, new biomarkers and individualised treatment measures.

**Objectives:** In this study, gene expression data as the basis, combined with bioinformatics tools and literature mining methods, firstly analyses the expression differences between normal people and patients with parotid gland parotid Sjogren syndrome gene, a key pathway and further study the effect of SS involved in the occurrence and development of the application of protein interaction network screening key genes, pathogenesis help to clarify SS, and for the future of this disease and provide a new direction.

**Methods:** The expression profiles of mRNA in parotid gland of patients with Sjogren syndrome and normal parotid gland were obtained from the GEO database. A total of 24 patients with Sjogren's syndrome, 6 patients with dry mouth and dry eye symptoms and 25 patients without dry mouth and dry eye were enrolled in the study. 65 samples were collected. The GEO2R tool screened the parotid differentially expressed genes in the patients with SS compared with the healthy people, and the DAVID tool enriched the function and pathway of the gene. The STRING database constructs a network that differentially expresses the interaction of gene protein products and screening core genes.

**Results:** 24 upregulated genes and 147 down regulated genes were screened. KEGG enriched 5 pathways including cell adhesion, intestinal immune network IgA secretion, viral myocarditis pathway, rheumatoid arthritis pathway and leukocyte transendothelial migration. String protein interaction database was used to subcellular localization of differentially expressed gene protein products in parotid gland, and differentially expressed proteins were identified. The interaction network was constructed by Cytoscape software. The protein interaction network was constructed based on the 171 differentially expressed genes of SS, and the isolated and non interacting protein nodes were screened out. 108 upregulated gene encoded proteins were found to interact with each other, forming a complex network containing 390 interactions. The Degree>20 of the node is selected as the standard selection centre node, and 5 Hub genes are obtained. It is found that PTPRC, CD86, STAT1, FYN and LCP2 are key genes and may play an important role in the pathogenesis of Sjogren syndrome.

**Conclusions:** Above all, we used bioinformatics to find genes and critical pathways related to SS, which is expected to provide new molecular markers for the diagnosis and treatment of SS. It provides a new way of thinking for the treatment and prognosis of Sjogren syndrome.

#### AB0021 A GENOME-WIDE SNP LINKAGE ANALYSIS SUGGESTS A NOVEL SUSCEPTIBILITY GENE FOR ANKYLOSING SPONDYLITIS

Z. Lin, L. Gui, Y. Zhang, Q. Lv, J. Qi, L. Fang, X. Zhang, J. Gu. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** Ankylosing Spondylitis (AS) is a chronic, progressive and inflammatory disease, which is considered to be hereditary. However, the responsible molecular genetic determinants remain unidentified.

**Objectives:** To detect susceptibility gene(s) for AS by using an affected-only linkage analysis and high density single nucleotide polymorphism (SNP) in genome-wide manner.

**Methods:** All AS patients in three families of Cantonese were recruited. Their clinical material were collected by questionnaires. Genomic DNA derived from individual peripheral blood leukocytes was genotyped using Illumina HuamHap 610-Quad SNP Chip. Genotype data were generated using the Illumina BeadStudio 3.2 software. An affected-only linkage analysis was carried out using non-parametric and parametric linkage analysis. The customised allele frequencies were based on the 980 Cantonese healthy controls. SNP genetic map positions were interpolated as their physical positions in megabyte.

**Results:** 1. *Clinical data:* The mean age was 42.3±14.9 years (ranging from 18~62 years), mean age of onset was 23.8±7.4 years (ranging from 10~30 years), mean duration of affection was 17.0±13.0 years (ranging from 0.2~50.0 years), and the sex ratio of male to female was 2.5: 1. There was no Iritis and dactylitis, hip involvement (4, 19.05%), peripheral arthritis (4, 19.05%), inflammatory back pain (21, 100%) and HLA-B27 positive (20, 95.24%). 2. *Results of non-parameter linkage analysis:* The highest LOD value was found in chromosome 16, which reached 2.362. Although chromosome 6 was considered to be relative to the pathogenesis of AS, its LOD value was 1.499 and the range of the peak was located in 6 p21, where 96 SNPs (such as rs6930977) were included. 3. *Results of parameter linkage analysis:* The LOD value of chromosome 16 was 4.6807 and higher than that of other chromosomes which were less than 3 by the same analysis. A susceptibility locus was found in 16q12, spanning 88.5 Kb with LOD value above 3 (ranging: 51030764~51915940). 4. *Susceptibility genes:* According to the result of parameter linkage analysis in chromosome 16, seven genes (TOX high mobility group box family member 3 (TOX3), LOC643714, LOC146253, LOC100132440, LOC390730, LOC100128523 and chromodomain helicase DNA binding protein 9 (CHD9)) could be detected in the position where the LOD value exceeded 3. Interestingly, six SNPs could be found in CHD9 gene. Likewise, they were also found in another association analysis, which included 400 AS patients and 977 healthy controls. P value for SNP rs10153130 was 0.005879 (adjust  $p<0.05/6=0.00833$ ).

**Conclusions:** Genome-wide SNP linkage analysis in three AS families supports that a susceptibility locus for AS was found in 16q12, spanning 88.5 Kb with LOD value above 3 (ranging: 51030764~51915940).

#### AB0022 FAMILY-BASED WHOLE-EXOME SEQUENCING REVEALS THE GENETIC BASIS OF RELAPSING POLYCHONDRIITIS

Z. Lin<sup>1</sup>, L. Gui<sup>1</sup>, J. Qi<sup>1</sup>, X. Guo<sup>2</sup>, Q. Lv<sup>1</sup>, Y. Zhang<sup>1</sup>, L. Fang<sup>1</sup>, X. Zhang<sup>1</sup>, J. Gu<sup>1</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Relapsing polychondritis (RP) is a rare systemic disease, characterised by recurrent episodes of inflammation of cartilaginous tissues and other proteoglycan rich structures involving the cartilage of the ears, nose, larynx, tracheobronchial tree and cardiovascular system.<sup>1,2</sup> The susceptibility to RP has been reported to be significantly related to genetic factors.<sup>3,4</sup> However, family occurrence has yet to be reported and the responsible molecular genetic determinants hasn't been clearly elucidated.

**Objectives:** The purpose was to detect the susceptibility genes of RP through whole-exome sequencing (WES) in a Chinese family and deepen our understanding of the pathogenesis of RP.

**Methods:** A 32 year-old Chinese female proband with RP and her family in which only her mother was RP patient were recruited in the current study. The genomic DNA of 6 human subjects was extracted from the peripheral blood monocyte cells (PBMCs) and then identified gene allele mutations using WES. Candidate variants with low frequency (<0.1%) in general population and predicted deleterious on gene function were identified. Sanger sequencing was then used to validate the analysis results of WES and further validated the gene variants in 12 human subjects.

**Results:** 38 genes mutated were confirmed by WES among RP patients. Of them, 10 gene mutated were validated by Sanger sequencing, including Collagen Type XXII Alpha 1 Chain (COL22A1) rs200464636, folliculin (FLCN) NM\_144606: c.G838A: p.E280K, glycosylphosphatidylinositol anchor attachment 1 (GPA1) rs201424010, DNA ligase 3 (LIG3) rs761808558, RecQ like helicase 4 (RECQL4) rs757703895, ring finger protein 207 (RNF207) NM\_207396: c.T425C:p.I142T, coiled-coil domain containing 61 (CCDC61) rs777816675, Purkinje cell protein 2 (PCP2) rs144974437, tubulin alpha 3e (TUBA3E) rs749780020 and myosin heavy chain 15 (MYH15) NM\_014981: c.G4462A: p.A1488T.

**Conclusions:** This study confirms that coinheritance of multigene mutated may contribute to the susceptibility to RP. The candidate genes mutated we discovered are potential targets for in-depth functional studies.

## Adaptive immunity (T cells and B cells) in rheumatic diseases

### AB0023 SEX-BASED DIFFERENCES IN ASSOCIATION BETWEEN CIRCULATING T CELL SUBSETS AND DISEASE ACTIVITY IN UNTREATED EARLY RHEUMATOID ARTHRITIS PATIENTS

J. Aldridge<sup>1</sup>, J. Pandya<sup>1</sup>, L. Meurs<sup>1</sup>, A. Kerstin<sup>1</sup>, I. Nordström<sup>1</sup>, E. Theander<sup>2</sup>, A.-C. Lundell<sup>1</sup>, A. Rudin<sup>1</sup>. <sup>1</sup>Medicine, Rheumatology Inflammation Research, Sahlgrenska Academy, Göteborg; <sup>2</sup>Rheumatology, Lund University, Lund, Sweden

**Background:** Genetic association studies strongly support the role of CD4<sup>+</sup> T cells in promoting RA pathology. In a cohort of untreated early RA patients, we recently demonstrated that the balance of helper T cell subsets in blood of ueRA patients is skewed towards Th2 cells relative to healthy controls.<sup>1</sup> RA has been shown to be a sexually dimorphic condition with current data suggesting that prevalence, disease course and treatment outcome varies between men and women.

**Objectives:** It is not known if sex-based disparities in immunological factors contribute to the disease process in rheumatoid arthritis (RA). Hence, we examined whether circulating T cell subset proportions and their association with disease activity differed in male and female patients with untreated early rheumatoid arthritis.

**Methods:** Proportions of T cell subsets were analysed in peripheral blood from 70 ueRA DMARD and prednisolone naïve patients with untreated early Rheumatoid arthritis (50 females and 20 males) and in 31 healthy age-matched controls. Broad analysis of helper and regulatory CD4<sup>+</sup> T cell subsets was done using flow cytometry. Disease activity in patients was assessed using DAS28, CDAI, swollen joint counts, tender joint counts, CRP and ESR.

**Results:** Multivariate factor analyses showed that male and female untreated early rheumatoid arthritis patients display distinct profiles of association between disease activity and circulating T cell subset proportions. In male, but not female, ueRA patients Th2 cells showed a positive association with disease activity and correlated significantly with DAS28-ESR, CDAI and tender joint counts. Likewise, proportions of non-regulatory CTLA-4<sup>+</sup> T cells associated positively with disease activity in male patients only, and correlated with DAS28-ESR. In contrast, there was a negative relation between Th1Th17 subset proportions and disease activity in males only. Proportions of Th1 and Th17 cells showed no relation to disease activity in either males or females. There were no significant differences in proportions of T cell subsets between the sexes in patients with untreated early rheumatoid arthritis.

**Conclusions:** In conclusion, our findings show sex-based differences in the association between T cell subsets and disease activity in ueRA patients, and that Th2 helper T cells may have a stronger role in the regulation of disease activity in male patients.

### AB0024

### IGA-EXPRESSING BM PC ARE RESPONSIBLE FOR ENHANCED PHOSPHORYLATION OF BCR-ASSOCIATED KINASES AFTER BCR STIMULATION INDEPENDENTLY OF THEIR CD19 EXPRESSION

A. Wiedemann, A.C. Lino, T. Dörner. *Rheumatology and Clinical Immunology, Department of Medicine, Charité Universitätsmedizin Berlin and German Rheumatism Research Center Berlin (DRFZ), Berlin, Germany*

**Background:** Plasma cells (PC) are considered key drivers of antibody mediated autoimmune diseases. Long-lived PC survive for years in their niches, preferentially in the bone marrow (BM) but also in inflamed tissues.<sup>1,2</sup> A subset of PC lacking expression of CD19 has been identified.<sup>3</sup> Better understanding of factors and pathways involved in survival and maintenance of long-lived PC is needed to find strategies to target PC in autoimmunity since targeting B cells or proliferating cells does not affect already existing PC.<sup>4</sup> B cell receptor (BCR) signalling is a critical mediator of B cell survival and it was shown before that IgA<sup>+</sup> and IgM<sup>+</sup> PC in the BM express a functional BCR suggesting a potential role for the BCR signalling pathway.<sup>5</sup>

**Objectives:** Expression of BCR associated molecules in BM PC and the response of CD19<sup>+</sup> and CD19<sup>-</sup> BM PC to BCR stimulation by anti-IgM/IgA/IgG was assessed to test whether these PC subsets are capable of responding to BCR mediated signals. We further investigated if the PC isotype has an impact on BCR signalling.

**Methods:** BM samples from patients undergoing routine total hip arthroplasty without systemic immune manifestations were stained for baseline expression of spleen tyrosine kinase (Syk) and Bruton's tyrosine kinase (Btk) as well as for the phosphosites pSyk (Y<sup>352</sup>) and pBtk (Y<sup>223</sup>). BM mononuclear cells have been isolated, stimulated with anti-IgM/IgA/IgG and the increase of fluorescence intensity of pSyk (Y<sup>352</sup>) and pBtk (Y<sup>223</sup>) was measured by intracellular flow-cytometric analyses. In some experiments, cells have been stimulated with anti-IgA alone and stained for the isotype additionally to the pPTK staining.

**Results:** Whole BM stainings revealed that both CD19<sup>+</sup> and CD19<sup>-</sup> PC express the PTKs Syk and Btk at baseline. Both PC subsets showed the ability to respond to BCR stimulation with enhanced phosphorylation of the PTKs with a clear trend to reduced responsiveness among CD19<sup>-</sup> PC. Ig staining revealed that IgA expression was identified on both membrane and intracellularly, whereas IgG was

only expressed intracellularly. Co-staining of IgA with pPTKs showed that IgA<sup>+</sup> PC in both subsets are responsible for enhanced PTK phosphorylation independently of CD19 expression.

**Conclusions:** CD19<sup>+</sup> and CD19<sup>-</sup> BM PC express kinases involved in BCR signaling and respond by enhanced phosphorylation of PTKs upon BCR stimulation with IgA-expressing cells being exclusively responsible for this increase. Further functional consequences of IgA expression in BM PC and autoimmunity remain to be delineated.

#### AB0025 MTOR PATHWAY ACTIVATION IN LARGE VESSEL VASCULITIS

C. Comarmond<sup>1</sup>, A. Maciejewski-Duval<sup>2</sup>, A. Leroyer<sup>3</sup>, M. Zaidan<sup>4</sup>, A. Le Joncour<sup>1</sup>, P. Cacoub<sup>1</sup>, D. Sadoun<sup>1</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Pitié Salpêtrière, Paris; <sup>3</sup>CHU, Marseille; <sup>4</sup>Nephrology, Necker, PARIS, France

**Background:** Mammalian target of rapamycin complex 1 (mTORC 1) drives the proinflammatory expansion of T helper (TH) type 1, TH17 cells and controls fibroblast proliferation, typical features of large vessel vasculitis (LVV) pathogenesis. Molecular pathways involved in arterial lesions of LVV are unknown.

**Objectives:** To analyse mTOR pathway activation in LVV (giant cell arteritis and Takayasu arteritis).

**Methods:** We evaluate pathway activation in the mTORC and the nature of cell proliferation in blood and vessels of patients with LVV compared non-inflammatory aorta by using double immunostaining, western blot and flow cytometry. Finally, using flow cytometry, we study the effect of rapamycin on T cells homeostasis in LVV compared to HD.

**Results:** Proliferation of both endothelial cells and vascular smooth-muscle cells was shown in vascular lesions in LVV. The vascular endothelium of proliferating aorta vessels from patients with LVV showed indications of activation of the mTORC1 pathway in endothelial cells (S6RP phosphorylation) compared to non-inflammatory aorta (45%<sup>24,48</sup> versus 10.4% [9.7;14.9] positive S6RP endothelial cells, p=0.03). In cultured vascular endothelial cells, sera from patients with LVV stimulated mTORC1 through the phosphorylation of S6RP. Activation of mTORC1 was also found in Th1 and Th17 cells both systemically and in the blood vessels. Patients with LVV exhibited a diminished S6RP phosphorylation in Tregs. Inhibition of mTORC1 pathway with rapamycin, increase Tregs and decrease effector CD4<sup>+</sup>IFN $\gamma$ <sup>+</sup>, CD4<sup>+</sup>IL17<sup>+</sup> and CD4<sup>+</sup>IL21<sup>+</sup> T cells in patients with LVV.

**Conclusions:** Our results suggest that the mTORC1 pathway is involved in the vascular lesions of LVV. Targeting mTORC pathway may represent a new therapeutic option in patients with LVV.

#### AB0026 TLR9 STIMULATION OF ANERGIC HCV-ASSOCIATED ATYPICAL MEMORY B CELLS TRIGGERS RHEUMATOID FACTOR AUTOIMMUNITY BY THE TNF-A PATHWAY

C. Comarmond, D. Saadoun. *Internal Medicine, Pitié Salpêtrière, Paris, France*

**Background:** Hepatitis C virus (HCV) infection contributes to the development of autoimmune disorders, but the mechanisms responsible for HCV-associated autoimmunity are not well understood.

**Results:** Here we show that TLR9 stimulation of atypical memory (AtM) B cells from patients with HCV-associated cryoglobulinemia vasculitis induce the secretion of IFN $\gamma$ , TNF $\alpha$  but not IL17A by CD4<sup>+</sup>CD25<sup>-</sup> effector T cells and stimulate their proliferation. Conversely, they reduce the proliferative capacity of CD4<sup>+</sup>CD25<sup>hi</sup>CD127<sup>low</sup>FoxP3<sup>+</sup> regulatory T cells. TLR9-stimulated AtM secrete TNF $\alpha$  and IgMs with rheumatoid factor activity. We identify a transcriptional

signature specific of TLR9-stimulated AtM, centred on TNF $\alpha$  overexpression. AtM B-cell expansions display intraclonal diversity of mutated IgM with features of antigen-driven maturation. AtM-derived antibodies possess rheumatoid factor activity, with each antibody clone targeting a unique epitope on the human IgG Fc region. AtM antibodies are neither polyreactive nor reactive to ubiquitous autoantigens and importantly, not cross-reactive against HCV antigens including NS3 and E2 proteins.

**Conclusions:** These data strongly suggest a central role for AtM in defective tolerance of HCV-CV patients through TLR9 reactivation of anergic AtM and production of IgM antibodies with rheumatoid factor activity.

**Disclosure of Interest:** None declared

#### AB0027 SCREENING FOR ANTIBODY REACTIVITY IN EARLY AXIAL SPONDYLOARTHRITIS IDENTIFIES NOVEL ANTIGENIC TARGETS

D. Quaden<sup>1</sup>, P. Vandormael<sup>1</sup>, K. Corten<sup>2</sup>, J. Vanhoof<sup>3</sup>, P. Geusens<sup>3,4,5</sup>, V. Somers<sup>1</sup>. <sup>1</sup>Hasselt University, Biomedical Research Institute, and Transnationale Universiteit Limburg, Diepenbeek; <sup>2</sup>Orthopaedic, Ziekenhuis Oost-Limburg; <sup>3</sup>ReumaClinic, Genk; <sup>4</sup>Universiteit Hasselt, Biomedical Research Institute, and Transnationale Universiteit Limburg, Diepenbeek, Belgium; <sup>5</sup>Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands

**Background:** Diagnosis of axial spondyloarthritis (axSpA) is challenging since clinical manifestations, such as inflammatory back pain, peripheral arthritis, enthesitis and inflammatory bowel disease, often overlap with other disorders. Despite the use of the genetic marker Human Leukocyte Antigen (HLA)-B27 in axSpA patients, an appropriate serological test is still lacking. Although antibodies are not considered to be a hallmark of axSpA, emerging evidence suggests plasma cells and antibodies to be involved in the disease course<sup>1</sup>.

**Objectives:** Our aim is to screen for antibodies reactive against antigenic targets in plasma of early axSpA patients which may potentially result in novel antibody biomarkers to improve axSpA diagnosis and can enhance the assessment of disease activity, prognosis and therapy response.

**Methods:** We applied Serological Antigen Selection (SAS), an unbiased and high-throughput antibody profiling procedure based on cDNA phage display. First, a cDNA phage display library was constructed from synovial hip tissue from 3 axSpA patients and screened for antibody reactivity in pooled plasma of early axSpA patients (n=10). By performing SAS, we identified antibodies in the axSpA plasma pool that were reactive against 104 different antigenic targets. These targets correspond to both known proteins and novel linear peptides. In a first validation, antibody reactivity against each of these 104 SAS-identified targets was determined in pooled plasma of additional early axSpA patients (n=50) and healthy controls (HC, n=30). Antigenic targets that showed highest reactivity in axSpA plasma pools were further validated in individual plasma samples of early axSpA patients (n=71) and HC (n=73) using phage enzyme-linked immunosorbent assay (ELISA).

**Results:** Increased antibody reactivity against 7 targets was found in pooled plasma of additional early axSpA patients. Further validation of these 7 antigenic targets in individual plasma samples revealed antibody reactivity in 39% of the early axSpA patients (28/71) compared with 21% of the HC (15/73). By forming a biomarker panel with 4 of these targets, specificity could be improved to 88% (9/73 HC) with only a slightly decrease in sensitivity (34%, 24/71).

**Conclusions:** We identified autoantibody reactivity to novel antigenic targets in early AS patients. In order to establish the true biomarker potential, antibody reactivity against our identified novel antigenic targets will be further validated in an independent cohort of axSpA patients, rheumatic controls and low back pain controls. Identification of antibody reactivity against novel antibody targets in early axSpA patients can contribute to novel biomarkers for an enhanced diagnosis and might provide more insight into the underlying disease pathology, resulting in novel treatment strategies and eventually improve disease outcome in axSpA patients.

**AB0028** **ACTIVATED STROMAL CELLS INDUCE CCL20 RELEASE AND T CELL MIGRATION**

G. Cafaro<sup>1,2</sup>, E. Garcia-Melchor<sup>2</sup>, M. Akbar<sup>2</sup>, D.S. Gilchrist<sup>2</sup>, S.M. Kitson<sup>2</sup>, S. Siebert<sup>2</sup>, N.L. Millar<sup>3</sup>, I.B. McInnes<sup>2</sup>. <sup>1</sup>Rheumatology Unit, Department of Medicine, University of Perugia, Perugia, Italy; <sup>2</sup>Institute of Infection, Immunity and Inflammation; <sup>3</sup>University of Glasgow, Glasgow, UK

**Background:** Although the role of IL-23/Th17 axis in psoriatic arthritis (PsA) is well known<sup>1</sup>, little data is available on the contribution of stromal cells to this pathway<sup>2</sup>. Enthesitis is a common feature of PsA and it may represent the site of onset<sup>3,4</sup>, suggesting tendon stromal cells (tenocytes) may have an initiating role in Th17 driven pathogenesis.

**Objectives:** To assess the ability of stromal cells to produce CCL20, a chemokine able to recruit Th17 cells, and to induce T cell migration.

**Methods:** Healthy tenocytes cultured from hamstring tendons and fibroblast-like synoviocytes (FLS) from PsA patients were stimulated with human recombinant IL-1 $\beta$  (1 ng/ml) and IL-17A (1, 10 and 100 ng/ml). Expression of CCL20 transcript and protein were assessed by quantitative PCR and ELISA, respectively. T cell migration assays were performed with magnetically enriched CD3<sup>+</sup> cells from peripheral blood of PsA patients and healthy controls using a Transwell system. Following incubation with conditioned media from stimulated stromal cells, the migrated cells were harvested and analysed via light microscopy and flow cytometry.

**Results:** Both tenocytes and FLS were able to produce CCL20 following stimulation with IL-1 $\beta$ . Furthermore, the addition of IL-17A induced a synergistic effect with IL-1 $\beta$ . Following cytokine stimulation, diseased stromal cells produced greater levels of CCL20 compared to stimulated healthy tenocytes. In addition, conditioned media from stimulated tenocytes promoted T cell migration, compared with supernatants from unstimulated tenocytes.

**Conclusions:** We have shown that tendon and PsA synovium stromal cells are able to produce CCL20 and induce T cell recruitment, suggesting a role in the chemotaxis of Th17 cells. The positive feedback observed with IL1 $\beta$  and IL-17A suggests a close relationship between stromal cells and Th17 cells.

**AB0029** **CHARACTERISTIC PATTERNS OF HLA PRESENTATION AND T CELL DIFFERENTIATION IN ADULT-ONSET STILL'S DISEASE**

H.-A. Kim<sup>1</sup>, J.-Y. Jung<sup>1</sup>, C.-H. Suh<sup>1</sup>, S. Sohn<sup>2</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Department of Microbiology, Ajou University School of Medicine, Suwon, Korea, Republic of Ireland

**Background:** The role of T cells in AOSD pathogenesis remains controversial. In autoimmune and auto-inflammatory diseases, such as rheumatoid arthritis (RA) and Behçet's disease, a human leukocyte antigen (HLA)-restricted T cell response to antigen has been shown to affect disease progression, with several HLA alleles strongly associated with disease severity.

**Objectives:** In this study, we investigated the frequencies of cells presenting HLA-DP, DQ, and DR, as well as differentiated T cell populations including naïve and effector memory T cells in peripheral blood leukocytes (PBLs) of patients with AOSD. Frequencies of the markers were then compared based on clinical outcomes and disease activity, to better understand the role of these cell populations in the pathogenesis of AOSD.

**Methods:** This study enrolled 14 active AOSD patients, 20 rheumatoid arthritis (RA) patients, and 20 healthy controls (HC). The percentage of surface-stained cells presenting HLA-DP, DQ, and DR alleles, and the proportions of differentiated T cell populations in peripheral blood leukocytes (PBLs) were measured by flow cytometry.

**Results:** Patients with AOSD exhibited significantly higher percentages of lymphocytes presenting HLA-DP and HLA-DR, and lower percentages of cells presenting HLA-DQ, than patients with RA or HC. The proportions of CD4<sup>+</sup>, CD4<sup>+</sup>CCR7<sup>+</sup>, CD4<sup>+</sup>CD62L<sup>-</sup>, and CD8<sup>+</sup>CD62L<sup>-</sup> cells in PBLs were decreased in

patients with AOSD relative to patients with RA or HCs. In contrast, AOSD patients exhibited increased proportions of CD8<sup>+</sup> naïve T cells in whole blood relative to patients with RA or HC. The proportions of CD4<sup>+</sup> effector memory T cells, CD8<sup>+</sup> naïve T cells, and CD8<sup>+</sup> effector memory T cells in whole blood cells and CD4<sup>+</sup> effector memory T cell in lymphocytes were significantly associated with systemic score.

**Conclusions:** While the frequencies of CD4<sup>+</sup>, CD8<sup>+</sup>, CCR7<sup>+</sup>, CD4<sup>+</sup>CCR7<sup>+</sup>, CD4<sup>+</sup>CD62L<sup>-</sup>, and CD8<sup>+</sup>CD62L<sup>-</sup> cells were significantly decreased in patients with AOSD, the frequency of CD8<sup>+</sup> naïve T cells was elevated in patients with AOSD, and correlated with systemic score. Additional studies in a larger cohort of patients will be necessary to evaluate the role of these markers in the pathogenesis of AOSD.

**AB0030** **TARGETING NF-KB SIGNALLING IN B CELLS: A POTENTIAL NEW TREATMENT MODALITY FOR ANCA-ASSOCIATED VASCULITIS**

J.P. Van Hamburg<sup>1</sup>, P. Tuijnenburg<sup>2</sup>, B. Helder<sup>1</sup>, L. van Keep<sup>1</sup>, K. Wesenhagen<sup>1</sup>, P. Kucharzewka<sup>3</sup>, M.H. Jansen<sup>2</sup>, A. Al-Soudi<sup>1</sup>, P.L. Klarenbeek<sup>1</sup>, H. Olsson<sup>3</sup>, N. de Vries<sup>1</sup>, T.W. Kuijpers<sup>2</sup>, S.W. Tas<sup>1</sup>. <sup>1</sup>Amsterdam Rheumatology and immunology Center/Academic Medical Center/University of Amsterdam; <sup>2</sup>Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands; <sup>3</sup>AstraZeneca, Gothenburg, Sweden

**Background:** The pivotal role of B cells in the pathogenesis autoimmune diseases such as ANCA-associated vasculitis (AAV) is well-established and further substantiated by beneficial therapeutic effects of rituximab (anti-CD20 B cell targeted therapy). However, this results in prolonged B cell depletion while long-lived plasma cells are not targeted. Thus, there is a need for novel therapeutics targeting the B-cell lineage in AAV. NF- $\kappa$ B signalling pathways that act downstream of various B cell surface receptors, including the B cell antigen receptor, CD40, BAFFR and TLRs, are crucially involved in B cell responses and may be suitable as novel targets.

**Objectives:** To identify whether inhibition of NF- $\kappa$ B signalling by novel pharmacological inhibitors is effective in targeting B cell responses in general and more specifically blocks (auto)antibody production and plasmablast differentiation in B cells from AAV patients.

**Methods:** PBMC and sorted B cells from AAV patients and healthy donors were cultured with T cell-dependent (anti-IgM +anti CD40+IL-21) and T cell-independent (CpG +IL-2) stimuli. NF- $\kappa$ B signalling was targeted in these cultures by small molecule inhibitors of NF- $\kappa$ B inducing kinase (NIK, non-canonical NF- $\kappa$ B signalling) and Inhibitor of  $\kappa$ B kinase  $\beta$  (IKK $\beta$ , canonical NF- $\kappa$ B signalling). Downstream NF- $\kappa$ B signalling and nuclear NF- $\kappa$ B translocation was determined by Western blot and confocal imaging. Effects on B cell proliferation and differentiation were determined by CFSE dilution assays and flow cytometric analysis of B cell markers. (Auto)antibody production was measured by ELISA.

**Results:** In B cells of AAV patients and healthy donors, targeting of NIK and IKK $\beta$  effectively inhibited downstream non-canonical or canonical NF- $\kappa$ B signalling, respectively. In a B cell stimulation assay, NIK and IKK $\beta$  inhibition significantly reduced T cell-dependent (anti-IgM +anti CD40+IL-21) and T cell-independent (CpG +IL-2) B cell proliferation. In addition, B cell differentiation towards plasmablasts (CD27<sup>+</sup>/CD38<sup>+</sup>) and functional antibody production was attenuated by both NIK and IKK $\beta$  inhibitors. Interestingly, the effects of NIK inhibition appeared to be B cell-specific as T cell proliferation was largely unaffected.

**Conclusions:** These data demonstrate that inhibition of NF- $\kappa$ B signalling in AAV B cells results in the modulation of various B cell responses. Ongoing studies will indicate whether targeting of NF- $\kappa$ B signalling in B cells may be an effective novel treatment modality for AAV.

**AB0031** **DEEP IMMUNE-PROFILING OF CD4+ T CELLS IN BEHÇET'S DISEASE**

J. Nowatzky<sup>1</sup>, Y. Xia<sup>1</sup>, O. Manches<sup>2</sup>. <sup>1</sup>NYU Langone Health, New York, USA; <sup>2</sup>INSERM – National Institute of Health and Medical Research, Grenoble, France

**Background:** Functionality and immune-phenotypes of the human CD4<sup>+</sup> T-cell compartment in Behçet's disease (BD) are under-investigated, but several lines of evidence point to its relevance in the pathogenesis, progression and remission of the disease.

**Objectives:** We aimed to apply an unbiased single cell approach to assess protein expression levels of phenotypic and functional markers within the human CD4<sup>+</sup> T cell compartment in subjects with prototypical BD in order to identify cell populations of potential biologic relevance.

**Methods:** We determined single cell surface/intra nuclear expression levels of CD3, CD4, CD8, CD127, CD25, CD45RA, CCR7, FoxP3, HELIOS, Ki67, HLA-DR, CD38, CD39 in PBMC by flow cytometry and computed the representation of all mathematically possible cell populations within pre-defined starting populations. PBMC from BD subjects (n=13), healthy donors (HD) (n=25) and diseased subjects with non-BD auto-immune uveitis (n=11; VKH, Sarcoidosis, and HLA-B27 associated uveitis) were used. BD subjects met ISG criteria and were Arab or Chinese. 62% had pan-uveitis, 23% major vascular disease, and 7% parenchymal CNS disease. 46% were HLA-B51 carriers.

**Results:** Computation of all populations defined by CD127, CD25, CD45RA, CCR7, FoxP3, HELIOS, Ki67, HLA-DR within the CD4<sup>+</sup> T cell compartment yielded a total of 6560 (3<sup>8</sup>-1) cell populations out of which 45 reached a significance level of p<0.000001 in ANOVA testing to differentiate 3 groups (BD, non-BD uveitis, and HD). All of these populations comprised sub-types of the human regulatory T (Treg) cell compartment with a strong predominance of non-proliferating, non-activated, FoxP3<sup>+</sup>HELIOS<sup>+</sup> Treg carrying central-memory phenotypes (CD45RA<sup>-</sup>, CCR7<sup>+</sup>). Unpaired testing of BD vs non-BD revealed 43 distinct cell populations at a significance level of p<0.002 representing CD25<sup>+</sup> non-Treg; comparison of BD vs HD uncovered 58 populations at a significance level of p<0.0001 representing FoxP3<sup>+</sup>HELIOS<sup>+</sup> subpopulations, and non-BD vs HD identified 61 populations at p<0.001, comprising CD25<sup>+</sup>CD127<sup>+</sup> FoxP3<sup>+</sup>, but consistently HELIOS<sup>-</sup> cells. A separate analysis using CD38, CD39, CD227, TIGIT, CD45RA, CCR7 within the CD3<sup>+</sup>CD4<sup>+</sup>CD8<sup>-</sup>CD127<sup>+</sup>CD25<sup>+</sup> compartment that contains most human Treg, showed 48 populations (p<0.0001) in 3-way comparison pointing to high significance of TIGIT and CD226 staining Treg subpopulations, and 18 populations with differential expression of CD39<sup>+</sup> between BD and non-BD diseased subjects. TIGIT and CD226 co-expressing Treg (CD127<sup>+</sup>CD25<sup>+</sup>) subpopulations also reached significance (p<0.02) in a longitudinal paired analysis of 7 BD subjects in active vs inactive disease states, as did 56 out of 6560 populations within total CD4<sup>+</sup> T cells, mostly representing non-Treg cells in active BD.

**Conclusions:** Differential expression of CD4<sup>+</sup> Treg and non-Treg cells shapes the immune-phenotype of BD vs states of health and non-BD autoimmune diseases that have phenotypic overlap with BD (uveitis). The populations with the highest significance for differentiating BD from healthy states seem to exist within the HELIOS<sup>+</sup>FOXP3<sup>+</sup> compartment of non-activated, non-proliferating Treg, suggesting relevance of a true Treg phenotype. This is likely not specific to BD. Non-Treg CD25<sup>+</sup> cell populations seem more indicative of BD vs non-BD uveitic disease as well as of clinically active BD while populations with high CD39 expression may signify non-BD states of immune-mediated disease.

### B-CELL SUBPOPULATIONS IN NEWLY DIAGNOSED EORA AND YORA PATIENTS

K. Thorarinsdottir, A. Camponeschi, L. Jacobsson, I.-L. Mårtensson, I. Gjertsson. Department of Rheumatology and Inflammation Research, University of Gothenburg, Gothenburg, Sweden

**Background:** B-cells are thought to have an important role in rheumatoid arthritis (RA). This is demonstrated by the success of B-cell depleting therapy as well as the negative prognostic value of anti-citrullinated protein antibodies (ACPA)<sup>1</sup>. However, the pathogenesis of the disease is unclear. Studies have suggested that there are differences in disease characteristics between elderly-onset RA patients (EORA, defined by disease onset at ≥60 years of age) and younger-onset RA patients (YORA, with disease onset <60 years of age).<sup>2</sup>

**Objectives:** Our aim was to study the B-cell subpopulations in newly diagnosed EORA and YORA patients. We investigated whether there were differences in B-cell subpopulations between the groups and whether there was a correlation between B-cell subpopulations and disease activity, autoantibody profile and inflammatory parameters in these two RA patient groups.

**Methods:** Treatment-naive EORA (n=29) and Yora (n=31) patients with newly diagnosed RA were included at their first visit to the Rheumatology clinic. The patients' clinical response (DAS28), autoantibodies and B-cells were assessed. Flow cytometry was used for the analysis of cellular surface markers on leukocytes in peripheral blood: CD19, CD27, CD24, CD27, CD38, PD-1, PD-L1, IgG,

IgD and IgM. Non-parametric tests were used for comparing groups and Spearman's test was used for correlation.

**Results:** We found a correlation between the ACPA titers and the frequency of the CD27<sup>+</sup> and CD27<sup>-</sup> memory B cell populations in EORA patients but not in YORA patients. This was further supported by a correlation of the ACPA titer and IgG<sup>+</sup> B cells in the EORA patients (r=0.7, p=0.003) and not in the YORA patients. There was neither a correlation between age and ACPA titer nor between age and memory B cell populations. We did not find any significant difference between the B cell subpopulations in the two patient groups.

**Conclusions:** Our results suggest that the memory B cell compartment in peripheral blood in EORA patients reflects the ACPA titer. This was not seen in the YORA patients. The mechanisms behind these findings need to be further elucidated.

### B REGULATORY CELLS POSITIVELY CORRELATE WITH ANTIBODIES AGAINST SS-A RO52 IN SYSTEMIC SCLEROSIS

A. Mavropoulos, A. Gkoutzourelas, T. Simopoulou, C. Liaskos, D.P. Bogdanos, L. I. Sakkas. Rheumatology and Clinical Immunology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece

**Background:** We and Japanese Investigators have shown that IL-10-producing regulatory B cells (B10 cells) are decreased in systemic sclerosis (SSc).<sup>1,2</sup> Contrary to the Japanese, we did not find a negative correlation between B10 cells and SSc-specific autoantibodies (autoabs) against centromere, Scl-70 or RNA polymerase III.<sup>3</sup> Since we found anti-Ro52 SS-A antibodies in approx. 30% of patients with SSc,<sup>4</sup> this being the 3rd most frequent autoantibody in this disease, we considered what is the relation of B10 cells with anti-Ro52 antibodies.

**Objectives:** We examined the number and function of Bregs in SSc in relation to anti-Ro52 autoabs.

**Methods:** Serum samples and PBMCs were collected from 40 SSc patients (15 anti-Scl-70, 20 anti-CEN and 5 anti-RNA pol III) and were further divided according to anti-Ro52-positivity into 22 anti-Ro52(+) and 18 anti-Ro52 (-). All serum samples were tested for the presence of disease-specific autoantibodies against Scl-70, CENP, RNA-pol, and against Ro52 using a line assay (Euroimmun Germany). The function of Bregs was determined by the ability to express IL-10 following activation with ODN 2006 (TLR-9). Percentages of transitional (CD19<sup>+</sup>CD24<sup>high</sup>CD38<sup>high</sup>) and memory (CD19<sup>+</sup>CD27<sup>+</sup>CD24<sup>high</sup>) Bregs were assessed by flow cytometry using fluorochrome conjugated antibodies (BD Biosciences).

**Results:** IL-10(+) Bregs (B10) were significantly elevated in SSc patients (6.7% ±2.6% n=15) with high-titre antibodies against Ro52 (mean anti-Ro52 arbitrary units AU >100; positivity cut-off AU >20) compared to patients (4.2%±1.9%, n=22) totally negative for Ro52 (mean AU <10) (p=0.03). Transitional Bregs were also significantly increased in all SSc patients tested positive for anti-Ro52 autoantibodies (7.5%±1.9%) compared to SSc patients negative for anti-Ro52 autoantibodies (3.7±0.8, p=0.02). Furthermore, transitional Bregs positively correlated with anti-Ro52 antibody levels (r<sup>2</sup>=0.39 p=0.01). In contrast, memory Bregs were not significantly different between anti-Ro52-positive (14.1%±2.7%) and -negative SSc patients (11.8%±2.2%) (p>0.05).

**Conclusions:** IL10-producing Bregs are higher in SSc patients with high anti-Ro52 antibodies and transitional Bregs correlated with antiRo52 antibodies in patients with SSc suggesting that this autoantibody could be a potential marker of Breg efficiency.

#### LOOKING FOR A SLE SIGNATURE ON PERIPHERAL B CELL SUBSETS: DOES A PREPONDERANT CD38 +PLASMA BLAST-SUBPOPULATION LACK CD73 AS A SIGN OF A DISTURBED ADENOSINE AXIS?

M. Siekierka-Harreis, M. Schroedter, G. Chehab, J. Richter, M. Schneider, G. Pongratz. *Rheumatology, Heinrich-Heine University Duesseldorf, Medical Faculty, Duesseldorf, Germany*

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune disorder characterised by polyclonal Bcell activation, production of dsDNA-autoantibodies and cytokines. Subsets of Bcells play a central role in SLE-pathogenesis. The inflammatory milieu is characterised by the accumulation of adenosine, which confers immunosuppressive effects.

**Objectives:** In SLE, the role of CD73, an enzyme involved in the extracellular generation of adenosine from ATP, is not well characterised. This study aimed to characterise expression of CD73 Bcell subsets of SLE-patients as compared to healthy controls (HC).

**Methods:** Bcell subsets were characterised from peripheral blood of 23 SLE patients attending the outpatient clinic at the Rheumatology Unit of University Hospital Düsseldorf and of 15 HC by FACS. All patients fulfilled the revised SLE-criteria of ACR and were randomly collected in clinical remission state (SLEDAI 1.1±1.9).

**Results:** By comparison of Bcell subsets between SLE and HC, CD38 was dominantly expressed by SLE-patients (SLE 74.2%±12.9% vs. HC 64.2%±12.2%; p(MWU)=0.018). Furthermore, SLE-patients showed an increase in CD19 +IgD CD27+CD38 high plasmablasts (SLE 2.1%±3.4% vs HC 0.4%±0.4%, p(MWU)<0.001). Furthermore, SLE-plasmablasts showed decreased CD73 expression as compared to HC(SLE 2.1%±1.9% vs HC 3.5%±2.2%; p(MWU)=0.034). SLE-Bcells revealed a trend towards an augmented CD38highCD138+plasmacell fraction (SLE 0.40%±0.5% vs HC 0.08%±0.07%; p=0.07), without any difference in CD73 expression. On the other hand, exhausted-memory B cell fraction (CD19 +IgD CD27-CD21-CD138-), showed an increased CD73 expression in SLE (SLE 13.7%±9.2% vs HC 6.2%±5.4%; p=0.004).

**Conclusions:** Our study confirms CD38 +plasmablasts as being increased in peripheral blood from SLE patients as compared to HC. Furthermore, the data reveal a deficiency for CD73 on SLE plasmablasts, which suggests a decreased anti-inflammatory capacity of SLE plasmablasts as compared to HC, supporting the notion of a disturbed adenosine axis in SLE. On the other hand, the enlarged CD73 +exhausted memory pool in SLE could point to an accelerated flow of CD73 +B cells into an exhausted B cell fraction. These findings support the hypothesis of dysregulation of the adenosine axis in SLE even in inactive SLE patients.

**Background:** Since the time when Paul Ehrlich conceived the term “horror auto-toxicus”, autoantibodies have been associated with the development of autoimmune diseases. However, several works have recently shown the presence of autoantibodies in sera from healthy subjects (n=489), who do not develop autoimmune diseases.

**Objectives:** Here, we report a network of immunoglobulin G (IgG) autoantibodies targeting G protein-coupled receptors (GPCRs), growth factors and growth factor-related molecules in sera from healthy subjects.

**Methods:** Autoantibody levels in sera were assessed using ELISA. Autoantibody network was analysed by exploratory factor analysis (EFA), dandelion plot method, hierarchical clustering, and multi-study factor analysis (MFA). We also reverse engineered autoantibody functions through *in silico* evaluation of autoantibody target interactions using STRING and gene ontology (GO). To test the autoantibodies functionality we assessed the *in vitro* production of IL-8 by PMBCs and neutrophil migration in response to IgG from healthy subjects as well as ETAR-immunised and control mice. Leukocyte cellularity to secondary immune organs was analysed comparing ETAR-immunised with control mice.

**Results:** Gender, age and the presence of pathological conditions (systemic sclerosis n=84, Alzheimer's disease n=91 and ovarian cancer n=207) changed correlations between the autoantibodies and their hierarchical clustering distribution. Notably, subjects at age below and above 65 years or with pathological conditions exhibited particular autoantibody hierarchical clustering signatures. In addition, females at age above 65 years, representing the group of subjects with higher risk to develop SSc, displayed the closest link to SSc in terms of autoantibody hierarchical clustering. Finally, autoantibody directed against the endothelin receptor type A (ETAR) showed an essential role in the autoantibody network by orchestrating neutrophil trafficking *in vitro* and in ETAR-immunised mice.

**Conclusions:** Our data provide a framework for the existence of a physiological network of autoantibodies and reveal a new paradigmatic view on these physiological molecules.

AB0036

#### ROLE OF PROGRAMMED DEATH-1 PATHWAY ON CD8+ T CELLS CYTOTOXICITY IN PRIMARY BILIARY CHOLANGITIS

S. Zhang, X. Tao, L. Wang, L. Zhao, J. Sun, Z. Chen, H. Chen, F. Zhang. *Peking Union Medical College Hospital, Beijing, China*

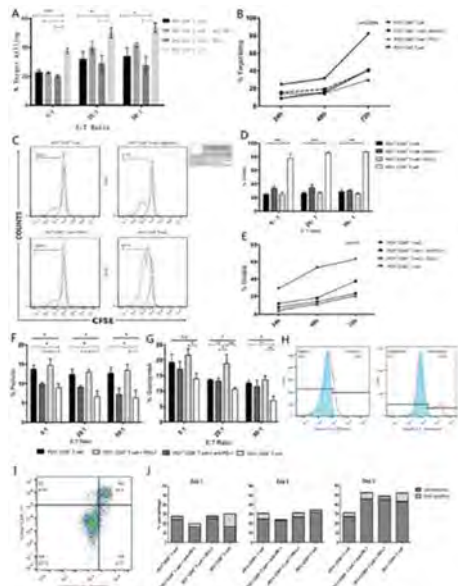

**Background:** Primary Biliary Cholangitis (PBC) is a chronic progressive autoimmune disease. It has been proven that there was abnormal activation of CD8 +T cells. Previous studies have shown that abnormal expression programmed death-1 (PD-1) and its ligand (PD-L1) in PBC. However, no study was found to confirm the abnormality of PD-1/PD-L1 pathway in CTL in PBC.

**Objectives:** To investigate the role of PD-1 and its ligand PD-L1 on CD8+ T cells cytotoxicity in the immunological mechanism of PBC.

**Methods:** The expression of PD-1 in peripheral CD8+ T cells of 69 patients diagnosed with PBC as well as 58 health controls (HC) was detected by flow cytometry. Plasma cytokines related to PD-1/PD-L1 pathway were detected by ELISA. The co-localization of PD-1 and CD-8, PD-L1 and CK19 in portal region in liver biopsy was analysed by immunofluorescence assay. Meanwhile, the relative gene expression of PD-1 regulatory pathway in CD8+ T lymphocytes were measured by RT-PCR. And co-culture of PD-1+ CD8+ CTL and HiBEC was done *in vitro* to detect the cytotoxicity, proliferation and cytokine expression of CD8+ CTL and the apoptosis of HiBEC.

**Results:** The proportion of peripheral PD-1+ CD8+ T cell decreased in PBC (12.0%±8.8%) than HC (19.9%±12.5%) (p<0.001). The plasma concentration of IL-10, IFN-γ and TGF-β in the PBC group were higher than that in HC (8.29±9.00 pg/ml v.s. 4.43±5.08 pg/ml, p=0.0066; 51.94±52.94 vs 26.71±26.26 pg/ml, p=0.0015; 1302.0±1972.8 pg/ml vs 205.8±298.9 pg/ml, p=0.0018, resp.). Compared with HC (n=19), *Tbet* gene expression in CD8+ T lymphocytes was increase

in PBC group (n=21) ( $0.82 \pm 0.76$  vs  $3.03 \pm 4.23$ ,  $p=0.028$ ). Immunofluorescence co-localization revealed that increased PD-1 positive cells in early PBC stage than late one, and less PD-L1 positive cells as well as PD-L1 and CK19 co-localised ones in PBC patients compared to HC. In the CTL and HiBEC co-culture system *in vitro*, the cytotoxicity of PD-1<sup>+</sup> CD8<sup>+</sup> T cells was weaker, with less proliferation and tendency of decreased production of IFN- $\gamma$  and TGF- $\beta$  compared to PD-1<sup>-</sup> CD8<sup>+</sup> T cells. Meanwhile, HiBEC apoptosis was relatively more in PD-1<sup>-</sup> CD8<sup>+</sup> T cells co-culture group. These effects could be antagonised by anti-PD-1 antibody and enhanced by PD-L1.

Abstract AB0036 – Figure 1

**Conclusions:** In PBC, the expression of Tbet is up-regulated in CD8<sup>+</sup> T cells, which leads to the down-regulated expression of PD-1 on. Meanwhile, the expression of PD-L1 in HiBEC may be down-regulated. The silenced PD-1/PD-L1 pathway caused more CD8<sup>+</sup> T cells proliferation, more related cytokines production and the enhanced CTL cytotoxic effects on HiBEC. PD-1/PD-L1 pathway functions as an important pathway in the immunological mechanism of PBC.

#### AB0037 MIR-155 PROMOTES THE DIFFERENTIATION OF TH17 CELL BY TARGETING ETS-1 IN RHEUMATOID ARTHRITIS

Z. Yin<sup>1</sup>, W. He<sup>1</sup>, X. Chen<sup>1</sup>, X. Luo<sup>1</sup>, Y. Zhang<sup>1,2</sup>, Z. Ye<sup>1</sup>. <sup>1</sup>Shenzhen Futian Hospital for Rheumatic Diseases, Shenzhen; <sup>2</sup>Rheumatology and Immunology, First Clinical College of Harbin Medical University, Harbin, China

**Background:** MicroRNAs play important roles in arthritis. MiR-155 emerges as a central regulator of the immune response, but its function in autoimmune arthritis is poorly understood.

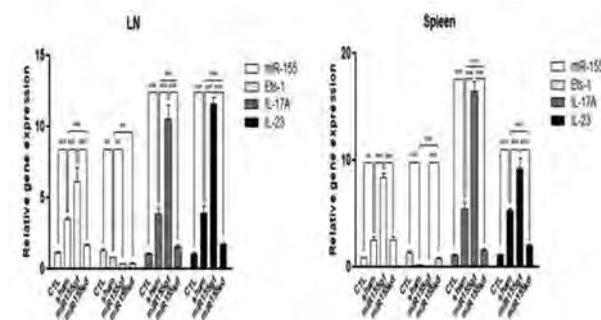

**Objectives:** To clarify the role of miR-155 in the balance of CD4<sup>+</sup>Th17 and Treg cell differentiations as well as how their mechanisms function in autoimmune arthritis.

**Methods:** CD4<sup>+</sup>T cells were *in vitro* isolated from DBA1 mice. The transfections of miR-155 mimics and miR-155 inhibitors in CD4<sup>+</sup>T cells were performed for

enhanced or knockdowns of miR-155 expression and RNA interference was applied to silence Ets-1 gene expression. In addition, we carried out *in vivo* experiments of enhanced miR-155 expression by lenti-virus mediated miR-155 (LV-miR-155) infection and silencing of miR-155 expression by lenti-virus-anti-miR-155 (LV-anti-miR-155) within our well-established type II collagen (CII)-induced arthritis (CIA) mice model. The ratios of IL-17<sup>+</sup> TH17 cells were analysed using flow cytometry (FCM). The expressions of some key autoimmune-response of genes including ROR $\gamma$ t, IFN-g, Ets-1, IL-17, IL-23, and Stat3 were further determined by (Taqman) Quantitative Real-time PCR and Western blotting. Initially n=6 per group if not indicated further; totally 6 groups in parallel per experiment. \* $p < 0.05$ , considered as significantly; \*\* $p < 0.01$ , considered as highly significantly.

**Results:** For the first time we showed that miR-155 may promote Th17 cell differentiation in RA pathogenesis. Firstly, we observed that miR-155 may significantly induce the expressions of some key autoimmune-response genes including ROR $\gamma$ t, IFN-g, IL-17, IL-23, and Stat3 but it significantly inhibited Ets-1 gene expression. 2ndly, miR-155 may in part modulates Th17 cell differentiation by targeting Ets-1 in that indeed the expression of miR-155 significantly co-related with disease index in CIA mice. Furthermore, the CIA mice with *in vivo* forced expression of miR-155 have significantly more Th17 cells (i.e. high ratio) and severe CIA disease index compared to their control CIA mice; strikingly, they also have a significantly higher expression of aforementioned autoimmune-response genes compared to their corresponding controls along with the response of Ets-1 exactly in a verse direction. Consistently, the CIA mice with *in vivo* knockdown of miR-155 expression resulted in significantly less Th17 cells and lesser severe CIA disease index compared to their control CIA mice. However, they have a significantly lower expression of above-mentioned autoimmune-response genes compared to their corresponding controls along with a response of Ets-1 in a verse direction (the data in part shown in Figure 1; sham=CIA treated with LV-nonspecific sequence).

**Conclusions:** For the first time our data show miR-155 has a critical role in Th17 differentiation and the RA pathogenesis via targeting the Ets-1. Although it warrants further investigations, miR-155 might be a promising therapeutic target for autoimmune diseases, esp. RA.

## Innate immunity in rheumatic diseases

#### AB0038 TBK1: A KEY REGULATOR AND POTENTIAL TREATMENT TARGET FOR INTERFERON POSITIVE SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLEROSIS

E. Huijiser<sup>1</sup>, I. Bodewes<sup>1</sup>, C. van Helden-Meeuwse<sup>1</sup>, L. Tas<sup>1</sup>, R. Huizinga<sup>1</sup>, V. Dalm<sup>2</sup>, M. van Hagen<sup>2</sup>, N. Groot<sup>3</sup>, S. Kamphuis<sup>3</sup>, P. van Daele<sup>2</sup>, M. Versnel<sup>1</sup>. <sup>1</sup>Immunology, <sup>2</sup>Internal Medicine, <sup>3</sup>Pediatric Rheumatology, Erasmus MC, Rotterdam, Netherlands

**Background:** Upregulation of type I interferons (IFN-I) is a hallmark of systemic autoimmune diseases like systemic lupus erythematosus (SLE) and systemic sclerosis (SSc). Three different receptor families are implicated in the induction of IFN-I production: Toll-like receptors (TLRs), RIG-like receptors (RLRs) and DNA-sensing receptors (DSRs). TANK-binding kinase (TBK1), is an important signalling hub downstream of RLRs and DSRs. TBK1 activates IRF3 and IRF7, leading

to IFN- $\gamma$  production and subsequent induction of interferon-stimulated genes (ISGs).

**Objectives:** To explore the potential of TBK1 inhibitors to downregulate IFN- $\gamma$  activation in SLE and SSc.

**Methods:** TBK1, IRF3, IRF7 and STAT1 were determined by qPCR in PAXgene samples and phosphorylated-TBK1 (pTBK1) was analysed by flowcytometry in plasmacytoid dendritic cells (pDCs) from IFN- $\gamma$  positive (IFNpos) patients. Peripheral blood mononuclear cells (PBMCs) from SLE and SSc patients and TLR7-stimulated PBMCs from healthy controls (HCs) were cultured with the TBK1 inhibitors BX795 followed by analysis of ISGs.

**Results:** Increased expression of TBK1, IRF3, IRF7 and STAT1 in whole blood and pTBK1 in pDCs was observed in IFNpos pSS, SLE and SSc patients compared to HCs. Upon treatment with BX795, PBMCs from IFNpos pSS, SLE, SSc and TLR7-stimulated HCs downregulated the expression of the ISGs MxA, IFI44, IFI44L, IFIT1 and IFIT3. The TBK1 inhibitor inhibited the secretion of IFN- $\gamma$  by TLR7-stimulated PBMCs from HCs.

**Conclusions:** TBK1 inhibition reduced expression of ISGs in PBMCs from IFNpos SLE and SSc patients indicating TBK1 as a potential treatment target.

AB0039

#### IMMUNOSUPPRESSIVE EFFECT OF MESENCHYMAL STEM CELLS ON MONOCYTES DERIVED FROM PATIENTS WITH RHEUMATOID ARTHRITIS

G. Vasilev<sup>1</sup>, M.G. Ivanova<sup>1</sup>, E. Ivanova-Todorova<sup>1</sup>, K. Tumangelova-Yuzeir<sup>1</sup>, E. Krassimirova<sup>1</sup>, R. Stoilov<sup>2</sup>, D. Kyurkchiev<sup>1</sup>. <sup>1</sup>Laboratory of Clinical Immunology, University Hospital "St. Ivan Rilski" Sofia; <sup>2</sup>Clinic of Rheumatology, University hospital "St. Ivan Rilski" Sofia, Medical University of Sofia, Sofia, Bulgaria

**Background:** Mesenchymal stem cells (MSCs) are a heterogeneous population of fibroblast-like progenitor cells that may be isolated and expanded from bone marrow, umbilical cord and other tissues. Moreover, MSCs display the capacity to self-renew and differentiate into various mesodermal cell lineages. They also have drawn considerable attention for their regenerative and immunosuppressive effects in a range of autoimmune diseases, which raises the question for their potential use as therapeutic tool in rheumatoid arthritis.

**Objectives:** In line with aforementioned and taking in mind that monocytes playing pivotal role in orchestrating immunological tolerance, we aimed to study the immunosuppressive effects of adipose tissue derived mesenchymal stem cells (AT-MSC) on monocytes derived from patients with rheumatoid arthritis (RA).

**Methods:** We enrolled 12 patients matching the ACR<sup>EULAR</sup> 2010 criteria for RA. AT-MSC were isolated and cultured according to well established protocols. ELISA was performed for testing the cytokines produced by AT-MSC (IL-1, IL-10, IL-4, IFN- $\gamma$ , IL-6, IL-8, CCL-5, RANTES, IL-17). Peripheral blood mononuclear cells (PBMCs) isolated from RA patients' samples were cultured in AT-MSC conditioned media and in control media. Flow cytometry was used for detection of monocytes markers (CD14, CD80, CD86, HLA-DR).

**Results:** Our results revealed considerable increase in number of cells expressing the myeloid lineage surface marker CD14 ( $p=0.026$ ) under the influence of AT-MSC medium. We further demonstrated decrease in percentage values of monocytes expressing HLA-DR ( $p=0.004$ ) and CD80/86 surface molecules ( $p=0.47$ ). Moreover, significant reduction in mean fluorescent intensity of HLA-DR surface expression ( $p=0.016$ ) was also demonstrated.

**Conclusions:** Our study unambiguously points out that under the impact of AT-MSC media monocyte development into dendritic cells was hampered and was also skewed into direction of accumulation of monocytes displaying more tolerogenic phenotype characterised by down regulation of HLA-DR and B7 complex (CD80/86) surface expression. Furthermore, antigen presentation alongside with expression of the co-stimulatory B7 complex and cytokine ambience forms a three-way signalling pathway responsible for T helper activation and proliferation and consequent antibody production by plasma cells. Hence, effects exerted by AT-MSC conditioned media on monocyte lineage development should not be neglected in the context of developing novel therapeutic approaches and strategies for treatment of RA.

#### TOLL-LIKE RECEPTOR 9 INFLUENCES INFLAMMATORY ARTHRITIS AND OSTEOCLASTOGENESIS

A. Fischer<sup>1</sup>, S. Abdollahi-Rodsaz<sup>2,3</sup>, A.C.Y. Yau<sup>4</sup>, E. Lönnblom<sup>4</sup>, B. Meyer<sup>1</sup>, B. Niederreiter<sup>1</sup>, R. Holmdahl<sup>4</sup>, G. Steiner<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Internal Medicine III, Medical University of Vienna, Vienna, Austria; <sup>2</sup>Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; <sup>3</sup>Division of Rheumatology, Department of Medicine, New York University School of Medicine, New York, USA; <sup>4</sup>Medical Inflammation Research, Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden

**Background:** Release and insufficient removal of endogenous nucleic acids may be involved in triggering autoimmune reactions important in the initiation of systemic autoimmune diseases including rheumatoid arthritis (RA). Nucleic acid sensing molecules, such as the endosomal Toll-like receptors (TLRs) 7 and 9, have been linked to pathogenic autoimmune processes, but their role in RA is less clear. Data obtained in rats with pristane-induced arthritis (PIA) suggested involvement of TLR9 in the pathogenesis of this arthritis model<sup>1</sup>.

**Objectives:** To gain more insight into the role of TLR9 in autoimmune arthritis, TLR9 inhibition with specific oligodeoxynucleotide sequences (ODN)<sup>2</sup> was investigated in rats with PIA. To further investigate TLR9 involvement, streptococcal cell wall (SCW) arthritis was induced in TLR9<sup>-/-</sup> mice.

**Methods:** Arthritis was induced in mice with SCW lysates and in rats with the mineral oil pristane. Rats were treated with a TLR9 antagonist, starting before disease induction. Arthritis was scored using established scoring systems, inflammation and bone erosion were quantified by histological analysis. Levels of  $\alpha$ -1-acid-glycoprotein (AGP), rheumatoid factor (RF) and IL-6 in sera were analysed. The role of TLR9 in osteoclast differentiation and activation was investigated *in vitro*.

**Results:** In PIA, the TLR9 antagonist reduced arthritis severity by ~50%, which was accompanied by a reduction of AGP, IL-6 and RF. TLR9 inhibition led to reduced inflammation, bone erosion and cartilage degradation. Moreover, the T cell-dependent chronic phase of SCW arthritis was significantly suppressed in TLR9<sup>-/-</sup> mice. Remarkably, TLR7 and TLR9 mRNA levels strongly differed in the course of *in vitro* osteoclastogenesis. Whereas TLR7 expression did not change throughout osteoclastogenesis, expression of TLR9 was higher in precursor cells than in mature osteoclasts and stimulation with a TLR9 agonist (CpG) completely inhibited osteoclastogenesis.

**Conclusions:** Taken together, the results suggest a role for TLR9 in the T cell-dependent phases of PIA and SCW arthritis thus an important involvement of the DNA (CpG) recognising TLR9 in the initiation of autoimmune arthritis and during osteoclastogenesis. The precise role(s) of TLR9 in the different stages of arthritis needs to be further elucidated in future experiments.

AB0041

#### HETEROGENEITY OF THE TYPE I INTERFERON SIGNATURE IN RHEUMATOID ARTHRITIS MAY ACCOUNT FOR DIFFERENCES IN ITS CLINICAL RELEVANCE

J. Rodríguez-Carrio<sup>1,2</sup>, M. Alperi-López<sup>2,3</sup>, P. López<sup>1,2</sup>, F.J. Ballina-García<sup>2,3</sup>, A. Suárez<sup>1,2</sup>. <sup>1</sup>Area of Immunology, University of Oviedo; <sup>2</sup>Instituto de Investigación Sanitaria del Principado de Asturias (ISPA); <sup>3</sup>Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain

**Background:** increased expression of interferon-responding genes (IRGs), the so-called IFN signature, has been reported in rheumatoid arthritis (RA) in peripheral blood and synovial tissue. However, some controversy exists concerning its clinical relevance, since longitudinal changes of the IFN signature have been reported upon different treatments and a physiological diversification of the type I IFN signature among different conditions has been recently described. Additionally, the relevance of the IFN signature in the very early stage of RA is unknown.

**Objectives:** to evaluate (i) whether quantitative and qualitative differences in the activation of the IFN signature can be found in RA patients depending on the clinical stage and (ii) if these differences may be linked to a clinical relevance of the IFN signature.

**Methods:** expression of IFI44, IFI44L, IFI6 and MX1 was determined in peripheral blood in 98 RA patients and 28 controls. RA patients were classified into groups according to their clinical stage and treatments received: very early RA (VERA, recruited at onset and not exposed to any treatment), bDMARD-naïve (patients on csDMARD treatment) and bDMARD (patients on biological treatment, all anti-TNF $\alpha$  agents). An additional group of 13 RA patients candidate for TNF $\alpha$ -blockade was also recruited and samples were taken before and after anti-TNF $\alpha$  treatment. The associations among IRGs were evaluated by network and principal component analyses.

**Results:** all IRGs was increased in RA, although differences were noted among them. The IFN score was increased in all RA groups (VERA, bDMARD-naïve and bDMARD), but differences in their degree of activation and in the relationships among IRGs were observed. VERA patients exhibited a lower activation of the IFN signature and a distinct picture of the structure of the IRG network (figure 1) compared to both their established disease-counterparts and the HC group. The IFN score correlated the accumulated DAS28 over one year ( $r=0.593$ ,  $p=0.025$ ) and it was found to be a predictor of a good clinical outcome (EULAR good clinical response) in VERA (AUC=0.917,  $p=0.004$ ). However, no differences in the IFN score were observed between the bDMARD-naïve and bDMARD groups, but opposite associations with the clinical parameters were noted. Interestingly, the correlations among IRGs delineate different pictures between these two groups. The IFN score at baseline predicted poor clinical outcome upon TNF $\alpha$ -blockade. Although no absolute changes in the IFN score were found, TNF $\alpha$ -blockade shifted the associations among IRGs. These differences mirrored those found when comparing bDMARD-naïve and bDMARD groups.

Abstract AB0041 – Figure 1

**Conclusions:** a certain heterogeneity within the IFN signature can be recognised in RA, depending on the clinical stage. The structure of the IFN signature may be a potential explanation for the controversy in this field and may represent a limitation for its use as a clinical biomarker.

#### ESSENTIAL OIL EXTRACTED FROM CHAMAECYPARIS OBTUSA ATTENUATES THE SEVERITY OF COLLAGEN-INDUCED ARTHRITIS

J. Lee<sup>1</sup>, Y. Park<sup>2</sup>, C.-H. Yoon<sup>2</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Uijeongbu Saint Mary's Hospital; <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea., Seoul, Korea, Republic of Ireland

**Background :** *Chamaecyparis obtusa* (*C. obtusa*) is a tropical tree species found in Japan and the southern region of South Korea. Although the biological activities of essential oil extracted from *C. obtusa* (EOCO) are not yet fully understood, essential oil has been shown to have antibacterial activities and anti-inflammatory effects.

**Objectives:** We investigated the effect of essential oil extracted from *Chamaecyparis obtusa* on the development of collagen-induced arthritis (CIA), a well-characterised preclinical model of human RA.

**Methods:** DBA1/J mice were injected intraperitoneally with EOCO dissolved in dimethyl sulfoxide (DMSO) 3 times a week for 5 weeks after type II collagen (CII) immunisation. Arthritis severity was evaluated by clinical and histological parameters. Serum anti-CII antibody levels were assayed by ELISA. Interleukin-17 (IL-17) expressions in the joints were determined by immunohistochemistry. Effect of EOCO on Th17 cells and natural killer (NK) cells was analysed using flow cytometry.

**Results:** EOCO markedly reduced the clinical and histological severity of CIA. Serum anti-CII antibody levels and the expression of IL-17 in the joints were significantly lower in mice treated with EOCO than those treated with DMSO alone. EOCO inhibited the differentiation of Th17 cells in total splenocytes, not in isolated CD4<sup>+</sup> T cells, from mice. EOCO increased the production of granzyme B and perforin in NK cells.

**Conclusions:** Our data demonstrate a protective effect of EOCO on the development of CIA through the inhibition of Th17 cell differentiation. This effect may be related with NK cell activity enhanced by EOCO.

#### THE ELASTICITY PROPERTIES OF PROBIOTIC BACTERIA WALL ASSOCIATED WITH BENEFICIAL MODULATORY ACTIVITY ON INNATE IMMUNITY OF THE HOST

L.P. Babenko, R.V. Bubnov, L.M. Lazarenko, M.Y. Spivak. *Interferon, Zabolotny Institute of Microbiology and Virology, National Academy of Sciences of Ukraine, Kyiv, Ukraine*

**Background:** Probiotics have tremendous potential to develop healthy diets and integrated approach for immunity-related diseases treatment and prevention;<sup>1,2</sup> are effective actors in distant sites<sup>3</sup> with strong potential for applications in rheumatology. The cell wall of probiotic bacteria plays an essential role in many aspects of modulating beneficial immune response;<sup>4</sup> its elasticity properties associated with probiotic beneficial effects and can warrant to stratify strains on their modulatory activity on innate immunity to justify individualised and personalised approach for nutrition and prevention.

**Objectives:** The aim was to study the effect of lactic acid bacteria (LAB) and bifidobacteria strains on phagocytic system cells functional activity and immunoregulatory cytokines synthesis *in vitro* in regards to the bacteria surface properties as cell walls elasticity using atomic force microscopy (AFM).

**Methods:** We conducted experimental studies on BALB/c line mice 18–20 g weight using lyophilized strains of LAB – *Lactobacillus acidophilus* IMV B-7279, *L. casei* IMV B-7280, *L. delbrueckii* subsp. *bulgaricus* IMV B-7281 and bifidobacteria – *Bifidobacterium animalis* VKL, *B. animalis* VKB. We cultivated the macrophages received from the peritoneal cavity of mice by common method individually with the strains of LAB and bifidobacteria. We estimated the impact of LAB and bifidobacteria strains on the functional activity of peritoneal cavity macrophages using the conventional methods of study oxygen-dependent bactericidal activity, nitric oxide production, their effect on the immunoregulatory cytokines. We used AFM scanning to estimate bacteria cell walls elasticity.

**Results:** All strains demonstrated a stimulating effect on the functional activity of macrophages and ability to produce NO/NO<sub>2</sub> *in vitro*. Lactobacilli strains increased the production of IL-12 and IFN- $\gamma$  *in vitro*. The AFM demonstrated different degree of the cell walls elasticity in various strains of LAB and bifidobacteria. Among lactobacilli the most elastic cell wall was found in *L. delbrueckii* subsp. *bulgaricus* IMV B-7281, and among bifidobacteria – in *B. animalis* VKL, which induced the considerable activation of the phagocytes. Probiotic strains survival in

the macrophages depended on the elasticity of bacterial cell walls and on the time of their joint cultivation.

**Conclusions:** LAB and bifidobacteria strains stimulate immunomodulatory cytokines and active oxygen and nitrogen oxides compounds production in macrophages. Strains with a more elastic cell wall according to AFM data demonstrated higher resistance to intracellular digestion in macrophages and higher level of their activation. AFM might be considered as a fast and accurate method to assess parameters of probiotic strains cell wall to predict their beneficial immunomodulatory properties. Further large-scale preclinical research needed for future application in rheumatic diseases treatment and prevention.

#### AB0044 HYPER IGD SYNDROME TREATMENT WITH HYDROXYCHLOROQUINE

M.P. Abi Saab<sup>1</sup>, R.M. Alsmad<sup>2</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Dermatology, Al Ahli Hospital, Doha, Qatar

**Background:** Hyper IgD syndrome is a minor form of mevalonate kinase deficiency caused by a its gene mutation and considered an auto-inflammatory disease inherited in an autosomal recessive manner, characterised by periodic episodes of fever, arthralgia, lymphadenopathy, skin rash, headaches, and abdominal pain. These attacks can occur spontaneously or be triggered by infections. Treatment options include courses of NSAIDs, steroids, colchicine, statins, I.V immunoglobulin, Cyclosporine, anti-IL-1 agents (anakinra or canakinumab) and anti-TNF antagonist Etanercept, with transient response. To date, there is no report with long term hydroxychloroquine treatment<sup>1-3</sup>.

**Objectives:** To report a case of Hyper Ig-D syndrome with multiple recurrent episodes and successful treatment using Hydroxychloroquine alone.

**Methods:** We report a case of 36-year-old female, presented with a first manifestation at age 35 with fever and extended cellulitis of the left arm treated successfully with antibiotic, rapidly followed with urticarial rash involving the upper side of the body, face and upper limbs migratory type lasting less than 24 hours suspecting allergic reaction. She was under supportive treatment (anti-histaminic and low dose steroids) that improved her condition temporarily. She developed multiple recurrent similar episodes for 7 months with high grade fever up to 39°C, inflammatory polyarthralgia affecting small joints, recurrent left elbow erythematous plaque with few subcutaneous nodules, considered as panniculitis type lesion (Picture-1) along with urticarial rash. Series of tests were undertaken along with skin biopsy.

**Results:** Biopsy of the lesion showed intense deep dermal neutrophil infiltrates. CRP fluctuating between 50 to 95 mg/L during the episodes. Neutropenia (1.7 to 1.9), Normal findings for ANA and SSA antibodies, ACE, Lysozyme enzyme, C3 and C4. Other infectious work-up was negative including Quantiferon God test. Protein electrophoresis found hypergammaglobulinemia. The Ig-D level was 263 mg/L and on another occasion 313 mg/L (normal <153 mg/L), the samples were taken during flare up and after recovery. The patient was treated by Colchicine for more than 3 months without beneficial effect. A trial with hydrochloroquine 400 mg daily brought a progressive improvement with lesser episodes at 3rd month and no recurrences at 6 months. After one year of therapy the patient was symptomless on a lower dose 200 mg daily with completely normalised inflammatory markers.

**Conclusions:** We conclude that Hyper Ig-D syndrome can be treated by hydroxychloroquine. This is the first report in the literature conducting this treatment option that can bring attention for further case by case trials.

#### AB0045 ACTIVATED RNASE L AS A NOVEL DISEASE ACTIVITY BIOMARKER IN PSORIATIC ARTHRITIS

S.K. Zarabi<sup>1</sup>, M. Hasipek<sup>2</sup>, Y. Guan<sup>2</sup>, E. Husni<sup>1</sup>, J. Ko<sup>3</sup>, A. Kontzias<sup>1</sup>, B.K. Jha<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Taussig Cancer Institute – Cancer Center Research; <sup>3</sup>Pathology, Cleveland Clinic, Cleveland, USA

**Background:** Almost 60% of psoriasis (PsO) patients with psoriatic arthritis (PsA) are estimated to be untreated, undertreated or/and undiagnosed.<sup>1</sup> Delayed diagnosis leads to permanent joint damage causing major functional decline and diminished quality of life. However, in the absence of diagnostic biomarkers, the diagnosis of psoriatic arthritis is clinical and hence difficult to establish from non-rheumatologists.<sup>2</sup> Recent studies have demonstrated the upregulation of type I interferon (IFN)-inducible genes in paired peripheral blood cells (PBC) and synovial biopsies of patient with PsA.<sup>3</sup> Oligoadenylate synthetases (OAS) are type I IFN-stimulated family of proteins that are activators of the latent Ribonuclease L (RNase L) pathways. The OAS-RNase L system is a potent host antiviral IFN-responsive system that is completely inactive in normal conditions, but once activated mediates a broad array of pro-inflammatory cellular processes.<sup>4</sup>

**Objectives:**

1. To investigate the role of OAS–RNase L pathway in PsA;
2. To quantify the hypothesised increased OAS–RNase L activity.

**Methods:** To further explore the gene expression data, we developed a highly sensitive ELISA and fluorescence resonance transfer (FRET) assay to access and compare the RNase L activity in plasma and serum derived from PsA (n=10), PsO (n=10) patients or healthy control donors (n=5).

**Results:** We found that RNase L activity was 2–3 fold higher in PsO and 3–5 fold in PsA compared to normal control (figure 1). Consistent with the gene expression analysis of upregulated type I IFN inducible genes, we also observed amplification of the downstream pro-inflammatory pathway consisting of RNase L dimer (active) and the produced cleaved RNA, which further induce IFN- $\beta$  production and other inflammatory signalling.

Abstract AB0045 – Figure 1. RNASEL\_Activity

**Conclusions:** The proportionally increased activation of OAS/RNase L in psoriatic arthritis merits further investigation into this pathway as a potential disease activity biomarker. RNase L is an easily quantifiable enzyme that could categorise disease severity and progression in daily routine lab ordered by primary physician. The timely diagnosis is key to improved function and quality of life in PsA patients.

**AB0046** **TOFACITINIB IMPAIRS MONOCYTE-DERIVED DENDRITIC CELL DIFFERENTIATION IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS**

V. Marzaioli<sup>1</sup>, M. Canavan<sup>1</sup>, S. Wade<sup>1</sup>, C. Low<sup>2</sup>, D.J. Veale<sup>2</sup>, U. Fearon<sup>1</sup>.  
<sup>1</sup>Molecular Rheumatology, Trinity College Dublin; <sup>2</sup>Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland

**Background:** Tofacitinib (Pfizer) is an oral Janus kinase inhibitor, recently approved for the treatment of rheumatoid arthritis (RA). Although its mechanism

of action has been explored in circulating cells, in particular neutrophils and lymphocyte, its effect on dendritic cells development remains still to be elucidate. Monocyte-derived dendritic cells are a subset of inflammatory DC derived from circulating monocytes and have a key role in inflammation and infection.

**Objectives:** The aim of this project is to evaluate the effect of Tofacitinib on inflammatory monocyte-derived dendritic cells (Mo-DC) from RA and PsA patients, and in particular on the ability of monocyte to differentiate into dendritic cells, an important step in innate immunity.

**Methods:** Mo-DC were isolated from blood of RA and psoriatic arthritis (PsA) patients by magnetic separation. Monocyte were plated in presence/absence of GM-CSF/IL-4 cocktail for 7 days, to acquire immature dendritic cell phenotype. To evaluate the effect of Tofacitinib on Mo-DC differentiation, monocyte were treated with 1  $\mu$ M Tofacitinib (or DMSO as control) for 15 min prior to cytokine stimulation. CD209 (immature DC marker) and CD14 (monocyte marker) were evaluated by flow cytometry in the CD11c positive population. Phagocytosis was investigated by the analysis of dendritic cell uptake of soluble antigens through two different mechanisms: non-specific macropinocytosis (using Lucifer Yellow), and receptor-mediated endocytosis (using DQ<sup>TM</sup> Ovalbumin).<sup>1</sup> Western blot analysis was utilised for analysis of NOX5 and Actin protein expression on the total cell lysate.

**Results:** The pre-treatment of Mo-DC with Tofacitinib inhibited Mo-DC differentiation in RA and PsA patients, as shown by reduced CD209 surface marker expression, and a mirrored increase of CD14 marker. The decreased ability of monocyte to differentiate into dendritic cells was translated into a function impairment of phagocytosis ability, as observed by the decreased uptake of both DQ<sup>TM</sup> Ovalbumin (receptor-mediated endocytosis) and Lucifer Yellow (micropinocytosis) PsA cells treated with Tofacitinib. Low phagocytosis was observed in RA patients. NOX5 has previously been shown to play a key role in Mo-DC differentiation,<sup>2</sup> therefore we sought to investigate whether Tofacitinib could exert its effect on Mo-DC development through modulating NOX5. NOX5 protein expression was significantly decreased in Mo-DC pre-treated with Tofacitinib in PsA, and to a lesser extent in RA patients.

**Conclusions:** Together, these observations suggest a novel mechanism of action of Tofacitinib in RA and PsA, by inhibiting Mo-DC development, which may alter migration of DC to the joint and subsequent activation of the immune response.

## Cytokines and inflammatory mediators

**AB0047** **EXPRESSION OF IFN TYPE I RESPONSIVE GENES IN A CARDIOVASCULAR DISEASE CONTINUUM OF RHEUMATOID ARTHRITIS**

A.N. Burska<sup>1,2</sup>, G. Harrison<sup>1</sup>, E.M. Hensor<sup>1,2</sup>, Y. El Sherbiny<sup>1,2</sup>, L.-A. Bissell<sup>1,2</sup>, G. Fent<sup>3</sup>, S. Plein<sup>3</sup>, J. Andrews<sup>1,2</sup>, E.M. Vital<sup>1,2</sup>, M.H. Buch<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>2</sup>NIHR Leeds Biomedical Research Centre; <sup>3</sup>Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, Leeds, UK

**Background:** Rheumatoid Arthritis (RA) patients have a prominent increase in cardiovascular disease (CVD) not fully explained by traditional risk factors<sup>1</sup>. Interferons type 1 (IFN-I) have been associated with premature CVD in SLE<sup>2</sup> and are implicated in several aspects of atherosclerosis and acute coronary syndromes<sup>3</sup>. A subpopulation of RA patients also display a peripheral blood IFN-I signature from 25% to 65%<sup>4</sup>, associated with clinical response to biologics<sup>5</sup>. The IFN-I signature association with CVD in RA remains unclear.

**Objectives:** To analyse expression of interferon type 1 response genes (ISGs) along a cardiac MRI (CMR) phenotyped CVD continuum in patients with RA.

**Methods:** PBMC samples from 94 RA patients and 21 healthy controls (HC) were obtained. RA patients were stratified based on CMR into: RA CMRneg (no CVD-

RA, n=13), RA CMRpos (subclinical CVD-RA, n=54), and RA with clinical CVD (defined as history of cerebrovascular disease or ischaemic heart disease) (RA-CVD n=25). qPCR of ISGs was performed using TaqMan Gene Expression Assays on Biomark (Fluidigm) with compatible reagents. Factor analysis of Ct values from 51 genes was used to create scores by calculating median dCt for genes loaded by each factor.

**Results:** RA cohort median (IQR) age 63 (13.3) yrs, 69% female, disease duration 148.7 (215.3) mths; HC age 43 (16.5) y, 62% female. Three IFN-I factors (IFN Score 1, 2, 3) were present in the dataset and were composed of 19, 21 and 7 genes respectively. The Jonckheere-Tepstra test showed significant increases in expression of Score 2 across the 4 groups ( $p=0.002$ ), consistent with a continuum, and multiplicity-corrected post-hoc analysis identified differences between HC and subclinical CVD ( $p=0.034$ ), HC and RA-CVD ( $p=0.004$ ); as well as between no CVD-RA and subclinical CVD-RA ( $p=0.034$ ); and subclinical CVD-RA with RA-CVD ( $p=0.029$ ). Scores 1 and 3 did not show consistent directional trends across all studied groups. In no CVD-RA expression of Score 1 and 2 positively correlated with CRP ( $\rho=0.744$ ,  $p=0.002$  and  $\rho=0.659$ ,  $p=0.010$  respectively). Score 1 with Low-Density Lipoproteins ( $\rho=0.527$ ,  $p=0.044$ ), Framingham 10y risk ( $\rho=0.595$ ,  $p=0.019$ ) and Score 3 with Pulse Wave Velocity ( $\rho=0.584$ ,  $p=0.022$ ). In subclinical CVD-RA score 3 expression negatively correlated with Left Ventricular mass ( $\rho=-0.381$ ,  $p=0.005$ ), in RA-CVD score 3 expression positively correlated with Glucose ( $\rho=0.724$ ,  $p=0.042$ ), Triglycerides ( $\rho=0.821$ ,  $p=0.023$ ) and Total Cholesterol/High-Density Lipoprotein ratio ( $\rho=0.505$ ,  $p=0.039$ ).

Abstract AB0047 – Figure 1

**Conclusions:** An IFN-I score (Score 2) emerged as a possible factor characterising progression along a CVD continuum in RA patients, from no CVD to subclinical and clinical CVD; also distinguishing between HC and RA with subclinical and clinical CVD. IFN-I is involved in metabolic disturbances associated with CVD development in RA. These results warrant further evaluation to confirm the findings in a larger cohort.

#### AB0048 SERUM CXCL13 LEVELS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS CORRELATION TO DISEASE ACTIVITY AND LUPUS NEPHRITIS

A.M. Abdalla<sup>1</sup>, E.A.E. Baraka<sup>2</sup>, M. El-Bhissy<sup>3</sup>. <sup>1</sup>Rheumatology and Rehabilitation, Aswan University, Aswan; <sup>2</sup>Rheumatology and Rehabilitation; <sup>3</sup>Clinical Pathology, Benha University, Benha, Egypt

**Background:** Systemic lupus erythematosus (SLE) is a complex autoimmune disease that is characterised by the production of pathogenic autoantibodies against nuclear structures.<sup>1</sup> B lymphocyte chemoattractant (BLC) or CXC motif ligand 13 (CXCL13) play an important regulatory role of B1 and B2 cell trafficking for activation of autoreactive T helper cells.<sup>2</sup> CXCL13 can induce trafficking of the CXCR5<sup>+</sup> T lymphocyte subset designated as follicular helper T lymphocytes which are specifically involved in production of autoantibodies during the development of lupus.<sup>3</sup>

**Objectives:** To detect serum CXCL13 levels in SLE patients and determine its relation to the disease activity and lupus nephritis

**Methods:** The study included 32 SLE patients and 20 healthy individuals as a control group. Patients' group was further subdivided according to disease activity and renal involvement. Serum samples from all studied individuals were analysed for the concentrations of CXCL13 by ELISA.

**Results:** There was a high statistically significant increase ( $p<0.001$ ) in the mean of serum CXCL13 on comparing its levels in SLE patients [242 (121.5–855.6) pg/ml] versus control group [73.8 (22.8–120.3) pg/ml], and on comparing its levels in lupus nephritis patients [542.4 (171–855.6) pg/ml] versus other patients without lupus nephritis [212.9 (121.5–580.5) pg/ml]. Moreover, CXCL13 Concentrations were correlated with SLEDAI ( $r=0.771$ ,  $p<0.001$ ) and double-stranded DNA titres ( $r=0.374$ ,  $p<0.05$ ).

**Conclusions:** Our data suggest that CXCL13 has an important role in pathogenesis of SLE and lupus nephritis. Also, pharmacological regulation of CXCL13 and its receptor CXCR5 may be a useful therapy in lupus nephritis.

#### AB0049 EVALUATION OF CASPASE-3, CASPASE-9, CASPASE-14 AND PANNEXIN-1 LEVELS IN BEHÇET'S DISEASE

A. İlhan<sup>1</sup>, M.E. Derin<sup>2</sup>, I. Karadağ<sup>2</sup>, H.O. Doğan<sup>3</sup>, A.C. Urhan<sup>2</sup>, M. Şahin<sup>3</sup>, A. Şahin<sup>2</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Rheumatology – Internal Medicine; <sup>3</sup>Biochemistry, Cumhuriyet University Medical Faculty, Sivas, Turkey

**Background:** Behçet's disease (BD) is a rheumatic disease in which various systemic findings such as especially recurrent oral ulcers, and genital ulcers, eye involvement, skin lesions, gastrointestinal involvement, neurological involvement, vascular involvement and arthritis can be seen.<sup>1</sup> The pathogenesis of the disease has not yet been fully understood. Caspases play a central role in apoptotic signal transduction. They are cysteine bound aspartate specific proteases.<sup>2</sup> There are three main types of caspases, the initiator caspases, the effector caspases and the inflammatory caspases. Pannexin-1 is a high-conduction voltage-gated channel protein that is commonly found in many organs and tissues including sensory systems and both neuronal and non-neuronal cell types.<sup>3</sup>

**Objectives:** The aim of this study is to examine the role of initiator, effector and inflammatory caspases in BD and the levels of pannexin duct protein, which is thought to be active in inflammation in BD and to compare clinical findings with healthy individuals.

**Methods:** Between January 2017 – June 2017, forty-six patients diagnosed with BD admitting to Cumhuriyet University Medical Faculty, Department of Internal Medicine Rheumatology and forty-four healthy volunteers without any rheumatic, systemic and metabolic diseases enrolled in this study. Clinical findings of all patients were recorded. The blood from a peripheral vein using suitable blood tubes was withdrawn to measure serum caspase-3, caspase-9, caspase-14 and pannexin-1 levels. Blood tests were examined by Elisa method in Cumhuriyet University Department of Biochemistry.

**Results:** The mean serum caspase-3 level was measured as 12.04 (11.25–43.69) pg/ml in BD group and 12.1 (11.19–484.3) pg/ml in healthy control (HC) group. There was no statistically significant difference between two groups ( $p=0.143$ ). The mean serum levels of caspase-9 in the BD group were measured as 22 (5.14–29.33) pg/ml and 22.01 (11.23–850) pg/ml in the HC group. There was no statistically significant difference between the two groups ( $p=0.593$ ). The mean serum caspase-14 level was 6 (5.2–8.21) pg/ml in the BD group and 6.15 (5.7–353) pg/ml in the HC group. There was no statistically significant difference between the two groups ( $p=0.053$ ). The mean serum pannexin-1 levels were 6.36 (4.21–527.2) pg/ml in the BD group and 255.8 (5.38–2000) pg/ml in the HC. Serum pannexin-1 levels were statistically significant higher in the HC group ( $p<0.0001$ ) (figure 1).

**Abstract AB0049 – Figure 1.** Serum levels of caspase-3, caspase-9, caspase-14 and pannexin-1 in patients with behçet's disease and healthy controls

**Conclusions:** Serum caspase-3, caspase-9 and caspase-14 levels were not statistically significant different between BD and HC groups. Serum pannexin-1 levels were statistically significant lower in the BD group.

#### BIOMAP<sup>®</sup> PHENOTYPIC PROFILING OF TWO BATCHES OF ORIGINATOR ETANERCEPT REVEALS EQUIVALENT ACTIVITY SIGNATURES CONSISTENT WITH CONSERVED BIOLOGICAL ACTIVITY

A. O'Mahony<sup>1</sup>, E.L. Berg<sup>1</sup>, H.E. Jones<sup>2</sup>, B. Fitzpatrick<sup>3</sup>, B. Hassett<sup>3</sup>, S.M. Vicik<sup>4</sup>, L. Marshall<sup>2</sup>, K. Roshak<sup>2</sup>, E. Choy<sup>5</sup>. <sup>1</sup>Eurofins DiscoverX Corporation, South San Francisco; <sup>2</sup>Pfizer, Collegeville, USA; <sup>3</sup>Pfizer Biotech, Dublin, Ireland; <sup>4</sup>Pfizer Biotech, Andover, USA; <sup>5</sup>Cardiff University School of Medicine, Cardiff, UK

**Background:** The BioMAP<sup>®</sup> platform is a complex human primary cell-based system for modelling tissue and disease states that is used to characterise drug activities based on the analyses of 148 clinically relevant biomarker readouts.

**Objectives:** To confirm that the BioMAP phenotypic signatures of two originator etanercept (ETN) samples remained comparable over time.

**Methods:** Two different ETN samples (ETN\_1 and ETN\_2) were independently profiled with a 5 year interval across a panel of 12 disease-relevant systems (3C and 4 hour [endothelial inflammation]; LPS [monocyte activation]; SAg [T cell activation]; BT [B cell activation]; BF4T and BE3C [epithelial inflammation]; CASM3C [vascular inflammation]; HDF3CGF, KF3CT, and MyoF [tissue remodelling, fibrosis]; Mphg [macrophage activation]). BioMAP systems consist of human primary cells or cocultures from healthy donors cultured in the presence of cytokines and growth factors. Protein levels, measured using immune-based methods or functional assays for cell viability and proliferation, were used to generate a BioMAP activity profile for each sample. ETN activities were annotated if they differed from the vehicle control and had an effect size >20%. The profiles of the 2 samples were compared using Pearson's correlation.

**Results:** BioMAP phenotypic profiling of ETN\_1 versus ETN\_2 samples at 10 µg/mL revealed similar signatures across 148 biomarkers in 12 disease-relevant systems. The Pearson's correlation coefficient was 0.781, which is above the determined threshold for mechanistic similarity ( $r \geq 0.7$ ). Key efficacy-related anti-inflammatory and immunomodulatory activities were commonly inhibited in multiple systems including tumour necrosis factor alpha (LPS and BT), interleukin (IL)-2 (BT), vascular cell adhesion molecule 1 (MyoF and Mphg), IL-8 (SAg and MyoF), and E-Selectin (SAg and Mphg). The profiles of ETN samples at 1 µg/mL in the SAg system modelling T cell activation responses also revealed statistically significant similarity in signatures ( $p < 0.01$ ) in both magnitude and direction across all biomarker activities (figure 1).

**Abstract AB0050 – Figure 1.** SAg system profile of ETN\_1 and ETN\_2 samples at 1 µg/mL.

**Conclusions:** The BioMAP phenotypic signatures of the ETN\_1 and ETN\_2 samples profiled in independent experiments using different primary cell pools remained comparable, which was consistent with conserved ETN mechanisms of action. The BioMAP platform represents a useful orthogonal approach for assessing ETN activity.

#### THE INFLUENCE OF ANTI-INFLAMMATORY LIPOXIN A4 ON GENERATION OF CYTOKINES BY PBMCs OF PATIENTS WITH PSORIATIC ARTHRITIS

A.M. Lewandowska-Polak<sup>1</sup>, M. Kubiak<sup>1</sup>, O. Brzezinska<sup>1</sup>, E. Pomorska<sup>1</sup>, M. L. Kowalski<sup>2</sup>, J. Makowska<sup>1</sup>. <sup>1</sup>Dept of Rheumatology; <sup>2</sup>Dept of Immunology, Rheumatology and Allergy, Medical University of Lodz, Łódź, Poland

**Background:** Psoriatic arthritis (PsA) is affecting up to 40% of the patients with psoriasis. The pathogenesis of PsA is not completely understood. One of the hypothesis suggest that repeated micro injuries and trauma and lack of proper inhibition of inflammation lead to chronic inflammation spreading to surrounding tissue and other joints and ligaments. One of the mediators which lead to inhibition of inflammation in healthy conditions are derivatives of arachidonic acid – lipoxins.

**Objectives:** The aim of the study was to assess if the influence of lipoxin A4 on inhibition of synthesis of pro-inflammatory cytokines by peripheral blood mononuclear cells (PBMCs) of patients with psoriatic arthritis.

**Methods:** The study group consisted of 10 patients with psoriatic arthritis and 5 healthy controls. The peripheral blood mononuclear cells from patients with PsA and healthy controls were isolated and were stimulated with lipopolysaccharide (LPS) with or without 200 nM of lipoxin A4 for 24 hours. The supernatants were collected after 24 hour stimulation. The levels of IL-1b, IFN-gamma, TNF-alfa, MCP-1, IL-6, IL-8 and IL-33 were assessed by cytometric bead array system.

**Results:** Incubation of cells with LPS, increased production of all cytokines assessed either in patients with psoriatic arthritis or in healthy controls. In PBMCs from healthy controls incubation of cells with lipoxine A4 decrease production of proinflammatory cytokines (IL-1b, MCP-1, IL-8, IL-6, IL-33 and TNF-alfa;  $p < 0,05$ ). However in patients with psoriatic arthritis addition of lipoxine A4 did not inhibit LPS – induced proinflammatory cytokines release (IL-1b, MCP-1, IL-6, IL-8, IL-33 and TNF-alfa,  $p < 0,05$ )

**Conclusions:** Our study demonstrated that modulation of Inflammation by lipid mediators in patients with psoriatic arthritis is dysregulated.

**Disclosure of Interest:** None declared

### TREATMENT WITH BACTERICIDAL/PERMEABILITY-INCREASING PROTEIN REDUCES CRYSTAL-INDUCED INFLAMMATION AND COLLAGEN-INDUCED ARTHRITIS IN MICE

A. Scanu<sup>1</sup>, R. Luisetto<sup>2</sup>, B. Raffener<sup>1</sup>, L. Corain<sup>3</sup>, P. Galozzi<sup>1</sup>, R. Ramonda<sup>1</sup>, F. Oliviero<sup>1</sup>, L. Punzi<sup>1</sup>. <sup>1</sup>Rheumatology Unit, <sup>2</sup>Dept. of Experimental Surgery, <sup>3</sup>Dept. of Management and Engineering, University of Padova, Padova, Italy

**Background:** Bactericidal/permeability-increasing protein (BPI) is an antibacterial glycoprotein produced by polymorphonuclear cells (PMN). Although BPI has been detected in synovial fluid of patients with different type of arthritis, its effects in these diseases remain unexplored.

**Objectives:** To investigate the effects of BPI in mouse models of crystal-induced inflammation and collagen-induced arthritis (CIA).

**Methods:** Air pouches were raised on the backs of CD1 mice (n=14 per condition). 2 mg of calcium pyrophosphate (CPP) crystals in 1 ml of PBS were injected into the pouch in the presence or absence of 0.1 mg of BPI for 3 hour. Controls received 1 ml of PBS. After the sacrifice, pouch fluids were recovered by washing with 2 ml of PBS. Leukocyte count in lavage fluids was obtained using a hemocytometer and the PMN percentage was determined by May-Grünwald-Giemsa staining. CIA was induced in C57Bl/6 mice (n=12 per condition) by immunisation with collagen/complete Freund's adjuvant emulsion at days 0 and 21. Arthritis was monitored by measuring paw swelling with a calliper and scored (0–5) every 2 days. Arthritic mice (paw score=2) were intraperitoneally injected with 200 µl of BPI (50 µg/ml) or vehicle only (PBS). Treatment and arthritis evaluation were carried out twice a week for 2 month. At the experiment endpoints, mice were subjected to knee and ankle ultrasound (US) and then euthanized. Hind paws were processed for histological analysis to assess inflammation, pannus formation, cartilage and bone destruction in knee and ankle joints (score 0–5). IL-1β, IL-6, CXCL1 and TNF levels were measured by ELISA in pouch fluids and serum from collected blood.

**Results:** The injection of CPP crystals into the pouches induced leukocyte infiltration (26.27±4.14 × 10<sup>5</sup> cells/ml) comprising 73.5%±2.12% of PMN. IL-1β (80.99 ±3.65 pg/ml), IL-6 (892.90±28.14 pg/ml), CXCL1 (762.82±50.08 pg/ml) and TNF (52.70±0.49 pg/ml) were measured in lavage fluids. The co-injection of crystals and BPI inhibited leukocyte influx by 67% and PMN infiltration by 55% and, in turn, the levels of all assessed cytokines were reduced (46% IL-1β, 35% IL-6, 60% CXCL1, 64% TNF). CIA mice reached an arthritis score of 2 after 28–33 days and showed a progressive worsening of clinical signs that picked at day 49–56, and then improved only in BPI group. At the end of the experiment, hind paw swelling and scores were lower in BPI-mice (paw thickness=4.76±0.33 mm; score=4 ±0.5) than in controls (paw thickness=6.39±0.95 mm; score=5). US revealed synovial hypertrophy in all joints considered, but the presence of effusion only in knees of untreated animals. Power Doppler was positive in controls but not in BPI group. BPI decreased histological scores for pannus formation and inflammation by 3-fold, and for cartilage and bone destruction by 2-fold as compared to PBS-mice. CIA induction led to high levels of IL-1β (656.80±45.6 pg/ml), IL-6 (376.04 ±46.33 pg/ml), CXCL1 (834.08±68.8 pg/ml) and TNF (277.72±15.24 pg/ml), which were reduced with BPI treatment by 66%, 46%, 47% and 93%, respectively.

**Conclusions:** This study shows inhibitory effects of BPI on crystal-induced inflammation and CIA, suggesting a therapeutic potential of this protein for arthritis by down-regulating inflammatory process.

AB0053

### A BIOASSAY TO MEASURE TGFβ ACTIVITY REVEALS DECREASED TGFβ ACTIVITY IN SSC SERUM

A. Van Caam<sup>1</sup>, E. Vitters<sup>1</sup>, F. van den Hoogen<sup>2</sup>, M. Vonk<sup>2</sup>, P. van der Kraan<sup>1</sup>. <sup>1</sup>Experimental Rheumatology; <sup>2</sup>Rheumatology, RADBOUDUMC, Nijmegen, Netherlands

**Background:** Systemic sclerosis (SSc) is a severe disease characterised by auto-immunity, vasculopathy and excessive fibrosis of connective tissues. The pathophysiology of SSc is still poorly understood, but its symptoms imply a role for dysregulated transforming growth factor β (TGFβ) signalling; e.g. this cytokine is known to regulate vascular and connective tissue biology. TGFβ circulates in blood in an inactive form bound to latency associated peptide and latent TGFβ binding proteins. This latent TGFβ first has to be activated before it can become bioactive. With the use of a bioassay, TGFβ's bioactivity can be measured in a complex mixture like serum, unlike with an ELISA which cannot take cellular activation processes into account.

**Objectives:** To determine the bioactivity of TGFβ in SSc serum compared to that of healthy control serum

**Methods:** Serum was collected of 10 SSc patients and 10 age and sex matched healthy controls. Primary human fibroblasts of 3 donors were

transduced with CAGA<sub>12</sub>-luc which produces luciferase in response to TGFβ/Smad3 or BRE-luc which produces luciferase in response to BMP/Smad1/5. These cells were treated with 10% serum for 16 hour and luciferase activity was measured. To activate all TGFβ, sera were treated with 4M HCl for 1 hour at RT, after which pH was normalised with 4M NaOH. Controls were treated with HCl and NaOH simultaneously. To verify that TGFβ signalling was measured in this reporter assay, sera were treated with anti-TGFβ1/2/3 for 1 hour at RT before use.

**Results:** Control sera significantly induced reporter activity by 4.5-fold. However, SSc sera only induced a 2.5-fold increase in luciferase activity, indicating significantly lower bioactivity of TGFβ (p<0.0001). This difference was not due to a difference in total TGFβ levels; after activation of all TGFβ both HC and SSc sera induced a similar 6-fold increase in signal strength. These data show that in HC sera approximately 75% of all TGFβ is bioactive compared to only 42% in SSc. Addition of anti-TGFβ1/2/3 inhibited all CAGA<sub>12</sub>-luc reporter activity (p<0.0001) of both HC and SSc serum, and of both acidified and not acidified sera (p<0.0001), showing that our bioassay is indeed TGFβ-dependent. To investigate if reduced bioactivity is a more general phenomenon we measured BMP activity. BMP proteins are structurally closely related to TGFβ and also circulate in inactive form. Both HC and SSc sera induced a similar 8-fold increase in BRE-luc activity, and this activity was increased to a 16-fold induction after acidification for both groups. BMPs in SSc sera are thus not less bioactive. This illustrates the uniqueness of our observation on TGFβ bioactivity.

**Conclusions:** TGFβ in SSc serum is less bioactive than in control serum whereas BMPs are not less bioactive.

### PDE4 INHIBITOR ATTENUATION OF IL-23 SECRETION FROM MONONUCLEAR CELLS

C. Bridgewood, R. Cuthbert, M. Wittmann, D. McGonagle. Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK

**Background:** IL-23 is a cytokine heavily implicated in the immunopathology of both psoriasis and psoriatic arthritis. Emerging evidence suggest IL-36λ, a novel inflammatory cytokine which has been heavily implicated in psoriatic immunopathology, is able to stimulate the release of IL-23. 1–3 PDE4 inhibitors, which elevate cyclic AMP (cAMP) are known to exert anti-inflammatory effects by regulating transcription factors such as NF-κB. The PDE4 inhibitor, Apremilast has proved successful in treating both psoriasis and psoriatic arthritis with patients showing a decrease in inflammatory cytokine levels, including IL-23.<sup>4</sup> However, the ability and mechanism of PDE4 inhibitors to lower IL-23 secretion from immune cells induced by disease relevant stimuli is presently unknown. Additionally, any potential relationship between IL-36λ driven inflammation and potential PDE4 inhibition is yet to be determined.

**Methods:** Blood mononuclear cells from healthy patients, (n=5) were pre-treated with either the PDE4 inhibitor Rolipram or other compounds known to elevate cAMP levels, such as histamine and 8-bromo-cAMP. Cells were subsequently treated with either bacterial or fungal toll like receptor adjuvants (LPS and Mannan) or the novel psoriatic cytokine IL-36λ. IL-23 was subsequently measured in culture supernatants by ELISA and by intracellular IL-23p19 flow cytometry.

**Results:** LPS, Mannan and IL-36λ all induced IL-23 secretion which could be attenuated in a dose dependent manner by the PDE4 inhibitor, Rolipram. Other compounds also known to increase cAMP levels, histamine and 8-bromo-cAMP similarly were able to reduce IL-23 secretion from all stimuli.

**Conclusions:** This data suggests a direct link between PDE4 inhibition and reduced IL-23 secretion in circulating immune cells. Additionally, it provides insight into how IL36/IL-23/IL-17 driven inflammation may be reduced by PDE4 inhibitors in psoriasis and psoriatic arthritis.

### HYDROXYCHLOROQUINE INHIBITS SOLUBLE CD154 PRODUCTION THROUGH CA<sup>2+</sup> AND PKC SIGNALLING PATHWAY

C.H. Tung, J.-M. Hsu, M.-C. Lu, N.-S. Lai. *Division of Allergy, Immunology and Rheumatology, Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi, Taiwan, Republic of China, Chia-yl, Taiwan, Province of China*

**Background:** Over-expression of membranous CD154 and soluble CD154 (sCD154) in T lymphocytes is important in pathogenesis of autoimmune diseases. PKC pathway induces sCD154 production through promoting shedding of membranous CD154.

**Objectives:** Hydroxychloroquine (HCQ) has been used in the treatment of autoimmune diseases for decades. We sought to identify the effects of HCQ on sCD154 and a possibly regulatory mechanism.

**Methods:** CD4<sup>+</sup>T cells were isolated from the blood of healthy donor. After stimulated with ionomycin +PMA and various concentrations of HCQ, concentration of sCD154 in the medium, expression of membranous CD154, Ca<sup>2+</sup> pathway and PKC signalling pathway were assessed.

**Results:** HCQ attenuated intracellular sustained calcium storage release and membranous CD154 synthesis in activated T cells. Besides, HCQ inhibited PKC activation and subsequently shedding of membranous CD154.

**Conclusions:** HCQ inhibited production of sCD154 in activated T cells through suppressing Ca<sup>2+</sup> and PKC signalling pathway. These findings provide one of the mechanistic insights into HCQ treatment.

### MEASUREMENT OF THE PRO-COAGULANT ACTIVITY OF MICROPARTICLES IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES: PROSPECTIVE STUDY

C. Mekhail<sup>1</sup>, X. Guillot<sup>1</sup>, C. Prati<sup>1</sup>, P. Saas<sup>2</sup>, G. Mourey<sup>2</sup>, D. Wendling<sup>1</sup>.  
<sup>1</sup>Rheumatology, CHRU Besançon; <sup>2</sup>EFS, Besançon, France

**Background:** Microparticles (MPs) are small membrane-bound vesicles that arise from activated and dying cells. Although the majority of MPs in the blood originate from platelets, all cells appear to be able to release MPs. Many studies have raised the implication of these MP in various processes: inflammation, thrombosis, angiogenesis. Previous studies reported inconsistent results in inflammatory rheumatic diseases. Studies have shown the correlation between the circulating MPs, platelet MPs and lymphocyte MPs in patients with spondyloarthritis (SpA) compared to control patients. For rheumatoid arthritis (RA), platelet MPs levels were correlated with DAS28.

**Objectives:** The aim of this study was to search a possible correlation between the disease activity and the pro-coagulant property of microparticles, potential indirect marker of inflammation.

**Methods:** The test used (STA Procoag PPL) is a standardised automated test. Results are expressed as coagulation times (in seconds). It is a functional test that provides information on the procoagulant potential of microparticles. The microparticles supply the phospholipids expressed on their membrane surface and the test provides calcium and factor Xa necessary to initiate coagulation: the shorter the coagulation time the greater the procoagulant activity of the phospholipids being studied, suggesting a higher number of MP.

This is a prospective, single-centre study, including 39 patients with spondyloarthritis (ASAS criteria), 37 with rheumatoid arthritis (ACR criteria) and 26 control patients (healthy subjects, osteoarthritis). All patients underwent STA Procoag PPL test, and we collected medical data: disease activity (BASDAI, BASFI,

DAS28vs and DAS28crp and HAQ), biological inflammation (VS, CRP), duration of disease, and current treatment.

**Results:** The *in vitro* clotting time of serum of patients with spondyloarthritis and rheumatoid arthritis compared with controls was not significantly different (p=0.23 and p=0.44, respectively). Regarding the activity scores of inflammatory rheumatic disease: BASDAI and BASFI, DAS28esr, DAS28crp and HAQ for patients with RA, no correlation between these data and coagulation time was found; the same goes for biological inflammation (ESR, CRP), duration and type of treatment (Nonsteroidal anti-inflammatory drugs, DMARDs, biologics).

Abstract AB0056 – Table 1

STA PPL	Controls (n=26)	SpA (n=39)	p	RA (n=37)	p
Mean±SD	62,70±11,58	66,48±12,77	p=0,23	65,25±13,54	p=0,44
BASDAI	r=0,0602	p=0,72	DAS28 esr	r=0,0230	p=0,17
BASFI	r=-0,125	p=0,45	DAS28 crp	r=0,151	p=0,37

**Conclusions:** In this study, there is neither difference in values of procoagulant activity of MPs between inflammatory rheumatic diseases and control subjects, nor correlation with their activity scores or biological inflammation.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.2581

AB0057

### DECREASED IRISIN LEVEL AS RISK FACTOR OF PATHOLOGICAL FRACTURES IN RHEUMATOID ARTHRITIS PATIENTS

D. Lavrova<sup>1</sup>, B. Zavadovsky<sup>1,2</sup>, L. Sivordova<sup>2</sup>, Y. Akhverdyan<sup>2</sup>, Y. Polyakova<sup>2</sup>, A. Yakovlev<sup>1</sup>. <sup>1</sup>Volgograd State Medical University, Volgograd, Russian Federation; <sup>2</sup>Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation

**Background:** Recent studies have been suggested that adipokines and myokines may be implicated in bone metabolism and pathogenesis of osteoporosis (OP).<sup>1</sup> Previous studies have revealed inverse correlation between irisin levels and vertebral fragility fractures, but no significant correlation was found between irisin and bone mineral density (BMD) as well as with lean weight. There is no previously published data about irisin levels in rheumatoid arthritis (RA) patients.<sup>2-4</sup>

**Objectives:** To investigate serum irisin levels in patients with RA.

**Methods:** We studied 170 people: 110 RA patients (mean age 53.58±12.32; hereinafter M±SD) and 60 healthy controls. All patients with RA were examined using dual-energy X-ray absorptiometry using LUNAR DPX-Pro densitometer. Osteoporotic fractures were confirmed by X-ray examination and/or by anamnesis data. All patients were passed through extensive clinical and laboratory examination, including N-terminal propeptide of procollagen type I, C-telopeptide of type I collagen, 25(OH)-vitamin D concentration. Serum irisin levels were measured by ELISA (BioVender test system, Cat №RAG018R).

**Results:** The mean concentration of irisin in RA group was 14.48±7.07 mg/ml, which was significantly lower than of healthy donors – 20.49±4.82 mg/ml (p<0,001). We subsequently divided all of RA patients into two groups: the first one (n=44) included patients with reduced serum irisin levels (below 10.85 mg/ml), and the second one (n=66) with normal irisin levels (above 10.85 mg/ml). The first group had significantly higher activity (DAS28), increased frequency of extra-articular manifestations, disease duration more than 5 years, class III of functional joints disability and lower levels of 25(OH)-vitamin D. We also observed higher incidence of pathological bone fractures in this group (p=0,047). There wasn't any significant correlation between serum irisin level and BMD at any localization, lean, or fat weight. We did not reveal any difference of bone turnover markers (serum C-terminal telopeptide of type I collagen, serum N-terminal propeptide of type I procollagen (P1NP)) between these groups.

**Conclusions:** We have therefore revealed relationships between decreased serum irisin levels, 25(OH)-vitamin D concentration and higher incidence of pathological bone fractures in RA patients. We found no connexion between serum irisin levels and BMD at any site and body composition. We could consequently suppose, that irisin levels may reflect bone quality or increased fall risk.

Roman<sup>1</sup>. <sup>1</sup>Rheumatology Department, HUP La Fe; <sup>2</sup>Biostatistical Unit, IIS La Fe; <sup>3</sup>Rheumatology Section, H. Aneu de Vilanova; <sup>4</sup>Medical School, UCV, Valencia, Spain

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease characterised by deregulation of cytokine production. INF1A is a proinflammatory cytokine considered as a key molecule in the SLE etiopathogenesis, being responsible indirectly of IL10 upregulation. BLYS is involved in autoantibodies production and clinical activity in SLE, and its expression is regulated by other cytokines as IL10 and INF1A. IL2 is an anti-inflammatory cytokine in SLE, but its loss leads to the production of Th2 proinflammatory cytokines as IL4, IL5 and IL13.

**Objectives:** To analyse the association among inflammatory cytokine levels and clinical activity, as well as to identify a cytokine profile related to disease activity in SLE.

**Methods:** A cross-sectional, observational study of 142 patients diagnosed of SLE<sup>SLEICC 2012</sup> criteria, and 35 healthy controls, was performed. A complete blood-test and an interview were carried out to collect their clinical data. We analysed inflammatory cytokines serum levels by colorimetric methods. Biostatistical analysis with R was performed.

**Results:** Mean cytokine levels for the SLE patients and healthy controls are shown in the table 1.

**Abstract AB0058 – Table 1**

	SLE patients (pg/ mL)	Healthy controls (pg/ mL)
	Mean (SD)	Mean (SD)
IL2	4.34 (12.2)	4,96 <sup>4,5</sup>
IL4	58.65 (64.6)	89,05 <sup>70,18</sup>
IL5	18 (5.71)	7,33 <sup>8,59</sup>
IL10	12.29 (32.82)	1,92 <sup>3,67</sup>
IL13	44.97 (273.78)	42,85 <sup>93,05</sup>
IL21	3.18 (5.61)	2,82 <sup>3,35</sup>
INF1A	15.69 (24.59)	4,84 <sup>1,91</sup>
BLYS	2293.82 (6948.46)	1181,15 <sup>260,04</sup>

The mean clinical activity measured by SLEDAI was 5.91±5.06, and we observed a statistically significant association between high levels of IL10 and high clinical activity (p=0.001).

Statistical analysis indicates that complement consumption is associated with increased levels of IL10 (p=0.029), INF1A (p<0.001), IL4 (p=0.004), IL5 (p=0.009) and decreased levels of IL2 (p=0.045); or anti-DNA positivity is associated with increased levels of INF1A (p=0.002) and decreased levels of IL2 (p=0.045), IL4 (p=0.034) and IL5 (p=0.007).

Moreover, BLYS seems to have increased in patients with positive antiphospholipid antibodies and anti-DNA. IL10 is associated with ENAs positivity (p=0.022). In patients with other autoimmune disease associated with SLE, an increase of INF1A (p=0.008) and IL5 (p=0.044) is observed.

SLE patients were categorised by normal, low or high level of the eight cytokines. Despite the fact that no specific cytokine profile associated with clinical activity was observed, those patients with high SLEDAI score had increased levels of IL10 and INF1A and decreased levels of IL2 and IL21.

**Conclusions:** Our SLE patients displayed mainly IL10, INF1A and BLYS increased, and IL2 decreased. Although IL10 seems to be the cytokine which best fits to clinical activity in SLE, altered levels of INF1A, IL2, IL4, and IL5 are associated with complement consumption or anti-DNA positivity.

**Disclosure of Interest:** None declared

**AB0059 FETUIN-A: CLINICAL AND LABORATORY ASSOCIATIONS IN WOMEN WITH RHEUMATOID ARTHRITIS**

E. Papichev<sup>1</sup>, L. Sivordova<sup>1</sup>, J. Polyakova<sup>1</sup>, Y. Akhverdyan<sup>1</sup>, B. Zavodovsky<sup>1</sup>, T. Rogatkina<sup>2</sup>. <sup>1</sup>Treatment and Prevention of Joint Disease Laboratory, Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy»; <sup>2</sup>Volgograd State Medical University, Volgograd, Russian Federation

**Background:** Fetuin-A is an acute-phase protein with contradictory effects. It is well known that fetuin-A low levels are associated with calcification and higher risk of cardiovascular diseases and its level is downregulated by pro-inflammatory cytokines.<sup>1</sup> Nevertheless, it was shown, that fetuin-A induces synthesis of pro-inflammatory cytokines in adipocytes and macrophages.<sup>2</sup>

**Objectives:** To investigate the level of fetuin-A in women with rheumatoid arthritis (RA).

**Methods:** At baseline we measured fetuin-A level, femoral neck, total hip and L<sub>1-4</sub> BMD by DXA in 110 women with RA (mean age 54.5±12.6; hereinafter M±Std. dev.) and 30 healthy controls. Serum CRP and ESR were measured to assess inflammation. DAS28 was calculated to determine RA activity. The diagnosis of osteoporosis was set according to the recommendations of world health organisation – T-scores≤-2,5 for patients without glucocorticoid therapy in anamnesis, T-scores≤-1,5 for patients treated with glucocorticoid for 3 months in anamnesis or with an osteoporotic fracture in anamnesis. Fetuin-A in serum was determined by enzyme-linked immunosorbent assay.

**Results:** Mean concentration of fetuin-A in group with RA was 765,69 ±120,64 ug/ml, which was lower than of healthy controls – 812,95 ug/ml (p=0,0438). Secondary osteoporosis was revealed in 52 patients (47%) with RA with mean level of fetuin-A at 733,7±18,83 ug/ml vs. 794,36±12,83 ug/ml (p=0,0078) of 58 (53%) non-osteoporotic patients. Moderate negative correlations were observed between fetuin-A and DAS28 (r=-0,4334; p<0,001), fetuin-A and CRP (r=-0,3148; p<0,001), fetuin-A and ESR (p=-0,344; p<0,001). Mean concentrations of fetuin-A were significantly different between the subgroups with moderate (3,2≤DAS28<5,1) and high disease activity (5,1≤DAS28) of RA patients and healthy controls: 742,41±12,07 ug/ml vs. 812,95 ug/ml (p=0,0021) and 663,9 ±39,14 ug/ml vs. 812,95 ug/ml (p<0,001).

**Conclusions:** Our study confirms that lower levels of fetuin-A are associated with higher activity of RA and with the loss of bone mineral density.

**AB0060 MECHANISMS OF ACTION OF CHONDROITIN SULFATE AND GLUCOSAMINE IN MUSCLE TISSUE: IN VITRO AND IN VIVO RESULTS. A NEW POTENTIAL TREATMENT FOR MUSCLE INJURIES?**

E. Montell<sup>1</sup>, P. Contreras-Muñoz<sup>2</sup>, A. Torrent<sup>1</sup>, M. de la Varga<sup>3</sup>, G. Rodas<sup>4</sup>, M. Marotta<sup>5</sup>. <sup>1</sup>Pre-Clinical RandD Area, Bioibérica, S.A.U.; <sup>2</sup>Bioengineering Cell Therapy and Surgery in Congenital Malformations Laboratory, Vall D'Hebron Institute. Leitat Technological Center; <sup>3</sup>Leitat Foundation, Leitat Technological Center; <sup>4</sup>Leitat Technological Center, FC Barcelona Medical Services; <sup>5</sup>Bioengineering Cell Therapy and Surgery in Congenital Malformations Laboratory, Vall D'Hebron Institute. Leitat Technological Center, Barcelona, Spain

**Background:** Musculoskeletal injuries are the most common cause for severe, chronic pain and physical disability affecting hundreds of millions of people around the world and represent a major concern also in sports medicine. A preclinical study evaluated the impact of chondroitin sulfate (CS) and glucosamine (GLU) combination (both compounds used in the treatment of osteoarthritis) on muscle healing and force recovery. Although the mechanisms of action of the combination CS +GLU have been largely studied in articular tissue, its potential therapeutic effects for muscle healing remain still unknown.

**Objectives:** The aim of the present study is to elucidate the mechanisms of action responsible for this interesting benefit.

**Methods:** Human skeletal muscle biopsies were digested with Protease type XIV and the resulting tissue suspension were collected by centrifugation. The digested muscle pellet was then triturated to liberate the human satellite cells. Differential centrifugations were used to enrich the cell fraction. Cell suspension was then transferred onto cell-culture dishes in Growth media (DMEM/M-199 medium (3:1) with 10% FBS, 10 µg/ml insulin, 2 mM glutamine, 25 ng/ml fibroblast growth factor, and 10 ng/ml epidermal growth factor) and cells were expanded in a growing monolayer. The effect of CS+GLU treatment in primary human skeletal muscle

cells was evaluated in a cell proliferation assay. NF- $\kappa$ B intracellular levels were determined by Western Blot. TNF- $\alpha$  production was measured in culture medium supernatants by ELISA.

**Results:** An enhancement in cell proliferation was found in CS+GLU treatments at a concentrations of 100 and 200  $\mu$ g/ml, increasing 1,60-fold ( $p < 0.01$ ) and 2,04-fold ( $p < 0.001$ ), respectively, compared to untreated cells. In addition, myoblasts were then incubated with IL-6 (50 ng/ml) for 72 hour in order to induce an inflammatory environment. The results showed an IL-6 induced-reduction on cell proliferation in all groups, although the data did not reach statistical significance. Therefore, an IL-6 inhibitory effect on cell proliferation in human muscle cannot be ensured. We also measured the effect of the combined treatment CS+GLU on NF- $\kappa$ B activation and TNF- $\alpha$  production in human skeletal muscle cells in primary culture. Despite of TNF- $\alpha$  levels were undetectable in cell supernatants, preliminary data showed a slight reduction on NF- $\kappa$ B signalling pathway. Global gene expression profiles, measured by microarrays and GeneChip Human Gene 1.0 ST Arrays (Affymetrix), will also be analysed.

**Conclusions:** The mechanisms of action involved in the potential therapeutic effect described in an *in vivo* injured muscle model seem to be related with an increase in muscle cell proliferation, together with blocking NF- $\kappa$ B nuclear translocation and TNF $\alpha$  production. Although further investigation is required, these pre-clinical data suggests potentially positive effects of CS and GLU administration for the treatment of skeletal muscle injuries in sports medicine.

### AB0061 SERUM IL-37 AS AN EFFICIENT BIOMARKER OF DISEASE ACTIVITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS: POST-HOC ANALYSIS OF PLANETAS STUDY

G.Y. Ahn<sup>1</sup>, S. Kang<sup>2</sup>, B. Nam<sup>1</sup>, J.S. Kim<sup>1</sup>, J. Kang<sup>1</sup>, D.-H. Yoo<sup>1</sup>. <sup>1</sup>Hanyang University Hospital for Rheumatic Diseases; <sup>2</sup>Institute of Rheumatology, Hanyang University, Seoul, Korea, Republic of Ireland

**Background:** IL-37 is an anti-inflammatory cytokine which belongs to IL-1 cytokine superfamily. Patients with ankylosing spondylitis (AS) also had a higher serum IL-37 concentration than controls, and were also associated with other inflammatory markers such as CRP, ESR, and BASDAI levels.<sup>1</sup> However, the relationship between serum IL-37 and disease activity after anti-TNF treatment has not been reported.

**Objectives:** To investigate the association of serum IL-37 level with disease activity in AS patients who were treated with infliximab.

**Methods:** Patients were recruited from the PLANETAS study (NCT01220518). Patients with active AS were treated with CT-P13 or infliximab originator. The serum levels of IL-37 were measured at week 0 and week 30 with specific ELISA. Other demographic, laboratory and clinical variables were evaluated simultaneously.

**Results:** Fifty patients with active AS (BASDAI  $> 4$ ) were analysed. The median age of patients was 40 years old [Interquartile range (IQR), 33.8–49.5], and the median BASDAI score was 6.7 (IQR 5.3–7.9). Compared to baseline, all measured clinical and laboratory parameters and serum IL-37 were significantly reduced. There was a statistically significant correlation between IL-37 and CRP, BASDAI at baseline, but not at week 30. Additionally, the differences ( $\Delta$ ) of parameters at baseline and at week 30 were assessed on their associations with other disease activity parameters. Delta IL-37 was significantly correlated with  $\Delta$ CRP,  $\Delta$ BASFI and  $\Delta$ BASDAI. The ROC curves of serum biomarkers for ASAS 20 achievement revealed that AUC value for  $\Delta$ IL-37 (AUC=0.74) was similar with  $\Delta$ ESR (AUC=0.71,  $p=0.64$ ) and superior than  $\Delta$ CRP (AUC=0.54,  $p < 0.01$ ). AUC value for  $\Delta$ IL-37 of ASAS 40 achievement was 0.66, which was similar with  $\Delta$ ESR (AUC=0.60,  $p=0.38$ ) and superior than  $\Delta$ CRP (0.46,  $p < 0.01$ ).

**Abstract AB0061 – Table 1.** Demographic & Clinical characteristics of analysed patients, comparing at baseline and at week 30.

Variables	At baseline	At week 30	P
Age	40.0 (33.8–49.5)	-	N/A
Female sex	7 (14%)	-	N/A
IL-37	105.1 (25.9–286.9)	44.5 (18.2–153.9)	$< 0.01$
ESR	35.0 (28.0–41.3)	7.5 (5.0–16.0)	$< 0.01$
CRP	158.1 (53.4–291.4)	20.0 (7.4–73.1)	$< 0.01$
BASDAI	6.7 (5.3–7.9)	3.3 (1.9–4.5)	$< 0.01$
BASMI	4.0 (3.0–5.0)	3.0 (2.0–4.0)	$< 0.01$
BASFI	6.6 (5.3–8.1)	3.3 (1.6–5.9)	$< 0.01$
PGD	70.5 (57.3–80.8)	33.0 (14.8–53.3)	$< 0.01$

**Abstract AB0061 – Table 2.** Correlations between IL-37 and other disease activity markers; at baseline and the differences between baseline and at week 30.

	At baseline			Difference between baseline and week 30		
	IL-37	ESR	CRP	$\Delta$ IL-37	$\Delta$ ESR	$\Delta$ CRP
IL-37		0.14	0.39**		0.24	0.36*
ESR	0.14		0.57**	$\Delta$ ESR	0.24	0.50**
CRP	0.39**	0.57**		$\Delta$ CRP	0.36*	0.50**
BASDAI	0.31*	0.31*	0.23	$\Delta$ BASDAI	0.32*	0.25
BASMI	0.05	0.09	0.16	$\Delta$ BASMI	-0.05	0.06
BASFI	0.20	0.36**	0.25	$\Delta$ BASFI	0.34*	0.35*
PGD	0.25	0.10	0.06	$\Delta$ PGD	0.16	0.28
						-0.06

**Abstract AB0061 – Figure 1.** Figure 1 ROC Curves of disease activity markers of ASAS 20 and ASAS 40 achievement.

**Conclusions:** Serum IL-37 levels are associated with BASDAI, patient's pain score, and CRP in active AS patients. Change in serum IL-37 level may serve as an efficient biomarker predicting the improvement of BASDAI and the achievement of ASAS 20 and 40 after anti-TNF treatment in AS patients.

### AB0062 RECIPROCAL INTERACTION BETWEEN MACROPHAGE MIGRATION INHIBITORY FACTOR AND INTERLEUKIN-8 IN GOUT

H.-R. Kim, S.-H. Lee, K.-A. Lee, K.-W. Kim. *Konkuk University School of Medicine, Seoul, Korea, Republic of Ireland*

**Background:** Macrophage migration inhibitory factor is a proinflammatory, chemotactic, and tissue destructive cytokine.

**Objectives:** This study determined monosodium urate crystal-induced macrophage migration inhibitory factor production and its interaction with interleukin-8 in gout.

**Methods:** Peripheral blood, synovial fluid, and clinical data were obtained from 98 patients with gout. Synovial fluid and serum concentrations of macrophage migration inhibitory factor and interleukin-8 were measured. Synovial fluid monocytes and neutrophils were cultured with monosodium urate crystals and the cytokine production was determined. The signalling pathways involved were determined using signal inhibitors. The interaction between macrophage migration inhibitory factor and interleukin-8 was investigated.

**Results:** Synovial fluid macrophage migration inhibitory factor was higher in acute gout and that in serum was higher in patients with intercritical gout compared with controls. Synovial fluid macrophage migration inhibitory factor was positively correlated with synovial fluid leukocyte and neutrophil counts and interleukin-8. The expression of macrophage migration inhibitory factor was similar in synovial fluid neutrophils and monocytes, while interleukin-8 was higher in monocytes. Monosodium urate crystals induced macrophage migration inhibitory factor production in monocytes and interleukin-8 production in neutrophils. This effect was decreased by inhibiting Fc-gamma receptor 1 and toll-like receptor 4. Interleukin-8 increased macrophage migration inhibitory factor production in monocytes while macrophage migration inhibitory factor increased interleukin-8 production in neutrophils.

**Conclusions:** Macrophage migration inhibitory factor and interleukin-8 are highly produced in acute gout. Monosodium urate crystals induced macrophage migration inhibitory factor production in monocytes and interleukin-8 production in neutrophils with a reciprocal interaction between the two cytokines.

### HIGH-EFFICIENCY TRANSDUCTION OF MESENCHYMAL STEM CELLS BY AAV2/DJ VECTOR FOR THEIR POTENTIAL USE IN AUTOIMMUNE DISEASES

H. Zhang<sup>1</sup>, X. Tang<sup>1</sup>, C. Wang<sup>2</sup>, L. Sun<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China; <sup>2</sup>Viral Core, F.M. Kirby Neurobiology Center, Boston Children's Hospital, Boston, USA

**Background:** Mesenchymal stem cells (MSC), multipotential non-hematopoietic progenitors, can be isolated from various tissues and can modulate allogeneic immune cell responses. These properties make MSC as a promising potential treatment of autoimmune diseases.<sup>1</sup> Our previous studies have found that bone marrow-derived (BM)-MSC from systemic lupus erythematosus (SLE) patients are defective structurally and functionally,<sup>2</sup> treatment with modified and optimised MSC may bring a better effect on patients with autoimmune diseases. Most efforts have relied on adeno- and lentiviral vectors for delivering genes to MSC. Effective as these vectors may be, concerns regarding their immunogenicity and, in the case of lentivirus, the risk of insertional mutagenesis, have led to the pursuit of safer alternatives. Among these, adeno-associated virus (AAV) holds several advantages as a vector for human gene therapy. There are many serotypes of AAV available, and certain serotypes have been found to transduce specific cell types more efficiently than others.

**Objectives:** To determine the efficiency of different serotypes of AAV vectors for their ability to mediate transduction of different sources of MSC and assess whether AAV transduction affects MSC multipotentiality.

**Methods:** Serotypes 1, 2, 5, 6, 8, 9, PHP and DJ of AAV vectors were constructed in Viral Core, Boston Children's Hospital. The enhanced green fluorescent protein (eGFP) gene under transcriptional control of a CAG promoter was cloned into the AAV vector backbone. MSC derived from umbilical cord (UC), BM and amniotic fluid (AF) were isolated and approximately  $1 \times 10^5$  MSC were used for transductions with AAV vectors. eGFP expression was evaluated 3 days after transduction by fluorescence microscopy and flow cytometry. The capacity of MSC to differentiate *in vitro* was assessed.

Fig1 A: the transduction efficiencies of AAVs (MOI=5:1) in AF-MSC, BM-MSC and UC-MSC. B: the transduction efficiencies of AAV/DJ in UC-MSC with different MOI.

**Abstract AB0063 – Figure 1.** A: the transduction efficiencies of AAVs (MOI=5:1) in AF-MSC, BM-MSC and UC-MSC. B: the transduction efficiencies of AAV/DJ in UC-MSC with different MOI.

#### Results:

- AAV serotype DJ vector was the most efficient in transducing MSC. AAV was added directly to the medium at 5 multiplicities of infection (MOI), 41% UC-MSC was transduced by AAV2/DJ, while the transfection is 0.47%, 0.3%, 10.5%, 0.3%, 1.84%, 0.06%, 0.16% by AAV2/1, AAV2/2, AAV2/5,

AAV2/6, AAV2/8, AAV2/9, AAV2/PHP (Fig 1A). Transduction efficiencies ranged from 73.5% for MOI 10% to 91.3% for MOI 320 in UC-MSC (Fig 1B).

- MSC derived from different tissues share a comparable level of transduction with the same AAV vector serotype. In our result, AAV2/DJ was the most efficient in transducing UC-MSC and AF-MSC.
- AAV2/DJ transduced MSC retained the same multipotential activity to differentiate into osteogenic and adipogenic lineage as comparable to untransduced cells.

**Conclusions:** AAV2/DJ vector can be used as a highly efficient tool to modify MSC *ex vivo* for therapeutic transplantation for autoimmune diseases.

### ROLE OF IL-35 IN THE REGULATION OF IMMUNE RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Adamova<sup>1</sup>, M. Mravcova<sup>1</sup>, M. Vlcek<sup>1</sup>, A. Penesova<sup>1</sup>, K. Krskova<sup>1</sup>, Z. Radikova<sup>1</sup>, A. Havranova<sup>1</sup>, R. Imrich<sup>1,2</sup>. <sup>1</sup>Biomedical Research Center, Slovak Academy of Sciences, Bratislava; <sup>2</sup>National Institute of Rheumatic Diseases, Piestany, Slovakia

**Background:** Interleukin 35 (IL-35) is a recently identified member of the IL-12 family of cytokines and represents a novel target for therapies of autoimmune, inflammatory, and infectious diseases, including rheumatoid arthritis (RA).<sup>Choi et al. 2015</sup>

IL-35 is a heterodimer consisting of EBV-induced gene 3 (EBI3) and IL-12 $\alpha$  chain p35 (Nakano et al. 2015). In contrast to other IL-12 cytokine family members, IL-35 appears to have anti-inflammatory and immunosuppressive properties mediated by induction of regulatory T and B cells; (Choi et al. 2015. Huang et al. 2017). In particular, IL-35 may play an important role in suppressing the inflammatory response by expanding regulatory T cells and in dampening the differentiation of Th17 cells (Niedbala et al. 2007).

**Objectives:** This study was designed to analyse effects of IL-35 on stimulated peripheral blood mononuclear cells (PBMC) and their subpopulations in RA patients and healthy controls.

**Methods:** PBMCs of 10 RA patients and 10 controls as well as CD14+ and CD4+ cells isolated from PBMCs using magnetic separation were cultured for 24 hours, and subjected to three conditions: no stimulation, stimulation with LPS (PBMC and CD14+) or stimulation with anti-CD3/anti-CD28 antibodies (PBMC and CD4+), and stimulation with added IL-35 (100 ng/ml). A panel of nine cytokines (IL-1 $\beta$ , IL-6, IL-8, IL-10, IL-12 (p70), IL-17a, IFN- $\gamma$ , MIP-1 $\beta$  and TNF) was analysed in the cell culture supernatants.

**Results:** RA patients had higher serum levels of IL-35 compared to healthy controls. A decreased secretion of IL-8 and increased secretion of TNF in the presence of IL-35 was observed *in vitro* in stimulated PBMCs of RA patients. In the control group, we observed an increased secretion of IL-6 by PBMCs and decreased secretion of IL-10 by T lymphocytes as a result of IL-35 addition to stimulated cells.

**Conclusions:** In this study, we found elevated serum levels of IL-35 in RA patients suggesting a possible involvement of IL-35 in the pathogenesis of RA. However, *in vitro*, the effect of IL-35 on stimulated immune cells was partially anti-inflammatory and partially pro-inflammatory, suggesting that the effect of IL-35 is pleiotropic and depends on the type and the state of the affected immune cell.

**AB0065** **N-CADHERIN IS DOWN-REGULATED BY DECOY RECEPTOR 3 IN SPECIFICALLY RHEUMATOID SYNOVIAL FIBROBLASTS**

K. Fukuda<sup>1</sup>, Y. Miura<sup>2</sup>, S. Hayashi<sup>1</sup>, T. Maeda<sup>3</sup>, R. Kuroda<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan; <sup>2</sup>Division of Orthopedic Science, Department of Rehabilitation Science, Kobe University Graduate School of Health Sciences, Kobe, Japan; <sup>3</sup>Department of Immunology and Rheumatology, Stanford University, Stanford, USA

**Background:** Decoy receptor 3 (DcR3) is a secreted decoy tumour necrosis factor receptor and competitively binds and inhibits the TNF family including Fas ligand, LIGHT, and TL1A. We previously reported that DcR3 overexpressed in rheumatoid synovial fibroblasts (RA-FLS) stimulated by TNF $\alpha$  protects the cells from Fas-induced apoptosis.<sup>1</sup> We recently reported that DcR3 binds to TL1A expressed on RA-FLS resulting in the negative regulation of cell proliferation induced by inflammatory cytokines.<sup>2</sup> Further, we newly revealed the gene expression profiles in RA-FLS regulated by DcR3 by using microarray data analysis.<sup>3</sup> Among the genes in the profile, we demonstrated the possible involvement of tryptophan hydroxylase 1 down-regulated,<sup>4</sup> interleukin 12B up-regulated by DcR3<sup>5</sup> and centrosomal protein 70 kDa<sup>6</sup> in the pathogenesis of RA. The profiles also indicated that Cadherin 2/type 1/N-cadherin (CDH2) was up-regulated by DcR3 (fold change 1.93).<sup>3</sup> CDH2 has been reported to be associated with cell attachment and migration,<sup>7</sup> osteoblast differentiation,<sup>8</sup> and the proliferation of RA-FLS.<sup>9</sup> The hemophilic interaction of CDH2 suppresses the proliferation of RA-FLS through increasing the P27<sup>Kip1</sup> that inhibit cell-cycle progression.<sup>9</sup>

**Objectives:** In this study, we analysed CDH2 expression in RA-FLS stimulated with DcR3 in detail to reveal the involvement of CDH2 and DcR3 in the pathogenesis of RA.

**Methods:** Real-time polymerase chain reaction (real-time PCR). RA-FLS were stimulated with various concentration of DcR3-Fc or 1,000 ng/ml of IgG1, or left untreated in serum-free Opti-MEM for 12 hour. The relative expression levels of CDH2 mRNA were quantified by real-time PCR.

**Immunohistochemistry.**

Anti-CDH2 antibody was applied to frozen sections of synovial tissues from patients with RA or OA for overnight. After that, the expression of CDH2 protein was evaluated by immunohistochemical analysis.

**Results:** Real-time PCR demonstrated that DcR3-Fc significantly increased the expression of CDH2 mRNA in RA-FLS (104% with 10 ng/ml, 112% with 100 ng/ml, and 200% with 1000 ng/ml). Immunohistochemistry revealed that CDH2 was expressed more in the sublining layer of rheumatoid synovium than OA synovium.

**Conclusions:** In the gene expression profiles, we focused on CDH2 as the gene was highly up-regulated and belonged to major functional clustering categories; protein complex assembly, cell motility, regulation of transcription, cell membrane and glycosylation. In this study, we showed that the expression of CDH2 mRNA in RA-FLS was induced by DcR3 and that CDH2 was increased in the sublining layer of rheumatoid synovium. In this study, we demonstrated that DcR3 significantly induced CDH2 expression in RA-FLS. Considering the fact that CDH2 inhibits RA-FLS proliferation, DcR3 signalling may control the hyperplasia of RA synovium.

**AB0066** **COMBINATION OF IL-10 AND IL-18 BUT NOT IL-6 AND IL-18 INDUCES IFN-GAMMA PRODUCTION AND SURFACE EXPRESSION OF TRAIL ON NK CELLS**

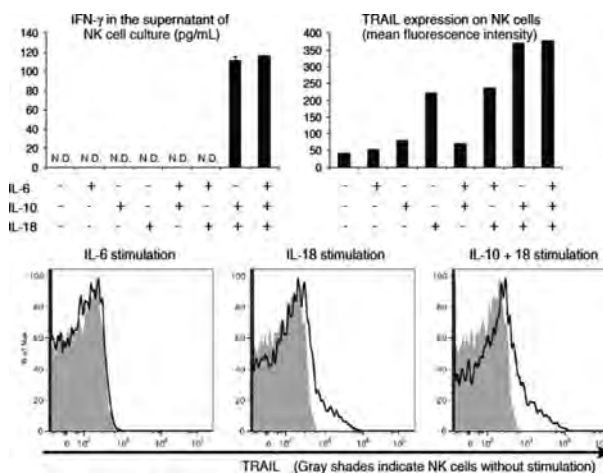

K. Sato, Y. Aizaki, H. Yazawa, T. Mimura. Department of Rheumatology and Applied Immunology, Saitama Medical University, Saitama, Japan

**Background:** Adult-onset Still's disease (AOSD) is a systemic inflammatory disease, the cause of which is largely unknown. AOSD has been recently classified as one of the autoinflammatory diseases, in which innate rather than acquired immunity plays an important role. Serum IL-18 has been shown to be significantly high in AOSD patients.

**Objectives:** The aim of this study was to quantify the levels of multiple cytokines in the serum of AOSD patients, and compare the serum cytokine profile with that of healthy controls. We also attempted to evaluate the effects of the cytokines that were upregulated in the AOSD serum on natural killer (NK) cells, since NK cells are cells of innate immunity and IL-18 has been shown to enhance their cytotoxicity.<sup>1</sup>

**Methods:** We quantified the serum levels of 10 cytokines (IFN- $\alpha$ , IFN- $\gamma$ , IL-1 $\beta$ , IL-2, IL-4, IL-6, IL-10, IL-12p70, IL-17A and TNF- $\alpha$ ) in patients with AOSD and healthy controls using multiplex bead array assays and IL-18 using ELISA. We next sorted NK cells from peripheral blood mononuclear cells (PBMCs) of healthy controls, stimulated them *in vitro*, and quantified the level of IFN- $\gamma$  in the culture supernatant by ELISA and also assessed the surface expression level of tumour necrosis factor-related apoptosis-inducing ligand (TRAIL) on the cells.

**Results:** Compared to samples from healthy controls, the mean serum levels of IL-6 and IL-18 from AOSD patients were significantly higher. IL-10 was detectable in some of the patients. Originally, IL-18 was identified as a stimulator of IFN- $\gamma$  production<sup>2</sup>, however, serum IFN- $\gamma$  was below the detection limit. When NK cells were stimulated *in vitro* with IL-18 alone, the protein level of IFN- $\gamma$  in the culture supernatant was still below the detection limit. When we further added IL-6 and/or IL-10 to the culture, the combination of IL-10 and IL-18, but not IL-6 and IL-18, induced IFN- $\gamma$ . As IL-6 is a classic pro-inflammatory cytokine and IL-10 is considered to be an anti-inflammatory cytokine, this result was rather unexpected. Thus, we evaluated the expression of IL-6 and IL-10 receptors on NK cells and found that IL-10 receptors (IL-10R and IL-10R $\beta$ ) were present, but IL-6 receptors (IL-6R and gp130) were absent. We also assessed TRAIL expression on NK cells. Here, too, the combination of IL-10 and IL-18 induced TRAIL expression the most potently. Although a previous research showed that the combination of TLR3 and IL-18 signalling synergistically induced TRAIL on NK cells in an IFN- $\gamma$  dependent manner<sup>3</sup>, the addition of an anti-IFN- $\gamma$  antibody did not diminish the TRAIL expression.

**Abstract AB0066 – Figure 1**

**Conclusions:** A combination IL-10 and IL-18, not IL-6 and IL-18, induced the production of IFN- $\gamma$  and surface expression of TRAIL in NK cells. This TRAIL expression did not evidently depend on IFN- $\gamma$ . TRAIL was expected to be useful for the treatment of malignancy, but it turned out to be toxic to hepatocytes<sup>4</sup>. Since NK cells are rich in the liver and the abnormality of liver function is among the major symptoms in AOSD, we suggest that the combination of IL-10 and IL-18 may cause liver dysfunction by inducing TRAIL on NK cells in the liver.

### ALLOSTERIC RECEPTOR MODULATION OF A FREE FATTY ACID RECEPTOR TURNS NATURAL AGONISTS INTO POTENT ACTIVATORS OF THE SUPEROXIDE GENERATING NEUTROPHIL NADPH-OXIDASE

L. Björkman, J. Mårtensson, A. Holdfeldt, H. Forsman, M. Gabl, M. Sundqvist, C. Dahlgren. *Rheumatology and inflammation research, University of Gothenburg, Gothenburg, Sweden*

**Background:** Short chain fatty acids are generated in the colon by bacterial fermentation of dietary fibres and serve as natural agonists for the free fatty acid receptor 2 (FFA2R/GPR43) which belongs to the large family of G-protein coupled receptors. We have earlier shown that acetate triggers an increase in the cytosolic concentration of free  $Ca^{2+}$  in neutrophils without any assembly/activation of the superoxide generating NADPH-oxidase (Mol Cell Biol. 2016 Sep 26;36(20):2583–95). Allosteric modulators bind to receptors at sites topographically distinct from the agonist/antagonist binding site and can regulate receptor functions positively or negatively.

**Objectives:** We undertook this study to determine whether an FFA2R selective modulator affects the neutrophil response induced by natural FFA2R agonists.

**Methods:** Neutrophils were collected from healthy blood donors. Release of superoxide anions generated by the assembled/activated NADPH-oxidase was recorded by sensitive isoluminol/HRP amplified chemiluminescence method. Intracellular  $Ca^{2+}$  transients were measured with FURA 2-AM labelled neutrophils.

**Results:** The allosteric modulator lacked a direct activating effect on neutrophils, but turned natural FFA2R agonists into potent activating agonists that triggered not only a transient rise in the cytosolic concentration of free  $Ca^{2+}$  ions but also an assembly of the NADPH-oxidase. The NADPH-oxidase activity induced by the combined effect of the allosteric modulator and the natural agonist acetate could be further increased in neutrophils treated with the pro-inflammatory cytokine TNF- $\alpha$ . The receptor selectivity was demonstrated through the inhibition of the neutrophil activity by the novel FFA2R antagonist CATPB. In addition, the allosteric modulator lacked effect on neutrophil responses triggered by a novel and selective agonist for the closely related GPR84, a receptor that recognises medium chain fatty acids.

**Conclusions:** Allosteric modulators that positively co-operate with natural FFA2R agonists and prime neutrophils in their response to such agonists may serve as good tools for further unravelling the physiological functions of the FFA2R and its involvement in various diseases. In this study, allosteric modulation of FFA2R is introduced as a receptor selective mechanism to prime neutrophils to produce increased amounts of reactive oxygen species.

### ALARMIN S100A8 AND S100A9 MODULATE THE INFLAMMATORY MICROENVIRONMENT IN EARLY TENDINOPATHY

L.A.N. Crowe<sup>1</sup>, M. Akbar<sup>1</sup>, K. Patommel<sup>1</sup>, S.M. Kitson<sup>1</sup>, E. Garcia Melchor<sup>1</sup>, D. S. Gilchrist<sup>1</sup>, G.A. Murrell<sup>2</sup>, I.B. McInnes<sup>1</sup>, N.L. Millar<sup>1</sup>. <sup>1</sup>Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, UK; <sup>2</sup>Department of Orthopaedic Surgery, St. Georges Hospital Campus, University of New South Wales, Sydney, Australia

**Background:** Alarmins- also referred to as damage associated molecular patterns (DAMPs)- are endogenous molecules mobilised in response to tissue damage known to activate the innate immune system in the early stages of disease. The molecular mechanisms that regulate inflammatory and remodelling pathways

in tendinopathy are largely unknown therefore identifying early immune effectors is essential to understanding the pathology. S100A8 and S100A9 are constitutively expressed by cells of myeloid origin; under pathological conditions they are induced in other cell types in response to environmental triggers and cellular damage.

**Objectives:** Based on previous investigations we sought evidence of S100A8/A9 expression in human tendinopathy and thereafter, to explore mechanisms whereby S100 proteins may regulate release of inflammatory mediators and matrix synthesis in human tenocytes.

**Methods:** Torn supraspinatus tendon (established pathology) and intact subscapularis tendon (early pathology) biopsies were collected from patients undergoing arthroscopic shoulder surgery. Control samples of healthy hamstring tendon were collected from patients undergoing hamstring tendon ACL reconstruction. S100A8/A9 expression was analysed at transcript and protein level using quantitative RT-PCR and immunohistochemistry, respectively. Primary human tenocytes were cultured from hamstring tendon tissue. The *in vitro* effect of recombinant human S100A8/A9 on human tenocytes was measured using quantitative RT-PCR and release of inflammatory mediators was measured at protein level by ELISA.

**Results:** Immunohistochemical staining of tendinopathic tissues indicated the presence of S100A8 and S100A9 in tendinopathy with early diseased tissue displaying a distinct increase in S100A8 and S100A9 expression compared with control and established pathology. These findings were mirrored by data obtained at transcript level from both early and late pathology. Treating tenocytes with exogenous S100A8/9 significantly increased release of IL-6 and CCL2; however, no alterations in genes associated with matrix remodelling were observed at a transcript level.

**Conclusions:** The presence of S100A8 and S100A9 in early tendinopathic lesions suggests expression is upregulated in response to cellular damage. We have confirmed the presence of S100A8, S100A9, CCL2 and IL-6 in tendinopathy and propose that S100A8 and S100A9 participate in early pathology by modulating the stromal microenvironment and influencing the inflammatory profile of tenocytes. S100A8 and S100A9 may participate in a positive feedback mechanism involving enhanced leukocyte recruitment and release of pro-inflammatory cytokines from tenocytes that perpetuates the inflammatory response within the tendon in the early stages of disease. This, in turn, may contribute aberrant matrix remodelling and associated morphological deficiencies within the tendon. We propose S100A8 and S100A9 are active alarmins in early tendinopathy that indirectly influence matrix remodelling by perpetuating the stromal inflammatory environment. Selective targeting of DAMP signalling may offer novel therapeutic approaches in the management of human tendon disorders.

### INCREASED EXPRESSION OF SOLUBLE MIC-A IN THE SYNOVIAL FLUID OF RHEUMATOID ARTHRITIS PATIENTS

L. Bernardi<sup>1,2</sup>, A. Mariotte<sup>1</sup>, A. Scanu<sup>2</sup>, D. Noël<sup>3</sup>, L. Punzi<sup>2</sup>, S. Bahram<sup>1</sup>, P. Georget<sup>1</sup>, J. Sibilia<sup>1</sup>. <sup>1</sup>INSERM UMR\_S 1109, Fédération de Médecine Translationnelle de Strasbourg, Université de Strasbourg, Strasbourg, France; <sup>2</sup>Rheumatology Unit, Department of Medicine-DIMED, University of Padova, Padova, Italy; <sup>3</sup>INSERM UMR\_S 1183, Montpellier University, Montpellier, France

**Background:** MIC-A (Major histocompatibility complex class I chain-related gene A)<sup>1</sup> is a transmembrane or soluble protein that interacts with the activating NKG2D receptor. MIC-A stimulates effector responses mediated by NK and CD8 +T cells under cellular stress conditions, like cancer or infections.<sup>2</sup> MIC-A is also associated with autoimmune diseases (such as rheumatic disorders) characterised by immune dysregulation triggered by environmental factors, and plays important roles in immune activation and surveillance.<sup>3</sup> In mice, various NKG2D ligands were discovered: Rae-1, H60 and MULT1 families.<sup>4</sup>

**Objectives:** This study aims at investigating the potential pathological relevance of soluble MIC-A (sMIC-A) protein in inflammatory rheumatic diseases involving articular structures in humans. The expression of orthologous NKG2D ligands in mouse models of experimental joint inflammation is also quantified.

**Methods:** We collected synovial fluid (SF) from 118 subjects: 22 Rheumatoid Arthritis (RA), 13 Psoriatic Arthritis (PSOA), 12 Gout Disease (GOUT), 18 Calcium

Pyrophosphate Deposition Disease (CPPD), 8 Reactive Arthritis (REA) and 45 Osteoarthritis patients. Gout and CPPD diseases were confirmed by the presence of crystals in SF. Clinical data were collected. The concentration of soluble MIC-A (sMIC-A), interleukin (IL)-1, IL-6 and IL-8 was measured by ELISA. Murine Rae-1, H60 and Mult1 transcripts were quantified by real-time quantitative PCR (RT-qPCR) in 3 models of joint inflammation: Serum Transfer Arthritis (STA), Collagen-induced arthritis (CIA) and Collagenase-Induced Osteoarthritis (CIOA).

**Results:** Significantly higher levels of sMIC-A were found in the synovial fluid of RA patients in comparison with all others diseases ( $p < 0.001$ , figure n.1). sMIC-A levels were correlated to white blood cell counts and levels of inflammatory cytokines IL-1, IL-6 and IL-8. Similarly, higher expression levels of Rae-1, H60 and Mult1 were found in chronic arthritis mouse models in comparison with osteoarthritic mice.

Abstract AB0069 – Figure 1

**Conclusions:** Our data identifies synovial sMIC-A as an important player in rheumatoid arthritis compared to other rheumatic diseases and osteoarthritis. Investigations in mouse models are in agreement with this finding

#### AB0070 ADIPOKINES AND CYTOKINES IN THE PATHOGENESIS OF PSORIASIS AND METABOLIC DISORDERS

M. Khobeysh<sup>1</sup>, K. Sysoev<sup>2</sup>, E. Sokolovskiy<sup>1</sup>, S. Lapin<sup>3</sup>. <sup>1</sup>Department of Dermatology and Venereal Diseases, Academician I.P. Pavlov First St. Petersburg State Medical University; <sup>2</sup>Pavlov Institute of Physiology, RAS; <sup>3</sup>Academician I.P. Pavlov First St. Petersburg State Medical University, St. Petersburg, Russian Federation

**Background:** Psoriasis is a systemic immune-associated disease with a specific comorbidity. The manifestations of the metabolic syndrome in this category of

patients are changes that develop on systemic immune-associated inflammatory psoriatic process background and contribute to the progression of chronic inflammation.

**Objectives:** The aim of the study was determination of the main adipokines and cytokines content in the serum of peripheral blood, severity and activity of the disease in patients with psoriasis; clinical and laboratory evaluation of metabolic disorders. The interconnection between the production of adipokines and cytokines in psoriasis was analysed depending on the severity and activity of the psoriatic process and the nature of metabolic disorders.

**Methods:** Serum levels of adipokines (C-peptide, ghrelin, insulin, glucagon, leptin, visfatin, resistin, GIP, GLP-1 and PAI-1) and cytokines (IL-1 $\beta$ , IL-1ra, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12 (p70), IL-13, IL-15, IL-17, eotaxin, FGF-2, G-CSF, GM-CSF, IFN- $\gamma$ , IP-10, MCP-1, MIP-1 $\alpha$ , MIP-1 $\beta$ , PDGF-BB, RANTES, TNF- $\alpha$  and VEGF) were measured in 36 patients with moderate and severe psoriasis, psoriatic arthritis. There was control group of 15 basically healthy persons. Clinical and laboratory evaluation of metabolic disorders (BMI, dyslipidemia, carbohydrate metabolism disorders) and cardiovascular diseases was performed for all examined patients. The duration, severity and the amount of body surface area involved in psoriasis were evaluated in all patients using recommended indices (BSA, PASI).

**Results:** Patients with psoriasis showed an increase in the production of glucagon, leptin, visfatin, GLP-1 ( $p < 1.0E-03$ ) and a decrease in the level of C-peptide, insulin, GIP, PAI-1, resistin ( $p < 1.0E-06$ ) compared with the control group. The difference of ghrelin concentrations in both groups was not statistically significant. Patients with psoriasis showed an increase in the level of IL-1 $\beta$ , IL-1ra, IL-2, IL-4, IL-5, IL-6, IL-8, IL-9, IL-10, IL-12 (p70), IL-13, IL-15, IL-17, eotaxin, FGF-2, GM-CSF, IFN- $\gamma$ , IP-10, MCP-1, MIP-1 $\beta$  and TNF- $\alpha$  compared to control group ( $p < 0, 01$ ). Positive correlations between the level of adipokines and cytokines were revealed.

**Conclusions:** The obtained data allow us to define adipokines as mediators between immune and endocrine systems. The imbalance between the proinflammatory and anti-inflammatory effects of adipokines observed in psoriasis demonstrates lipid metabolism dysfunction as one of the possible provoking factors of chronic inflammation determining the severity of the underlying disease. According to the results of the study, the following biological adipokines and cytokines should be classified as early biological markers of severity of the psoriatic immune-associated inflammatory process, with all its comorbid risks: GLP-1, glucagon, leptin, visfatin, IL-1ra, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-12, IL-13, IL-17, eotaxin, FGF-2, GM-CSF, IFN- $\gamma$ , IP-10, MCP-1, MIP-1 $\beta$ , TNF- $\alpha$ . The levels of adipokines and cytokines are probably the earliest biological markers in patients with metabolic syndrome and psoriasis, the control of adipokines and cytokines level can be used to optimise therapy.

#### AB0071 EFFECTS OF CHONDROITIN SULPHATE AND GLUCOSAMINE ON INFLAMMATORY CYTOKINES IN MACROPHAGES

M.-F. Hsueh<sup>1</sup>, E. Montell<sup>2</sup>, V.B. Kraus<sup>1</sup>. <sup>1</sup>Molecular Physiology, Duke University, Durham, USA; <sup>2</sup>Pre-Clinical RandD Area, Bioibérica, S.A.U., Barcelona, Spain

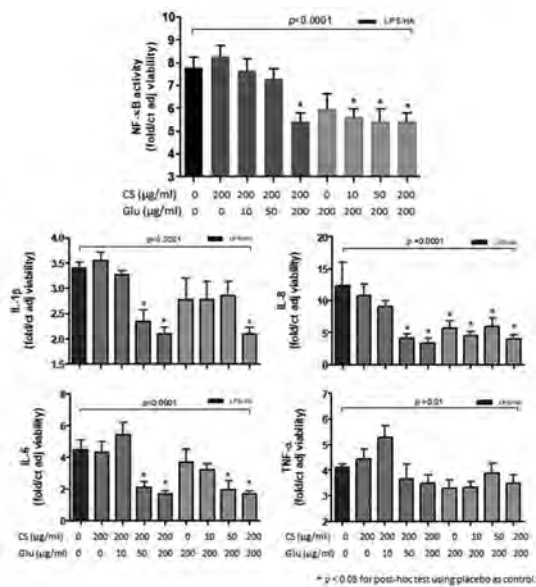

**Background:** The combination of pathogen-associated molecular patterns (PAMPs), such as lipopolysaccharide (LPS), and endogenous danger-associated molecular patterns (DAMPs), such as hyaluronan (HA) fragments, are known to be able to induce an inflammatory response from macrophages characterised by the release of pro-inflammatory cytokines<sup>1</sup>. We have previously shown that pharmaceutical grade chondroitin sulphate (CS), commonly used in the symptomatic treatment of osteoarthritis (OA), can attenuate the inflammatory response.

**Objectives:** To evaluate the synergistic effects of CS and glucosamine (GLU) in combination on LPS/HA mediated inflammatory responses of an immortalised human macrophage cell line (THP-1) and primary synovial fluid cells.

**Methods:** THP-1 monocyte cells were grown and differentiated into mature macrophages by the addition of 200 nM of phorbol 12-myristate 13-acetate (PMA) as previously described<sup>1</sup>. Cells were cultured with a physiologically achievable range of concentrations of CS and GLU (0, 10, 50, 200  $\mu$ g/ml of each, Bioibérica, S.A. U.) for 6 hours, then primed with physiologically relevant concentrations of LPS (10 ng/ml) (n=12/group). After 24 hours, cell culture media were replaced with serum free Opti-MEM supplemented with the previously mentioned concentrations of CS and GLU, LPS, and 10  $\mu$ g/ml HA fragments (ultra-low molecular weight, Lifecore). After a further 24 hours, supernatants were harvested for NF- $\kappa$ B activity and pro-inflammatory cytokine (IL-1 $\beta$ , IL-6, IFN- $\gamma$ , and TNF- $\alpha$ ) assessment. Cell viability was measured using PrestoBlue reagent. The human knee

primary synovial fluid cells were collected at the time of joint replacement and cultured with CS (200 µg/ml) and GLU (200 µg/ml), singly or in combination, with the addition of LPS and HA (n=2/group). After normalisation for cell viability, all results were expressed as fold change from the negative control (media only). One-way ANOVA with Dunnett's post-hoc test was performed using GraphPad Prism.

**Results:** CS and GLU in combination (200 µg/ml of each) significantly reduced NF-κB activity by 70% compared to the positive control group (LPS/HA only). Although CS (200 µg/ml) alone did not reduce NF-κB activity, the addition of the lower concentration of CS (10–50 µg/ml) to GLU (200 µg/ml) significantly reduced NF-κB activity compared with GLU (200 µg/ml) alone. Addition of lower concentrations of GLU (10–50 µg/ml) to CS (200 µg/ml) modestly reduced NF-κB activity (Fig 1). Similar trends were observed in secreted pro-inflammatory cytokines (IL-1β, IL-6, IFN-γ, and TNF-α); namely, CS and GLU in combination significantly attenuated the LPS/HA mediated pro-inflammatory responses (p<0.05) (Fig 1). Although, a diverse range of inflammatory responses to the LPS/HA activation was observed, constitutive pro-inflammatory cytokine production by primary synovial fluid cells was reduced by the combination of CS and GLU.

Abstract AB0071 – Figure 1

\*p<0.05 for post-hoc test using placebo as control.

**Conclusions:** Inflammatory reactions of THP-1 macrophages, induced by physiologically relevant concentrations of LPS and HA fragments, were suppressed synergistically by the combination of physiologically achievable concentrations of CS and GLU. A similar trend was observed in primary human synovial cells but further investigations are required. These data could explain, at least in part, the clinical efficacy of CS and GLU in combination observed in OA patients.

#### AB0072 EVALUATION OF ANTI-INFLAMMATORY EFFECTS OF NAPROXEN SODIUM ON HUMAN OSTEOARTHRITIS SYNOVIAL CELLS

M.-F. Hsueh, V.B. Kraus. *Molecular Physiology, Duke University, Durham, USA*

**Background:** Inflammation is increasingly recognised as an essential factor in the pathogenesis and progression of osteoarthritis (OA). Etarfolatide imaging for

activated macrophage quantification in knee joints confirms a high prevalence (~70%–80%) of joint inflammation in association with OA<sup>1</sup>. Naproxen sodium is a non-steroidal anti-inflammatory drug that is widely available over-the-counter (OTC) and has been shown to be effective in different pain models including OA<sup>2,3</sup>. Naproxen pre-treatment reduces inflammatory responses of chondrocytes. However, the effects of naproxen sodium on human OA synovial cells are not well known.

**Objectives:** Evaluate the ability of naproxen sodium to block the inflammatory responses and to reduce the activated inflammatory responses of a human monocyte cell line and primary human synovial fluid (SF) cells *in vitro*.

**Methods:** The immortalised human monocytic cell line, THP-1, was grown and differentiated into mature macrophages using phorbol 12-myristate 13-acetate as described previously<sup>4</sup>. Mature macrophages were treated with various concentrations of naproxen sodium two hours before or 24 hours after inducing an inflammatory reaction using lipopolysaccharide (LPS) and hyaluronan (HA) fragments (n=8/group). After a further 24 hours, the cell culture supernatants were assessed for NF-κB activity, pro-inflammatory cytokines (IL-1β, IL-6, IFN-γ, and TNF-α), and prostaglandin E<sub>2</sub> (PGE<sub>2</sub>). Cell viability was assessed using PrestoBlue reagent. Primary human SF cells were collected at the time of knee joint replacement for OA and treated 24 hours with naproxen sodium with and without the addition of LPS/HA (n=2/group). All results were expressed as fold change from the negative control (media only) after normalisation for cell viability. One-way ANOVA with Dunnett's post-hoc tests were done using GraphPad Prism.

**Results:** Compared to the placebo group, NF-κB activity of THP-1 cells was significantly reduced by as little as 28.9 mg/L naproxen sodium (corresponding to a trough plasma concentration achieved by a daily oral dose of 55 mg naproxen sodium) when added before or after the activation by LPS/HA (84% and 78% NF-κB activity reduction, respectively) (Fig1). When cells were treated before the activation with 33 mg/L naproxen sodium (corresponding to the concentration achieved by a 220 mg daily OTC dose), NF-κB activity was reduced 79% and IL-6 secretion was reduced by 77%. Cyclooxygenase enzyme activity, represented by PGE<sub>2</sub> production, was reduced to basal levels by as little as 28.2 mg/L naproxen sodium (p<0.05) when cells were treated either before or after the activation. Primary human SF cells treated with LPS/HA showed a striking increase in cytokine secretion ranging from 50-fold (IL-8) to 600-fold (IL-6). Cytokine production was reduced by naproxen sodium but a rebound phenomenon was observed for the highest concentration of 55/mg/L, which may indicate the cell stress response.

Abstract AB0072 – Figure 1

\*p<0.05 for post-hoc test using placebo as control.

\*p<0.05 for post-hoc test using placebo as control.

**Conclusions:** Naproxen sodium at low dose can both prevent and reduce inflammatory responses of a human monocytic cell line and primary human SF cells *in vitro*. These results highlight the potent activity of the OTC dose of naproxen sodium to dramatically reduce PGE<sub>2</sub>, NF-κB activity and cytokine production.

### EARLY MARKERS OF BONE – CARTILAGE RESORPTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Rekalov, N. Rozdolska. *Rheumatology, Zaporizhzhia Regional Clinical Hospital, Zaporizhzhia, Ukraine*

**Background:** Systemic disorganisation of connective tissue with early metabolic disorder of its matrix is an inherent characteristic feature of rheumatoid arthritis (RA). The determination of the key extracellular matrix molecules in patients with early RA can adequately characterise a metabolism of connective tissue, stage of its destruction and the duration.

**Objectives:** to evaluate the significance of bone-cartilage resorption as an integral indicator of inflammatory-destructive processes in patients with early RA

**Methods:** We included 168 patients with early RA. The quantitative content and qualitative composition of glycosaminoglycans (GAG) in blood serum and excretion of GAG in urine were evaluated. Oxiprolin (OP) and its fractions (free OP), protein-bound (OPp) and hydroxyproline were determined in serum and urine. The presence of antibodies to the cyclic citrullinated peptide (ACPA) was studied, as well as the C-terminal telopeptides of serum collagen I (CTX).

**Results:** We identified the results of excretion of GAGs in urine depending on disease activity. And according to our data, in patients with low inflammatory process (IP) the level was  $6.31 \pm 1.09$  mg/g of creatinine (CR); moderate IP  $5.21 \pm 1.20$  mg/g of CR, and high disease activity  $6.53 \pm 0.96$  mg/g of CR. All these results were significantly higher in comparison with the control group by 55.9%, 29.1% and 67.7%, respectively. It means that GAG excretion rate did not depend on the stage of disease activity in patients with early RA, although even with a minimal IP it was significantly higher than normal. At the same time, the fractional composition of excreted GAGs in the urine in RA patients varied, as evidenced by a significant decrease in the sulfated GAGs content by 35% compared to the control group, although the differences between the groups were statistically unreliable.

CTX also proved to be 2.86 times higher than the level of healthy persons in whom the indicated index was 0.15 ng/ml.

In addition to a statistically significant increase of serum concentration of OP as compared to practically healthy persons, the qualitative composition of its fractions also changes, as evidenced by a significant elevation of OPp by 167.81%. No significant differences were found in the evaluation of OPfree and hydroxyproline

**Abstract AB0073 – Table 1.** Baseline demographic and clinical characteristics of RA patients, (n=168)

Characteristic		Value
Age, years		47,52±13,05
Gender	Male, n (%)	59 (35)
	Female, n (%)	109 (65)
Duration of symptoms, months		13,74±6,2
DAS28 (ESR)		5.9 (4.6-6.3)
ACPA positive, n (%)		102 (61)
Using GCs, n (%)		18 (11)
Using NSAIDs, n (%)		122 (73)
HAQ, points		1.3 (0.7-1.9)
RF positive, n (%)		83 (49)

#### Conclusions:

1. Progression of RA is accompanied by a progressive loss of the main functionally significant components of the extracellular matrix and manifested by a significant increase in the concentrations of proteoglycans and oxypoline.
2. The level of C-terminal telopeptides of type I of serum collagen – was elevated even in patients with early RA, indicating the activity of bone resorption processes.
3. The concentration and qualitative composition of blood serum GAGs adequately reflect the clinical symptoms of RA, being a sensitive integral

test that reliably indicates the severity of inflammatory and destructive changes.

### DAILY EXERCISE SUPPRESSES ACUTE PRO-INFLAMMATORY CYTOKINE EXPRESSION SYSTEMICALLY AND IL-1β LOCALLY IN A MURINE MODEL OF GOUT

N.A. Young<sup>1</sup>, K. Jablonski<sup>1</sup>, B. Sandoval<sup>1</sup>, A. Kalyanasundaram<sup>2</sup>, P. Harb<sup>1</sup>, J. Hampton<sup>1</sup>, W. Jarjour<sup>1</sup>, N. Schlesinger<sup>3</sup>. <sup>1</sup>*Rheumatology and Immunology, <sup>2</sup>Physiology and Cell Biology, The Ohio State University Wexner Medical Center, Columbus;* <sup>3</sup>*Rheumatology, Rutgers Robert Wood Johnson Medical School, New Brunswick, USA*

**Background:** Recent gout clinical practice recommendations/guidelines released by the ACR (2012) and the ACP (2017) do not address exercise as an interventional strategy; in contrast, the 2016 EULAR gout recommendations suggest that regular physical activity might decrease the excess mortality associated with chronic hyperuricemia. Referencing animal studies performed nearly a half century ago, many rheumatologists recommend resting the involved joints during an acute attack. However, recent evidence has demonstrated the anti-inflammatory effects of exercise in patients with rheumatic disease.

**Objectives:** The purpose of this study was to investigate the effects of exercise intensity on an immunological level in an animal model of gout by characterising pro-inflammatory cytokine expression.

**Methods:** BALB/C-Tg(NFκB-RE-luc)-Xen mice were exercised daily by treadmill walking (45 min/day) at low intensity (35% VO<sub>2</sub>max), moderate intensity (55% VO<sub>2</sub>max), and high intensity (75% VO<sub>2</sub>max). Following the 2 week training period, monosodium urate (MSU) crystal-mediated arthritis was induced by intra-articular injection of MSU crystals (0.5 mg) into the tibio-tarsal joint (ankle). At 16 hours post-MSU crystal injection, tissue was collected for immunohistochemistry (IHC) and both serum and synovial aspirates were processed to measure cytokine levels.

**Results:** Infiltrates consisted primarily of neutrophils and macrophages, as determined by IHC. The inflammatory responses were significantly reduced with low and moderate exercise when compared to either high intensity training or mice that were not exercised. Electrochemiluminescence detection assays quantifying the expression of a panel of pro-inflammatory cytokines showed that IL-2, IL-4, IL-5, IL-10, and IFN-γ were not detectable in the serum of MSU crystal-injected mice at levels greater than un-injected male/female controls. Furthermore, IL-12, CXCL1, TNF-α, and IL-6 expression was elevated in the serum with MSU crystal injection compared to un-injected counterparts, but this response was suppressed with low, moderate, or high intensity exercise training and undetectable in synovial aspirates. Conversely, IL-1β was not induced relative to un-injected controls systemically in the serum, but was increased locally in synovial aspirates. IHC staining of the ankle joint region for IL-1β confirmed this observation and further demonstrated a significant inhibition with low and moderate exercise relative to both high intensity training and non-exercised controls.

**Conclusions:** Our results demonstrate that daily exercise can have a measurable effect systemically in reducing pro-inflammatory cytokine expression in MSU crystal-mediated arthritis. Moreover, high-intensity exercise can suppress pro-inflammatory cytokine expression systemically, however, only low/moderate training suppressed the localised inflammatory response. Collectively, these data suggest a paradigm shift; emphasising physical activity in gout patients is potentially efficacious and warrants further investigation.

### INTRAAARTERIAL INJECTION OF HUMAN ADIPOSE-DERIVED MESENCHYMAL STEM CELLS (HAD-MSCS) ATTENUATES INFLAMMATION IN ACUTE ARTHRITIS MODEL

J.P. Medina, S. Pérez-Baos, E. Naredo, A. López-Reyes, G. Herrero-Beaumont, R. Largo. Bone and Joint Research Unit, Instituto Investigación Sanitaria Fundación Jiménez Díaz, Madrid, Spain

**Background:** MSC are a potential therapeutic approach for the treatment of inflammatory diseases. Their anti-inflammatory role in both local and systemic diseases has been demonstrated in different experimental models and human diseases. Gouty arthritis is a systemic disease characterised by deposition of monosodium urate (MSU) crystals in soft tissues and joints. Frustrated phagocytosis of MSU crystals by resident leukocytes leads to NLRP3 inflammasome activation and subsequent amplification of inflammatory response resulting in severe tissue damage. MSCs are able to attenuate inflammatory response through different mechanisms, including NLRP3 inflammasome inhibition. Thus, MSCs could be a promising therapy for the attenuation of acute flares in gouty arthritis

**Objectives:** To study the antiinflammatory effect of hAD-MSCs in an acute gouty arthritis model

**Methods:** Acute gout flare was induced in 15 NZ rabbits by intra-articular injection of MSU crystals in both knees. 7 of these rabbits received a single dose of  $2.5 \times 10^6$  hAD-MSCs/kg, administered through the right femoral artery 1 hour after MSU injection (MSU+MSC group), while 8 animales were not treated (MSU group) This route of administration allowed the study of the effect of a direct MSC administration in the right knee synovial membrane (SM) in comparison to the contralateral knee, which received the cells after their vascular distribution through the organism. Inflammation was followed up measuring knee swelling and serum CRP. 4 healthy rabbits were simultaneously followed (Ctrl group). Animals were sacrificed 72 hour after MSU injections and SM were collected for further studies

**Results:** hAD-MSCs were able to attenuate joint swelling in both knees 24 hour after MSU injections, inducing a decrease in knee perimeter. Additionally, a significant decrease in serum CRP after 24 hour was observed in the treated group (Ctrl  $73 \pm 51$ ; MSU  $818 \pm 238^*$ ; MSU+MSC  $270 \pm 241$  mg/ml\*#;  $p < 0.05$  \*vs. Ctrl; # vs. MSU). Histopathological analysis showed that hAD-MSCs were able to significantly diminish SM inflammation after 72 hours of MSU injection (Krenn Score: Ctrl  $0.2 \pm 0.4$ ; MSU,  $5.6 \pm 2.3^*$ , MSU+MSC  $3.4 \pm 1.2^* \#$ ). SM vascularisation was reduced in treated animal (%CD31 +staining: Ctrl  $0.5 \pm 0.2$ ; MSU  $0.8 \pm 0.2^*$ ; MSU +MSC  $0.6 \pm 0.2^* \#$ ). hAD-MSC treatment also evoked a significant reduction of the inflammasome components in the SM: pro-IL1 $\beta$  (Ctrl  $0.9 \pm 0.2$ ; MSU  $1.5 \pm 0.5^*$ ; MSU+MSC  $1.1 \pm 0.2^* \#$ ), pro-caspase-1 (Ctrl  $1 \pm 0.6$ ; MSU  $3.5 \pm 3.1^*$ ; MSU+MSC  $1.4 \pm 0.5^* \#$ ), NALP3 (Ctrl  $1 \pm 0.3$ ; MSU  $2.9 \pm 2.1^*$ ; MSU+MSC  $1.4 \pm 0.7^* \#$ ). The synthesis of the pro-inflammatory cytokines COX-2 (Ctrl  $0.9 \pm 0.1$ ; MSU  $4.2 \pm 3.3^*$ ; MSU +MSC  $2.1 \pm 1.4^* \#$ ) and TNF $\alpha$  (Ctrl  $0.9 \pm 0.3$ ; MSU  $1.3 \pm 0.3^*$ ; MSU+MSC  $0.9 \pm 0.2^* \#$ ) were also reduced in the MSU+MSC animals, while TGF $\beta$  (Ctrl  $0.9 \pm 0.2$ ; MSU  $0.7 \pm 0.2^*$ ; MSU+MSC  $1.3 \pm 0.3^* \#$ ) and IL10 (Ctrl  $1.1 \pm 0.5$ ; MSU  $1.1 \pm 0.7^*$ ; MSU+MSC  $1.8 \pm 0.5^* \#$ ) were increased in comparison to MSU group. There were no differences between the direct and the indirect treatment, since both right and left SMS were equally damaged

**Conclusions:** Our data showed that a single dose of hAD-MSCs is able to modulate the inflammatory response in an acute gouty arthritis model in rabbit. Therefore, it is a promising therapeutic approach to attenuate gout flares, especially in patients with different comorbidities that complicate a conventional treatment

### JAK INHIBITOR BARICITINIB MODULATES HUMAN INNATE AND ADAPTIVE IMMUNE SYSTEM

S. Kubo, S. Nakayamada, X. Ma, S. Lee, K. Yamagata, K. Nakano, S. Iwata, K. Hanami, S. Fukuyo, I. Miyagawa, Y. Tamaki, Y. Tanaka. The First Department of Internal Medicine, Univeruniversity of Occupational and Environmental Health, Japan, Fukuoka, Japan

**Background:** Janus kinase (JAK), which constitutively binds to cytokine receptors, plays an important role in the cytokine signalling. While JAK is comprised of JAK1, JAK2, JAK3, and tyrosine kinase-2 (Tyk2), more than 40 types of cytokines transmit signals through JAK. After several clinical studies, baricitinib, a highly selective inhibitor of JAK1 and JAK2, has been approved recently for treatment of RA in Europe, Japan, and other countries. Although this drug is available orally due to its small molecular weight, it has comparable efficacy to the biological DMARDs (bDMARDs).

**Objectives:** The present study was designed to determine the effects of a highly-selective JAK1 and JAK2 inhibitor, baricitinib, on human immunocompetent cells, in order to establish the significance of JAK and the potential for baricitinib in the therapeutic armamentarium against immune-mediated diseases.

**Methods:** The effects of baricitinib and tofacitinib were evaluated using human monocyte-derived dendritic cells (MoDCs), plasmacytoid dendritic cells (pDCs), B cells and T cells.

**Results:** The expression of costimulatory molecules CD80/86 on MoDCs were induced 48 hours after LPS stimulation. Baricitinib concentration-dependently suppressed the expression of CD80/CD86. Inhibition of CD80/CD86 expression by tofacitinib was comparable to that induced by baricitinib. pDCs stimulated for 5 hours with CpG produced both TNF- $\alpha$  and IFN- $\alpha$ . Baricitinib reduced the proportion of these IFN- $\alpha$  producing pDCs in a concentration-dependent manner. On the other hand, TNF- $\alpha$  production was not affected by baricitinib. Baricitinib also suppressed the differentiation of B cells into plasmablasts by B cell receptor (BCR) and type-I IFN stimuli, and inhibited the production of IL-6 from B cells. Tofacitinib also suppressed BCR- and IFN- $\alpha$ -induced plasmablast differentiation and IL-6 production. However, neither baricitinib nor tofacitinib altered IgG production by B cells. Human CD4 +T cells proliferated after T cell receptor stimulation with anti-CD3 and anti-CD28 antibody; however, such proliferation was suppressed by baricitinib in a concentration-dependent manner. In addition, baricitinib inhibited Th1 differentiation after IL-12 stimulation and Th17 differentiation by TGF- $\beta$ 1, IL-6, IL-1 $\beta$  and IL-23 stimulation. Tofacitinib showed similar effects in these experiments. In naive CD4 +T cells, IFN- $\alpha$  and IFN- $\gamma$  induced phosphorylation of STAT1, which was inhibited by baricitinib as well as tofacitinib. Furthermore, IL-6-induced phosphorylation of STAT1 and STAT3 was also inhibited by JAK inhibitors.

**Conclusions:** The present study demonstrated that JAK inhibitors affect innate and adaptive immunity in humans. They can fine-tune various immune networks through a variety of mechanisms and seem suitable potential therapeutic agents for the treatment of diverse autoimmune diseases.

### HIGH-MOBILITY GROUP BOX 1 MEDIATED MONOSODIUM URATE CRYSTAL-INDUCED NLRP3 INFLAMMASOME ACTIVATION IN HUMAN MACROPHAGES

S.-K. Kim, J.-Y. Choe, S.-H. Park, H. Lee. Catholic University of Daegu School of Medicine, Daegu, Korea, Republic of Ireland

**Background:** High-mobility group box 1 (HMGB1) was identified originally as a highly conserved non-histone DNA-binding factor and recently noted as a potent inflammatory mediator under inflammatory conditions.

**Objectives:** This study is to investigate the inflammatory cascade between HMGB1 protein and activation of NLRP3 inflammasome in human macrophage under uric acid-induced inflammation.

**Methods:** The study used human U937 macrophage cell line under stimulation with monosodium urate (MSU) crystal or HMGB1. Total reactive oxygen species (ROS) were measured by flow cytometry. Interleukin-1b (IL-1b), NLRP3, TXNIP, HMGB1, NF- $\kappa$ B, I $\kappa$ Ba, and caspase-1 protein expression was detected using western blotting. IL-1b, IL-18, caspase-1, and HMGB1 gene expression were assessed by quantitative real-time polymerase chain reaction. Intracellular HMGB1 expression was assessed by immunofluorescent staining with Mito-Tracker Red.

**Results:** MSU crystals induced HMGB1 and ROS production by activation of NF- $\kappa$ B signal pathway in human macrophages. HMGB1 mRNA expression was markedly attenuated under stimulation using TXNIP siRNA. Enhanced release of IL-1 was noted through increased HMGB1 expression and TXNIP-mediated NLRP3 inflammasome activation under stimulation of MSU. Combination of MSU and HMGB1 augmented NLRP3 inflammasome, compared to either MSU or HMGB1 stimulation.

**Conclusions:** This study demonstrated that HMGB1 is a crucial molecule for ROS-mediated TXNIP and NLRP3 inflammasome activation in uric acid-induced inflammation.

**AB0078 SYSTEMIC AND LOCAL IL-17A AND MIR-223 LEVELS IN RHEUMATOID ARTHRITIS PATIENTS**

R. Shumnalieva<sup>1</sup>, D. Kachakova<sup>2</sup>, T. Velikova<sup>3</sup>, R. Kaneva<sup>2</sup>, Z. Kolarov<sup>1</sup>, S. Monov<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Clinic of rheumatology; <sup>2</sup>Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Medical University – Sofia; <sup>3</sup>University Hospital “Lozenetz”, Sofia, Bulgaria

**Background:** IL-17 is a proinflammatory cytokine, which overproduction promotes the autoimmune reaction in rheumatoid arthritis (RA). Recent studies have shown that IL-17 production in lymphocytes or its function could be regulated by miR-223 by targeting Roquin ubiquitin ligase or its receptors<sup>1–4</sup>.

**Objectives:** To examine a possible correlation between the expression levels of miR-223 and IL-17A in peripheral blood (PB) and synovial fluid (SF) of RA patients.

**Methods:** Expression levels of miR-223 were determined in matched PB and SF samples of RA patients by relative quantitation method 2<sup>-ΔΔCt</sup>. As reference control for normalisation RNU6B gene was used. Concentrations of IL-17A in matched serum and SF samples were determined by Human IL-17A ELISA kit (Gene probe, Diaclone). The results were compared to healthy control (HCs) as well as within the RA group.

**Results:** 58,73% of the RA patients showed overexpression of miR-223 in PB when compared to HCs (p=0.008) with AUC=0.673 (95 CI: 0.562/0.784), with 71.4% sensitivity and 46.9% specificity (p=0.006). miR-223 was overexpressed in 79.17% of RA SF (p=1.64 × 10<sup>-3</sup>) when compared to HCs SF with AUC=0.841 (95 CI: 0.724/0.958) with 87.5% sensitivity and 72.7% specificity (p=4.6 × 10<sup>-4</sup>). Within the RA group, SF miR-223 was underexpressed in 58.7% of the patients compared to its systemic levels. Levels of IL-17A were higher in RA SF compared to serum (8.645 pg/ml versus 0.315 pg/ml, p=0.012).

**Conclusions:** The difference between the systemic and local levels of miR-223 and IL17A in RA patients shows that the inflammatory disease process leads to their altered expression with a possible role of both molecules in the disease pathogenesis. The opposite changes in their systemic and local levels confirm the data about the possible role of miR-223 in regulating IL-17 function.

**AB0079 ALFACALCIDOL SUPPLEMENTATION MODULATES CYTOKINE PRODUCTION IN PERIPHERAL BLOOD MONONUCLEAR CELLS CULTURE OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS**

T. Zivanovic Radnic<sup>1</sup>, K. Simic Pasalic<sup>1</sup>, M. Sefik Bukilica<sup>2</sup>, N. Damjanov<sup>2</sup>, J. Vojinovic<sup>3</sup>. <sup>1</sup>Institute for Rheumatology, Belgrade; <sup>2</sup>Institute of Rheumatology, Faculty of Medicine, University of Belgrade, Belgrade; <sup>3</sup>Clinical Center, School of Medicine, University of Nis, Nis, Serbia

**Background:** Hormone D and its analogues display immunomodulatory activities that provide a beneficial effect in immunoinflammatory diseases. However, whether this hormone has an additive immunosuppressive effect when it is used with corticosteroids has not been investigated, although these agents are commonly used together.

**Objectives:** Testing the immunomodulatory *in vitro* effects of vitamin D analogue, alfacalcidol, in peripheral blood mononuclear cells (PBMC) cultures of patients with active rheumatoid arthritis (RA).

**Methods:** Sixteen patients with active RA were enrolled in the study. Patients PBMCs were isolated, stimulated with PMA/Ionomycin and cultivated for 48 hours at 37°C, 5% CO<sub>2</sub> in cell cultures medium with or without supplementation. *In vitro* effects of supplementation with alfacalcidol (concentration

10 nM), calcitriol (concentration 10 nM), methylprednisolone (concentration 400 nM) and cotreatment with alfacalcidol/methylprednisolone on cytokine production were studied. Stimulated production of cytokines IL-6, IL-17, IL-21, TNF-α, IL-4, IL-10, TGF-β and IFN-γ were determined in cell culture supernatant by standard ELISA method.

**Results:** *In vitro* alfacalcidol supplementation reduces the production of proinflammatory cytokines IL-17 (p=0.001), IL-21 (p=0.001), TNF-α (p=0.002) and IL-6 (p=0.4), and induce more intense anti-inflammatory cytokine production IL-4 (p<0.0001), IFN-γ (p=0.05), TGF-β (p<0.0001) and IL-10 (p=0.09), in PBMC cultures of patients with active RA. There was no significant difference between the effects of alfacalcidol and calcitriol, except decreased TGF-β production (p=0.535) after calcitriol supplementation. Methylprednisolone supplementation leads to a significant reduction of the IL-6 (p=0.002), IL-17 (p=0.0001), TNF-α (p=0.0001) and IL-4 (p=0.017) production, while increased production of IL-21, IL-10, IFN-γ didn't reach statistical significance. Cotreatment with alfacalcidol and methylprednisolone leads to additional, more significant reduction of IL-17 (p=0.0001) and TNF-α (p<0.0001) in PBMCs of patients with active disease.

**Conclusions:** Alfacalcidol, *in vitro*, showed a significant immunomodulatory effect through the specific inhibition of Th1- cytokine production, while Th2 cell response was enhanced – “Th2 switch”. Our results demonstrate that alfacalcidol has significant additive effects on glucocorticoid-mediated inhibition of Th1 cytokine production when combined with methylprednisolone. These findings demonstrate the potential use of alfacalcidol as an immunosuppressive agent when combined with corticosteroids in Th1, but not Th2, immune response.

**AB0080 DIFFERENTIAL EFFECTS OF TR14 VERSUS DICLOFENAC ON PRO-RESOLVING LIPID MEDIATORS REVEALED BY RNASEQ**

G. St. Laurent, III<sup>1</sup>, I. Toma<sup>2</sup>, M. Tackett<sup>3</sup>, J. Zhou<sup>1</sup>, M. Ri<sup>4</sup>, D. Shtokalo<sup>5</sup>, Y. Vyatkin<sup>4</sup>, T. Jepson<sup>1</sup>, K. Cesnulevicius<sup>6</sup>, B. Seilheimer<sup>6</sup>, T. Mccaffrey<sup>2</sup>. <sup>1</sup>The St. Laurent Institute, Vancouver, WA; <sup>2</sup>Department of Medicine/Division of Genomic Medicine, The George Washington University, Washington, DC; <sup>3</sup>SeqLL, Inc., Woburn, MA, USA; <sup>4</sup>AcademGene, LLC; <sup>5</sup>A.P. Ershov Institute of Informatics Systems, Novosibirsk, Russian Federation; <sup>6</sup>Biologische Heilmittel Heel GmbH, Baden-Baden, Germany

**Background:** Anti-inflammatory agents are used widely in treating numerous pain and inflammatory conditions. With a focus on the specialised pro-resolving mediators (SPM) pathways in cutaneous wound repair in mice, the therapeutic activities of Tr14 (Traumeel), a multicomponent/multitarget natural product, and diclofenac (NSAID), a non-selective cyclooxygenase (COX) inhibitor were compared. COX inhibitors can block the synthesis of prostaglandins and thromboxanes from arachidonic acid, and can have important effects on the synthesis of resolvins and protectins produced by similar enzymes from eicosapentanoic and docosahexanoic acid substrates. Differential effects were identified via transcriptome analysis (RNAseq).

**Objectives:** To compare the transcriptomic changes after administration of Tr14 or diclofenac in a mouse cutaneous wound healing model, with particular emphasis on the SPM pathways, which include resolvins and protectins.

**Methods:** After abrasive wounding, the wounds were treated with topical Tr14 (34 mg/ml) in combination with subcutaneous Tr14 injections (9.5 mg/ml), or with subcutaneous Tr14 injections only, or topical diclofenac at clinically relevant doses (2 mg/ml). Skin samples were analysed for RNA transcript profiling by RNAseq at specific times (12 hour, 24 hour, 36 hour, 72 hour, 96 hour, 120 hour, 192 hour) after injury. Differentially expressed genes (DEGs) were computed at each time point between diclofenac vs control or Tr14 vs control, using EdgeR.

**Results:** At early time points (12–36 hour), Tr14-treated wounds, and to a lesser extent diclofenac-treated wounds, showed marked induction of 3 lipoxigenase

enzyme mRNAs involved in SPM synthesis. Even more striking was a pronounced effect of Tr14 at 12–36 hours on Fpr1 and Fpr2 mRNAs, which are the transmembrane receptors for the SPM lipid mediators. Consistent with elevated levels of enzymes regulating SPM synthesis, and SPR receptors, there was a noticeable decrease in the mRNA levels of the p65/RelA subunit of NFkB at 72–96 hours. NFkB is a critical transcription factor in inflammation, regulating numerous cytokines and chemokines.

**Conclusions:** Tr14 and diclofenac had very different effects on the SPM synthetic pathway after cutaneous wounding. Tr14 stimulated mRNA levels of several key regulators of SPM synthesis, and had a marked effect on the mRNA levels of the SPM receptors. Tr14, *not* diclofenac, suppressed mRNA levels for NFkB subunit p65/RelA, which may explain some of the anti-inflammatory and proresolving properties of Tr14.

### LOW LIPOCALIN-2 IN SYSTEMIC LUPUS ERYTHEMATOSUS PREGNANCIES- A POSSIBLE MECHANISM FOR LOSS OF TOLERANCE

T.T. Pedersen<sup>1</sup>, M.H. Fenstad<sup>2</sup>, B. Jakobsen<sup>1</sup>, H.S. Koksvik<sup>1</sup>, T.S. Moksnes<sup>1</sup>, M. Wallenius<sup>1</sup>, T.H. Flo<sup>3</sup>, M. Haug<sup>3</sup>. <sup>1</sup>Norwegian National Advisory Unit on Pregnancy and Rheumatic diseases; <sup>2</sup>Dept. of Immunology and Transfusion Medicine, St. Olavs Hospital; <sup>3</sup>Centre of Molecular Inflammation Research and Dept. of Clinical and Molecular Medicine, NTNU, Trondheim, Norway

**Background:** Lipocalin-2 (LCN2) has become increasingly relevant as a potential clinical biomarker of rheumatic diseases.<sup>1</sup> The biological role of LCN2 in the adaptive immunity is less understood. It has been shown that LCN2 can induce immune tolerance by upregulation of human leukocyte antigen G (HLA-G) expression and by expansion of T-regulatory cells.<sup>2</sup> LCN2-deficient mice have been found to be more susceptible to induction of autoimmunity.<sup>3</sup> Systemic lupus erythematosus (SLE) is a disease associated with loss of tolerance. Pregnancy complications seen in SLE are also regarded as a consequence of immune dysregulation. LCN2 might therefore play a role as an immune modulator in SLE-pregnancies.

**Objectives:** The study objective was to obtain a better understanding of immune regulation in pregnant women with SLE. In this study, we analysed serum LCN2 and clinical parameters in women with RA, SLE and healthy controls during pregnancy and postpartum.

**Methods:** The Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases collects serum samples in a biobank from women with inflammatory rheumatic diseases. Samples were obtained before pregnancy, in each trimester and 6 weeks, 6 months and 12 months postpartum from pregnant women with SLE (n=28), RA (n=34) and healthy pregnant controls (n=19). A sandwich ELISA was used to measure LCN2 in the serum samples. The biobank database was linked to RevNatus, a Norwegian quality registry collecting comprehensive clinical data about these women.

**Results:** Our cohort of pregnant women with SLE and RA had low disease activity throughout pregnancy and 67%–95% used medication (table 1). LCN2 levels in serum samples from women with SLE were found significantly lower compared to samples from women with RA and healthy controls at all time-points (p<0.05) (graph).

Abstract AB0081 – Table 1. Disease activity and medication

	SLE patients			RA patients		
	1st trimester	2nd trimester	3rd trimester	1st trimester	2nd trimester	3rd trimester
<b>Disease activity</b>						
LAI-P Mean (range) [SD]	0,04 (0–0,25) [0,08]	0,02 (0–0,16) [0,05]	0,005 (0–0,08) [0,02]			
DAS28 Mean (range) [SD]				2,34 (1,79–3,91) [0,76]	2,57 (1,42–5,02) [1,06]	2,57 (1,79–4,90) [0,94]
<b>Medication</b>						
Prednisolone, receiving (%) (dose range [mg])	17 (2,5–7,5)	48 (2,5–7,5)	48 (2,5–10)	28 (2,5–10)	33 (2,5–15)	38 (2,5–12,5)

\*>1: more than one of the following: SLE: hydroxychloroquine; azathioprine, RA: sulfasalazine, methotrexate, hydroxychloroquine, TNF inhibitors

Abstract AB0081 – Figure 1

**Conclusions:** Pregnant women with SLE had lower levels of LCN2 compared to pregnant women with RA and healthy controls. Our cohort of women had well controlled disease, making it likely that our findings represent inherent biological differences rather than effects of disease activity. Low LCN2 levels can be a possible mechanism for loss of tolerance seen in SLE patients during pregnancy.

Rispens<sup>1</sup>. <sup>1</sup>Immunopathology, Sanquin Research; <sup>2</sup>Rheumatology, Amsterdam Rheumatology and immunology Center, Amsterdam; <sup>3</sup>Queen Beatrix Hospital, Winterswijk; <sup>4</sup>Erasmus MC University Medical Center, Rotterdam; <sup>5</sup>Reinier de Graaf Groep, Delft; <sup>6</sup>Onze Lieve Vrouwe Gasthuis; <sup>7</sup>Amsterdam Rheumatology and immunology Center; <sup>8</sup>Sanquin Research, Amsterdam, Netherlands

**Background:** Accurate measurements of rheumatoid factors (RFs), autoantibodies binding IgG, are important for diagnosing rheumatoid arthritis (RA) and for predicting disease course. Worldwide, various RF assays are being used that differ in technique and target antigens.

**Objectives:** To study whether assay choice leads to clinically important discrepancies in RF status and level.

**Methods:** RF measurements using 4 commercial RF assays were compared in 32 RF<sup>+</sup> samples. Using ELISAs, the influence of the target antigen source—human IgG (hIgG) versus rabbit IgG (rIgG)—on measured RF levels was investigated in arthralgia patients and RA patients.

**Results:** Substantial discrepancies were found between RF levels measured in the four commercial assays. 6 samples (19%) with RF levels below or slightly above the cut-off in an rIgG-based assay were RF<sup>+</sup> in three assays using hIgG as the target antigen, some with very high levels. Direct ELISA comparisons of RF reactivity against hIgG and rIgG estimated that among 173 ACPA<sup>+</sup> arthralgia patients, originally RF negative in rIgG-based assays, up to 10% were single positive against hIgG. Monoclonal RFs binding to hIgG and rIgG or hIgG only supported these findings. In a cohort of 69 early RA patients, virtually all RF responses reacted with both targets, although levels were still variable.

**Conclusions:** The use of RF assays that differ in technique and target antigen, together with the different specificities of RF responses, leads to discrepancies in RF status and levels. This has important consequences for patient care if RA diagnosis and disease progression assessments are based on RF test results.

### LOCAL ICE CRYOTHERAPY DECREASES PROSTAGLANDIN-E<sub>2</sub>, NF-KB AND IL-6 SYNOVIAL LEVELS IN ARTHRITIC KNEES COMPARED TO CONTRALATERAL NON-TREATED JOINTS

X. Guilloit<sup>1,2,3</sup>, N. Tordi<sup>2</sup>, C. Laheurte<sup>4</sup>, L. Pazar<sup>5</sup>, C. Prati<sup>2,3</sup>, P. Saas<sup>4</sup>, D. Wendling<sup>3,6</sup>, <sup>1</sup>Rheumatology Department, Felix Guyon University Hospital, Saint-Denis, Réunion; <sup>2</sup>PEPITE EA4267, FHU Increase, Bourgogne-Franche-Comté University; <sup>3</sup>Rheumatology Department; <sup>4</sup>INSERM U1098, Biomonitoring Platform, EFS; <sup>5</sup>CIC IT, INSERM Center CIT 808, Besançon University Hospital; <sup>6</sup>EA 4266, Bourgogne-Franche-Comté university, Besançon, France

**Background:** Cryotherapy is widely used in rheumatic diseases, with a low level of evidence. Tissue mild hypothermia was reported to inhibit pivotal pro-inflammatory enzyme pathways such as COX-2/PGE<sub>2</sub> and NF-kB.

**Objectives:** We hypothesised that local cryotherapy (LC) might reduce joint inflammation through PGE<sub>2</sub> and NF-kB repression.

**Methods:** 47 patients suffering from non-septic knee arthritis were included (17 gout, 11 calcium pyrophosphate dehydrate crystal deposition diseases, 6 spondyloarthritis, 13 rheumatoid arthritis), taking no concurrent anti-inflammatory drug/DMARD. They were first randomised to receive local ice (30 min-N=16) or cold pulsed CO<sub>2</sub> (2 min – Cryo+ Cryonic-N=16) at 9 A.M and 5 P.M. Synovial fluid was collected just before the first cold application then 24 hours later (9 A.M). Synovial fluid IL-6, IL-1β, TNF-α, IL-17A, VEGF (Multiplex flow cytometry), NF-kB P65 (total/phosphorylated) and PGE<sub>2</sub> (ELISA) were measured and compared before and after 2 LC applications. Contralateral non-treated knees were then used as paired controls (in 16 other ice-treated patients).

**Results:** Synovial IL-6 significantly decreased after 2 LC applications (n=43 paired Wilcoxon:p=0.00015). This decrease was also significant in ice-treated subgroup (n=16 p<0.005) but not in CO<sub>2</sub>-treated patients (n=14;p=0.1). IL-1β and VEGF levels also decreased after treatment (n=44-p=0.02 and n=47-p=0.03) but not significantly in treatment subgroups. By contrast, IL-6 (n=13), IL-1β (n=15) and VEGF (n=15) didn't change in contralateral non-treated knees. LC had no significant effect on IL-17A nor TNF-α synovial levels. LC significantly reduced synovial NF-kB (n=38-p=0.04) and NF-kB-P levels (n=38-p=0.004). These levels were also significantly decreased in ice-treated patients (n=26-p=0.03 and 0.003) but not in CO<sub>2</sub>-treated patients (n=13). We observed no effect on the NF-kB levels in contralateral non-treated knees (n=12). NF-kB variations correlated significantly with IL-6 (Pearson's r=0.48-N=32 p<0.01) and VEGF (r=0.34-N=36-p=0.038) variations, and with the maximal skin temperature drop induced by LC (r=0.32-N=36-p=0.047). LC significantly reduced synovial PGE<sub>2</sub> (n=38-p=0.04), which was also significantly decreased in ice-treated patients (n=26-p=0.02) but not in CO<sub>2</sub>-treated patients (n=13). Conversely, we observed a significant increase in PGE<sub>2</sub> levels in contralateral non-treated knees (n=12-p=0.04), with a significant inter-class effect-size (weighted mean difference –1329 [–2232;–426] pg/mL-in 12 bi-arthritic patients).

**Conclusions:** Local ice cryotherapy applied twice during one day showed superior anti-inflammatory effects compared to local CO<sub>2</sub>, notably by reducing synovial IL-6 levels in arthritic knees. We also showed for the first time that this inhibitory effect on cytokine levels might be PGE<sub>2</sub> and NF-kB dependent, notably through significant inhibitory effects on the PGE<sub>2</sub> and (to a lesser extent) NF-kB pathways.

### ELEVATED LEVELS OF IL-37 ARE ASSOCIATED WITH TOPHUS AND SUPPRESSED THE PRODUCTION OF INFLAMMATORY CYTOKINES IN PATIENTS WITH GOUT

X. Hong, L. Ding, Q. Huang, D. Liu. Department of Rheumatology and Immunology, Shenzhen People's Hospital, the Second Clinical Medical College of Jinan University, Shenzhen, China

**Background:** IL-37 has been identified as a natural inhibitor of innate immunity. Although increasing evidence shows elevated IL-37 expression in various autoimmune diseases, its correlation with clinical symptoms in gout is still unclear.

**Objectives:** This study aims to determine the correlation between the levels of IL-37 and clinical indexes in gout patients, and to examine the inhibitory effect of IL-37 on pro-inflammatory cytokine including IL-1β, IL-6 and IL-18 from peripheral blood mononuclear cells (PBMC) of gout patients in culture.

**Methods:** Levels of serum IL-37 and concentrations of IL-1β, IL-6, IL-18 in cell culture from 42 patients with gout and 40 healthy controls (HCs) were measured by enzyme-linked immunoassay (ELISA). Moreover, the relative mRNA

expression of these cytokines in PBMCs was detected by real-time PCR (RT-PCR). The correlations between serum IL-37 levels and clinical values in gout patients were analysed by Spearman correlation test.

**Results:** Both protein and mRNA levels of IL-37 were higher in gout patients than healthy controls, especially in patients with tophus. Serum IL-37 levels of gout patients were positively correlated with C-reactive protein and uric acid. Furthermore, the expression of IL-1β, IL-6 and IL-18 in PBMCs from gout patients was significantly increased, which were markedly suppressed by IL-37 in culture.

**Abstract AB0084 – Figure 1.** IL-37 suppresses the expression of pro-inflammatory cytokines in PBMCs from gout patients

**Conclusions:** Serum levels of IL-37 are closely associated with clinical symptoms in gout patients and may represent a potential biomarker for the disease activity.

### THE MECHANISM OF TOTAL GLUCOSIDE OF PAEONY AND SINOMENINE ON THE PREVENTION OF ACUTE GOUT FLARES

Z. Li, X. Ma, D. Li, Z. Lu. Rheumatology, Bethune International Peace Hospital, Shijiazhuang, China

**Background:** The compliance of drug prevention for acute gout flares (GFs) during urate-lowering treatment (ULT) is very low. New preventive drugs of GFs during ULT is required. Our previous study found that the total glucoside of paeony (TGP), a traditional Chinese drug's extracts, has a good effect on the prevention and treatment for urate induced acute gouty arthritis (AGA) in rat.

**Objectives:** To explore the possible mechanism of TGP and Sinomenine (SIN) in the prevention and treatment of acute gouty arthritis.

**Methods:** Logarithmic growth phase of RAW264.7 cells were seeded into 96 well plate at a density of  $5 \times 10^4$ /mL. Cultured overnight in a humidified atmosphere of 5% CO<sub>2</sub> at 37°C. Then, the medium was changed to serum-free DMEM. Then divided into Control group (DMEM), Model group (DMEM +50 mg/L MSU), Colchicine group (DMEM +50 mg/L MSU +1 μmol/L Colchicine), TGP group (DMEM +50 mg/L MSU +40 mg/L TGP), SIN group (DMEM +300 μmol/L SIN), SIN +TGP group (DMEM +40 mg/L TGP +300 μmol/L SIN). The final volume of solution was 2 ml in each well, and each group had 3 wells, culturing for 24 hour in a humidified atmosphere of 5% CO<sub>2</sub> at 37°C. Then, culture supernatant was collected. NO level were detected by method of nitrate reductase, the level of IL-1β,

TNF- $\alpha$ , IL-8, MCP-1, MIF were detected by ELISA method. Western blot method was used to detect the expression of MyD88, NF- $\kappa$ B, ASC, and Caspase-1 in macrophages.

**Results:** The expression level of MyD88, NF- $\kappa$ B, ASC and Caspase-1 protein in macrophages of model group was significantly up-regulated, and the levels of IL-1 $\beta$ , TNF- $\alpha$ , IL-8, MCP-1, MIF and NO in the supernatant is increased significantly. TGP, SIN, TGP +SIN and Colchicine group compared with the model group, the expression of NF- $\kappa$ B, MyD88, ASC, Caspase-1 protein in macrophage and the level of IL-1 $\beta$ , TNF- $\alpha$ , IL-8, MCP-1, MIF and NO in supernatant were significantly decreased, the difference was statistically significant ( $p < 0.05$ ). TGP +SIN group compared with Colchicine group, the expression of inflammatory pathways proteins and the levels of inflammatory cytokines were no differenced ( $p > 0.05$ ) (table 1).

**Abstract AB0085 – Table 1.** Expression of major inflammatory cytokines and signalling pathway proteins (X $\pm$ S)

## Cartilage, synovium and bone

### AB0086 TYPE II COLLAGEN AND GLYCOSAMINOGLYCAN TURNOVER IN BOVINE ARTICULAR CARTILAGE IS MODULATED BY LONG-TERM DYNAMIC COMPRESSION

A. Engström<sup>1,2</sup>, A.-C. Bay-Jensen<sup>2</sup>, M.A. Karsdal<sup>2</sup>, C.S. Thudium<sup>2</sup>. <sup>1</sup>Department of Biomedical Sciences, University of Copenhagen, Copenhagen; <sup>2</sup>Nordic BioScience, Herlev, Denmark

**Background:** Osteoarthritis (OA) patients suffer from progressive degradation of articular cartilage, to which there is no available treatment to block or reverse the catabolic mechanisms. Articular cartilage confers a biomechanical function in the joints, and in concordance chondrocytes have shown to be mechanosensitive. The effect of dynamic compression on cartilage extracellular matrix (ECM) could prove to be crucial for translational research in development and screening of new OA drug candidates.

**Objectives:** This study investigates the effect of long-term dynamic compression of a bovine articular cartilage *ex vivo* model through quantification of cartilage associated biomarkers.

**Methods:** Full depth bovine cartilage explants were cultured for 2 weeks. The explants were treated 3 times a week with either OSM [10 ng/mL] and TNF- $\alpha$  [2 ng/mL] (O+T), or TGF-B1 [50 ng/mL]. Untreated samples were included as negative controls (w/o). For each condition two groups were established; an unloaded group and a group compressed 3 times a week. Compression was applied using Electroforce 5500 (TA Instruments), in a sine wave with a maximum load per cycle of 1 MPa, at 1 Hz frequency for 1200 cycles. Metabolic activity was measured once a week using AlamarBlue. Biomarkers released to the supernatant were assessed using the following well-described ELISAs: formation of type II collagen was measured by ProC2, and MMP-degradation of type II collagen was

measured by C2M. Sulfated glycosaminoglycans (sGAG) released to media, and sGAG extracted from the explants on the last day using a 4 mM GuHCl solution were quantified using a 1,9-dimethylmethylene blue (DMB) assay.

**Results:** Compression of bovine explants significantly decreased release of C2M compared to unloaded samples in O-T and w/o groups with 42% and 48% respectively. ProC2 release was not affected by compression. Compression of w/o or TGF-b treated explants increased sGAG release with 195% and 152% relative to their unloaded controls. However, the total amount of sGAG extracted from the explants on the last day remained unchanged. Compression of the explants did not affect the metabolic activity.

**Abstract AB0086 – Figure 1**

**Conclusions:** Compression significantly reduced the degradation of type II collagen, which in combination with unaltered formation as measured by ProC2, may suggest suppression of the involved catabolic processes and increased deposition of type II collagen in the cartilage matrix. Furthermore, compression elevated the sGAG release without reduction in the explant GAG content, indicating an increased turnover of GAG. In conclusion, the cartilage ECM turnover is significantly modulated by dynamic compression. This method adds essential translational value to the continuous research addressing OA.

### AB0087 SYNOVIAL TISSUE MACROPHAGES POLARISATION (M1, M2) IN PATIENTS WITH UNDIFFERENTIATED ARTHRITIS MEETING DIAGNOSTIC CRITERIA FOR RHEUMATOID ARTHRITIS OR PSORIATIC ARTHRITIS ALONG THE FOLLOW UP

A. Cuervo Aguilera<sup>1</sup>, S. Fuentelsaz-Romero<sup>2</sup>, L. Estrada-Capetillo<sup>2</sup>, R. Celis<sup>1</sup>, R. Samaniego<sup>3</sup>, J. Ramirez<sup>1</sup>, A. Puig-Kröger<sup>2</sup>, J.D. Cañete<sup>1</sup>. <sup>1</sup>Rheumatology, Arthritis Unit, Hospital Cínic and IDIBAPS, Barcelona; <sup>2</sup>Laboratorio de Inmunometabolismo; <sup>3</sup>Unidad de Microscopía Confocal, Hospital General Universitario Gregorio Marañón, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain

**Background:** Undifferentiated arthritis (UA) is defined as an inflammatory oligo- or polyarthritis that does not fulfill criteria for a definitive diagnosis. Earlier diagnosis would permit a better functional prognosis. Synovial tissue (ST) macrophages have been associated with disease activity, radiographic erosion and response to therapy in RA. Furthermore, it has been reported that M1 polarised macrophages predominate in RA synovitis, whereas M2 predominate in SpA synovitis.<sup>1</sup>

**Objectives:** To analyse polarised macrophages (M1 proinflammatory and M2 anti-inflammatory) in ST of patients with UA which evolved to RA or PsA, after a long follow-up, to explore their diagnostic value.

**Methods:** To determine the polarisation state of macrophages in ST obtained by arthroscopy from patients with UA that evolved to RA (UA-RA=8) or PsA (UA-PsA=9), the expression of proteins associated to GM-CSF-driven polarisation M1 (INHBA, TNF $\alpha$  and MMP12) and M-CSF-driven polarisation M2 (CD209) was assessed in ST CD163<sup>+</sup> macrophages. Patients with established RA (n=12) or PsA (n=10) were included as control. 4  $\mu$ m cryosections of ST in OCT were blocked for 10 min with 1% human immunoglobulins and incubated with primary (1–5  $\mu$ g/ml) and secondary antibodies. Imaging was performed with an inverted confocal microscope (SPE, Leica Microsystems) and glycerol immersion objective (ACS-APO 20x/NA 0.60). Single cell mean fluorescence intensity (MFI) was

assessed using ImageJ software (National Institutes of Health, Bethesda, MD, USA). At least three random fields were evaluated for each type of ST, quantifying the expression of INHBA, TNF- $\alpha$ , MMP12 and CD209 in all segmented CD163<sup>+</sup> macrophages. Macrophages density was normalised based on selected tissue area (mm<sup>2</sup>). After background subtraction, data were plotted using GraphPad software (GraphPad Software, La Jolla, CA, USA).

**Results:** CD163<sup>+</sup> sublining (SL) macrophages from UA-RA expressed abundantly the INHBA-encoded activin A, whereas TNF $\alpha$  and MMP12 were variably detected. Regarding the M-CSF-associated marker CD209, 2 populations of CD163<sup>+</sup> macrophages were found in the SL of UA-RA, CD163<sup>+</sup>CD209<sup>+</sup> and the other CD163<sup>+</sup>CD209<sup>-</sup>, with higher than 100 arbitrary units (au) for CD163<sup>+</sup>CD209<sup>+</sup> and lower than 100 au for CD163<sup>+</sup>CD209<sup>-</sup>. Similarly, INHBA, MMP12 and TNF $\alpha$  expression and 2 populations of CD209 were detected in CD163<sup>+</sup> macrophages from UA-PsA. Macrophage density was also found comparable between UA, with 650/mm<sup>2</sup> in UA-RA and 649/mm<sup>2</sup> in UA-PsA. Quantification of the above indicated markers in CD163<sup>+</sup>ST macrophages from established RA and PsA revealed similar levels of INHBA, TNF $\alpha$ , MMP12 and CD209 than those from UA-RA and UA-PsA.

**Conclusions:** This study shows for the first time that the polarisation state of ST CD163<sup>+</sup> macrophages in UA progressing to RA and PsA is similar to that of established RA and PsA in terms of INHBA, MMP12, TNF $\alpha$  and CD209 expression. Therefore, the inflammatory polarisation state of macrophages is similar in RA and PsA and it is already detected at the earlier steps.

#### HISTOPATHOLOGICAL CHANGE CAUSED BY BIOLOGICAL TREATMENT IN RHEUMATOID ARTHRITIS SYNOVIAL TISSUE

A. Kubota<sup>1</sup>, T. Suguro<sup>1</sup>, A. Nakajima<sup>2</sup>, S. Masayuki<sup>1</sup>, S. Masato<sup>2</sup>, T. Kentaro<sup>1</sup>, T. Kazuaki<sup>1</sup>. <sup>1</sup>Toho University School Of Medicine, Department of Orthopaedic Surgery, Tokyo; <sup>2</sup>Departments of Orthopaedics and Rheumatology, Toho University Sakura Medical Center, Chiba, Japan

**Background:** Multiple studies addressing the effects of biologics on the synovial tissue in rheumatoid arthritis (RA) patients have been reported. There are, however, few studies comparing histopathological changes in the synovial tissue in the same RA patients between before and after biologics treatment.

**Objectives:** We examined biologics impacts on RA synovial tissues based on pathological findings in them collected during surgeries for the same patient before and after biological drug usage.

**Methods:** Synovial tissues were collected from 34 RA joints before and after biologics. The average age and disease duration of the study subjects were 64.0 and 22.5, respectively. Synovial tissues were evaluated by hematoxylin. Histopathological changes in the synovial tissues were compared based on Rooney's score, and presence or absence of fibrinoid degeneration and proliferation of villi in the subsynovial tissue. We examined correlation between pathological findings in RA synovium and disease activity under biologics. Disease activity was assessed by CDAI. We examined the Histopathological changes in the Remission, Low disease activity group (RL group) and Moderate disease activity (M group). Etanercept, Infliximab, Tocilizumab, Adalimumab and Abatacept was used as biological drug for 18, 6, 5, 3 and 2 joints respectively.

**Results:** Rooney score between before and after biological usage improved from 28.4 to 12.0 showing significant difference. Significant improvement in Rooney score was observed in all items. Fibrinoid degeneration was observed in 29 cases (85.3%) and 6 cases (17.6%) before and after biologics treatment, respectively, demonstrating a significant reduction with biologics treatment. Proliferation of villi was observed in 32 cases (94.1%) and 11 (32.4%) before and after biologics treatment, respectively, demonstrating a significant reduction with biologics treatment. After biologics treatment, Rooney's score in RL group and M group were 10.4 and 15.3, respectively, showing a statistically significant difference. In addition, the M group had significantly higher scores in lymphoid follicle and lymphocyte infiltration compared to the RL group.

**Conclusions:** The study results demonstrated that biologics treatment significantly ameliorated inflammatory changes in the synovial lining layers and sublining layers. In addition, the results suggested that histopathological findings in the sublining layers reflected disease activity.

#### VERBASCOSIDE AND HYDROXYTYROSOL DOWNREGULATE STRESS-RELATED PATHWAYS IN HUMAN OSTEOARTHRITIC ARTICULAR CHONDROCYTES

Z. Elmazoglu<sup>1</sup>, M. Colakoglu<sup>1</sup>, S. Banerjee<sup>2</sup>, B. Bitik<sup>3</sup>, C.N. Aktekin<sup>4</sup>, B. Goker<sup>1</sup>, C. Karasu<sup>1</sup>. <sup>1</sup>Gazi University; <sup>2</sup>Middle East Technical University; <sup>3</sup>Rheumatology; <sup>4</sup>Ankara Research and Education Hospital, Ankara, Turkey

**Background:** Osteoarthritis (OA), is a leading cause of joint dysfunction and the disease is characterised by progressive destruction of the articular cartilage.<sup>1</sup> At the molecular level, degeneration of the cartilage is attributed to multifactorial events including oxidative stress, mitochondrial dysfunction, apoptosis and associated changes in inflammatory and catabolic gene expression.<sup>2</sup> Recent studies have revealed the essential role of plant-derived antioxidants in preventing pathological events observed in joint diseases by modulating redox signalling.<sup>3</sup>

**Objectives:** Here, we studied whether the polyphenolic compounds verbascoside and hydroxytyrosol exert chondroprotective effects by suppressing oxidative stress pathways and IL-1, IL-1 $\beta$ -converting enzyme (ICE) expression in human OA chondrocytes.

**Methods:** Chondrocytes were isolated from the joint cartilages of OA patients (grade 3–4) during total knee arthroplasty with the approval of Kecioren Training and Research Hospital, Clinical Research Ethics Committee (B.10.4.İSM.4.06.68.49), as described previously.<sup>4</sup> The alterations in cell counts, viability (MTT, NRU), proliferation (RTCA-iCELLigence System), reactive oxygen species (ROS) generation, stress-related signalling proteins and inflammatory progenitors ICE/caspase-1 (ELISA) were determined.

**Results:** Cell viability was increased at lower concentrations of hydroxytyrosol in OA chondrocytes (P1, 30th day). On the other hand, verbascoside treated cells did not show any difference in the activity of mitochondrial oxidoreductases by the MTT assay. However, both polyphenols significantly increased proliferation and reduced intracellular ROS generation in OA chondrocytes at lower concentrations. Although verbascoside has no effect on ICE/caspase-1, treatment with hydroxytyrosol downregulated ICE/caspase-1, indicating a potential anti-inflammatory effect. Both polyphenols modulated the activation of stress activated signalling pathways via p38 and JNK proteins.

**Conclusions:** At low concentrations the antioxidants hydroxytyrosol and verbascoside may have potential chondroprotective effects in OA.

#### MECHANICAL EXPOSURE AND DIACEREIN TREATMENT MODULATES INTEGRIN-FAK-MAPKS MECHANOTRANSDUCTION IN HUMAN OSTEOARTHRITIS CHONDROCYTES

B. Lohberger<sup>1</sup>, L. Weigl<sup>2</sup>, A. Mann<sup>2</sup>, W. Kulich<sup>3</sup>, A. Leithner<sup>1</sup>, B. Steinecker-Frohniesser<sup>3</sup>. <sup>1</sup>Department of Orthopedics and Trauma, Medical University Graz, Graz; <sup>2</sup>Department of Special Anaesthesia and Pain Therapy, Medical University Vienna, Vienna; <sup>3</sup>Ludwig Boltzmann Department for Rehabilitation, Ludwig Boltzmann Cluster for Arthritis and Rehabilitation, Saalfelden, Austria

**Background:** Progression of osteoarthritis (OA) is characterised by destruction of articular cartilage, thickening of subchondral bone, and formation of osteophytes. The disease modifying OA drug (DMOAD) diacerein functions as a slow acting drug through anti-inflammatory, anti-catabolic, and pro-anabolic effects on cartilage and the synovial membrane. Mechanical loading of joint tissue directly affects the homeostasis of matrix degrading enzyme production and matrix repair.

**Objectives:** To explore the impact of diacerein and moderate mechanical stimulation on the anabolic metabolism of OA and non-OA chondrocytes, as well as on the integrin-FAK-MAPKs signal transduction cascade in these cells.

**Methods:** Mechanical stimulation was applied in terms of three different intensities by the Flexcell tension system. Influence on catabolic parameters such as MMPs, ADAMTS, and IL-6 were assessed by qPCR. Changes in phosphorylation of FAK, STAT3 as well as MAP kinases were verified by western blot analysis. Intracellular calcium was measured fluorimetrically using fura-2.

**Results:** Mechanical stimulation at moderate intensity (SM/SA) proved to be most efficient in terms of reducing production of matrix degrading enzyme and IL-6 expression. Treatment with diacerein by itself and diacerein in combination with SM/SA reduced phosphorylation of FAK and STAT3, which is more pronounced in OA cells. Pretreatment with diacerein for 7 days resulted in an increase in the sensitivity to Yoda1, the agonist for the mechanically activated ion channel Piezo1. However, in OA cells a significant reduction in Piezo1 expression was observed following treatment with diacerein.

**Conclusions:** Cyclic tensile strain can reduce matrix destroying enzymes, and when used in combination with diacerein, the activity of integrin signalling components is changed. The observed effects can be mainly attributed to diacerein's capacity to modulate STAT3 and Piezo1, which are both potential targets to prevent the progression of OA.

#### AB0092 IL37 INHIBITS PROTEOGLYCAN LOSS IN HUMAN OA CARTILAGE: LINK BETWEEN IL37 AND MMP3

E. Van Geffen<sup>1</sup>, A. van Caam<sup>1</sup>, C. Thudium<sup>2</sup>, A.-C. Bay-Jensen<sup>2</sup>, E. Blaney Davidson<sup>1</sup>, P. van der Kraan<sup>1</sup>. <sup>1</sup>Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands; <sup>2</sup>Rheumatology, Nordic Bioscience, Herlev, Denmark

**Background:** Glycosaminoglycans (GAGs) are essential for the pressure-resistant function of cartilage. During osteoarthritis (OA), GAGs are lost from cartilage. This loss impairs the functional and structural integrity of cartilage, thereby accelerating further cartilage damage. Proteoglycan degradation is mediated by enzymes such as MMP3, MMP13 and ADAMTS5.

**Objectives:** Recently we discovered that interleukin 37 (IL37) lowers the expression of these enzymes in human OA chondrocytes. The goal of this study was to investigate if IL37 protects against GAG loss in freshly obtained human OA explants.

**Methods:** Human cartilage was obtained from ten OA patients undergoing total knee or hip arthroplasty. Per condition 6 cartilage explants of 4 mm in diameter were used. Explants were incubated with recombinant IL37 (rhIL37) for up to 6 days. Every other day new rhIL37 was added. Additionally, an MMP3-inhibitor, or MMP13-inhibitor or ADAMTS5-inhibitor was added in the same protocol. Sulfated GAGs (sGAGs) were visualised by histology, and sGAG release in culture medium was quantified using 1,9-dimethylmethylene blue. To study sGAG synthesis, explants were incubated with rhIL37 followed by 4 hour labelling with <sup>35</sup>SO<sub>4</sub>. Alternatively, explants were pre-labelled for 4 hour with <sup>35</sup>SO<sub>4</sub> followed by incubation with rhIL37 to study sGAG degradation. Additionally, expression levels of proteoglycans and cartilage matrix degrading enzymes were measured by qPCR and Western Blot. Activity of MMP and ADAMTS enzymes was determined by measuring FFGV, ARGS and NITEGE neo-epitope levels in the supernatant of the cultures, using ELISA.

**Results:** Culturing human OA explants for up to 6 days, caused a reduction in GAG content as observed by loss of Safranin O staining. In addition, a release of sGAGs was measured in the supernatant of on average 17,5 µg/ml per mg cartilage. Incubation of cartilage explants with rhIL37 significantly reduced the release of GAGs. A maximal reduction of 24% was already observed with the lowest dose of rhIL37 (1 ng/ml). No effect of rhIL37 on the amount of incorporated <sup>35</sup>SO<sub>4</sub> was observed, indicating that rhIL37 does not alter the synthesis of GAGs. This is supported by the observation that rhIL37 does not affect the mRNA expression of the large proteoglycans and SLRPS. In contrast, we did find that rhIL37 significantly reduced the loss of <sup>35</sup>SO<sub>4</sub>-labelled GAGs from cartilage explants. In addition, rhIL37 reduced MMP3 and MMP13 protein expression and lowered both MMP and ADAMTS mediated degradation of proteoglycan fragments: FFGV neo-epitope and ARGS and NITEGE neo-epitopes, confirming that rhIL37 reduces active degradation of sGAGs. Lastly, to investigate which proteolytic enzyme contributes to the sGAG release in our culture system, a MMP3-, MMP13- or ADAMTS5-inhibitor was added to the explants. Strikingly, we found that only MMP3 inhibition mimicked IL37 function, suggesting that the effects of rhIL37 run via MMP3.

**Conclusions:** Our data show that rhIL37 reduces sGAG release of cartilage explants, indicating that IL37 supports cartilage matrix integrity. To our knowledge this is the first report demonstrating this anti-destructive effect of IL37 on freshly

obtained human OA cartilage explants. Possible these effects run via MMP3 because IL37 reduced MMP3 expression and only MMP3 inhibition results in similar effects as rhIL37 addition.

#### AB0093 NATURAL POLYMER-BASED HYDROGELS FOR CARTILAGE REGENERATION

E. Montell<sup>1</sup>, L. García-Fernández<sup>2</sup>, A. Torrent<sup>1</sup>, J. San Román<sup>2</sup>. <sup>1</sup>Pre-Clinical RandD Area, Bioibérica, S.A.U., Barcelona; <sup>2</sup>Biomaterials Group, CIBER's Bioengineering, Biomaterials and Nanomedicine (CIBER-BBN), Institute of Polymer Science and Technology (ICTP-CSIC), Instituto de Salud Carlos III, Madrid, Spain

**Background:** Cartilage is a tough, flexible tissue found throughout the body. It can become damaged because of a sudden injury, such as a sports injury, or gradual wear and tear (osteoarthritis). Injured articular cartilage has a poor regenerative capability, for this reason, tissue engineering may provide a fundamental therapeutic solution to repair cartilage injury.

Human articular cartilages are composed of dense extracellular matrix and chondrocytes. One of the major components in the extracellular matrix is hyaluronic acid. The combination of hyaluronic acid with other natural polymers to prepare hydrogel scaffolds may be potentially useful in many tissue engineering applications, including cartilage regeneration.

**Objectives:** We propose the synthesis of hydrogels based on hyaluronic acid and chitosan by a new strategy of synthesis using di-isocyanates to obtain an interpenetrated network of chitosan and hyaluronic acid.

**Methods:** Different kinds of hydrogels were synthesised using hyaluronic acid (Bioibérica, Spain), natural polymers (gelatine, chitosan) and stabilised with diisocyanates. The hydrogels were charged with chondroitin sulfate (Bioibérica, Spain).

**Morphological Characterisation:** The hydrogels were characterised by scanning electron microscopy and energy dispersive X-ray microscopy in order to study the morphology and the composition of the hydrogels.

**Hydrogel Swelling:** Dynamic swelling experiments were performed by placing discs of stabilised hydrogels in PBS at 37.0°C, and measuring their weight gain as a function of time.

**Biocompatibility:** Cytotoxicity *in vitro* assays (MTT) and cell adhesion tests (Alamar Blue) were performed on the hydrogels using different cell lines to corroborate the biocompatibility of the hydrogels.

**Results:** All the synthesised hydrogels presented a high interconnected porosity. The studied hydrogels swelled around 200%. After five hours equilibrium was reached and this equilibrium depended on the ratio hyaluronic acid/natural polymer increasing with the amount of hyaluronic acid present on the hydrogel. MTT assay indicated that the extracts collected at different times from the hydrogels were not cytotoxic and could be considered biocompatible. Cell adhesion assay demonstrated that the hydrogels supported cell adhesion and proliferation, and this behaviour was better on SC-loaded hydrogels.

**Conclusions:** Hydrogels based on hyaluronic acid and natural polymers are proposed as scaffolds for tissue engineering. The presence of interconnected porous and the good swelling properties, as well as the biocompatibility, represent a great advantage for application in cartilage regeneration. The addition of drugs or glycosaminoglycans is being studied to improve the cartilage regeneration.

#### AB0094 POSITIVE EFFECTS OF CHIROPRACTIC MANIPULATION ON SUBCHONDRAL BONE MINERAL DENSITY, CARTILAGE DAMAGE AND SYNOVIAL INFLAMMATION IN OSTEOARTHRITIC RABBITS

F.M. Conesa<sup>1</sup>, R. Fujikawa<sup>2</sup>, A. Mediero<sup>1</sup>, P. Gratal<sup>1</sup>, F. Mulero<sup>3</sup>, G. Herrero-Beaumont<sup>1</sup>, R. Largo<sup>1</sup>, A. Ortega-de Mues<sup>1,2</sup>. <sup>1</sup>IIS-Fundación Jiménez Díaz-UAM; <sup>2</sup>Madrid College of Chiropractic-FCUEMC; <sup>3</sup>Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain

**Background:** Osteoarthritis (OA) is a degenerative joint disease characterised by the degradation and inflammation of cartilage and synovium with bone damage. Different approaches that decrease subchondral bone remodelling during OA have demonstrated to improve cartilage damage and synovial inflammation. Chiropractic is a therapeutic approach focused on the diagnosis, treatment and prevention of musculoskeletal disorders. Chiropractic manipulation (CM) is essentially manual, allowing the chiropractor to restore the normal range of motion and function of the joints, muscles, and ligaments. We have previously observed

that CM is able to increase subchondral bone mineral density (BMD) in an experimental model of osteoporosis<sup>1</sup>.

**Objectives:** To evaluate if CM could prevent the subchondral BMD alterations induced by OA, in association to an improvement in synovial membrane inflammation and cartilage damage in an OA model in rabbits.

**Methods:** Ten male New Zealand rabbits were submitted knee surgery to induce OA by transection of anterior cruciate ligament. CM was performed using the chiropractic adjusting instrument ActivatorV 3 times a week during 8 weeks as follows: Force 2 setting was applied onto the tibial tubercle of the rabbit right hind limb (CM-OA group), at an angle of 90°, whereas the corresponding left hind limb received a false manipulation (FM-OA group) consisting of ActivatorV firing in the air and touching the tibial tubercle. Three healthy animals were used as controls. Following sacrifice, tibiae and femora were removed for mCT and histological evaluation. Synovial inflammation was evaluated by Krenn's score and the protein presence of VEGF, MMP3 and CollagenVI in the synovial membrane was evaluated by western blot.

**Results:** In the OA rabbits, subchondral BMD decreased in relation to control animals (OA 4729±193 vs Control 5181±209 mg/cc), been partially reversed in the tibiae of OA rabbits with CM (TM-OA 5055±216 vs FM-OA 4404±170 mg/cc). Subchondral trabecular bone structural parameters were analysed by microCT and a significant decrease of bone volume/trabecular volume (BV/TV), trabecular number (TbN) and trabecular thickness (TbTh) was observed in the OA rabbits, while trabecular separation (TbS) increased compared to control animals. TM-OA group showed a significant improvement of these parameters compare to FM-OA group. TM-OA had lower cartilage damage compare to FM-OA (TM-OA 4±0,67 AU vs FM-OA 8±1,25 AU). TM-OA synovial membranes presented a total Krenn score lower than FM-OA joints (TM-OA 3±0,35 vs FM-OA 4.5±0,38 AU). OA synovial membranes showed higher levels of CollagenVI respect to control ones; TM-OA synovial membranes presented less expression of CollagenVI than FM-OA group (TM-OA 1.4±0,13 vs FM-OA 2.2±0,3 AU), been this associated with a decrease of both MMP3 (TM-OA 1.2±0,1 vs FM-OA 1.7±0,2 AU) and VEGF (TM-OA 1.2±0,14 vs FM-OA 1.9±0,26 AU).

**Conclusions:** These results support the hypothesis that CM may ameliorate subchondral BMD alterations induced by OA, in association to an improvement on synoviopathy and cartilage degradation.

#### ATTEMPT TO DEVELOP A CHIMERIC CO-CULTURE SYSTEM TO DIFFERENTIATE MOUSE OSTEOCLASTS BY CULTURING MOUSE PRECURSOR CELLS WITH HUMAN SYNOVIAL FIBROBLASTS

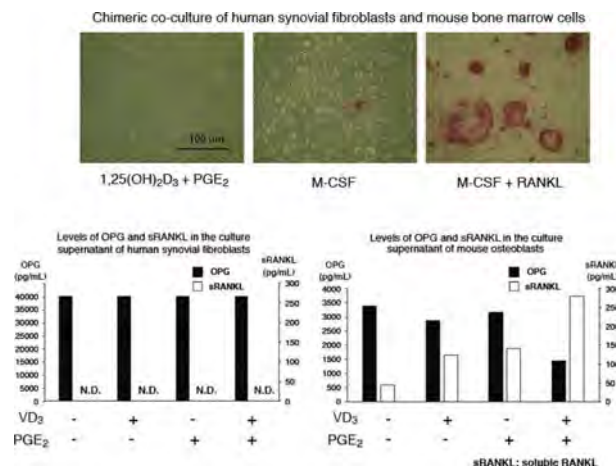

H. Yazawa, M. Yanagisawa, Y. Aizaki, Y. Araki, K. Sato, T. Mimura. *Department of Rheumatology and Applied Immunology, Saitama Medical University, Saitama, Japan*

**Background:** In rheumatoid arthritis (RA), inflammatory synovial tissue called the pannus proliferates and erodes the articular cartilage and bone in the affected joints. Osteoclasts, multinucleated cells of monocyte/macrophage lineage, are implicated in the bone destruction in RA. Thus, osteoclasts are considered an important therapeutic target in the prevention of the joint destruction. Mouse bone marrow cells differentiate into osteoclasts when co-cultured with osteoblasts or stromal cells in the presence of reagents such as 1,25-dihydroxyvitamin D<sub>3</sub> (1,25(OH)<sub>2</sub>D<sub>3</sub>) and prostaglandin E<sub>2</sub> (PGE<sub>2</sub>). There are no osteoblasts in the RA synovium, but there are fibroblasts and various inflammatory cells such as macrophages and lymphocytes. Thus, synovial fibroblasts may function as supporting cells for osteoclastogenesis in place of osteoblasts.

**Objectives:** The aim of this study was to establish a chimeric co-culture system of osteoclast differentiation using human synovial fibroblasts and mouse monocyte/macrophage lineage cells.

**Methods:** Synovial tissues were obtained from RA patients who underwent joint replacement surgery. Mouse osteoblasts were obtained from the calvariae of 2- or 3-day-old newborn C57BL/6 (B6) mice. Mouse bone marrow cells were prepared from femoral bones. Osteoclasts were visualised with tartrate-resistant acid phosphatase (TRAP) staining. The protein levels of RANKL and its decoy receptor, osteoprotegerin (OPG), in the culture supernatant were quantified using ELISA.

**Results:** We confirmed that mouse osteoclasts could be differentiated *in vitro* by culturing bone marrow cells in the presence of human M-CSF and RANKL. We then cultured mouse osteoclast precursors with human synovial fibroblasts in the presence of 1,25(OH)<sub>2</sub>D<sub>3</sub> and PGE<sub>2</sub>. The murine cells seemed to disappear in the course of the co-culture, whereas they survived when exogenous human M-CSF was added to the system. Interestingly, however, they did not become TRAP-positive multinuclear cells, suggesting that synovial fibroblasts do not provide a sufficient amount of the osteoclast differentiation factor, RANKL. Following these results, we used ELISA to quantify the level of human RANKL and OPG in the culture supernatant of synovial fibroblasts. Predictably, the level of RANKL was below the detection limit with or without the presence of 1,25(OH)<sub>2</sub>D<sub>3</sub> and/or PGE<sub>2</sub>. In contrast, that of OPG was very high, irrespective of the reagents added. We also quantified the levels of mouse RANKL and OPG in the culture supernatant of mouse osteoblasts. As expected, RANKL was detectable in this case. Interestingly, the level of OPG was very high and comparable to that of human OPG produced from synovial fibroblasts.

Abstract AB0095 – Figure 1

**Conclusions:** Synovial fibroblasts cannot be substituted for osteoblasts in a co-culture system of osteoclast differentiation. This is probably because synovial fibroblasts do not provide sufficient RANKL and M-CSF. Instead, they produce a large amount of OPG. This may be a mechanism by which ectopic osteoclastogenesis is inhibited. Thus, the osteoclasts observed in the pannus may be dependent on membrane-bound RANKL from other sources, like lymphocytes, or may be differentiated by stimulation with cytokines other than RANKL, such as TNF- $\alpha$  and IL-6.<sup>1,2</sup>

#### EXPRESSION AND FUNCTION OF NEUROPEPTIDE Y RECEPTORS IN HUMAN ARTICULAR CARTILAGE: INFLUENCE OF GENDER AND OSTEOARTHRITIS

I. Ferreira<sup>1</sup>, C. Sousa<sup>2</sup>, S. Silva<sup>1</sup>, F. Judas<sup>3</sup>, C. Cavadas<sup>2</sup>, A.F. Mendes<sup>2</sup>. <sup>1</sup>Center for Neuroscience and Cell Biology; <sup>2</sup>Faculty Pharmacy and CNC, University of Coimbra; <sup>3</sup>Orthopaedics Department and Bone Bank, University and Hospital Center of Coimbra, Coimbra, Portugal

**Background:** Elevated levels of neuropeptide Y (NPY) were reported in osteoarthritic (OA) joints<sup>1</sup>. No information exists regarding the role of NPY in OA joints, besides mediating or potentiating nociceptive transmission.

**Objectives:** To determine whether NPY receptors are present and functional in human chondrocytes, by evaluating the ability of NPY to activate important signalling pathways and to modulate autophagy, which was shown to be induced by this neuropeptide in hypothalamic neurons<sup>2</sup> and to be a crucial homeostatic mechanism in chondrocytes, whose reduction contributes to OA pathogenesis<sup>3</sup>.

**Methods:** Immunofluorescence for the NPY receptor subtypes, Y<sub>1</sub>, Y<sub>2</sub> and Y<sub>5</sub>, was performed in the human chondrocytic cell line, C28/I2, and in human cartilage sections obtained from multi-organ donors (4 males, 55–75 years old, mean=67.25, 3 females, 33–68 years old, mean=55.33) at the Bone and Tissue

Bank, University and Hospital Centre of Coimbra, with approval by the Ethics Committee. Phosphorylated levels of JNK, p38, ERK1/2, PKA, Akt and PKC and the levels of LC3B-I and II were evaluated by Western Blot of total cell extracts from C28/I2 cells.

**Results:** Immunoreactivity for Y<sub>1</sub>, Y<sub>2</sub> and Y<sub>5</sub> NPY receptors was observed in C28/I2 cells. In human cartilage, a positive signal was found for the Y<sub>2</sub> receptor in all samples while Y<sub>5</sub> receptor immunoreactivity was undetectable, regardless of disease state, gender and age of the donors. Y<sub>1</sub> receptor immunoreactivity was observed in male and female OA cartilage samples, as well as in those from non-OA females, but not in those from non-OA males. 50 nM NPY was sufficient to significantly increase the levels of phospho-JNK, -p38, -ERK1/2, -PKA, Akt and PKC with similar kinetics, but much slower than IL-1 $\beta$ . A 6 hour stimulation with 50 or 100 nM NPY decreased LC3B-I and II levels in comparison with untreated cells. In the presence of chloroquine (ChQ), NPY increased LC3B-II levels relative to those found in cells treated with ChQ alone, indicating an increased delivery of LC3B-II to the lysosome consistent with autophagy activation by NPY.

**Conclusions:** This study shows that distinct NPY receptor subtypes are present and functional in C28/I2 cells and in human chondrocytes *in situ* in the articular cartilage, strongly suggesting that non-neuronal cells and tissues of the joints, namely chondrocytes, are relevant as NPY targets. The presence of each receptor subtype seems to be determined by gender and, in males, also by the disease state. The role of age is unclear as most cartilage donors were aged >55 years old. Future studies will be addressed at further elucidating the role of NPY and its receptors in modulating male and female chondrocyte functions, both in health, ageing and osteoarthritis.

#### INDIVIDUAL FUNCTIONS OF THE HISTONE-ACETYLTRANSFERASES CBP AND P300 IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

G. Lee<sup>1</sup>, C. Kolling<sup>2</sup>, O. Distler<sup>1</sup>, C. Ospelt<sup>1</sup>, K. Klein<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Center of Experimental Rheumatology, University Hospital Zurich, Schlieren; <sup>2</sup>Schulthess Clinic, Zurich, Switzerland

**Background:** The close homologues cAMP-response element binding protein (CREB) binding protein (CBP) and p300 are writers of H3K27 histone acetylation marks found in active enhancers. In addition, their bromodomains are readers of acetylated lysine residues on histone tails and are subject of drug development for inflammatory and malignant diseases. CBP and p300 are widely accepted as redundant proteins and unique functions have not been investigated yet in depth.

**Objectives:** To analyse individual functions of CBP and p300 in rheumatoid arthritis synovial fibroblasts (SF).

**Methods:** SF were treated with the pan inhibitor I-CBP (1  $\mu$ M, 5  $\mu$ M), targeting the bromodomains of CBP and p300, in presence and absence of TNF- $\alpha$  (10 ng/ml) for 24 hour. The expression of CBP and p300 was silenced by transfection of antisense LNA gapmeRs (5 nM) in SF. Knockdown was verified by Western blotting. 24 hour after transfection cells were stimulated with TNF- $\alpha$  (10 ng/ml) for 24 hour. The mRNA expression of potential target genes was measured by quantitative Real-time PCR, using RPLP0 as an endogenous control. The protein expression of HOXD10 after CBP and p300 silencing was verified by Western blotting.

**Results:** I-CBP dose-dependently reduced the TNF- $\alpha$ -induced expression of MMP1 (p<0,05), MMP3, IL6 and IL8 in SF (n=3). Antisense LNA gapmeRs targeting CBP reduced the protein expression of CBP by 68,7% ( $\pm$ 12,9%, p<0,01, n=5) in unstimulated cells and by 89,7% ( $\pm$ 12,9%) in presence of TNF- $\alpha$ . The protein expression of p300 was reduced by 55,3% ( $\pm$ 29,8%, p<0,05, n=6) in unstimulated cells and by 62,7% ( $\pm$ 27,9%) in presence of TNF- $\alpha$  after transfection of LNA gapmeRs targeting p300. Silencing of CBP in SF (n=7) reduced the TNF- $\alpha$ -induced expression of IL6 (p<0,05), IL8 (p<0,05), MMP3 (p<0,05), as well as the basal (p<0,001) and the TNF- $\alpha$ -induced expression of MMP1 (p<0,05). In contrast, silencing of p300 induced the basal expression of IL6 (p<0,05), IL8 (p<0,01),

MMP1 (p<0,05), and MMP3 (p<0,05), as well as the TNF- $\alpha$ -induced expression of IL6 (p=0,078), IL8 (p=0,078), MMP1 (p<0,05) and MMP3 (p=0,063). Silencing of CBP in hand SF (n=4) reduced the expression of hand-specific HOX genes including HOXD10 (0,53 $\pm$ 0,10 fold; p<0,01), HOXD11 (0,76 $\pm$ 0,19 fold; p=0,098) and HOXA13 (0,75 $\pm$ 0,17 fold; p=0,063), whereas HOXA9, HOXA10 and HOXA11 were not affected. Silencing of p300 reduced the expression of HOXD10 (0,65 $\pm$ 0,24 fold; p=0,061), HOXD11 (0,45 $\pm$ 0,10 fold; p<0,01), HOXA10 (0,70 $\pm$ 0,14 fold; p<0,05) and HOXA13 (0,55 $\pm$ 0,19 fold; p<0,05). The down regulation of HOXD10 after silencing of CBP and p300 in hand SF was confirmed on protein levels by Western blotting.

Abstract AB0097 – Table 1

	CBP gapmeR	CBP gapmeR +TNF	p300 gapmeR	p300 gapmeR +TNF
MMP1	0,46 $\pm$ 0,17	0,41 $\pm$ 0,75	25,86 $\pm$ 26,82	1,96 $\pm$ 1,35
MMP3	0,97 $\pm$ 0,31	0,64 $\pm$ 0,35	2,60 $\pm$ 1,62	3,05 $\pm$ 2,89
IL6	1,21 $\pm$ 0,43	0,29 $\pm$ 0,17	4,51 $\pm$ 3,32	1,90 $\pm$ 1,20
IL8	8,27 $\pm$ 9,70	0,52 $\pm$ 0,20	207,8 $\pm$ 96,17	4,75 $\pm$ 2,67

**Conclusions:** Our results unravel opposing functions of CBP and p300 in regulating the TNF- $\alpha$ -induced expression of inflammatory and matrix-degrading target genes in SF. In addition, CBP and p300 likely contribute to the maintenance of a joint-specific gene expression in SF by regulating the expression of hand-specific HOX genes.

#### PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-GAMMA COACTIVATOR-1B FACILITATES MIGRATION AND INVASION OF FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS VIA ACTIVATION OF CANONICAL AND NON-CANONICAL NF-KB SIGNALLING PATHWAY

J.-D. Ma<sup>1</sup>, T. Yan<sup>2</sup>, Y.-S. Mou<sup>2</sup>, J. Jing<sup>1</sup>, Y.-Q. Mo<sup>1</sup>, L. Dai<sup>1</sup>. <sup>1</sup>Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University; <sup>2</sup>Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou, China

**Background:** Fibroblast-like synovocytes (FLS) in rheumatoid arthritis (RA) manifest tumor-like properties including increased proliferation, prolonged survival, apoptosis resistance, adherence and invasiveness of adjacent tissues. Peroxisome proliferator-activated receptor-gamma coactivator-1 (PGC-1)  $\beta$  is a transcriptional coactivator which plays important roles in regulating energy metabolism and cytokine signalling pathways. Our previous study showed that elevated PGC-1 $\beta$  expressed in RA-FLS promoted their pro-inflammatory effect. However, the roles of PGC-1 $\beta$  on regulating migration and invasion of RA-FLS remains to be identified.

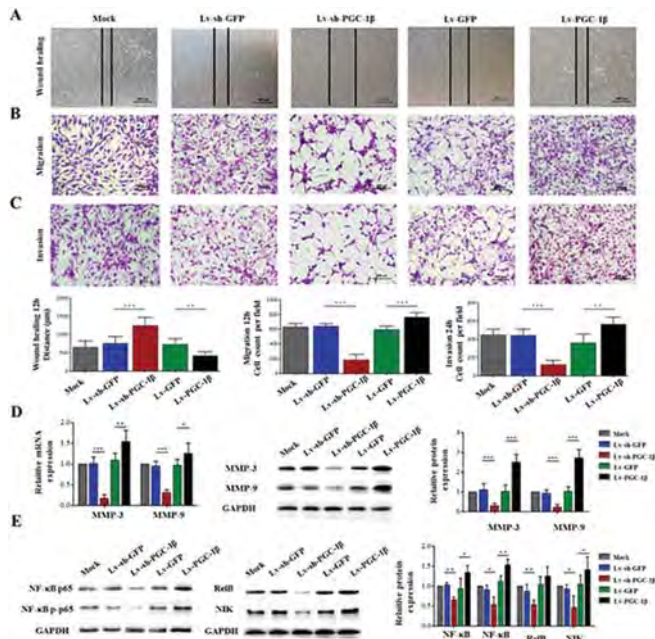

**Objectives:** To investigate the role of PGC-1 $\beta$  on regulating migration and invasion of RA-FLS and underlying mechanism.

**Methods:** Synovial tissues were obtained by closed needle biopsy from six patients with active RA and FLS were isolated and cultured. PGC-1 $\beta$  in RA-FLS was down-regulated or over-expressed by lentivirus with same vectors marked Lv-sh-GFP or Lv-GFP as negative controls. Effects of PGC-1 $\beta$  on migration and invasion capacity were detected by wound healing assays and transwell migration and invasion assays. The change of proteases in culture supernatants were detected by Proteome Profiler human protease array kit (R and D Systems, USA) and verified by qRT-PCR and western blot. The expression of key signalling molecules in canonical and non-canonical NF- $\kappa$ B signalling pathway was detected by western blot.

**Results:** Down-regulation of PGC-1 $\beta$  by Lv-sh-PGC-1 $\beta$  transfection inhibited migration and invasion of RA-FLS compared with Lv-sh-GFP transfection group (wound healing: 1252 $\pm$ 214 vs. 764 $\pm$ 184  $\mu$ m, p<0.001; migration: 184 $\pm$ 74 vs. 642 $\pm$ 32 cells/field, p<0.001; invasion: 124 $\pm$ 47 vs. 445 $\pm$ 67 cells/field, p<0.001), while

over-expression of PGC-1 $\beta$  promoted migration and invasion of RA-FLS (all  $p < 0.05$ , figure 1A-C). Down-regulation of PGC-1 $\beta$  in RA-FLS significantly decreased the expression of MMP-3 and MMP-9 in the culture supernatant which was measured by Proteome Profiler human protease array (MMP-3:  $p = 0.032$ , MMP-9:  $p = 0.037$ ). Further qRT-PCR and western blot analysis verified that both mRNA and protein expression of MMP-3 and MMP-9 in RA-FLS were significantly decreased compared with Lv-sh-GFP transfection group (all  $p < 0.05$ , figure 1D). Down-regulated PGC-1 $\beta$  in RA-FLS significantly suppressed the expression of NF- $\kappa$ B p65, NF- $\kappa$ B p-p65, RelB and NIK in protein level, while over-expression of PGC-1 $\beta$  promoted the expression of NF- $\kappa$ B p65, NF- $\kappa$ B p-p65, RelB and NIK (all  $p < 0.05$ , figure 1E).

**Abstract AB0098 – Figure 1.** Effects of PGC-1 $\beta$  on the migration and invasion capacity as well as proteases expression, canonical and non-canonical NF- $\kappa$ B signalling pathway activation in RA-FLS. **A–C** After down-regulation or over-expression of PGC-1 $\beta$ , wound healing and transwell assay showed the capacity of horizontal migration (A), vertical migration (B) and invasion (C) of primary RA-FLS. **D** After down-regulation or overexpression of PGC-1 $\beta$ , the expression of MMP-3 and MMP-9 was measured by qRT-PCR and western blot. **E** After down-regulation or overexpression of PGC-1 $\beta$ , the expression of NF- $\kappa$ B p65, NF- $\kappa$ B p-p65, RelB and NIK was measured by western blot. The data were representative as means  $\pm$  SD from six different RA patients. \* $P < 0.05$ , \*\* $P < 0.01$ , \*\*\* $P < 0.001$ .

**Conclusions:** Our findings suggested that PGC-1 $\beta$  facilitates the migration and invasion capacity and MMP-3/9 expression in RA-FLS through activation canonical and non-canonical NF- $\kappa$ B signalling pathway.

#### AB0099 ARTHROSCOPIC PECULIARITIES OF THE INFLAMMATORY PROCESS OF SYNOVIAL SHELL IN UROGENIC ARTHRITIS

M. Salokhiddinov, I. Xodjanazarov. *Traumatology, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Background:** In recent years there has been an increase in the incidence of reactive arthritis (ReA), associated with urogenital infection. Chronic synovitis of urogenital etiology is a nonspecific process, pathogenesis is very close to rheumatoid arthritis (RA), which complicates differential diagnosis. According to the literature, the inflammatory process in the synovial membrane (SM) supports the persistence of chlamydia, which reduces the effectiveness of standard anti-

inflammatory therapy of arthritis in patients with undifferentiated seronegative oligoarthritis, spondyloarthritis, RA.

**Objectives:** Arthroscopic assessment of the level of the inflammatory process in the synovial membrane, depending on the duration of the disease and the activity of the pathological process in patients with urogenital arthritis.

**Methods:** The study involved 39 patients with RA of urogenital etiology complicated by synovitis of knee joint (KJ) were examined; 23 of them were women and 16 men; mean age was  $35.5 \pm 38.0$  years. They received inpatient treatment at the Department of Traumatology and Orthopaedics of the 2nd TMA Clinic in 2014–2016 years. All these patients underwent diagnostic arthroscopy of KJ. Laboratory tests included enzyme-linked immunosorbent assay (ELISA) for TORCH infection, a polymerase reaction (PCR), determination of a rheumatic factor in synovial fluid and blood before and after treatment, arthroscopy of the joint.

**Results:** In arthroscopic examination in the acute phase (early period) of ReA, dull SM, vasodilation, and oedema are revealed, which is accompanied by an increase in the production of turbid synovial fluid (SF). On the surface of SM there are sections of fibrin filaments, expansion and hyperemia along the vessels. In the long-term (subacute phase) these violations partially disappear. The surface of the synovium can again become single-rowed, with moderate hyperemia of the vessels. The deposits of fibrin on the entire surface of SM can be significant. However, with reduced immunoreactivity of the organism, the reactive synovitis persists for a long time, and the chronic course of the pathological process leads to abundant deposits of fibrin masses and to the formation of villi in the form of large and flat petals. In some parts of the vascular vessels are pale, accompanied by disorganisation of the collagen frame of SM, which directly affects the cells of the articular cartilage.

**Conclusions:** Thus, reactive urogenital arthritis due to the persistence of an infectious agent is characterised by the polymorphism of the damage to the joint and cartilage of the joint. The arthroscopic changes revealed at various stages of the inflammatory process reflect the reactivity of the pathological process and determine the extent of the lesion. Arthroscopic examination of biopsy specimens of SM and cartilage allows to determine the dynamics of the disease, the degree of lesion, evaluate the effectiveness of the preventive and therapeutic measures being carried out, and also to determine the indications for joint synovcapsulectomy.

#### AB0100 NEUROGENIC INFLAMMATION CHARACTERISED BY NERVE GROWTH FACTOR, TRKA AND SUBSTANCE P IS PREVALENT IN HUMAN FACET JOINT OSTEOARTHRITIS

M.F. Seidel<sup>1</sup>, J. Geurts<sup>2</sup>, N. Busso<sup>3</sup>, V. Chobaz<sup>3</sup>, T. Hügler<sup>3</sup>. <sup>1</sup>*Rheumatology, Schmerzlinik Basel*; <sup>2</sup>*Spine Surgery, University Hospital of Basel, Basel*; <sup>3</sup>*Rheumatology, University Hospital Lausanne (CHUV), Lausanne, Switzerland*

**Background:** Facet joint osteoarthritis (FOA) is a frequent cause of chronic low back pain and spinal stenosis. Neuron-derived molecules regulate pain sensation and inflammation. Nerve growth factor (NGF) is one of the most important mediators for this mechanism that is termed neurogenic inflammation.<sup>1</sup> Among many other effects, it regulates substance P (SP) expression as pivotal downstream peripheral pro-inflammatory molecule. Consequently, NGF inhibitors (NGFi) as a novel class of pain medication have shown significant efficacy in OA and to some extent also low back pain. However, it is unknown which tissue compartments in facet joints are involved in NGF signalling.

**Objectives:** To determine expression patterns of NGF, its high affinity transmembrane tyrosine kinase A (TrkA) receptor and SP in cartilage, subchondral bone marrow and capsular tissues of facet joints (FJ).

**Methods:** Dissected human FOA specimens of six donors were examined. OA severity was graded on HE-stained tissue sections. NGF, TrkA and SP expression was evaluated by immunohistochemistry with monoclonal antibodies. Similarly, new bone formation was assessed by staining for osteocalcin.

**Results:** FJ had low (n=2), high (n=2) and intermediate (n=2) inflammatory bone marrow infiltrates. NGF was strongly expressed in capsular tissue (figure, 40x),

focally in degenerated cartilage and differentially in FJ with active bone marrow infiltrates. TrkA was primarily found in all bone marrows and capsular tissues but not in cartilage. TrkA expression colocalized with osteocalcin in subchondral bone, indicating an association with new bone formation. SP strongly positive cells were found in the bone marrow, cartilage and synovial tissue of all FJ.

Abstract AB0100 – Figure 1

**Conclusions:** Here we define for the first time tissue compartments of the NGF axis in human FOA. The findings indicate that neurogenic inflammation is prevalent in different compartments of FOA. Based on these data NGFi might be efficient by targeting inflamed joint capsule or subchondral bone marrow as a source of pain. NGFi may thus have an impact on bone remodelling. Further studies are needed to more precisely examine this mechanism.

#### AB0101 MESENCHYMAL STEM CELLS DERIVED FROM BONE MARROW, UMBILICAL CORD AND ADIPOSE TISSUE DO NOT HAVE THE SAME EFFECT ON HUMAN OSTEOARTHRITIC CARTILAGE

N. Alaaeddine<sup>1</sup>, N. saliba<sup>2</sup>, M. moussa<sup>3</sup>, G. hilal<sup>3</sup>, C. khaili<sup>3</sup>, G. haykal<sup>3</sup>.

<sup>1</sup>CRCHUM, Lab of Cellular and Molecular Immunology, Montreal, Canada;

<sup>2</sup>Regenerative and Inflammation lab, Hotel Dieu de France; <sup>3</sup>Regenerative and Inflammation Lab, Laboratory of Regenerative Medicine, Faculty of Medicine, St. Joseph University, Beirut, Lebanon

**Background:** Osteoarthritis is a chronic debilitating disease characterised by degeneration of cartilage, synovitis and osteophytes formation.<sup>1</sup> This disease does not only affect aged people but it afflicts also young athletes where until today no medications has proven efficacy in stopping the progression of the disease and/or regenerate the loss of cartilage.<sup>2</sup> Recently cell therapy has attracted attention in many medical fields and especially in rheumatology and orthopaedic specialty. Stem cells due to their differentiation capacity, trophic and paracrine effects have been shown to serve as promising new modality in treating osteoarthritis.<sup>3,4</sup>

**Objectives:** Our objective in this study is to investigate the effect and mechanism of action of the three sources of stem cells; bone marrow derived stem cells (B-MSC), adipose derived stem cells (A-MSC) and umbilical cord stem cells (U-MSC) on osteoarthritic chondrocytes.

**Methods:** Mesenchymal stem cells were isolated from bone marrow, adipose tissue and umbilical cord from 5 different donors respectively and cocultured with human osteoarthritic chondrocytes obtained from 5 patients undergoing total knee arthroplasty. The effect autophagy was determined using flow cytometry analysis. Quantitative polymerase chain reaction (qPCR) and ELISA were used to measure the changes in the major factors playing a role in OA such as (a disintegrin and metalloproteinase with thrombospondin motifs-5(ADAMTS-5), Metalloproteinases (MMP-3, MMP13), tissue inhibitor of metalloproteinases (TIMP-1–2–3), Collagen, Cox-2, Il-6, the regulators of autophagy FOXO1, FOXO3, and LC3II and Beclin I in the tissues and cocultured media.

**Results:** In our study we found that the three stem cells sources increased significantly the proliferation of chondrocytes, and increased autophagy via increasing

Beclin 1 and LC3II, along with its regulators FOXO1, FOXO3 in human osteoarthritic chondrocytes with  $p < 0.05$ . Furthermore, the three sources of stem cells caused a dose dependent significant decrease in MMP-3, MMP-13, ADAMTS-5, IL-6, CCL20 and COX-2 with  $p < 0.05$ . Aggregan, collagen, TIMPs were also significantly increased by the co-culture of A-MSC, B-MSC, U-MSC.

**Conclusions:** These results suggest that stem cells could be a promising therapeutic target for the treatment of osteoarthritis.

#### THE GINGER DERIVATIVE 6-SHOGAOL AS A TREATMENT IN OSTEOARTHRITIS. MODULATION OF CHONDROCYTE HYPERTROPHY AND MATRIX CALCIFICATION

P. Gratal, A. Lamuedra, A. Mediero, G. Herrero-Beaumont, R. Largo. IIS-Fundación Jiménez Díaz UAM, Madrid, Spain

**Background:** Osteoarthritis (OA) is a complex joint disease characterised by a progressive loss of articular cartilage (AC), synovial inflammation and subchondral bone alterations. The latest theories of OA pathogenesis implicate the interplay between mechanical damage and chronic inflammation that has been associated to the activation of the innate immune system, intricately involved in the development of this low-grade inflammation. During the course of OA, Toll like receptor (TLR) activation has been related to the release of cytokines and inflammatory mediators, which further aggravate synovitis and AC damage.<sup>1</sup> In this scenario, hyaline chondrocytes seem to acquire a hypertrophic-like phenotype associated to AC degradation. 6-shogaol (6S), an effective anti-inflammatory Ginger derivative, is able to inhibit TLR4-mediated innate immune responses.<sup>2</sup>

**Objectives:** Our aim was to study the therapeutic benefit of 6-shogaol studying its anti-inflammatory effects in an OA mice model, and in the modulation of hypertrophic markers in chondrocyte cultures.

**Methods:** C57BL/6 male mice were randomly assigned to two groups: control (n=7) and OA (n=17). OA was induced by transection of the medial menisco-tibial ligament. Nine OA mice started receiving 6S (15 mg/kg/day; OA +6S) since surgery. After 8 weeks, animals were euthanized and joints were collected. Chondrogenic differentiation was induced *in vitro* in the pre-chondrogenic cell line ATDC5 in presence or absence of  $5 \times 10^{-6}$  M 6S. Gene expression of hypertrophic markers, as well as mineralization and proteoglycan synthesis were determined.

**Results:** Both synovial inflammation and AC damage were more severe in OA animals (Control:  $0.1 \pm 0.1$ ; OA:  $3.0 \pm 0$ ;  $p < 0.005$ , and Control:  $0.5 \pm 0.2$ , OA:  $5.4 \pm 0.6$ ;  $p < 0.005$ , respectively) with a significant reduction in OA+6S animals ( $2.4 \pm 0.2$ ;  $p < 0.05$  and  $2.6 \pm 0.5$   $p < 0.01$  vs. OA, respectively). Collagen X and MMP13 immunohistochemistry showed an increase in the AC of OA and OA-6S mice, while a significant reduction was found in 6S-treated mice (ColX: Control:  $0.13 \pm 0.03$ , OA:  $0.93 \pm 0.1$ ; OA-6S:  $0.43 \pm 0.1$ ;  $p < 0.05$  and MMP13: Control:  $0.35 \pm 0.1$ , OA:  $0.68 \pm 0.1$ , OA-6S:  $0.28 \pm 0.07$ ,  $p < 0.05$ ). Similar results were found in the synovium and meniscus for these two markers. 6S was able to significantly inhibit the expression of Collagen X, Ihh and MMP13 in ITS-stimulated cells after 14 and 21 days of culture. Furthermore, 6S prevented the increase in mineralization and proteoglycan synthesis in ITS-stimulated ATDC5 cells after 14 days of culture ( $p < 0.05$ ), as seen by Alizarin red and Alcian blue staining, respectively.

**Conclusions:** Our results showed that 6S significantly prevented cartilage degradation and synovial inflammation, in parallel to a reduction in the presence of hypertrophic markers in the cartilage of OA mice. *In vitro*, 6S inhibited the chondrogenic differentiation of ATDC5 cells. These results suggest that 6S could work as a good treatment in OA both inhibiting differentiation markers and reducing the severity of joint damage in an OA murine model.

### ESTABLISHMENT OF A HUMAN INDUCED PLURIPOTENT STEM CELL-LINE FROM PATIENTS WITH HAND OSTEOARTHRITIS

R. Castro-Viñuelas<sup>1</sup>, C. Sanjurjo-Rodríguez<sup>1</sup>, M. Piñeiro-Ramil<sup>1</sup>, T. Hermida-Gómez<sup>2</sup>, I.M. Fuentes-Boquete<sup>1</sup>, F.J. De Toro-Santos<sup>1</sup>, F.J. Blanco-García<sup>3</sup>, S. M. Díaz-Prado<sup>1</sup>. <sup>1</sup>Biomedical Sciences, Medicine and Physiotherapy, University of A Coruña; <sup>2</sup>Unidad de Bioingeniería Tisular y Terapia Celular (GBTTC-CHUAC). Grupo de Investigación en Reumatología; <sup>3</sup>Grupo de investigación en Reumatología, Instituto de Investigación Biomédica de A Coruña, A Coruña, Spain

**Background:** To date, there is no drug able cure such a prevalent disorder as it is hand osteoarthritis (OA). Cell therapies using stem cells have emerged as a promising strategy to explore and develop new treatments. Specifically, induced pluripotent stem cells (iPSc) are considered ideal tools not only for this purpose, but also for modelling the disease. The advantages of using an established iPSc line are unlimited cell source with regeneration capacity and chondrogenic differentiation potential. However, there are not many studies published generating iPSc from patients with hand OA.

**Objectives:** The aim of this study has been to generate an iPSc-line from human fibroblasts obtained from patients with radiographic hand OA, which can be useful for drug discovery, disease modelling and regenerative medicine applications.

**Methods:** Patients with radiographic hand OA and a healthy control were selected for the study. Using the explant culture technique, fibroblasts from 3 mm skin biopsies of these patients were isolated. These cells were histologically characterised and positivity for fibroblast markers was quantified. These cells were also karyotyped in order to confirm that chromosomal abnormalities did not exist before reprogramming. Four transcriptional factors were used for the reprogramming process: Oct4, Sox2, Klf4 and c-Myc. These were delivered using a non-integrative methodology that involves the use of Sendai virus. Cell lines obtained were clonally expanded over 20 passages and characterised for pluripotency markers by immunohistochemistry and RT-PCR, before and after reprogramming (figure 1). The best two clones of each one of the patients were selected according to the expression of the pluripotency markers to establish the cell-line.

**Results:** Cells were isolated from skin biopsies of two patients with radiographic hand OA and one healthy donor. Histological and immunohistochemical analyses showed that the 85%–95% of cells in the culture were fibroblasts, which presented a normal karyotype: 46, XX. Three weeks after reprogramming, embryonic stem cell-like colonies emerged in culture. These cells were positivity stained for alkaline phosphatase activity and the pluripotency markers Tra1–81 and Nanog. Alkaline phosphatase staining shows in blue the colonies correctly reprogrammed. Molecular analyses showed high relative expression levels of the endogenous pluripotency associated genes OCT4, SOX2, KLF4, NANOG and CRIPTO in the iPSc, but not in the no-reprogrammed fibroblasts. No presence of Sendai Virus-related genes was detected.

Abstract AB0103 – Figure 1

### CARTILAGE-LIKE TISSUE GENERATION BY 3D-BIOPRINTING OF INDUCED PLURIPOTENT STEM CELLS IN A MODIFIED NANOCELLULOSE/ALGINATE BIOINK

R. Castro-Viñuelas<sup>1</sup>, A. Forsman<sup>2</sup>, E. Karabulut<sup>3</sup>, E. Romberg<sup>3</sup>, C. Brantsing<sup>2</sup>, M. Brittberg<sup>4</sup>, A. Lindahl<sup>2</sup>, P. Gatenholm<sup>3</sup>, S. Simonsson<sup>2</sup>. <sup>1</sup>Biomedical Sciences, Medicine and Physiotherapy, University of A Coruña, A Coruña, Spain; <sup>2</sup>Clinical Chemistry and Transfusion Medicine, Institute of Biomedicine at Sahlgrenska Academy, University of Gothenburg; <sup>3</sup>Chemistry and Chemical Engineering, 3D Bioprinting Center, Chalmers University of Technology, Gothenburg; <sup>4</sup>Cartilage Repair Unit, University of Gothenburg, Region Halland Orthopaedics, Kungsbäck Hospital, Kungsbäck, Sweden

**Background:** Today, several hundreds of million people all over the world are suffering from different joint disorders; like osteoarthritis (OA). Further, traumatic cartilage lesions can develop into OA. Recent studies indicate that human-derived induced pluripotent stem cells (iPSCs) can be 3D bioprinted and directed to form cartilage-like tissue, thus offering new approaches to treat cartilage lesions.<sup>N-guyen et al. 2017</sup> The advantages of using an established iPSc line are unlimited cell source with regeneration capacity and chondrogenic differentiation potential.

**Objectives:** The aim of this study was to improve the generation of cartilage-like tissue when 3D bioprinting of iPSCs by using molecularly modified nanocellulose/alginate bioink to resemble natural environment found in the tissue.

**Methods:** In this study the chondrocyte-derived iPSc line "A2B" was used (Borestrom et al. 2014). These cells were bioprinted in combination with a modified nanocellulose and alginate bioink. Constructs obtained after the 3D bioprinting were cultured in chondrogenic medium in order to stimulate chondrogenic differentiation. Cell number and viability inside the prints was studied and histological analyses of the 3D printed constructs were performed. Furthermore, expression of pluripotency and chondrogenic specific genes was assessed by Taqman qPCR before and after differentiation.

**Results:** After 3D bioprinting high cell viability was found inside the constructs. 3D printed constructs were positively stained for alcian blue van gieson (AB-vG) staining, showing proteoglycans presence inside the prints (figure 1B). Molecular analyses showed high relative expression levels of the pluripotency-related gene Oct4 before starting the differentiation protocol. Cells inside the constructs express chondrogenic specific genes, such as collagen type 2 and Sox9 after 6 weeks of differentiation. Moreover, 3D printed constructs showed cartilage-resembles (figure 1A).

Abstract AB0104 – Figure 1

**Conclusions:** The 3D printing of the iPSc and the *in vitro* generation of cartilage-like tissue was successfully achieved using the modified nanocellulose/alginate bioink. This approach could be use in the future to model OA disease and to perform screenings of different therapeutic compounds.

**AB0105** EFFECTS OF CARRAGEENAN INDUCED SYNOVITIS ON JOINT DAMAGE AND PAIN IN A RAT MODEL OF KNEE OSTEOARTHRITIS

S. Ashraf, P. Mapp, D.A. Walsh. *Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, UK*

**Background:** Knee osteoarthritis (OA) is associated with ongoing pain and joint damage that can be punctuated by acute flares of pain and inflammation. Acute synovitis in normal knees might resolve without long-term detriment to joint function.

**Objectives:** We hypothesised that osteoarthritis is associated with impaired resilience to acute inflammation.

**Methods:** We induced synovitis by intra-articular injection of carrageenan into rat knees with or without meniscal transection-induced OA, and measured synovitis, weightbearing asymmetry (an index of pain behaviour), and joint damage up to 35 days after OA induction (23 days after carrageenan-injection).

**Results:** Intra-articular injection of carrageenan was followed by weightbearing asymmetry for 1 week, synovitis, indicated by a transient increase in knee diameter for 2 days after injection, and a more sustained (through day 23) increase in synovial macrophages, endothelial cell proliferation and vascular density compared with naïve controls. Meniscal transection was followed by weightbearing asymmetry and histological evidence of OA through day 35. Carrageenan-injection in OA knees was followed for 2 days by increased weightbearing asymmetry compared either to OA knees, or to carrageenan-injected, SHAM-operated knees. OA structural damage and synovitis at day 35 were greater after carrageenan injection on day 12 compared to saline-injected, MNX-operated knees, and compared to carrageenan-injected, SHAM-operated knees. Carrageenan injection alone did not induce OA in SHAM-operated knees.

**Conclusions:** OA knees were more sensitive to pain behaviour, inflammation and structural damage following an episode of acute inflammatory pain flare than were non-arthritic knees. Preventing inflammatory flares may be particularly important in preventing symptoms and long term joint damage in OA.

**AB0106** FIBRIN-TRIGGERED CHONDROSYNOVIAL ADHESION AS A NOVEL MECHANISM OF CARTILAGE DAMAGE IN RHEUMATOID ARTHRITIS

S. Nasi<sup>1</sup>, V. Chobaz<sup>1</sup>, E. Straden<sup>1</sup>, J. Degen<sup>2</sup>, N. Busso<sup>1</sup>, A. So<sup>1</sup>, T. Hügle<sup>3</sup>. <sup>1</sup>DAL, CHUV, Lausanne, Switzerland; <sup>2</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, USA; <sup>3</sup>DAL, CHUV, Lausanne, Switzerland

**Background:** Synovial pannus infiltration and inflammatory cytokines production are the main factors responsible for cartilage damage in rheumatoid arthritis (RA). The crosstalk between inflammation and coagulation further amplifies and maintains chronic inflammation. Although synovial extravascular fibrin deposits in synovial fluid and synovial membranes being hallmarks of RA, there are no reports on direct fibrin deposition is widespread in RA, little is known about fibrin deposition and its relation to cartilage damage in RA.

**Objectives:** To investigate if fibrin deposition occurs in murine and human RA cartilage, and its relationship with cartilage degradation. Moreover, to determine the possible mechanism by which fibrin could play a role in the pathogenesis of RA.

**Methods:** Full-thickness cartilage explants were obtained from RA patients undergoing total knee replacement. Immunohistochemistry was performed on paraffin sections to study fibrin deposition, while Safranin-O staining was used to investigate cartilage damage. An *in vitro* model of chondrosynovial adhesion was established using primary human RA synoviocytes seeded on human RA cartilage explants. Adherent synoviocytes to cartilage were evaluated on H and E-stained histological sections and fibrin immunohistochemistry was performed on adjacent sections. Antigen induced arthritis (AIA) was induced in wild-type (WT) and fibrinogen knock-out mice and paraffin sections of knee joints assessed for fibrin deposition, cartilage damage, and chondrosynovial adhesion.

**Results:** In human RA cartilage, the extent of fibrin deposits positively correlated with the degree of cartilage degradation (figure 1). In WT mice, fibrin deposition was preferentially found on damaged cartilage and on cartilage areas in direct contact with synovial membrane (i.e chondrosynovial adhesions) (figure 2). In contrast, cartilage degradation and chondrosynovial adhesion were significantly lower in fibrin deficient mice (figure 2). Moreover, loss of superficial cartilage layers stained with fibrin was observed in regions of chondrosynovial adhesion (figure 3). Finally, in the *in vitro* model, synoviocytes were found to adhere to human OA cartilage, especially in severely damaged and fibrin-rich areas (figure 4).

**Abstract AB0106 – Figure 1**

**Conclusions:** Our results demonstrate that fibrin deposition on cartilage is highly associated with chondrosynovial adhesion and subsequent cartilage erosion in RA. We hypothesise that fibrin mediates chondrosynovial adhesion especially during joint resting periods (i.e night-time), leading to mechanical stripping of superficial cartilage layers following motion.

**AB0107** INFLUENCE OF COBALT (II) + AND CHROMIUM (III)-IONS ON BONE FORMATION IN HUMAN OSTEOBLAST-LIKE CELLS IN-VITRO

S. Drynda<sup>1,2</sup>, A. Drynda<sup>1</sup>, J. Kekow<sup>2</sup>, C.H. Lohmann<sup>1</sup>, J. Bertrand<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, University of Magdeburg, Magdeburg; <sup>2</sup>Clinic of Rheumatology, University of Magdeburg, Vogelsang, Germany

**Background:** Healthy bone is a result of the homeostasis between bone formation and resorption. The process of bone formation includes two major functions, which are the secretion of the organic matrix (mainly type I collagen) and the deposition of minerals into this matrix. This function of osteoblasts can be affected by numerous factors, as hormones, inflammation, mechanical load and other external stimuli.

In patients with artificial joint replacements, the release of particles or ions of cobalt and chromium ions from arthroplasties may exert local effects on the periprosthetic tissue leading to prosthesis loosening.

**Objectives:** It was the aim of the study to analyse the effect of Co<sup>2+</sup> and Cr<sup>3+</sup> ions on the capability of osteoblast-like cells to form bone.

**Methods:** Two human osteoblast-like cell lines MG63 and SaOs-2 were used to study the influence of Co<sup>2+</sup> and Cr<sup>3+</sup> ions on matrix secretion and mineralization. Cells (3 × 10<sup>5</sup>) were seeded in 2 ml DMEM (10% FCS) onto 12 well plates and stimulated with CoCl<sub>2</sub> and CrCl<sub>3</sub> in concentrations between 50–250 μM for 24 hours. Total RNA was extracted and changes of expression levels of collagen1A1 were analysed by real-time PCR. Secretion of collagen1 was analysed by Sirius Red staining (0.1% in water-saturated picric acid). After extraction of dye with 0.1N NaOH the absorption was measured at 540 nm.

For mineralization the cells were cultured for up to 4 weeks in DMEM (10% FCS) supplemented with 0.2 mM ascorbic acid, 10 nM dexamethasone and 10 mM glycerophosphate and different concentrations of Co<sup>2+</sup> and Cr<sup>3+</sup>. Calcium deposits were detected by 1% Alizarin Red S staining (pH 4.1), for quantification the dye was extracted using cetylpyridinium chloride, the absorption was determined at 562 nm.

**Results:** We observed that SaOs-2 cells, the more differentiated cells compared to MG63, exhibited a high potential for mineralization but secreted low amounts of collagen type 1. In contrast, MG63 cells produced high amounts of collagen1 and had a low potential for mineralization. When cultures were treated with Co<sup>2+</sup> and

Cr<sup>3+</sup>, we found that bivalent cobalt ions and trivalent chromium ions had different effects on osteoblasts. While Co<sup>2+</sup> reduced the secretion of collagen type 1 in osteoblast-like cells, Cr<sup>3+</sup> did not impair the collagen type 1 production. The secretion of this protein was partially attributable to a reduced gene transcription. In contrast, the mineralization was not impaired by Co<sup>2+</sup>. However, Cr<sup>3+</sup> at a concentration of 250 µM resulted in a decrease of mineralisation by 89% compared to controls. Even at the concentration of 50 µM a reduced mineralization by 34% was observed. The increase of the phosphate source resulted in an increased mineralization, suggesting that the capture of phosphate by Cr<sup>3+</sup> (formation of CrPO<sub>4</sub>), which is required for the mineralization could explain the inhibitory effect of chromium.

**Conclusions:** Our data suggest that Co<sup>2+</sup> and Cr<sup>3+</sup> ions affect bone formation at various stages of differentiation. While Co<sup>2+</sup> ions impair the formation of the bone organic matrix, Cr<sup>3+</sup> ions affect the deposition of inorganic minerals. Whether the inhibitory effect of chromium ions on the mineralization is caused by soluble Cr<sup>3+</sup> ions itself or by solid CrPO<sub>4</sub> needs to be clarified in further studies.

## Rheumatoid arthritis – etiology, pathogenesis and animal models

### AB0108 RELATIONSHIP BETWEEN PROGRANULIN AND MUSCULOSKELETAL ULTRASOUND IN RHEUMATOID ARTHRITIS

A.A. Negm<sup>1,2</sup>, M.H. Nassr<sup>3</sup>, H.M. Fathi<sup>3</sup>, N.A. Fouad<sup>3</sup>, O. Zaki<sup>4</sup>, S.H. Senara<sup>3</sup>.  
<sup>1</sup>Rheumatology unit, Dubai Hospital, Dubai Health Authority, Dubai, United Arab Emirates; <sup>2</sup>Rheumatology, Faculty of Medicine, Al-Azhar University, Cairo; <sup>3</sup>Rheumatology, <sup>4</sup>Clinical Pathology, Faculty of Medicine, Fayoum University, Fayoum, Egypt

**Background:** Progranulin (PGRN) is a pluripotent, secretory growth factor, mainly present in cells of the epithelium, central nervous system and immune system. PGRN known to directly regulate regulatory T cells and recently found to be upregulated in Rheumatoid Arthritis (RA) and related to its activity. No attempts was made to explore the relation between PGRN and RA activity measured by clinical and Ultrasound score (USS).

**Objectives:** To explore PGRN levels in the serum of patients with RA, and its correlation with disease activity assessed clinically combined by ultrasonography (USS).

**Methods:** RA patients: 52 RA patients were included in this study. They were consecutively recruited from the outpatient clinic of Rheumatology Department for regular follow-up at Fayoum University Hospitals. Patients were classified according to the 2010 ACR/EULAR criteria. Control group: 20 age and sex matched healthy volunteers were recruited as controls for level of serum PGRN. Informed consent was obtained from all patients and controls for inclusion in the study.

All patients were subjected to full history taking, and clinical examination. Assessment of disease activity by modified DAS-28 score. Progranulin is measured by an ELISA Kit (Elabscience), this kit uses sandwich-ELISA as the method.

The ultrasound examination was performed with GE LOGIQ 7 PRO equipment using a linear transducer with 18 MHz frequency. The patients were examined according to the German US7 score in 7 joint areas.

**Results: Demographic and clinical data of the RA group:** Females represents 90.4% (47 of 52). Age ranged from 21–72 years, mean age was 42.8±10.4 years. Disease duration ranged from 1 to 30 years, median 4 years. Their mean ESR level was 36.4±16 (Range: 5–70). The median of Ultrasound score assessment was 8 while the mean was 8.73±6.9 (Range: 0–33).

**Serum PGRN concentrations in RA patients and healthy controls:** The median of serum PRGN levels in RA patients was 65 ng/ml (mean, 92.54±45.4) which is much higher in comparison to those in normal controls, median 31 ng/ml (mean, 32.74±9.2); the difference showed high statistical significance, p<0.001.

**Correlation analysis:** The relationships between PRGN levels and other continuous variables were analysed using Spearman's rank correlation. There was high statistically significant correlation between PRGN level and USS score (r=0.37, p=0.006). Also, there was high statistically significant correlation between PRGN level and ESR (r=0.67, p<0.000) and between PRGN level and DAS 28 (r=0.74, p<0.000). There was high statistically significant correlation between USS score and ESR level (r=0.54, p<0.000) and between USS score and DAS 28 (r=0.68, p<0.000).

**Conclusions:** The serum Progranulin levels were higher in the serum of RA patients than age and sex matched controls. It is positively correlated with diseases activity measured by DAS 28, ESR and Ultrasound activity measured by

German US7 score. Serum PGRN levels may be a useful biomarker in RA disease. Ultrasound positively correlated with ESR and DAS 28 in our cohort of RA patients.

### AB0109 CHARACTERISATION AND COMPARISON OF SERUM BIOMARKERS IN PATIENTS WITH RHEUMATOID ARTHRITIS VERSUS OSTEOARTHRITIS USING MASS SPECTROMETRY

A. Ciurciaru<sup>1,2</sup>, C. Butnaru<sup>3</sup>, M. Bojinca<sup>1</sup>, S. Petrescu<sup>4</sup>. <sup>1</sup>Department of Internal Medicine and Rheumatology, "Dr. I. Cantacuzino" Clinical Hospital; <sup>2</sup>Department Molecular Biology of the Cell; <sup>3</sup>Department of Bioinformatics and Structural Biochemistry; <sup>4</sup>Institute of Biochemistry, Romanian Academy, Bucharest, Romania

**Background:** There is increasing interest in biomarkers in medicine, especially for their use as a diagnostic tool and in disease outcome prognosis. Rheumatoid arthritis (RA) is a chronic autoimmune disease with important debilitating outcome potential, therefore a biomarker panel may improve early diagnosis meaning better therapeutic management and lower social costs. Recently, mass spectrometry has emerged as one of the leading methods to identify new biomarkers for different pathologies as well as being able to determine their potential interactors in their cellular pathway.

**Objectives:** To characterise biomarkers using mass spectrometry, from sera of patients with RA and make a comparison between RA, osteoarthritis (OA) and healthy controls.

**Methods:** Blood was collected from 26 subjects, 12 patients with RA, 12 patients with OA, and 2 HC, centrifuged and sera was collected in dedicated tubes. Sera were separated by SDS-Page electrophoresis and stained with Coomassie staining. The samples were subjected to in gel digestion followed by LC/MS analysis. The obtained spectra were searched with Proteome Discoverer v1.4 using SEQUEST algorithm.

**Results:** A total of 985 proteins were identified, from which 323 were specific to the RA study group and 159 were characteristic to the OA group. Prevalent peptides found in the RA group were EGF-containing fibulin-like extracellular matrix protein 2, isoform DeltaL1 of lactotransferrin, BPI fold-containing family B member 1 and isoform 2 of BPI fold-containing family A member 1. In the OA study group there was a prevalence in homeobox protein TGIF1, major facilitator superfamily domain-containing protein 9, methyltransferase-like protein 23, a fragment of the salivary acidic proline-rich phosphoprotein, serine/threonine-protein phosphatase 4 regulatory subunit 1, zinc finger protein 229.

**Conclusions:** Our results show a prevalence of peptides linked to cell migration, proliferation and activation in the RA sera as compared to peptides related to cell turnover and tissue senescence observed in OA sera. We believe further mass spectrometry studies of biomarkers in larger cohorts to be a promising tool for diagnosis and outcome prognosis in RA.

### AB0110 SERUM AND SALIVARY IGA1 AND IGA2 ACPA SUBCLASSES IN ESTABLISHED RHEUMATOID ARTHRITIS AND ASSOCIATIONS TO SMOKING

A. Svärd<sup>1</sup>, K. Roos Ljungberg<sup>1,2</sup>, A. Kastbom<sup>2</sup>, T. Skogh<sup>2</sup>, K. Martinsson<sup>2</sup>. <sup>1</sup>Center for Clinical Research Dalarna, Falun; <sup>2</sup>Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden

**Background:** A prevailing hypothesis regarding the pathogenesis of rheumatoid arthritis (RA) involves an association between mucosal immunity and the development of RA. A pathogenetic role for antibodies against citrullinated peptides (ACPA) is assumed, and there are indications of mucosal immunisation in the lungs, the oral mucosa and the intestinal mucosa preceding overt RA.<sup>1</sup>

IgA antibodies are produced both locally, at mucosal membranes, and systemically. Among the two IgA subtypes, IgA1 dominates in serum IgA2 in mucosal secretions.

We have previously reported the presence of ACPA of IgA isotype in both serum and saliva of RA patients,<sup>2</sup> and that IgA ACPA is associated with cigarette smoking.<sup>3</sup>

**Objectives:** To investigate the presence and levels of mucosal and circulating IgA1 and IgA2 isotypes of ACPA in patients with RA, and to investigate their association to cigarette smoking habits.

**Methods:** Patients with established RA, mean disease duration of 12.2 years (n=196), and healthy controls (n=101), included in the Secretary Antibodies in Rheumatoid Arthritis (SARA) study were analysed by enzyme immunoassays regarding total IgA ACPA and the subclasses IgA1 and IgA2 ACPA in serum and saliva. The results are presented as delta-values of optical density (OD) between each IgA ACPA subclass and the corresponding arginine peptide.

**Results:** Serum IgA1 ACPA was detected in 44% of the RA patients and serum IgA2 in 39%. 10% of the RA patients had detectable salivary IgA1 and/or IgA2 ACPA. Both serum and salivary IgA2 levels were higher among smokers than never-smokers, while this association was not seen for IgA1 class antibodies.

**Abstract AB0110 – Table 1.** Levels of serum and salivary IgA anti-CCP subclasses among RA patients, comparing ever smokers and never smokers.

Antibody level	Smokers (n=85)	Never smokers (n=93)	T-test (p value)
Serum IgA aCCP, AU/mL (SD)	100 (211)	39 (59)	0.013
Serum IgA1 aCCP, AU/mL (SD)	101 (328)	33 (43)	0.061
Serum IgA2 aCCP, AU/mL (SD)	333 (745)	140 (156)	0.022
Salivary IgA aCCP* (SD)	0.31 (0.62)	0.21 (0.65)	0.271
Salivary IgA1 aCCP* (SD)	0.29 (0.55)	0.21 (0.46)	0.283
Salivary IgA2 aCCP* (SD)	0.24 (0.38)	0.14 (0.17)	0.026

aCCP=Antibodies to Cyclic Citrullinated Peptides, SD=Standard Deviation

\*Delta value between Optical Density (OD) value for CCP (Cyclic Citrullinated Peptide) and OD for CAP (Cyclic Arginine Peptide), the corresponding arginine peptide.

**Abstract AB0110 – Figure 1.** Levels of IgA anti-CCP subclasses in RA patients and controls.

**Conclusions:** In this study of patients with established RA, IgA2 ACPA but not IgA1 ACPA was associated to cigarette smoking. As IgA2 predominate over IgA1 in mucosal secretions, this finding strengthens the hypothesis that smoking via mucosal ACPA production is one pathway to develop RA.

#### AB0111 MEMBRANE TNF EXPRESSION ON MONOCYTES AND DIFFERENTIATION OF MONOCYTES INTO M2-M1 MACROPHAGES: 2 NEW BIOMARKERS OF RHEUMATOID ARTHRITIS

A. Paoletti<sup>1</sup>, G. Nocturne<sup>2</sup>, S. Bitoun<sup>1</sup>, E. Riviere<sup>1</sup>, J. Pascaud<sup>1</sup>, B. Ly<sup>1</sup>, X. Mariette<sup>1</sup>.  
<sup>1</sup>Service Rhumatologie, U1184 INSERM IMVA; <sup>2</sup>Service Rhumatologie, U1184 IMVA, Le Kremlin Bicetre, France

**Background:** Three monocyte subsets have been described based on their CD14 and CD16 expression profiles, the subpopulation CD14<sup>+</sup>CD16<sup>+</sup> being expanded in rheumatoid arthritis (RA) patients. Macrophages contribute *in situ* to the RA pathogenesis. They can display various states of activation or «

polarisation ». Two distinct states of polarisation for macrophages have been recognised: the “classically activated macrophage phenotype” (M1) and the “alternatively activated macrophage phenotype” (M2). To sum-up, M1 are considered to be pro-inflammatory and M2 to be regulatory and anti-inflammatory.

**Objectives:** Here, we have assessed monocytes subsets and their capacity of differentiation into M2 or M1 macrophages in RA patients and controls.

**Methods:** PBMCs were isolated and we first determined monocytes subpopulations and looked at expression of membrane TNF (mTNF). After negative selection of monocytes, Macrophages were Derived from Monocytes(MDM) by 7 days of culture in the presence of M-CSF (M2 differentiation) or GM-CSF (M1 differentiation). Expression of total macrophages markers (CD11b and CD71) and the M2 macrophage polarisation markers (CD163 and CD206) were evaluated.

**Results:** We have confirmed that the CD14<sup>+</sup>CD16<sup>+</sup> monocytes subset was expanded in RA patients. For the first time, we have demonstrated that mTNF expression was significantly increased only in monocytes in RA patients (CD14<sup>+</sup>: Mean 5.6% HD versus 10.6% RA, CD14<sup>+</sup>CD16<sup>+</sup>: Mean 3.3% HD versus 11.1% RA, CD16<sup>+</sup>: Mean 2.4% HD versus 6.3% RA). Moreover, mTNF expression on monocytes correlated with the activity of the disease assessed by DAS28 CRP (Spearman r 0.548 and p=0.0021\*). We have observed a significant decrease of macrophages induction by M-CSF in RA patients as shown by a decreased expression of CD11b-CD71 (Mean 87.2% HD versus 57.1% RA, P value \*\*\*\*). Among MDM, we have found a specific decreased level of M2 markers (CD206 Mean 78.1% HD versus 27% RA and CD163 56.2% HD versus 37.2% RA) suggesting an impaired maturation to M2 stage in RA patients.

**Conclusions:** Monocytes from RA patients have an increased expression of mTNF linked to activity of the diseases. RA patients have an impaired maturation of monocytes to M2 macrophages. This might suggest that RA monocytes have a propensity for preferential maturation towards a pro-inflammatory M1 phenotype thus contributing to synovial inflammation. Deeper characterisation of M1/M2 and effect of the different types of anti-TNF on this differentiation process are on-going and will be presented.

#### AB0112 PATHOGENETIC MECHANISMS IN EARLY RHEUMATOID ARTHRITIS: POSSIBLE CORRELATION BETWEEN TH17 AND TREG CELLS AND GUT MICROBIOTA STRUCTURE: A PILOT STUDY

M.P. Guzzo<sup>1</sup>, B. Lucchino<sup>1</sup>, G. Bonfiglio<sup>2</sup>, C. Barbatì<sup>1</sup>, M. Vomero<sup>1</sup>, B. Neroni<sup>2</sup>, C. Gioia<sup>1</sup>, A. Gagliardi<sup>2</sup>, C. Alessandri<sup>1</sup>, G. Valesini<sup>1</sup>, S. Schippa<sup>2</sup>, M. Di Franco<sup>1</sup>.  
<sup>1</sup>Department of Internal Medicine and Medical Specialities; <sup>2</sup>Department of Public Health and Infectious Diseases, Microbiology Section, Sapienza Università di Roma, Rome, Italy

**Background:** In Rheumatoid Arthritis (RA) pathogenesis T helper17 (Th17) and T regulatory cells (Treg) are largely represented.<sup>1</sup> Recent studies highlighted the role of intestinal mucosa environment in modulation of T cells function. The composition of gut microbiota influences the Th17/Treg cells balance and the host immune response,<sup>2</sup> so the exposure to deranged intestinal microbiota may be crucial in RA.

**Objectives:** The aim of the study was to compare Th17 and Treg cells and gut microbiota composition in patients with early RA (ERA) and in a control group (CG) at baseline and after treatment.

**Methods:** Currently, 10 ERA patients and 10 subjects belonging to the CG have been enrolled. All ERA patients were evaluated before (T0) and after 3 months (T1) of treatment with methotrexate (MTX) and glucocorticosteroids (GCS). Blood and faecal samples were collected. After PBMC isolation, staining with conjugated mAbs targeting specific surface and intracellular antigens (CD4 and CD25, IL-17 and FoxP3 respectively) have been used in order to distinguish Th17 and Treg cells. The composition of the faecal microbiota has been analysed by Next Generation Sequences on Illumina MiSeq platform, through 16S rDNA V3-V4 targeted sequencing.

**Results:** At T0, the percentage of Th17 cells was higher in patients than in the CG (p<0.0001) while Treg cells were higher in the CG (p=0.013). At T1, the total number of CD4<sup>+</sup> and Th17 cells was decreased (p=0.007, p=0.027) while the frequency of Treg cells increased (p=0.028). A normalisation of Treg cells, with frequencies comparable to CG, was present after treatment. Regarding gut microbiota, at phylum level no difference between patients at T0 and the CG were present but we observed a tendency to decrease in the frequency of Actinobacteria after therapy. Furthermore, the relative abundance of Actinobacteria correlated positively with the circulating levels of Th17 (p=0,012, r=0,59) and with the Th17/Treg at T0 (p=0,010, r=0,6), while Nitrospirae correlated positively with Treg (p=0,028, r=0,68) at T1. A significant increase of the relative abundance in the Lachnospiraceae family in patients at T1 compared with T0 (p=0,042) and CG (p=0,043) were noticed.

**Conclusions:** Our results highlight the presence of an imbalance between Th17 and Treg cells in patients with ERA. In agreement with literature,<sup>3</sup> MTX and GCS

influence on Th17 decreasing and Treg cells increasing in patients with ERA, so we can hypothesise that part of the clinical response is own to the improvement in T cells balance. Previous data<sup>4</sup> reported that Actinobacteria are strongly correlated with the production of IL-17 and a reduction of Nitrospirae has been associated to increased inflammatory responses and to gut permeability in mice.<sup>5</sup> Lachnospiraceae family play an important role in the maintenance of intestinal homeostasis.<sup>6</sup> The correlation between gut microbiota composition and Th17/Treg axis observed in our patients may suggest the involvement of some bacteria family in Th17/Treg cells balance in the lamina propria of RA patients treated with MTX, even in the early phases of the disease.

Belmonte<sup>1</sup>, S. Manrique-Arija<sup>1</sup>, A. Fernández-Nebro<sup>2</sup>. <sup>1</sup>UGC de Reumatología del Hospital Regional Universitario de Málaga (HRUM), Instituto de Investigación Biomédica de Málaga (IBIMA), Universidad de Málaga; <sup>2</sup>UGC de Reumatología del Hospital Regional Universitario de Málaga (HRUM), Instituto de Investigación Biomédica de Málaga (IBIMA), Departamento de Medicina y Dermatología, Universidad de Málaga, Málaga, Spain

**Objectives:** To study the effectiveness of the use of probiotics in the control of inflammatory activity of patients with rheumatoid arthritis and analyse its effect on their metabolic profile.

**Methods:** A bibliographic search was carried out in Medline and Embase. The search strategy included the terms MeSH and the free text of "lactobacillus", "bacillus", "probiotics" and "rheumatoid arthritis." The search strategies were carried out by two authors, which were included according to the type of studies: meta-analysis, systematic reviews and clinical trials, depending on the type of participant: adults with RA who have received probiotics, the main outcome measures: changes in the Disease Activity Score (DAS28), Simplified Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI), as well as each of the parameters that constitute them: C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), visual analogue scale of the doctor and the patient (EVA), number of painful joints (NAD) and inflamed (NAI) and functional status by Health Assessment Questionnaire (HAQ) Secondary variables: number of adverse events and parameters of metabolic activity. The quality of the evidence was analysed following the guidelines of the Scottish Network of Intercollegiate Guidelines (SIGN).

**Results:** After the selection of 34 articles, 9 articles were finally included. All were randomised, double-blind, placebo-controlled clinical trials (RCTs) with a level of evidence between 1+ and 1++ and a recommendation grade of A and B. Seven CDs showed improvement in arthritis measurements. In Peltonen et al. observed a high rate of improvement in the experimental group than in the control group (3.1 vs 2, p=0.027). Mandel et al. they described improvement of the EVA in the experimental group (p=0.046). Zamani et al. they described an improvement in DAS28 (-0.3±0.4 versus -0.1±0.4, p=0.01). Vaghef-Mehrabany et al defined this improvement (p<0.01). Pineda et al. showed an improvement in HAQ at 3 months in the experimental group (from 0.97 to 0.80, p=0.02), although not in ACR20 (p=0.33). Allipour et al. found improvements in CRP between the two groups (mean [95% CI]=2.03 [0.54–3.51], p=0.009); NAD: (mean [95% CI]=0.72 [0.25, 1.19], p=0.003); NAI: (mean [95% CI]=0.351 [0.13, 0.58], p=0.003); EVA: (mean [95% CI]=16.71 [8.91, 24.50] p<0.001; DAS-28: (average [CI] 95%)=0.31 [0.02, 0.61], p=0.039) and in cytokine levels, Hatakka et al observed no significant improvement in the experimental group in HAQ, NAD and NAI, and Nenonen et al. Did not observe differences in DAS28. In the last, EC of Vaghef-Mehrabany of 2017 metabolic measures were evaluated without finding significant improvements. If an improvement in insulin resistance was observed as measured by the HOMA B index in the study by Zamani et al.

**Conclusions:** Treatment with probiotics seems to be effective in controlling the inflammatory activity of rheumatoid arthritis.

**Disclosure of Interest:** None declared

#### AB0114 MODULATION OF ENDOTHELIAL FUNCTION BY PROINFLAMMATORY CYTOKINES INVOLVED IN RHEUMATOID ARTHRITIS. FOCUS ON IL-17A, IL-20, IL-23 AND IL-9

P. Totoson<sup>1</sup>, D. Wendling<sup>2,3</sup>, C. Prati<sup>1</sup>, C. Demougeot<sup>1</sup>. <sup>1</sup>EA 4267 PEPITE « Pathologies et Epithéliums: Prévention, Innovation, Traitements, Evaluation»; <sup>2</sup>Service de Rhumatologie, CHRU Besançon; <sup>3</sup>EA 4266, Univ. Bourgogne Franche-Comté, Besançon, France

**Background:** Rheumatoid Arthritis (RA) is the most common inflammatory rheumatic disease, characterised by high circulating of pro-inflammatory cytokines. RA is associated with an increased cardiovascular risk secondary to the accelerated atherogenesis which is the consequence of endothelial dysfunction (ED)<sup>1</sup>. In addition to the well-known cytokines (TNF- $\alpha$ , IL-1 $\beta$  and IL-6), emerging data identified new cytokines such as IL-17A, IL-20, IL-23 and IL-9 as putative key-players of the pathogenesis of RA. To date, whether these cytokines might contribute to RA-associated endothelial dysfunction is not known.

**Objectives:** This study investigated the effect of IL-17A, IL-20, IL-23 and IL-9 on endothelium-dependent relaxation in response to acetylcholine (Ach) in rat aortic rings.

**Methods:** Experiments were conducted on thoracic aortic rings from male Lewis rats (11 week old), incubated for 1 hour or 24 hour at 37°C with 2 concentrations of each cytokine (IL-17A: 250 pg/ml and 10 ng/ml; IL-20: 500 pg/ml and 5 ng/ml; IL-23: 80 pg/ml and 10 ng/ml; and IL-9: 300 pg/ml and 10 ng/ml). Incubation with 10 ng/ml TNF- $\alpha$  was used as a positive control and with vehicle as negative control. At the end of the incubation period, endothelial function was studied by assessing concentration-response curves to Ach (10<sup>-1</sup>–1<sup>-4</sup>–4 mol/L) after phenylephrine (PE, 10–5 mol/L) or KCl (30 mmol/L)-induced contractions.

**Results:** As described in the literature<sup>2</sup>, a 24h- but not 1h-incubation with TNF- $\alpha$  reduced Ach-induced relaxation. The same result was obtained with IL-17A (10 ng/mL). By contrast, IL-20 did not change Ach-induced relaxation whatever the concentration and the incubation time. Impairment in vascular relaxation was observed after exposure to IL-9 (10 ng/mL), both after 1h- and more severely after 24h-incubation. As regards IL-23, an effect was observed only after 1 hour incubation and with high concentration.

**Conclusions:** Our data demonstrated that IL-17A, IL-23 and IL-9 but not IL-20 induced endothelial dysfunction, with different kinetics profiles. Among the cytokines evaluated, IL-9 exhibited the most important effect thus revealing a new putative role of this pleiotropic cytokine in RA-associated cardiovascular risk. Further studies are needed to confirm these data on animal models of diseases.

#### AB0115 PROPHYLACTIC AND THERAPEUTIC ACTIVITY OF ALKALINE PHOSPHATASE IN ARTHRITIC RATS: SINGLE AGENT ACTIVITY AND IN COMBINATION WITH METHOTREXATE

D.M. Chandrupatla<sup>1</sup>, C.F. Mollhoff<sup>2</sup>, W.I. Ritsema<sup>2</sup>, R. Vos<sup>2</sup>, E. Elshof<sup>2</sup>, T. Matsuyama<sup>3</sup>, P.S. Low<sup>4</sup>, R.J. Musters<sup>5</sup>, A. Hammond<sup>6</sup>, A.D. Windhorst<sup>2</sup>, A. A. Lammertsma<sup>2</sup>, C.J. van der Laken<sup>1</sup>, R. Brands<sup>7</sup>, G. Jansen<sup>1</sup>. <sup>1</sup>Amsterdam Rheumatology and Immunology Center; <sup>2</sup>Radiology and Nuclear Medicine, VU University Medical Center, Amsterdam, Netherlands; <sup>3</sup>Immunology, Kagoshima University, Kagoshima, Japan; <sup>4</sup>Chemistry, Purdue University, West Lafayette, USA; <sup>5</sup>Physiology, VU University Medical Center, Amsterdam, Netherlands; <sup>6</sup>Rheumatology, KIMS Hospital, Kent, UK; <sup>7</sup>AMRIF BV, Wageningen, Netherlands

**Background:** Alkaline phosphatase (AP) is a gate-keeper of innate immune system responses by detoxifying (dephosphorylating) inflammation triggering moieties (ITMs) released from endogenous and external sources<sup>1</sup> and maintaining physiological barriers.

**Objectives:** We examined whether AP's broad mechanism of action may serve as a safe therapeutic, either as single agent or combined with methotrexate (MTX), in rheumatoid arthritis (RA).

**Methods:** A rat model for RA was used with repeated intra-articular methylated bovine serum albumin (mBSA) injections in one knee ("arthritic" knee), the contralateral knee serving as internal control. Recombinant human AP (200 µg, s.c.) was administered twice (spaced 4 days) before mBSA injections (*prophylactic setting*) or after arthritis induction (4x, 2x/wk, *therapeutic setting*), or combined with MTX (0.3 mg/kg or 1 mg/kg, i.p.) in 4 rats/group. Plasma pharmacokinetics of AP in arthritic and healthy rats was monitored by colorimetric enzymatic assay. As an endpoint of AP/MTX treatment outcome, macrophage infiltration (marking arthritic conditions) in knee sections, liver and spleen was assessed by immunohistochemistry (ED1 and ED2-macrophage specific antibodies), immunofluorescence (macrophage marker; Folate Receptor-β, FRβ), and positron emission tomography (PET) scans and *ex vivo* tissue distribution with the macrophage tracer [<sup>18</sup>F] fluoro-PEG-folate targeting FRβ.

**Results:** After AP administration, both in healthy and arthritic rats, plasma AP levels increased over 1 hour to reach a maximum of 50%–70% above baseline. Increased plasma AP levels in healthy rats were retained for at least 4 hours, whilst in arthritic rats AP plasma levels steadily returned to baseline levels within this time frame, suggesting consumption of available AP by conjugating to its ITM substrates. Prophylactic and therapeutic schedules of AP treatment, either as single agent or in combination with MTX, were well tolerated. Both prophylactic and therapeutic AP markedly reduced synovial macrophage infiltration in arthritic knees (ED1; 3.5–4 fold, ED2; 3.5–6 fold), comparable with MTX treatment effects. AP/MTX combinations slightly improved on single agent effects. PET monitoring and *ex-vivo* tissue distribution studies corroborated the impact of AP, MTX and AP/MTX on reducing synovial macrophage infiltration. Beyond localised articular effects, AP also displayed systemic anti-inflammatory effects by a 2-fold reduction of ED1, ED2 and FRβ-positive macrophages in liver and spleen of arthritic rats.

**Conclusions:** AP as single agent and combined with MTX elicits local and systemic anti-arthritic activity in arthritic rats and appears promising as a new therapeutic compound against arthritic conditions.

#### ADIPOSE DERIVED STEM CELLS SUPPRESSED SYNOVIAL INFLAMMATION IN SKG/JCL MICE IN VIVO AND INFLAMMATORY CYTOKINE IN SYNOVIAL FIBROBLAST IN VITRO

H. Ueyama, T. Okano, K. Orita, H. Nakamura. *Orthopedics, Osaka City University, Osaka, Japan*

**Background:** Adipose derived stem cell (ADSC) is one of the stem cells produced by adipose tissue which can be collected easily and in large quantities. It has been reported the anti-inflammatory effect of ADSC in some disease models.<sup>1</sup> However, the effect of ADSC for synovitis such as rheumatoid arthritis (RA) is unknown.

**Objectives:** The aim of this study is to investigate the effects of ADSC for joint synovitis and cartilage degeneration in SKG/Jcl mice *in vivo* and the effects of ADSC for synovial fibroblast *in vitro*.

**Methods:** SKG/Jcl mice which developed auto-immune arthritis by adjuvant stimulation were used as RA animal model.<sup>2</sup> *In vivo*, the intra-articular injections of ADSC (ADSC group; n=10) or PBS (PBS group, n=10) were performed to the bilateral knee of SKG mice with arthritis. The knee joint was histologically assessed with synovitis score and Mankin score at 2 weeks after ADSC injection. *In vitro*, the anti-inflammatory effect of ADSC for stimulated human synovial fibroblast was analysed by real-time RT-PCR.

**Results:** *In vivo*, the synovitis score and Mankin score were statistically lower in ADSC group (synovitis score 2.0±0.7 vs 6.0±1.6, p<0.01 and Mankin score 2.2±0.8 vs 4.9±0.8, p<0.01) (figure 1). *In vitro*, the expression of tumour necrosis factor-stimulated gene-6 (TSG-6), the anti-inflammatory cytokine, was significantly higher in ADSC than in synovial cell (p<0.01). The inflammatory cytokine levels in

stimulated synovial cell were significantly decreased by ADSC treatment (p<0.01) (table 1).

**Abstract AB0116 – Table 1.** Gene expressions in each cell by real-time RT-PCR

	Relative gene expressions referenced GAPDH as 1 (mean ±SD)		
	IL-6	TNF-α	TSG-6
ADSC	0.39±0.03	0.37±0.1	0.77 ±0.06*
Synovial fibroblast	0.21±0.07	0.35±0.1	0.08±0.03
Stimulated synovial fibroblast (non-treatment, 24 hour)	77.8±1.5	38.9±0.1	5.2±0.7
Stimulated synovial fibroblast (non-treatment, 48 hour)	34.9±0.5	39.9±0.1	4.2±0.3
Stimulated synovial fibroblast (ADSC treatment, 48 hour)	5.2 ±0.06**	9.8 ±0.1**	1.9±0.1

ADSC; adipose derived stem cell, IL; interleukin, TNF; tumour necrosis factor, TSG; tumour necrosis factor-stimulated gene.

\*p<0.01 (the comparison to synovial cell by Mann-Whitney U test)

\*\*p<0.01 (the comparison to non-treatment group by Mann-Whitney U test)

**Abstract AB0116 – Figure 1.** The anti-inflammatory effects of intra-articular ADSC injection. The H-E stain of knee joint in SKG/Jcl mice (a) and PBS treated SKG/Jcl mice after induction of synovitis (b). The synovial proliferation was suppressed in ADSC treated SKG/Jcl mice after induction of synovitis (c). The Safranin-O stain in SKG/Jcl mice without synovitis (d), PBS treated SKG/Jcl mice (e) and ADSC treated SKG/Jcl mice (f) after induction of synovitis. The cartilage staining was reduced in SKG/Jcl mice with inflammatory synovitis (yellow arrows).

**Conclusions:** This is the first report to show the anti-inflammatory effect of ADSC for synovitis in RA animal model. ADSC can be collected with a minimally invasive technique more easily than other mesenchymal stem cells. ADSC might have potential to be one of the RA treatment.

#### ASSOCIATION OF VITAMIN D DEFICIENCY WITH CRP/ACPA POSITIVITY IN ALGERIAN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Allam, R. Djidjik. *Immunology, Beni Messous Teaching Hospital, Algiers, Algeria*

**Background:** Vitamin D (VD) is a steroid hormone belonging to the class of secosteroids with myriad immune functions and seems to be involved in the development and severity of rheumatoid arthritis (RA).<sup>1–3</sup>

**Objectives:** The aim of this study was to estimate the prevalence of vitamin D deficiency in patients with rheumatoid arthritis as compared to healthy controls and to analyse the association between levels of vitamin D and CRP (C-reactive protein)/ACPA (anti citrullinated protein antibodies) positivity.

**Methods:** Serum 25(OH)D levels were measured in 115 RA patients and 104 age- and gender-matched healthy controls using the chemiluminescent immunoassay method (CLIA).

CRP (mg/dl) was measured by the nephelometric method and ACPA antibodies were evaluated using enzymatic linked immuno-assay (ELISA).

**Results:** There was no statistically significant difference between levels of 25 (OH)D in RA (25.08±9.22 ng/ml) and healthy controls (15.62±5.34 ng/ml).

The vitamin D deficiency (<10 ng/ml) was found in 10% of RA patients, while 60% were insufficient (<20 ng/ml).

Low 25-OHD levels were negatively associated with CRP (23 ng/ml vs 29 ng/ml;  $p=0.023$ ) and ACPA positivity (23 ng/ml vs 28 ng/ml;  $p=0.03$ ).

**Conclusions:** The 25(OH) D levels are inversely related to CRP and ACPA values in Algerian RA patients.

**Background:** Hormonal and reproductive factors are implicated in the etiology of rheumatoid arthritis (RA). The association between oral contraceptive (OC) use and the risk of RA has been reported, but the findings are inconsistent across different populations.

**Objectives:** We investigated the association between OC use and risk of RA stratified by anti-citrullinated peptide antibody (ACPA) status in the Malaysian female population.

**Methods:** Data from the Malaysian Epidemiological Investigation of rheumatoid Arthritis (MyEIRA) population-based case control study involving 902 female early RA and 906 age and residential area-matched female controls were analysed. OC use data was assessed through a questionnaire. Never users of OC were compared with ever users of OC to estimate the risk of developing ACPA-positive and ACPA negative RA. The odds ratio (OR) with 95% confidence interval (CI) was calculated.

**Results:** In this study, a total of 28.4% (n=254) RA cases and 34.2% (n=310) controls had reported as ever OC users. Compared with never users, ever OC users had a decreased risk of developing RA in the Malaysian population particularly in ACPA-negative RA (OR 0.68, 95% CI 0.51–0.90,  $p<0.001$ ). No significant

association was observed between ever OC users and ACPA-positive RA (OR 0.80, 95% CI 0.64–1.01). Further stratification analysis by duration of OC use (less than or more than 7 years versus never OC use) demonstrated significant decreased risk of developing ACPA-positive RA (OR 0.66, 95% CI 0.51–0.86,  $p<0.01$ ) and ACPA-negative RA (OR 0.57, 95% CI 0.41–0.80,  $p<0.001$ ), respectively.

**Conclusions:** Oral contraceptives decreased the risk of RA, particularly ACPA-negative RA in the Malaysian population. A long duration of OC use was however decreased the risk in both ACPA-positive and ACPA-negative RA subsets.

#### RHEUMATOID ARTHRITIS (RA)-ASSOCIATED AUTOANTIBODIES ARE PRESENT IN THE PERIODONTAL EXUDATE OF PATIENTS WITH AND WITHOUT RA

M.J. de Smit<sup>1,2</sup>, P.S. Rahajoe<sup>3</sup>, G.J. Schuurmans<sup>1</sup>, E. Eelsing<sup>1</sup>, N. Kertia<sup>4</sup>, A. Vissink<sup>2</sup>, J. Westra<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>Oral and Maxillofacial Surgery, University Medical Center Groningen, Groningen, Netherlands; <sup>3</sup>Oral and Maxillofacial Surgery; <sup>4</sup>Rheumatology, Dr. Sardjito General Hospital, Gadjah Mada University, Yogyakarta, Indonesia

**Background:** Seropositivity for anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) is a hallmark of RA and can be present years before clinical disease onset. Environmental factors, including smoking and chronic inflamed mucosal tissues of the lungs, gastro-intestinal tract or oral cavity (i.e., the periodontium) are suggested to contribute to initiation of these autoantibodies. While it is known that the inflamed periodontium contains citrullinated proteins and peptides, only Harvey et al. (2013) showed that IgG ACPA is indeed present in periodontal exudate (n=9).

**Objectives:** As the IgA isotype is specific for mucosal immunity, we assessed in patients with and without RA whether IgA RF and IgA ACPA are present gingivocrevicular fluid (GCF), i.e., the periodontal inflammatory exudate.

**Methods:** RA patients fulfilling the ACR<sup>EULAR</sup> 2010 classification criteria were recruited at the Rheumatology department of the Dr. Sardjito General Hospital, Yogyakarta, Indonesia. Patients without RA (non-RA) were recruited from the Oral and Maxillofacial Surgery department of the same hospital. In both groups, patients with diabetes or cardiovascular disease were excluded. Periodontitis was defined as periodontal inflamed surface area (PISA) >130 mm<sup>2</sup> (Leira et al. 2017). RF and ACPA were determined by ELISA in serum (IgM RF, IgA RF, IgG ACPA, IgA ACPA) and GCF (IgA RF, IgA ACPA). Total IgG and IgA were determined in GCF. IgA ACPA seropositivity and IgA RF- and IgA ACPA positivity in GCF were defined as >mean +2 SD of healthy controls (non-RA patients, never smokers, no periodontitis, n=88).

**Abstract AB0119 – Figure 1.** Non-RA patients (n=151)

**Results:** In non-RA patients (n=151), PISA was correlated with total IgG and IgA in GCF ( $p<0.0001$ ). IgA RF and IgA ACPA were present in GCF and correlated with total IgA in GCF ( $p<0.05$  and  $p<0.01$  respectively). In contrast to RA patients (n=72), IgA RF and IgA ACPA in GCF of non-RA patients did not correlate with IgA RF and IgA ACPA in serum. In non-RA patients, IgA ACPA positivity in GCF was more frequent in ever smokers (18%) than in never smokers (9.8%); the same held for presence or absence of periodontitis (18% and 9.3% IgA ACPA positivity, respectively). In non-RA patients PISA was correlated with IgA ACPA in serum ( $p<0.01$ ) and GCF ( $p=0.05$ ) (figure 1).

**Conclusions:** RA-associated autoantibodies are present in GCF of patients with and without RA. In contrast to RA patients, in whom this presence is probably due to leakage from serum, presence of RA-associated autoantibodies in GCF of patients without RA is presumably the result of local formation of these autoantibodies due to periodontitis.

#### AB0120 ADIPONECTIN COULD BE A MEDIATOR OF THE PRESENCE OF P GINGIVALIS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

J.A. Chaparro<sup>1,2</sup>, J.M. Bello-Gualtero<sup>1,2</sup>, R. Valle-Oñate<sup>1</sup>, W. Bautista-Molano<sup>2,3</sup>, L. Chila<sup>3</sup>, D.M. Castillo<sup>3</sup>, G. Lafaurie<sup>3</sup>, P. Chalem Ch<sup>4</sup>, C. Romero-Sanchez<sup>1,2,3</sup>.  
<sup>1</sup>Rheumatology and immunology, Hospital Militar Central; <sup>2</sup>Clinical Immunology Group, Universidad Militar Nueva Granada; <sup>3</sup>Unit of Oral Basic Investigation, Universidad El Bosque; <sup>4</sup>Fundación Instituto de Reumatología Fernando Chalem, Bogotá D.C., Colombia

**Background:** Rheumatoid arthritis (RA) is a systemic chronic inflammatory disease characterised by joint destruction, deformity, lower functional status and decrease in life expectancy. The *Porphyromonas gingivalis* (*P. gingivalis*) has been reported to be significantly associated with RA. The adipokines are suggested to be a common link between periodontitis and RA

**Objectives:** To determine the association between serum adipokines levels and presence of *P. gingivalis* in patients with early rheumatoid arthritis (eRA) compared to healthy individuals

**Methods:** A cross sectional study was conducted. Patients with the diagnosis of (eRA) according to the ACR/<sup>EULAR</sup> 2010 criteria were studied in Bogota-Colombia. A complete medical history related to RA was obtained. Adiponectin levels measured by Luminex technology (MILLIPLXMAP), IL6 by chemiluminescence (Immulate 1000, Siemens) and leptin quantification by ELISA (Dia-source, ), high-sensitivity CRP (hs-CRP) (Immulate 1000, Siemens) and ESR (Test 1 THL Ali FAX), and the detection of periodontopathic bacteria was carried out by qPCR from subgingival plaque samples. Cancer, autoimmune disease, infection, antibiotic use, diabetes, orthodontics treatment were exclusion criteria. An association analysis was made to evaluate the relationship between adipokines levels and periodontal, rheumatologic conditions using X2 test, Mann Whitney test and logistic regression model was performed to confirm this associations. All the results were performed with a level of significance of 95%

**Results:** A total of 51 patients with eRA and 51 healthy individuals were matched by age and gender. The mean age in RA patients was 48.54±10.93 years, 80.39% were female, between RA patients, 17.64% were in high activity and 27.45% in remission by DAS 28-ESR. 45.1% had APCA>20 UE. 37.25% were overweight and 13.72% were obese. 82.35% of patients had treatment, of which 80.39% received treatment with conventional disease modifying therapy, being methotrexate the most frequent one in 86.8%. In turn, 64.7% and 51% had high leptin and adiponectin levels respectively. An association of high adiponectin levels was found with Body Mass Index-BMI <25 ( $p=0.017$ ). The presence of *P. gingivalis* in RA patients was 78.4% and in healthy individuals was 45.09%  $p=0.001$ . The adiponectin levels>47755 pg/ml were found associated with the absence of *P. gingivalis* (OR=0.078 95% CI 0.01–0.62) adjusted an ever smoking history of cigarette smoking, Body Mass Index>30 and high level of leptin and IL6.

**Conclusions:** The adiponectin plays an anti-inflammatory role in the pathophysiology of several chronic inflammatory diseases and it has been reported to inhibit LPS-induced NFκB nuclear translocation and to affect other LPS-triggered pathways. To promote the weight control in eRA could be to prevent the oral infection

#### AB0121 RESVERATROL-ENHANCED AUTOPHAGIC FLUX REDUCES SEVERITY OF EXPERIMENTAL RHEUMATOID ARTHRITIS

J.A. Fernández-Rodríguez<sup>1</sup>, M. Almonte-Becerril<sup>1</sup>, O. Ramil-Gómez<sup>1</sup>, S. Viñas-Diz<sup>1</sup>, L. Hermida-Carballo<sup>1</sup>, Á. Vela-Anero<sup>2</sup>, Á. Concha<sup>3</sup>, M. Camacho-Encina<sup>4</sup>, F. J. Blanco<sup>4</sup>, M.J. Lopez-Armada<sup>5</sup>. <sup>1</sup>Aging and Inflammatory Research Lab; <sup>2</sup>Terapia Celular y Medicina Regenerativa; <sup>3</sup>Servicio de Patología; <sup>4</sup>Rheumatology Division, INIBIC; <sup>5</sup>Aging and Inflammatory Research Lab, RIER-Red de Inflamación y Enfermedades Reumáticas, INIBIC, Sergas, A Coruña, Spain

**Background:** Previously, we have demonstrated that dietary supplementation with resveratrol (RSV) lowers synovial hyperplasia, chemokines and oxidative damage in an acute antigen-induced arthritis (AIA) model developed in rats, and that autophagic cell death and limiting angiogenic response were involved<sup>1</sup>.

**Objectives:** Here, we investigated the autophagic flux induced by RSV and its relation with serum interleukin (IL)-1β levels, since autophagy could regulate IL-1β via inflammasome. Moreover, C-reactive protein (CRP) and prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), which are also closely linked to inflammation and correlated with disease activity, were also evaluated.

**Methods:** Animals were randomly divided into 3 groups: healthy, AIA, and RSV-treated AIA group. RSV (12.5 mg/kg/day) was given orally 8 weeks before AIA induction until sacrifice day (48 hour after intra-articular injection). Healthy and AIA animals were administered 100 μl of water. RSV effects on autophagy were evaluated by the expression of the autophagy proteins, microtubule-associated protein 1 light chain 3 (LC3), and Beclin1 (an autophagic-related protein which up-regulation is associated with increased autophagosome formation), and p62 (an autophagic adaptor protein whose accumulation is associated with autophagic degradation dysfunction), by confocal and immunohistochemistry, respectively. Specific enzyme-linked immunosorbent assay kits and cytokine magnetic milliplex were used to measure CRP and PGE<sub>2</sub> and IL-1β in serum samples, respectively.

**Results:** At the end of the study, RSV significantly reduced the serum levels of IL-1β, CRP and PGE<sub>2</sub> ( $p\leq 0.01$  for IL-1β and PCR, and  $p\leq 0.05$  for PGE<sub>2</sub>). In relation to autophagy proteins, results showed that the expression of LC3 was greater in the AIA synovial membranes than in control synovial samples, in which the presence of vesicles was easily observed. Interestingly, the synovial tissues from the RSV group showed a significantly ( $p<0.001$ ) higher signal for LC3, compared with the AIA samples. As compared with healthy controls, AIA synovial membranes showed increased p62 expression, which was markedly inhibited by RSV treatment ( $p\leq 0.01$ ). The protein level of Beclin 1 was higher in AIA synovial membranes than in healthy samples; however, RSV did not increase the signal of Beclin 1. Moreover, there was a significant correlation between p62 expression and serum IL-1β levels ( $p\leq 0.05$  and  $r=0.617$ ), PGE<sub>2</sub> ( $p\leq 0.01$  and  $r=0.604$ ), and PCR ( $p\leq 0.001$  and  $r=0.692$ ).

**Conclusions:** These data suggest that resveratrol is capable of inducing the non-canonical (Beclin1 independent) autophagy pathway, and in consequence, modulates the cross-talk existence with inflammation in an acute AIA model, which could also ameliorate the severity of rheumatoid arthritis.

### RP53 INDUCES ECTODOMAIN SHEDDING OF TNF RECEPTOR 1 AND THEREBY INHIBITS INFLAMMATORY RESPONSES IN RHEUMATOID FIBROBLAST-LIKE SYNOVIOCYTES

J. Kim<sup>1</sup>, H.S. Byun<sup>2</sup>, K. Kang<sup>2</sup>, S.-J. Yoo<sup>1</sup>, S.W. Kang<sup>1</sup>, G.M. Hur<sup>2</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Pharmacology, Chungnam National University College of Medicine, Daejeon, Korea, Republic of Ireland

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease by autoimmune disorder that primarily affects joints. Usually RA has been treated with disease modifying anti-rheumatic drugs but biological response modifiers has developed the treatment of RA. Among these anti-tumour necrosis factor (TNF) agents were the first to be successfully used in treating RA. Various anti-TNF- $\alpha$  therapy might be lead to substantial functional improvement in RA patients.

**Objectives:** We studied the isolated two polypeptides (Rp53, Rp54) from *Rubia philippinensis*, traditional medicine plant, about anti-inflammation effects in fibroblast-like synoviocytes (FLS) derived from patients with RA.

**Methods:** The effects of polypeptides on anti-inflammation were measured by cytokine assay kits (TNF- $\alpha$ , IL-6). The underlying for NF- $\kappa$ B signalling pathway was examined by western blot and NF- $\kappa$ B reporter activity. We examined the effect of Rp53 on the formation of the TNFR1 signalling complex, recruitment of TRADD, RIP in response to TNF by immunoprecipitation experiments. To determine whether Rp53 induced TNF receptor 1 shedding were exposed to these compounds for 1 hour, and then culture media and cell lysates were analysed by Western blotting using anti-TNF receptor 1 antibody.

**Results:** Pretreatment with Rp53 resulted in a remarkable decrease of the secretion of TNF-induced proinflammatory cytokines TNF- $\alpha$  and IL-6 in RA-FLS. Rp53 strongly inhibited the nuclear factor  $\kappa$ B (NF- $\kappa$ B) signalling pathway induced by TNF- $\alpha$ , but not that induced by IL-1 $\beta$ . Analysis of the upstream signalling events affected by Rp53 revealed that it strikingly inhibited the TNF-induced recruitment of TNFR1-associated death domain protein (TRADD) and receptor-interacting protein (RIP) to TNFR1. Rp53 reduced the interaction with TNFR1 to TNF cytokines and enhanced the activation of the p38 mitogen-activated protein (MAP) kinase. Rp53, the polypeptides induced the proteolytic cleavage of TNF-R1 and its release into the culture medium by shedding of TNF receptor 1 ectodomain by TNF- $\alpha$ -converting enzyme (TACE). Along with the TACE inhibitor TAPI-2, the p38 kinase inhibitor SB203580 suppressed the ectodomain shedding of TNF receptor 1 induced by Rp53.

**Conclusions:** Rp53 induces the TACE-dependent ectodomain shedding of TNF receptor 1 through the activation of p38 MAP kinase, and thereby inhibits the TNF- $\alpha$  induced NF- $\kappa$ B signalling pathway in RA-FLS cells.

### EXPLORING THE METABOLOMIC PROFILE OF SYNOVIAL FLUID TO REFLECT THE DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

J.K. Ahn<sup>1</sup>, J.-W. Hwang<sup>2</sup>, E.-M. Koh<sup>3</sup>, H.-S. Cha<sup>3</sup>, H. Jeong<sup>4</sup>, Y. Eun<sup>3</sup>, J. Lee<sup>3</sup>, H. Kim<sup>3</sup>. <sup>1</sup>Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine; <sup>2</sup>National Police Hospital; <sup>3</sup>Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul; <sup>4</sup>Soonchunghyang University School of Medicine, Bucheon, Gyeonggi-Do, Korea, Republic of Ireland

**Background:** Rheumatoid arthritis (RA) is a chronic, inflammatory disease that mainly affects the synovial joints. Metabolomics, which is defined as the comprehensive analysis of the small-molecule metabolites in a biological system, is a rapidly developing approach in biomarker research.

**Objectives:** This study was to determine whether there is variation in the synovial fluid (SF) metabolome in RA patients according to the degree of disease activity using gas chromatography/time-of-flight-mass spectrometry (GC/TOF-MS), in order to gain more insight into the pathologic metabolic alterations in RA.

**Methods:** SF samples were analysed in 47 patients with active RA, divided into moderately active- (2.8<DAS28 ESR<5.1, n=35, male 28.6%, mean age 55.1 years) and highly active group (DAS28-ESR $\geq$ 5.1, n=12, male 41.7%, mean age 59.1 years). SF metabolite profiles of RA based on DAS28-ESR value were performed using GC/TOF MS, with univariate analysis such as student t-test and correlation analysis followed by multivariate analysis such as partial least-squares regression-discriminant analysis (PLS-DA) and pathway analyses such as metabolite set enrichment analysis.

**Results:** There was no differences in demographic data and medications use between two groups. A total of 123 metabolites were identified from samples. These 123 identified metabolites were classified into various chemical classes, such as amino acids (21% of identified metabolites), organic acids (20%), sugar

and sugar alcohols (19%), fatty acids (15%), amines (11%), and phosphates (6%). The SF metabolite profiles obtained from GC/TOF-MS analysis can distinguish moderately active group from highly active group. The variation values of the PLS-DA model are  $R^2X$  of 0.171,  $R^2Y$  of 0.849, and  $Q^2$  of 0.504, respectively, indicating strong explanation and prediction capabilities of the model. To find potential metabolic biomarkers reflecting the disease activity of RA, variable importance on projection (VIP) values of all the metabolites from the PLS-DA model were determined. Also, other statistical criteria including correlation coefficient and  $P$  value were assessed. Twelve potential metabolites reflecting the disease activity of RA are found (2-hydroxyvalerate, fucose, tryptophan, indole-3-lactate, isothreonate, thymine, phenylalanine, lactose, arabinol, and mannose-6-phosphate, citrate, oxoproline). In pathway analysis, we found six unique pathways, namely, fructose and mannose degradation, phenylalanine and tyrosine metabolism, citric acid cycle, galactose metabolism, tryptophan metabolism and pyrimidine metabolism that were significantly associated with disease activity in RA.

**Conclusions:** Synovial metabolite profiles are robustly altered along the disease activity of RA. Metabolomic approaches based on GC/TOF-MS could provide valuable information on the underlying pathogenic mechanisms of RA activity, and a novel perspective on the search of new biomarkers and drug targets.

### DETECTION OF PRECURSORS OF RANK-OSTEOCLAST-LIKE CELLS (OLCS) IN PERIPHERAL BLOOD AND OLCS IN BONE TISSUE FROM RHEUMATOID ARTHRITIS PATIENTS

K. Yokota<sup>1</sup>, S. Tanaka<sup>2</sup>, M. Sekikawa<sup>2</sup>, Y. Aizaki<sup>1</sup>, K. Sato<sup>1</sup>, H. Oda<sup>2</sup>, T. Mimura<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Applied Immunology, Faculty of Medicine; <sup>2</sup>Department of Orthopaedic Surgery, Saitama Medical University, Iruma, Japan

**Background:** Previously, we reported that novel osteoclast-like cells (OLCs) were induced, both *in vitro* and *in vivo*, from mouse bone marrow-derived macrophages (BMMs) by addition of a combination of TNF $\alpha$  and IL-6<sup>1</sup>. Recently, O'Brien *et al* showed that TNF/IL-6 can drive osteoclastogenesis in BMMs from *RANK*-deficient mice<sup>2</sup>.

**Objectives:** We aimed to examine the differentiation of OLCs, which were induced by a combination of TNF $\alpha$  and IL-6 from human peripheral blood mononuclear cells (PBMCs) and CD14 +monocytes and to identify differences in molecular expression patterns between OLCs and conventional osteoclasts. Furthermore, we identified OLCs and osteoclasts on the bone tissue of the joint in patients with rheumatoid arthritis (RA).

**Methods:** PBMCs and CD14 +monocytes from healthy volunteers and/or RA patients were stimulated with TNF $\alpha$  and IL-6 or RANKL. Quantitative RT-PCR was used to measure mRNA expression levels of *RANK*, *cathepsin K*, *calcitonin receptor*, and *dendritic cell-specific transmembrane protein*. Prepared undecalcified tibial bone from 6 RA or osteoarthritis (OA) patients undergoing joint surgery were stained by tartrate-resistant acid phosphatase (TRAP) staining and immunohistochemistry with anti-RANK antibody, expression of which were analysed. Osteoclasts and OLCs were identified as multinucleated TRAP+/RANK+ cells and TRAP+/RANK- cells, respectively, adherent to the bone surface.

**Results:** The number of OLCs treated with a combination of TNF $\alpha$  and IL-6 from PBMCs or CD14 +monocytes in RA patients was significantly increased compared to that in healthy volunteers. Expression levels of *RANK* mRNA was clearly up-regulated in osteoclasts, and was obviously down-regulated in OLCs compared to that in osteoclast precursors. In cancellous bone, the number of TRAP+/RANK+ osteoclasts was significantly increased in RA patients compared to that in OA patients. Interestingly, numerous TRAP+/RANK- OLCs were present in the cancellous bone of RA patients, while almost none were observed in the cancellous bone of OA patients.

**Conclusions:** The combination of TNF $\alpha$  and IL-6 strongly induced the differentiation of OLCs from PBMCs or CD14 +monocytes in RA patients. OLCs was characterised with TRAP+/RANK- multinucleated cells, which can distinguish conventional TRAP+/RANK+ multinucleated osteoclasts. TRAP+/RANK- OLCs also were present in the bone tissue of RA patients. These results suggest that conventional osteoclasts and novel OLCs could be involved in the pathogenic mechanisms of inflammatory bone destruction such as RA.

**Background:** Arthralgia is one of the common symptoms seen in RA and in mosquito-borne viral diseases (dengue and chikungunya infections). Studies have reported that both dengue and chikungunya infections are associated with long-term persistent rheumatic symptoms including joints, muscle and bone pain.

**Objectives:** We investigated the association between anti-dengue IgG antibody positivity and risk of developing anti-citrullinated peptide antibody (ACPA)-positive and ACPA-negative RA in the multi-ethnic Malaysian population.

**Methods:** A total of 1147 early RA cases (515 Malay, 254 Chinese and 378 Indians) and 1519 age, sex and residential area matched population-based controls (1,023 Malay, 208 Chinese, and 288 Indians) were included in this study. Anti-dengue IgG antibody was determined by ELISA method. The presence of anti-dengue IgG antibody and risk of developing ACPA-positive/ACPA-negative RA were estimated by calculating the odds ratio (OR) with 95% confidence interval (95% CI).

**Results:** Our data demonstrated that 79.1% (n=1,003) and 77.1% (n=1,255) RA and control subjects were positive for anti-dengue IgG antibody, respectively. Data analysis revealed that the Chinese RA patients has highest frequency of anti-dengue IgG antibody (86.6%) followed by the Indian (80.4%) and Malay (74.4%) RA patients while 83.7%, 87.5% and 73% Chinese, Indian and Malay healthy controls were positive for this antibody, respectively. The anti-dengue IgG antibody positivity was significantly associated with decreased risk of RA in the Indian population (OR 0.59, 95% CI: 0.38–0.91, p=0.02) and particularly for the ACPA-positive subset of RA (OR 0.60, 95% CI 0.37–0.96, p=0.03). Interestingly, we observed a non-significant increased risk for ACPA-positive RA in the Chinese (OR 1.49, 95% CI 0.81–2.72) and Malay populations (OR 1.06, 95% CI: 0.79–1.41) with anti-dengue IgG antibody. No association was observed between ACPA-negative RA and the antibody positivity.

**Conclusions:** Our study describes the association between anti-dengue IgG antibody occurrence and ACPA-positive RA, but not ACPA-negative RA in an ethnicity-dependent manner. Future research is needed to explore the biological mechanisms behind these findings.

**AB0126 LOW PREVALENCE OF ANTIBODIES AGAINST MALONDIALDEHYDE-ACETALDEHYDE ADDUCTS IN SPANISH PATIENTS WITH RHEUMATOID ARTHRITIS**

L. Rodriguez-Martinez, E. Perez-Pampin, A. Mera-Varela, C. Conde, A. Gonzalez. *Experimental and Observational Rheumatology, Instituto Investigacion Sanitaria-H. Clinico Universitario de Santiago, Santiago de Compostela, Spain*

**Background:** Patients with rheumatoid arthritis (RA) present increased oxidative stress that leads to lipid peroxidation and the formation of malondialdehyde (MDA) and acetaldehyde (AA). These two compounds under oxidative stress form malondialdehyde-acetaldehyde (MAA) adducts with proteins, which are highly immunogenic. Recently, Thiele *et al.*<sup>1</sup> described the presence of antibodies against human albumin MAA adducts in patients with established RA from the Veterans Affairs Rheumatoid Arthritis (VARA) registry. Of particular relevance was the reported presence of IgG anti-MAA antibodies in 92% of the patients, including 88% of the anti-CCP negative patients. These results suggest MAA adducts could contribute to the pathogenesis of RA and the anti-MAA antibodies could drastically reduce the number of patients with seronegative RA.

**Objectives:** To replicate the association of anti-MAA antibodies with RA and explore their value as biomarkers.

**Methods:** Sera from 515 Spanish patients with established RA that fulfilled the 1987 ACR classification criteria and from 274 healthy controls were included. Available information included history of smoking, anti-CCP status, and genotype of HLA-DRB1 and PTPN22 rs2476601. Human serum albumin MAA adducts and hexyl-MAA standard were chemically synthesised. Anti-MAA antibodies against the albumin MAA adducts were determined by indirect ELISA using isotype-specific secondary antibodies for IgG, IgM and IgA.

**Results:** Anti-MAA antibodies were detected in a small fraction of the RA patients, who had slightly increased antibody titers compared to healthy controls, 6.4% were positive for IgG, 15.7% for IgM and 8.0% for IgA. The low prevalence of anti-MAA antibodies persisted in spite of multiple variations in the ELISA protocols including the use of different albumin sources, albumin MAA adducts produced in two different laboratories, and various secondary antibodies. IgM anti-MAA antibody titers were increased in smokers compared to non-smokers. Moreover, the presence of IgM and of IgA anti-MAA antibodies were associated with anti-CCP and RF positivity.

**Conclusions:** Anti-MAA antibodies were detected in a small fraction of the Spanish RA patients, but their low sensitivity questions the value of these antibodies as biomarkers of RA. Due to the contradictory findings, additional studies should be performed that will need to address also the role of MAA adducts on RA pathogenesis.

**AB0127 ANTI-INFLAMMATORY AND PRO-APOPTOSIS EFFECTS OF 18BETA-GLYCYRRHETINIC ACID IN IN VIVO AND IN VITRO MODELS OF RHEUMATOID ARTHRITIS**

M. Wang<sup>1,2</sup>, R. Huang<sup>1</sup>, on behalf of Runyue Huang Group. <sup>1</sup>Rheumatology, Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China; <sup>2</sup>Center for Molecular Medicine, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** Rheumatoid arthritis (RA) is one of the most common autoimmune diseases and it affects 0.5%–2.0% of the human population worldwide.<sup>1</sup> Though disease modifying anti-rheumatic drugs (DMARDs) can improve the clinical condition of patients with RA, toxicities of these drugs will be accumulated with long-term use and the unwanted side effects still cannot be avoided. 18β-glycyrrhetic acid (18β-GA), an active component of licorice, exhibits potential anti-cancer, anti-inflammatory, anti-allergic, and anti-microbial activities.<sup>2</sup> Moreover, 18β-GA has been elucidated to attenuate hepatotoxicity or nephrotoxicity caused by chemical drugs, included methotrexate(MTX).<sup>2</sup> These evidences suggested 18 β-GA may become a candidate for low toxicity RA therapy as the mechanism was revealed.

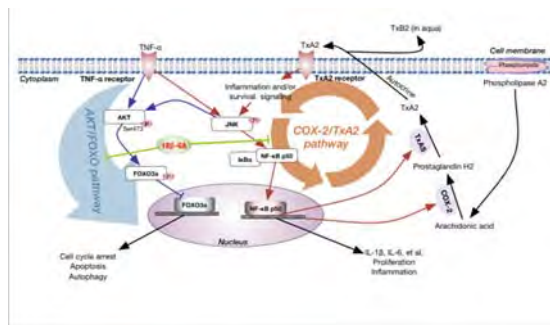

**Objectives:** The aim of this study is to investigate the underline mechanism of 18β-GA on anti-inflammation and anti-proliferation in *in vivo* and *in vitro* models of RA.

**Methods:** CIA rats were treated with 18β-GA, methotrexate, celecoxib and three combination therapies for 30 days. Paw swelling volume, thromboxane synthase (TxAS), proliferating cell nuclear antigenprotein (PCNA), interleukin (IL)–1β, IL-6, and thromboxane B2 (TxB2) were detected to assess the anti-inflammation and

anti-proliferation effects of different treatments. To further study the potential mechanism, TNF- $\alpha$ -induced *in vitro* model was applied. With different treatments, cell proliferation was detected using MTS, meanwhile, cell cycle distribution and apoptosis were examined by flow cytometric analysis. Western blotting and real-time quantitative PCR were conducted to evaluate many molecular targets involved in interested pathways like COX-2/TxA2 pathway and AKT/FOXO3a pathway.

**Results:** The paw swelling volume and histological data indicate that 18 $\beta$ -GA administration attenuates arthritis severity in rats with CIA. Lower level of IL-1 $\beta$ , IL-6, and TxB2 were observed in serum of 18 $\beta$ -GA group as compared with model group. In addition, synovial immunohistochemistry data shows that 18 $\beta$ -GA decreased about half of PCNA intensity induced by collagen. However, *in vivo*, all data exhibited no significant differences among groups with monotherapy and combination therapy. *In vitro*, 18 $\beta$ -GA inhibited the mRNA and protein levels of COX-2 and TxAS that induced by TNF- $\alpha$  in MH7A cell line. Both p-JNK and NF- $\kappa$ B1 (p50) were inhibited by 18 $\beta$ -GA as well as TxAS siRNA transfection. Moreover, 18 $\beta$ -GA inhibited MH7A proliferation in a time- and dose- dependent manner from MTS assay. Flow cytometric analysis revealed that 18 $\beta$ -GA induced cell apoptosis and caused G1-phase cell cycle arrest. Finally, AKT and FOXO3a were predominantly phosphorylated by TNF- $\alpha$ , whereas such effect was blocked by 18 $\beta$ -GA treatment.

Abstract AB0127 – Figure 1

**Conclusions:** This study has for the first time shown that 18 $\beta$ -GA has an inhibitory role in synovial cell inflammation and proliferation, which is, at least in part, dependent on the regulation of COX-2/TxA2 pathway and AKT/FOXO3a pathway. Thus, 18 $\beta$ -GA should be regarded as a new potential drug candidate for RA therapy.

#### AB0128 CXCL1, BUT NOT AUTO-ANTIBODIES OR CD4+CCR6+ MEMORY TH CELLS WITHIN BLOOD, IS A MARKER TO DIFFERENTIATE MICE INTO COLLAGEN INDUCED ARTHRITIS POSITIVE OR NEGATIVE PRIOR TO CLINICALLY MANIFEST DISEASE

M. Molendijk, A.M. Mus, P.S. Asmawidjaja, E. Lubberts. *Erasmus MC, Rotterdam, Netherlands*

**Background:** There is currently a knowledge gap on early pathogenesis prior to Rheumatoid Arthritis (RA) diagnosis. Additionally, current medication available for RA treatment has not been developed for prevention. Collagen induced arthritis (CIA) could aid in extending knowledge on early RA pathogenesis and testing the preventive effects of medicines.

**Objectives:** In this study we sought a marker that can differentiate mice prior to clinically manifest disease into their future CIA status with the aim to facilitate research into early disease processes and preventive treatment strategies.

**Methods:** Blood was obtained at time points prior (days 12 and 19) and after clinically manifest disease (days 27 and 35) during CIA. Antibodies against bovine and mouse collagen type II (mCII) were measured from plasma by ELISA. CD4<sup>+</sup>CCR6<sup>+</sup> memory Th cells as well as other T cell types were determined in

blood. Cytokines and chemokines were detected in plasma by Luminex. Mice were divided into CIA negative and CIA positive groups based on CIA score reached on day 35.

**Results:** Antibodies against mCII of the IgG2a isotype differed prior to clinically manifest disease but are not suitable as a differentiation marker. CD4<sup>+</sup>CCR6<sup>+</sup> memory Th cells in blood differed only at day 35. The same holds for IL-6, TNF $\alpha$  and CXCL2. In contrast, CXCL1 differed prior to clinically manifest disease with an AUC significantly better (p=0.003) than random.

**Conclusions:** Here we identified CXCL1 as a marker that can differentiate mice prior to clinically manifest disease into CIA positive and CIA negative mice. This might help facilitate research into early disease processes and preventive pre-clinical treatment strategies.

#### AB0129 ASSESSMENT OF MORPHOLOGY OF THE EARLY AND LATE STAGE OF JUVENILE RHEUMATOID ARTHRITIS

M. Salokhiddinov<sup>1</sup>, U. Anarmetova<sup>1</sup>, G. Haydarova<sup>1</sup>, I. Xodjanazarov<sup>2</sup>. <sup>1</sup>Tashkent Medica Academy; <sup>2</sup>Traumatology, Tashkent Medical Academy, Tashkent, Uzbekistan

**Background:** One of the current problems of modern rheumatology is chronic inflammatory diseases of the knee joint in children. With juvenile rheumatoid arthritis (JRA), an uncontrolled inflammatory process can lead to the formation of contractures and deformities of the limbs

**Objectives:** Our aim is to study morphology of the early and late stage of juvenile rheumatoid arthritis

**Methods:** In total, 81 knee joint surgery was performed on 71 children of the child age in connexion with the JRA. The average age of the patients was 11 years (6–14). To verify the diagnosis during diagnostic arthroscopy, a multifocal biopsy from 7 points was performed. Pathomorphological study of the material was performed according to the conventional histological method of studying soft tissues

**Results:** The results of the pathomorphological examination were analysed for the time frame of the appearance of the JRA. Pathomorphological early and late synovitis criteria were found. Early criteria (typical for the first three months after the JRA debut) – the phenomenon of necrosis in synoviocytes and the subintimal layer, palisade-like cell structures in the sub-synovial layer, synoviocyte proliferation, fibrinoid superimpositions on the surface of the cover layer, productive endovascular endolytic endotheliosis, lymphocyte infiltration and plasmocytes. Late criteria (duration of the disease – more than 3–6 months): marked plasmacytic infiltration with the formation of lymphoid nodules with a hermetic centre, activation of fibrinoid and sclerotic processes with the formation of extensive fibrinoid necrosis with perifocal sclerosis, the formation of rheumatoid nodules, productive synovial hyperplasia, deposition of amyloid masses, formation of pannus granulation tissue with destructively invasive growth articular cartilage and synovium

**Conclusions:** Determining the stage of JRA is of great clinical importance for the early initiation of treatment and prevention of irreversible destructive complications. The proposed new method for determining the prevalence of pathological changes in the synovial membrane of the knee joint in children with JRA using a combined arthroscopic and pathomorphological evaluation of pathological changes in synovium in 7 joints allows to accurately determine the prevalence of the pathological process in the synovium, which has macroscopically only local manifestations

#### AB0130 SERUM LEPTIN AND ADIPONECTIN LEVELS IN RHEUMATOID ARTHRITIS PATIENTS, THEIR ASSOCIATION WITH INFLAMMATORY PROCESS

O. Galiutina, S. Shevchuk, Y. Sehedra, I. Kuvikova. *Institute of Invalid Rehabilitation, Vinnitsya, Ukraine*

**Background:** It is well known that such bioactive substances as leptin and adiponectin are involved in different pathologic process including inflammation. At the same time, in a number of studies it was demonstrated anti-inflammatory properties

of adipokines. Many studies have shown increasing leptin level and reducing adiponectin level in patients with rheumatoid arthritis (RA) compared with healthy ones. On the other hand the roles of adipokines in pathogenesis of autoimmune disorders are still controversial due to their both pro-inflammatory and anti-inflammatory effects.

**Objectives:** The aim of this study was to evaluate adipokine levels in patients with RA and to assess their association with the activity of inflammatory process

**Methods:** The study included 62 patients with RA and 35 practically healthy sex and age matched persons of control group. The diagnosis of RA was established according to the ACR 2010. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) were used to assess inflammation. Disease activity and functional impairment were evaluated using the Disease Activity Score (DAS28). Serum leptin and adiponectin levels were studied by immunoassay using standard sets (DRG, Germany and "Orgenium", Finland). Results are expressed as mean  $\pm$  standard error of the mean. Spearman's  $r$  was used to calculate correlations between markers of disease activity (ESR, CRP, DAS28) and serum adipokine levels. A  $p$  value  $<0.05$  was considered statistically significant for all tests

**Results:** It was found that the mean value of leptin and adiponectin levels were  $20.7 \pm 12.3$  ng/ml and  $2.47 \pm 1.34$  ng/ml respectively in patients with RA and  $6.47 \pm 3.17$  ng/ml and  $4.21 \pm 1.4$  ng/ml respectively in the control group. Thus, the leptin level in patients with RA was 3.2 times higher, and adiponectin level was 1.7 times lower than in healthy individuals. Levels of adipokines were associated with the activity of the inflammatory process. Thus, serum concentration of leptin level was increased ( $r=0.33$  and  $r=0.35$ ) and adiponectin level was decreased ( $r=-0.25$  and  $r=-0.24$ ) with the increasing of ESR and CRP. Similar patterns were observed for the integral index of RA activity DAS28. In particular, DAS28 was 1.6 times higher in subjects with leptin levels above  $44.7 \pm 9.4$  ng/ml than in the group of patients with leptin levels below  $44.7 \pm 9.4$  ng/ml. The correlation analysis has also confirmed the close association between the leptin and adiponectin levels with DAS28 activity index ( $r=0.37$  and  $r=-0.28$ , respectively).

**Conclusions:** Disadipokineemia in patients with RA is characterised by the increasing of serum leptin level and the decreasing of serum adiponectin level and is closely related to the activity of the inflammatory process.

**Disclosure of Interest:** None declared

AB0131

#### RHEUMATOID FACTOR IS DETECTED ON CIRCULATING EXTRACELLULAR VESICLES IN A SUBPOPULATION OF RHEUMATOID ARTHRITIS PATIENTS WITH A MORE SEVERE DISEASE PHENOTYPE

O. Arntz, B. Pieters, R. Thurlings, P.V.D. Kraan, F.V.D. Loo. *Experimental Rheumatology, Dept. of Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** Extracellular vesicles (EVs) play a role in cell-cell communication and contain numerous signalling molecules inside and on their cell membrane. Although their function remains to be elucidated, evidence accumulates that EVs play a regulatory role in immunity during health and disease. They contain numerous proteins, lipids, RNA, DNA and sometimes cell organelles such as mitochondria. In a recent study was shown that Immunoglobulin M-Rheumatoid factor (IgM-RF) is present on milk derived exosomes.<sup>1</sup> High IgM-RF levels in Rheumatoid Arthritis (RA) predict a more severe disease and comorbidities, probably due to their involvement in immune complex formation and activation of complement (crucial mediators of the effector phase of inflammation in the pathogenesis of RA).

**Objectives:** In this study we investigate whether RF +EVs are detectable in the circulation of RA patients and if this relates to parameters of disease activity.

**Methods:** EVs were isolated from platelet-free plasma of 38 RA patients and from age and sex-matched 24 healthy controls (HC) by size exclusion chromatography. EV markers (tetraspanins) were detected by Western blot and miRNA content by RT-qPCR. Particle size and concentration were measured by electron microscopy and nanosight tracking analysis. Protein concentration was determined by micro-BCA. RF levels were measured using a commercial ELISA. The percentage of RF +EVs was determined by measuring bound and unbound PHK labelled EVs to Protein L magnetic beads in a fluorometer.

**Results:** Mean EV particle size, concentration and protein content were not different between RA patients and HC. 27 of the 38 RA patients were classified as RF+ ( $>10$  IU/ml) and of the clinical parameters studied only their erythrocyte sedimentation rate (ESR) was higher ( $31$  vs  $14$  mm/hr). In 14 RF +patients, RF was detectable on a small portion of EVs not exceeding 4% of the total number of circulating EVs. Interestingly, RA patients with RF +EVs showed higher disease activity as assessed by patient global health assessment using a visual analogue scale ( $63$  vs  $31$ ), blood C-reactive protein ( $22$  vs  $9$  mg/L) and ESR ( $43$  vs  $19$  mm/hr) levels, than RA patients with undetectable RF +EVs.

**Conclusions:** This study shows for the first time that in a subpopulation of RA patients RF is present on EVs, which might originate from their B-cells. The higher

disease activity in RA patients expressing RF on their EVs suggests that RF +EVs are involved in RA pathogenesis.

#### FRAXINELLONE ATTENUATES RHEUMATOID INFLAMMATION IN MICE

S.M. Jung<sup>1</sup>, J. Lee<sup>2</sup>, S.Y. Baek<sup>2</sup>, J. Lee<sup>2</sup>, S.G. Jang<sup>2</sup>, S.-M. Hong<sup>2</sup>, D. Kim<sup>1</sup>, H. W. Kim<sup>3</sup>, S.-K. Kwok<sup>2</sup>. <sup>1</sup>Internal Medicine, Yonsei University College of Medicine; <sup>2</sup>Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul; <sup>3</sup>Internal Medicine, Seoul National University Bundang Hospital, Bundang, Korea, Republic of Ireland

**Background:** Fraxinellone is isolated from *Dictamnus dasycarpus*, a traditional herbal medicine that attenuates inflammatory conditions.<sup>1,2</sup> Recent studies have suggested that fraxinellone has a potential therapeutic effect in animal models with inflammatory diseases.<sup>3–5</sup>

**Objectives:** We aimed to evaluate the therapeutic effect of fraxinellone on inflammatory arthritis and identify the underlying mechanisms.

**Methods:** Fraxinellone (7.5 mg/kg) or a vehicle control was injected into mice with collagen-induced arthritis (CIA). The severity of arthritis was evaluated clinically and histologically. The differentiation of CD4 +T cells and CD19 +B cells was investigated in the presence of fraxinellone. Osteoclastogenesis after fraxinellone treatment was evaluated by staining with tartrate-resistant acid phosphatase (TRAP) and by measuring the mRNA levels of osteoclastogenesis-related genes.

**Results:** Fraxinellone attenuated the clinical and histologic features of inflammatory arthritis in CIA mice. Fraxinellone suppressed the expression of interleukin-17, and T helper 17 cell-related transcription factors (ROryt and phosphorylated STAT3) in CD4 +T cells. CD19 +B cells showed lower expression of activation-induced cytidine deaminase (AID) and Blimp-1 after treatment with fraxinellone. The formation of TRAP-positive cells and the expression of osteoclastogenesis-related markers were reduced in the presence of fraxinellone. Inhibition of interleukin-17 and osteoclastogenesis was also observed in experiments using human peripheral mononuclear cells.

**Conclusions:** Fraxinellone alleviated synovial inflammation and osteoclastogenesis in mice. The therapeutic effect of fraxinellone was associated with the inhibition of cellular differentiation and activation. The data suggests that fraxinellone could be a novel treatment for inflammatory arthritis, including rheumatoid arthritis.

**AB0133 EXPRESSION OF PRO-RESOLVING SPECIALISED MEDIATORS' RECEPTORS IN RHEUMATOID ARTHRITIS**

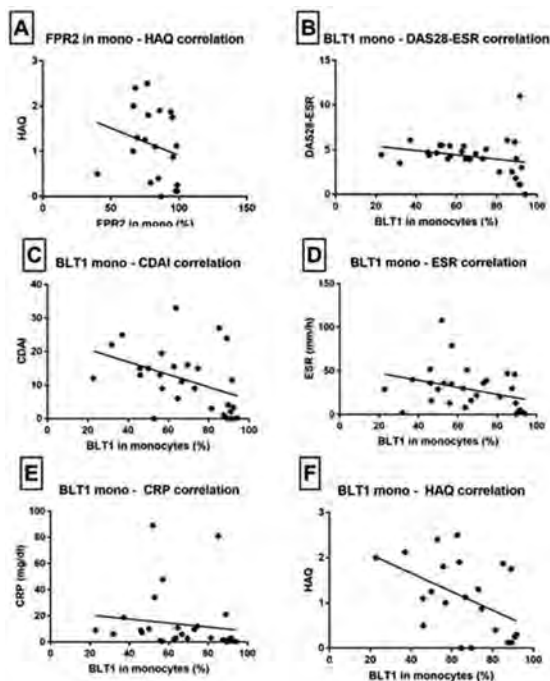

S. Pemiola, L. Dinoa, N. Lacarpia, D. Natuzzi, R. Bizzoca, F. Iannone.  
Rheumatology Unit – Department of Emergency Medicine and Transplantation,  
University of Bari, Bari, Italy

**Background:** Inflammation is the physiologic response against noxious stimuli to restore homeostasis and tissue repair. At the initial phase, characterised by an increase in pro-inflammatory cytokines aiming to neutralise the tissue injury, the resolution process must follow to down-regulate the inflammation and to promote the tissue repair. That latter phase is driven by the so called Pro-Resolving Specialised Mediators (SPMs), such as Resolvin (RvD and RvE), Protectins, Maresins and Lipoxin A4 (LXA4), bioactive metabolites of omega-3 fatty acids that act by interacting with specific cellular receptors: CMKLR1 and BLT1 for RvE1, FPR2 and GPR32 for RvD1 and FPR2 for LXA4. In rheumatoid arthritis (RA) the reactive inflammation becomes persistent and the innate immune response turns into the adaptive immune activation. Nowadays there is no evidence whether SPMs are involved in RA pathogenesis.

**Objectives:** Purpose of this study was to evaluate the expression of CMKLR1, FPR2 and BLT1 in RA patients and to correlate it to the disease activity.

**Methods:** Patients affected with RA, according to the 2010 EULAR/ACR classification criteria, were enrolled in this study. Exclusion criteria were: minority age, status of pregnancy or breastfeeding, concomitant any other autoimmune disease. At entry, ESR, CRP, DAS28-ESR, CDAI, Health Assessment Questionnaire Disability Index (HAQ) and peripheral venous blood sample were collected. Based on DAS28-ESR, patients were divided into high-moderate (H-Mo/RA if DAS28-ESR  $\geq 3.2$ ) and low-remission (L-Rem/RA if DAS28  $< 3.2$ ) disease activity group. The expression of CMKLR1, FPR2 and BLT1 in peripheral T cells (CD3) and monocytes (CD14) was evaluated by flow-cytometry assay. Differences for continuous variables were evaluated using the Mann-Whitney test, while for categorical data the Fisher's probability test. Correlations were assessed using the Spearman test.

**Results:** Thirty RA patients, 21 H-Mo/RA and 9 L-Rem/RA, were studied. While no difference in the expression of CMKLR1, FPR2 and BLT1 in CD3-T cells between the 2 groups was found, SPMs receptors were differently expressed on CD14-monocytes. BLT1<sup>+</sup>CD14<sup>+</sup> cells were significantly higher in L-Rem/RA (90,96%) than in H-Mo/RA/RA (56,70%) ( $p: 0.0001$ ). Likewise, FPR2<sup>+</sup>CD14<sup>+</sup> cells were significantly higher in L-Rem/RA (92,29%) than in H-Mo/RA/RA (79,94%) ( $p: 0.01$ ). CMKLR1 expression in monocytes was not regulated by disease activity. We also demonstrated an inverse correlation between BLT1 level in monocytes and ESR ( $p: 0.01$ ), CRP levels ( $p: 0.008$ ), DAS28-ESR ( $p: 0.03$ ), CDAI ( $p: 0.0076$ ) and HAQ ( $p: 0.0138$ ) and a weak correlation between FPR2 expression and HAQ ( $p: 0.05$ ) (figure 1).

**Abstract AB0133 – Figure 1.** Statistically significant correlation between the expression of FPR2 or BLT1 in monocytes and different parameters such as ESR ( $p: 0.0166$ ;  $r: -0.434$ ), CRP ( $p: 0.0084$ ;  $r: -0.4726$ ), DAS28-ESR ( $0.0318$ ;  $r: -0.3927$ ), CDAI ( $p: 0.0076$ ;  $r: -0.4936$ ) and HAQ (FPR2:  $p: 0.05$ ;  $r: -0.4438$ ; BLT1:  $p: 0.0138$ ;  $r: -0.5169$ ).

ESR: Erythrocyte Sedimentation Rate; CRP: C-Reactive Protein; DAS28-ESR: Disease Activity Score of 28 joints; CDAI: Clinical Disease Activity Index; HAQ: Health Assessment Questionnaire Disability Index.  $P$ -value  $< 0.05$  was considered statistically significant.

**Conclusions:** In this study, FPR2 and BLT1 expression seem to be regulated by the activity of RA disease. As FPR2 and BLT1 should be involved in down-regulating the inflammation by monocytes, it might be hypothesised that a defective signalling through these SPMs receptors may contribute to sustain chronic inflammation in active RA. However, further studies are needed to explore the intricate mechanisms beyond inflammation and its resolution.

**AB0134 PHOSPHORELATED STAT3 EXPRESSION IN PERIPHERAL BLOOD MONONUCLEAR CELLS IN RHEUMATOID ARTHRITIS**

S. Pemiola, F. Cacciapaglia, D. Natuzzi, R. Bizzoca, N. Lacarpia, F. Iannone.  
Rheumatology Unit – Department of Emergency Medicine and Transplantation,  
University of Bari, Bari, Italy

**Background:** The JAK-STAT pathway is mainly involved in the regulation of the expression of cytokines and growth factors; so it controls the proliferation, differentiation, migration and death of the cells of the immune system. In patients with RA, studies have shown increased activation of STAT3 with undergoes phosphorylated (pSTAT3), probably due to increased levels of cytokines such as IL-6, IL-11, IL-12.

**Objectives:** This study aims at investigating the level of expression of STAT3 and pSTAT3 in peripheral blood lymphomonocytes cells of patients with Rheumatoid Arthritis (RA), correlating them with disease activity (ESR, CRP, clinimetric tests).

**Methods:** Patients affected with RA, according to the 2010 EULAR/ACR classification criteria, were enrolled in this study. Exclusion criteria were: minority age, status of pregnancy or breastfeeding, concomitant any other autoimmune disease. At entry (new treatment with csDMARDs or biological drugs) ESR, CRP, DAS28-ESR, CDAI and peripheral venous blood sample were collected. The expression of STAT3 and pSTAT3 in lymphomonocytes cells, CD4 and CD14 cells were evaluated by flow-cytometry assay. The level of STAT3 gene was studied by qPCR. Differences for continuous variables were evaluated using the Mann-Whitney test, while for categorical data the Kolmogorov-Smirnov test. Correlations were assessed using the Spearman test.

**Abstract AB0134 – Figure 1**

**Results:** Twenty RA patients were studied, comparing STAT3 and pSTAT3 levels with 9 seronegative arthritis patients (SA) and 8 healthy control (HC). While no difference in the expression of STAT3 levels between the 3 groups (in flow-cytometry and qPCR assays), pSTAT3 was higher in RA (9,5%) than in SA (2,74%) ( $p:$

0.005) or HC (4.81%) ( $p$ : 0.04); between the 3 groups, pSTAT3 was differently expressed in CD4-lymphocytes and CD14-monocytes (figure 1). We also demonstrated a correlation between pSTAT3 level in CD14 +cells and ESR ( $p$ : 0.026;  $r$ : 0.4625). We found no correlation between pSTAT3 expression and Body Mass Index or disease duration.

**Conclusions:** In this study, STAT3 seems to be activated more in RA than SA or HC. Monocytes (as macrophage) and T-cells have important role in RA. Isomaki et al. demonstrated a correlation between IL-6 level and STAT3 activation so it might be suggested a possible role of pSTAT3 as a biomarker of disease activity. However, further studies are needed to explore the important role of JAK-STAT pathway in RA.

#### AB0135 CIRCADIAN RHYTHMS OF IMMUNE CELLS IN HEALTHY INDIVIDUALS AND PATIENTS WITH RHEUMATOID ARTHRITIS

S. Wilantri<sup>1,2</sup>, on behalf of AG Buttgerit, C. Strehl<sup>1,2</sup>, on behalf of AG Buttgerit, D. Abdirama<sup>1,2</sup>, on behalf of AG Buttgerit, T. Gaber<sup>1,2</sup>, on behalf of AG Buttgerit, F. Buttgerit<sup>1</sup>, on behalf of AG Buttgerit. <sup>1</sup>Rheumatology and Clinical Immunology, Charité Universitätsmedizin Berlin/DRFZ Berlin; <sup>2</sup>Glucocorticoid and Bioenergetic, Deutsches Rheuma Forschungszentrum, Berlin, Germany

**Background:** Clinical symptoms of rheumatoid arthritis (RA), such as joint stiffness, swelling and pain, manifest in circadian pattern with the highest intensity occurs at early dawn. This is known to correlate with the circadian expression of IL-6, which peaks before the onset of the symptom. Despite this finding, the circadian behaviour of immune system in cellular and molecular level in RA patients has not yet been extensively investigated.

**Objectives:** Our previous study suggested that immunological circadian rhythms in patients with RA were altered when compared to the healthy individuals. Currently, we are performing 24 hours study involving RA patients and healthy individuals to further monitor the dynamic occurrence of diverse immune cells in the periphery.

**Methods:** Up to this time five eligible RA patients aged 45–75 years and twelve eligible healthy controls were recruited to join the study. On the study day, the blood was drawn in two hours interval throughout 24 hours. The participants were provided with regular meal, allowed to eat snacks ad libitum and carry passive activities. The absolute number of circulating immune cells was determined using TruCount. RNA were isolated from CD14<sup>+</sup> monocytes and analysed by real-time PCR.

**Results:** The major populations of immune cells in the periphery of healthy controls, including CD4 T cells, CD8 T cells, regulatory T cells, B cells and monocytes, displayed circadian rhythm that peaks during the rest phase. The rhythms are in general shifted a few hours later in the RA patients. Noteworthy, CD14 monocyte, which is one of the major sources of IL-6 in RA, showed a more pronounced rhythm with higher amplitude in RA patients compared to healthy individuals. Furthermore, the following clock genes are rhythmically expressed in CD14 monocytes of both groups: *Rorα*, *Per1*, *Per2*, *Per3* and *DBP*. The peak of *Rorα*, *Per1*, *Per3* *DBP* and *CRY1* is shifted a few hours later in RA patients. Interestingly, circadian variation is not observed in the expression of *RevErbα* in healthy individuals, while in the RA patients a rhythm is established.

**Conclusions:** In general, circadian rhythm of immune system in cellular and molecular level in RA patients appears to undergo phase shift and peaks a few hours later in comparison to healthy individuals. New established rhythms were also observed in cellular and molecular level. Another round of study involving seven RA patients is planned this spring to complete the project. Considering our data, we will continue to investigate circadian rhythms in expanded immune cell population using mass cytometry, immunoassay and microarray. Identification of immunological circadian rhythms in patients with RA and healthy individuals will help us to expand our knowledge in autoimmunity and provide an outlook on potential future implications.

#### AB0136 THE EFFECT OF IL-6 RECEPTOR ANTIBODY FOR THE TREATMENT OF MCH-LPR/LPR-RA1 MICE THAT SPONTANEOUSLY DEVELOPED ANKYLOSING ARTHRITIS

T. Izumiya<sup>1</sup>, Y. Mori<sup>1</sup>, S. Mori<sup>2</sup>, K. Takeda<sup>3</sup>, S. Horie<sup>3</sup>, T. Kodama<sup>3</sup>, E. Itoi<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Tohoku University Graduate School of Medicine; <sup>2</sup>Oral and Maxillofacial Surgery, Tohoku University Graduate School of Dentistry; <sup>3</sup>Laboratory of Biomedical Engineering for Cancer, Department of Biomedical Engineering, Graduate School of Biomedical Engineering, Miyagi, Sendai, Japan

**Background:** Mch-lpr/lpr-RA1 (RA1) mice are new strain mice which spontaneously developed arthritis in ankle and finally leads to ankylosis. There is no report that drug treatment has been applied to these mice.

**Objectives:** To examine the effect of mouse IL-6 receptor antibody MR16-1 for the treatment of RA-1 mice.

**Methods:** Male RA1 mice were randomly divided into treated and control groups. MR 16-1 was applied from 10 weeks of age for the treatment group. Saline was applied for the control group. The drug was administered every two weeks with the initial dose of 2 mg, then 0.5 mg. The effects were evaluated by histological synovitis score, *in vivo* imaging using ICG-encapsulated liposomes and the expression of serum SAA and IL-6.

**Results:** The tissue evaluation was carried out at 14 weeks, 17 weeks and 20 weeks of age. The histological score of treated groups were significantly improved compared with control group at every age. The interclass correlation coefficient was 0.771. *In vivo* imaging using ICG-encapsulated liposomes showed that significant signal decrease in treated groups at 14 weeks, but no significant difference was observed after 16 weeks. Blood SAA was significantly improved at 17 weeks of age.

**Abstract AB0136 – Figure 1**

**Conclusions:** IL-6 receptor antibody is effective for the treatment of ankylosing arthritis of RA1 mice. IL-6 might be a new potential target of treatment for ankylosing arthritis.

#### AB0137 ARTHRITIS-ASSOCIATED EGGERTHELLA LENTA MODULATE DISEASE VIA METABOLIC AND MICROBIAL ALTERATIONS

V. Taneja. *Mayo Clinic, Rochester, USA*

**Background:** Role of environmental factors in predisposition to develop rheumatoid arthritis (RA) has gained interest due, in part, to the studies showing an association of gut microbiota with immune homeostasis. Although the etiology of RA is unknown, recent studies on the role of gut microbiota in inflammatory adaptive immune response have led to the concept that interaction between the host microbiome and genetic factors influences autoimmunity. We have shown an association of rare lineage commensals, *Eggerthella lenta*, with RA.

**Objectives:** In this study, we aimed to determine how human gut commensal *E. lenta* modulates gut epithelial integrity and inflammation via metabolites in humanised mice expressing RA-susceptible HLA-DQ8.

**Methods:** DQ8 mice following immunisation with type II collagen develop arthritis and antigen-specific cellular and humoral response. DQ8 mice orally gavaged

with RA-associated *E. lenta* on alternate days for one week and were induced for arthritis. Gavage with microbes continued for 4 weeks. Mice were monitored for onset and progression of arthritis. Epithelial integrity was done by FITC-Dextran assay and citrulline levels in faecal and plasma samples were measured by liquid chromatography mass spectrometry

**Results:** Mice gavaged with *E. lenta* showed a much higher load of gut microbes compared to controls. Surprisingly, *E. lenta* did not augment gut permeability as it was similar to non-gavaged arthritic mice. *Eggerthella lenta* is involved in ornithine pathway leading to generation of citrulline. To test if gavage with *E. lenta* accumulates citrulline in the gut, we tested citrulline levels in faecal samples by liquid chromatography mass spectrometry. Surprisingly, mice gavaged with *E. lenta* had lower levels of citrulline in faecal samples as compared to mice naïve mice with no gavage or arthritic mice without gavage. One can speculate from these observations that there is an expansion of commensals, like *E. lenta* in RA, leading to production of citrulline. To determine if citrulline could be accumulated outside of gut, we measured citrulline in sera of mice in various groups, gavaged with *E. lenta*, naïve and mice induced for arthritis but no *E. lenta* gavage. Surprisingly, mice gavaged with *E. lenta* and induced for arthritis had lower levels of citrulline as compared to controls induced for arthritis but no gavage,  $p < 0.05$ . Naïve mice gavaged with *E. lenta* also showed significantly much lower levels compared to sera of naïve mice.

**Conclusions:** This data suggests that *E. lenta* may be a major player in determining certain metabolic pathways. If Citrulline is being converted to arginine and used in other pathways is currently under investigation. Our studies suggest that gut commensals influence immune response in and away from the gut. Commensals and their products may provide novel targets for therapeutic strategies in arthritis.

#### AB0138 THE BONE MARROW OEDEMA IS LINKED TO A OSTEOCLASTIC ENVIRONMENT IN BONE MARROW DURING COLLAGEN INDUCED MICE ARTHRITIS DEVELOPMENT

W. Tan, W. Xuan, Q. Wu, A. Luo, W. Yan, F. Wang. *Rheumatology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

**Background:** Bone erosion is a central pathogenic event in Rheumatoid arthritis (RA) and is associated with joint damage and poor functional outcome. The synovitis is traditionally regarded as the primary event of bone erosion in RA and synovial cells are usually thought to play a critical role in this pathologic process. However, the synovitis-centred concept has long been challenged by recent clinical finds. Bone erosion formation also could be found in joints without clinical traits of synovitis, suggesting that synovitis and joint erosion could be uncoupled. Moreover, recent study demonstrated that bone marrow oedema (BME) that identified by magnetic resonance imaging (MRI) is strongly associated with erosive progression, which independent of local synovitis in RA.

**Objectives:** BME is also called osteitis, which represent the replacement of adipose tissue with inflammatory cells in bone marrow. In this study we addressed 2 questions: 1) the course of BME and synovitis in a same joint during CIA development; 2) how BME cause the bone erosion in CIA.

**Methods:** Using collagen induced mice arthritis model, we compared the compared the time course of appearance of BME, synovitis and arthritic symptoms during the development of CIA. The changes RANKL, cytokines, osteoclast and immune cells expression in bone marrow during the development of CIA were analysed by flow cytometric analysis, immunofluorescence staining and RT-qPCR.

**Results:** MRI BME can be identified as early as 25 days after first immunisation, when there is no any histopathological changes and arthritis symptoms. Flow cytometry and immunofluorescence staining indicated that the proportion of pre-OCs were significantly increased in bone marrow after day 25 with the presence of BME. At day 25, accompanied by presence of BME and increased pre-OCs, the number of trabecular bone was significantly diminished as compared with those at day 20 and reached its lowest number at day 35. We then examined the transcription of several pro-inflammatory cytokines and chemokines related to OCs differentiation, migration and activation, such as RANKL, IL-17, TNF $\alpha$ , CCL3, CCL4, CCL12, CCR5 by Real-time PCR. The most prominent RANKL

change was observed at day 35. IL-17 and TNF $\alpha$  mRNA were elevated from day 25, reaching a peak at day 28 and thereafter gradually decreasing. Expression of CCL3 and CCL12 were only higher at day 28 and day 25, respectively, while there was no significant change in CCR5 and CCL4 mRNA in the bone marrow. The proportion of T cells and monocytes in bone marrow were significantly higher from day 25 to day 45. No differences in B cells and plasma cells were detectable at any time points. Bone marrow cells from the presence of BME showed significantly increased ability to formation OCs *in vitro*.

**Conclusions:** BME precede the synovitis and arthritic symptoms during the development of CIA. Accompanied BME appearance, we identified an altered bone microenvironment that favours OCs differentiation and survival in CIA mice. We proposed that BME linked to a unique "osteoclastic environment" in CIA disease progression. These findings provide a new perspective for comprehending the development of erosions in RA.

#### AB0139 INVESTIGATION OF PREVOTELLA COPRI FROM RHEUMATOID ARTHRITIS PATIENTS

Y. Maeda<sup>1</sup>, D. Mitoaka<sup>2</sup>, T. Nii<sup>1</sup>, Y. Matsumoto<sup>2</sup>, M. Matsushita<sup>3</sup>, Y. Saeki<sup>3</sup>, M. Narazaki<sup>1</sup>, A. Kumanogoh<sup>1</sup>, S. Nakamura<sup>2</sup>, K. Takeda<sup>4</sup>. <sup>1</sup>Department of Respiratory Medicine and Clinical Immunology; <sup>2</sup>Department of Infection Metagenomics, Genome Information Research Center, Research Institute for Microbial Diseases, Osaka University, Suita; <sup>3</sup>Rheumatology, National Hospital Organization Osaka Minami Medical Center, Kawachinagano; <sup>4</sup>Department of Microbiology and Immunology, Osaka University, Suita, Japan

**Background:** We have previously reported some of the rheumatoid arthritis (RA) patients had *Prevotella copri* in the intestine. By using germ-free (GF) SKG mice, we also showed that *Prevotella*-dominated gut microbiota contribute to the development of arthritis<sup>1</sup>. However, *P. copri* itself has not been isolated from RA patients and their molecular biology was unknown.

**Objectives:** Firstly, we planned to evaluate the intestinal microbiota in RA patients before and after the treatment. Second, we isolated *P. copri* strains from RA patients and healthy controls (HCs) and analysed whether RA patients-derived *P. copri* expanded in the intestine of GF mice.

**Methods:** We first examined whether RA patients have altered composition of microbiota. All the patients were diagnosed according to the American College of Rheumatology/<sup>European League Against Rheumatism 2010</sup> classification criteria for RA. We collected faecal samples from 55 RA patients (61.5 $\pm$ 9.5 years, mean ages  $\pm$ SD) and 33 HCs (56.2 $\pm$ 8.2 years) to investigate the microbiota by 16S rRNA-based deep sequence technique. We also analysed bacterial counts of *Prevotella* and *Bacteroides fragilis* by qPCR method. Moreover, we isolated *P. copri* from faecal contents of RA patients and HCs. GF mice were inoculated with *P. copri* from RA patients and HCs for further analysis.

**Results:** We found that 34.5% (19/55) of RA patients and 18.1% (6/33) of healthy controls have relatively high abundance of *Prevotella* (>4%) in the intestine. These results were compatible with our previous observations. When we focused on the patients who harboured high abundance of *Prevotella* in the gut, *Prevotella/B. fragilis* ratio was decreased after the treatment. The mean *Prevotella/B. fragilis* ratio were changed from 1.28 to 0.75 ( $p=0.08$ ). Further analyses revealed that RA patients-derived *P. copri* successfully colonised to GF-mice and induced Th17 cells in the large intestine.

**Conclusions:** We found that alternation of microbiota composition was observed after the RA treatment. Moreover, we successfully isolated *P. copri* from RA patients and HCs. RA patients-derived *P. copri* efficiently expanded in the intestine of GF mice.

#### AB0140 THE ROLE OF RAF KINASE INHIBITORY PROTEIN IN RHEUMATOID ARTHRITIS

Y.-H. Cheon<sup>1</sup>, Y.S. Suh<sup>2</sup>, S.M. Yi<sup>1</sup>, M. Kim<sup>1</sup>, S.-I. Lee<sup>1</sup>, H.S. Noh<sup>1</sup>. <sup>1</sup>Gyeongsang National University Hospital, Jin-Ju; <sup>2</sup>Gyeongsang National University Changwon Hospital, Changwon, Korea, Republic of Ireland

**Background:** Rheumatoid arthritis (RA) is an autoimmune inflammatory disease of the joints and is characterised by immune cell infiltration, synovial hyperplasia, and destruction of cartilage and underlying bone<sup>1</sup>. Raf kinase inhibitory protein

(RKIP), an endogenous inhibitor of the extracellular signal-regulated kinase (ERK) pathway, has been implicated as a suppressor of metastasis and NF- $\kappa$ B pathway in cancers<sup>2</sup>.

**Objectives:** The NF- $\kappa$ B and ERK pathways are considered to be one of the most important pro-inflammatory signalling pathways in RA. Therefore, RKIP might be a potential therapeutic target for RA. However, whether and how RKIP regulates RA is not fully understood. The present study was performed to examine whether and how RKIP are differentially regulated in RA.

**Methods:** The expressions of RKIP were assessed in synovial tissue, fluid and fibroblast-like synoviocytes (FLS) from patients with RA and osteoarthritis (OA) by immunofluorescence staining and western blotting. RA- or OA-FLS were infected with either a recombinant adenoviral RKIP overexpressing vector (Ad-RKIP) or shRNA-expressing vector (Ad-shRKIP). Control cells infected with a GFP-targeted recombinant adenoviral vector (Ad-shGFP) (figure 1C). And then, we investigated the effects of RKIP on the migratory activity and invasion rates of FLS by transwell migration and invasion assay.

**Results:** Here, we show that RKIP expression is inversely correlated with RA. The levels of RKIP were significantly decreased in fibroblast-like synoviocytes (FLS), synovial fluid and synovium of RA patients compare to OA patients. And also find that migration and invasion of RA-FLS were significantly increased by the inhibition of RKIP compare to OA-FLS. Knockdown of RKIP in RA or OA-FLS resulted in a dramatic increase of MMP3 and IL6. We also found osteoclastogenesis of RAW cells were increased by the knockdown of RKIP.

**Conclusions:** Our data identify a role of RKIP in RA and suggest that further studies on the potential involvement of RKIP will be beneficial in better understanding the pathology of and providing a new target for treatment for RA.

## Spondyloarthritis – etiology, pathogenesis and animal models

### AB0141 CERTOLIZUMAB PEGOL LIKE REDUCES INFLAMMATION AND BONE DAMAGE IN TMTNF TRANSGENIC MICE

E. Vieira-Sousa<sup>1</sup>, S. Caetano Silva<sup>2</sup>, B. Vidal<sup>2</sup>, I. Lopes<sup>2</sup>, H. Canhão<sup>3</sup>, J. E. Fonseca<sup>1</sup>. <sup>1</sup>Rheumatology and Metabolic Bone Diseases Department, Hospital de Santa Maria, CHLN and Rheumatology Research Unit, Instituto de Medicina Molecular, Faculty of Medicine, University of Lisbon, Lisbon Academic Medical Centre; <sup>2</sup>Rheumatology Research Unit, Instituto de Medicina Molecular, Faculty of Medicine, University of Lisbon, Lisbon Academic Medical Centre; <sup>3</sup>CEDOC, EpiDoC Unit, NOVA Medical School, Lisbon, Portugal

**Background:** Transmembrane (tm)TNF (TgA86) mice is a transgenic line that spontaneously develops peripheral arthritis and spondylitis at 4 weeks of age, mimicking human spondyloarthritis (SpA).

**Objectives:** The aim of this work is to understand the effect of TNF blockade in this SpA-like phenotype mouse strain, focusing on histological inflammation and bone damage.

**Methods:** (tm)TNF (TgA86) mice were treated with a certolizumab pegol like product mice equivalent (Ab501), 100 mg/kg twice a week intraperitoneal, or with vehicle (phosphate buffer saline), for 12 weeks, in a therapeutic (10 weeks of age) and preventive (4 weeks of age) experimental settings. A semi-quantitative score for the severity of histologic inflammation and bone damage, in the paws (infiltration, lining cells, erosions and global), and in the spine (inflammation, intervertebral disc destruction, cartilage damage, bone erosion and ectopic chondrocytes/chondrocyte) was applied to haematoxylin and eosin stained slides.

**Results:** 14 (tm)TNF (TgA86) mice (6M/8F) at 10 weeks of age (therapeutic group), and 15 (tm)TNF (TgA86) mice (10M/5F) at 4 weeks of age (preventive group), were treated with Ab501; and 30 (tm)TNF (TgA86) mice with the respective vehicles, for a period of 12 weeks. A statistically significant reduction of the inflammatory infiltrate ( $p \leq 0.001$ ), lining cells layers ( $p \leq 0.05$ ), erosions ( $p \leq 0.05$ ) and global inflammatory score ( $p \leq 0.05$ ) of the paws, was observed in the Ab501

treated group, when compared to the vehicle group, both in the 10 and 4 weeks of age treatment groups. In the spine, statistically significant reductions of the inflammation ( $p \leq 0.001$ ), intervertebral disc destruction ( $p \leq 0.05$ ), cartilage damage ( $p \leq 0.001$ ), bone erosion ( $p \leq 0.05$ ), and ectopic chondrocytes/chondrocyte scores ( $p \leq 0.001$ ) was also depicted in Ab501 treated group in comparison with vehicle.

**Conclusions:** The certolizumab pegol like product mice equivalent reduced histologic inflammatory infiltrate in paws and spine of (tm)TNF (TgA86) mice. Bone damage, as defined by erosions in the paws and spine and ectopic chondrocytes/chondrocyte formation in the spine, also significantly improved in (tm)TNF (TgA86) mice.

**Acknowledgements:** To Leonie M van Duivenvoorde and Dominique Baeten (Amsterdam Academic Medical Centre) for providing (tm)TNF (TgA86) mice for breeding and colony establishment. George Kollias from Flemming Institute for authorisation for the use this mice line.

This investigator-initiated study was supported (financial and product) by UCB.

### AB0142 A REGULATORY CCR10+ CD8+ T CELL POPULATION DIFFERENTIATES PSORIATIC ARTHRITIS FROM PSORIASIS LIMITED TO CUTANEOUS INVOLVEMENT

E.F. Leijten<sup>1,2</sup>, T.S. van Kempen<sup>1,2</sup>, M.A. Olde Nordkamp<sup>1,2</sup>, J.S. Mertens<sup>1,2</sup>, C. Angiolilli<sup>1,2</sup>, M.L. Boes<sup>2,3</sup>, T.R. Radstake<sup>1,2</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology; <sup>2</sup>Laboratory of Translational Immunology; <sup>3</sup>Department of Pediatrics, UMC Utrecht, Utrecht, Netherlands

**Background:** Few studies have compared the immune cell phenotype or function from patients with psoriatic arthritis (PsA) to patients with psoriasis limited to cutaneous involvement (Pso). Head-to-head comparisons of the immune cells in PsA and Pso can provide essential insights into the link between epithelial/cutaneous disease and rheumatic disease.

**Objectives:** Compare the immune cell phenotype and function from patients with PsA compared to Pso.

**Methods:** PBMCs were collected from 23 healthy controls, 21 patients with psoriasis in whom psoriatic arthritis was excluded by a rheumatologist (Pso), 23 patients with psoriatic arthritis (PsA) and 16 patients with ankylosing spondylitis. The Pso and PsA cohorts were free from immunomodulatory therapy and matched for demographics and skin severity. Extracellular and intracellular immunophenotyping using a highly standardised flow-cytometric approach detected over 110 different myeloid and lymphoid cell populations. Lesional and non-lesional skin biopsies and synovial fluid samples were collected from a subset of patients.

**Results:** The circulating immune cell composition showed a remarkable overlap in Pso and PsA, and only one specific cell population was different: CCR10 +CD8 +T cells, being enriched in PsA PBMCs as compared to Pso PBMCs. Further phenotypic and functional evaluation characterised them as effector memory, CXCR3-CCR6-, co-expressing the skin homing markers CCR4 and CLA, but lacking the gut homing marker  $\alpha 4\beta 7$ . Upon re-stimulation, CCR10 +CD8+T cells showed low IFN $\gamma$  production, high IL-10 production and were enriched for FOXP3<sup>high</sup>CD25+ phenotype. Their frequencies in PBMCs were unrelated to joint disease activity and were stable throughout joint disease fluctuations. Synovial fluid displayed low frequencies of CCR10 +CD8+T cells whereas skin contained the most abundant CCR10 +CD8+T cell frequencies. Lesional psoriasis skin displayed relatively fewer CCR10 +CD8+T cells compared to non-lesional skin.

Abstract AB0142 – Figure 1

**Conclusions:** CCR10 +CD8+T cells have regulatory properties and differentiate Pso from PsA. Future studies are needed to uncover if aberrances in regulatory, cutaneous CD8 +T cells precede the transition to joint disease.

**Disclosure of Interest:** None declared

AB0143

#### IMPLICATION OF OSTEONECTIN ON CARDIOVASCULAR RISK IN AXIAL SPONDYLOARTHRITIS: A SEROLOGICAL AND GENETIC STUDY

F. Genre<sup>1</sup>, J. Rueda-Gotor<sup>1</sup>, S. Remuzgo-Martínez<sup>1</sup>, J. Irure-Ventura<sup>2</sup>, A. Corrales<sup>1</sup>, V. Mijares<sup>1</sup>, V. Portilla<sup>1</sup>, R. Blanco<sup>1</sup>, L. Rodríguez-Rodríguez<sup>3</sup>, J. L. Hernández<sup>4</sup>, J. Llorca<sup>5</sup>, J.G. Ocejo-Vinyals<sup>2</sup>, R. López-Mejías<sup>1</sup>, M.A. González-Gay<sup>1</sup>. <sup>1</sup>Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, IDIVAL; <sup>2</sup>Immunology Division, Hosp. Univ. M. de Valdecilla, Santander; <sup>3</sup>Rheumatology Dept, Inst. de Inv. Sanitaria del Hosp. Clín. San Carlos (IDISSC), Hosp. Clín. San Carlos, Madrid; <sup>4</sup>Bone Metabolism Unit, Dept. of Internal Medicine, Hosp. Univ. M. de Valdecilla, IDIVAL, Univ. of Cantabria, Reticef; <sup>5</sup>Dept. of Epidemiology and Computational Biology, School of Medicine, Univ. of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander, Spain

**Background:** Cardiovascular (CV) disease and atherosclerosis are common causes of morbidity in axial spondyloarthritis (axSpA),<sup>1</sup> a disease characterised by changes in the osteoproliferative process. A dysregulation in the molecules involved in bone remodelling could also affect the atherosclerotic process, since both processes are linked.<sup>2,3</sup> Osteonectin (ON), a key molecule in bone homeostasis,<sup>4</sup> was associated to obesity, insulin resistance and diabetes.<sup>5</sup>

**Objectives:** Since the exact role of ON on CV risk in axSpA has not been elucidated yet, we evaluated its role in the development of subclinical atherosclerosis and its association with CV risk factors in axSpA patients at the serological and genetic level.

**Methods:** 171 axSpA patients fulfilling the classification criteria for axSpA<sup>6,7</sup> and 84 controls were included in this study. Serum ON levels were measured by multiplex assays. Carotid ultrasound was performed to evaluate the presence of markers of subclinical atherosclerosis. Five ON polymorphisms (rs1054204 [G/C], rs11950384 [G/A], rs13182103 [A/G], rs11745387 [G/A] and rs4958487 [A/G]) were selected by tagging and genotyped using TaqMan assays.

**Results:** No difference was observed in ON levels between axSpA and controls. Serum ON and CRP levels at study positively correlated in axSpA (p=0.008). Higher ON levels were observed in men, smokers and patients with an atherogenic index indicative of dyslipidemia (p=0.008, 0.01 and 0.001, respectively). No association was found between ON and subclinical atherosclerosis in axSpA. Interestingly, we disclosed that the presence of the A allele of rs13182103 and rs11950384 ON polymorphisms led to lower ON serum levels in axSpA (p<0.05). Furthermore, the presence of the A allele of rs13182103 was linked to a later diagnosis of axSpA when compared to those patients bearing the G allele (p=0.002).

**Conclusions:** Our results show that ON is linked to inflammation and CV risk factors in axSpA and suggest that the A allele of rs13182103 and rs11950384 ON polymorphisms may have a protective effect in axSpA, leading to reduced ON serum levels and later diagnosis of the disease. These data support an implication of ON in the development and progression of atherosclerotic disease in axSpA.

#### NMR BASED SERUM AND SYNOVIAL FLUID METABOLOMICS REVEAL SIMILAR METABOLOMIC PROFILE IN PATIENTS WITH REACTIVE ARTHRITIS AND UNDIFFERENTIATED SPONDYLOARTHRITIS

R. Misra<sup>1</sup>, D. Dubey<sup>2</sup>, S. Ahmed<sup>3</sup>, S. Chaurasia<sup>1</sup>, S. Chaudhary<sup>1</sup>, A. Guleria<sup>2</sup>, D. Kumar<sup>2</sup>. <sup>1</sup>Clinical Immunology, Sanjay Gandhi Post Graduate Institute of Medical Sciences; <sup>2</sup>Centre for Biomedical Research; <sup>3</sup>Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

**Background:** Reactive arthritis (ReA) and undifferentiated spondyloarthritis (USpA) have similar clinical picture, the former is preceded by mucosal infections and the latter do not meet criteria of well defined entity of seronegative spondyloarthritis (SSA) We have shown that both ReA and uSpA have similar synovial fluid T cell response to salmonella antigens and cytokine profile.

**Objectives:** To investigate if the metabolic profiles of ReA in sera and synovial fluid are different from those of USpA

**Methods:** Standard definitions were used to classify patients as ReA<sup>2</sup> and uSpA<sup>3</sup> Metabolic profiles in sera and synovial fluid samples were measured using 1D <sup>1</sup>H NMR spectroscopy and analysed using CHENOMX® software. The quantitative profiles between the groups were compared using Partial Least Square-Discriminatory Analysis (PLS-DA) and Q<sup>2</sup> parameter was used to assess the metabolic differences between the groups.

**Results:** The study involved 19 ReA and 13 USpA patients with median age 26 (21–33.75) years. Of 32 patients: 7 (22%) were females, three(12%) had mono-phasic illness, 16 (64%) polyphasic, and six(24%) persistent arthritis (follow-up data was not available for 7). 27% had monoarticular, 59% oligoarticular and 14% polyarticular involvement. Six had inflammatory backpain, three had oral ulcers, one dactylitis, but none had mucocutaneous manifestations. Two had asymptomatic sacroiliitis on radiographs.

Compared to normal controls (n=18, median age=29 years, male:female=17:1), the sera of ReA/USpA patients were characterised by elevated levels of malonate, mannose, N-nitrosodimethylamine, and pyruvate, whereas 3-hydroxyisovalerate was decreased significantly (T-test p-value<0.001). PLS-DA analysis between sera and synovial fluid samples showed clear demarcation with higher pyruvate and acetoacetate and lower aspartate, methanol, ethanol, and methylsuccinate in synovial fluid samples compared to sera (t-test p<0.01). The PLS-DA analysis of sera showed little difference between ReA and USpA (figure 1) while that of synovial fluid showed Q<sup>2</sup> <0 for all models. Further no significant metabolic differences in sera/synovial fluid were found between HLA-B27 positive and negative groups (Q<sup>2</sup> <0 in all models).

**Abstract AB0144 – Figure 1.** (a) PLSDA of sera of HLA B27 positive versus negative patients (b) PLSDA of synovial fluid of HLA B27 positive versus negative patients

**Conclusions:** ReA and USpA have indistinguishable metabolomics profiles in sera and synovial fluid reflecting similar metabolo-inflammatory pathways involved.

### AB0145 REGULATION OF OSTEOBLASTS BY ALKALINE PHOSPHATASE IN ANKYLOSING SPONDYLITIS

S. Jo<sup>1</sup>, J. Han<sup>2</sup>, Y.L. Lee<sup>1</sup>, T.-H. Kim<sup>1</sup>. <sup>1</sup>Rheumatology, Hanyang University Hospital for Rheumatic Disease; <sup>2</sup>Gencurix, Inc, Seoul, Korea, Republic of Ireland

**Background:** Ankylosing spondylitis (AS) is characterized by excessive spinal ankylosis and bone formation. Alkaline phosphatase (ALP) activity is reported to be high in AS, but little is known about the molecular relationship between ALP and AS.

**Objectives:** The aims of this study were to investigate the relevance of ALP to AS and the role of ALP in the regulation of osteoblast differentiation in AS.

**Methods:** The high-throughput data were downloaded from Gene Expression Omnibus with accession numbers GSE73754 and GSE41038. We retrospectively collected the ALP levels of male patients with AS, to compare with those of gender and age-matched healthy controls (HC) and rheumatoid arthritis (RA) patients. Total ALP and ALP activity in patient's sera were measured in AS and RA groups. ALP gene expression and intracellular ALP activity were analyzed in microarray data of primary bone-derived cells (BdCs) and in In Vitro experiments. Furthermore, the effect of ALP knockdown and inhibitor were performed in primary BdCs and human osteoblasts cells, respectively.

**Results:** ALP level was increased in AS compared with RA and HC. Increased ALP level in AS was associated with radiograph progression. ALP expression was also enriched in bone tissue of AS patients. Furthermore, AS BdCs exhibited elevated ALP activity, leading to accelerating osteoblastic activity and differentiation. Intriguingly, suppression of ALP expression and activity inhibited expression of osteoblastic genes, which are critical for osteogenic differentiation.

**Conclusions:** A multifaceted analysis showed ALP was highly expressed in AS patients. ALP may be involved in the ankylosis of AS and a therapeutic target for preventing ankylosis.

**Disclosure of Interest:** None declared

### AB0146 APREMILAST POTENTIALLY INHIBITS IL-12/IL-23P40 PRODUCTION IN HUMAN ARTHRITIC EX VIVO MODELS

T.W. Kragstrup<sup>1,2</sup>, M. Adams<sup>3</sup>, S. Lomholt<sup>1</sup>, M. Nielsen<sup>1</sup>, L. Heftdal<sup>1</sup>, P. Schafer<sup>3</sup>, B. Deleuran<sup>1,4</sup>. <sup>1</sup>Department of Biomedicine, Aarhus University, Aarhus C; <sup>2</sup>Department of Internal Medicine, Randers Regional Hospital, Randers, Denmark; <sup>3</sup>Department of Translational Development, Celgene Corporation, Summit, USA; <sup>4</sup>Department of Rheumatology, Aarhus University Hospital, Aarhus C, Denmark

**Background:** Apremilast (Otezla) is a phosphodiesterase 4 (PDE4) inhibitor approved for the treatment of psoriasis and psoriatic arthritis (PsA), but the reason why apremilast shows clinical effect in PsA is not fully understood.

**Objectives:** The objective of this study was to study the downstream effects of apremilast on cells of the inflamed joint in *ex vivo* models of immune mediated inflammatory arthritis. First, we tested the effect of apremilast on the secretion of several cytokines, chemokines and growth factors by synovial fluid mononuclear cells (SFMCs). Then, we tested whether apremilast affect factors involved in structural changes by studying fibroblast-like synovial cells (FLSs), osteoclasts, synovial macrophages, and osteoblasts.

**Methods:** Synovial fluid was obtained from a study population consisting of patients with active rheumatoid arthritis (RA), psoriatic arthritis (PsA) or peripheral spondyloarthritis (SpA) with at least one swollen joint (n=18). Synovial fluid mononuclear cells (SFMCs) cultured for 48 hours were used to study the effect of apremilast on secretion of a large panel of cytokines, chemokines and growth factors using the Olink Proseek Multiplex interferon I panel. These effects were compared with the effects of the tumour necrosis factor alpha (TNF $\alpha$ ) inhibitor adalimumab. Further, fibroblast-like synovial cells (FLSs) were used to study metalloproteinase secretion, SFMCs cultured for 21 days were used to study inflammatory osteoclastogenesis and macrophage differentiation, an osteoclast pit formation assay was used to study osteoclast activity, and a mineralization assay was used to study new bone formation.

Abstract AB0146 – Figure 1

**Results:** In SFMCs cultured for 48 hours apremilast decreased the production of IL-12/IL-23p40 (the shared subunit of IL-12 and IL-23) ( $p < 0.00001$ ), colony stimulating factor 1 ( $p = 0.009$ ), CD6 ( $p = 0.03$ ), CD40 ( $p = 0.04$ ), and MCP-1 ( $p = 0.02$ ), and increased the production of C-X-C motif chemokine 5 ( $p = 0.003$ ) dose-dependently. In sub-analyses, the apremilast induced decrease in cytokine production was greater in cultures with a high lymphocyte count and in cultures from patients with a low C-reactive protein level. Further, apremilast had a very different response signature compared with adalimumab, e.g. with a much greater inhibition of IL-12B ( $p = 0.01$ ) and less inhibition of IL-8 ( $p = 0.0001$ ) (see Figure). In SFMCs cultured for 21 days apremilast increased the secretion of IL-10 ( $p = 0.04$ ) and in FLS cultures apremilast decreased MMP3 production ( $p = 0.005$ ). Apremilast decreased osteoclast pit formation but did not change mineralization by human osteoblasts.

**Conclusions:** This study reveals the downstream effects of apremilast in *ex vivo* models of arthritis with a strong inhibition of IL-12/IL-23p40. Our findings could explain some of the efficacy of apremilast seen in IL-12/IL-23 driven immune mediated inflammatory diseases such as psoriasis and psoriatic arthritis.

### AB0147 FAECAL MICROBIOTA STUDY IDENTIFIES DYSBIOSIS IN ANKYLOSING SPONDYLITIS PATIENTS

Z. Chen, J. Qi, X. Zheng, X. Wu, X. Li, J. Gu. Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

**Background:** Ankylosing spondylitis (AS), a prototype of spondyloarthritis (SpA), is a chronic inflammatory disorder with diverse clinical phenotypes. It is widely accepted that AS is genetically determined and trigger of environmental factors is common. Accumulating research have indicated that gut microbiota may play a role in the pathogenesis of AS.

**Objectives:** We conduct this study to characterise and investigate differences in the gut microbiome between patients and healthy donors.

**Methods:** 41 patients with AS fulfilled the modified New York criteria for AS and 19 healthy controls (HCs) were recruited in this study. Fresh faecal samples were collected and microbial DNA were extracted by faecal DNA extraction kit according to the manufacture's instruction. V4 hypervariable region of the 16S ribosomal RNA (16S rRNA) was amplified and sequenced on an IlluminaHiSeq2500 platform. The resulting sequencing data were analysed through an in-house bioinformatics pipeline, including removing the barcodes and primers, merging forward and reverse reads, filtering tags, removing chimaeras, clustering and annotation. The mean species diversity for each sample and the differentiation among those samples are captured by alpha and beta diversity, respectively. Principle Coordinate Analysis (PCoA) was performed to get principal coordinates and visualise from complex, multidimensional data.

**Results:** 16S rRNA community profiling of the faecal sample yielded high sequencing depth, with quality-filtered and connexion to generate a mean number of Taxon\_tag being 66398 $\pm$ 5606 versus 63061 $\pm$ 5474 in AS and HCs group respectively. The gut microbial communities were significantly different and more diverse in AS patients when compared with the HCs by calculating metrics (Chao1) of a diversity ( $p < 0.001$ ). PCoA analysis shown that gut microbiota was able to predicted samples to be AS or HCs. At phylum level, the profile of gut microbiota were dominated by *Bacteroidetes* (56.15% vs 53.31%), *Proteobacteria* (11.19% vs 9.97%) and *Firmicutes* (30.10% vs 34.22%) in both AS and HCs groups respectively. However, difference of distribution were appeared between two groups, such that *Bacteroidetes* and *Proteobacteria* were more common in AS group, while *Firmicutes* was more common in HCs group. At genus level, both group were dominated by *Bacteroides* and *Prevotella-9*. Abundance of *Prevotella-9* were great different between AS patients and HCs with relative abundance of 16.07% and 2.86%, respectively.

**Conclusions:** These results suggested that faecal microbiota of patients with AS differed significantly from that of healthy controls. Further analysis and larger cohort replication will be helpful to identified specific microbial marker of AS.

Roelofs<sup>7</sup>, A.E. Voskuyl<sup>2</sup>, M. Pegtel<sup>1</sup>. <sup>1</sup>Pathology, <sup>2</sup>Rheumatology, Amsterdam Rheumatology and Immunology Center, <sup>3</sup>Gynaecologic oncology, VU University Medical Center, <sup>4</sup>Experimental immunology, Academic Medical Center, Amsterdam; <sup>5</sup>Clinical Chemistry and Hematology, University Medical Center Utrecht, Utrecht; <sup>6</sup>Functional Genomics, VU University; <sup>7</sup>Pathology, Academic Medical Center, Amsterdam, Netherlands

**Background:** In lupus nephritis (LN), genetic and environmental factors drive the chronic activation of antiviral defenses leading to immune complex-mediated glomerular and tubular damage. Increasing evidence suggests the involvement of extracellular vesicles (EVs) in autoimmune disease. Currently a role for EVs in the pathogenesis of lupus nephritis has not been proposed.

**Objectives:** To investigate the role of EVs in the pathogenesis of LN.

**Methods:** To determine the presence of EVs in kidneys, biopsies from LN patients and IgA-nephropathy and Focal Segmental Glomerulosclerosis control patients were used. Serum samples from SLE patients and from RA patients as controls were used to determine the presence of circulating EVs. Primary renal tubular epithelial cells (TEC) were cultured, and Kidney injury molecule-1 (KIM1) expression was assessed by FACS. Exosomes were analyzed by electron microscopy and western blot. mRNA analysis was performed by qPCR. TLR3 inhibition was performed with TLR3/dsRNA complex inhibitor and with hydroxychloroquine.

**Results:** We show that EVs deliver virus-derived small RNA and activate TEC via toll-like receptor 3 (TLR3). Highly specific stem-loop RT-PCRs revealed Epstein Barr Virus (EBV)-encoded small RNAs in LN biopsies while quantitative EBV-DNA PCR, sensitive to a single copy was negative. In situ hybridization failed to detect nuclear EBV-EBER1 (i.e. EBV-infected cells) in LN biopsies. However, we observed atypical EBER signal in the cytoplasm of TECs in LN but not in disease control biopsies, suggestive of uptake of extra-renal EBER. Consistent with this, we detected EBER1 in circulating EVs of SLE sera. The LN tissues express strongly elevated levels of TLR3, Interferon induced transmembrane-1 and -3, and TNF $\alpha$ . Primary TEC cultured in vitro endocytose EBER1-EVs secreted by EBV-infected B cells via phosphatidylinositol receptors such as KIM-1. Importantly, EV-EBER1 uptake by TEC triggers antiviral immunity and pro-inflammatory cytokine secretion in a Toll-like receptor 3 (TLR3)-dependent manner. Treatment with hydroxychloroquine (HCQ) or a small molecule inhibitor that blocks TLR3-RNA interactions strongly reduced the pro-inflammatory effects of EBER1.

**Conclusions:** We propose that small RNA-loaded EVs exacerbate pre-existing autoimmunity in SLE patients by engaging tubular epithelial TLR3, supporting the rationale for TLR3-blockade as therapeutic strategy in the treatment of lupus nephritis.

### AB0149 DECREASED MICRORNA-130A EXPRESSION DRIVES ACTIVATION OF CLASSICAL DENDRITIC CELLS FROM PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

A.P. Lopes<sup>1</sup>, J.A. van Roon<sup>1,2</sup>, S.L. Blokland<sup>1,2</sup>, M. Wang<sup>3</sup>, E. Chouri<sup>1,2</sup>, A. A. Kruize<sup>1</sup>, B.M. Burgering<sup>3</sup>, M. Rossato<sup>2,4</sup>, T.R. Radstake<sup>1,2</sup>, M.R. Hillen<sup>1,2</sup>. <sup>1</sup>Department of Rheumatology & Clinical Immunology; <sup>2</sup>Laboratory of Translational Immunology; <sup>3</sup>Center for Molecular Medicine, University Medical Centre Utrecht, Utrecht University, Utrecht, Netherlands; <sup>4</sup>Functional Genomics Center, University of Verona, Verona, Italy

**Background:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands and dryness of mouth and eyes. Classical dendritic cells are very potent antigen presenting cells known to induce strong T-cell proliferation and cytokine production.

**Objectives:** Considering the critical role of microRNAs (miRNAs) in regulation of gene expression, we investigated miRNA expression in circulating CD11c<sup>+</sup> dendritic cells (cDCs) of patients with pSS.

**Methods:** Two independent cohorts consisting of pSS patients and healthy controls were established: a discovery cohort (15 pSS, 6 HC) was used to screen the

expression of a large panel of 758 miRNAs. An independent validation cohort (14 pSS, 11 HC) was used to test the reproducibility of the results. cDCs were isolated from peripheral blood using MACS and miRNA profiling of 758 targets was performed using the OpenArray platform in the discovery cohort. A selection of 16 differentially expressed miRNAs was measured in the validation cohort using a custom-made array. Isolated cDCs from HC were stimulated with a panel of Toll-like receptor (TLR) ligands and the expression of miR-130a and miR-708 was measured by qPCR. The effect of transfection with miR-130a on protein synthesis was analysed by using the pulsed stable isotope labelling by amino acids in cell culture (pSILAC) method (quantitative mass spectrometry-based technique) in a HEK-293T cell-line.

**Results:** A total of 24 miRNAs was downregulated in pSS patients versus HC in the discovery cohort ( $p < 0.05$ , with a difference between the groups of  $> \log_2$ ). Of the 16 miRNAs that were selected for replication, the decreased expression of miR-130a and miR-708 in pSS was validated. Activation of cDCs via TLR3 and TLR7/8 induced downregulation of both miRNA-130a and miRNA-708. Transfection with a miR-130a mimic resulted in downregulation of several proteins with a seed match for the miRNA. These proteins are known to be involved in membrane trafficking and cell activation through CREB/NF-kB signalling.

**Conclusions:** miR-130a and miR-708 are significantly downregulated in cDCs of patients with pSS. We show that the expression of these miRNAs is decreased upon cDC activation and that upregulation of miR-130a decreases the expression of proteins involved in the CREB/NF-kB pathway. As such, these miRNAs seem to be involved in cDC activation and reflect enhanced activation of circulating cDCs from pSS patients.

### AB0150 DIMINISHED EXPRESSION OF PD-L1 BY ACTIVATED B CELLS IS CHARACTERISTIC OF SLE

A.-L. Stefanski<sup>1,2</sup>, A. Wiedemann<sup>1</sup>, K. Reiter<sup>1</sup>, A.C. Lino<sup>1</sup>, T. Dömer<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, Department of Medicine, Charité Universitätsmedizin Berlin and German Rheumatism Research Center Berlin (DRFZ), Berlin, Germany; <sup>2</sup>Department of Rheumatology, Immunology and Allergology, Inselspital University Hospital Bern, Bern, Switzerland

**Background:** Programmed cell death 1 (PD-1) and its ligands PD-L1 and PD-L2 are known to play an important role in immune response regulation via a co-inhibitory signal during T cell activation. Genome-wide association studies in humans and the fact that PD-1 knock-out mice develop a lupus-like pathology point toward the involvement of the PD-1 pathway in the pathogenesis of systemic lupus erythematosus (SLE).<sup>1,2</sup> However, little is known regarding the role of this pathway in B cells from patients with SLE.

**Objectives:** This study addressed the kinetics of PD-1, PD-L1 and PD-L2 expression on B cells from patients with SLE.

**Methods:** Blood samples were obtained from healthy donors (HD) and SLE patients. PBMCs from HD and SLE patients were stimulated with IL2/IL10, aBCR (IgG/IgM/IgA), CpG oligodeoxynucleotides (CpG) and CD40L alone or in combination. The membrane expression of PD-1, PD-L1 and PD-L2 on CD19<sup>+</sup>CD20<sup>+</sup>B cells was measured by FACS at baseline and after 48 hour stimulation.

**Results:** At baseline, the expression of PD-1, PD-L1 and PD-L2 on B cells between HD and SLE patients was similar. Notably, 48 hour stimulation of B cells with IL2/IL10, aBCR, CpG and CD40L gave rise to twofold reduced expression of PD-L1 by SLE compared to HD B cells. Interestingly, PD-L1 expression by SLE B cells was increased only in presence of CD40L, whereas in HD the mix of CpG, aBCR, and IL2/IL10 led also to a significant increase in PD-L1 expression.

**Abstract AB0150 – Figure 1.** Diminished PD-L1 expression in activated B cells may explain increased activation of T cells in SLE. (A) CD40L activated HD B cells upregulate PD-L1 that suppress activated T cells via PD-1. (B) CD40L activated SLE B cells fail to upregulate PD-L1 leaving activated T cells unchecked

**Conclusions:** The data suggest that activation of B cells from SLE patients require CD40/CD40L interaction to increase PD-L1 expression, which is, however, reduced compared to HD. Diminished PD-L1 expression upon B cell stimulation is consistent with impaired inhibition of T cells in SLE (figure 1).

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune disease associated with systemic inflammatory processes. Chronic inflammation alters the number and type of non-cellular elements, including lipoproteins and glycoproteins.

**Objectives:** Here we investigate the plasmatic lipoprotein and glycoprotein profiles associated with SLE.

**Methods:** Plasma samples were obtained from 50 healthy control individuals and 50 SLE patients. All patients fulfilled the ACR criteria for classification of SLE. <sup>1</sup>H-NMR was used to determine the lipoprotein and glycoprotein profiles from cases and controls. For the lipoprotein profiles, VLDL, LDL, IDL and HDL concentration, lipid composition and particle properties were quantified. The glycoprotein profile was decomposed in four reproducible peak regions LMW, Glyc-B, Glyc-A, Glyc-Lipid and baseline, and quantified for concentration, position and aggregation state. Association analysis to disease was performed using logistic regression fitting for age, gender and body mass index. Classifiers were built using recursive-partition algorithm and classification accuracy was evaluated using receiver operating curves.

**Results:** We found a significant perturbation of the lipoprotein profile in SLE patients compared to controls. A statistically significant ( $P < 0.05$ ) reduction of cholesterol-LDL and HDL lipoproteins as well as an increase in triglyceride VLDL was found in SLE. Particle number for LDLs, were found to be reduced compared to controls ( $P < 0.05$ ), and mostly due to lower quantities of large LDL particles ( $P < 0.005$ ). The glycoprotein profile was also significantly altered for several NMR measures. The most significant changes were related to the reduction of the width and area of the Glyc-Lipid peak in SLE patients ( $P < 0.005$  and  $P < 0.05$ ,

respectively). Using the plasma molecular patterns to predict the presence of SLE, we found a significant classifier for the lipoprotein pattern (ROC AUC(95% CI)=0.85(0.78–0.93)), and an optimal classifier for the glycoprotein pattern (ROC AUC(95%CI)=0.90(0.84–0.97))

**Conclusions:** SLE is characterized by perturbations of the plasmatic lipoprotein and glycoprotein profiles. The increase of triglyceride VLDL in patients compared to controls, could explain the increased risk for cardiovascular disease observed in SLE. Our results also show that SLE patients have a significantly different glycoprotein profile compared to controls. In both cases, plasmatic <sup>1</sup>H-NMR profiling could be a valuable source of informative biomarkers for SLE.

#### AB0152 MICROARRAYS GENE EXPRESSION PROFILING OF MONOCYTES FROM SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: NOVEL GENES AND PATHWAYS INVOLVED IN THE DISEASE

C. Perez-Sanchez<sup>1</sup>, I. Cecchi<sup>2</sup>, M.A. Aguirre<sup>1</sup>, L. Pérez-Sánchez<sup>1</sup>, M. Luque-Tevar<sup>1</sup>, N. Barbarroja<sup>1</sup>, P. Ruiz-Limón<sup>1</sup>, Y. Jiménez-Gómez<sup>1</sup>, I. Arias de la Rosa<sup>1</sup>, M.D.C. Abalos-Aguilera<sup>1</sup>, P. Seguí<sup>1</sup>, E. Collantes<sup>1</sup>, M.J. Cuadrado<sup>3</sup>, C. López-Pedraza<sup>1</sup>. <sup>1</sup>IMBIC/Reina Sofia Hospital/ University of Cordoba, Cordoba, Spain; <sup>2</sup>University of Turin, Turin, Italy, <sup>3</sup>St Thomas Hospital, London, UK

**Objectives:** 1. To identify altered genes and pathways in monocytes from Systemic Lupus Erythematosus (SLE) patients involved in the pathogenesis of the disease. 2. To evaluate the contribution of anti-dsDNA antibodies to the regulation of these processes.

**Methods:** Eighty three subjects, including 53 SLE patients and 30 healthy donors (HDs), were recruited. Total RNA was extracted from monocytes isolated of 6 subjects .analyzed as exploratory cohort- and microarray studies were performed in an Agilent G4112F platform (Whole Human Genome Microarray 44k). By using the Ingenuity Pathway Analysis Software (IPA) the altered gene, pathways, and network profiles were identified and functionally categorised. The top differentially expressed genes were validated by RT-PCR in monocytes purified from all the subjects enrolled. The inflammatory profile was evaluated in serum by multiplex assay. The activation of intracellular proteins was analysed by PathScan intracellular signalling protein array. Correlation and association studies were performed with clinical and analytical variables. The effect of anti-ds-DNA antibodies in the altered gene expression signature was evaluated by in vitro studies on monocytes from HD

**Results:** Microarray gene expression profiling identified 553 significantly altered genes in monocytes from SLE patients in relation to HDs ( $p < 0.05$  and fold change  $> 2$ ). IPA analysis showed that the altered genes were mainly related to inflammatory and immunological disease (32,4%), as well as cardiovascular (22,5%), neurological (21,9%), musculoskeletal (10%), renal (6,5%), dermatological (4,5%) and reproductive system disorders (2,2%). The top altered canonical pathway identified was the interferon signalling, and the main altered genes, validated by RT-PCR, were PGC1- $\alpha$  (master regulator of mitochondrial biogenesis and oxidative stress), IFI27, IFI44, IFI44L, IFIT1, IFI6 and RSAD2 (interferon signalling), EDNRB (endothelin receptor involved in the vascular system homeostasis), SERPINE1 (serpine related to haematopoiesis and apoptosis), CDKN1B and CCND2 (proliferation regulators), and IL22RA1 and CMKLR1 (inflammatory mediators). The altered gene signature was associated with the presence of anti-dsDNA antibodies, and clinical features of SLE (early atherosclerosis and nephropathy), and correlated with the disease activity and the levels of inflammatory serum markers (CRP, ESR, C3, C4, IL8, MCP1, IFN $\gamma$ , IP10, PDGFBB). The activation of numerous intracellular signalling proteins was also noticed. *In vitro* studies demonstrated the modulation of several genes by effect of anti-dsDNA.

**Conclusions:** Gene expression profile allowed the identification of relevant genes and pathways altered in monocytes of SLE patients, which were associated with the pathogenesis of the disease and modulated, at least partially, by anti-dsDNA. The identification of relevant genes whose products regulate specific pathological processes might contribute to the development of targeted therapies in SLE

**Background:** Sjögren's syndrome (SS) is a chronic, heterogeneous disease with hallmark features of auto-inflammation and autoantibody production. We previously identified association between the *DDX6-CXCR5* locus and SS surpassing genome-wide significance.

**Objectives:** This study aims to determine the mechanism by which this association contributes to disease.

**Methods:** Fine mapping and imputation allowed enrichment of existing genetic datasets from a total of 1916 SS cases and 3684 controls with 971 testable variants in the *DDX6-CXCR5* interval. Candidate variants were prioritized using statistical and bioinformatics approaches. Electromobility shift assays (EMSAs) and pull-downs (PDs) followed by mass spectrometry (MS) were used to determine allelic-specific differences in binding using lysates from HSB-2 (T), Jurkat (T), Reh (B), Ramos (B), Daudi (B), THP-1 (monocyte), and HEK 293T (epithelial) cells.

**Results:** Bioinformatic analysis of the top associated variants after imputation (rs7125066 and rs7119038) in the *DDX6-CXCR5* region did not yield evidence of regional functionality. However, 46 other candidates that span the region of association were identified through imputation. Chromatin methylation pattern data from the Roadmap database showed several variants in this region were within transcription start sites or enhancer elements depending on the cell type and state. Using RegulomeDB, Haploreg, and other databases, rs4938572, rs12365699, rs57494551, and rs10892294 showed strong evidence affecting binding and/or expression of one or more target genes in the region and were selected for further study. Using EMSAs, statistically significant increase in binding for the risk allele as compared to the non-risk allele was found for rs4938572 ( $p < 0.01$ ) for cell lysates from HSB-2, Reh, THP-1, Ramos, Jurkat, and Daudi but not HEK 293T cells. While decreased binding of risk allele for rs10892294 and rs12365699 were found for Ramos cells only, rs57494551 showed decreased binding for both Ramos and THP-1 cell lysate. The risk allele of rs57494551 also decreases binding using THP-1 cell lysate. Preliminary MS analysis showed several immune related transcription factors likely binding this region, including: IRF8, GTF1, RFX5, IKZF3, PAX5, and IKZF1. Cell type-specific expression of the genes in the region shows the expression of *DDX6* spans many immune cells subsets while the *CXCR5* expression is more restricted.

**Conclusions:** The genetic variants in the *DDX6-CXCR5* locus that were selected based on bioinformatics data resulted in a difference in the direction of binding, with the risk allele all residing on the same risk haplotype. The change in binding of protein to each associated variant likely would alter expression of both protein coding genes in a cell/context specific manner. Ongoing studies will assess the regulatory role of these sequences using luciferase assays and CRISPR/Cas9 based genetic modification of target SNPs in various cell types.

**NOTCH3 IS UPREGULATED IN LUPUS NEPHRITIS AND ITS DEFICIENCY ACCELERATES LUPUS PROGRESSION**

D. Breittkopf<sup>1</sup>, D. Hermert<sup>1</sup>, E. Groene<sup>2</sup>, I. Martin<sup>1</sup>, J. Floege<sup>1</sup>, T. Ostendorf<sup>1</sup>, U. Raffetseder<sup>1</sup>, T. Rauen<sup>3</sup>. <sup>1</sup>Department of Nephrology and Clinical Immunology, RWTH Aachen University, Aachen; <sup>2</sup>DKFZ Heidelberg, German Cancer Research Center, Heidelberg; <sup>3</sup>Department of Nephrology and Clinical Immunology, RWTH Aachen, Aachen, Germany

**Background:** Systemic lupus erythematosus (SLE) is a chronic inflammatory disease that affects the kidneys in about 50% of patients. Lupus nephritis (LN) is a major risk factor for overall morbidity and mortality in SLE patients. Notch signaling constitutes an evolutionarily conserved pathway that determines major decisions in cell proliferation, survival, and differentiation.

**Objectives:** To address the role of Notch-3 signalling in the disease development of SLE and particularly LN.

**Methods:** We measured renal expression of Notch-3 in kidneys of both, LN patients and lupus-prone MRL.lpr mice. Notch-3<sup>-/-</sup> and B6. Fas<sup>lpr/lpr</sup> mice were

crossbred to generate a B6. Fas<sup>lpr/lpr</sup> Notch-3<sup>-/-</sup> genotype and we analyzed the spontaneous disease manifestations in 40 week-old mice. Furthermore, we administered antisense oligodeoxynucleotides (ODNs) targeting Notch-3 or scrambled controls in the more aggressive lupus-prone mice strain (MRL. Fas<sup>lpr/lpr</sup>) mice starting at week 12 for 3 weeks and analyzed these mice at the age of 16 weeks.

**Results:** In 20-week old MRL.lpr mice, receptor Notch-3 and its target gene *Hes2* were significantly up-regulated in kidneys in comparison to 8 and 12 week-old littermates. *De novo* renal Notch-3 expression in lupus mice and SLE patients was especially pronounced in the glomerular compartment. B6. Fas<sup>lpr/lpr</sup> Notch-3<sup>-/-</sup> mice exhibited an aggravated lupus phenotype with earlier mortality, increased lymph nodes/spleen size, enhanced glomerular collagen IV deposition and increased immune cell infiltration in the kidneys. In line with this, application of anti-sense Notch-3 ODNs in MRL.lpr mice at the time of the transition from clinically inapparent to a manifested disease state (starting at week 12), resulted in accelerated disease progression as evidenced by enhanced lymphadenopathy, splenomegaly and an increase of inflammatory markers

**Conclusions:** Overall, these results demonstrate that Notch-3 exerts protective effects in the course of SLE, and its deficiency or inhibition accelerates the development of SLE manifestations.

**Disclosure of Interest:** None declared

AB0155

**1,25 DIHYDROXYVITAMIN D SUPPLEMENTATION REDUCES HIND PAW EDEMA IN PRISTANE-INDUCED LUPUS MODEL**

E.C. Freitas, T.H. da Rosa, J.M.S. Silva, R.C. Espirito Santo, O.A. Monticeli. Serviço de Reumatologia, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

**Background:** Systemic lupus erythematosus (SLE) is a multifactorial, autoimmune inflammatory disease with pleomorphic clinical manifestations involving different organs and tissues. Vitamin D (VITD) deficiency is highly prevalent and evidence is mounting that it contributes to the morbidity and mortality in SLE. VITD is an essential steroid hormone with well-established effects on mineral metabolism, skeletal health, and more recently established profound effects on immune system health.

**Objectives:** To evaluate the development of SLE after VITD supplementation in pristane-induced lupus model.

**Methods:** Female BALB/c mice divided into 3 groups: healthy animals (CO), SLE animals (PIL) and SLE animals + vitamin D supplementation (PIL+VITD). PIL +VITD group received a subcutaneous injection of Calcijex® [2 ug/kg] in PBS-Tween 20 buffer every second day during 180 days. Animals were monitored every 2 months for body weight, free exploratory locomotion, grip strength, endurance exercise performance and edema size. Interleukin 2 (IL-2), IL-4, IL-6, IFN-γ and TNF-α were measured by Luminex technology. The histological and immunofluorescence parameters (IgG, IgM and C3) of the kidney and the joints are under analysis. Data was analyzed with ANOVA Two-Way followed by Bonferroni and independent sample t-test.  $p < 0.05$  was considered significant. All data are represented as Mean±SEM.

**Results:** When compared with CO group (5.12±1.23 g), both PIL (7.53±1.09 g) and PIL+VIT D (8.08±2.28 g) groups exhibited a greater body weight gain by day 180 of the experiment ( $p < 0.05$ ). There was no statistically significant difference in free exploratory locomotion and grip strength between the groups, but both the PIL (29.39±6.75 min) and the PIL+VITD (25.75±12.48 min) groups showed increased fatigue compared to the CO group (42.08±3.47 min). Still, VITD supplementation reduced mean paw swelling to compared PIL group (0.207±0.29 vs 0.24±0.051,  $p < 0.05$ )

**Conclusions:** The supplementation of VITD improves the clinical severity of PIL-manifestations, such as the reduction of hind paw edema. Further analysis of the histology of the joints and the kidney will complement the evaluation of the vitamin D modulating effects on the immune system.

**POLYSACCHARIDES FROM DENDROBIUM OFFICINALE AMELIORATE THE DEVELOPMENT OF MURINE SJÖGREN'S SYNDROME VIA INDUCING IL-10-PRODUCING B CELLS**

E. Xiao<sup>1</sup>, X. Lin<sup>1</sup>, D. Liu<sup>2</sup>, L. Lu<sup>1</sup>. <sup>1</sup>Department of Pathology, The University of Hong Kong, Hong Kong; <sup>2</sup>Department of Rheumatology and Immunology, 2nd Clinical Medical College of Jinan University, Shenzhen People's Hospital, Shenzhen, China

**Background:** Primary Sjögren's syndrome (SS) is a chronic autoimmune disease with salivary gland (SG) hypofunction and inflammation. Currently, effective

therapies for SS patients are still lacking. Polysaccharides derived from *Dendrobium officinale* (DOP) have been shown to possess immunomodulatory functions in various animal models. However, it remains unclear whether DOP can modulate immune responses and have potential therapeutic effects on SS.

**Objectives:** To investigate the immune modulatory and therapeutic effects of DOP on experimental SS (ESS) in mice.

**Methods:** Polysaccharides were extracted from *Dendrobium officinale* with removal of endotoxin. C57BL/6 mice were immunized with SG-derived proteins for ESS induction, followed by daily oral treatment of vehicle and different dosages of DOP. SG functions were assessed by monitoring saliva flow rates whereas lymphocytic infiltration and tissue destruction in SG were examined by histological analysis. Both T and B cell populations in peripheral lymphoid organs were analyzed by flow cytometry. The effects of DOP on IL-10-producing B cell (B10 cell) induction and Th17 cell differentiation were examined in culture. Moreover, TLR4 and TLR9 inhibitors were used to identify the function of TLR4/TLR9 in DOP-mediated effects.

**Results:** ESS mice with DOP treatment displayed significantly higher saliva flow rates than vehicle-treated ESS mice. DOP treatment ameliorated SG tissue destruction accompanied with profoundly reduced lymphocytic infiltration in ESS mice when compared with vehicle-treated counterparts. Moreover, DOP treatment markedly increased the numbers of B10 cells but decreased numbers of Th17 cells in peripheral lymphoid organs of ESS mice. Notably, DOP markedly increased frequencies and numbers of B10 cells but did not affect Th17 cells generation in culture. Moreover, TLR4 inhibitor, but not TLR9 inhibitor, significantly suppressed DOP-induced IL-10 production in B cells.

**Conclusions:** The results show that DOP treatment ameliorates ESS disease development by inducing regulatory B10 cells, suggesting that DOP might be a promising candidate for treating SS.

#### AB0157 TARGETING T-CELL TRAFFICKING IN A MURINE MODEL OF SJÖGREN'S SYNDROME

J. Campos<sup>1</sup>, S. Nayar<sup>1</sup>, M. Chimen<sup>2</sup>, V. Iannizzotto<sup>1</sup>, H.M. McGettrick<sup>1</sup>, B. Fisher<sup>1</sup>, S.J. Bowman<sup>1</sup>, C.D. Buckley<sup>1</sup>, G.E. Rainger<sup>2</sup>, F. Barone<sup>1</sup>. <sup>1</sup>Rheumatology Research Group, Institute of Inflammation and Ageing; <sup>2</sup>Institute of Cardiovascular Sciences, University of Birmingham, Birmingham, UK

**Background:** Salivary glands of primary Sjögren's syndrome (pSS) are characterised by complex leukocyte infiltration organised into tertiary lymphoid structures (TLS). The mechanisms regulating leukocyte trafficking into inflamed salivary glands are poorly described, but dysregulated T-cell recruitment during inflammation is believed to contribute to disease onset and chronicity. We recently described a homeostatic pathway in which a B cell-derived peptide (PEPITEM), secreted in response to adiponectin, regulates T-cell trafficking during inflammation via sphingosine-1-phosphate activity on endothelial cells<sup>1</sup>. Disruption of this pathway by downregulation of adiponectin receptors on circulating B cells has been demonstrated in type-1 diabetes and rheumatoid arthritis, suggesting a potential role for PEPITEM in the pathogenesis of autoimmune diseases, and indicating a role for adiponectin receptors as biomarkers in these conditions<sup>1</sup>.

**Objectives:** We aimed to investigate the efficacy of PEPITEM as an inhibitor of T-cell trafficking in an inducible animal model of salivary gland inflammation that mimics the histological features of pSS, and to investigate the potential translatability of this pathway in patients with pSS.

**Methods:** Submandibular salivary glands of C57BL/6 mice were intra-ductally cannulated with luciferase-encoding replication-deficient adenovirus to induce TLS formation as previously described<sup>2</sup>. Mice were administered daily either PBS or PEPITEM by intraperitoneal injection from day 0, and their salivary glands dissected at day 5 post cannulation. T-cell infiltration into salivary glands was assessed using a combination of flow cytometry, immunofluorescence, and qRT-PCR for inflammatory chemokines.

**Results:** B cells in sera from cannulated animals express lower levels of both adiponectin receptors 1 and 2 in comparison with non-inflamed control mice. In cannulated animals treated with PEPITEM, histological analysis of salivary glands revealed fewer, as well as less aggregated, infiltrating T cells. Both CD4<sup>+</sup> and CD8<sup>+</sup> numbers were significantly lower in the salivary glands of PEPITEM-treated animals. Furthermore, administration of PEPITEM also decreased mRNA transcripts for lymphotoxin beta, IL-7, lymphoid chemokines (CCL19 and CXCL13)

and T-cell chemokine receptor CCR7, cytokines and chemokines known to regulate ectopic lymphoneogenesis in pSS. Samples from pSS patients are currently being assessed to validate the relevance of this pathway in pSS.

**Conclusions:** These results demonstrate that administration of exogenous PEPITEM can reduce T-cell influx into salivary glands. This may represent a rescue of the homeostatic regulation of leukocyte trafficking which is disrupted in inflammation. Our work suggests that PEPITEM should be considered to address therapeutic needs in chronic inflammatory conditions, and that the detection of decreased levels of adiponectin receptors could serve as a biomarker in pSS.

#### AB0158 HISTOLOGICAL AND SEROLOGICAL CHARACTERISTICS CONTRIBUTE TO DIVERGENT OUTCOMES FOR INDIGENOUS PATIENTS WITH LUPUS NEPHRITIS

J. Nossent<sup>1,2</sup>, W. Raymond<sup>2</sup>, A. Kang<sup>3</sup>, M. Ognejovic<sup>2</sup>, A. Chakera<sup>4,5</sup>, D. Wong<sup>3</sup>. <sup>1</sup>Rheumatology, Sir Charles Gairdner Hospital, Nedlands; <sup>2</sup>Rheumatology, School of Medicine, University of Western Australia, Crawley; <sup>3</sup>Pathology, PathWest Laboratory Medicine, Nedlands; <sup>4</sup>School of Medicine, University of Western Australia, Crawley; <sup>5</sup>Nephrology, Sir Charles Gairdner Hospital, Nedlands, Australia

**Background:** Renal outcomes for Indigenous Australians (IA) with Lupus Nephritis (LN) are worse than for other ethnic groups.

**Objectives:** To investigate whether differences in renal biopsy findings can explain the worse renal outcome in Indigenous patients

**Methods:** A single centre cohort study of 83 SLE patients undergoing a first renal biopsy at our institution for LN evaluation. Histological assessment included review of ISN classification, A/AC/C sub classification, NIH tubulointerstitial activity and chronicity indices, tubulointerstitial index, semiquantitative IF scores for IgG, IgM, IgA, C3 and C1q deposits, localisation of electron dense deposits (EDD) and presence of thrombosis, vasculitis and tubuloreticular inclusions (TRI). Differences in histological and routine clinical findings including autoantibody profiles between IA patients (n=11) and the pooled data from Asian (n=29) and Caucasian (n=43) patients were analysed by non-parametric statistical methods.

**Results:** IA patients were younger at diagnosis (31 vs 38.5 years., p=0.08) and their biopsies contained fewer glomeruli (11 vs 21, p<0.01), more class I/II (28 vs 15%) and no class V lesions (0 vs 21%) (p=0.06 for overall comparison). IA patients were less likely to have cellular crescents (0 vs. 25%, p=0.03), more likely to have fibrous crescents and a low tubulointerstitial index (p=0.08). The overall AI (5.1 vs 4.9) and CI scores (1.1 vs. 1.3) or presence of full house IF deposits (67 vs 71%), renal thrombosis (0 vs 4%) or TRI (55 vs. 39%) was similar across groups (all p>0.3). IA patients had lower eGFR (43 vs 65, p=0.025), more often carried anti-SSA52kd Ab (73 vs 33%, p=0.02) and during a mean follow-up of almost nine years, had a higher proportion of patients developing ESRD (18 vs 3%, p=0.02).

**Conclusions:** IA patients with SLE who develop LN have fewer glomeruli, an increased frequency of mesangial abnormalities with absence of cellular crescents and membranous nephropathy and a high prevalence of anti-SSA 52KD Ab. Although based on small numbers, this suggests that lower nephron mass and immunological pathways involving IFN-inducible anti-SSA expression may contribute to LN development and worse renal outcome in Indigenous patients.

#### AB0159 CYTOKINE PRODUCTION BY ACTIVATED PLASMACYTOID DENDRITIC CELLS AND NK CELLS IS SUPPRESSED BY AN IRAK4 INHIBITOR

K. Hjorton<sup>1</sup>, N. Hagberg<sup>1</sup>, E. Israelsson<sup>2</sup>, O. Berggren<sup>1</sup>, J. Sandling<sup>1</sup>, K. Thom<sup>2</sup>, J. Mo<sup>2</sup>, M.-L. Eloranta<sup>1</sup>, L. Rönnblom<sup>1</sup>. <sup>1</sup>Dept of Rheumatology, Uppsala University, Akademiska Sjukhuset, Uppsala; <sup>2</sup>Bioscience, Respiratory, Inflammation & Autoimmunity, Innovative Medicines and Early Development Biotech unit, AstraZeneca, Gothenburg, Sweden

**Background:** In SLE, immune complexes containing self-derived DNA or RNA (RNA-IC) trigger the synthesis of several pro-inflammatory cytokines by immune cells. Treatment with anti-malarials, such as hydroxychloroquine (HCQ), which

through endosomal TLR inhibition effectively blocks IFN- $\alpha$ , is standard of care. However, few patients experience complete remission.

**Objectives:** We asked how an IL-1 receptor associated kinase 4 (IRAK-4) inhibitor I92 (ND-2158, Nimbus Discovery),<sup>1</sup> acting downstream of TLR 7/9, affects RNA-IC-induced cytokine production compared to hydroxychloroquine (HCQ).

**Methods:** Plasmacytoid dendritic cells (pDCs) and natural killer (NK) cells were isolated from peripheral blood mononuclear cells (PBMCs) of healthy individuals. PBMCs from 15 SLE patients were depleted of monocytes. Cells were stimulated with RNA-IC, consisting of IgG from SLE patient sera and U1snRNP particles, in the presence or absence of I92 or HCQ. Cytokines were measured by immunoassays or flow cytometry. RNA-sequencing was performed on RNA-IC stimulated pDCs from four healthy individuals and the effect of I92 and HCQ was assessed.

**Results:** RNA-IC induced IFN- $\alpha$ , TNF- $\alpha$ , IL-6, IL-8, IFN- $\gamma$ , MIP1- $\alpha$  and MIP1- $\beta$  production in pDC and NK cell co-cultures. I92 reduced the pDC and NK cell derived cytokine production by 74.95%. HCQ interfered with cytokine production in pDCs, but not in NK cells. In monocyte-depleted SLE PBMCs I92 blocked TNF- $\alpha$ , IFN- $\gamma$ , MIP1- $\alpha$  and MIP1- $\beta$  production more efficiently than HCQ. IL-8 production was high in monocyte depleted PBMC from SLE patients, and not blocked by neither drug, despite significant inhibition of IL-8 in pDC-NK co-cultures from healthy individuals. Following RNA-IC activation of pDCs, 975 differentially expressed genes were observed (FDR<0.05), many connected to cytokine pathways, cell regulation and apoptosis. The IRAK4 inhibitor significantly changed more RNA-IC induced genes than HCQ (492 vs. 65 genes). Several top upregulated genes were reversed by both I92 and HCQ, including *IFNA2*, *IFIT2-3*, *OASL*, *CXCL10*, *CD274*, *TNFSF10*, *APOL6*. Genes such as *DKK4*, *LAD1* and *EAF2* were significantly more downregulated by I92 than by HCQ.

**Conclusions:** Whereas both HCQ and the IRAK4 inhibitor block important pro-inflammatory cytokines, the IRAK4i I92 exhibits a broader inhibitory effect than HCQ on pathways triggered by RNA-IC, which suggests that IRAK4 inhibition could be a future therapeutic option in SLE and possibly other systemic autoimmune diseases characterized by the presence of ICs containing nucleic acid.

#### AB0160 LOSS OF LET-7 MICRORNA UPREGULATES IL-6 IN BONE MARROW-DERIVED MESENCHYMAL STEM CELLS TRIGGERING TREG/TH17 IMBALANCE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

L. Geng, X. Xu, J. Liang, C. Zhao, L. Sun. *Department of Rheumatology and Immunology, The Drum Tower Clinical Medical School of Nanjing University, Nanjing, China*

**Background:** Systemic lupus erythematosus (SLE) patients exist an imbalance between CD4+CD25+FoxP3+ T regulatory (Treg) and IL-17-producing cells (Th17). Correction of this Treg/Th17 imbalance may have therapeutic impact for SLE patients. Our previous study demonstrated that bone marrow derived mesenchymal stem cells (BMSCs) from SLE patients are defective in immune modulation, which might be involved in Treg/Th17 imbalance and disease onset, but the mechanisms are not clear yet. The expression imbalance of microRNAs (miRNAs) can cause cell dysfunction, which participates in a variety of diseases development. As an important computer predicted target of let-7, interleukin-6 (IL-6) is an important negative immune regulatory factors secreted by BMSCs. Our previous experiments found that the expressions of let-7 are markedly down-regulated in SLE BMSCs by microRNA array analysis, and the synthesis of IL-6 is significantly higher in SLE BMSCs compared to normal controls.

**Objectives:** To investigate whether loss of let-7 could play its role in SLE BMSCs immune modulation defects by directly up-regulating IL-6 mRNA, which might contribute to Treg/Th17 imbalance in PBMCs from SLE patients, to further understand the pathogenesis of SLE.

**Methods:** BMSCs were isolated, cultured and expanded from iliac crest bone marrow of four healthy donors and four SLE patients. Real-time PCR was used to further determine the let-7 expression and IL-6 mRNA level in BMSCs from healthy controls and SLE patients. The important computer predicted target of let-7, IL-6 was determined using the luciferase reporter assay. Let-7-mimics, let-7-inhibitor, and let-7-negative control were transfected to BMSCs with using Lipofectamine 2000. BMSCs from healthy controls and SLE patients were co-cultured

with PBMCs from SLE patients for 72 hours to detect their effect on the ratio of Treg/Th17.

**Results:** Compared to normal controls, the expression of let-7 was markedly down-regulated in BMSCs from SLE patients by RT-PCR, and the synthesis of IL-6 mRNA and protein levels were significantly higher in BMSCs from SLE patients. Compared to let-7-negative controls, transfection of BMSCs with let-7-mimics markedly lower synthesis of TGF- $\beta$ 1 mRNA, and let-7-inhibitor led to an opposite effect. The mean value of Treg/Th17 was significantly decreased in PBMCs from SLE patients compared to normal controls. Transfection of normal BMSCs with let-7-inhibitor caused significant downregulation of Treg/Th17 compared to let-7-negative controls, while transfection with let-7-mimics led to an opposite effect.

**Conclusions:** SLE patients exist an imbalance between Treg and Th17 cells, which might be associated with up-regulation of IL-6 secretion of BMSCs by loss of let-7.

#### AB0161 INTERLEUKIN-37: A THERAPEUTIC FOR LUPUS NEPHRITIS IN MRL-FASLPR MICE

L. Ding<sup>1</sup>, X. Hong<sup>1</sup>, Z. Huang<sup>2</sup>, D. Liu<sup>1</sup>. <sup>1</sup>*Department of Rheumatology and Immunology, Shenzhen People's Hospital, the Second Clinical Medical College of Jinan University;* <sup>2</sup>*Department of Immunology and Microbiology, Biological Therapy Institute, Shenzhen University School of Medicine, Shenzhen, China*

**Background:** Systemic lupus erythematosus (SLE) is a serious and noticed autoimmune disease, and lupus nephritis (LN) as one of its major complications without effective treatment. IL-37 has been identified as a natural inhibitor of innate immunity. Although increasing evidence shown that serum IL-37 correlated with SLEDAI and nephritis activity, However, it is still unclear that the therapeutic effect of IL-37 on lupus mice *in vivo*.

**Objectives:** This study aims to determine the inhibitory effect of IL-37 in lupus mice and lupus nephritis *in vivo*, and to expose the IL-37 related mechanisms of cell and molecules that inhibits the inflammation in lupus nephritis.

**Methods:** MRL-Fas<sup>lpr</sup> mice with mild and advanced disease were treated with lentiviral vector pLVX-IL-37b. The protein levels of IL-37b in serum and tissue, IL-17, IL-6, IL-10 and TGF $\beta$ -3 produced by cell culture from spleen and kidney of mice were measured by ELISA, the relative mRNA expression of these cytokines in PBMCs was detected by RT-PCR, and the frequency of Th17 and Treg cells in splenocyte were determined by FACS.

**Results:** Our results show that IL-37 was highly effective in prolonging survival, alleviating the pathologic characteristics of lupus nephritis (LN) in MRL-Fas<sup>lpr</sup> mice by reducing the autoimmune complex deposition such as IgM, IgG and C3, decreasing the production of Inflammatory cytokines such as IL-17, IL-6 and promoting the anti-inflammatory cytokines IL-10 and TGF $\beta$ -3. We also found that IL-37 protect lupus mice from LN associated with increasing the frequency of Treg cells and reducing the frequency of Th17 cells.

**Conclusions:** These results indicate the protective action of IL-37 in LN, and strengthen the support for IL-37 as a new target for therapy of SLE.

#### AB0162 KLRG1 EXPRESSION IS REDUCED ON NK CELLS FROM SLE PATIENTS AND INVERSELY CORRELATES WITH DISEASE ACTIVITY AND CLINICAL FEATURES

L. Novelli, C. Barbati, F. Ceccarelli, M. Vomero, C. Perricone, F. Morello, C. Garufi, F.R. Spinelli, C. Alessandri, G. Valesini, F. Conti. *Sapienza University of Rome, Rome, Italy*

**Background:** Systemic Lupus Erythematosus (SLE) is a multifactorial autoimmune disease, with different immunological alterations and clinical phenotypes. Natural killer (NK) cells participate in the regulation of several immune responses but their function in SLE is not well understood.<sup>1</sup> KLRG1 (killer cell lectin like receptor G1) is a trans-membrane protein expressed in humans especially on NK cells, working as an inhibitory receptor of their cytotoxic activity. Thus, KLRG1-mediated signal might have a role in preventing autoimmunity, increasing the activation threshold of NK cells.<sup>2</sup> KLRG1 gene also, emerged as a disease susceptibility gene for SLE in four different ethnic groups.<sup>3</sup>

**Objectives:** The aim of this study was to characterize KLRG1 expression on NK cells (both CD56<sup>dim</sup> and CD56<sup>bright</sup>) from SLE patients compared to healthy subjects (HS) and to investigate its possible correlations with clinical features, including SLE disease activity.

**Methods:** We enrolled 14 patients (14F, mean age $\pm$ SD 37 $\pm$ 10.7 years, mean disease duration  $\pm$ SD 10.5 $\pm$ 7.9 years) affected by SLE according to the 1997 ACR criteria, and 7 HS (7F, mean age $\pm$ SD 33 $\pm$ 5.5 years). Disease activity was measured by SLEDAI-2K. Peripheral blood mononuclear cells (PBMCs) were purified

and phenotypic characterization was performed. All experiments were conducted by flow cytometry.

**Results:** KLRG1 was expressed in a statistically significant lower amount on total NK cells from SLE patients compared to HS ( $p=0.0007$ ). Analysis of CD56<sup>dim</sup> and CD56<sup>bright</sup> populations showed less amount of KLRG1 in SLE patients compared to HS ( $p=0.0051$  and  $p=0.0068$ ) (figure 1). The low levels of KLRG1 on NK cells inversely correlated with the SLEDAI-2K ( $p=0.029$ ) and were inversely associated with the presence of arthritis ( $p=0.029$ ), arthralgias ( $p=0.0024$ ) and hematological disorders ( $p=0.025$ ). A direct association between KLRG1 expression on NK cells and the use of HCQ was found ( $p=0.001$ ). Analyzing the two main subpopulations of NK cells, we observed an inverse association between KLRG1 on CD56<sup>dim</sup> cells and arthritis ( $p=0.0089$ ), arthralgias ( $p=0.0001$ ), hematological disorders ( $p=0.0329$ ) and SLEDAI-2K ( $p=0.0105$ ). KLRG1 on CD56<sup>dim</sup> was directly associated with the use of HCQ ( $p=0.0010$ ). KLRG1 on CD56<sup>bright</sup> cells was also directly associated with the use of HCQ and MMF ( $p=0.03$  and  $p=0.014$ ).

Abstract AB0162 – Figure 1

**Conclusions:** This study shows for the first time a reduced expression of KLRG1 in SLE patients. The inverse associations between the levels of this receptor on NK cells and the SLEDAI-2K and clinical features, together with the direct association with HCQ and MMF, suggest a possible role of KLRG1 in the pathogenesis of this disease. KLRG1 could be a possible therapeutic target in SLE.

#### AB0163 INCREASED ERYPTOSIS LEVELS IN ERYTHROCYTES TREATED WITH ANTIBODIES FROM APS PATIENTS: ERYPTOSIS AS NEW ACTOR IN APS PATHOGENESIS

M. Vomero<sup>1</sup>, F. Ceccarelli<sup>1</sup>, A. Finucci<sup>1</sup>, C. Barbati<sup>1</sup>, T. Colasanti<sup>1</sup>, C. Pensa<sup>1</sup>, F. R. Spinelli<sup>1</sup>, C. Perricone<sup>1</sup>, L. Novelli<sup>1</sup>, L. Massaro<sup>1</sup>, F. R. Mauro<sup>2</sup>, R. Foà<sup>2</sup>, F. Conti<sup>1</sup>, G. Valesini<sup>1</sup>, C. Alessandri<sup>1</sup>. <sup>1</sup>Lupus Clinic; <sup>2</sup>Department of Cellular Biotechnologies and Hematology, Sapienza University of Rome, Rome, Italy

**Background:** Erythrocytes (RBCs) are highly sensitive cells constantly exposed to several stress stimuli including inflammatory mediators. Despite the absence of nuclei and the lack of crucial elements in the machinery of apoptosis, they have developed a rapid self-destruction process called eryptosis. During this process the externalization of phosphatidylserine (PS) activates the correct elimination of erythrocytes by phagocytes preventing inflammation and intravascular hemolysis. It has been recently demonstrated that PS-exposing erythrocytes are able to adhere to endothelial cells causing an impairment of circulation,<sup>1</sup> suggesting a possible involvement of eryptosis in the increased risk of thrombotic episodes typical of antiphospholipid syndrome (APS).

**Objectives:** Enhanced eryptosis is known to contribute to several pathological conditions but the role of this process in APS has not been investigated yet. For this reason, we evaluated the effect of antibodies (Abs) purified from APS patients and healthy subjects positive for antiphospholipid antibodies without clinical manifestations (aPL carriers) on eryptosis activation. Moreover, spontaneous eryptosis levels in APS, aPL carriers, autoimmune haemolytic anaemia (AIHA) and healthy donors (HD) were analyzed.

**Methods:** 30 patients with primary APS (M/F 7/23, mean age 50.5±8.2 years), 17 aPL carriers (M/F 4/13, mean age 48.6±8.3 years) were recruited after written informed consent. Moreover 13 AIHA patients and 17 HD were also enrolled as positive and negative control group respectively. Ammonium sulfate precipitation is used to purify Abs from sera of APS and aPL carriers subjects. RBCs, isolated from whole blood by centrifugation, were incubated with APS and aPL carriers Abs at concentration of 20ug/mL and after 4 hours the percentage of annexin V-positive cells (PS-exposing cells) was analyzed by flow cytometry. The same technique was used to estimate spontaneous eryptosis levels in all cohorts studied.

**Results:** *In vitro* Abs from APS induced eryptosis in RBCs isolated from HD after 4 hours of culture compared to untreated and RBCs stimulated with Intravenous Immunoglobulins (IVIg), both  $p=0.02$ . On the contrary, Abs from aPL carriers had no effect on the percentage of PS-exposing RBCs (figure 1). *Ex vivo*, APS patients showed higher levels of spontaneous eryptosis compared to HD ( $p=0.001$ ). As expected, eryptosis was upregulated in AIHA patients compared to all populations studied ( $p<0.0001$ ). Interestingly, the percentage of annexin V-positive RBCs was lower in aPL carriers respect to APS patients ( $p=0.001$ ). No significant correlation between eryptosis and clinical parameters was found.

Abstract AB0163 – Figure 1

**Conclusions:** In this study we demonstrated a new aspect of APS pathogenesis based on the capacity of Abs isolated from APS patients, and not those from aPL carriers, to stimulate eryptosis suggesting a possible contribution of this process in APS clinical manifestations.

#### AB0164 NUMBERS OF B-LYMPHOCYTES INCREASE WHEN FORMATION OF LYMPHOEPITHELIAL LESIONS PROGRESSES IN SALIVARY GLANDS OF PRIMARY SJÖGREN'S SYNDROME PATIENTS

M.S. Van Ginkel<sup>1</sup>, E.A. Haacke<sup>1,2</sup>, H. Bootsma<sup>1</sup>, S. Arends<sup>1</sup>, J.F. van Nimwegen<sup>1</sup>, G.M. Verstappen<sup>1</sup>, F.K. Spijkervet<sup>3</sup>, A. Vissink<sup>3</sup>, B. van der Vegt<sup>2</sup>, F.G. Kroese<sup>1</sup>.

<sup>1</sup>Department of Rheumatology and Clinical Immunology; <sup>2</sup>Department of Pathology and Medical Biology; <sup>3</sup>Department of Oral and Maxillofacial Surgery, University of Groningen, University Medical Center Groningen, Groningen, Netherlands

**Background:** The major histopathological finding in salivary glands of primary Sjögren's syndrome (pSS) patients are periductal lymphocytic infiltrates (foci). In association with these infiltrates, lymphoepithelial lesions (LELs) may be formed. LELs are defined by infiltration of lymphocytes within the epithelium with hyperplasia of ductal cells. Although it has been suggested that B-lymphocytes predominate in LELs, the relative role of B- and T-lymphocytes in LEL formation is not known. Since LELs are a characteristic finding in salivary glands of pSS patients, quantification of B- and T-lymphocytes in the different stages of LEL development will give more insight in their formation as well as in the pathogenesis of pSS.

**Objectives:** To quantify the numbers of B- and T-lymphocytes in different stages of LEL development in parotid and labial gland biopsies of pSS patients.

**Methods:** The study population consisted of 15 pSS patients, who fulfilled the ACR-EULAR criteria and underwent salivary gland biopsies of both the parotid and labial gland. Patients were not treated with biologicals and 13 patients were not using other immunosuppressive therapy. Presence and severity of LELs were evaluated on HE stained sections. Severity of lesions was scored from stage 0 to stage 3 (stage 0: lymphocytic ductal infiltration without hyperplasia of the epithelium; stage 1: lymphocytic ductal infiltration and <50% hyperplastic epithelium; stage 2: lymphocytic ductal infiltration and ≥50% hyperplastic epithelium; stage 3: lymphocytic ductal infiltration and fully circumferentially hyperplastic epithelium with occluded lumen). Numbers of B- and T-lymphocytes within LELs were counted (10 ducts per biopsy) by using Image J cell counter on serial CD20 and CD3 stained sections. High molecular weight cytokeratin staining was used to identify ductal borders. Generalized estimating equations (GEE) were used to analyse the numbers of B- and T-lymphocytes and B/T ratio's over the different stages of severity of LELs.

**Results:** B- and T-lymphocytes can both infiltrate within the ductal epithelium forming LELs in salivary glands of pSS patients. T-lymphocytes were present in all LELs, scattered through the whole ductal epithelium. Whereas B-lymphocytes were found in clusters, mostly located in the hyperplastic area of the ductal epithelium. With higher severity of LELs, the numbers of B- and T-lymphocytes increased significantly, in both the parotid and labial gland. The numbers of B-lymphocytes increased relatively more with higher severity of LELs than T-lymphocytes. This has led to an increased intraepithelial B/T ratio in more pronounced LELs. This increased B/T ratio was even more pronounced in parotid than in labial glands. In both glands, there was a predominance of T-lymphocytes in lower LEL stages. In more severe LEL stages, B-lymphocytes outnumbered the T-lymphocytes.

**Conclusions:** Given the relative increase in the number of B-lymphocytes with higher severity of LELs as well as their close association with proliferating ductal epithelial cells, we conclude that B-lymphocytes play a major role in the hyperplasia of the ductal epithelium.

#### AB0165 RANK/RANK-LIGAND INTERACTION REGULATES PATHOGENIC T CELL RECRUITMENT IN SJÖGREN'S SYNDROME

S. Nayar<sup>1</sup>, B.A. Fisher<sup>1</sup>, J. Campos<sup>1</sup>, D.H. Gardner<sup>1</sup>, A. Dumusc<sup>2</sup>, V. Iannizzotto<sup>1</sup>, C. Smith<sup>1</sup>, C.D. Buckley<sup>1</sup>, S.J. Bowman<sup>3</sup>, C.G. Mueller<sup>4</sup>, F. Barone<sup>1</sup>.

<sup>1</sup>Rheumatology Research Group, Institute of Inflammation and Ageing, University of Birmingham, Birmingham, UK; <sup>2</sup>rheumatology department, Departement de l'appareil locomoteur, Lausanne University Hospital (CHUV), Lausanne, Switzerland; <sup>3</sup>University Hospitals Birmingham National Health Service Foundation Trust, Birmingham, UK; <sup>4</sup>Institut de Biologie Moleculaire et Cellulaire, Strasbourg, France

**Background:** The RANKL (ligand)-RANK-OPG triad, members of the TNF(R) superfamily, is implicated in lymphoid organ development and bone homeostasis. It has recently been demonstrated that RANK-activated astrocytes release CCL20 and attract T cells to the central nervous system in a model of Multiple Sclerosis and that transgenic RANK expression in the skin promotes aberrant epithelial cell proliferation and is sufficient to induce ectopic formation of tertiary lymphoid structures (TLS). Ductal epithelial cells (SGEs) have been implicated in Sjögren's Syndrome (SS) pathogenesis where they mediate immune recruitment by expression of pro-inflammatory chemokines and support the formation of pre-malignant myoepithelial lesions.

**Objectives:** A combination of human and mouse studies were used to address the role of RANK-RANKL interaction in primary (p) SS.

**Methods:** Salivary glands (SGs) and saliva samples from patients recruited in the OASIS cohort (University of Birmingham) were studied to evaluate this pathway in human disease. Consecutive stimulated saliva samples (n=69) were analysed using Proseek Multiplex INF<sup>96 × 96</sup>, covering 92 unique inflammation-related protein biomarkers. Taking advantage of a viral induced model of pSS we studied the effect of this pathway with a RANKL blocking antibody and by inducing gain of function with direct cannulation in the salivary glands of recombinant RANKL. Murine SGs were studied by immunofluorescence, flow cytometry and qPCR on total tissue and sorted cells.

**Results:** Fourteen proteins in saliva were significantly separated between pSS and sicca controls, and elevated levels of just two proteins, RANKL and TNFβ, could classify pSS or sicca with 75% accuracy. Levels of salivary RANKL and CCL20 were strongly correlated (r=0.6; p<0.01). We demonstrated that both human and murine inflamed SGEs upregulate both RANK and CCL20, a chemokine known to recruit pathogenic T cells. Upregulation of RANKL was found in human Th2 cells, classically associated with humoral responses and germinal centre (GC) formation. SGs from mice treated with anti-RANKL antibody showed decreased epithelial proliferation, reduced T cell infiltration and defective TLS

establishment. On the contrary, viral infected SGs treated with recombinant RANKL showed increased T cell infiltration, CCL20 expression and enhanced differentiation of GC B cells.

**Conclusions:** *In vivo* RANK/RANKL interaction mediates recruitment of activated T cells that are skewed toward a Th2 phenotype. These, in turn, will favour the establishment of TLS in the SG. Those data were confirmed in human pSS, where expression of RANK is found in inflamed epithelium and RANKL detection in saliva is able to differentiate patients with pSS from sicca controls, thus candidates this pathway both for drug targeting and patient stratification.

#### AB0166 TRACKING OF MUCOCUTANEOUS AND MUSCULOSKELETAL FLARES IN SLE USING SERUM FAS, FERRITIN, IGFBP2 AND sTNFR II

S. Soliman<sup>1,2</sup>, K. Vanarsa<sup>2</sup>, A. Swilling<sup>2</sup>, J. Merrill<sup>3</sup>, C. Mohan<sup>2</sup>. <sup>1</sup>Rheumatology and Rehabilitation, Faculty of Medicine, Minia University hospital, Minya, Egypt; <sup>2</sup>biomedical engineering, university of Houston, Houston; <sup>3</sup>Oklahoma Medical research foundation, Oklahoma, United States

**Background:** SLE is a multisystemic autoimmune disease characterized by unpredictable disease course with periods of flares and remission. The lack of reliable methods which can predict a disease flare hampers the exploration of effective and preventive strategies for disease relapses.

**Objectives:** To study the performance of serum FAS, sTNFR II, Igfbp2 and Ferritin as biomarkers for tracking lupus flares in non-renal SLE patients.

**Methods:** Twenty-nine patients, who met the requirements of American College of Rheumatology (ACR) for classification of SLE, were recruited from Oklahoma Medical Research Foundation (OMRF) for serological testing of all four serum protein markers. None of the patients had lupus nephritis. Serum samples were obtained over 4 consecutive visits. Serum FAS, sTNFR II, Igfbp2 and Ferritin molecules were measured in all patients. Lupus disease activity was assessed by both SLEDAI and BILAG activity indices.

**Results:** In our study, all 4 tested biomarkers (FAS, Ferritin, Igfbp2 and sTNFR II) showed significant correlations with SLEDAI and BILAG. FAS (r= 0.36, p<0.0001 for SLEDAI & r= 0.29, p= 0.0002 for BILAG), Ferritin (r= 0.13, p=0.0494 for SLEDAI & r= 0.22, p= 0.0035 for BILAG), Igfbp2 (r= 0.24, p= 0.0013 for SLEDAI & r= 0.18, p= 0.0106 for BILAG) and sTNFR II (r= 0.30, p<0.0001 for SLEDAI & r= 0.19, p= 0.0112 for BILAG). When serial disease activity changes were examined, different serum markers performed better in different SLE patients, tracking with mucocutaneous or musculoskeletal disease flares. In studying a total of 72 disease intervals, FAS and Ferritin exhibited the highest concordance with concurrent disease activity (58–62%), followed by Igfbp2 (50%) and sTNFR II (46%), all of which were superior to the performance of complement C3, C4 and anti-DNA. Furthermore, adding FAS to other tested molecules increased its ability to track concordant disease activity changes (81% for FAS±Ferritin; 76% for FAS±Igfbp2 and FAS±sTNFR II).

**Conclusions:** Serum FAS and Ferritin emerge as potential serum markers for tracking mucocutaneous or musculoskeletal disease flares in SLE patients.

#### AB0167 METFORMIN HAS ANTI-INFLAMMATORY POTENTIAL BY REDUCING P-GP EXPRESSION ON PBMCs OF PATIENTS WITH LUPUS

S. Kansurkar, M.K. Rai, D.P. Misra, V. Agarwal. *Clinical Immunology and Rheumatology, Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGI), Lucknow, Uttar Pradesh, India, Lucknow, India*

**Background:** Metformin causes immunomodulation by activation of AMP-kinase and thereby inhibition of a mTOR pathway. Metformin reduces disease activity in lupus mouse models.<sup>1</sup> A study has shown that its use in lupus patients decreased corticosteroid dose and prevented flares.<sup>2</sup> P-glycoprotein expression is linked to drug resistance and increased cytokine production. Metformin inhibits expression of P-glycoprotein (P-gp) in cancer cells.<sup>3</sup> There is scarce data on effect of metformin on P-gp expression and cytokine secretion on immune cells in autoimmune diseases like lupus.

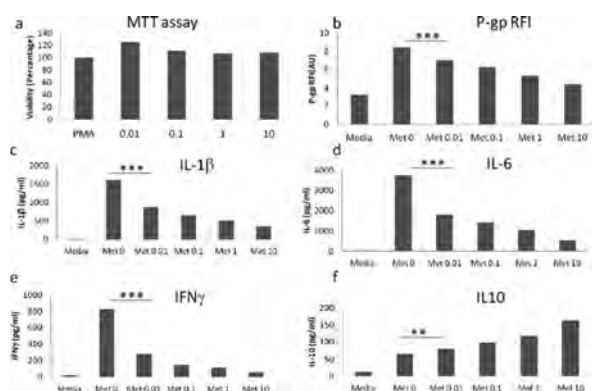

**Objectives:** To study the effect of metformin on P-gp expression in PBMCs of lupus patients and its effect on inflammatory cytokines secretion. To determine optimum concentration required for such an effect.

**Methods:** PBMCs of nine lupus patients (Mean age 30 yrs, all females) were cultured using RPMI medium and then stimulated with PMA/ ionomycin, with or without increasing dose of metformin (0.01, 0.1, 1, 10 mMol/L) for 24 h. Cytokines IL-1b, IL-6, IFN-g and IL-10 were analyzed by ELISA in culture supernatant. Cell

viability was independently assessed by MTT assay. P-gp expression was measured in same samples by flow-cytometry.

**Results:** In MTT assay viability of cells was maintained across all concentrations of metformin used in this study (figure 1a). Metformin decreased expression of P-gp in PBMCs in dose dependent manner ( $p=0.003$ ). (figure 1b). In the PBMC cultures with PMA and increasing concentration of metformin, there was decrease in production of pro-inflammatory cytokines: IL-1 $\beta$  ( $p=0.001$ ), IL-6 ( $p=0.007$ ) and IFN $\gamma$  ( $p<0.001$ ) at even the lowest concentration of metformin. There was increase in production of anti-inflammatory cytokine IL-10 ( $p=0.014$ ). The suppression of IL-1, IL-6, IFN $\gamma$  and increase in IL10 production was dose dependent.

**Abstract AB0167 – Figure 1.** a: MTT assay for cell viability (ns) b: P-gp expression with increasing metformin concentration (shown on X axis in mMOL/L), c,d,e,f: cytokine analyses of IL-1 $\beta$ , IL-6, IFN- $\gamma$  and IL-10 resp. In all experiments, PBMCs were stimulated by PMA and Metformin. \*\*\*= $P<0.01$ , \*\*= $P<0.03$

**Conclusions:** Metformin inhibits P-gp expression which is responsible for resistance to action of various drugs including corticosteroids which are cornerstones of treatment in SLE. Metformin thus may help to reduce corticosteroid dose. Anti-inflammatory activity seen in this study is occurring at concentrations which are therapeutically achievable. Plasma levels of metformin at the therapeutic doses commonly used for diabetes are usually around 0.01–0.04 mM/L.<sup>4</sup> Present study has demonstrated anti-inflammatory effect of metformin at this concentration. Metformin offers dual advantage which has anti-inflammatory activity and also has a potential to reduce drug resistance to other therapeutic agents.

#### AB0168 ELEVATED SERUM LEVELS OF HMGB1 AND SRAGE IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

S. Truglia<sup>1</sup>, V. Manganelli<sup>2</sup>, A. Capozzi<sup>2</sup>, C. Alessandri<sup>1</sup>, E. Lococo<sup>2</sup>, T. Garofalo<sup>2</sup>, M. Sorice<sup>2</sup>, A. Longo<sup>2</sup>, R. Misasi<sup>2</sup>, F. Conti<sup>3</sup>, G. Valesini<sup>1</sup>. <sup>1</sup>Dipartimento di Medicina Interna e Specialità Mediche; <sup>2</sup>Department of Experimental Medicine, Sapienza University; <sup>3</sup>Dipartimento di Medicina Interna e Specialità Mediche, POLICLINICO UMBERTO 1, Rome, Italy

**Background:** Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterised by the presence of at least one clinical event among vascular thrombosis and/or pregnancy morbidity, in the presence of circulating antiphospholipid antibodies (aPL). High-mobility group box-1 (HMGB1) is a non-histonic protein belonging to the family of alarmins. It is associated with chromatin and has

a dual function depending on the cell state: in basal conditions it is located in the nucleus and promotes the interaction of some transcription factors with DNA, in inflammatory conditions it is secreted in the extracellular space and exerts the functions of a pro-inflammatory cytokine. One of the main receptor system responsible for the HMGB1 activity is the "receptor for advanced glycation end products" (RAGE). Increased serum HMGB1 levels have been reported in patients with Systemic Lupus Erythematosus and pre-eclampsia, as other alarmins are increased in patients with early abortions.

**Objectives:** To evaluate the serum levels of HMGB1 and soluble RAGE (sRAGE) in patients with obstetric and thrombotic APS.

**Methods:** 43 consecutive patients with APS, diagnosed according to the Sapporo criteria, were enrolled. The study cohort included both primary APS (=15) and APS associated with SLE (=28). In addition, 30 healthy subjects (HC) matched for age and sex were studied as controls. Serum levels of HMGB1 and sRAGE were analysed by Western blot.

**Results:** The clinical features of the enrolled patients (40 females and 3 males, mean age 40.98 $\pm$ 13.48 years,) are reported in table 1. HMGB1 and sRAGE serum levels were significantly increased in APS patients in comparison with controls ( $p<0.001$ ) (figure 1). Furthermore, no difference in HMGB1 serum level was detected among patients with thrombotic or obstetric APS and patients with primary or secondary APS. APS patients with thrombosis showed higher levels of HMGB1 than APS patients without thrombosis; in addition, in APS patients there is a correlation between HMGB1 serum levels and thrombosis.

**Abstract AB0168 – Table 1.** Clinical characteristics of APS patients.

Characteristics n (%)	APS (n=43)
Vascular thrombosis	39 (90.7)
Venous thrombosis	26 (60.5)
Arterial thrombosis	18 (41.9)
Recurrent thrombosis	15 (34.9)
Pregnancy morbidity	15/40 (37.5)
Normal fetus deaths	2 (5)
Premature births	1 (2.5)
Spontaneous abortions	13 (32.5)
Vascular thrombosis and Pregnancy morbidity	11 (27.5)
Non-criteria APS features	
Livedo reticularis	16 (37.2)
Thrombocytopenia	11 (25.6)
Migraine	11 (25.6)
Seizures	7 (16.3)

**Abstract AB0168 – Figure 1.** Serum levels of HMGB1 and sRAGE in APS patients and controls.

**Conclusions:** In this study, we investigated for the first time the serum levels of HMGB1 and sRAGE in patients with APS, showing increased levels in both primary and secondary APS compared to controls. Larger studies are needed to assess whether monitoring serum HMGB1/sRAGE levels could be a useful tool for risk stratification in patients with APS.

### NEURONAL SURFACE P ANTIGEN (NSPA), THE CROSS-REACTING TARGET OF LUPUS ANTI-RIBOSOMAL P AUTOANTIBODIES, IS A POTENTIAL UBIQUITIN-LIGASE THAT REGULATES NMDAR FUNCTION

A. González<sup>1,2</sup>, S. Espinoza<sup>1,2</sup>, F. Segovia<sup>2</sup>, F. Carvajal<sup>3</sup>, W. Cerpa<sup>3</sup>, U. Wyneken<sup>4</sup>, P. Zamorano<sup>5</sup>, A. Rojas<sup>5</sup>, L. Massardo<sup>1</sup>. <sup>1</sup>Centro de Biología Celular y Biomedicina, Facultad de Medicina, Universidad San Sebastián; <sup>2</sup>Centro de Envejecimiento y Regeneración; <sup>3</sup>Departamento de Biología Celular y Molecular, Facultad Ciencias Biológicas, Pontificia Universidad Católica de Chile; <sup>4</sup>Facultad de Medicina, Universidad de los Andes, Santiago; <sup>5</sup>Departamento Biomédico, Universidad de Antofagasta, Antofagasta; <sup>6</sup>Facultad de Medicina, Universidad Austral de Chile, Valdivia, Chile

**Background:** Anti-ribosomal P protein autoantibodies (anti-P) are found in 10%–15% of all patients with lupus<sup>1</sup> and their pathogenic role is supported by clinical studies showing association with psychosis<sup>2</sup> and cognitive deficit,<sup>3</sup> as well as by experiments in rodents showing depression like behaviour,<sup>4</sup> memory impairment<sup>5</sup> and electrophysiological alterations.<sup>6, 7</sup> The Neuronal Surface P Antigen (NSPA) identified as an anti-P cross-reacting protein<sup>8</sup> very likely mediates anti-P-driven brain diffuse dysfunctions through AMPAR and NMDAR synaptic transmission and plasticity.<sup>6</sup>

**Objectives:** To analyse molecular link between NSPA and NMDAR function involved in synaptic transmission and plasticity associated with memory, as a new approach to understand the neuropathogenic mechanism of anti-P antibodies.

**Methods:** Comparative studies in wild-type and NSPA knock-out mice on water maze performance (spatial memory), electrophysiology of CA3-CA1 glutamatergic transmission by field excitatory postsynaptic potential in hippocampal slices, biochemical analysis of synaptosomes and post-synaptic densities, including the mass and post-translational modifications (tyrosine phosphorylation and ubiquitylation) of relevant proteins.

**Results:** NSPA KO mice displayed the following alterations: 1) Impaired hippocampal-mediated spatial memory; 2) Decreased NMDAR-mediated glutamatergic transmission and long-term potentiation deficit, reflecting synaptic plasticity defects; 3) Selective lowered mass of GluN2A and GluN2B subunits of NMDAR in hippocampal synaptosomes and synaptic densities, accompanied by an enhanced mass and decreased ubiquitylation of the tyrosine phosphatase PTPN4 that interacts with NSPA and dephosphorylates the Tyr1472 of GluN2B of NMDAR. In addition, NSPA contains an APC-10 domain belonging to E3 ubiquitin ligases and a cotransfection assay in HEK293 cells demonstrated NSPA ubiquitylation as expected for these kinds of enzymes.

**Conclusions:** All together, these results suggest that NSPA is an ubiquitin ligase that having PTPN4 as a substrate regulates the tyrosine phosphorylation status and consequently the function of NMDAR at the synaptic region.

### CCR9+ PATHOGENIC T HELPER CELLS FROM PRIMARY SJÖGREN'S SYNDROME PATIENTS ARE CHARACTERISED BY DEREGULATED PATHWAYS ASSOCIATED WITH EFFECTOR T CELL FUNCTION

S. Blokland<sup>1,2</sup>, C.G. Wichers<sup>1,2</sup>, A. Pandit<sup>1,2</sup>, A.A. Kruijze<sup>1</sup>, T.R. Radstake<sup>1,2</sup>, J. A. van Roon<sup>1,2</sup>. <sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>Laboratory of Translational Immunology, UMC UTRECHT, Utrecht, Netherlands

**Background:** CCR9 +Th cells produce large amounts of IFN- $\gamma$  and IL-10, lack CXCR5 expression but have features similar to Tfh cells and the recently

described pathogenic PD1 +CXCR5 cells, including expression of ICOS, PD-1, IL-21 and Bcl6, but no CXCR5 expression. CCR9 Th cells and their ligand CCL25 are elevated in salivary glands of primary Sjögren's syndrome (pSS) patients. Since CCR9 Th cells strongly induce antibody production and robustly respond to IL-7, which is indicated to play an essential role in pSS pathogenesis and in formation of ectopic lymphoid structures, these cells may play an important role in pSS immunopathology.

**Objectives:** The goal of this study was to identify the molecular dysregulation of CCR9 Th cells in pSS patients.

**Methods:** CCR9+, CXCR5 +and CCR9-CXCR5- Th cells were sorted from peripheral blood of 7 healthy individuals and 7 pSS patients and RNA sequencing of these sorted cell subsets was performed. Computational analysis identified differentially expressed genes (DEG) and gene expression networks. Pathway enrichment analysis was performed in order to assess differentially regulated pathways. Target genes are technically validated and knockdown experiments will assess the functional role of identified targets.

**Results:** The sorted Th subsets could robustly be distinguished based on their transcriptomes. In the CCR9 +Th cell subset 2777 DEGs (1249 up and 1528 down) were identified between healthy controls and pSS patients, and 1416 and 1077 in the CXCR5 +and CCR9-CXCR5- subsets, respectively. Using network analysis 15 modules were constructed, consisting of genes showing coherent expression patterns. Four modules of interest were selected based on pathway enrichment analysis, revealing pathways involved in e.g. cytokine and chemokine production, proliferation and migration. DEGs of interest within these networks were selected, including upregulated expression of integrin  $\alpha$ E, integrin  $\alpha$ 1 and downregulation of regulatory T cell associated genes FoxP3 and IL2RA. Expression of these markers is being validated using flow cytometry. In addition, knockdown of predicted key transcription factors is studied to reveal their role in the pathogenic potential of CCR9 +Th cells.

**Conclusions:** Transcriptomic analysis of CCR9 +Th cells from pSS patients revealed multiple dysregulated pathways previously shown to be involved in increased effector T cell function. Upregulation of genes associated with pathogenicity and downregulation of regulatory T cell associated genes were found in pSS patients. Targeting predicted key molecules might reveal (novel) therapeutic targets to halt pathogenic processes induced by CCR9 +Th cells.

### B CELL SUBPOPULATIONS IN LUPUS NEPHRITIS PATIENTS: CORRELATIONS WITH DISEASE ONSET AND OUTCOMES

V. Varriano<sup>1</sup>, L. Petricca<sup>1</sup>, B. Toluoso<sup>1</sup>, S. Costanzi<sup>2</sup>, G. Maria Rita<sup>1</sup>, A. Paglionico<sup>1</sup>, C. Di Mario<sup>1</sup>, G. Tanti<sup>1</sup>, G. Vischini<sup>1</sup>, G. Gambaro<sup>2</sup>, G. Ferraccioli<sup>1</sup>, E. Gremese<sup>1</sup>. <sup>1</sup>UOC of Rheumatology; <sup>2</sup>UOC of Nephrology, Fondazione Policlinico Universitario A. Gemelli Catholic University of the Sacred Heart, Rome, Italy

**Background:** the relationship between B cells subsets distribution, clinical and laboratory parameters, therapeutic response and prognosis in lupus nephritis (LN) is still underestimated.

**Objectives:** The aim of our study is to establish the value of B cells subsets as biomarkers in patients with active LN than controls, in patients at the onset of renal manifestation than patients with renal flare, and finally in nephritic patients in relation to their clinical and laboratory characteristics at the baseline and during the course of the disease.

**Methods:** 50 patients with a diagnosis of LN have been evaluated every three months. Laboratory, immunological and disease activity data were collected at the baseline and at 6 (T6), 12 (T12), 24 (T24), 36 (T36) months and at the last follow-up (FU). Number of renal flares, time to renal remission and persistent proteinuria at the last FU were evaluated. B cell subsets were obtained through cytofluorimetry and classified using C27/IgD classification. The characterisation of B cells subsets was realised in 50 LN patients and 37 healthy controls.

**Results:** LN patients had a lower percentage of CD19 +cells than controls (9.2% vs 10.6%; p=0.01) as well as a lower percentage of memory unswitched cells CD27 +IgD+ (10.7% vs 15.3%; p<0.001) while patients had an higher percentage of plasmablasts and double negative memory cells CD27-IgD- (respectively 5.9% vs 1%; p<0.001% and 10.9% vs 4.1%; p=0.01).

No significant differences regardless B cells subsets were found between early LN patients and long ones as well as between LN patients at the onset and LN patients during renal flare. We found a correlation between an higher disease activity (assessed with SLEDAI 2K) and lower percentage of memory B cells IgD-CD27+ (p=0.02). Double negative B cells CD27-IgD- tended to be correlated with an higher disease activity. Of interest the correlation between persistent proteinuria detected during the follow-up and a lower percentage of plasmablasts at the baseline (p=0.01).

**Conclusions:** The alteration of B cells subsets is an early event in LN without differences regardless the period of renal involvement (nephritic onset or later LN development). The association between persistent proteinuria and a lower percentage of plasmablasts at the baseline could be a negative prognostic factor considering the correlation between persistent proteinuria and worse renal outcome.

#### AB0172 THE RELATIONSHIP BETWEEN THE DIFFERENT TYPES OF CELL DEATH IN SYSTEMIC CONNECTIVE TISSUE DISEASES

V. Shishkin, G.V. Kudriavtseva, Y.A. Malenkov, V.V. Shishkin. *Saint Petersburg State University, Saint Petersburg, Russian Federation*

**Objectives:** To study the basic mechanism of cell death (autophagy, apoptosis and necrosis) typical of patients with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and systemic scleroderma (SSD). During systemic connective tissue diseases and especially in SLE, a close relationship between various types of cellular death is observed.

**Methods:** 7 SLE-, 10 RA-, 10 SSD patients' and 5 donors' sera were studied. The level of Ca ions was registered by the method of **atomic absorption spectrometry**. Adenosine monophosphate-activated protein kinase (AMPK) was estimated by the Western blotting method. The activity of ATP-ase was measured spectrophotometrically. In order to find out the level of p53 protein, the immune-enzyme "Human p53 Platinum ELISA" method was employed. The quantity of hemoprotein (Cyt c) and the level of 8-hydroxy-2'-deoxyguanosine (8-OH-dG) was measured by employing the immune-enzyme method.

**Results:** Assessing the functional activity of AMPK is an specific marker and a strategic biopower regulator of autophagy, as well as a specific indicator of red-ox cellular potential. In systemic connective tissue diseases, the oxidative stress is matched by urinary calcium and a decrease in the level of calcium in the blood. It reflects the level of seriousness of osteoporosis especially in case of RA. Molecular chaperones (HSP) play a key role in the changing of the way of cellular death. The family of chaperones HSP60 – HSP 100 shows ATPase activity which is most distinct during SLE and RA. The de-energisation of cells during systemic connective tissue diseases and the disappearing of the link between respiration and oxidative phosphorylation lead to proapoptotic protein – Cyt c is being released from mitochondria. High levels of Cyt c reflect cellular mitochondrial apoptosis and show the growing of hypoxia in SLE and RA. The level of protein p53 – a biological marker of apoptosis – is expressed when the DNA is destroyed. It reflects a higher level of the oxidative damage done to the DNA and the extent of the oxidative stress in SLE. This is also evidenced by the data collected by finding out the level of 8-OH-dG which is a biological marker of the free-radical damage of the DNA.

Comparison of markers of autophagy, apoptosis and necrosis in sera in SLE, RA and SSD: AMPK activity (units-mg of protein), the total level of ATP-ase active of HSP-60 – HSP-100 (nmol Pi/min-mg protein), (mM/l), quantity of (ng/ml): Cyt c, p53-protein, 8-OH-dG

**Abstract AB0172 – Table 1**

Groups	AMPK	ATP-ase	Cyt c	p53 protein	8-OH-dG	
SLE	8,7 ±0,3	8,4±0,3	1,99 ±0,12	39,7 ±1,4	1,45±0,03	27,9±3,2
RA	5,7 ±0,2	7,9±0,2	1,87 ±0,24	26,8 ±2,3	1,27±0,04	24,2±2,3
SSD	2,8 ±0,4	5,1±0,2	2,12 ±0,09	14,9 ±2,6	0,98±0,03	18,6±3,4
Donor	1,4 ±0,3	4,0±0,7	2,57 ±0,32	11,7 ±0,3	0,73±0,07	12,56 ±2,4

**Conclusions:** Chaperone-mediated induction of the immune response by autophagy, an evolutionary enshrined only in mammals, perhaps, is the central link in the pathogenesis of systemic connective tissue diseases.

#### AB0173 OVERWHELMING INFLAMMATION INCREASED SUSCEPTIBILITY OF SLE-PRONE MICE TO PULMONARY BACTERIAL INFECTION

W. Li<sup>1</sup>, X. Tang<sup>2</sup>, S. Huang<sup>2</sup>, L. Sun<sup>2</sup>. <sup>1</sup>The Affiliated Drum Tower Hospital of Nanjing University Medical School, nanjing, China; <sup>2</sup>Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, nanjing, China

**Background:** Aside from the disease itself, infections represent the major cause of morbidity and mortality in systemic lupus erythematosus (SLE) patients. Inherent defects in immune system play an important role in increasing rates of infection. However, the underlying mechanism of this deficiency remains largely unknown.

**Methods:** Lupus-prone mice B6/lpr were anaesthetized and infected with 1×10<sup>8</sup> CFU of *Haemophilus influenzae* (Hi) intranasally. Then bacterial clearance, body weight change and lung pathology were monitored. Apoptosis of lung cells was analysed by TUNEL assay. Both innate and adaptive immune response in the lung cells determined by flow cytometry. Cytokines in the bronchoalveolar lavage fluid (BALF) were measured by ELISA.

**Results:** Although both wild-type (WT) and B6/lpr mice survived after pulmonary Hi infection, a delay of bacterial clearance and inflammatory resolution was observed in B6/lpr mice. Tissue damage was more severe in the lungs of B6/lpr mice, as more apoptotic cells were detected on Day2 after infection. Cells from lupus-prone lungs produced more pro-inflammatory cytokines IL-6, MCP-1 and KC. TNF-α is comparable between the two groups. NK, γδ T and CD4 T cells are required for control bacterial infection. We that compared with WT controls, in response to infection fewer NK cells were detected in B6/lpr lungs. The numbers of γδ and CD4 T cells were not different, but their ability to secrete IFN-γ was significant lower in B6/lpr mice.

**Abstract AB0173 – Figure 1**

**Conclusions:** The increased susceptibility of SLE-prone mice to pulmonary *Haemophilus influenzae* infection may due to the elevated inflammatory responses and the deficient production of IFN-γ by immune cells.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3393

#### AB0174 TNF-A MODULATES MICROGLIA ACTIVATION VIA NF-KB ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH DEPRESSION

X. Kong<sup>1</sup>, K. Shen<sup>2</sup>, J. Ji<sup>1</sup>, T. Fu<sup>3</sup>, J. Yang<sup>3</sup>, Z. Gu<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Affiliated Hospital of Nantong University; <sup>2</sup>Department of Pharmacy, Affiliated Hospital of Nantong University; <sup>3</sup>Research Center of Clinical Medicine, Affiliated Hospital of Nantong University, Nantong, China

**Background:** Systemic lupus erythematosus (SLE) is a complex autoimmune disease accompanied by damage to a variety of tissue injuries, such as joints, kidney, and the peripheral and central nervous systems (CNS).<sup>1</sup> The diffuse CNS lupus manifests with a diverse array of neuropsychiatric symptoms that range from headaches, anxiety, depression, to cognitive impairment and, in rare cases, psychosis.<sup>2</sup> Additionally, up to 24% of SLE patients will display

depression.<sup>3</sup> Previous studies have suggested microglia, as critical mediators of depression in SLE.

**Objectives:** To date, the pathophysiology of most depression symptoms in SLE has not been well determined. We focused our attention on the potential role of microglia in neuroinflammation in SLE patients.

**Methods:** Cerebrospinal fluid was collected from 3 healthy people and 3 SLE patients. According to the hospital anxiety and depression scale (HADS), we investigate the depression of SLE patients. The cytokines were screened using a RayBio Human Cytokine Antibody Array in cerebrospinal fluid samples by analysing a variety of inflammatory cytokines such as IL-6, Leptin and TNF- $\alpha$ . Cerebrospinal fluid of SLE patients and normal people were tested by ELISA for TNF- $\alpha$ . The depression status of MRL/lpr (C3MRL-Faslpr/J) mice and Balb/c mice was determined by tail suspension test, open-field test and sucrose preference test. Immunofluorescence and Western blot was utilised to detect the activation of microglial cells in brain tissue. Microglia cells were stimulated by TNF- $\alpha$ , Western blot showed the expression of CD68 and activated NF- $\kappa$ B. The concentrations of IL-6 and IL-1 $\beta$  in the cell supernatants were measured by ELISA. After using of NF- $\kappa$ B signalling pathway inhibitor PDTC, the activation of microglia stimulated by TNF- $\alpha$  was determined by immunofluorescence, quantitative PCR, Western blot analysis and ELISA.

**Results:** The results showed that the level of TNF- $\alpha$  in cerebrospinal fluid of patients with lupus was higher than normal people. At 14 weeks, MRL/lpr mice appear depression by tail suspension test, open-field test and sucrose preference test, MRL/lpr mice had more reactive microglia in the cortex when compared to Balb/c. After microglial cell were stimulated by TNF- $\alpha$ , microglia were active and effectively release IL-6, IL-1 $\beta$  and iNOS. Moreover, the expression of CD68 and activated NF- $\kappa$ B signalling pathway were also higher significantly. However, the use of NF- $\kappa$ B signalling pathway inhibitor PDTC reverse the TNF- $\alpha$  induced microglial activation.

Abstract AB0174 – Table 1. Disease characteristics in SLE patients and control.

patient	Sex	Age, years	disease	depression	cerebrospinal fluid test results	course of disease, years
1.	female	25.	normal	no	negative	0.

Abstract AB0174 – Figure 1. The level of TNF- $\alpha$  in cerebrospinal fluid of patient with lupus was higher than normal people.

Abstract AB0174 – Figure 2. MRL/lpr mice appear depression by tail suspension test, open-field test and sucrose preference test, MRL/lpr mice had more reactive microglia in the cortex when compared to Balb/c at 14 weeks.

Abstract AB0174 – Figure 3. After microglial cell were stimulated by TNF- $\alpha$  (25 pg/ml), microglia were active and effectively release IL-6, IL-1 $\beta$  and iNOS.

Abstract AB0174 – Figure 4. the use of NF- $\kappa$ B signalling pathway inhibitor PDTC reverse the TNF- $\alpha$  induced microglial activation.

**Conclusions:** The study showed that the different level of inflammatory cytokines of cerebrospinal fluid of SLE patients. Our results highlight the potential role of microglia in neuroinflammation in SLE patients with depression.

AB0175 **DYSREGULATION OF NF- $\kappa$ B IN GLANDULAR EPITHELIAL CELLS RESULTS IN SJÖGREN'S-LIKE FEATURES**

X. Wang<sup>1</sup>, A. Shalaan<sup>2</sup>, S. Liefers<sup>1</sup>, G. Proctor<sup>2</sup>, H. Bootsma<sup>1</sup>, F. Kroese<sup>1</sup>, S. Pringle<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, UMCG, Groningen, Netherlands; <sup>2</sup>Division of Mucosal and Salivary Biology, King's College London Dental Institute, London, UK

**Background:** Hyposalivation and lymphocytic infiltration in salivary glands are common manifestations of primary Sjögren's syndrome<sup>1</sup>. NF-kappa B (NF $\kappa$ B) signalling is one of the most important proinflammatory pathways, and is inhibited by A20 (also known as TNFAIP3)<sup>2</sup>. Although mounting studies are pointing to the central role of epithelial cells in pSS<sup>3-5</sup>, whether pSS-like features can be initiated by immune activation of epitheliums remains to be explored.

**Objectives:** We sought to investigate the hypothesis that epithelial cells are capable of initiating the major pathological salivary gland hallmarks of primary Sjögren's syndrome. In order to achieve this we employ a keratin 14 (KRT14) promoter-driven knockout of the A20 NF $\kappa$ B signalling inhibitor.

**Methods:** A20 gene expression was knocked out in KRT14<sup>+</sup> cells, namely ductal and myoepithelial cells. Whole pilocarpine-stimulated saliva was collected from A20<sup>-/-</sup> mice and wildtype (WT) littermate controls at 10, 20 and 30 weeks of age. Submandibular SGs were harvested at all time points for histological examination and qPCR.

**Results:** In submandibular SGs of A20<sup>-/-</sup> mice at 30 weeks of age, 10% of all cells were CD45<sup>+</sup> leukocytes and 3% were CD3<sup>+</sup> T cells, both significantly more than controls. B cell proportion increased over time in A20<sup>-/-</sup> mice, but was not significantly different to controls. CD45<sup>+</sup> cells formed immune foci (>50 CD45<sup>+</sup> cells together) localised to striated ducts, present at significantly greater frequencies than control mice. CD45<sup>+</sup> cells, T cells and occasional B cells in A20<sup>-/-</sup> mice also invaded striated ducts. Expression of the pro-inflammatory cyto/chemo-kines IFN $\gamma$ , TNF $\alpha$ , IL-6, CXCL10 and CXCL13 was also significantly greater in A20<sup>-/-</sup> mice. Functionally, both volume and mucin 10 content of whole stimulated saliva from A20<sup>-/-</sup> mice was significantly reduced compared to controls.

**Conclusions:** We present a model for epithelial cell involvement in pSS SG pathology development. We confirm that saliva production defects, foci formation and striated duct invasion can be triggered solely by immune activated epithelial cells.

#### AB0176 MORPHOLOGICAL HEART CHANGES IN ANIMALS WITH EXPERIMENTAL SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Yehudina<sup>1</sup>, O. Syniachenko<sup>2</sup>, T. Bevzenko<sup>3</sup>. <sup>1</sup>Dnepropetrovsk Medical Academy, Dnipro; <sup>2</sup>Donetsk Medical University, Lyman; <sup>3</sup>Shupyk National Medical Academy of Postgraduate Education, Kyiv, Ukraine

**Background:** Heart pathology in systemic lupus erythematosus (SLE) refers to the most common manifestations of the disease and largely determines its prognosis.<sup>1,2</sup> The pathogenetic constructions of myocardium, endocardium and coronary vessel lesions remain insufficiently studied.<sup>3,4</sup> Histological evaluation of separate cardiac structures is performed on native models of SLE in linear mice.

**Objectives:** to study in the experiment on animals (rats) with SLE model the degree of cardiomyocytes, myocardium, endocardium, valves and cardiac vessel damage, comparing the results with thymus and spleen tissues histological data.

**Methods:** The SLE modelling was performed in 53 white non-breeding rats (34 females and 19 males) using full Freund's adjuvant, splenic deoxyribonucleic acid of cattle, cyclophosphamide, azid and sodium deoxyribonucleate. Cadmium sulfate, lithium oxybutyrate and ammonium molybdate were added for feeding animals. Histological heart specimen were stained with hematoxylin and eosin, altsyon blue (pH=2.6), van Gieson. PAS-reaction was applied.

**Results:** Experimental SLE is accompanied by the development of cardiopathy in all animals with cardiomyocytes hypertrophy, dystrophy and necrosis, morphological signs of coronary vessel, myocardial stroma, endocardium and heart valves sclerosis, proliferation of vascular endothelium, which has dispersion and direct correlation relationships with the degree of lymphoma-macrophage infiltration, interstitial tissue, perivascular and valvular histiocytic cell infiltration, and the vessels endothelium damage nature is closely linked to the presence of mast cells in myocardial stroma, it is defined by endocardium necrosis and valves collagenolysis, decrease in spleen lymphoid tissue, and also in the brain layer cells and Gassal cells in the thymus.

**Conclusions:** In the case of experimental lupus cardiopathy, there is determine heart structures lesion, what is more, the immune disorders are involved in their pathogenetic constructions, as indicated by the damage of the immunocompetent organs' (thymus and spleen) corresponding structures.

#### AB0177 TOLL-LIKE RECEPTOR 7(TLR7) IS UPREGULATED ON PERIPHERAL B CELLS AND ASSOCIATED WITH DISEASE ACTIVITY AND DAMAGE IN PRIMARY SJOGREN SYNDROME

Y. Xue, T. Wang, X. Song, M. Li, X. Zeng. *Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Key Laboratory of Rheumatology and Clinical Immunology, Ministry of Education, Beijing, China, Beijing, China*

**Objectives:** Primary Sjogren Syndrom(pSS) is characterised by activation of B cells, increased production of RNA-associated antibodies and elevated proportion of transitional B cell. Toll-like receptors 7(TLR7) have been reported promoting the effects above in some murine models of SS. We took up this study to identify if TLR7 expression is associated with disease activity and the role of TLR7 in pSS.

**Methods:** 21 pSS patients and 12 healthy controls(HCs) were selected. The mRNA expression of TLR7 was determined by real-time PCR on peripheral B cells of both pSS patients and HCs. We measured BAFF serum concentrations by ELISA, and the BAFF-R, TACI and BCMA expression was analysed on each B cell subset (CD27<sup>+</sup>CD24<sup>hi</sup>CD38<sup>hi</sup>/transitional B cell; CD27<sup>+</sup>CD24<sup>lo</sup>CD38<sup>lo</sup>/naive B cell;) by flow cytometry. The results were compared among patients with diverse degree of disease activity and damage to HCs.

**Results:** The expression level of TLR7 mRNA were elevated in pSS patients compared with HCs(p=0.004), and correlated with the SSDAI (SS disease activity index) (r=0.803; p=0.009) and the SSDI(SS damage index)(r=0.881;p=0.002). Serum BAFF concentrations increased in pSS patients compared with HCs (p=0.041), but not correlated with TLR7 expression. TACI expression in pSS patients in total B cells and traditional B cells compared to HCs were elevated and are both associated with TLR7 expression (r=0.763,p=0.048,r=0.820,p=0.004, respectively). A lower BAFFR expression was seen in transitional B cell compared with HCs(p=0.018). BCMA expression was of no significance.

**Conclusions:** Increased TLR7 expression on peripheral B cells were associated with disease activity and damage, suggesting that TLR7 may play a role in the development in pSS. Increased serum BAFF concentration and TACI expression were associated with TLR7 expression, indicating that BAFF may regulate TLR7 expression through TACI according to previous studies.TLR7 may be a potential treatment target of pSS and worth of further study.

#### AB0178 SUPPRESSION OF ENDOPLASMIC RETICULUM STRESS BY 4-PBA IMPROVES THE MANIFESTATIONS OF MURINE LUPUS THROUGH MODULATING REGULATORY T CELLS

Y.J. Choi<sup>1</sup>, E.-K. Lee<sup>2</sup>, J.-H. Jeong<sup>2</sup>, K.M. Kim<sup>3</sup>, C. Lee<sup>4</sup>, M.S. Lee<sup>4</sup>, W.-H. Yoo<sup>1</sup>. <sup>1</sup>Internal medicine; <sup>2</sup>Chonbuk National University Hospital, Jeonju-si, Korea, Republic of Ireland; <sup>3</sup>Pathology, Chonbuk National University Hospital, Jeonju-si; <sup>4</sup>Internal medicine, Wonkwang University Hospital, Iksan, Korea, Republic of Ireland

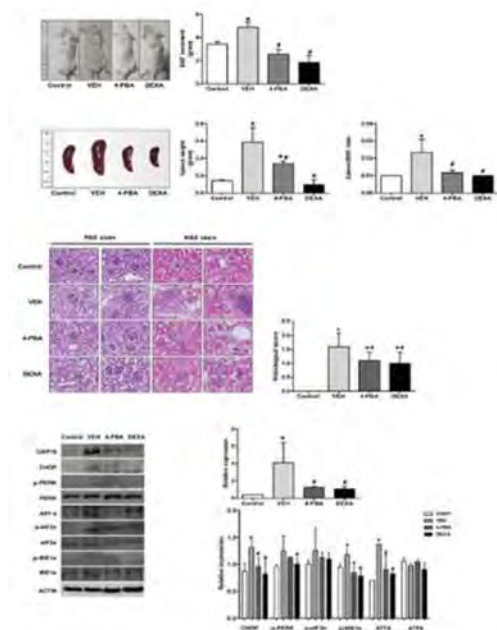

**Background:** Impaired function of regulatory T cells (Treg) contributes to the pathogenesis of systemic lupus erythematosus (SLE). It has been reported that the aberrant responses of T lymphocytes to endoplasmic reticulum (ER) stress in patients with SLE.

**Objectives:** In the present study, we investigated whether ER stress inhibition through 4-phenylbutyric acid (4-PBA) ameliorates lupus manifestation on

experimental lupus model and the effect of ER stress inhibition by 4-PBA on the frequency and function of Treg.

**Methods:** Murine lupus model were induced with female BALB/c mice at 7 or 8 weeks of age through Toll-like receptor (TLR) agonist 7 treatment for 4 weeks. From the 8th week, the mice were treated with phosphate buffered saline (PBS), 4-PBA (500 mg/kg, three times weekly) and dexamethasone (1 mg/kg, once a day) for 4 weeks. The increment of body weight, spleen weight, anti-double-stranded DNA (anti-dsDNA) antibody titer, serum cytokine level and the pathology of glomerulonephritis were analysed at 12 weeks of age. The population of immune cellular subset including activated T, B lymphocyte and Treg and suppressive functions of Treg were measured.

**Results:** 4-PBA significantly decreased the level of anti-dsDNA antibodies, serum TNF- $\alpha$  in murine lupus model, and which were comparable with the efficacy of dexamethasone. A significant decrease in accumulation of immunoglobulin, glomerulonephritis score was also observed in 4-PBA-treated and dexamethasone-treated mice compared with vehicle-treated group. ER stress inhibition decreased the activated T and B lymphocytes population of splenocytes, but the population of Treg was not significantly different between vehicle group and 4-PBA group. However, there was the markedly enhanced suppressive capacity of Treg in 4-PBA-treated group.

Abstract AB0178 – Figure 1

**Conclusions:** The results suggest that ER stress inhibition attenuates disease activity in experimental model, especially in nephritis through improving the suppressive capacity of Treg. Thus, reduction of ER stress could be used as a beneficial therapeutic strategy in SLE.

#### AB0179 SERUM LEVELS OF INTERLEUKIN-33 ARE ASSOCIATED WITH DEPRESSIVE SYMPTOMS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Z. Li<sup>1</sup>, T. Fu<sup>1</sup>, C. Dong<sup>1</sup>, L. Li<sup>2</sup>, Z. Gu<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Affiliated Hospital of Nantong University; <sup>2</sup>Department of Gastroenterology, Affiliated Hospital of Nantong University, Nantong, P.R. China., Nantong, China

**Background:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease which is more common among women than men. Extraglandular manifestations are commonly reported, including central nervous system (CNS) involvement such as headaches, cognitive deficits and mood disorder. Among mood disorder, depression is one of the most frequent disorders observed in patients with pSS. The pathogenesis of depression in pSS remains unclear.

**Objectives:** The aim of this study was to explore potential relationships between serum interleukin-33 (IL-33) levels and depressive symptoms in primary Sjögren's syndrome (pSS) patients.

**Methods:** We included 116 consecutive pSS patients (36 depression patients), and 71 (18 depression patients) age- and sex-matched healthy controls. The presence of depressive symptoms was determined through the Hospital Depression Scale (HDS). IL-33 levels were measured by enzyme-linked immunosorbent assay (ELISA) using commercial kits.

**Results:** There was no significant difference between pSS patients and controls. But, in pSS patients, the serum IL-33 levels were significantly lower in depression patients as compared to patients without depression [40.18 (IQR, 31.79–66.70) ng/ml vs. 39.95 (IQR, 121.73) ng/ml;  $Z = -3.029$ ,  $p = 0.002$ ]. A direct negative correlation between the score of HDAS-D and sera IL-33 levels ( $r = -0.805$ ,  $p = 0.000$ ) in pSS was also observed. In logistic regression model using depression as the dependent variables, IL-33 is the independent predictors of depression in pSS ( $\beta = 0.004$ ; OR = 1.004; 95% CI: 1.998–0.011;  $p = 0.170$ ). Surprisingly, sera IL-33 levels were lower in depression patients with pSS compared to depression patients without pSS ( $Z = -2.316$ ,  $p = 0.021$ ).

Abstract AB0179 – Figure 1

**Conclusions:** Conclusion: In pSS, IL-33 is the independent predictors of depressive disorders. Serum IL-33 levels are decreased in pSS patients with depressive symptoms, suggesting that IL-33 may play a unique role in depression with pSS.

#### AB0180 IDENTIFICATION OF LNCRNA LNCMKLN1 CONTRIBUTED TO ABNORMAL ACTIVATION OF TYPE I INTERFERON PATHWAY IN SYSTEMIC LUPUS ERYTHEMATOSUS

Z. Ye, Y. Tang, Z. Yin, X. Chen, Y. Chen. Shenzhen Futian Hospital for Rheumatic Diseases, Shenzhen, China

**Background:** Dysregulation or dysfunction of some key moleculars in signalling pathway is involved in disease pathogenesis. Type I interferon pathway abnormal activation has been identified as major molecular phenotype of lupus patients. Long non-coding RNA (lncRNA), as a regulator of gene expression, plays great role in signalling pathway.

**Objectives:** We hypothesised that dysregulation of lncRNA may involve in key signalling pathway of SLE.

**Methods:** Deep sequencing of human renal samples to screen differential expression of lncRNAs between LN patients and healthy donors. RNA-FISH was used to identify subcellular location of lncRNA. Stimulation in human renal mesangial cells (HRMC) by all kinds of TLR ligands, IFNs, and TNF $\alpha$ , and transfection in HRMC cells by antisense oligonucleotides (ASOs), and quantitative real-time polymerase chain reaction (RT-qPCR), enzyme linked immunosorbent assay (ELISA) were used to analyse the relative genes expression. LncMKLN1 transcription was activated or inhibited through CRISPR-dCas9 system in Hela cell line. RNA-seq was executed to examine the gene expression profile after changing lncMKLN1 expression, and western blot was applied to determine the key signalling molecules of IFN pathway.

**Results:** lncMKN1, dominantly located in nucleus, was up-regulated in lupus patients compared to healthy donors, and could be induced by IFN $\alpha$  and TLR ligands in HRMC. Silencing lncMKN1 significantly reduced the expression of a group of interferon-inducible genes, including IFIT3, OAS1, CXCL10, etc. We used lose-of-function and gain-of-function strategy through CRISPR system to confirm that lncMKN1 positively regulated type I interferon pathway. Furthermore, it was identified the involvement of lncMKN1 in interferon signalling pathway was through regulating the expression of STAT1, IRF9 and phosphorylation of IRF9 and STAT1 although its mechanism is also needed to investigate.

**Conclusions:** Upregulated lncMKN1 expression contributed to abnormal activation of interferon pathway of SLE.

**Disclosure of Interest:** None declared

#### AB0181 ENHANCED THERAPEUTIC EFFICACY OF APOPTOTIC CELL TREATED MESENCHYMAL STEM CELLS IN LUPUS PRONE MRL/LPR MICE

Z. Zhang, H. Chen, L. Sun. *The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Mesenchymal stem cells (MSCs) exhibit promising therapeutic potential in systemic lupus erythematosus (SLE). Increased apoptotic cells (ACs) were observed in SLE and our previous study showed MSC transplantation reduced AC levels in patients with SLE. Yet the effects of ACs on MSCs are not clear.

**Objectives:** This study aims to investigate the effects of ACs on MSCs and efficacy of AC treated MSCs (AC-MSCs) in SLE.

**Methods:** Jurkat T cells were irradiated by ultraviolet ray to induce apoptosis and then co-cultured with umbilical cord derived MSCs. Then, ACs were removed and MSCs were further co-cultured with human peripheral blood mononuclear cells (PBMCs). The inhibition of MSCs on PBMC proliferation was detected by flow cytometry. MSCs and AC-MSCs were infused into lupus prone MRL/lpr mice respectively to compare their therapeutic effects.

**Results:** The suppression of MSCs on PBMC proliferation was significantly enhanced after co-culture with ACs. *In vivo* study showed that AC-MSCs significantly increased the survival rate of MRL/lpr mice and decreased urine protein as early as one week after treatment, while MSCs decreased urine protein eight weeks post infusion. Moreover, AC-MSCs remarkably reduced the number of splenic plasma cells and serum anti-dsDNA levels, whereas MSCs only showed decreased tendency.

**Conclusions:** ACs enhanced therapeutic effects of MSC transplantation in lupus mice, which provides new insights into MSC modification in the treatment of SLE.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3450

## Systemic sclerosis, myositis and related syndromes – etiology, pathogenesis and animal models

#### AB0182 MOLECULAR MECHANISMS MEDIATING ANTIOXIDANT EFFECT OF EPIGALLOCATECHIN-3-GALLATE IN EXPERIMENTAL SCLERODERMA MODEL

A. Kocak<sup>1</sup>, D. Harmanci<sup>2</sup>, M. Birlik<sup>3</sup>, G. Guner<sup>4</sup>. <sup>1</sup>Molecular Medicine, Dokuz Eylul University, Institute of Health Sciences; <sup>2</sup>Molecular Medicine, Dokuz Eylul University, Institute of Health Sciences, Molecular Medicine Dpt; <sup>3</sup>Dokuz Eylul University, Faculty of Medicine, Rheumatology; <sup>4</sup>Biochemistry, Izmir University of Economics, Izmir, Turkey

**Background:** Scleroderma (SSc) is an autoimmune multisystemic connective tissue disease characterised by skin and internal organ fibrosis.<sup>1</sup> Underlying mechanism is still unclear for SSc. Besides there is no specific treatment for SSc, various treatments may alleviate symptoms and improve the quality of life. Epigallocatechin-3-gallate (EGCG) is a phenol with antioxidant effects in many disease processes.<sup>2</sup> In this disease, oxidative stress may play a role for pathogenesis.<sup>3-5</sup> Recent studies showed a relationship between oxidative/antioxidative markers and SSc.<sup>5</sup>

**Objectives:** The aim of this study was to investigate the antioxidant effects of epigallocatechin-3-gallate in the scleroderma process in experimental mouse model with bleomycin.

**Methods:** Thirty-two healthy female Balb-c mouse species were used and randomly divided into four groups: control, bleomycin, bleomycin +EGC, EGCG. At the end of the experiment, skin tissues were collected. Sodium dismutase enzyme (SOD) and malondialdehyde (MDA) levels have been analysed for oxidative

stress. High performance liquid chromatography (HPLC) was used for MDA measurements. Colorimetric kit was used for SOD analysis. Furthermore, the ratio of phosphorylated p-38/total p-38 protein, and phosphorylated-Akt/total Akt protein and NF-kappa B were measured by western blotting. Immunohistochemistry ( $\alpha$ -SMA), histochemistry (masson trichrome-hematoxylin and eosin) studies were also performed on FFPE skin samples.

**Results:** When the experimental and control groups were compared, the degree of fibrosis in the connective tissue of the dermis areas stained with masson trichrome decreased in the EGCG groups. SOD activity was increased in the EGCG groups compared to the positive control group, and MDA was significantly decreased in the EGCG groups. According to Western blotting results, pp-38 MAPK and NF- $\kappa$ B were found to decrease significantly in the EGCG groups compared with the controls. Parallel to these findings, phosphorylated Akt protein was found to increase in the EGCG groups compared with the control groups.

**Conclusions:** It has been shown that EGCG can antioxidative effect in scleroderma.

#### AB0183 VITAMIN D AND VITAMIN D RECEPTOR IN PATIENTS WITH SCLERODERMA SUBTYPES

A. Kocak<sup>1</sup>, D. Harmanci<sup>1</sup>, M. Birlik<sup>2</sup>, G. Guner<sup>3</sup>. <sup>1</sup>Molecular Medicine, Dokuz Eylul University, Institute of Health Sciences, Molecular Medicine Dpt; <sup>2</sup>Dokuz Eylul University, Faculty of Medicine, Rheumatology; <sup>3</sup>Biochemistry, Izmir University of Economics, Izmir, Turkey

**Background:** The aim of this study was to compare the expression of Vitamin D receptor (VDR) and vitamin D in scleroderma subtypes.

**Objectives:** VDR is a member of the nuclear localised hormone receptor family. 1,25-(OH) 2D, a form of metabolically active Vitamin D3, is the ligand of VDR. When VDR and 1,25-(OH) 2D are linked, many genes initiate molecular interaction reactions that will modulate the transcription.<sup>1</sup> VDR has been shown to be a negative regulator of the TGF- $\beta$ /Smad signalling pathway, which is important in the pathogenesis of scleroderma.<sup>2, 3</sup> Thus, reduced expression of VDR and decreased ligand levels may contribute to hyperactivity of the TGF-beta pathway in SSC and abnormal fibroblast activation. Also, Vitamin D has pleiotropic effects including immunomodulatory and antifibrotic properties in scleroderma pathogenesis.

**Methods:** 19 SSC patients and 6 healthy controls were included in the study and they were classified according to the 2013 ACR/EULAR criteria. They were applied to Dokuz Eylul University, Faculty of Medicine, Department of Rheumatology-Immunology, between 2015–2017. Rodnan scores were calculated of all scleroderma patients. 11 were of the limited type and 8 were of the diffuse type of scleroderma. Informed consent was obtained from all participants. 1 ml of total blood was collected. Vitamin D levels were determined in serum.

VDR gene expression was determined by quantitative PCR in isolated RNAs from the blood. Changes in mRNA levels were analysed according to the  $\Delta\Delta$ CT method and beta-actin was used as the housekeeping gene. Student-t-test was used as a statistic. In addition, Pearson correlation test was used to determine the relationship between Rodnan score and VDR gene expression.

**Results:** VDR gene expressions in diffuse type scleroderma patients were statistically significantly decreased compared to the control (p<0.01).

It was found that VDR gene expression in limited type scleroderma patients did not show any significant difference when compared to control (p: 0.16).

Also, Vitamin D levels and vitamin D expressions were no correlation in scleroderma subtypes (p:0.2)

**Conclusions:** VDR gene expression decreased in patients with diffuse type scleroderma and showed negative correlation with Rodnan score. Further studies are planned to increase the number of samples to obtain more information.

AB0184 **DIAGNOSTIC IMPACT IN THE CLINICAL SETTING OF NAILFOLD VIDEOCAPILLAROSCOPY ON CONNECTIVE DISEASES**

C. Soletó, L. Torrens, J.C. Nieto González, on behalf of Claudia Sáenz Tenorio, Ana M. Anzola, Liz. Rocío Caballero Motta, Leticia. García, María Correyero. Plaza, D.D.D. González Benitez, Belén Serrano. Benavente, Julia Martínez. Barrio, Javier. López-Longo, Alfonso. Ariza, Indalecio Monteagudo. Sáez. *Rheumatology, Hospital General Universitario Gregorio Marañón (H.G.U.G.M.), Madrid, Spain*

**Background:** Nailfold video-capillaroscopy (NVC) is a non-invasive technique that allows visualisation of structure and distribution of capillaries at the nailfold level<sup>1</sup>, altered somehow in some connective diseases, specially in the Scleroderma (Scl) disease spectrum. The main indication of this technique is the investigation of Raynaud's phenomenon (RF).

**Objectives:** Our objective is to investigate the diagnostic impact of NVC in the daily clinical practice.

**Methods:** The design is an observational, longitudinal, retrospective and descriptive study, which included patients with at least one NVC between June 2012 and December 2016 from our Rheumatology register of patients. We collected demographic data (age, gender, indication, autoantibodies, etc.), number of explorations performed and their result. We also collected in a dichotomist fashion if the NVC contributed in the diagnostic workup, between one consultation and the other after the NVC realisation.

**Results:** 437 patients were included with a total of 637 explorations. Of these 437 patients, 115 (24.1%) had a second NVC, 39 (8.2%) a third one, 9 (1.9%) a fourth and only two with a fifth NVC (both with diagnostic of Scl). We noticed a diagnostic change between the first consultation and the next one in 35 cases (5.49%). In 14/35 (40%) of these cases, the NVC played an important role in the diagnostic change, with changes in the NVC pattern, from normal or unspecific to Scl pattern (table 1). These changes, occurred after the first NVC in 10 patients (71.4%), 3 (21.4%) after the second, and 1 (7.1%) after the third exploration in addition of new disease manifestations, diagnostic tests and other image techniques. Of these 14 patients, 100% had positive ANA, 5 (35.7%) Anticentromere Antibodies (Ab), 1 (7.1%) anti-Ro Ab and 1 (7.1) Antiphospholipid Ab.

Abstract AB0184 – Table 1

Change	n:14 (%)	Pattern
RF to Scl	11 (78.5%)	Early 7/11 (63.6%) Active 2/11 (18.1%) Late 2/11 (18.1%)
UC to Scl	2 (14.2%)	Early 2 (100%)
RF to UC	1 (7.1%)	Early 1 (100%)

Raynaud phenomenon (RF); Scleroderma (Scl); Undifferentiated connective disease (UC); Mixed connective tissue disease (MCTD); Systemic Lupus Erythematosus (SLE); primary Sjögren syndrome (pSS).

Of the 21 patients with a diagnostic change who did not developed a Scl pattern we have:

Normal pattern: 1 RF to possible Scl and 1 RF to UC.

Limit of normality: 1 SLE to MCTD, 4 RF to UC, 1 RF to pSS, 1 RF to MCTD and 1 UC to MCTD.

Unspecific (mild): 3 RF to UC, 2 RF to Scl and 1 UC to overlap syndrome.

Unspecific (moderate): 1 RF to UC, 1 RF to Scl, 1 UC to MCTD and 1 RF to MCTD.

**Conclusions:** The NVC in our centre had a limited but important impact in the diagnostic process of connective diseases. This impact was specially relevant in patients diagnosed with Scleroderma. The probability of having a diagnostic change diminishes with successive explorations.

AB0185 **ALTERED EXPRESSION OF RELAXIN RECEPTOR RXFP1/LGR7 IN DERMAL FIBROBLASTS CONTRIBUTES TO THE INEFFECTIVITY OF RELAXIN-BASED ANTI-FIBROTIC TREATMENTS IN SYSTEMIC SCLEROSIS**

C. Corallo<sup>1</sup>, M. Cutolo<sup>2</sup>, S. Soldano<sup>2</sup>, S. Cheleschi<sup>3</sup>, A. Fioravanti<sup>3</sup>, A.M. Pinto<sup>4</sup>, A. Renieri<sup>4</sup>, R. Nuti<sup>1</sup>, N. Giordano<sup>1</sup>. <sup>1</sup>Scleroderma Unit, Department of Medicine, Surgery and Neurosciences, University of Siena, Siena; <sup>2</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Polyclinic San Martino Hospital, Genoa; <sup>3</sup>Rheumatology Unit, Department of Medicine, Surgery and Neurosciences; <sup>4</sup>Medical Genetics, Department of Medical Biotechnologies, University of Siena, Siena, Italy

**Background:** Systemic Sclerosis (SSc) is an autoimmune disease characterised by progressive fibrosis of the skin and internal organs, coupled to widespread vascular pathology.<sup>1</sup> The pathogenesis is still poorly understood and there is no effective treatment for the fibrotic process.<sup>1</sup> Relaxin is a potent anti-fibrotic hormone that has been tested in the past to ameliorate skin, lung and kidney fibrosis in SSc, but the results remain controversial.<sup>2</sup>

**Objectives:** The aim of the study is to evaluate the presence of mutations in RXFP1 gene (encoding the relaxin receptor RXFP1/LGR7), and to assess mRNA and protein levels of the receptor in dermal fibroblasts of SSc patients, in order to understand the clinical inefficacy of relaxin-based anti-fibrotic treatments in the disease.

**Methods:** Fibroblasts were isolated from unaffected and affected skin samples of (n=20) of limited cutaneous SSc (LcSSc) and from (n=20) affected skin of diffuse cutaneous SSc (DcSSc) patients. Fibroblasts derived from healthy subjects were used as controls. Sequencing of exonic target regions of interest for gene RXFP1 was performed coupled with mRNA transcript variant analysis. RXFP1/LGR7 mRNA and protein levels were assessed by quantitative-real-time-PCR (qPCR) and by immunocytochemistry (ICC) in cultured SSc and healthy fibroblasts. Finally, synthesis of collagen and alpha-smooth-muscle actin (a-SMA) of transforming-growth-factor-beta-1 (TGF- $\beta$ 1) induced fibroblasts were assessed after 24 hours pre-treatment with serelaxin (a recombinant form of human relaxin-2 targeting the relaxin receptor RXFP1/LGR7).

**Results:** Sequencing of RXFP1 gene showed no relevant (single nucleotide polymorphisms) SNPs or small insertions and deletions (InDels) in affected LcSSc/DcSSc fibroblasts. No relevant mutations were found in unaffected LcSSc and healthy fibroblasts as well. However, alternatively spliced transcript variants encoding multiple isoforms were observed for this gene in all the fibroblast populations. The total RXFP1 mRNA levels resulted upregulated (p<0.05) in the affected LcSSc/DcSSc fibroblasts compared to unaffected LcSSc (p<0.05) and to healthy ones (p<0.05). On the contrary, ICC demonstrated the absence of RXFP1/LGR7 receptor in affected LcSSc/DcSSc fibroblasts and the regular expression in unaffected LcSSc and healthy fibroblasts. In fact, serelaxin pre-incubation was unable to counteract the TGF- $\beta$ 1 driven upregulation of collagen and a-SMA in affected LcSSc/DcSSc fibroblasts only, but not in unaffected LcSSc and healthy ones.

**Conclusions:** The absence/altered expression of relaxin receptor RXFP1/LGR7 in the affected fibroblasts of SSc patients could explain the inefficacy of relaxin-based anti-fibrotic treatments in the disease. The exclusion of RXFP1 gene mutations could lead to the hypothesis that the presence of receptor splice variants could exert a dominant negative effect on the wild type isoform in terms of maturation, and subsequent trafficking to the cell surface, resulting in loss of function.

### HIGH-DOSE NARROWBAND ULTRAVIOLET A1 INDUCES THE REGRESSION OF DERMAL FIBROSIS IN ANIMAL MODEL OF SCLERODERMA

D. Karpeć<sup>1,2</sup>, R. Rudys<sup>2</sup>, L. Leonaviciene<sup>2</sup>, Z. Mackiewicz<sup>2</sup>, R. Bradunaite<sup>2</sup>, G. Kirdaite<sup>2</sup>, R. Ruginė<sup>1,2</sup>, A. Venalis<sup>1,2</sup>. <sup>1</sup>Center of Rheumatology, Vilnius University Hospital Santaros Klinikos; <sup>2</sup>State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania

**Background:** Ultraviolet A1 (UVA1) phototherapy implications for systemic sclerosis still remain area of research. The wide spectral waveband of UVA1 could react with many chromophores in the skin, leading to different effects of the immune system.<sup>1</sup> In accordance with the physical properties of UVA1 and the optical features of the skin, the narrowband UVA1 would influence collagen metabolism with a reduced chance of side effects. None of the previously conducted studies evaluated the effectiveness of narrowband UVA1 on dermal fibrosis.

**Objectives:** The main objective of the present study was to define the impact of high-dose of 365±5 nm UVA1 on the dermal thickness in pre-established, bleomycin-induced mouse model of scleroderma.

**Methods:** Forty two DBA/2 line mice were randomly divided into the following 6 groups (7 animals in each): group I – mice injected with sodium chloride (NaCl) for 3 weeks; group II – mice injected with bleomycin (Bleo) for 3 weeks; group III – mice injected with NaCl for 8 weeks; group IV – mice injected with Bleo for 3 weeks and then with NaCl for 5 weeks; group V – mice injected with Bleo for 8 weeks; group VI – mice injected with Bleo for 8 weeks and parallel treated with average cumulative dose of 1200 J/cm<sup>2</sup> of UVA1 for the last 5 weeks (the treatment group). Light source emitting a narrow band UVA1 of 365±5 nm and 21 mW/cm<sup>2</sup>; power density was used in the study. Histological analysis was performed for the evaluation of dermal thickness. The Mann – Whitney U test was used for statistical analysis.

**Results:** After bleomycin injections that spanned a period of 3 and 8 weeks, the dermal thicknesses were significantly (p=0.002) higher (group II – 433.69 ±54.37 μm and group V – 497.43±57.83 μm, respectively) as compared to that of the healthy controls (group I – 166.04±25.29 μm and group III – 178.18 ±42.35 μm, respectively). The 3 weeks of bleomycin injections and the following 5 weeks of NaCl did not cause any spontaneous regression of dermal fibrosis (group IV – 443.87±41.77 μm; group II – 433.69±54.38 μm; p=0.482). Dermal thickness in mice injected with bleomycin for 8 weeks and irradiated with UVA1 for the last 5 weeks was significantly lower than that in mice challenged only with bleomycin for 8 weeks (group VI – 253.96±31.83 μm and group V – 497.43 ±57.83 μm, respectively; p=0.002). Furthermore, treatment with 1200 J/cm<sup>2</sup> of UVA1 in parallel with profibrotic stimulus of bleomycin resulted in a lower dermal thickness as compared with pre-existing fibrotic changes in the group IV observed after 3 weeks of bleomycin injections (group VI – 253.96±31.83 μm and group IV – 443.87±41.77 μm; p=0.002) (figure 1).

Abstract AB0186 – Figure 1

**Conclusions:** The cumulative dosage of 1200 J/cm<sup>2</sup> of narrowband UVA1 not only prevented the progression of dermal fibrosis, but also induced the regression of pre-existing fibrotic changes in bleomycin-induced mouse model of scleroderma.

### THE ASSOCIATION BETWEEN ACTIVITY OF PURINE AND PYRIMIDINE METABOLISM ENZYMES AND DISEASE ACTIVITY IN SYSTEMIC SCLERODERMA PATIENTS

E. Mozgovaya<sup>1</sup>, S. Bedina<sup>1</sup>, A. Trofimenko<sup>1,2</sup>, I. Zborovskaya<sup>1,2</sup>. <sup>1</sup>Federal State Budgetary Institution « Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy»; <sup>2</sup>Volgograd State Medical University, Volgograd, Russian Federation

**Background:** Recent studies report various metabolic disturbances in systemic sclerosis (SSc) patients. Purine and pyrimidine metabolic pathways are closely interrelated, underlying the central processes of cellular life. Alterations of the enzymes that control these metabolic conversions can disturb proliferation and differentiation of lymphocytes, therefore contributing initiation and progression of the immunopathological phenomena.

**Objectives:** to characterise enzymatic patterns of the major purine and pyrimidine metabolic pathways enzymes in blood plasma and lysed lymphocytes depending on the SSc activity.

**Methods:** 51 SSc patients and 30 healthy controls were enrolled in the study. Mean age of patients (Mean ±SD) was 42,8±1,3 years, mean SSc duration was 7,9±0,7 years. The diagnosis was verified in accordance with the international standards (ACR/<sup>EULAR</sup> 2013). Disease activity was assessed in accordance with the national classification.<sup>1</sup> Adenosine deaminase (ADA; EC 3.5.4.4); adenosine kinase (AK; EC 2.7.1.20); guanylate kinase (GK; EC 2.7.4.8), dihydroorotate dehydrogenase (DODH; EC 1.3.1.14); IMP dehydrogenase (IMPDH; EC 1.1.1.205); purine nucleoside phosphorylase (PNP; EC 2.4.2.1); thymidine kinase (TK; EC 2.7.1.21); thymidine phosphorylase (TP; EC 2.4.2.4); uracil/thymidine dehydrogenase (UDH; EC 1.17.99.4); cytidine deaminase (CDA; EC 3.5.4.5) activities were measured in blood plasma and lysed lymphocytes.

**Results:** We revealed substantial changes in enzymatic activities related to both purine and pyrimidine metabolism in SSc. The increased DODH (p<0,001), IMPDH (p<0,001), PNP (p<0,001), TK (p<0,001), TP (p<0,01), UDH (p<0,001) activities in plasma and AK (p<0,001), IMPDH (p<0,001), TK (p<0,001) activities in lysed lymphocytes; the decreased ADA (p<0,001), GK (p=0,02), PNP (p<0,001) activities in lysed lymphocytes were observed in SSc patients in comparison with healthy controls. Plasma AK, DODH, IMPDH, PNP, TK, UDH activities positively correlated with SSc activity, as well as lymphocytic AK, IMPDH, TK activities did. Negative correlations with SSc activity were revealed for plasma ADA, GK, TP, and also for lymphocytic ADA, GK, DODH, PNP, TP, UDH, CDA. Plasma and lymphocytic adenosine deaminase as well as adenosine kinase activities were the most informative for minimal SSc activity detection, being a promising candidate marker.

**Conclusions:** The changes in enzymatic activity of purine and pyrimidine metabolism participate in pathogenesis of SSc. The enzymatic patterns studied can be used as auxiliary markers of SSc activity. The correction of purine and pyrimidine metabolism changes can be considered as one of the promising ways of increasing the effectiveness of SSc treatment.

**AB0188** **ACTIVATED PLATELETS ARE INCREASED IN CIRCULATION OF PATIENTS WITH SYSTEMIC SCLEROSIS AND ASSOCIATED WITH CLINICAL CHARACTERISTICS**

H. Yasuoka<sup>1</sup>, K. Sakata<sup>1</sup>, K. Yoshimoto<sup>1</sup>, K. Yamaoka<sup>1</sup>, M. Kuwana<sup>2</sup>, T. Takeuchi<sup>1</sup>.  
<sup>1</sup>Keio University School of Medicine; <sup>2</sup>Nippon Medical School Graduate School of Medicine, Tokyo, Japan

**Background:** Systemic sclerosis (SSc) is a systemic connective tissue disease characterised by excessive fibrosis, microvascular injury and autoantibody production (1), but mechanisms of disease process are still under investigation. Recent studies focused on the role of circulating blood cells in the pathogenesis, especially lymphocytes (2,3) or monocytes (4,5), however other cellular components are not well-examined. Platelets play a significant role in hemostasis physiologically. However, recent studies have revealed that platelets contain various kinds of humoral factors such as cytokines, chemokines and growth factors and can distribute systemically through circulation and contribute to the disease process through activation and release of these factors (6).

**Objectives:** To elucidate the role of platelets in the pathogenesis of SSc, activation status of circulating platelets in patients with SSc and association with clinical characteristics were examined.

**Methods:** Twenty-one patients with SSc who fulfilled 2013 ACR/EULAR classification criteria and 16 healthy controls were involved. Platelets or microparticles (MPs) were defined as vesicles in platelet-rich plasma which is more or less than 1 µm in diameter by forward and side scatter, respectively, and positive staining with anti-CD41 antibody using flow cytometry. Activation status of platelets was examined by the expression of activation markers on platelets such as P-selectin (CD62P) or activated glycoprotein IIb/IIIa (PAC1). Production of microparticles (MPs) is defined as ratio of proportion of MP to that of platelets. Release reaction of platelets was evaluated by release of platelet factor 4 (PF4) in culture supernatant of coculture with skin fibroblasts using enzyme-linked immunosorbent assay (ELISA). Association or correlation between proportion of activated platelets and clinical characteristics or parameters of patients with scleroderma was also examined.

**Results:** As for the characteristics of 21 patients with SSc, male to female ratio was 3: 18, proportion of diffuse cutaneous SSc was 24%, mean age was 63±13 years, and mean disease duration was 16±13 years. In SSc, both proportion of CD62p+or PAC1 +activated platelets (p<0.05, p<0.05, respectively) and production of MP were higher (p<0.05) compared to those in healthy controls. Of these, proportion of CD62p+platelets and MP production were correlated each other (r=0.88, p<0.05). Also, release reaction of platelet was upregulated in platelets from patient with SSc compared to healthy controls (p<0.05). When activation status of platelets was compared to clinical parameters, both proportion of CD62p +activated platelets and MP production were higher in diffuse cutaneous SSc (p<0.05, p<0.05, respectively) and correlated with modified Rodnan skin score (p<0.05, p<0.05, respectively).

**Conclusions:** In SSc, proportion of activated platelets were higher and associated with skin sclerosis, suggesting the involvement in the pathogenesis of SSc.

**AB0189** **3D SKIN ORGANOID MIMICKING SYSTEMIC SCLEROSIS GENERATED BY PATIENT-DERIVED INDUCED PLURIPOTENT STEM CELLS: 'DISEASE IN A DISH' AND DEVELOPMENT OF ANIMAL MODEL**

J.-W. Kim<sup>1</sup>, Y. Kim<sup>2</sup>, J. Kim<sup>2</sup>, M.-J. Park<sup>3</sup>, E. Kwon<sup>1</sup>, J. Lee<sup>1</sup>, S.-K. Kwok<sup>1</sup>, J. H. Ju<sup>1,2</sup>, S.-H. Park<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul St. Mary's Hospital; <sup>2</sup>Catholic iPSC Research Center, College of Medicine, The Catholic University of Korea; <sup>3</sup>Rheumatism Research Center, Catholic Research Institute of Medical Science, The Catholic University of Korea, Seoul, Korea, Republic of Ireland

**Background:** Systemic sclerosis (SSc) is a rare autoimmune disease characterised by vasculopathy and fibrosis of various organs including skin. Although SSc has high morbidity and mortality, evidences for disease modifying treatment are

still lacking due to difficulties in performing clinical trials. Patient-specific induced pluripotent stem cells (iPSCs), which can differentiate into various cell types, are used in 3D organoid formation.

**Objectives:** We generated 3D skin organoid model from SSc-derived iPSCs by differentiating them into keratinocytes and fibroblasts. SSc-mimicking 3D skin organoid can be used in studies for disease modelling and drug screening.

**Methods:** Peripheral blood mononuclear cells (PBMCs) from patients with SSc were reprogrammed to iPSCs. SSc-derived iPSCs differentiated into keratinocytes and fibroblasts *in vitro*. Expression of markers for iPSCs, keratinocytes, and fibroblasts were determined by reverse transcription polymerase chain reaction (RT-PCR) analysis and immunofluorescence assay (IFA). 3D skin organoid using iPSC-derived differentiation cell line was generated by 3D culture system. Histologic analysis was performed on 3D skin organoid. SSc-derived 3D skin organoid was applied to SCID skin defect mice. Histologic analysis was also performed on SCID skin graft model.

**Results:** SSc-derived iPSCs formed colonies that resemble embryonic stem cells. Alkaline phosphatase staining showed undifferentiated state of iPSCs. Expression of iPSC markers was increased on SSc-iPSCs. Differentiated keratinocytes and fibroblasts from iPSCs highly expressed their markers for keratinocytes and fibroblasts, respectively. Dermis of SSc-derived 3D skin organoid was thicker and denser than that derived from healthy control. Epidermis and dermis of SCID skin graft model were thickened in those derived from SSc compared to those derived from healthy control.

**Conclusions:** Patient-derived 3D skin organoid and animal model well represented the characteristics of SSc. These models can serve as useful research tools to understand the disease and screen new drugs for SSc.

**AB0190** **IMPAIRED ACTIVATION OF ATAXIA-TELANGIECTASIA MUTATED PROTEIN KINASE IN IMMUNE CELLS IS ASSOCIATED WITH CLINICAL FEATURES IN PATIENTS WITH SYSTEMIC SCLEROSIS**

K. Sakata<sup>1</sup>, H. Yasuoka<sup>1</sup>, K. Yoshimoto<sup>1,2</sup>, K. Yamaoka<sup>1</sup>, T. Takeuchi<sup>1</sup>.  
<sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Keio University School of Medicine; <sup>2</sup>Clinical and Translational Research Center, Keio University Hospital, Tokyo, Japan

**Background:** Ataxia-telangiectasia mutated (ATM) is a protein kinase associated with ataxia-telangiectasia (AT), which is an autosomal recessive disorder due to defective functional activity of ATM. Telangiectasia, seen in AT, is also well known as one of the major characteristics of systemic sclerosis (SSc). ATM plays an important role not only in DNA damage repairing system, but also in the process of regulation of oxidative stress.<sup>1</sup> Moreover, it has been reported that oxidative stress may contribute to disease process of SSc<sup>2,3</sup>. Based on these background, we hypothesised that ATM may play a substantial role in the pathogenesis of SSc. However, the possible association between ATM activity and SSc development is not fully understood.

**Objectives:** To clarify the role of ATM in the pathogenesis of SSc, we demonstrated the expression and activation level of ATM in circulating immune cells and analysed the association with clinical characteristics of the patients.

**Methods:** Whole blood samples were collected from twenty-four patients with SSc and 12 healthy controls (HC). Expression levels of total ATM and active phosphorylated ATM (pATM) were examined in each immune cell subset (neutrophil, monocyte, T cell, B cell and NK cell) by mean fluorescence intensity (MFI) using flow cytometer. Each MFI level of ATM and pATM was compared between patients with SSc and HC, and was analysed the correlation with clinical characteristics of SSc patients, retrospectively collected from patients' records.

**Results:** The expression level of pATM was significantly lower in monocytes, neutrophils, and T cells in SSc as compared with HC (<sup>1887</sup>±128 vs 2386±181, p=0.03; <sup>10265</sup>±861 vs 16087±1218, p=0.0004; <sup>1326</sup>±73 vs 1675±103, p=0.009; respectively), whereas no significant difference in total ATM level was observed in each cell subset between two groups. Notably, the expression levels of pATM in monocytes of the patients with interstitial lung disease (ILD) was lower than that of the patients without ILD (<sup>1663</sup>±136 vs 1999±96, p=0.05). Furthermore, there was a tendency of correlation between pATM level in monocyte and parameters of pulmonary function test, such as forced vital capacity. No significant differences and/or correlation between pATM expression level in other cell subsets and clinical parameters of the patients, such as SSc subtype, SSc-specific autoantibodies, presence of pulmonary arterial hypertension, gastrointestinal involvement, digital tip ulcer, pitting scar and modified Rodnan skin score were observed.

**Conclusions:** In SSc, phosphorylated level of ATM in monocytes, neutrophils, and T cells was significantly lower than that of HC. Importantly, we found that ATM activation was impaired in monocyte of the SSc patients with ILD. These results

collectively suggest that the loss of ATM activation in monocytes may contribute to the disease process of SSc, and is possibly due to DNA damage and oxidative stress.

#### AB0191 ANTI-SSA AND ANTI-JO1 LEVELS IN INTERSTITIAL LUNG DISEASE RELATED TO IDIOPATHIC INFLAMMATORY MYOPATHIES

M. Giannini<sup>1</sup>, M. Tampona<sup>2</sup>, L. Abbracciavento<sup>2</sup>, F. Girolamo<sup>3</sup>, A. Lia<sup>3</sup>, E. Mascolo<sup>4</sup>, D. D'Abicco<sup>5</sup>, L. Coladonato<sup>1</sup>, F. Iannone<sup>1</sup>. <sup>1</sup>Rheumatology Unit, University of Bari; <sup>2</sup>University Clinical Pathology Laboratory; <sup>3</sup>D.S.M.B.N.O.S, Neurology; <sup>4</sup>Hospital Clinical Pathology Laboratory; <sup>5</sup>Marinaccio General Surgery, Bari, Bari, Italy

**Background:** The lung is the most frequently involved extramuscular organ in idiopathic inflammatory myopathies (IIMs); the most common form of lung involvement is interstitial lung disease (ILD). Some autoantibodies are strongly associated with ILD and with specific phenotypes and prognosis of ILD. Among myositis-specific auto-antibodies (MSAs), antibodies against aminoacyl-tRNA-synthetases (AsAb) are the strongest predictive factors for ILD, and anti-Jo-1 is the most common AsAb. Among myositis-associated auto-antibodies (MAAs), anti-SSA/Ro52 is frequently found in sera of patients with IIM and ILD, often associated with anti-Jo-1. The coexistence of anti-SSA/Ro52 and anti Jo-1 seems to be related to a more severe and extensive pulmonary fibrosis with higher score in HRCT compared with the patients with only anti-Jo-1 antibodies. Furthermore, some reports suggest that presence of anti-Jo-1 could be a biomarker for good prognosis<sup>1</sup>. The significance of antibodies levels for the prognosis of ILD in IIMs was not widely investigated.

**Objectives:** To investigate the relationship between antibody levels and clinical manifestations, laboratory data, pulmonary function tests (PFTs), disease activity indices in ILD associated to IIMs.

**Methods:** Among 130 IIMs admitted to Rheumatology Unit of Bari from January 2010 to January 2018, we retrospectively examined 49 patients (40 F; 22 PM, 25 DM, 1 IBM; mean age at ILD onset 51 years, range: 23–83) because of ILD defined by high resolution computed tomography (HRCT). Clinical manifestations, laboratory data, HRCT pattern, PFTs (FVC, FEV1 and DLCO), therapy, disease activity as Manual Muscle Test (MMT-12), Health Assessment Questionnaire (HAQ), Physician Global Assessment (PGA) at ILD onset, were obtained from medical records. Ferritin levels and autoantibodies were detected in serum samples collected at ILD onset. ANA were tested by IIF on HEp-2 cell substrates, MSAs (JO1, EJO, OJ, PL7, PL12, SRP, HMGCR, Mi2, TIF1 $\gamma$ , MDA5, NXP2, SAE) and MAAs (Ro52, Ku, PM/Sci 75–100, RNP, Sci70) by line-blot method. Anti-SSA and anti-Jo1 were also detected by CLIA method. Correlation analysis were run using parametric and non-parametric test according to data distribution.

**Results:** 45 of 49 (91,8%) patients were positive for MSAs and/or MAAs. 40 of 45 (88%) were positive at least one of MSAs. The double presence of MSAs and anti-Ro52 was observed in 21 of 40 (52,5%), showing anti-Jo1/SSA in most cases (15/21, 71,4%). Among all correlations studied between anti-Jo1 or anti-SSA levels and PGA or PFTs, we found a significantly correlation between anti-Jo1 and PGA ( $p=0,03$ ,  $R=0,46$ ). We didn't find significantly correlation between autoantibodies and ferritin serum levels.

**Conclusions:** These findings confirm that ILD was associated with autoantibodies positivity. Further studies in larger cohort need to investigate if autoantibodies levels have a prognostic role in global outcome. Unlikely some controversial works in literature, serum ferritin does not seem a biomarker of severity of lung involvement in IIMs.

#### DISCOVERY OF POTENTIAL SKIN BIOPSY BIOMARKERS FOR SYSTEMIC SCLEROSIS BY HIGH-THROUGHPUT PROTEOMIC APPROACHES

P. Chairta<sup>1</sup>, P. Nicolaou<sup>2</sup>, K. Sokratous<sup>3</sup>, G. Spyrou<sup>3</sup>, A. Oulas<sup>3</sup>, C. Galant<sup>4</sup>, F. Houssiau<sup>5</sup>, B. Lauwerys<sup>5</sup>, K. Christodoulou<sup>2</sup>. <sup>1</sup>Neurogenetics Department, Cyprus School of Molecular Medicine, Nicosia, Cyprus; <sup>2</sup>Neurogenetics Department; <sup>3</sup>Bioinformatics Department, Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, Nicosia, Cyprus; <sup>4</sup>Department of Pathology, Université catholique de Louvain; <sup>5</sup>Rheumatology Department, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium

**Background:** Systemic Sclerosis (SSc) is an autoimmune connective tissue rheumatic disease characterised by three main hallmarks; vasculopathy, immune system abnormalities and fibrosis. It is considered a multisystemic and heterogeneous disease as many organs of the body may be affected and symptoms vary among patients. Up to date, SSc is untreated and its etiology and pathogenesis remain unclear. Early prognosis and diagnosis of the disease are challenging.

**Objectives:** The aim of this study was to analyse the proteomic profile of SSc patients in order to gain insights into the mechanisms implicated in disease pathogenesis and also discover new biomarkers that would facilitate early prognosis, more accurate diagnosis and therapeutic targeting of SSc.

**Methods:** Human biopsies were obtained from ten affected and three non-affected skin areas of SSc patients and have been classified based on histological criteria. Biopsies were cryo-pulverised and proteins were extracted, purified, reduced, alkylated and digested by trypsin. Purified peptides were analysed on a Waters Synapt G2Si HDMSE instrument operated in ion mobility mode using a UDMS<sup>E</sup> approach. Data were processed by the Progenesis QIP and functional annotation analysis was carried out using multiple bioinformatics resources.

**Results:** Proteomic analysis led to the identification and quantification of approximately 1500 non-redundant proteins per sample. About 400 of these proteins, including interferons and interleukins, are differentially expressed between affected and non-affected samples. Functional annotation analysis of these proteins showed that they are involved in multiple pathways including, antigen processing and presentation, complement, ubiquitin mediated proteolysis and Notch signalling, which are known to be associated with autoimmune diseases and fibrosis.

**Conclusions:** Using a Mass Spectrometry-based proteomic approach for the analysis of SSc human skin biopsies, we identified a number of proteins that might be involved in the development and pathogenesis of SSc. Interestingly, some of these proteins are differentially expressed in specific histological groups and thus could be considered as potential biomarkers for specific SSc stages.

#### SEMAPHORIN4A INDUCES TH17 CYTOKINE PRODUCTION IN SYSTEMIC SCLEROSIS

S. García Pérez, T. Carvalho, A.J. Affandi, B. Malvar Fernandez, I. Dullemond, M. Cossu, W. Marut, K.A. Reedquist, T.R. Radstake. *Laboratory for Translational Immunology (LTI) and Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands*

**Background:** Systemic sclerosis (SSc) is an autoimmune disease characterised by inflammation, vascular injury and excessive fibrosis in different organs. Different studies have shown that Th17 cells and Th17 cytokines (IL-17, IL-21 and IL-22) play a key role in the pathogenesis of the disease. Semaphorin 4A (Sema4A) is a transmembrane protein that belongs to a large family of proteins initially described as ligands essential for neuronal development. Further studies have shown that they also play a role in other biological processes including the control of immune responses. Importantly, Sema4A has a critical role in the skewing of CD4<sup>+</sup> T cells towards a Th17 phenotype. However, it is unknown if Sema4A contributes to the elevated number of Th17 cells observed in SSc patients.

**Objectives:** The aim of this study was to analyse the potential role of Sema4A as a regulator of Th17-skewing in SScs.

**Methods:** Plasma levels of Sema4A were measured by ELISA. Expression of Sema4A and its receptors PlexinB2, PlexinD1 and neuropilin-1 (NRP-1) was determined by (q)quantitative PCR, western blot and flow cytometry in monocytes and CD4<sup>+</sup> T cells of healthy donors (HD) and SSc patients. Monocytes were stimulated with Poly IC (5  $\mu$ g/ml) or CXCL-4 (5  $\mu$ g/ml) and Sema4A expression

was analysed by qPCR and ELISA. CD4<sup>+</sup> T cells were stimulated with anti-CD3/anti-CD28 beads (ratio 1 bead: 5 cells) alone or in combination with recombinant human Sema4A (200 ng/ml), in the presence or absence of neutralising anti-NRP1 or PlexinD1 antibodies, and the expression of PlexinB2, PlexinD1, NRP-1 and the production of Th17 cytokines was analysed by qPCR, ELISA and flow cytometry.

**Results:** Plasma levels of Sema4A were significantly higher in SSc patients compared to healthy controls (HC) and positively correlated ( $r=0.611$ ) with the skin disease severity. Sema4A and PlexinB2 expression was significantly higher in monocytes and CD4<sup>+</sup> T cells from SSc patients, respectively. Moreover, Poly IC and CXCL-4 significantly up-regulated the expression and secretion of Sema4A in monocytes from SSc patients, and CD4<sup>+</sup> T cells stimulation with anti-CD3/anti-CD28 beads increased the expression of PlexinB2 and NRP-1 in both HC and SSc patients. Finally, functional assays showed that Sema4A significantly enhanced the expression of Th17 cytokines induced by CD3/CD28 in CD4<sup>+</sup> T cells from both HC and SSc patients, and the blocking of the Sema4A signalling using neutralising antibodies anti-PlexinD1 and anti-NRP-1 significantly reduced this expression. Importantly, the Sema4A-induced IL-17 secretion was significantly higher in stimulated CD4<sup>+</sup> T cells from SSc patient compared to HC.

**Conclusions:** Sema4A signalling is deregulated in SSc patients and plays an important role in Th17 skewing. Therefore, Sema4A and its receptors could be promising therapeutic targets for the treatment of SSc.

#### SPARC IS ELEVATED IN THE AFFECTED SKIN OF SYSTEMIC SCLEROSIS PATIENTS AND INDUCES THE EXPRESSION OF FIBROTIC GENES IN DERMAL FIBROBLASTS AND MACROPHAGES

S. García Pérez<sup>1</sup>, B. Malvar Fernández<sup>1</sup>, M. Bergin<sup>2</sup>, T. Johnson<sup>2</sup>, W. Marut<sup>1</sup>, K. A. Reedquist<sup>1</sup>, T.R. Radstake<sup>1</sup>. <sup>1</sup>Laboratory for Translational Immunology (LTI) and Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; <sup>2</sup>UCB, Slough, UK

**Background:** Systemic sclerosis (SSc) is an autoimmune disease characterised by inflammation, vascular injury and excessive fibrosis in multiple organs. SPARC is a matricellular glycoprotein that can bind to extracellular matrix (ECM) components, as well as cellular receptors and secreted growth factors. In doing so, SPARC regulates biological activities dependent upon cellular interactions with the ECM as well as processes dependent upon cell adhesion, including tissue remodelling, wound healing, angiogenesis and immune responses. Several studies have implicated SPARC in the pathology of SSc but the specific role of SPARC in fibrosis is still unknown.

**Objectives:** The aim of this study was to analyse the potential role of SPARC as a regulator of fibrosis in SSc.

**Methods:** Expression of SPARC in the skin of healthy donors (HD) and SSc patients was measured by immunohistochemistry. Peripheral blood-derived monocytes from HD and SSc patients were differentiated into macrophages with M-CSF (25 ng/ml). Dermal fibroblasts and M-CSF macrophages from both HD and SSc patients were stimulated with SPARC (0.1 and 1 µg/ml) for 6 hour and 24 hour. mRNA and protein expression of SPARC and other fibrosis-related genes were measured by qPCR and western blot.

**Results:** We found increased expression of SPARC in the affected skin of SSc patients compared to HD. We also observed a higher expression of SPARC and ECM components (collagen(Col)-1 and fibronectin-1 (FN1) in dermal fibroblasts derived from SSc patients. SPARC stimulation induced mRNA expression of important fibrosis-related genes such as *TGFβ1*, *PDGFB*, *SERPINE1* and *CTGF*, and ECM components including *COL1A1*, *COL3A1*, *COL4A1* and *FN1* in dermal fibroblasts from SSc patients, but not healthy donors. In M-CSF macrophages from SSc patients, SPARC also up-regulated mRNA expression of *TGFβ1*, *PDGFB*, *STAB1*, *COL1A1* and *FN1*.

**Conclusions:** These results suggest that SPARC is an important pro-fibrotic mediator contributing to the pathology driving SSc. Therefore, SPARC could be a promising therapeutic target for reducing fibrosis in SSc.

#### PROTEOMIC APPROACH IDENTIFIES DIFFERENTIAL PROTEIN EXPRESSION IN CULTURED FIBROBLASTS UNDER STIMULATION WITH TGF-β1

S. Vivier<sup>1</sup>, A. Chepy<sup>1,2,3</sup>, F. Bray<sup>4</sup>, T. Guerrier<sup>1,5</sup>, M. Balden<sup>1,5</sup>, C. Rolando<sup>4</sup>, E. Hachulla<sup>1,2,3</sup>, D. Launay<sup>1,2,3</sup>, S. Dubucquoil<sup>1,2,5</sup>, V. Sobanski<sup>1,2,3</sup>. <sup>1</sup>Lille Inflammation Research International Center (LIRIC), Univ. Lille, U995; <sup>2</sup>Département de Médecine Interne et Immunologie Clinique; <sup>3</sup>Centre national de référence maladies systémiques et auto-immunes rares (sclérodémie systémique), CHU Lille; <sup>4</sup>Miniaturisation pour la Synthèse, l'Analyse and la Protéomique (MSAP), CNRS, USR 3290; <sup>5</sup>Institut d'Immunologie, Centre de Biologie Pathologie, CHU Lille, F-59000 Lille, France

**Background:** Fibroblasts (Fb) are key effectors cells in systemic sclerosis (SSc).<sup>1</sup> Fb stimulation with TGF-β1 is usually considered as the positive control in studies assessing the fibrogenesis in SSc.<sup>2</sup> Yet, the lack of standardisation of TGF-β1 stimulation might be responsible for discrepancies in experiments performed in different conditions. Proteomic approach allows the analysis of differential expression of the whole proteins (proteome) in Fb, and appears an interesting approach to compare different culture conditions.

**Objectives:** We designed this study to compare the whole protein expression in Fb stimulated by TGF-β1 in different conditions.

**Methods:** At fifth passage, primary culture of human Fb from healthy subjects (ATCC; PCS-201-012) were stimulated or not with different concentrations of recombinant human active TGF-β1 (0.04, 1, and 5 ng/mL) (R and D Systems; 240-B-002) during 24, 48 and 72 hours. Proteins were extracted and analysed using an eFASP LC-MS/MS approach on an Orbitrap mass spectrometer (Thermo Scientific; Q Exactive +). Proteins quantitation was performed by Max-quant and statistical analysis by Perseus using ANOVA and principal component analysis (PCA).

**Results:** A total of 3267 proteins were identified, of which 1957 showed differential expression using ANOVA analysis. PCA revealed several clusters of differential proteins expression (figure 1). There were clear clusters of protein expression related to (i) unstimulated and stimulated conditions, (ii) between the three different times of stimulation and (iii) to TGF-β1 concentrations used. Although the expression of proteins in Fb exposed to 0.04 and 1 ng/mL of TGF-β1 during 72 hour were rather close, there was a unique proteins profile related to the condition with 5 ng/mL of TGF-β1 during 72 hour.

Figure 1: PCA representation of differential proteins expression in different conditions. [TGF-β1]=0.04 ng/mL: square; [TGF-β1]=1 ng/mL: circle; [TGF-β1]=5 ng/mL: diamond. The more the points appear distanced, the more different is the protein expression.

**Abstract AB0195 – Figure 1.** PCA representation of differential proteins expression in different conditions.

**Conclusions:** This study highlights a variation of proteins expression depending on both stimulation time and TGF-β1 concentrations in Fb culture. The identification of protein differentially expressed will provide insights in the impact of TGF-β1 on Fb physiology under stimulation conditions. These data underline the need of standardisation of culture conditions to allow inter-data comparisons using in sensitive “omic” approaches.

### AB0196 ENDOPLASMIC RETICULUM STRESS IN SYSTEMIC SCLEROSIS

S. O'Reilly. Life sciences, Northumbria University, Newcastle Upon Tyne, UK

**Background:** Systemic sclerosis is an autoimmune connective tissue disease in which there is inflammation and skin fibrosis. Currently there is no disease modifying treatment due to the limited understanding of the pathogenesis of the disease. Endoplasmic reticulum (ER) stress, characterised by misfolded proteins, can be induced by a variety of stressors such as redox imbalance and calcium depletion. This activation of ER stress by whatever trigger results in activation of an evolutionary conserved cell sensors and a resulting signalling cascade to help restore homeostasis. It is suggested in other fibrotic diseases that ER stress is prominent.

**Objectives:** The aim of this study is to determine the role of ER stress in Systemic Sclerosis.

**Methods:** Healthy dermal fibroblasts where cultured *in vitro* and stimulated with the ER stress inducer thapsigargin and in some experiments with small interfering RNA to X-Box binding protein-1 or scramble controls at the matched concentration. Cells were then lysed and subjected to western blotting of XBP-1, IRE- $\alpha$ , ATF-6, collagen-1 and alpha tubulin for a loading control. In some experiments the dermal fibroblasts were treated with ER stress and 4-phenylbutric acid to inhibit ER stress and markers measured. q-RT-PCR was performed for Fli-1 and 18S using specific primers and subjected to real time with SYBR green and normalised to 18S.

**Results:** ER stress mediated by thapsigargin results in activation of classical ER stress pathways. Inhibition of these pathways through small interfering RNA results in attenuation of collagen expression in dermal fibroblasts. This was also the case with dermal fibroblasts treated with the chemical inhibitor 4-phenylbutric acid. The epigenetic modifier Fli-1 is reduced after ER stress. This is known to act as a brake on collagen regulation.

**Conclusions:** ER stress induced collagen accumulation and could be blocked by chemical and genetic reduction of XBP-1. Mechanistically this could be due to reduced Fli-1 thereby releasing the brake on collagen1 expression. Modulation of ER stress via chemical inhibitors could be a promising new treatment in SS.

### AB0197 METALLOPROTEINASE-7 AS AN EARLY MARKER OF LUNG DAMAGE AMONG POLYMYOSITIS AND DERMATOMYOSITIS PATIENTS

V. Kmyta<sup>1</sup>, E. Prystupa<sup>2</sup>, L. Prystupa<sup>1</sup>, A. Kovchun<sup>1</sup>. <sup>1</sup>internal medicine department postgraduate education, Sumy State University, Sumy; <sup>2</sup>Lviv State University of Physical Culture, Lviv, Ukraine

**Background:** Interstitial lung disease (ILD) can complicate the course of polymyositis/dermatomyositis (PM/DM) almost in the half of patients and represents as a high risk factor of mortality among such cohort of patients from chronic pulmonary insufficiency. Lung function monitoring and chest high resolution computer tomography (HRCT) are obligatory methods of investigation among PM/DM patients. However, these methods allow to determine already formed interstitial changes in the lungs. Therefore, there is a need for biomarkers to seek early changes of lung tissue, what allows to prescribe basic treatment in time, encountering its side effects.

Metalloproteinase 7 (MMP-7) reflect lung damage and can also be an early biomarker of ILD which complicates PM/DM. It was early reported that -181A/G (rs11568818) polymorphism in MMP-7 promoter modulates gene expression and plays pivotal role in the MMP-7 upregulation in that way affects ILD progression. Here, we evaluated the impact of -181A/G polymorphism in MMP-7 promoter activity and its association with MMP-7 elevation.

**Objectives:** Our study was aimed to analyse the level of MMP-7 as an early marker of lung damage among PM/DM patients and also probable influence of rs11568818 on the MMP-7 elevation.

**Methods:** 17 patients with PM/DM have been observed in the rheumatology department with primary established diagnosis, 9 patients among them has proved diagnosis of ILD with HRCT. All patients have been examined according to the recommended EULAR standards and paraneoplastic reaction have been excluded. Patients have been divided into 2 groups, 1st group include 9 patients with PM/DM complicated with ILD, 2nd – 8 patients with isolated PM/DM. Control group included 17 healthy volunteers. MMP-7 level was assayed by the enzyme immunoassay system in the blood serum. -181A/G (rs11568818) polymorphism was genotyped by polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP) method. All statistical calculations were done using SPSS software 21.0.

**Results:** Results. Mean age of patients of the 1st group – 48,44±2,74, 2nd – 54,25±2,55, control group – 49,0±2,4 (p=0,33). DM have been established in 7 patients and PM – 10. Mean level of MMP-7 in the 1st group was 4,02±1,58 (CI 95% 2,81–5,24), 2nd – 1,43±0,2(CI 95% 0,93–1,92), control group – 1,3±0,75 (F=30,87, p<0,001). It was determined that the level of MMP-7 was positively correlated with Anti-Jo1 antibodies (r=0,82, p=0,007) and it was higher among PM/DM patients complicated with ILD (p=0,001). Analysis of genotypes frequency AA/AG/GG with regard to rs11568818 polymorphism, shows no significant distribution (p=0,984) and is following in the 1st group – 66,7%/22,2%/11,1% and 62,5%/25%/12,5% – in the 2nd, in the control group – 70,6%/17,6%/11,8% respectively. The analysis of the connexion between studied genetic polymorphism with the level of MMP-7 didn't show any interdependence (p=0,771).

**Conclusions:** The level of MMP-7 is higher among the 1st group, in comparison with 2nd and control groups. Positive correlation connexion between the level of MMP-7 and Anti-Jo1 antibodies among PM/DM patients with ILD was found. The difference between genotypes distribution according to the rs11568818 gen polymorphism depending on existence of ILD and MMP-7 level is absent. Taking into account the results, we can admit that MMP-7 is a perspective marker of lung tissue damage among PM/DM patients.

### AB0198 BIOLOGICAL PROPERTIES OF URINE-STEM CELLS AND THERAPEUTIC EFFECT ON SYSTEMIC SCLEROSIS FIBROSIS

Y. Yang<sup>1</sup>, A. Xiong<sup>2</sup>, Q. Zhang<sup>1</sup>, Y. Luo<sup>1</sup>, Q. Xie<sup>1</sup>, Y. Liu<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Immunology; <sup>2</sup>West China Hospital of Sichuan University, Chengdu, China

**Background:** Because of the lack of effective treatment of systemic sclerosis (SSc), cellular therapy is considered as a salvage option.<sup>1-4</sup> Mesenchymal stem cells (MSCs) are gaining attentions in the field of cell therapy of SSc. However, current isolation methods of MSCs are all invasive and challenging.<sup>5</sup> Some studies have reported the isolation from urine recently, and definition of urine-derived stem cells (USCs).<sup>6</sup> The collection of USCs is noninvasive that could be a desired resource of MSC. So far, the information of therapeutic effect on SSc is limited.

**Objectives:** We aimed to explore the biological characterizations of USCs and investigate the therapeutic effect on murine SSc model.

**Methods:** USCs were isolated and cultivated from sterile urine samples of healthy adult individuals. The related cell markers were examined by flow cytometry. The differentiation potentials were observed in adipogenic, osteogenic and chondrogenic medium, respectively. SSc murine models were conducted by daily intradermal injections of bleomycin and were further divided as treated and untreated group. Also, the healthy control group was conducted by daily injection of phosphate buffered saline (PBS). Treated group received an infusion of 2.5 × 10<sup>5</sup> USCs in the tail vein twice in one week after the 3 week modelling. Skin samples were obtained one week after the treatment. Hematoxylin-eosin and Masson staining were accomplished to observe the skin thickness and the hydroxyproline content was detected by hydroxyproline kit. The relative expression of collagen type I alpha 1 chain (Col1- $\alpha$ 1), alpha-smooth muscle actin ( $\alpha$ -SMA), and fibronectin 1 (Fn-1) were detected by real-time quantitative PCR.

**Results:** The morphology of USCs was spindle-shaped. They express CD73, CD90, and CD105 but CD34, CD45, CD19, CD11b, or HLA-DR. USCs possessed the abilities to differentiate into adipocytes, osteoblasts, and chondrocytes. In USCs treated group, the skin thickness (p=0.031) (Figure1A), the deposition of collagen in HE and Masson trichrome-staining (p=0.007) (Figure1B), and Col1- $\alpha$ 1 gene expression (p=0.010) (Figure1C) were significantly reduced in comparison with untreated group and were close to healthy controls.

Abstract AB0198 – Figure 1

**Conclusions:** USCs can be isolated from adult sterile urine. They possess the multipotent differentiation abilities and displays a therapeutic effect on bleomycin-induced skin fibrosis and collagen synthesis.

## Rheumatoid arthritis – prognosis, predictors and outcome

### AB0199 ENDOCAN LEVELS AND SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Tuzcu<sup>1</sup>, A.U. Uslu<sup>2</sup>, A. Tuzcu<sup>3</sup>, R. Aydogan Baykara<sup>4</sup>, A. Omma<sup>5</sup>, A. Kucuk<sup>6</sup>.

<sup>1</sup>Radiology, Balikesir State Hospital, Balikesir; <sup>2</sup>Internal Medicine, Yunus Emre State Hospital, Eskisehir; <sup>3</sup>Biochemistry, Balikesir State Hospital, Balikesir; <sup>4</sup>Physical Medicine and Rehabilitation, Malatya Education and Research Hospital, Malatya; <sup>5</sup>Rheumatology, Ankara Numune Training and Research Hospital, Ankara; <sup>6</sup>Rheumatology, Necmettin Erbakan University, Konya, Turkey

**Background:** Rheumatoid arthritis (RA) is an inflammatory autoimmune disease with unknown etiology. Accelerated atherosclerosis (AS) and AS with heart disease are among the major causes of morbidity and/or mortality in RA. Endothelial-specific molecule 1 (endocan) is a potential indicator of vascular events and is expressed in response to inflammatory mediators in endothelial cells. Carotid intima media thickness (cIMT) is used to detect early signs of AS but also progression in cardiovascular diseases related to AS.

**Objectives:** The aim of the present study is to evaluate the relationship of serum endocan levels with RA and cIMT as a candidate marker of diseases to be used in clinical practice.

**Methods:** The study was conducted between June 2012 and March 2013 at the Rheumatology Clinics of Necmettin Erbakan Meram Medical School, Turkey. Thirty nine<sup>39</sup> RA patients, diagnosed according to the 1987 criteria of the American College of Rheumatology, and 30 age- and sex-matched healthy subjects as the control group were included in this study.

**Abstract AB0199 – Table 1.** The clinical and laboratory parameters in two groups.

	RA patients (n=39) (mean±SD)	Controls (n=30) (mean±SD)	P value
Age (years)	47.7±8.8	43.0±10.8	0.057
Gender (M/F), n (%)	33 (84.6)/6 (15.4)	21 (70)/9 (30)	0.238
BMI (kg/m <sup>2</sup> )	28.0±4.3	27.1±5.1	0.443
ESR (mm/h)	28.56±16.16	18.70±12.27	0.005
CRP (mg/dL)	0.55±0.54	0.42±0.55	0.336
TC (mg/dL)	198.28±48.15	165.43 ±30.59	0.001
TG (mg/dL)	153.58±93.02	132.73 ±55.74	0.252
LDL-c (mg/dL)	123.02±44.88	118.81 ±24.76	0.622
HDL-c (mg/dL)	50.43±10.18	42.12±8.18	<0.001
cIMT (mm)	0.63±0.17	0.51±0.12	0.001
Endocan	14.11±3.27	12.10±2.92	0.009

RA, Rheumatoid arthritis; BMI, body mass index; cIMT, carotid intima media thickness; TC, total cholesterol; TG, triglyceride; LDL-c, low density-lipoprotein cholesterol; HDL-c, high density-lipoprotein cholesterol; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein;

**Abstract AB0199 – Figure 1**

**Results:** No significant difference was detected between groups with respect to age, sex and body mass index. In the patient group the Endocan and cIMT values were found to be 14.11±3.27 ng/mL and 0.63±0.17 mm, while in the control group they were 12.10±2.92 ng/mL and 0.51±0.12 mm, the Endocan and cIMT values were significantly higher in the patient group (p=0.009 and p=0.001, respectively). Positive correlations was found between Endocan, cIMT and Disease Activity Score of 28 joints (p=0.008 and p=0.029, respectively). When assessing the endocan levels of RA patients in the study population, cut off value of 12.21 with sensitivity of 71%, specificity of 57% and p=0.012 (area under curve: 0.678, 95% confidence interval (CI) 0.555–0.805) were observed according to ROC curve analysis.

**Conclusions:** Endocan might be a useful marker to evaluate atherosclerotic lesions in patients with RA and also to assess disease severity.

**Disclosure of Interest:** None declared

### AB0200 FACTORS ASSOCIATED WITH FUNCTIONAL CAPACITY IN A BRAZILIAN COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM THE "REAL" STUDY

A.A.V. Pugliesi<sup>1</sup>, E.D.A. Macedo<sup>1</sup>, M.B. Bertolo<sup>1</sup>, R. Giorgi<sup>2</sup>, S. Radominski<sup>3</sup>, I. Pereira<sup>4</sup>, M.F. Guimaraes<sup>5</sup>, P. Louzada Jr<sup>6</sup>, M.D.F. Cunha<sup>7</sup>, K. Bonfiglioli<sup>8</sup>, C. Breno<sup>9</sup>, L.M.H. Mota<sup>10</sup>, G. Castelar-Pinheiro<sup>11</sup>. <sup>1</sup>Internal Medicine, Rheumatology Unit, Universidade Estadual de Campinas, Campinas; <sup>2</sup>Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo; <sup>3</sup>Universidade Federal do Paraná, Curitiba; <sup>4</sup>Universidade Federal de Santa Catarina, Florianópolis; <sup>5</sup>Universidade Federal de Minas Gerais, Belo Horizonte; <sup>6</sup>Universidade de São Paulo – Ribeirão Preto, Ribeirão Preto; <sup>7</sup>Universidade Federal do Pará, Pará; <sup>8</sup>Universidade de São Paulo, São Paulo; <sup>9</sup>Universidade Federal do Rio Grande do Sul, Rio Grande do Sul; <sup>10</sup>Universidade de Brasília, Brasília; <sup>11</sup>Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

**Background:** Rheumatoid arthritis (RA) is associated with impairments in functionality, affecting aspects such as physical capacity, independence, mental health, social and professional life. Health Assessment Questionnaire-Disability Index (HAQ-DI) is a validated tool for assessing functional capacity in RA patients. A simple questionnaire with a score of 0 to 3 is applied, with an inverse relationship between grade and functionality. Previous studies have shown worse functional indexes in patients with high disease activity and established joint damage.

**Objectives:** To relate clinical, laboratory and therapeutic aspects with HAQ-DI in a large cohort of Brazilian patients.

**Methods:** A prospective, multicenter cohort study ("REAL" Study) involving 11 Brazilian centres specialised in the treatment of RA patients. All patients were submitted to at least 3 clinical evaluations in a 12 month period. Only patients older than 18 years and classified as RA according to 1987 (ACR) or 2010 (ACR/EULAR) criteria were evaluated. HAQ-DI was applied for assessing functional capacity, and the results were analysed for association with clinical, laboratory and therapeutic elements. Comparison between groups was performed using Mann-Whitney or Kruskal-Wallis tests.

**Results:** Overall, 1116 patients (89.43% females, mean age 58±11 years) took part in the study. Rheumatoid factor (RF) in high levels and bone erosion were both associated with higher HAQ-DI indexes (p: 0.0244 and p<0.0001, respectively). Of all patients, 89.7% were using conventional synthetic disease-modifying antirheumatic drugs (DMARDs) and 36.5% were on biologic DMARDs or

targeted-synthetic DMARDs. The use of any conventional synthetic DMARD was associated with lower HAQ-DI indices ( $p: 0.0243$ ), while the use of any biologic DMARD or targeted-synthetic DMARD was related to greater functional impairment ( $p: 0.0018$ ). By evaluating separately, abatacept ( $p: 0.0046$ ), rituximab ( $p: 0.0001$ ) and tocilizumab ( $p: 0.0441$ ) were associated with higher levels of HAQ-DI. The results are summarised in table 1.

**Abstract AB0200 – Table 1.** Health assessment questionnaire-disability index score position and dispersion measurements and result of comparison between groups

	Yes	9	0.93	0.78	0.75	

**Conclusions:** In our prospective cohort, patients with high levels of RF, bone erosion, in use of any biologic DMARD or targeted-synthetic DMARD, abatacept, rituximab or tocilizumab had worse functional capacity indexes. When compared to non-use, the use of any conventional DMARD was associated with better rates of HAQ-DI.

#### AB0201 ASSOCIATION BETWEEN BASELINE CALPROTECTIN SERUM LEVELS AND RESPONSE TO BIOLOGICAL THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Martínez-Feito<sup>1</sup>, C. Plasencia<sup>1</sup>, A. Jochems<sup>1</sup>, V. Navarro-Compan<sup>1</sup>, D. Pascual-Salcedo<sup>1</sup>, B. Hernández-Breijo<sup>1</sup>, P. Nozal<sup>2</sup>, D. Peiteado<sup>1</sup>, A. Villalba<sup>1</sup>, A. Mezcueta<sup>2</sup>, A. Balsa<sup>1</sup>. <sup>1</sup>Immuno-Rheumatology research group; <sup>2</sup>Immunology, University Hospital La Paz, Madrid, Spain

**Background:** Calprotectin (CLP) is an important proinflammatory factor of innate immunity released from activated granulocytes and macrophages during inflammation, which has also been identified in synovial fluid. It is a potential pro-inflammatory biomarker reflecting joint damage. CLP levels in synovial fluid are well correlated with levels in plasma, which allows measuring it easily in patients with rheumatoid arthritis (RA). However, the additional value of CLP over other biomarkers is unclear

**Objectives:** To study the association of baseline CLP serum levels with the clinical response and serum drug levels in patients under biological therapy at 6 and 12 months after starting treatment.

**Methods:** Prospective observational study including 109 patients with RA who started biological treatment (Infliximab(Ix);Adalimumab(Ada);Etanercept(Etn); Certolizumab(Ctz);Golimumab(Glm); Tocilizumab(Tcz) and Rituximab(Rtx) in a tertiary hospital since 1999 to 2016. Serum CLP levels were measured by ELISA

with the commercial kit CALPROLAB (Lysaker, Norway). Levels of biological drug and ADA were measured by capture and bridging ELISA respectively, except Certolizumab which was measured by Sanquin Diagnostic Service. Clinical response was assessed by  $\Delta$ DAS28. Serological and clinical parameters were evaluated at baseline, 6 and 12 months. For analysis, linear regression models adjusted for confounders (age, sex, BMI, DMARDs, smoking status) and with standardised beta as estimate were employed.

**Results:** Out of 109 studied patients, 22% patients received Ix, 6% Ada, 16% Etn, 18% Ctz, 5% Glm, 25% Tcz and 9% Rtx. Most patients were woman (84%), with a median (IQR) age of 62 (52.3–73.1) and disease duration of 9.5 (4.8–15.3). At baseline, CLP levels directly correlated well with CRP and DAS28( $r=0.411$ ;  $p<0.001$  and  $r=0.308$ ;  $p<0.001$ ). On the other hand, an inverse correlation between baseline CLP levels and the presence of drug at 6 ( $\beta=-0.325$ ;  $p=0.01$ ) and 12 months ( $\beta=-0.397$ ;  $p<0.001$ ) was also found. Moreover, in the adjusted analyses a trend for this correlation at 6 months ( $\beta=-0.199$ ;  $p=0.07$ ) and a significant correlation at 12 months ( $\beta=-0.381$ ;  $p<0.001$ ) was observed. Additionally, in the non-adjusted models, baseline CLP levels significantly directly correlated with the clinical response at 6 months ( $\beta=0.194$ ;  $p=0.04$ ) while the correlation at 12 months was not significant ( $\beta=0.186$ ;  $p=0.06$ ). However, after adjusting for confounders, no significant correlation was found at any study point ( $\beta=0.213$ ;  $p=0.06$  at 6 months and  $\beta=0.206$ ;  $p=0.07$  at 12 months).

**Conclusions:** In patients with RA initiating biological therapy, baseline CLP concentrations are inversely correlated with the circulating drug levels along the treatment. However, the additional value of CLP as a predictor of clinical response remains unclear.

#### AB0202 GLUCOCORTICOIDS IN THE INITIAL TREAT-TO-TARGET STRATEGY OF EARLY RHEUMATOID ARTHRITIS

A.L. Fedele, L. Petricca, B. Toluoso, S. Alivernini, M.R. Gigante, S.L. Bosello, C. Di Mario, G. Ferraccioli, E. Gremese. *UOC of Rheumatology, Fondazione Policlinico Universitario A. Gemelli - Università Cattolica del Sacro Cuore, Rome, Italy*

**Background:** As stated in the 2013 update of RA recommendations, glucocorticoids (GCs) should be used as bridging therapy for up to 6 months, ideally tapering them at earlier time points.<sup>1</sup>

**Objectives:** To evaluate whether initial combination therapy with GCs and disease modifying anti-rheumatic drugs (DMARDs) influences clinical and radiological outcome in the real-life practice of a cohort of early rheumatoid arthritis (ERA) patients.

**Methods:** A total of 367 ERA patients with less than 12 months of disease duration were enrolled in the study. ERA patients fulfilled the 2010 ACR criteria for RA and were followed according to the treat-to-target strategy. The mean follow-up (FU) was 38.2±32.8 months. At baseline, and every three months, the ACR/EULAR core data set variables were recorded. At baseline and every year, hand and foot radiographs were examined according to modified Total Sharp score (mTSS). At each visit, clinical improvement and remission were evaluated according to EULAR criteria. The achievement of CDC (28-joint Disease Activity Score using C reactive protein <2.6, Health Assessment Questionnaire <0.5 and change from baseline in mTSS ≤0.5) was assessed every year of follow-up.

**Results:** At baseline 291 (71.9%) ERA patients started GCs at a dosage of 0.2 mg/kg, gradually tapered and withdrawn as rapidly as clinically feasible. As expected, these patients presented higher values of acute phase reactants ( $p=0.001$ ), and higher levels of disease activity scores ( $p<0.001$ ) and disability index ( $p=0.001$ ), compared to the 76 subjects (18.8%) who had not been prescribed GCs. Patients not treated with GCs were in higher percentages anti-citrullinated peptide antibody (ACPA) (75.0%) and IgM-rheumatoid factor (RF) (64.5%) positive, compared to subjects taking GCs (62.9%,  $p=0.05$ ; 49.8%,  $p=0.02$ , respectively). There were no differences regarding age, disease duration, BMI, smoking habit and presence of erosions at onset. The mean duration of GC treatment was 7.5±7.9 months and the mean dosage during FU was <5 mg prednisone per day. During the FU, in the two groups a similar percentage of patients started a combination therapy with biological (b)-DMARDs and no differences were observed regarding radiographic progression.

A higher rate of remission defined according to DAS values, 2011 ACR/EULAR criteria, and CDC criteria, was registered in patients not treated with GCs compared to subjects who required corticosteroid therapy. ERA patients that didn't manage to stop GCs at the sixth month (38.8%) had a higher BMI ( $p=0.04$ ) and a lesser chance of achieving remission defined according to DAS values, 2011 ACR/EULAR criteria, and CDC criteria during follow-up. Moreover, a higher percentage of them required a combination therapy with bDMARDs during FU ( $p<0.0001$ ).

**Conclusions:** In our cohort ERA patients initially treated with GCs had higher disease activity scores at onset compared to subjects without GCs. The lesser chance of achieving remission and the higher rate of bDMARD therapy in ERA

patients not able to stop GCs, reflect a more aggressive disease, refractory to conventional drugs.

#### CLINICAL PHENOTYPE AND ULTRASOUND CHARACTERISTICS OF RHEUMATOID ARTHRITIS FLARE AFTER DISCONTINUATION OF CONVENTIONAL SYNTHETIC DMARDS

A. Manzo, S. Bugatti, F. Benaglio, G. Sakellariou, R. Caporali, C. Montecucco. *Arthritis Remission Clinic, Division of Rheumatology, IRCCS Policlinico San Matteo Foundation/University of Pavia, Pavia, Italy*

**Background:** Current protocols based on early and intensive treatment with csDMARDs in rheumatoid arthritis (RA) have allowed the achievement of remission in a considerable proportion of the patients and opened the perspective, in selected cases, of a drug-free monitoring scheme. Treatment discontinuation can lead, however, to possible recurrence of joint inflammation and clinical flare. Understanding the dynamics acting upstream these events remains a fundamental research task with direct clinical and patho-biologic implications.

**Objectives:** To delineate the clinical, serological and ultrasonographic changes associated to a drug-free flare in patients discontinuing csDMARD after achievement of stable remission. Co-primary objective was to compare, through a retrospective analysis in the same patients, these changes with early features of the pathology at onset, before treatment introduction.

**Methods:** 92 RA patients in stable DAS28 remission following a DAS-steered treatment strategy with MTX were recruited in our Centre and introduced to a drug-free monitoring scheme according to the following inclusion criteria: a) treatment introduced within 12 months from symptoms' onset, b) at least 24 months of continuative treatment, c) DAS28 <2.6 for at least 6 months in the absence of glucocorticoids. After discontinuation, all patients were follow-up at three months intervals across 24 months through complete clinical, ultrasonographic (power Doppler ultrasound –PDUS- in hands-feet and tendons) and serological analyses. Treatment was re-introduced upon occurrence of moderate disease activity (DAS28 ≥3.2) in a single occasion.

**Results:** A total drug-free follow-up of 1398 person-months was analysed with a median (IQR) of 15<sup>6–24</sup> months. Thirty-eight patients (27/38 in ACR/EULAR Boolean remission, 16/38 with PD score=0 at withdrawal visit) required treatment re-introduction after a median (IQR) time from discontinuation of 6<sup>3–9</sup> months (range 3–18). DAS28 variations at re-treatment showed a mean (SD) increase of 2.26 (1.03), reflecting significant differences in all DAS components (p<0.001 for ESR, tender joint count, swollen joint count and GH). Clinical activity in flaring subjects was paralleled by average changes in synovial US, with increased PD scores in hands joints (median [IQR]: 3.5 [0.5–7] vs 1 [0–2], p<0.001), feet (1 [0–4] vs 0 [0–0.5], p=0.002) and tendons (0 [0–2] vs 0 [0–0], p=0.002), determining *ex-novo* PD positivity in 85.7% of PD negative patients (p<0.001). Despite stringent remission achieved at the time of discontinuation, no significant differences were observed between disease onset and drug-free flare in DAS28 (p=0.26), patient global assessment of disease activity (p=0.53) and synovial US scores (p=0.61 for grey scale, p=0.31 for PD) with recurrence of similar patterns of clinical joint involvement.

**Conclusions:** Drug-free clinical flare can occur over a wide temporal window, in the absence of detectable signs of inflammation at the time of treatment discontinuation. It can associate with *ex-novo* recurrence of US pathologic changes at joint and tendon level, reproducing some of the quantitative/qualitative features of disease onset.

AB0204

#### RADIOGRAPHIC PROGRESSION OF LARGE JOINT DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS (BDMARDS) AND ITS PREDICTIVE FACTORS: RESULTS OF 3 TO 4 YEARS FOLLOW-UP

A. Nakajima, K. Terayama, M. Sonobe, H. Takahashi, Y. Akatsu, S. Taniguchi, M. Yamada, K. Nakagawa. *Toho University Sakura Medical Center, Sakura, Japan*

**Background:** Although damage to large joints such as the shoulder, elbow, hip, knee, and ankle has a substantially larger impact on functional ability than

damage to the small joints of the hand and foot,<sup>1 2</sup> large joints are not routinely monitored for progressive damage in patients with rheumatoid arthritis (RA). Furthermore, a little information is available regarding long-term follow-up results of radiographic progression of damage (RPD) to the large joints during treatment with biological disease-modifying antirheumatic drugs (bDMARDs).

**Objectives:** We investigated ratios of RPD to the large joints in RA patients treated with bDMARDs for 3 to 4 years and analysed association between RPD and patient backgrounds or Larsen grades of individual large joint.

**Methods:** Sixty-eight patients (naive: 42, switch: 26) receiving bDMARDs (IFX: 5, ETN: 9, ADA: 7, GLM: 3, CZP: 5, TCZ: 28, ABT: 11) for 3 to 4 years or achieving bDMARDs-free status were included in this study. The mean age and disease duration at the start of bDMARDs was 62.7 year-old and 10.7 years, respectively, and baseline DAS28-ESR and HAQ was 4.61 and 1.014, respectively. A total of 311 joints including shoulder, elbow, hip, knee, and ankle were evaluated whether there was RPD during the observation period by comparing radiographs before and after the treatment.

**Results:** RPD was found in 22 patients (31.4%) and 32 joints (10.0%), and it occurred during the former half period in 17 joints and during the latter half period in 15 joints. Joints with Larsen grade (LG) III or more had significantly higher ratios of RPD than those with LG II or less (p<0.01). An ROC analysis was performed to calculate the cut-off value for the progressive damage, which was 2.5 (sensitivity: 50.0%, specificity: 79.6%), suggesting that exceeding LG III would be a risk factor for the RPD to the large joints. A multivariate logistic regression analysis revealed that stage and baseline HAQ were independent risk factors for RPD (cut-off value: 2.5, odds ratio: 8.864 for stage; cut-off value: 1.4375, odds ratio: 6.316 for baseline HAQ).

**Conclusions:** The stage and baseline HAQ were associated with RPD to the large joints, and progressive damage is expected to increase when the stage exceeds III and/or functional disability exceeds an HAQ score of 1.5. Progressive damage also increases when LG exceeds III. Treatment with bDMARDs should be started before stage, HAQ, and LG exceed III, 1.5, and III, respectively.

#### COMPARISON OF THORACIC HRCT AND SELF-REPORTED QUESTIONNAIRES IN THE ASSESSMENT OF PULMONARY INVOLVEMENT IN RHEUMATOID ARTHRITIS PATIENTS: PRELIMINARY RESULTS

A. Topcu<sup>1</sup>, Y. Yalcinkaya<sup>2</sup>, S. Karakurt<sup>3</sup>, H.H. Mursaloglu<sup>4</sup>, E. Albayrak<sup>4</sup>, N. Coşkun<sup>5</sup>, M. Demir<sup>1</sup>, E. Dalkılıç<sup>5</sup>, N. İnanç<sup>2</sup>. <sup>1</sup>Department of Internal Medicine; <sup>2</sup>Division of Rheumatology, Department of Internal Medicine; <sup>3</sup>Department of Chest Diseases; <sup>4</sup>Marmara University Faculty of Medicine, Istanbul; <sup>5</sup>Division of Rheumatology, Department of Internal Medicine, Uludağ University Faculty of Medicine, Bursa, Turkey

**Background:** Pulmonary involvement in rheumatoid arthritis (RA) is one of the extra-articular manifestations affecting morbidity and mortality during the course of the disease. Pulmonary function tests (PFTs) and thoracic high-resolution computerised tomography (HRCT) are the standard of care in the assessment of pulmonary involvement in RA. In this study, we aimed to compare the findings between self-reported questionnaires and HRCT to detect pulmonary abnormalities in RA patients.

**Methods:** Forty-two RA patients fulfilling ACR/EULAR classification criteria (2010) who had thoracic HRCT within 6 months of any symptom and/or any pathology on radiography of chest were included in the study. The patients were also assessed by modified Borg Scale, SF-36 Quality of Life Scale and Leicester Cough Questionnaire for the evaluation of respiratory symptoms.

**Results:** Demographics and clinical characteristics were summarised in table 1. Warrick score, assessing the severity and extent of alveolitis and fibrosis on thoracic HRCT, was evaluated in 15 patients with ILD (score range:4–28). DLCO values were lower in patients with Warrick score ≥1 (73±22% vs. 88±12%, p=0.019) while FVC were not found to be different. The findings of HRCT and self-reported questionnaires were summarised in table 2. Any relationship between self-reported questionnaires and Warrick scores was not detected. Presence of any parenchymal lesions was found to be associated with SF-36 total score (p=0.048). DLCO levels were found to be negatively correlated with SF-36 total scores (r=-0.470, p=0.006).

**Abstract AB0205 – Table 1.** Demographics and clinical characteristics (n=42)

Age (years)	59±9	DMARDs and Biologics	
Sex (W/M)	32/10	MTX	15 (36%)
Smoking (%)	12 (29%)	LEF	19 (45%)
RF(+)	31 (74%)	ADA	5 (12%)
AntiCCP(+)	27 (64%)	IFX	9 (21%)
DAS28-ESR	3.1±1.0	ETA	10 (24%)
Corticosteroids	28 (67%)	ABA	13 (31%)
		TOC	2 (5%)
		TOF	2 (5%)
		RTX	20 (50%)

**Abstract AB0205 Table 2.** Thoracic HRCT findings and self-reported questionnaires in RA patients

Warrick Score (n=15)	
Alveolitis	2.6±1.2
Fibrosis	12±6.3
Total	15±7
Leicester Cough Questionnaire score (n=42)	
Modified Borg Scale	1.8±2.1
SF-36	53±17

**Conclusions:** In this study, we could not show any relationship between self-reported questionnaires and thoracic HRCT findings, except a weak association of the presence of parenchymal lesions with SF-36 scores. Alveolitis and/or fibrosis on thoracic HRCT were found to be associated with lower DLCO. DLCO was shown to be negatively correlated with SF-36 scores. SF-36 might be included in the detection of pulmonary evaluation in RA patients. The relationship between thoracic HRCT findings and self-reported questionnaires in RA necessitates further studies.

#### AB0206 EXPRESSION OF INFLAMMATORY GENES AND THE IL1B GENE ASSOCIATION WITH THE SEVERITY OF RHEUMATOID ARTHRITIS IN TAMIL NADU POPULATION

B. Vellingiri, A. V. A. I. V. B. D. V. S. C. *Human Genetics and Molecular Biology, Bharathiar University, Coimbatore, India*

**Background:** Rheumatoid Arthritis (RA) is a multifactorial complex and chronic inflammatory disease associated with progressive joint destruction, disabling and systemic complications. The prevalence is about 0.5%–1% worldwide and 0.9% in India. Genetic factors are recognised to have substantial effect on the susceptibility to RA.

**Objectives:** The present study aims to investigate the inflammatory caspase genes (*CASP5* and *CASP8*) as well as proinflammatory cytokine interleukin-1beta (IL-1β) in RA patients. Hence the study was designed to explore the possible association of inflammatory genes in Tamil Nadu population.

**Methods:** We conducted a study involving 55 RA patients and equal number of normal healthy controls and performed gene expression analysis in *CASP5* and *CASP8* genes. We also carried out genotyping of IL-1β gene using PCR-RFLP. For gene expression study, the mRNA levels of inflammatory genes were assessed using qPCR and the inflammatory marker levels (IL-1β) were estimated by ELISA.

**Results:** The gene expression analysis of RA patients showed activation of *CASP5* and *CASP8* compared to the healthy individuals. The inflammatory marker levels in the serum showed significantly higher levels (23.35±2.12 pg/mL) p<0.05) in RA patients compared to the control subjects. The homozygous and heterozygous mutant variants of *IL1B* were observed to be higher in the RA patients (OR=2.1, p<0.01).

**Conclusions:** Thus the results of our study suggests that, the mutant alleles of *IL1B* was associated with RA susceptibility which in turn has direct association with the increased levels of serum IL-1β in RA patients. In addition, the activation of inflammatory genes supports the role of inflammasome in the development of RA in Tamil Nadu population.

#### AB0207 CALPROTECTIN (S100A8/9) PLASMA LEVELS DECREASE AFTER ABATACEPT THERAPY AND CORRELATE WITH DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Šumová<sup>1,2</sup>, H. Hulejová<sup>1</sup>, K. Jarošová<sup>1,2</sup>, M. Olejárová<sup>1,2</sup>, Š. Forejtová<sup>1,2</sup>, H. Ciferská<sup>1,2</sup>, H. Mann<sup>1,2</sup>, L. Šedová<sup>1,2</sup>, J. Vencovsky<sup>1,2</sup>, K. Pavelka<sup>1,2</sup>, L. Šenolt<sup>1,2</sup>. <sup>1</sup>*Institute of Rheumatology, Prague, Czech Republic;* <sup>2</sup>*Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic*

**Background:** Calprotectin (S100A8/9) is a damage-associated molecular pattern molecule that is involved in the early phase of tissue injury. It is found mainly in circulating neutrophils, monocytes and macrophages of rheumatoid arthritis (RA) synovial tissue where it acts as a chemoattractant and induces production of proinflammatory cytokines. Several studies have reported its association with clinical disease activity and radiographic damage in patients with RA.

**Objectives:** The aim of our study was to analyse the plasma levels of calprotectin in patients with established RA after the abatacept treatment compared with healthy individuals, and to examine their potential association with disease activity and treatment response.

**Methods:** The plasma levels of calprotectin were determined by ELISA (BÜHL-MANN Laboratories AG) in 40 patients with established RA before and 3 months after initiation of abatacept treatment, and in 30 age-/sex-matched healthy subjects. Disease activity was evaluated by 28-joint Disease Activity Score (DAS28). The CRP levels and erythrocyte sedimentation rate (ESR) were determined by routine laboratory techniques. Data are presented as median ±IQR.

**Results:** Calprotectin levels at baseline were significantly higher in patients with established RA than in healthy individuals (1925 [741; 4093] vs. 506 [302; 754] p<0.0001; ng/ml). After 3 months of therapy, the levels significantly decreased (from 1925 [741; 4093] to 1569 [695; 3115] p=0.045; ng/ml). Calprotectin baseline levels significantly correlated with CRP, ESR and DAS28 at baseline (r=0.57, p=0.0003; r=0.56, p=0.0003; r=0.40, p=0.014, respectively), with change in DAS28 over 3 months (r=-0.54, p=0.001) and with change in CRP over 3, 6, 12 months (r=-0.56, p=0.0006; r=-0.61, p=0.001; r=-0.71, p=0.0001, respectively). Calprotectin levels at month 3 significantly correlated with ESR at month 3 (r=0.43, p=0.013), CRP levels at month 3 and 6 (r=0.39, p=0.27 and r=0.43, p=0.024, respectively) and with change in CRP over 12 months (r=0.45, p=0.023). Change in calprotectin levels over 3 months correlated with the change in DAS28 over 3 months (r=0.39, p=0.028) and with change in CRP over 3, 6 and 12 months (r=0.48, p=0.004; r=0.38, p=0.028; r=0.60, p=0.0009, respectively).

**Conclusions:** We demonstrate here decrease in plasma levels of calprotectin after 3 months of abatacept therapy in patients with established RA, its association with disease activity and disease activity improvement over time.

#### AB0208 UNFAVOURABLE CARDIOVASCULAR RISK PROFILE IN MALE PATIENTS WITH RHEUMATOID ARTHRITIS OF LOW DISEASE ACTIVITY

B. Targonska-Stepniak<sup>1</sup>, M. Biskup<sup>2</sup>, M. Majdan<sup>1</sup>. <sup>1</sup>*Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, Poland, Lublin;* <sup>2</sup>*Rheumatology, Regional Outpatient Clinic, Rzeszow, Poland*

**Background:** Rheumatoid arthritis (RA) is associated with the increased cardiovascular (CV) morbidity and mortality, mostly due to accelerating atherosclerosis. Both traditional and non-traditional factors seem to contribute to the excess of CV risk. Data in literature indicate a positive association between RA activity and the extent of CV disease (CVD) risk, suggesting a dominant effect of systemic inflammation. It is reported, that low disease activity is sufficient to achieve a protective effect against CVD and that atherosclerosis is not accelerated in RA of low activity or remission.

**Objectives:** The goal of the study was to assess CV parameters in female and male patients with RA of low disease activity in comparison with healthy controls.

**Methods:** The study was conducted in 70 patients with low RA activity, without known CVD (54 women, 16 men) and 33 healthy volunteers (18 women, 15 men). Patients underwent standard physical examination, assessment of disease activity in 28 joints (DAS28) and laboratory measurements including amino-terminal pro-brain natriuretic peptide (NT-proBNP). The following procedures were performed both in RA patients and controls: blood pressure (BP), carotid intima

media thickness (cIMT), electrocardiography (ECG) and echocardiography with assessment of ejection fraction (EF) and diastolic dysfunction (E/A ratio).

**Results:** The significant differences between male vs female RA patients included: higher mean values of cIMT [0.93 (0.19) vs 0.80 (0.22) mm,  $p=0.04$ ], atherogenic index [4.2 (1.4) vs 3.5 (1.0),  $p=0.03$ ] and SCORE [5.7 (3.7) vs 2.8 (2.7),  $p<0.001$ ]; as well as lower concentration of HDL-cholesterol [(50.2 (12) vs 59<sup>14,6</sup> mg/dl,  $p=0.04$ ) and NT-proBNP [66.6 (61.2) vs 106.8 (61.5) pg/ml,  $p=0.006$ ]. The mean values of age, disease duration, DAS28, C-reactive protein, body mass index, BP, QTc, E/A and EF were not significantly different in male and female patients with RA of low activity.

In the control group no significant differences were observed between male and female subjects, when considering: age, cIMT, BP, QTc, EF, E/A.

All the male RA patients had features of subclinical or advanced atherosclerosis (cIMT  $\geq 0.6$  mm), there were no male patients with normal cIMT ( $<0.6$  mm). In controls normal cIMT was found in 5 (33.3%) and subclinical atherosclerosis in 10 (66.7%), there was no control subject with advanced atherosclerosis ( $p=0.01$ ). The mean age of patients and controls did not differ significantly.

**Conclusions:** The results of the study suggest an unfavourable CV risk profile in male RA patients with low disease activity. The higher CV risk was observed in male RA patients in comparison with both controls of comparable age, as well as with female RA patients of comparable age, disease duration and activity. It seems that the male gender contributes considerably to CV risk in the period of low RA activity.

#### AB0209 OPTIMISATION OF ULTRASONOGRAPHIC EXAMINATION FOR THE DIAGNOSIS OF EROSIVE RHEUMATOID ARTHRITIS VERSUS EROSIVE OSTEOARTHRITIS WITH RADIOGRAPHY CONSIDERED AS GOLD STANDARD

C. Roux<sup>1</sup>, F. Gandjbakhch<sup>2</sup>, A. Pierreisnard<sup>2</sup>, M. Couderc<sup>3</sup>, C. Lukas<sup>4</sup>, R. Masri<sup>5</sup>, J.-P. Sommier<sup>1</sup>, I. Clerc-Urmes<sup>6</sup>, C. Baumann<sup>6</sup>, I. Chary-Valckenaere<sup>1</sup>, D. Loeuille<sup>1</sup>. <sup>1</sup>Rheumatology, University Hospital of Nancy, Vandœuvre-lès-Nancy; <sup>2</sup>Rheumatology, Academic Hospital Pitie Salpêtrière, Paris; <sup>3</sup>Rheumatology, University Hospital of Clermont-Ferrand, Clermont-Ferrand; <sup>4</sup>Rheumatology, University Hospital of Lapeyronie, Montpellier; <sup>5</sup>Rheumatology, University Hospital of Nancy, Vandœuvre-lès-Nancy; <sup>6</sup>Platform of Clinical Research Support PARC, University Hospital of Nancy, Vandœuvre-lès-Nancy, France

**Background:** Rheumatoid arthritis (RA) is the most prevalent chronic inflammatory joint disease<sup>1,2</sup> responsible for structural damage. Radiography (RX) is considered as the gold standard for visualising and quantifying bone lesions in RA.<sup>3</sup> Musculoskeletal ultrasound (US) is booming in clinical practice for the diagnosis of RA. US can detect more erosions than RX at the joint level, especially at an early stage of the disease.<sup>4</sup>

**Objectives:** To determine thresholds and better scenarios for the diagnosis of erosive RA by US in RA and osteoarthritic (OA) patients.

**Methods:** Patients fulfilling ACR 1987<sup>5</sup> and/or ACR/EULAR 2010<sup>6</sup> criteria for RA or hand OA criteria were prospectively included. A modified Sharp erosion score was assessed by two blinded readers and one adjudicator for discordant cases (number of eroded joints  $\leq$  three). Erosions in US were scored on six bilateral joints (MCP2–3, 5; MTP2–3, 5) with a four-grade scale.

**Results:** A total of 168 patients were included: 122 RA (32 early RA  $<2$  years; 90 late RA  $\geq 2$  years); 46 OA patients. On RX: 42 RA patients (6 early; 36 late) and 5 OA patients were eroded according to ACR/EULAR 2013<sup>6</sup> criteria (sensitivity: 34.4%, specificity: 89.1%). On US, 95 RA patients (21 early; 78 late) and 12 OA patients were eroded. Considering at least two joint facets eroded (threshold 1) or at least one joint facet eroded at grade 2 (threshold 2), sensitivities were good (68%–72.1%) and specificities excellent (89.1%–100%). With only six targeted joint facets examined, 73 and 74 patients were classified as erosive RA with threshold 1 and 2 with good sensitivities (59.8%–60.0%) and excellent specificities (95.6%–100%) respectively. For all scenarios, agreement between RX and US for the diagnosis of erosive RA was excellent (88.1% to 92.8%).

**Conclusions:** US erosion assessment of six targeted joint facets permitted to detect 1.7 times more erosive RA patients than RX in late and early RA.

#### AB0210 CLINICAL AND MUSCULOSKELETAL ULTRASOUND ASSESSMENT OF THERAPEUTIC RESPONSE TO TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: REAL-WORLD CLINICAL EXPERIENCE FROM A SINGLE CENTRE IN HONG KONG

C.K.-L. Yu. Hong Kong Autoimmune and Rheumatic Diseases Centre, Hong Kong, Hong Kong

**Background:** Increasingly, musculoskeletal ultrasound (MSUS) has been demonstrated as an effective method for monitoring disease activity and joint damage in patients with rheumatoid arthritis (RA).

**Objectives:** The objective of this single-centre, 12 week study was to evaluate the effects of tofacitinib therapy in Chinese patients with RA using clinical, laboratory and sonographic assessments, with the view to identifying factors that may predict response to tofacitinib. Furthermore, the study sought to determine whether MSUS would be comparable to conventional techniques for monitoring disease activity in RA.

**Methods:** Patients with RA (n=18) were treated with tofacitinib 5 mg bd for 12 weeks. Clinical, laboratory and ultrasound examinations were conducted at baseline (T0), and weeks 4 (T1), 8 (T2) and 12 (T3). Erythrocyte sedimentation rate, C-reactive protein, physician and patient visual analogue scale for disease activity, number of tender and swollen joints, Clinical Disease Activity Index (CDAI), Simple Disease Activity Index (SDAI) and Disease Activity Score in 28 joints (DAS28) were assessed and compared. MSUS was performed bilaterally in all metacarpophalangeal, interphalangeal, wrist and knee joints. A semi-quantitative score (0–3) was used to indicate the presence of a localised inflammatory process and/or structural damage. The cumulative total was used as an indicator of global change in each joint (single joint score). The sum of the single joint scores was used as an indicator of overall polyarticular involvement in each patient (total joint score).

**Results:** Of the 18 patients recruited into the study, all 18 were examined at T0, T1 and T2, and 17 patients were evaluated at T3. All clinical and laboratory measures, as well as MSUS scores, were significantly reduced during follow-up. There was a significant correlation between MSUS scores and conventional (clinical and laboratory) measures of disease activity. Correlation coefficients between the techniques and factors potentially predicting response to tofacitinib will be reported.

**Conclusions:** A positive response to tofacitinib treatment was shown by both MSUS examination and clinical evaluation, with good correlation between the methods. In a busy, every-day, clinical-practice setting in Hong Kong, MSUS was found to be a useful tool for monitoring and following-up the effects of biologic therapy in RA, for the assessment of both inflammatory and destructive changes.

#### AB0211 THE RELATIONSHIP BETWEEN THE ELEVATED SERUM IMMUNOGLOBULIN G4 LEVEL AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

C.-N. Son, H.-J. Jeong, J.-N. Chae, J.-M. Kim, S.-H. Kim. Internal Medicine, Keimyung University, Daegu, Korea, Republic of Ireland

**Background:** High levels of serum immunoglobulin G4 (IgG4) would comprise a useful diagnostic tool in IgG4-related disease, but little information is available about IgG4 in conditions other than IgG4-related disease, including rheumatic diseases. Previous studies indicate that the elevated serum IgG4 in rheumatoid arthritis (RA) is common and disproportional to total IgG.

**Objectives:** The aim of study is to evaluate the level of serum IgG4 and IgG4/total IgG ratio in patients with RA.

**Methods:** Ninety-six patients with RA and one hundred and thirty-five non-RA controls were enrolled between March 2014 and July 2017. All samples were collected before the treatments. The levels of Serum total IgG and IgG4 were determined by nephelometric assay. The cut-off value of serum IgG4 was 135 mg/dL. Data on clinical variables and disease activity markers, such as numbers of tender and swollen joints, levels of acute phase reactants and disease activity score 28 (DAS28) were recorded in RA patients. We compared the levels of serum IgG4 and the ratio of IgG4/total IgG in rheumatoid arthritis with healthy controls and other rheumatic diseases. This study also investigated the difference the relationship between levels of serum IgG4 and disease activity in RA.

**Results:** Among 96 RA patients, the mean of serum IgG4 was 48.0±45.4 mg/dL and 6.3% had elevated serum IgG4. The mean serum IgG4/IgG ratio of RA patients was 3.5%±2.8% (range 0.2%–16.9%). There was no patient with elevated serum IgG4 in ankylosing spondylitis, systemic lupus erythematosus, Sjogren's syndrome, and inflammatory myositis. When the patients were divided according to clinical activity, the percentages of the positive serum IgG4 were 25% in active disease group and 4% in low activity group. However, the serum IgG4 levels of the RA patients with active disease activity were not significantly higher than those of the RA patients with low disease activity (58.3±44.3 mg/dL vs. 39.9±30.1 mg/dL). No significant relationship was observed between the ratio of IgG4/total IgG and disease activity. The IgG4 concentrations and total IgG/IgG4 ratios were similar between RA and the other autoimmune diseases ( $p>0.05$ ).

**Conclusions:** Our results showed that elevated serum IgG4 in RA is relatively common. However the presence of the elevated serum IgG4 was not associated with disease activity of RA. Further investigations are needed to explore the clinical significance in a larger study population.

#### AB0212 DIAGNOSTIC DELAY FOR RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW

C.A. Hay<sup>1</sup>, J.A. Prior<sup>1</sup>, I. Scott<sup>1</sup>, K. Raza<sup>2</sup>, S. Hider<sup>1</sup>, C.D. Mallen<sup>1</sup>. <sup>1</sup>Research Institute for Primary Care and Health Sciences, Keele University, Keele; <sup>2</sup>Institute of Inflammation and Ageing, University of Birmingham, Birmingham, UK

**Background:** Rheumatoid arthritis (RA) is a common inflammatory condition, affecting 1% of the population and causing pain, stiffness and swelling, leading to significant disability and loss of function.<sup>1</sup> Delays in the diagnosis and treatment of RA can lead to worsened joint damage and disability, in addition to a reduced rate of disease-modifying antirheumatic drugs (DMARD)-free remission. <sup>Current (2016)</sup> EULAR guidelines specify that combination DMARD treatment be initiated within 3 months of the onset of persistent RA symptoms.<sup>2</sup> Unfortunately, this target is not always achieved due to delays between symptom onset to treatment initiation.

**Objectives:** The aim of this systematic review, was to determine the extent of delay that occurs at different points in the patient's journey from RA symptom onset to treatment initiation, providing benchmarks of delay.

**Methods:** Embase and Medline were searched for articles examining diagnostic and treatment delay of RA. To be included, articles had to report a time-period of delay in an adult RA population. Papers were screened by three authors (CAH, JAP, IS). The primary outcome was the reported time-period of delay at any point from RA symptom onset to treatment. Due to skewed delay data, medians (with Interquartile range (IQR)) were selected and reported using narrative synthesis. Different time-periods of delay were categorised to facilitate comparison.

**Results:** Of 4925 returned articles, 1501 duplicates were removed. The remaining articles were then screened by title, abstract and full text, leaving 26 from which we extracted data. Delay periods were categorised as 1) symptom onset to initiation of DMARDs (n=9), 2) symptom onset to diagnosis (n=14), 3) symptom onset to 1st healthcare professional (HCP) appointment (n=15), 4) 1st HCP appointment to rheumatology referral (n=4) and 5) 1st HCP appointment to diagnosis (n=4). Time-periods of delay were typically skewed to the right. The total delay from symptom onset to receiving DMARDs has dropped since the 1980's (429 weeks before 1987) and by 2014 data indicates an average delay of 23 (IQR 14, 43) weeks. Within this total delay period, delay from symptom onset to diagnosis is at a minimum 16<sup>(7,55)</sup> weeks and delay from symptom onset to first contact with a HCP predominantly ranges from 2 (1,8) to 10<sup>(4,24)</sup> weeks in data from 2010 onwards. Delay between 1st HCP appointment and Rheumatology referral can be as quick as 2 (1,5) weeks and is within 12<sup>(2,48)</sup> weeks across all data points. Delay acquired between 1st HCP appointment and receiving a diagnosis has decreased overtime, most recently, delay was reported as 21 weeks.

**Conclusions:** Time from RA symptom onset to receiving treatment has reduced considerably in recent decades. However, despite current guidelines and research indicating an optimal treatment window for RA of twelve weeks from symptom onset, this remains unmet, with this delay approximately twice the recommended period. Continued effort is required in reducing delay across all areas of the RA patients' journey to the early treatment needed to improve outcome.

#### AB0213 CORRELATION BETWEEN COMPONENTS OF THE DAS28 SCORE AND HEALTH ASSESSMENT QUESTIONNAIRE IN EARLY RHEUMATOID ARTHRITIS

C. Thurston, S. Rizvi, M. Bukhari. *Rheumatology, Royal Lancaster Infirmary, Lancaster, UK*

**Background:** The health assessment questionnaire (HAQ) in rheumatoid arthritis (RA) has been widely validated as a patient reported outcome measure (PROM). In the United Kingdom regulatory bodies such as the national institute of health-care and clinical excellence (NICE) have been using improvement in HAQ as a surrogate for efficacy of drugs in RA and has informed their calculation of quality adjusted life year, and calculating health costs using incremental costs effectiveness ratios. Most clinical trials in RA report their primary outcome as improvement in clinical parameters such as swollen and tender joints, inflammatory markers and patient and physician global assessment of disease. What is not clear how the two sets of parameters interact. Some reports<sup>1</sup> indicate that there is a strong correlation in early disease, but this has not been validated.

**Objectives:** We set out to determine the relationship between HAQ scores and clinical parameters of the Disease activity score (DAS28) in addition to physician global.

**Methods:** Patients were recruited from a single centre from the RAMS study in the North west of England. This is a study of patients with early newly diagnosed RA commencing methotrexate A subset of patients filled in the HAQ questionnaire and this as used as an outcome variable using linear regression and the swollen joints, tender joints, patient global assessment of disease as well as physician assessment of disease in addition to inflammatory markers were used as explanatory variables. These were then adjusted for age.

**Results:** 81 patients were included in the analysis. median age was 63.1 years (IQR 52.9,72.5). 50 (61.7%) were female. the median HAQ score at baseline was 1 (IQR 0.5,1.5) the median DAS28 score 5.3 (IQR 4.5,6.3). Tender joints at baseline correlated well with HAQ score Beta=0.058 95% CI, 0.04,0.08 ( $p<0.01$ ). Swollen joints did not correlate with the HAQ beta=0.000 (95%CI -0.3,0.3). Physician global correlated well with disease beta=0.014 (95%CI 0.005,0.022). Patient global assessment also correlated well with HAQ (beta 0.014 95% CI 0.008,0.020). CRP did not correlate with HAQ (beta 0.00261 95% CI -0.002,0.007)

**Conclusions:** In this small study, patient and physician related outcome measures correlate with HAQ scores at baseline more than measures of joint swelling and inflammatory markers. This indicates that using HAQ as an outcome measure underestimates the effect of treatment. When assessing the efficacy of drugs using HAQ this should be taken into account. Validity of the approach needs to be reviewed.

#### AB0214 THE TRAJECTORY OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS IN THE FIRST TWO YEARS OF TREATMENT IN AN ASIAN RA COHORT

C. Teo<sup>1</sup>, E.T. Koh<sup>1</sup>, C.M. Woo<sup>2</sup>, X. Tang<sup>2</sup>, J. Tan<sup>2</sup>, T.Y. Lian<sup>2</sup>, L.W. Koh<sup>2</sup>, K. P. Leong<sup>2</sup>. <sup>1</sup>Tan Tock Seng Hospital, Singapore, Singapore; <sup>2</sup>Rheumatology, Allergy and Immunology, Tan Tock Seng Hospital, Singapore, Singapore

**Background:** Response to disease-modifying antirheumatic drugs (DMARDs) is heterogenous. Clinical information and baseline characteristics do not allow reliable prediction of which trajectory patients will follow after DMARD initiation.

**Objectives:** We analysed the change in disease activity over the first two years of treatment in rheumatoid arthritis (RA) to identify different treatment response patterns among RA patients initiating DMARDs. We wanted to establish a predictive model for identifying patients with different treatment response patterns.

**Methods:** We selected patients from our prospective RA disease registry who have been treated for three months or fewer at study entry. We analysed the change of the disease activity, as defined by the DAS28–ESR, over the subsequent two years. A predictive model with parameters from three time points is proposed to stratify patients according to the outcomes.

Abstract AB0214 – Figure 1

**Results:** We analysed the data from 179 patients over 1044 study visits. We discerned three groups of patients according to disease activity trajectories:<sup>1</sup>the first group (53%) has high DAS at study entry and approach remission after 18 months;<sup>2</sup>the second group (22%) has high DAS at entry that remained elevated throughout the study period; and,<sup>3</sup>the third group of patients (25%) started with moderately high DAS and reached remission after 3 months of treatment. Patients at risk of being in the third group can be identified using data from three time points, at initiation of DMARDs, at 3 months and at 6 months.

**Conclusions:** RA patients showed three distinct disease activity trajectories with treatment. Our model can categorise patients into these groups.

AB0215

#### ASSOCIATION OF RHEUMATOID FACTOR IMMUNOGLOBULIN A SEROPOSITIVITY WITH RISK OF EROSIVE ARTHRITIS IN PATIENTS WITH RHEUMATOID ARTHRITIS: AN OBSERVATIONAL STUDY

A.I. Pereira<sup>1</sup>, C. Vaz<sup>1,2</sup>, J.M.R. Gama<sup>3</sup>, L. Inês<sup>1</sup>. <sup>1</sup>Faculty of Health Sciences, University of Beira Interior, Covilhã; <sup>2</sup>Rheumatology Department, Sousa Martins Hospital, Guarda Local Health Unit, Guarda; <sup>3</sup>Centre of Mathematics and Applications, University of Beira Interior, Covilhã, Portugal

**Background:** In patients with rheumatoid arthritis (RA), erosive arthritis is a major determinant of long-term prognosis. Seropositivity for immunoglobulin (Ig) M rheumatoid factor (RF) or cyclic citrullinated peptide antibodies (anti-CCP) are risk factors for erosive arthritis. However, RA patients can also present IgA RF. The risk for erosive arthritis associated with RF IgA seropositivity is not established.

**Objectives:** To evaluate the risk for erosive arthritis associated with IgA RF seropositivity in RA patients.

**Methods:** Cross-sectional observational study, including RA patients (fulfilling the 2010 ACR/EULAR classification criteria) and consecutively observed in a hospital-based rheumatology outpatient clinic, from April to August 2017. At time of inclusion, patient characteristics were evaluated, including: gender, age, RA duration since time of diagnosis, smoking habits, seropositivity for IgA RF, IgM RF and anti-CCP, erosive arthritis in hand and feet X-rays. Risk association for erosive arthritis was analysed with univariate and multivariable logistic regression models for the putative risk factors and confounders. Odds ratios (OR) and 95% confidence intervals (CI) of IgM RF, IgA RF, and anti-CCP seropositivity for erosive arthritis were estimated. Statistical significance was set at 0.05.

**Results:** 86 patients were included. The univariate logistic regression showed significant positive associations of IgA RF, IgM RF and anti-CCP with erosive arthritis. In the multivariate analyses, adjusting for confounders (gender, age, disease duration and smoking), the OR for erosive arthritis associated with IgA RF, IgM RF and anti-CCP were respectively: OR=2.42 (95% CI 0.72–8.07; p=0.152); OR=3.54 (95% CI 1.16–10.83; p<0.05); OR=4.13 (95% CI 1.33–12.82; p<0.05). The seropositivity for IgM RF, IgA RF and anti-CCP were strongly associated among each other (Chi-square test with p<0.001 for all associations).

**Conclusions:** In this RA cohort, the IgA RF was associated with erosive arthritis in univariate analysis, but did not prove to be an independent risk factor in multivariate regression, due to its strong association with IgM RF and anti-CCP. Determination of IgA RF does not seem to add predictive value for erosive arthritis in RA patients.

AB0216

#### LOW MORTALITY RATE IN ITALIAN RHEUMATOID ARTHRITIS PATIENTS FROM A TERTIARY CENTRE. PUTATIVE IMPLICATION OF A LOW ANTICARBAMYLATED PROTEIN ANTIBODIES PREVALENCE

D. Iacono<sup>1</sup>, E. Favoino<sup>2</sup>, A. Borgia<sup>1</sup>, S. Fasano<sup>1</sup>, I. Pantano<sup>1</sup>, V. D'Abrosca<sup>1</sup>, G. Picillo<sup>1</sup>, F. Perosa<sup>2</sup>, G. Valentini<sup>1</sup>. <sup>1</sup>Rheumatology, University of Campania Luigi Vanvitelli, Naples; <sup>2</sup>Rheumatology, University of Bari, Bari, Italy

**Background:** Rheumatoid Arthritis (RA) is a chronic systemic inflammatory disorder associated with increased mortality, in particular from cardiovascular (CV) disease, infections and cancer. We recently demonstrate a incidence mortality rate (IMR) in 654 RA patients enrolled over a 6 year period in a South-Italian tertiary Rheumatology Centre lower than that reported in the Norfolk Arthritis Registry.<sup>1</sup>

**Objectives:** The present study is devoted to investigate differences in IMR between our series and other European tertiary centre cohorts. Furthermore we evaluated the role, if any, of Anticarbamylated protein antibodies (anti-CarP Ab) in modulating the low IMR detected in our patients.

**Methods:** Clinical charts of patients consecutively admitted to our centre, from January 1st, 2008 to December 31st, 2014 were reviewed. IMRs and causes of death as assessed at December 31st 2015, were registered. Sera collected at the time of admission to our centre in 61 patients representative of our RA cohort were investigated for the presence and the level of anti-CarP Ab. Demographic and clinical features, mortality rates and prevalence of anti-CarP Ab detected in our series were compared with those reported in the Better Anti-rheumatic Farmaco-therapy (BARFOT) cohort, the Leiden Early Arthritis Clinic cohort (Leiden EAC) and a Spanish cohort.<sup>2,3</sup>

**Results:** Six hundred and eight patients were observed for a median of 3.51 years. All causes and cause-specific IMRs were significantly lower in our cohort with respect to the BARFOT and the Spanish cohort, while only all causes and CV IMRs were significantly lower in our series with respect to the Leiden EAC. These discrepancies might depend on demographic and clinical differences among the various cohorts. Nevertheless, we failed to find putative differences with respect to each North European cohort, but we detected a significantly lower prevalence of anti-CarP Ab in our series with respect to that reported in the other European cohorts considered (table 1).

**Conclusions:** In conclusion, we confirm that the mortality rate in our South Italian RA cohort is lower than that detected in patients from both North and South European countries.

We detected a very low prevalence of anti-CarP Ab in our sample representative of the entire cohort. Whether this is the aspect underpinning the low mortality rate detected in our series, awaits to be furtherly investigated.

### AB0217 CONSTRUCT VALIDATION OF THE ITALIAN VERSION OF THE 5-ITEM COMPLIANCE QUESTIONNAIRE FOR RHEUMATOLOGY (I-CQR5)

D. Azzolina<sup>1</sup>, F. Ometto<sup>2</sup>, B. Raffener<sup>3</sup>, C. Botsios<sup>3</sup>, M. Favero<sup>3</sup>, D. Astorri<sup>3</sup>, L. Friso<sup>2</sup>, D. Gregori<sup>3</sup>, J. Done<sup>4</sup>, A. Doria<sup>3</sup>. <sup>1</sup>Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiac, Thoracic and Vascular Sciences, University of Padova; <sup>2</sup>Department of Medicine – DIMED, University of Padova; <sup>3</sup>Department of Medicine – DIMED, University of Padova, Padova, Italy; <sup>4</sup>Department of Psychology and Sports Sciences, University of Hertfordshire, Hatfield, UK

**Background:** The 5-item Compliance Questionnaire for Rheumatology (CQR5) allows the identification of patients likely to be high adherers (HA) to anti-rheumatic treatment (i.e. taking ≥80% of their medications correctly), or “low” adherers (LA).<sup>1</sup>

**Objectives:** The objective was to validate the construct of an Italian version of CQR5 in rheumatoid arthritis (RA).

**Methods:** Cross-cultural adaptation comprised: forward translation, synthesis of the translations, back-translation, expert committee assessment and field-testing. Validation was conducted administering the adapted version (I-CQR5) to RA patients (disease duration >1 year, treated with ≥1 self-administered disease-modifying anti-rheumatic drug, capable of completing the questionnaire unaided) on one occasion. Questionnaires were anonymous but contained self-reported data. Construct validity and reliability were assessed with Rasch analysis (Partial Credit model Parametrisation, PCM). Martin-Loef Likelihood ratio test assessed invariance for gender, age, education, social status and disease duration.

**Results:** The adaptation process was closed by the expert committee assessment. I-CQR5 is reported in Figure 1. Among 604 patients, 274 were included in the validation process, 6 questionnaires were incomplete. Median age was 57 years (48–67), females were 201 (77%), disease duration was 13.5 years (8–19.3), most patients lived with partner/family (159,75%) and had a middle/secondary school education (184,69%). HA were 93 (67%) and LA 179 (35%). Factor analysis revealed ordered thresholds in most items, 2 factors were sufficient to explain variability (Chi-square=0.46,p=0.5) (Tab.1). Item-fit statistics showed overall agreement of items with parametrisation (Infit statistics=0.6–1.4; excluding item no.5). Chi-square showed agreement with PCM parametrisation by item (excluding the item no.1). Martin-Loef likelihood ratio test confirmed unidimensionality (Chi-square 65.8, df=53,p=0.11) and Separation Reliability Index confirmed internal consistency (Patient Separation Index 0.91) (Tab.1). I-CQR5 was invariant to age (Chi-square=40.6, df=28,p=0.059), education level (Chi-square=49.9, df=42,p=0.187), social status (Chi-square=10.5, df=15,p=0.79), disease duration (Chi-square=13.6, df=36,p=0.220); Martin-Loef test was significant for gender (Chi-square=25.4, df=14,p=0.031).

Abstract AB0217 – Table 2

### Questionario sulla Compliance in Reumatologia a 5 domande (I-CQR-5)

Di seguito sono riportate delle affermazioni di pazienti affetti da una malattia reumatica. Indichi quanto è d'accordo con ciascuna affermazione cerchiando il numero che riflette maggiormente la Sua opinione.

	Completamente in disaccordo	In disaccordo	D'accordo	Completamente d'accordo
Prendo i farmaci antireumatici perché in questo modo ho meno disturbi.	1	2	3	4
Non mi permette mai di saltare la somministrazione dei farmaci antireumatici.	1	2	3	4
Metto sempre le medicine nella stessa scatola per non dimenticare di prenderle.	1	2	3	4
Prendo i farmaci prescritti perché ho completa fiducia nel mio reumatologo.	1	2	3	4
Seguo sempre le indicazioni del mio medico.	1	2	3	4

**Conclusions:** I-CQR5 was well understood by patients and construct validity, unidimensionality and internal consistency were confirmed by factor analysis and PCM.

**AB0218 HIGH LEVEL OF CARTILAGINOUS OLIGOMERIC MATRIX PROTEIN IS ASSOCIATED WITH THE RADIOGRAPHIC PROGRESSION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS**

D. Rekalov, D. Nikitina. *Rheumatology, Zaporizhzhia Regional Clinical Hospital, Zaporizhzhia, Ukraine*

**Background:** Recent achievements have established that the very first years since the development of the RA are decisive in terms of the progression of the pathological process and the prediction of its remote consequences. This substantiated the need to reflect the heterogeneity and stage of the RA. First of all it concerns the early RA – a time point when the pathological process is in the primary exudative phase and its reversibility is significantly higher, because of not completely formed autoimmune mechanisms and the absence of pannus.

**Objectives:** Our aim was to establish the relationship between the levels of Anti-Citrullinated Peptide Antibody (ACPA), cartilaginous oligomeric matrix protein (COMP) and radiographic progression in patients with early RA

**Methods:** 75 patients with a diagnosis of early RA were examined, the duration of symptoms was less than 1 year (on average –  $4.91 \pm 2.90$  month) that were observed repeatedly on average after 12 months ( $11.8 \pm 1.2$  months). The average age of patients was 46.4 years (from 34 to 62 years), 69.33% of the examined ones were women, the average duration of the disease at the time of the initial study was 107 days (57–194 days). Immune dysregulation in early RA was confirmed with the evaluation of the key proinflammatory cytokines – ACPA and COMP by the enzyme-linked immunosorbent assay (ELISA) according to the instructions for diagnostic kits. For the testing of articular cartilage lesions and injury of flexor's and extensor's tendons, MRI (1.5 T) and ultrasound diagnostics (US) were performed

**Results:** Immunological analysis of serum samples of ACPA, COMP was shown the role of these cytokines as prognostic factors of development and prognosis of early RA. The serological features of the obtained data revealed a correlation between the increased concentration of COMP and the progression of joint lesions without ACPA level increase. According to the baseline US data, the tendons of general flexor muscles and extensor brushes were most commonly observed in the examined patients: in general, 52 patients (69.3%) and 23 (30.7%), respectively. The injury of the tendons of individual fingers (I-V) in the mode of longitudinal and transverse scanning had its own patterns (table 1).

**Conclusions:**

- In patients with seronegative (normal ACPA ranges) early RA and high levels of COMP – the highest frequency of erosive and destructive changes can be observed.
- Injury of the tendons of flexors and extensors determined in major part of the patients with early RA.

**Abstract AB0218 – Table 1.** Injury of the flexor's and extensor's tendons

**AB0219 IMPACT OF EARLY DIAGNOSIS ON LONG-TERM EFFECTIVENESS OF FIRST-LINE ANTI-TNF-ALPHA TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS**

D. Capocotta, S. Montalbano, D. Lubrano, E. Tirri. *Rheumatology Unit, San Giovanni Bosco Hospital, Naples, Italy*

**Objectives:** Aim of this work was to evaluate effectiveness and drug persistence of anti-tumour necrosis factor (TNF)-alpha therapies in early and late diagnosed rheumatoid arthritis (RA) patients naive for biological disease-modifying antirheumatic drug (bDMARD) use.

**Methods:** Baseline and follow-up (FU) charts RA patients with disease onset later than 2002 and access to rheumatology care between January 2007 and December 2016 were reviewed until December 2017. All patients fulfilled 2010 ACR/EULAR classification criteria. At baseline, demographic, anamnestic and serological characteristics were collected. Based on lag time between onset of symptoms and definite diagnosis, RA patients were categorised into two groups: early diagnosed (less than 12 months) and late diagnosed (more than 12 months). Disease activity and treatment response were assessed every three months by Simplified Disease Activity Index (SDAI). Anti-TNF-alpha survival was defined as the length of time from initiation to discontinuation of therapy due to loss of effectiveness over time. It was examined using Kaplan-Meier survival analysis.

**Results:** One hundred and fifteen RA patients (86.1% females, mean age 59.4) were included. The median disease duration between onset of symptoms and diagnosis was 25 months.<sup>20–43</sup> 68 patients (59.1%) were labelled as early diagnosed and 47 (40.9%) as late diagnosed. At baseline, no differences were found in age, gender, smoking habits, body mass index, and rheumatoid factor positivity. The most frequently used first-line anti-TNF drug was etanercept (30.4%), followed by adalimumab (20%), golimumab (18.3%), infliximab (16.5%), and certolizumab (14.8%). All patients received anti-TNF-alpha therapy in combination with csDMARD (methotrexate or leflunomide). Average steroid dosage was 5 mg/day of prednisone (or its equivalent) over time. The median time to initiation of any anti-TNF-alpha treatment after definite diagnosis was 18 months.<sup>6–30</sup> Kaplan-Meier analysis showed a lower anti-TNF-alpha discontinuation rate for early diagnosed RA patients than late diagnosed (9 year retention rate of 29.5% and 12.7%, respectively;  $p = 0.0049$ ) (figure 1).

Abstract AB0219 – Figure 1

**Conclusions:** This small real-world retrospective, observational, cohort study demonstrates that early diagnosis of RA provides higher retention rate of anti-TNF-alpha treatment as first-line bDMARD.

#### AB0220 SERONEGATIVE RA GROUP HAD Milder SYNOVITIS AND DELAYED PROGRESS OF BONE EROSION THAN SEROPosITIVE RA ON WRISTS AND HANDS IN DMARDs-NaïVE CHINESE COHORT

D.F. Lin<sup>1</sup>, Y.T. Jiang<sup>1</sup>, Y.L. Zhang<sup>1</sup>, J. Cao<sup>2</sup>, X.H. Guo<sup>1</sup>, Y.F. Pan<sup>1</sup>, J.R. Gu<sup>1</sup>.

<sup>1</sup>Rheumatology Department; <sup>2</sup>Ultrasound department, The 3rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Contrast to sp-RA, sn-RA was less studied. The report by Nordberg et al mentioned ultrasonic presentations for the first time. They declared early RA patients(with the duration <2 years) without the treatment of DMARDs had more severe synovitis than sp-RA. However, according to the criteria, for the diagnosis of sn-RA, more than 10 swollen joints is necessary. The huge gap of swollen joints counts(SJC)between two groups may influence the sum ultrasound scores and thus cause a prominent selective bias, which was questioned to affect the fact that sn-RA had more synovitis due to more joints involved relative to grouping rules.

**Objectives:** To investigate and compare the disease progress of seronegative Rheumatoid arthritis (sn-RA) and seropositive Rheumatoid arthritis (sp-RA) on typical sites including wrists and hands by means of ultrasound and x-ray in Chinese patients.

**Methods:** All cases were DMARDs-naïve (DMARDs) and conformed to 2010 classification criteria with the characteristics of abnormal swollen or pain in wrists, Proximal Interphalangeal (PIP), Metatarsophalangeal (MCP) joints. 5-joints ultrasound scoring system was improved from Backhaus's US7 scoring system. Erythrocyte sedimentation rate (ESR, mm/h), C reactive protein (CRP, mg/L), Visual analogue scale (VAS) scores (VASs), patient global assessment of disease activity on VASs (PGA), the physician's assessment of disease activity on VASs (PhGA), DAS28(Disease Activity Score-28, DAS28), van der Heijde-modified Sharp scores(vdHSS) were also used to evaluate the disease activity among<sup>1</sup> Group A: sp-RA (positive rheumatoid factor(RF) and/or anticitrullinated peptide antibody(ACPA)) combined with swollen joint counts(SJC)>10;<sup>2</sup> Group B: sp-RA combined with SJC ≤10 and<sup>3</sup> Group C: sn-RA (negative RF and negative ACPA), according to the 2010 criteria with SJC >10.

**Results:** 29 (11.6%) of 249 patients were seronegative. The score of DAS28, CRP, ESR, the sum ultrasound scores, vdHSS, phisican global VAS, Patient global VAS and pain VAS were significantly lower(p<0.05) in Group C than Group A, but no difference between Group B and Group A. The sum ultrasound scores were prominently lower in Group C with the duration over 2 years (p<0.05), and vdHSS were remarkably higher in all groups with the duration over 5 years, but more specifically, for the duration over 2 years(p<0.05), the vdHSS was shown to go up much more earlier in Sp-RA than Sn-RA patients.

**Conclusions:** Seronegative RA group had milder synovitis and delayed progress of bone erosion than seropositive RA on hands and wrists at the same level with SJC >10.

#### AB0221 THE USE OF ULTRASOUND TO IDENTIFY DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN CLINICAL REMISSION OR LOW DISEASE ACTIVITY IN A REAL-LIFE SETTING

E. Castillo<sup>1</sup>, S. Farietta<sup>1</sup>, D. Buitrago-Garcia<sup>2</sup>, L. Villarreal<sup>3</sup>, P. Santos-Moreno<sup>4</sup>.

<sup>1</sup>Ultrasound, Biomab, Center for Rheumatoid Arthritis, Bogota; <sup>2</sup>Epidemiology, SIIES; <sup>3</sup>Health services; <sup>4</sup>Rheumatology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia

**Background:** The goal of treatment in rheumatoid arthritis (RA) is to achieve remission or low disease activity for as long as possible, in order to prevent joint damage and loss of function. The evaluation and follow-up of disease activity relies on composite indexes with clinical outcomes. However, many studies have shown that a high proportion of patients categorised on remission or low disease activity by clinical methods could have disease activity by ultrasound (US).<sup>1</sup>

**Objectives:** The aim of this study was to evaluate disease activity by US in patients classified as to be in remission or in low disease activity disease activity by clinimetric evaluation.

**Methods:** We performed a cross-sectional study including patients with RA; Clinical follow-up was designed by the authors according to DAS28 as follows: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11–13 weeks (DAS28 <3.1). Additionally the patient was evaluated by a rheumatologist expert in ultrasound; US studies were carried out with a Esaote MyLab Seven US equipment (Biomedica, Genoa, Italy) equipped with a 10–18 MHz linear transducer; PD was adjusted according to the following parameters: frequency, 8.0, PRF, 0.500, wall filter 3, gain between 50 and 70. The rheumatologist reported erosions, synovitis, osteophytes and power Doppler, we defined as active disease when patients had synovitis or positive power Doppler. We calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We performed a bivariate analysis using Pearson's Chi<sup>2</sup>

**Results:** We included 243 patients 64% were in remission and 36% in low disease activity, 85% were woman, mean age was 60 years±10. Mean DAS28 was 2.53±0.53. 81% of patients received conventional DMARDs and 19% received biological DMARDs. The most frequent finding was erosions 70% in hands and 7% in feet followed by synovitis in hands 58%. See table 1. We found disease activity in 60% of our patients were 51% had positive Doppler and synovitis, 1% had only positive Doppler and 8% patients only had synovitis. We did not find statistical association between disease activity according to ultrasound and age, sex and type of pharmacological therapy in patients classified as to be in remission or LDA.

**Conclusions:** The evidence found in this real-life setting data, showed that two thirds of RA patients classified according to DAS28 to be in remission or LDA have subclinical disease activity; thus the ultrasound is a very useful tool to evaluate patients with RA in clinical practice. Further research is needed in order to identify the reasons of disease activity in patients were clinical findings point towards remission or LDA.

### DIFFERENCES OF DISEASE IMPRESSION AND TREATMENT EXPECTATION IN RHEUMATOID ARTHRITIS PATIENTS WITH DIFFERENT DISEASE ACTIVITY

E. Torikai<sup>1</sup>, D. Suzuki<sup>1</sup>, M. Suzuki<sup>2</sup>, Y. Matsuyama<sup>3</sup>. <sup>1</sup>Department of Rheumatology, Lwata City Hospital, Lwata; <sup>2</sup>Department of Orthopaedic Surgery, Hamamatsu University School of Medicine; <sup>3</sup>Department of Orthopaedic Surgery, Hamamatsu University School of Medicine, Hamamatsu, Japan

**Background:** Rheumatoid arthritis (RA) is a systemic chronic arthritic inflammatory disease that affects daily life and work. Therefore, the treatment goals include subjective indicators such as activities of daily living disorder and fatigue as well as objective indicators such as disease activity<sup>(1)</sup>. In recent years, the progress of RA therapy has been remarkable, and many patients have achieved low disease activity (LDA) or remission; however, one-third of the patients still have a high disease activity. Is it right to adapt all patients to the same subjective evaluation goal?

**Objectives:** We conducted a questionnaire survey in RA patients to evaluate the following factors: 1) RA influence on emotions, 2) RA influence on daily life or work, 3) patient expectations from RA treatment and 5) a comparison of patients' individual assessment of each disease activity.

**Methods:** We included 289 patients with RA and divided them into two groups based on their disease activity: those achieving LDA or remission (R/L group: n=192) and those with moderate or high disease activity (M/H group: n=97). The mean ages of the R/L and M/H groups were 52.3 (18–81) and 56.7 (25–84) years, respectively. The mean disease duration of the R/L and M/H groups were 4.3 years (2 months – 25 years) and 5.6 years (2 months – 31 years), respectively. The survey comprised 19 questions, which had predefined answers about daily activities, relationship with family and friends, emotional wellbeing, expectation from RA treatment effect, and treatment goal-setting.

**Results:** For questions regarding daily activities and emotional wellbeing, there were more negative responses from the M/H group than from the R/L group. Daily activity which conclude housework and outdoor activities were more restricted in the M/H group than in the R/L group. Regarding emotional wellbeing, 63% patients in the M/H group and 32% in the R/L group felt that RA was depriving their happiness. Furthermore, 56% patients in the M/H group and 25% in the R/L group were worried about their independence in the future. Conversely, patients in the M/H group exchanged views about RA symptoms with family and friends more frequently than those in the R/L group; they were seeking psychological stabilisation. There were also differences in both the groups' expectation of the treatment effect. The most and the second expected treatment effects in both groups were pain improvement and in the early stage, respectively. The third most expected treatment effect was being able to do their work at home and outside in the R/L group and clinical symptoms improvement in the M/H group. Morning stiffness was more important than arthritis in the R/L group because a higher goal was set.

Although it would be desirable for medical professionals to set treatment goals for both groups, this tendency was higher in the M/H group.

Abstract AB0222 – Figure 1. Questionnaire results

**Conclusions:** The subjective goals in RA treatment vary depending on disease activity. High social goal-setting is important for patients whose disease activity is controlled. For patients with high disease activity, emotional support from their family and friends and setting goals regarding clinical symptoms by medical professionals are important.

### HAS THE PRESENTATION AND SEVERITY OF RHEUMATOID ARTHRITIS CHANGED IN RECENT DECADES?

E. Chamizo Carmona<sup>1</sup>, C. Carrasco Cubero<sup>2</sup>, S.M. Rojas Herrera<sup>1</sup>, J. Malave Calzada<sup>1</sup>, L.M. Chaves Chaparro<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital Ciudad de Merida, Merida; <sup>2</sup>Rheumatology, CHU Badajoz, Badajoz, Spain

**Background:** In recent decades, there have been social, economic and health changes, also in the treatment of rheumatoid arthritis (RA). The development and severity of RA can be affected by these changes. It is discussed if RA is currently less frequent and severe than before<sup>1</sup>.

**Objectives:** To determine the changes in the clinical and demographic variables and the severity of RA that may have occurred over a period of four decades (from 1980 to 2015) and its repercussion in the response to methotrexate (MTX) monotherapy.

**Methods:** We conducted a retrospective study, reviewing the records of patients from a cohort of RA who received MTX monotherapy and compared the results of demographic and clinical variables by natural decades. The statistical analysis was performed using the Chi2 test and the one-way ANOVA test.

**Results:** We included 301 patients (202 women and 99 men) with a mean age at diagnosis of 49.6 (±13.2) years. The table 1 shows the characteristics of the complete sample and distributed by natural decades. The age at diagnosis was higher after 2000 (p<0.01), while the proportion of women, educational level, sedentary lifestyle, habits (tobacco, alcohol) and comorbidities did not change. There was also no variation in the joint pattern of presentation, percentage of RF/ACPA positive or mean value of RF and ACPA. There was a decrease in time from the onset of symptoms to diagnosis (from 21.7 to 15.3 months) (NS), but especially between the diagnosis and the first DMARD (from 34.5 to 1.4 months) and in the number of FAMES before MTX (p<0.01 for both), as well as in the baseline activity of the disease (PCR and DAS28-PCR), early erosions (<2 years) and extra-articular involvement (p<0.01). There were no changes in the dose of prednisone and MTX, nor in the route of administration, while folic acid supplements increased.

The suspension rate due to toxicity decreased ( $p<0.05$ ), while the clinical remission rate improved ( $p<0.01$ ).

Abstract AB0223 – Table 1

	Global	1980–1990	1991–2000	2001–2010	2011–2015	Valour P
<b>Diagnosis age</b> (years), mean (SD)	49,6 (13,2)	39,4 (11,6)	44,0 (11,0)	52,6 (13,5)	51,6 (11,9)	<0,01
<b>Diagnostic delay</b> (months) mean (SD)	17,2 (27,1)	21,7 (29,8)	21,0 (34,6)	15,7 (26,0)	15,3 (19,2)	NS
<b>Diagnostic-treatment interval</b> (months), mean (SD)	24,0 (38,9)	34,5 (66,8)	11,7 (25,2)	2,7 (7,7)	1,4 (3,2)	<0,01
<b>Extra-articular involvement</b> , n(%)	71 <sup>(23,6)</sup>	12 <sup>(52,2)</sup>	25 <sup>(99,1)</sup>	27 <sup>(18,2)</sup>	7 (10,6)	<0,01
<b>Baseline DAS28-RCP</b> , mean (SD)	4,5 (0,8)	5,2 (0,8)	4,6 (0,8)	4,3 (0,8)	4,3 (0,8)	<0,01
<b>Baseline RCP</b> (mg/l), mean (SD)	17,8 (21,3)	27,8 (28,9)	18,4 (17,8)	18,9 (23,3)	10,9 (13,7)	<0,01
<b>Erosions</b> , n(%)	163 <sup>(55,6)</sup>	20 <sup>(80,9)</sup>	48 <sup>(77,4)</sup>	77 <sup>(53,8)</sup>	18 <sup>(27,3)</sup>	<0,01
<b>MTX weekly</b> (mg), mean (SD)	16,5 (3,7)	16,5 (4,2)	16,6 (3,6)	16,5 (3,7)	16,2 (3,6)	NS
<b>MTX SC way</b> , n(%)	177 <sup>(58,8)</sup>	12 <sup>(52,2)</sup>	37 <sup>(27,8)</sup>	87 <sup>(58,8)</sup>	41 <sup>(62,1)</sup>	NS
<b>Withdrawn by AE</b> , n(%)	52 <sup>(17,3)</sup>	6 (27,3)	18 <sup>(27,7)</sup>	20 <sup>(13,5)</sup>	8 (12,1)	<0,05
<b>Remission</b> , n(%)	100 <sup>(33,2)</sup>	2 (8,7)	14 <sup>(21,9)</sup>	56 <sup>(37,8)</sup>	28 <sup>(42,4)</sup>	<0,01

**Conclusions:** In our cohort, the severity of RA has decreased during the last four decades, the time to start MTX has been reduced and better remission rates with MTX monotherapy have been achieved.

#### AB0224 CERVICAL PROPRIOCEPTIVE IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

F. Ulutatar<sup>1</sup>, M.T. Duruo<sup>2</sup>. <sup>1</sup>PMR Department, <sup>2</sup>PMR Department, Rheumatology Division, Marmara University School of Medicine, Istanbul, Turkey

**Background:** Rheumatoid arthritis (RA) is autoimmune disease that usually involves cervical part of the vertebral column which can cause cervical proprioceptive deficit.

**Objectives:** Assessment of cervical proprioception and its relation with radiographic, clinical and functional characteristics of patients with RA

**Methods:** Rheumatoid arthritis patients who diagnosed according to ACR 2010 criteria and control group with healthy volunteers were recruited in the study. Demographic and clinical parameters were noted. Cervical proprioception was evaluated by Cervical Joint Position Error Test (CJPET). Functional assessment scales that used in this study were Multidimensional Assessment of Fatigue (MAF), Beck Depression Inventory, Health Assessment Questionnaire (HAQ), Euroqol 5D (EQ-5D) and Berg Balance Scale. Cervical subluxations were noted according to cervical radiographic image. The difference in mean scores of CJPET between RA patients and healthy volunteers were analysed with Mann-Whitney U test. Spearman correlation coefficient ( $\rho$ ) was used for correlations between functional parameters. Regression analysis was used for grading factors which had relations with cervical proprioception.

**Results:** One hundred six rheumatoid arthritis patients and one hundred six healthy volunteers were enrolled in this study. Mean age of patients and healthy volunteers were 51,0 (Sd:11,1) and 48,9 (Sd:9,2), respectively. Scores of CJPET are statistically significantly higher in rheumatoid arthritis group than healthy volunteers ( $p=0,001$ ) (table 1). CJPET scores are negatively correlated with Berg Balance Scale results in all directions ( $\rho = -0,421, -0,473, -0,448, -0,515$ ). Scores of CJPET in patients with atlantoaxial subluxations (AAS) were statistically significantly higher than those without AAS ( $p=0,002-0,045$ ). Regression analysis results showed that AAS is related with worse cervical proprioception on right and left rotations. There were no correlation between CJPET scores and functional parameters. Weak correlation were found in scores of CJPET with age and educational status.

**Abstract AB0224 – Table 1.** Comparison of cervical joint position error test scores between rheumatoid arthritis patients and healthy volunteers

	Patients		Healthy Volunteers	P
	Min-Max	Mean±SD	Mean±SD	
<b>CJPET- Right Rotation</b> <sup>1-6</sup>	1,66–6,00	4,55±1,30	3,03±0,81	0001
<b>CJPET- Left Rotation</b> <sup>1-6</sup>	1,50–6,00	4,52±1,37	3,07±0,95	0001
<b>CJPET- Flexion</b> <sup>1-6</sup>	1,00–6,00	4,52±1,36	2,98±0,89	0001
<b>CJPET- Extension</b> <sup>1-6</sup>	1,50–6,00	4,57±1,29	3,00±0,93	0001

CJPET: Cervical Joint Position Error Test, SD: Standard Deviation,  $p<0,05$  is significant

**Conclusions:** Cervical proprioception is impaired in rheumatoid arthritis patients. This impairment is increased with the existence of atlantoaxial subluxations and balance problems.

**Background:** There is evidence that autoimmunity, namely RF and ACPA antibodies, may influence disease activities and impact the clinical outcomes in RA.

**Objectives:** There is evidence that autoimmunity, namely RF and ACPA antibodies, may influence disease activities and impact the clinical outcomes in RA.

**Methods:** We analysed longitudinal data of consecutive RA patients from the Italian registry GISEA, starting a treatment with golimumab (GOL) and tested for rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA). Demographic and disease related characteristics were collected at baseline, 6 months, 12, and 24 months or at last observation visit. Primary endpoint was the persistence on GOL in RF/ACPA +ve and RF/ACPA -ve patients. Secondary endpoint was the search of baseline predictors of drug survival and clinical outcomes in the two RA subsets. Drug survival was evaluated by Kaplan-Meier life table analysis. Estimates hazard ratios (HRs, 95% confidence intervals (CI)) of drug discontinuation or achievement of low-disease adjusted for patient's demographics, disease characteristics and prior biologic treatments were computed by Cox-regression stepwise backward models.

**Results:** 345 patients had data on RA and ACP testing and were included in this analysis. No significant difference in terms of age, BMI, disease activity, co-therapy with glucocorticoids or methotrexate (MTX) was detected between RF/ACPA+ve and RF/ACPA-ve patients, but the former had significantly higher disease duration (10.6±vs 8.2±6 years) and frequencies of comorbidities (60.6% vs 44.2%). The 2 years global drug retention was 64.5%, and it was almost identical in RF/ACPA+ve 64.2% and in RF/ACPA-ve 65% RA patients. Drug survival was not influenced by the gender or cause of discontinuation (adverse or inefficacy). To note, in 31% of the patients GOL was not associated to MTX.

The only predictor of drug discontinuation was the lack of MTX at baseline (HR 1.62, 95 CI 1.07–2.46,  $p=0.02$ ), and the GOL-naïve status (HR 0.62, 95 CI 0.39–0.99,  $p=0.04$ ). At two years, 44.4% achieved the state of low-disease activity (DAS28 <3.2) with no difference between RF/ACPA+ve (45.4%) and RF/ACPA-ve (42.0%) patients, and none baseline factor correlating with low disease activity. No safety issues were raised during the study.

**Conclusions:** In this study, we demonstrated that RF/ACPA positivity does not negatively impact on drug survival on golimumab. This may aid rheumatologists in their clinical decisions.

**Disclosure of Interest:** None declared

**AB0226** **DECLINE IN ANTI-CCP AND RHEUMATOID FACTOR LEVELS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS AFTER 2 YEARS OF TREATMENT WITH INTENSIVE COMBINATION STRATEGIES, INCLUDING PREDNISOLONE: THE COBRA-LIGHT TRIAL**

H.D. Folmo<sup>1</sup>, M.M. ter Wee<sup>1,2</sup>, D. den Uyl<sup>1</sup>, N.P. Konijn<sup>1</sup>, P.J. Kerstens<sup>3,4</sup>, A. E. Voskuy<sup>1</sup>, D. van Schaardenburg<sup>3,5</sup>, M.T. Nurmohamed<sup>1,3</sup>, M. Boers<sup>1,2</sup>, W. F. Lems<sup>1,3</sup>. <sup>1</sup>Department of Rheumatology, Amsterdam Rheumatology and Immunology Center; <sup>2</sup>Department of Epidemiology and Biostatistics, VU University Medical Center; <sup>3</sup>Department of Rheumatology, Amsterdam Rheumatology and Immunology Center, Reade, Amsterdam; <sup>4</sup>Department of Rheumatology, Westfriesgasthuis, Hoor; <sup>5</sup>Department of Rheumatology, Amsterdam Rheumatology and Immunology Center, Academic Medical Center, Amsterdam, Netherlands

**Background:** Previous studies have proven that the COBRA-light strategy has similar effectiveness and safety as the COBRA strategy in treating early rheumatoid arthritis (RA) patients<sup>1,2</sup>. However, the effect of these strategies on anti-cyclic citrullinated peptide (anti-CCP) and rheumatoid factor (RF) levels remains contradictory.

**Objectives:** To investigate whether levels of anti-CCP and RF have changed after 2 years of treatment with COBRA or COBRA-light strategy.

**Methods:** A total of 162 early RA patients were included in a randomised, open-label, multicenter trial and treated with either COBRA or COBRA-light strategy. After 1 year, the treatment protocol ended, and physicians continued treatment according to clinical judgment, aiming at clinical remission. Log-transformation was first performed before running any analyses in case of skewed distribution, and analyses were performed with Generalised Estimated Equations to evaluate the association between the medication strategies and the change of LN anti-CCP and LN RF levels on average over time.

**Results:** Over 2 years' time, median anti-CCP and RF levels decreased significantly in COBRA (6%, and 24% respectively) and COBRA-light (4%, and 13%, respectively; table 1). Of the 102 anti-CCP positive patients at baseline, 10 (10%) became anti-CCP negative during treatment (5 COBRA vs. 5 COBRA-light). No significant difference between the two treatment strategies on the change of anti-CCP and RF levels over 2 years' time was found. Additionally, a significant association between baseline DAS44 and remaining anti-CCP positive over time was found (OR=1.8; 95% CI: 1.2–2.8).

**Abstract AB0226 – Table 1.** Change in anti-CCP and IgM-RF levels over time

	Baseline	Week 52	Absolute median change	Percentage median change	Week 104	Absolute median change	Percentage median change
<b>COBRA</b>							
Anti-CCP	143 (8-1182)	81 (7-710)	-20 (-427-0)	-14	109 (7-507)	-9 (-314-0)	-6
IgM-RF	37 (6-102)	9 (6-40)	-9 (-41-0)	-24	8 (5-48)	-9 (-36-0)	-24
<b>COBRA-light</b>							
Anti-CCP	229 (10-941)	80 (7-499)	-13 (-249-0)	-6	32 (7-402)	-9 (-233-0)	-4
IgM-RF	40 (10-112)	12 (6-50)	-13 (-79-0)	-38	12 (6-84)	-5 (-48-1)	-13

Data are expressed as median (IQR) as well as percentage median change from baseline. Anti-CCP, anti-cyclic citrullinated peptide; IgM-RF, rheumatoid factor type IgM.

**Conclusions:** Both COBRA and COBRA-light strategies lead to substantial decreases in anti-CCP and RF levels over 2 years of treatment. Patients with a higher DAS44 at baseline have higher odds of being anti-CCP positive over 2 years' time.

**AB0227** **TRANSCRIPTIONAL PROFILING OF SYNOVIAL MACROPHAGES USING MINIMALLY INVASIVE ULTRASOUND-GUIDED SYNOVIAL BIOPSIES IN RHEUMATOID ARTHRITIS**

H. Perlman, on behalf of Rheumatoid Arthritis Synovial Tissue Network (REASON). *Medicine/Rheumatology, Northwestern University, Chicago, USA*

**Background:** Despite the many therapies for patients with rheumatoid arthritis (RA), there is little information to guide selection of the most effective treatment for an individual patient. Forty-six percent of patients with RA respond (defined by ACR50 response criteria) to conventional disease modifying anti-rheumatic drugs (cDMARDs) or cDMARDs plus anti-tumour necrosis factor (TNF) therapy. Moreover, 20%–40% of subjects in clinical trials never demonstrate even a minimal response (ACR20 response criteria). Based on a population of over 300 million in the United States, a disease prevalence of 0.6%, and a course of 3–4 months per biologic DMARD therapy, as much as \$2.5 billion is wasted annually on inadequate therapy. There is a clear need to develop precision-based therapy for patients with RA, whereby clinical information such as novel biomarkers will enhance our ability to predict the therapeutic response and thereby limit ineffective therapy.

**Objectives:** Currently, there are no reliable biomarkers for predicting therapeutic response in patients with rheumatoid arthritis (RA). The synovium may unlock critical information for determining efficacy as reduction in numbers of sublining synovial macrophages remains the most reproducible biomarker. Thus, a clinically actionable method for collection of synovial tissue, which can be analysed using high-throughput strategies, must become a reality.

**Methods:** Rheumatologists at six United States academic sites were trained in minimally invasive ultrasound-guided synovial tissue biopsy. Histology, fluorescence-activated cell sorting and RNA-seq were performed on biopsy synovial tissue from patients with RA and compared with osteoarthritis (OA) samples. An optimised protocol for digesting synovial tissue was developed to generate high quality RNA-seq libraries from isolated macrophage populations. Associations were determined between macrophage transcriptional profiles and clinical parameters of RA patients.

**Results:** Patients with RA reported minimal adverse effects in response to synovial biopsy. Comparable RNA quality was observed between synovial tissue and isolated macrophages from patients with RA and OA. Whole tissue samples from patients with RA demonstrated a high degree of transcriptional heterogeneity. In contrast, the transcriptional profile of isolated RA synovial macrophages highlighted a subpopulation of patients and identified six novel transcriptional modules that were associated with disease activity and therapy.

**Conclusions:** Performance of synovial tissue biopsies by rheumatologists in the United States is feasible and generates high-quality samples for research. By utilising cutting-edge technologies on synovial biopsies with corresponding clinical information, a precision-based medicine approach for patients with RA is attainable.

**AB0228** **INCREASE IN GLOBAL DNA METHYLATION AT 3 MONTHS OF METHOTREXATE USE IS NOT ASSOCIATED TO RESPONSE IN EARLY RA PATIENTS**

H.R. Gossell<sup>1</sup>, M.C. de Rotte<sup>1</sup>, J.M. Hazes<sup>2</sup>, R. de Jonge<sup>3</sup>, S.G. Heil<sup>1</sup>. <sup>1</sup>Clinical Chemistry; <sup>2</sup>Rheumatology, Erasmus Medical Center, Rotterdam; <sup>3</sup>Clinical Chemistry, VU Medical Center, Amsterdam, Netherlands

**Background:** Methotrexate (MTX) is a first-line therapy in early Rheumatoid Arthritis (eRA). Still, up to 40% of treated patients do not adequately respond to MTX. MTX interferes with the folate cycle, where it indirectly inhibits the global DNA methylation donor S-adenosylmethionine (SAM). Thus, we hypothesised that global DNA methylation changes during MTX use are associated with treatment response.

**Objectives:** To examine whether there is a change in global DNA methylation ( $\Delta\%$ Meth) upon MTX use and if this change is associated to MTX response ( $\Delta$ DAS28) in eRA patients.

**Methods:** DNA was isolated from whole blood (n=120) and Peripheral Blood Mononuclear Cells (PBMCs, n=83) of eRA patients, before and 3 months after MTX use. Samples were collected from the Treatment in the Rotterdam Early Arthritis Cohort (tREACH), a multicenter, stratified single-blind clinical trial of eRA patients. Selected patients received triple (MTX +SSZ + HCQ) or monotherapy (MTX) combined with corticosteroids. 7 CpG sites within Long-Interspersed Nuclear Elements (LINE-1), a proxy for global DNA methylation, were quantified by Sequenom Epityper. Paired t-tests or Wilcoxon Signed Rank tests were conducted to assess a change in methylation.  $\Delta$ DAS28 score over 3 months was used as a measure for response. Associations between  $\Delta$ DAS28 and  $\Delta\%$ Meth were corrected for baseline DAS28 in a linear regression model.

**Results:** In leukocytes, %Meth did not significantly change over time. However, in PBMCs %Meth in CpG1 ( $\Delta$ Meth=2.61%,  $p=0.008$ ), CpG2 ( $\Delta$ Meth=0.73%,  $p=0.039$ ) and CpG11.12 ( $\Delta$ Meth=0.56%,  $p=0.016$ ) significantly increased over 3 months of MTX use after Bonferroni correction.  $\Delta$ %Meth in CpG8.9 was significantly associated to the  $\Delta$ DAS28 ( $B=0.29$ ,  $p=0.039$ ), yet this was no longer significant after Bonferroni correction.  $\Delta$ %Meth was not significantly associated to  $\Delta$ DAS28 in any of the other LINE1 CpG sites tested.

**Conclusions:** PBMC global DNA methylation in LINE-1 CpG sites increased upon 3 months of MTX use. However, this change in methylation is not associated to MTX response. Further research is needed to investigate the role of global DNA methylation in these patients.

**Disclosure of Interest:** None declared

AB0229

#### WHAT WARRANT COMPREHENSIVE DISEASE REMISSION (CDR) AT LONG TERM? – PROBABILITY OF DAS28-CRP REMISSION AT SIX MONTHS –

I. Yoshii. *Rheumatology and Musculoskeletal Medicine, Yoshii Hospital, Shimanto City, Japan*

**Background:** Comprehensive disease remission (CDR) for rheumatoid arthritis (RA) patient is an ultimate challenge in treatment. Several reports suggested initial treatment is essential for attaining CDR, what means it is necessary to indicate clinical remission in the first treatment year.

**Objectives:** Aim of this study is to clarify how initial treatment until 6 months affect on CDR fulfilment, and whether patient's basic background influences.

**Methods:** We have 441 RA patients who had been treated consecutively for more than four years. These patients were recruited. Parameters such as 28-joints disease activity score with C-reactive protein (DAS28-CRP), modified Health Assessment Questionnaire Disability Index (mHAQ), pain score with visual analogue scale (PS-VAS), were monitored at every visit since first time. Sharp/van der Heijde Score (SHS) was calculated at first visit and every another year period. Average value of DAS28-CRP, mHAQ in fourth treatment year, and average progression of SHS per year (dSHS) were used to make judgment for CDR at fourth year, whether DAS28-CRP less than 2.3, mHAQ less than 0.5, and dSHS less than 0.5. Fulfilment of CDR is evaluated for patient's age, DAS28-CRP, mHAQ, SvdHS, and PS-VAS at first visit and sixth month was evaluated statistically with binary logistic regression analysis (BLR). Patient's background data at first visit were also evaluated in the same manner. For the significant factors, relationship with the background data was also evaluated with multivariate linear regression analysis (MLR). Statistical significance in both analyses was set below 5%. Receiver operating characteristic curve analysis (ROC) was also implicated for the significant factors.

**Results:** Because of lacking data, 310 patients were analysed. 146 (47.1%) of them had fulfilled CDR at fourth treatment year. Statistically significant factor for fulfilling CDR was mHAQ at first visit (odds ratio; 0.032, 95% CI; 0.008–0.139) and DAS28-CRP at sixth months (odds ratio; 0.273, 95% CI; 0.112–0.662). The mHAQ score at first visit correlated significantly with age at onset and first visit, patient's global assessment (PGA), CRP, and PS-VAS at first visit, whereas the DAS28-CRP score at sixth month correlated significantly with being male, tenderness joint count (TJC), physician's global assessment (EGA), CRP, and PS-VAS at first visit, and less reduction of TJC, swollen joint count (SJC), EGA, and CRP. Cut off point for each factor was 0 for mHAQ with 100% in sensitivity and 73.5% in specificity, whereas 1.105 for DAS28-CRP with 100% in sensitivity and 55.2% in specificity, which were used with ROC analysis.

**Conclusions:** These results suggest that treatment with treat-to-target (T2T) strategy, that aims clinical remission in three to six months from starting treatment, is available for attaining CDR. However, T2T is not enough for sustaining CDR in a long term. In order to fulfil and sustain CDR, basic background of the patient, such as age at onset and PGA, CRP, and PS-VAS, and age at first consult, is important factor. Therefore, CDR is not ultimate target at all for every RA patient

#### AN EFFECT OF DAS28 AND PS-VAS ON HAQ-DI SCORE IN RHEUMATOID ARTHRITIS PATIENT

I. Yoshii. *Rheumatology and Musculoskeletal Medicine, Yoshii Hospital, Shimanto City, Japan*

**Background:** Pain Score with visual analogue scale (PS-VAS) influences on Health Assessment Questionnaire Disease Index (HAQ-DI) in rheumatoid arthritis (RA) patient, as well as 28-joints disease activity score with C-reactive protein (DAS28-CRP). It is also suggested that these two indices have closely correlated and therefore have overlapping effect on HAQ-DI. However, the relationship of these indices for each other is still unclear.

**Objectives:** Our aim is to clarify what affects most out of the overlap, and what would make influence on when dissociation between the two occurs.

**Methods:** We have treated 549 RA patients consecutively more than four years. Their HAQ-DI, every component of DAS28-CRP, physician's global assessment (EGA), PS-VAS, and Sharp/van der Heijde Score (SHS) were monitored every 3 months. From these patients studies concerning relationship between the parameters were investigated as follows:<sup>1</sup> The relationship between average DAS28-CRP and average PS-VAS after the third year period was calculated using multivariate linear regression analysis (MLR).<sup>2</sup> Then residuals of the each parameter from the approximate equation of MLR were calculated. From these residuals, correlation between residual of DAS28-CRP and disease duration (DD), HAQ-DI, age, SHS, physician's global assessment (EGA), number of comorbidities in throughout treatment (Com) was evaluated with MLR.<sup>3</sup> Correlation between residual of PS-VAS and DD, HAQ-DI, age, SHS, EGA, and Com was evaluated with MLR.<sup>4</sup> Correlation between average HAQ-DI and the residuals, patient's DD, age, SHS, EGA, and Com, was evaluated with MLR. In these analyses, statistical significance between parameters were evaluated statistically. Statistical significance was set lower than 1%.

**Results:** Because of lacking of data, sixty-one cases had discarded, and then 488 cases had been analysed in this study.<sup>1</sup> The approximate equation of the relation between DAS28-CRP and PS-VAS was "DAS28-CRP=1.543+0.1565 \* PS-VAS" (R; 0.5050, Intercept;  $p=0$ , PS-VAS;  $p=0$ ) and "PS-VAS=-0.6528+1.63 \* DAS28-CRP" (R; 0.5050, Intercept;  $p=1.071*10^{-2}$ , PS-VAS;  $p=0$ ).<sup>2</sup> Correlation coefficients of the approximate equation of the correlation between residuals of DAS28-CRP and the other parameters was 0.6398. Parameters that demonstrated within 1% of statistical significance were EGA ( $p=0$ ), SHS ( $p=2.962*10^{-6}$ ), and Com ( $p=1.971*10^{-5}$ ).<sup>3</sup> Correlation coefficients of the approximate equation of the correlation between residuals of PS-VAS and the other parameters was 0.4856. Parameters that demonstrated within 1% of statistical significance were Com ( $p=9.38*10^{-1}$ ), HAQ-DI ( $p=5.738*10^{-9}$ ), and SHS ( $p=1.594*10^{-7}$ ).<sup>4</sup> Correlation coefficients of the approximate equation of the correlation between HAQ-DI and residuals of DAS28-CRP and PS-VAS, and DD, age, SHS, EGA, and Com, was 0.5848. Parameters that demonstrated within 1% of statistical significance were residual of DAS28-CRP ( $p=1.256*10^{-6}$ ), residual of PS-VAS ( $p=3.711*10^{-14}$ ), SHS ( $p=7.73*10^{-4}$ ), and age ( $p=2.389*10^{-10}$ ).

**Conclusions:** These results suggest that the influence of DAS28-CRP and PS-VAS on the HAQ-DI score works in commonly overlapped. However, residual (the independent part) of DAS28-CRP from PS-VAS on HAQ-DI is not statistically evident. Residual of PS-VAS affects on the HAQ-DI score. SHS and Com affect on both of residuals. The HAQ-DI score is influenced by both of common and independent part of DAS28-CRP and PS-VAS, and SHS and age.

AB0231

#### HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX SCORE LESS THAN 0.5 IS NO LONGER TARGET FOR REMISSION IN ELDERLY RHEUMATOID ARTHRITIS PATIENT, BUT IT IS INDEPENDENT FROM COMORBIDITIES

I. Yoshii<sup>1</sup>, T. Chijiwa<sup>2</sup>. <sup>1</sup>Rheumatology and Musculoskeletal Medicine, Yoshii Hospital, Shimanto City; <sup>2</sup>Rheumatology, Kochi Memorial Hospital, Kochi, Japan

**Background:** It is well known fact that ageing makes deep influence on Health Assessment Questionnaire (HAQ-DI) score in normalised population. We have suggested that it is also available in rheumatoid arthritis (RA) patient.<sup>1</sup> However, the effect of ageing on the HAQ score is thought to be due to comorbidities.

**Objectives:** The aim of this study is to investigate the impact of ageing on the HAQ score statistically and to evaluate the correlation between the HAQ score and age.

**Methods:** We have been treated 516 RA patient for more than 3 years. Patient's Age, HAQ-DI score, 28-joints disease activity score with C-reactive protein (DAS28), Sharp/van der Heijde Score (SvdHS), pain score measured with visual analogue score (PS) were monitored at every another year since first consult (BL). Relationship between HAQ-DI and the other parameters including number of comorbidities (Com) at BL and last observational year period (FU), and their changes from BL to FU were evaluated statistically with multivariate linear regression analysis (MLR). After correction that aimed to minimise effects on the HAQ score of other parameters but age, relationship between the HAQ score and age was also evaluated with MLR. Relationship between age and Com was also evaluated with MLR statistically. Statistical significant level was set within 5%.

**Results:** After exclusion of cases that lacked data, 441 patients have been analysed for this study. Their average ages at onset, BL, and FU were 60.4, 65.1, and 70.9 years, respectively, and average follow-up term was 5.76 years. Woman's ratio was 75.6%, and their anti-citrullinated cyclic peptide antibodies positive ratio was 77.2%.

At BL, correlation coefficient of the equation (the R-value) in MLR was 0.6251. Factors that demonstrated significant correlation with the HAQ score were PS,

age, and DAS28, and their correlation coefficients (CC) were 0.00004174, 0.01943, and 0.02941, respectively.

At FU, the R-value of the equation in MLR was 0.6309. Factors that demonstrated significant correlation with the HAQ score were age, Com, PS, and SvdHS, and their CCs were 0.00007042, 0.0004365, and 0.002886, 0.02354, respectively.

The R-value of the change of the HAQ score correlation equation demonstrated 0.4755. Factors that demonstrated significant correlation with change of the HAQ score were changes of DAS28-CRP, PS, age, and Com, and their CCs were 0.002703, 0.003750, 0.003480, and 0.009886.

Correlation procedure needed elimination of the case whose average DAS28 exceeded 2.6, SvdHS exceeded 100, and PS exceeded 20 mm. After correction, patients have been limited to 158. However, age demonstrated significant correlation with the HAQ score, and its CC was 0.00004439, and the constant of age was 0.01132. After correction, Com demonstrated no significant correlation with the HAQ score.

Com demonstrated significant correlation with age with 0.01253 for CC. However, the R-value of the equation was 0.1982.

**Conclusions:** These results suggested that age have deep influence on the HAQ score. Com also affects on the HAQ score, however, Com and ageing is independent factor for each other. Therefore effect of ageing on the HAQ score is concluded independent. The HAQ score increases its standard value for approximately 0.01 as age increase one.

#### AB0232 DISEASE ACTIVITY STATE IN PATIENTS WITH RHEUMATOID ARTHRITIS INCLUDED IN THE BIOBADABRASIL REGISTRY

*I.M.M. Laurindo, M. Pinheiro, J. Macieira, A. Duarte, B. Kahlow, R. Ranza, J. Miranda, M. Bertolo, V. Valim, G. Castro, M.D.F. Lobato, D. Titton, R. Teodoro, J. Moraes, C. Brenol, I. Costa, V. Fernandes, H. Carvalho, I. Pereira, W. Bianchi, A. Hayata, P. Louzada, A. Kakehasi, R. Toledo, G. Castelar, I. Silva, A. Ranzoline, G. Christopoulos, on behalf of BIOBADABRASIL. Brazilian Register of Biological Agents in Rheumatic Diseases, São Paulo, Brazil*

**Objectives:** to analyse disease activity of RA patients at the start of treatment with a biologic agent (adalimumab, infliximab, certolizumab, etanercept, golimumab, abatacept, rituximab and tocilizumab -bDMARDs), target (tofacitinib-tsDMARDs) therapy or conventional DMARDs (comparison cohort of RA patients – csDMARDs).

**Methods:** BiobadaBrasil is a prospective observational cohort study, part of an international initiative (biobadaAmerica) in collaboration with BiobadaSeR; established in 2009, is an ongoing study supported by the Brazilian Society of Rheumatology (29 public centres located at academic institutions and 2 in private practice) focused on the study of adverse events in patients on biologic therapy. Additionally, by decision of its investigators, disease activity scores were also recorded at the beginning of each treatment. Sex, age, disease duration, RA -DAS-28, concomitant treatments at baseline were collected. Results expressed in mean  $\pm$ SD, % (n)

**Results:** -Data from 1984 RA patients (67% on tsbDMARDs) were analysed: 86% of the patients were women; mean age=56.6 $\pm$ 14.95 years; disease duration=14.4 $\pm$ 9.42; 87% RF positive. There were 3802 treatment courses, 67% with aTNF (Adalimumab-ADA, Certolizumab-CTZ, Etanercept-ETA, Golimumab-GOL, Infliximab-INFL), 33% non-aTNF (Abatacept-ABA, Rituximab-RIT, Tocilizumab-TCL) including Tofacitinib-TOF. The table 1 below depicted the medications prescribed at the initiation of a new treatment course:

**Abstract AB0232 – Table 1**

n courses	ADA (855)	CTZ (85)	ETA (708)	GOL (113)	INFL (772)	ABA (163)	RIT (184)	TCL (192)	TOF (70)	cDMARDs (660)
DAS28	5.1	4.9	5.1	4.9	5.3	5.3	5.3	5.4	5.3	5.2 $\pm$ 2.8
	$\pm$ 1.6	$\pm$ 1.5	$\pm$ 1.6	$\pm$ 1.7*	$\pm$ 1.6	$\pm$ 1.4	$\pm$ 1.6	$\pm$ 1.4*	$\pm$ 1.3	
CE (%)	58	76	60	61	58	68	74	71	83	78
MTX (%)	55	57	53	56	59	54	51	62	49	83
LFN (%)	27	42	27	31	23	31	25	18	27	45
Chlor (%)	14	15	11	10	15	11	19	17	11	30

Considering the more recent medications patients beginning TCL have more active disease than the ones beginning GOL and CTZ ( $p < 0.006$ ); anti-TNF are prescribed in association with MTX in less than 60% of the treatments. Extensive use of corticosteroids was identified besides consistent use of leflunomide and of hydroxychloroquine. Starting of new treatments was related to moderate/high levels of disease activity.

**Conclusions:** patterns of bDMARDs, csDMARDs and corticosteroid use clearly surfaced. Possibilities of improvement can be addressed.

#### AB0233 CLINICAL AND FUNCTIONAL EFFICIENCY OF LARGE JOINTS REPLACEMENT IN PATIENTS WITH HIGH ACTIVITY OF RHEUMATOID ARTHRITIS

*I. Akhtyamov<sup>1</sup>, S. Lapshina<sup>1</sup>, S. Ardashev<sup>2</sup>, I. Gilmutdinov<sup>2</sup>, L. Myasoutova<sup>3</sup>. <sup>1</sup>49 Butlerov street, Kazan State Medical University; <sup>2</sup>Republic Clinical Hospital; <sup>3</sup>Clinical Hospital # 7, Kazan, Russian Federation*

**Background:** The synovium in rheumatoid arthritis (RA) produces a variety of cytokines that cause the destruction of articular cartilage, determining, in some cases, the need for replacement of the joint. Inflammatory substrate within the joint can be a source of high activity of RA. At the same time usually patients are taken to surgery only in the period of minimal activity of the disease.

**Objectives:** To evaluate the results of knee and hip joints replacement in patients with high RA activity and the quality of life of patients during the first year after the operation.

**Methods:** Replacement of knee and hip joints was performed in 36 patients (mean age 55.8 $\pm$ 9.4 years) with high RA activity DAS28 (mean 5.53 $\pm$ 0.67). At the time of surgery, the duration of the disease was 11.86 $\pm$ 4.92 years, RF positive in 27 (75%) pts. At baseline, 30 (83.3%) patients were treated with DMARDs (methotrexate-25 (69.4%), leflunomide-3 (8.3%), sulfasalazine 2 (5.6%), steroids (prednisolone in an average dose of 4.2 $\pm$ 4.3 mg per day) – 16 (44.4%) people, of whom, in combination with DMARDs – 8 (22.2%). The volume of therapy did not change after the operation. Biologics (infliximab, adalimumab, rituximab, etanercept) before surgery were given to 7 (19.4%) patients. Before the operation, after it, after 6 and 12 months, pain in the joints (VAS), activity of the disease – DAS28, functional capacity by the HAQ index was estimated.

**Results:** Reduction of VAS was observed already in the first month after surgery (47.3 $\pm$ 18.6 mm), initially it was 72.6 $\pm$ 14.2 mm, after 6 months it decreased 1.5 times to 48.7 $\pm$ 11, 2 mm ( $p < 0.05$ ), after 12 months – up to 29.8 $\pm$ 10.3 mm ( $p < 0.05$ ). After 6 months after surgery, the activity of the disease decreased reliably ( $p < 0.05$ ) with DAS28 from 5.53 $\pm$ 0.67 to 3.84 $\pm$ 0.56; to 12 months DAS28-3.24 $\pm$ 0.61. Positive dynamics of functional ability was recorded according to the HAQ index: 1.74 $\pm$ 0.25 before the operation, 1.64 $\pm$ 0.28 in a month after, and 1.22 $\pm$ 0.28 after 6 months ( $p < 0.05$ ), after 1 year – 1.03 $\pm$ 0.18 ( $p < 0.05$ ).

Complications after operations were not recorded.

**Conclusions:** Joints replacement in patients with high RA activity can be justified and effective in improving the functional ability and pain relief. Removal of pathologically altered joint tissues helps to reduce the activity of RA as a whole.

#### AB0234 PATIENT'S EXPECTATIONS ABOUT SURGERY FOR THE RHEUMATOID FOREFOOT DEFORMITY

*I. Sung, J. Lee, T. Kim, S. Kim. Hanyang University Medical Center, Seoul, Korea, Republic of Ireland*

**Background:** Forefoot deformity has been a common problem in rheumatoid patients, often demanding surgery. Typical deformities include hallux valgus and deformity of lesser metatarsophalangeal joints (MTPJ) and toes. Patient's satisfaction has not been well dealt in the literature as most studies have focused on radiological and clinical parameters following surgical treatment.

**Objectives:** to assess preoperative patient's expectations and postoperative satisfaction, and also factors (e.g. fulfilment of expectations, radiological parameters, and clinical outcomes) that could affect on postoperative satisfaction following first MTPJ arthrodesis and lesser toe resection arthroplasty in patients with rheumatoid forefoot deformity

**Methods:** 40 patients who underwent first MTPJ arthrodesis on great toe and resection arthroplasty for all less toes were enrolled. Clinical and radiological outcomes were investigated retrospectively. Preoperative primary expectations for surgery were questioned and fulfilment of expectation was assessed by 5-point

ordinal scale. Overall subjective satisfaction, radiological improvements, AOFAS forefoot score, and subjective Foot function index were also assessed. Correlation between overall satisfaction after surgery and above other factors was performed. Statistical analysis was done using SPSS and Spearman's rho rank correlation test was performed to analyse the correlation between factors.

**Results:** Mean follow-up was 38 months (range; 24–54). For preoperative expectations, 30 (75%) patients considered improvement in pain as the most important parameter and improvements in shoe wearable and gross appearance were expected in 7 (17.5%) and 3 (7.5%) patients, respectively. Fulfilment of expectations assessed showed very satisfied in 14 (35%), satisfied in 20 (50%), average in 5 (12.5%) and disappointed in 1 (2.5%) for great toe, and those regarding lesser toe showed very satisfied in 15 (37.5%), satisfied in 18 (45%), average in 6 (15%) and disappointed in 1 (2.5%), respectively. For overall postoperative satisfaction assessment, 16 patients (40%) were excellent while 16 (40%) were good, 6 (15%) fair, and 2 (5%) poor. AOFAS hallux and lesser toe score were 69.7 ±11.71 and 70.7±12.26, respectively. Foot function index was 20.5±12.07 at final follow-up. Preoperative and postoperative hallux valgus angle were 45.6° ±10.55 and 17.4°±5.13, respectively. Those of 1–2 intermetatarsal angle were 14.2°±3.84 and 8.4°±3.72, respectively. Correlation analysis showed that significant factors that affected on overall satisfaction were fulfilment of expectation on the great toe (Spearman's rho=0.842, p<0.001) and that of lesser toe, and AOFAS score. Radiological degree and improvement in HVA and IMA were not significantly associated with patient's satisfaction.

**Conclusions:** Expectations from surgery on rheumatoid forefoot deformity were improvement in pain as the most common parameter, improvements in shoe wearable and gross appearance. Fulfilment of patients' expectations on the great toe as well as on the lesser toe significantly affected on postoperative satisfaction. Careful counselling for patients' expectations and corresponding fulfilment should be performed before performing reconstructive surgery for rheumatoid forefoot deformity.

AB0235

#### POLYMORPHISMS OF HLA-DRB1 AND TNF-308 G/A ARE ASSOCIATED WITH RADIOGRAPHIC JOINT DESTRUCTION IN PATIENTS WITH VERY EARLY RHEUMATOID ARTHRITIS

I. Guseva<sup>1</sup>, A. Smirnov<sup>1</sup>, N. Demidova<sup>1</sup>, M. Krylov<sup>1</sup>, A. Avdeeva<sup>1</sup>, E. Samarkina<sup>1</sup>, E. Luchikhina<sup>2</sup>, E. Karateev<sup>2</sup>, D. Abramov<sup>3</sup>, E. Nasonov<sup>1</sup>. <sup>1</sup>V.A. Nasonova Research Institute of Rheumatology; <sup>2</sup>Moscow Regional Research and Clinical Institute; <sup>3</sup>Institute of Immunology FMBA, Moscow, Russian Federation

**Objectives:** To clarify the association between HLA-DRB1 and TNF $\alpha$  (–308G>A) genes polymorphism and joint destruction/further progression during 12 months of the follow-up period (FUP) in patients with early (<6 months), active, predominantly ACPA and RF-positive RA treated according to "Treat to target" strategy.

**Methods:** The study included 85 patients with early RA and duration of symptoms <6 months. RA diagnosis was established according to ACR<sup>EULAR 2010</sup> criteria. All patients were initially assigned to subcutaneous methotrexate (MTX) with rapid dose escalation to 20–25 mg/week. Combination MTX+biological therapy, mainly adalimumab, was used when MTX was ineffective. Joint destruction was assessed by Sharp-Van der Heijde modification scoring method at baseline and after 12 months FUP. Real time polymerase chain reaction (PCR-RT) was used for TNF $\alpha$  gene polymorphism (–308G>A) genotyping. Low resolution PCR-RT with subsequent sequence-based typing of \*04 were performed to study HLA-DRB1 gene polymorphism. The HLA-DRB1\*01, \*04:01, \*04:04, \*04:05, \*04:08, \*10 alleles were categorised as SE+ (Shared Epitope) alleles.

**Results:** It was revealed that the number of erosions and joint space narrowings as well as the total Sharpe score were not associated with the presence and the dose of the SE alleles, either at baseline or after 12 months FUP. However, the progression of joint destruction, assessed as the change ( $\Delta$ ) in the number of erosions, joint space narrowings and the total score, was statistically significantly associated with HLA-DRB1\*(SE) genotypes: the carriers of SE (SE+/SE+) double-dose had more advanced progression as compared to (SE+/SE-)/(SE-/SE-) carriers (p<0,028, p<0,019, p<0,035, respectively). As for TNF $\alpha$  gene polymorphism, it was demonstrated that the number of narrowings and total Sharp score values were almost twice as high at baseline in GG genotype carriers as

compared to GA genotype carriers (69,0<sup>49,5; 98,0</sup> and 37,0<sup>29,0; 63,0</sup> respectively, p<0,005) and (72,0<sup>49,5; 98,5</sup> and 37,0, <sup>29,0; 63,0</sup> respectively, p<0,004). Similar association was found after 12mo FUP, however, it should be mentioned that further progression of joint space narrowing and total Sharpe score was minimal (p>0,05).

**Conclusions:** Our data suggest that HLA-DRB1 (SE+) gene polymorphism is associated with the progression of radiographic joint destruction at 12mo FUP in treated pts. Meanwhile TNF $\alpha$  (–308G>A) polymorphism is associated with more pronounced joint destruction at baseline in terms of joint space narrowing and total Sharp score, but without further progression of joint destruction at 12mo in early and active RA pts managed according to "Treat to target" strategy.

#### DEVELOPMENT AND VALIDATION OF A SENSITIVE LC-MS/MS-BASED METHOD FOR ANALYSIS OF ENZYMIC ACTIVITY OF FOLYLPOLYGLUTAMATE SYNTHETASE AND METHOTREXATE POLYGLUTAMATES IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF RHEUMATOID ARTHRITIS PATIENTS

I.B. Muller<sup>1</sup>, P. Heydari<sup>1</sup>, M. Lin<sup>1</sup>, E.A. Struys<sup>1</sup>, R. Hebing<sup>2</sup>, C.J. van der Laken<sup>3</sup>, D. van Schaardenburg<sup>2</sup>, M.T. Nurmohamed<sup>2,3</sup>, W.F. Lems<sup>3</sup>, J. Cloos<sup>4</sup>, G. Jansen<sup>3</sup>, R. de Jonge<sup>1</sup>. <sup>1</sup>Clinical Chemistry, VU University Medical Center; <sup>2</sup>Amsterdam Rheumatology and immunology Center, Reade; <sup>3</sup>Amsterdam Rheumatology and immunology Center; <sup>4</sup>Pediatric Oncology/Hematology, VU University Medical Center, Amsterdam, Netherlands

**Background:** Methotrexate (MTX) is a widely applied anti-rheumatic and anti-leukemic drug. For its intracellular retention and pharmacologic activity, MTX relies on the enzymatic activity of folypolyglutamate synthetase (FPGS) to convert MTX into its polyglutamate forms (MTX-PG<sub>2-6</sub>). Loss of FPGS activity is associated with reduced MTX activity and although red blood cell (RBC) MTX-PG<sub>n</sub> levels correlate with disease activity in RA patients,<sup>1</sup> it is anticipated to be more relevant to measure MTX-PG<sub>n</sub> in peripheral blood mononuclear cells (PBMCs). Thus, the aim of our study was to develop a LC-MS/MS method to 1) measure FPGS activity replacing laborious radioactive assays, and 2) to measure MTX-PG<sub>n</sub> in PBMCs.<sup>2</sup>

**Objectives:** To validate a rapid, sensitive and non-radioactive assay to measure FPGS activity and MTX-PG<sub>n</sub> in PBMCs based on LC-MS/MS technology.

**Methods:** Protein extracts (n=5) of PBMCs of MTX-treated RA patients were incubated for 2 hours at 37°C in FPGS assay buffer (pH8.8) containing 250  $\mu$ M MTX and 4 mM l-glutamic acid as substrates. Next, MTX-PG<sub>2</sub> formation was analysed with AB Sciex 4000 Q Trap tandem mass spectrometer coupled to an Acquity Ultra Performance LC system. Measurement of PBMC-MTX-PG<sub>n</sub> (n=5) was performed by extraction of MTX-PG<sub>n</sub> from PBMCs by perchloric acid precipitation. Quantification was performed with <sup>13</sup>C<sub>5</sub><sup>15</sup>N-labelled MTX-PG<sub>1-5</sub> internal standards. In FPGS activity and MTX-PG validation studies, human CCRF-CEM leukaemia cells, CEM/R30dm (a FPGS-deficient, MTX-resistant subline of CCRF-CEM), and human acute lymphoblastic leukemia (ALL) cells served as reference.

**Results:** In CCRF-CEM, the FPGS enzymatic assay showed linearity with protein input (10–250  $\mu$ g) and incubation time (0.5–3 hours). Substrate affinity parameters (Km) for MTX (65  $\mu$ M) and l-glutamic acid (2.2 mM) were consistent with earlier reports.<sup>3</sup> FPGS activity in CEM/R30dm was <1% of CCRF-CEM. FPGS activity in ALL blasts was similar to CCRF-CEM while FPGS activity in RA patient PBMCs was 1%–5% of CCRF-CEM, and was non-detectable in RBCs. Average individual fractions of total MTX-PG<sub>n</sub> in RA patient PBMCs were 22,1% (range: 8,2%–36,2%) for MTX-PG<sub>2</sub>, 32,8% (27,1%–43,6%) for MTX-PG<sub>3</sub>, 34,4% (30,4%–41,3%) for MTX-PG<sub>4</sub> and 10,6% (0,0%–28,4%) for MTX-PG<sub>5</sub>. Average total MTX-PG<sub>n</sub> levels per number of RA patient PBMCs were 30–50 fold higher than matched numbers of erythrocytes, and 6–9 fold lower than ALL blasts incubated for 24 hours with 1  $\mu$ M MTX.

**Conclusions:** A sensitive LC-MS/MS based method was developed for the measurement of FPGS activity and MTX-PG<sub>n</sub> levels in PBMCs of RA patients. This method holds promise to guide future MTX-therapy response evaluations.

**AB0237 ANALYSIS OF THE IMPACT OF CONCOMITANT USE OF CORTICOSTEROIDS ON THE CLINICAL OUTCOMES OF PATIENTS WITH LONG-TERM RHEUMATOID ARTHRITIS IN DIFFERENT TREATMENTS**

M.J. Carmo<sup>1</sup>, M.M. Pereira<sup>1</sup>, M.D.S. Mastella<sup>1</sup>, I.M.S. Vale<sup>1</sup>, E. Pereira<sup>2</sup>, M. K. Schmitz<sup>1</sup>, S.C.D.M.S. Fialho<sup>3</sup>, G.R.W.D. Castro<sup>1</sup>, I.A. Pereira<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Epidemiology, University of South Santa Catarina, Palhoça; <sup>3</sup>Rheumatology, Federal University of Santa Catarina, Florianópolis, Brazil

**Objectives:** To analyse the impact of the concomitant use of corticosteroids on the treatment of patients with long-term rheumatoid arthritis in different clinical outcomes.

**Methods:** A cross-sectional study was carried out in a sample of 100 patients with rheumatoid arthritis attended at specialised centres in rheumatology in Florianópolis. Validated instruments were used to evaluate the disease activity (DAS-28 VHS, DAS-28 PCR, SDAI and CDAI), functional ability (HAQ-DI) and quality of life (SF-12 and SF-6D). Statistical analysis was performed using qui-square test (Pearson), Fisher's exact test, Student's t-test, seeking to study the association between the independent variables and the use of corticosteroids.

**Results:** The mean disease duration of the patients was 15.1±8.7 years, which of, 25% used corticosteroids, with an average dose of 6.7±3.9 mg/day. The mean of the physical component summary (PCS) of SF-12 increased significantly by 1.87 points (47.72±3.23 vs 45.85±2.52 p=0.013) in patients who used corticosteroids, on the other hand, in the mental component summary (MCS) we observed a reduction of the mean by 1.5 points (57.91±3.68 vs 56.41±2.98 p=0.046) in these patients. In the association between the use of corticosteroids with ICADs, HAQ and SF-6D no differences were found independent of the synthetic and/or biological DMARD used.

**Conclusions:** Use of corticosteroids in different treatment strategies is not associated with an increase in the frequency of clinical remission in patients with rheumatoid arthritis. In patients using corticosteroids there was a better quality of life evaluated by the PCS, but not by the MCS.

**AB0238 PATIENT-CENTRED APPROACH TO MANAGEMENT OF INFLAMMATORY ARTHRITIS WAS ASSOCIATED WITH IMPROVED SATISFACTION OF CARE AND PERCEIVED TREATMENT BENEFIT**

L. Attipoe, S. Virdee, J. Greenan-Barrett, D. Shah, A. Cotton, J. Guinto, J. Wilton, C. Ciurtin. *Department of Rheumatology, University College London Hospital, London, UK*

**Background:** Recently, there has been a paradigm shift from a paternalistic doctor-patient relationship towards more holistic, patient-centred care aimed at promoting patient autonomy. However, the effect of patient-centred care on important clinical outcomes, like patient satisfaction and disability, is unknown.

**Objectives:** To investigate how the various aspects of patients' experiences of the care they received for their inflammatory arthritis was correlated with disease activity and health satisfaction, and use this to guide our clinical practice.

**Methods:** 115 questionnaires (including 51 questions, in addition to HAQ) were randomly given to patients with inflammatory arthritis who attended rheumatology outpatient clinics at University College Hospital, London between November 2014 and January 2015 (104 were returned ~90% response rate). Questions were semi-structured using a Likert scale and focused on diagnosis, symptomatology, treatment history, health status and experiences of clinic attendance. The strength of association between health satisfaction and experience of care was correlated using Spearman's correlation test (p<0.05 was considered statistically significant).

**Results:** We calculated correlations between various aspects of patients' experiences of their care with other components of the questionnaire (table 1).

**Conclusions:** Patients who felt that they experienced a more patient-centred approach (through greater involvement in clinical decisions, emotional support and ease of contact with specialists) reported greater satisfaction and regarded their treatment as more efficacious. This suggests that clinicians who go beyond their role of medically managing inflammatory arthritis to provide more holistic care may improve patient-orientated health outcomes.

Patients in older age groups find it easier to contact the department, perhaps because they have more free time to make and receive calls. As ease of contact is a strong predictor of overall patient satisfaction, employing ideas to increase accessibility for younger age groups, such as improved access beyond working hours may improve satisfaction.

The positive correlation of HAQ with employment status and age is expected, as HAQ is the current gold standard measure of functional status. This reaffirms its accuracy in clinical practice as a measure of a functional ability.

Further research into comparing patients' experience of their care with objective measures of disease activity is needed.

**AB0239 DEVELOPMENT OF A NOVEL „MOLECULAR DISEASE ACTIVITY“ TOOL COMPOSED OF 8 SERUM BIOMARKERS FOR MONITORING RHEUMATOID ARTHRITIS**

J. Hurnakova<sup>1</sup>, M. Komarc<sup>2</sup>, R. Horvath<sup>3,4,5</sup>, H. Hulejova<sup>1</sup>, J. Zavada<sup>1</sup>, L. Palova Jelinkova<sup>4,5</sup>, K. Danova<sup>4,5</sup>, P. Hanova<sup>1</sup>, H. Mann<sup>1</sup>, J. Vencovsky<sup>1</sup>, K. Pavelka<sup>1</sup>, R. Spisek<sup>4,5</sup>, L. Senolt<sup>1</sup>. <sup>1</sup>Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic; <sup>2</sup>Dpt. of Methodology, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic; <sup>3</sup>Dpt. of Pediatric and Adult Rheumatology, University Hospital Motol, Prague, Czech Republic; <sup>4</sup>Dpt. of Immunology, University Hospital Motol and 2nd Faculty of Medicine, Charles University, Prague, Czech Republic; <sup>5</sup>Sotio a.s., Prague, Czech Republic

**Background:** Accurate disease activity measurement is a key component of rheumatoid arthritis (RA) management. In 2012, multi-biomarker disease activity (MBDA) test using 12 serum proteins was presented<sup>1</sup>.

**Objectives:** To develop a novel test for measuring inflammatory activity in RA.

**Methods:** Serum samples were obtained from 82 patients with RA (60 females, median disease duration 4.2 years, median age 55.2 years, RF positivity 60.3%, ACPA positivity 69.7%). A detailed stepwise analysis of 20 candidate biomarkers selected from the literature search (IL1β, IL-6, IL-7, IL-8, IL-12p70, IL-17A, IL-22, IL-33, IL-34, IFNγ, VEGF, YKL-40, CXCL-13, MMP-3, resistin, visfatin, leptin, adiponectin, calprotectin and CRP) was performed. Methods of factor analysis (a statistical method used to describe variability among observed, correlated variables in terms of a potentially lower number of unobserved variables called factors) were used in order to develop a tool composed of different serum markers that would optimally reflect disease activity in RA. Spearman correlation index was used to explore associations between newly designed tool and clinical as well ultrasound parameters (German US7 score) of disease activity.

**Results:** We have developed a "Molecular Disease Activity" test covering underlying pathophysiological processes composed of 8 serum markers: calprotectin, CRP, IL-6, MMP-3, VEGF, resistin, IL-22 and IL-7 that optimally reflected inflammatory activity in RA. This model was significantly associated with clinical (DAS28-ESR, DAS29-CRP, CDAI, SDAI) and ultrasound variables (PD syn score, GS syn score) of disease activity in RA, as shown in table 1.

Abstract AB0239 – Table 1. Cross-sectional correlations between "Molecular Disease Activity" tool composed of 8 biomarkers and clinical and ultrasound parameters of disease activity

Parameters	Molecular disease activity (factor score)	p (significance)
DAS28-ESR	0.664**	<0.001
DAS28-CRP	0.666**	<0.001
SDAI	0.731**	<0.001
CDAI	0.669**	<0.001
SJC	0.546**	<0.001
GS syn score	0.657**	<0.001
PD syn score	0.701**	<0.001

\*\* Correlation is significant at ≤0.01

CDAI, Clinical Disease Activity Index; DAS28-CRP, Disease Activity Score with C-reactive protein; DAS28-ESR, Disease Activity Score with erythrocyte sedimentation rate; GS syn, Grey Scale synovitis; PD syn, Power Doppler synovitis; SDAI, Simplified Disease Activity Index; SJC, swollen joint count

**Conclusions:** We believe that this newly designed test based on 8 serum markers may contribute to more accurate measurement of inflammatory activity in

RA and improvement of patients' outcomes. Further evaluation of this tool in a larger cohort is needed.

#### AB0240 REDUCTION IN FATIGUE AND PAIN ARE ASSOCIATED WITH IMPROVED WORK PRODUCTIVITY IN PATIENTS WITH RA

J. Pope<sup>1</sup>, K. Michaud<sup>2</sup>, P. Emery<sup>3</sup>, B. Zhu<sup>4</sup>, C. Gaich<sup>4</sup>, A. DeLozier<sup>4</sup>, X. Zhang<sup>4</sup>, C. Dickson<sup>4</sup>, J.S. Smolen<sup>5</sup>. <sup>1</sup>Joseph's Health Care, London, Alberta, Canada; <sup>2</sup>University of Nebraska Medical Center, Omaha, USA; <sup>3</sup>Leeds MSK Biomed/Chapel Allerton Hosp, Leeds, UK; <sup>4</sup>Eli Lilly and Company, Indianapolis, USA; <sup>5</sup>Medical University of Vienna, Vienna, Austria

**Background:** Despite current treatment options, patients with rheumatoid arthritis (RA) report fatigue and pain, important determinants of quality of life.<sup>1</sup> In prior analyses of a Phase 3 trial of baricitinib (RA-BEAM), baricitinib demonstrated superiority in pain and fatigue reduction over MTX and adalimumab<sup>2</sup> and this pain reduction was associated with improvement in work productivity.<sup>3</sup>

**Objectives:** In this *post hoc* analysis of RA-BEAM, the relationship between fatigue and pain with work productivity was assessed.

**Methods:** Fatigue was measured with the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F, range of 0–52, higher scores represent less fatigue) and pain with the patient's assessment of pain (0–100 mm VAS, higher scores represent greater pain). The Work Productivity and Activity Impairment Questionnaire-RA (WPAI-RA) instrument evaluated the percentages of activity impairment due to RA (impairment in regular daily activities), work-time missed due to RA (absenteeism), impairment while working due to RA (presenteeism), and overall work impairment due to RA (work productivity loss). Analyses were based on pooled data from randomised patients who received  $\geq 1$  dose of study drug. Analyses for impairment in regular daily activities included all patients and for absenteeism, presenteeism, and work productivity loss, patients employed both at baseline and at Weeks 12 or 24 were included. Pain was divided into pain reduction groups (<30%, 30%–<50%,  $\geq 50\%$ ) and actual pain score ( $\leq 10$  mm, >10–<20,  $\geq 20$ –<40,  $\geq 40$  mm); fatigue was divided into fatigue improvement groups (<3.56,  $\geq 3.56$ ) and actual FACIT-F normative value score (<40,  $\geq 40$ ). Pairwise comparisons on improvement in WPAI-RA scores between pain/fatigue reduction groups at Weeks 12 and 24 were assessed by ANCOVA.

**Results:** At baseline across treatment groups, patients reported impairment in all of the WPAI-RA domain scores (absenteeism: 12%–13%, presenteeism: 42%–46%, work productivity loss: 45%–49%, activity impairment: 56%–58%). Reductions in pain and fatigue were associated with improvements in regular daily activities, presenteeism, and work productivity (table 1). Patients who reported lower levels of pain and fatigue tended to experience greater improvement in presenteeism, work productivity, and regular daily activities compared to patients with higher levels of pain or fatigue (table 1). When patients reached a minimal pain level (pain VAS  $\leq 10$  mm), no significant differences were observed in presenteeism and work productivity between patients with different levels of fatigue whereas regular daily activity continued to improve as fatigue improved ( $p \leq 0.001$ ; table 1). No trends were observed with absenteeism. Similar results were observed by treatment group.

**Abstract AB0240 – Table 1.** Improvement in WPAI Domain Scores at Weeks 12 and 24

	Regular Daily Activities		Absenteeism		Presenteeism		Work Productivity	
	FACIT-F <40	FACIT-F $\geq 40$	FACIT-F <40	FACIT-F $\geq 40$	FACIT-F <40	FACIT-F $\geq 40$	FACIT-F <40	FACIT-F $\geq 40$
<b>Pain VAS <math>\leq 10</math> mm</b>

#### AB0241 WHAT PROPORTION OF RA PATIENTS ARE TRULY IN REMISSION? A SURVEY OF RHEUMATOLOGISTS OF THE AUVERGNE REGION OF FRANCE

J.J. Dubost<sup>1</sup>, B. Pereira<sup>2</sup>, A. Fan<sup>1</sup>, D. Meyer<sup>3</sup>, D. Verrière<sup>3</sup>, S. Melac-Ducamp<sup>3</sup>, B. Glace<sup>4</sup>, F. Demarquilly<sup>3</sup>, M. Gendey<sup>3</sup>, B. Mailet<sup>3</sup>, K. Zbadi<sup>4</sup>, C. Voquer<sup>3</sup>, J. P. Monghal<sup>2</sup>, A. Kabchou<sup>4</sup>, J. Ledoux-Eberst<sup>3</sup>, S. Cechetti<sup>3</sup>, J. Meloux<sup>2</sup>, M. Vayssade<sup>3</sup>, M. Soubrier<sup>1</sup>. <sup>1</sup>Rheumatology department; <sup>2</sup>Biostatistics Unit, CHU Clermont-Ferrand, Clermont-Ferrand; <sup>3</sup>Fédération des rhumatologues d'Auvergne, Auvergne; <sup>4</sup>Rheumatology department, CH Vichy, Vichy, France

**Background:** The treatment of rheumatoid arthritis (RA) is aimed to achieve remission.

**Objectives:** To determine the proportion of RA patients in remission among the population treated by rheumatologists in Auvergne, France.

**Methods:** A 3 month survey involving 24 rheumatologists, not practicing at university hospitals, from the Auvergne region of France. The rheumatologists completed records on each RA patient detailing the parameters of RA activity (tender joint count, swollen joint count, pain VAS, patient's assessed activity VAS, physician's assessed activity VAS, ESR and CRP), as well as the RA treatment administered, and if this treatment was modified.

**Results:** Overall, 15 rheumatologists provided 455 records. These comprised 330 women (74%) and 125 men, aged on average 64.8 years old  $\pm 12.6$ . The patients had suffered from RA for 7 years on average, <sup>4-14</sup> 77.3% were positive for rheumatoid factor, and 76.2% for anti-CCP. They underwent the following treatments: NSAIDs (19%), corticoids (24.4%; 5 mg<sup>4-6</sup>), methotrexate (80.4%; 15 mg.<sup>10-15</sup> leflunomide (4.4%), hydroxychloroquine (11%), sulfasalazine (2.4%), anti-TNF (21.9%), other biotherapy (8.8%), no DMARD (3.1%),  $\geq 2$  DMARDs (31.8%). The proportion of patients in remission varied depending on different definitions as follows: DAS28-ESR  $\leq 2.6$ : 61.5% (low activity: 79%); DAS28-CRP  $\leq 2.4$ : 59.5%, DAS 28-CRP  $\leq 2.1$ : 47.2%; SDAI  $\leq 3.3$ : 40.1% (low activity: 80%); CDAI  $\leq 2.8$ : 36.0% (low activity: 81.5%); ACR/EULAR: 31.8%; simplified ACR/EULAR: 39.1%; physician-assessed remission (VAS  $\leq 1$ ): 52.3%; patient-assessed remission (VAS  $\leq 1$ ): 47.3%. There was moderate to good correlation between the ACR/EULAR and SDAI criteria ( $\kappa = 0.70$ ) and CDAI criteria ( $\kappa = 0.72$ ), while there was weak correlation between ACR/EULAR and DAS 28-ESR ( $\kappa = 0.45$ ). The physicians' and patients' assessments did not correlate well with the remission criteria. Compared to those who were not in remission, the patients assessed as being in remission according to DAS28-ESR and ACR/EULAR criteria were younger, had been treated with less corticoids, had more frequently received anti-TNF, and had less frequently had their treatment modified.

**Conclusions:** Our findings were reassuring, with 32% (ACR/EULAR) to 62% (DAS) of RA patients followed up by rheumatologists outside of university hospitals assessed as being in remission, and 80% presenting with low disease activity. A total of 97% received DMARD, 30% received biotherapy, and a quarter corticoids. We found moderate to good correlation between ACR/EULAR and SDAI and CDAI; whereas there was low correlation between ACR/EULAR and DAS 28-ESR. The physicians' and patients' assessments did not correlate well with the remission criteria.

**AB0242 DELAY IN DMARD INITIATION IN PATIENTS NEWLY DIAGNOSED WITH RHEUMATOID ARTHRITIS: AN ANALYSIS OF UNITED STATES MILITARY HEALTH SYSTEM BENEFICIARIES**

L. Kimsey<sup>1</sup>, J.S. Weissman<sup>2</sup>, A. Patel<sup>3</sup>, A. Drew<sup>1</sup>, T. Koehlmoo<sup>3</sup>, J.A. Sparks<sup>2</sup>.  
<sup>1</sup>Georgia Southern University, Statesboro; <sup>2</sup>Brigham and Women's Hospital, Harvard Medical School, Boston; <sup>3</sup>Uniformed Services University of the Health Sciences, Bethesda, USA

**Background:** Prompt initiation of disease-modifying antirheumatic drugs (DMARDs) is recommended for patients diagnosed with rheumatoid arthritis (RA) to improve symptoms and prevent disease progression, but treatment delays may still occur.

**Objectives:** To investigate predictors and temporal trends for delay in DMARD initiation among patients with incident RA in the United States.

**Methods:** We performed a longitudinal cohort study using administrative data from the United States military's TRICARE program (2007–2012). TRICARE beneficiaries, who are demographically similar to the US, include active/retired military members, spouses, and dependents and receive care in military or civilian settings. We identified incident RA cases using billing codes and initial DMARD receipt using prescription fill date. We quantified the time between RA presentation and initial DMARD receipt, temporal changes in time to treatment over the study period, and investigated predictors of treatment delay (>90 days) using logistic regression.

**Results:** We identified 16 680 patients with incident RA that were later prescribed DMARDs. Mean age was 47.2 (SD 13.5) years, 77.6% were female, and 76.5% were spouses/dependents of the military sponsor. The mean time from initial RA presentation to first DMARD prescription was 125.3 days (SD 175.4). Over one-third (35.6%) of incident RA patients experienced treatment delay (>90 days between presentation and DMARD receipt). Time to DMARD initiation was shorter in later years of the study (mean 144.7 days in 2007; 109.7 days in 2012). Patients prescribed opioids between RA presentation and initial DMARD receipt had 4-fold increased risk for delay in initial DMARD (OR 4.07, 95% CI 3.78–4.37). Patients prescribed opioids had mean time to DMARD of 212.8 days (SD 207.4) compared to mean of 77.3 days (SD 132.3) for those who did not use opioids (p<0.0001). Use of prescription NSAIDs between initial RA presentation and DMARD initiation was also associated with delay (OR 3.32, 95% CI 3.09–3.57). Men were less likely than women to experience delay (OR 0.89, 95% CI 0.82–0.98).

**Abstract AB0242 – Table 1.** Odds ratios for delay in DMARD initiation (>90 days) after initial presentation for incident rheumatoid arthritis (n=16,680)

\*The multivariable model was also adjusted for age, US region, care setting (military or civilian), military rank of sponsor, number of clinic visits prior to index date, and Charlson Comorbidity Index.

**Conclusions:** In this large US nationwide study, delays in initial DMARD receipt after incident RA were common but time to treatment improved in later years of the study. Avoiding opioid use may decrease delay in initiating DMARDs during this vulnerable period when pain and disease activity are often most pronounced.

**AB0243 REAL WORLD CLINICAL TRIAL COMPARING THE PATIENT REPORTED OUTCOMES MEASUREMENT INFORMATION SYSTEM SHORT FORMS AND PROFILES TO CDAI DISEASE CLASSIFICATION IN RHEUMATOID ARTHRITIS PATIENTS**

J. Curtis<sup>1</sup>, S. Schwartzman<sup>2</sup>, S. Kafka<sup>3</sup>, D. Parenti<sup>3</sup>, S. Black<sup>3</sup>, S. Xu<sup>4</sup>, W. Langholff<sup>5</sup>, C.O. Bingham III<sup>6</sup>. <sup>1</sup>U of Alabama, Birmingham; <sup>2</sup>Weill Cornell Medical College, New York; <sup>3</sup>Janssen Scientific Affairs, LLC, Horsham; <sup>4</sup>Janssen Research and Development, LLC, Spring House; <sup>5</sup>Janssen Research and Development, LLC, Horsham; <sup>6</sup>Johns Hopkins U, Baltimore, USA

**Background:** Pt reported outcomes (PROs) play a role in disease evaluation, therapeutic assessment and care of RA pts. The Pt Reported Outcomes Measurement Information System (PROMIS [P]) questionnaires developed by NIH have been used in RA clinical practice and studies.<sup>Bartlett 2015</sup> AWARE (Comparative and Pragmatic Study of Golimumab Intravenous [IV] Versus Infliximab in RA) is a noninterventional, multi-centre US-based, study of golimumab IV (GLM) vs. infliximab (IFX) in RA and will assess disease activity (DA) and use PROs.

**Objectives:** 1. PRO assessments of Pt response to treatment using PROMIS-29 Profile v2.0 (P29v2), P Pain Interference Short Form-6b (PISF) and P Fatigue Short Form-7a (FSF), and Clinical DA Index (CDAI), and 2. assess relationship between PROMIS T-score and CDAI category.

**Methods:** AWARE is a 1200 adult pt study enrolling pts on initiation of treatment w/GLM or IFX. We report an interim analysis (IA) of 747 pts' baseline PROMIS questionnaire and CDAI scores. PROMIS results are normalised to the US population, reported as a "T-score" (mean=50, SD=10) w/higher scores indicating more of the trait measured. PROMIS T-scores were compared between High DA (HDA) w/Moderate DA (MDA), low DA (LDA) and remission. Data shown are mean ±SD. Statistical testing compared T-scores across CDAI categories using ANOVA for these data (before drug admin). Data from GLM and IFX pts are combined.

**Results:** Mean baseline CDAI score was 32.5±15.4, w/71.7% of pts in HDA, 22.5% in moderate MDA, 5.2% in LDA and 0.7% in remission. PROMIS T-scores were compared to 4 CDAI categories. HDA Pt T-scores were (\*, p<0.05) different from those of MDA, LDA and Remission pts (except between HDA and remission for Anxiety, Depression and Sleep Disturbance domains).

**Abstract AB0243 – Table 1**

	All Patients (n=672-682)	Remission CDAI≤2 (n=5)	LDA 2.8<CDAI≤10 (n=38)	MDA 10<CDAI≤22 (n=165)	HDA CDAI>22 (n=526)
Physical Function	37.9±6.6	47.5±5.7	45.0±7.6	40.0±6.7	36.6±5.9*
Anxiety	53.8±10.4	45.2±6.7*	47.7±8.6	51.3±10.0	55.2±10.4*
Depression	52.5±10.3	42.6±3.6*	45.9±6.3	49.4±9.8	54.0±10.3*
Fatigue	58.8±9.9	42.3±5.4*	49.7±9.7	55.6±9.2	60.8±9.4*
Sleep Disturbance	55.5±8.7	48.2±3.6*	51.5±7.9	51.2±8.4	56.7±8.6*
Ability to participate in Social Roles & Activities	48.2±8.6	57.3±7.6	50.8±8.5	45.9±8.5	41.6±8.0*
Pain interference	63.5±7.7	46.9±7.2*	53.9±8.4	60.1±7.7	65.4±6.5*
Fatigue Short Form 7a	59.3±8.5	46.7±8.8*	51.6±9.0	56.2±7.5	61.0±8.1*
Pain Interference Short Form 6b	62.5±7.6	45.9±7.5*	53.9±9.3	59.3±5.6	64.3±6.4*
Pain intensity (scored 0-10 scale)	6.0±2.2	1.6±2.6	3.5±2.3	5.1±2.2	6.6±1.9*

T-scores >50 indicate worsening, except "Physical Function" & "Ability to participate in Social Roles & Activities", where T-scores <50 indicate worsening. \* = p<0.05 vs respective scores in MDA, LDA & remission categories. † = not different from HDA.

**Conclusions:** Our interim findings demonstrate the feasibility of using PROMIS short forms and profiles to evaluate RA Pts in clinical trials. These results confirm the domain validity of PROMIS measures according to CDAI DA category. PROMIS measures show the range of impact across multiple domains of physical, emotional, and social health experienced by RA Pts.

### DEVELOPMENT OF AN ADJUSTED MULTI-BIOMARKER DISEASE ACTIVITY (MBDA) SCORE FOR RHEUMATOID ARTHRITIS (RA) THAT ACCOUNTS FOR AGE, SEX AND ADIPOSITY, WITH SUBSEQUENT EVALUATION OF ABILITY TO PREDICT RISK FOR RADIOGRAPHIC DAMAGE

J.R. Curtis<sup>1</sup>, D.D. Flake II<sup>2</sup>, M. Weinblatt<sup>3</sup>, N.A. Shadick<sup>4</sup>, M. Østergaard<sup>5</sup>, M. L. Hetland<sup>6</sup>, C. Heegaard Brahe<sup>6</sup>, Y.G. Hwang<sup>7</sup>, D.E. Furst<sup>8</sup>, V. Strand<sup>9</sup>, C. J. Etzel<sup>10</sup>, D. Pappas<sup>11</sup>, X. Wang<sup>12</sup>, C.C. Hwang<sup>12</sup>, E.H. Sasso<sup>12</sup>, A. Gutin<sup>2</sup>, E. Hitraya<sup>12</sup>, J.S. Lanchbury<sup>2</sup>. <sup>1</sup>University of Alabama at Birmingham, Birmingham; <sup>2</sup>Myriad Genetics, Inc., Salt Lake City; <sup>3</sup>Brigham and Women's Hospital; <sup>4</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, USA; <sup>5</sup>Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet; <sup>6</sup>Copenhagen Center for Arthritis Research, Copenhagen, Denmark; <sup>7</sup>University of Pittsburgh, Pittsburgh; <sup>8</sup>David Geffen School of Medicine at UCLA, Los Angeles; <sup>9</sup>Stanford University, Palo Alto; <sup>10</sup>Corrona, LLC, Waltham; <sup>11</sup>Columbia University, New York City; <sup>12</sup>Crescendo Bioscience Inc., South San Francisco, USA

**Background:** The MBDA score, based on 12 serum proteins, is a validated tool for assessing disease activity in RA patients. MBDA biomarkers may be influenced by age, sex and adiposity.

**Objectives:** To develop and validate an adjusted MBDA score that accounted for these three factors, using BMI or serum leptin as proxies for adiposity.

**Methods:** The MBDA score as a continuous variable was adjusted to account for age, sex and a proxy for adiposity (serum leptin) using data from 325,781 RA patients for whom MBDA tests had been ordered as part of routine care. Leptin values came from the MBDA test. As an alternative to using leptin to adjust for adiposity, a cohort of 1411 patients from 5 studies/registries (BRASS, Corrona-CERTAIN, InFoRM, OPERA, RACER) was used to adjust for BMI, which was not available in the larger cohort, adding this BMI adjustment to that for age/sex from the larger cohort. Both types of adjusted MBDA score use the low, moderate, and high disease activity cutpoints of the original MBDA score. The two adjusted MBDA scores and other variables were evaluated for the prediction of radiographic progression (RP) in the 2 cohorts with available data (OPERA, BRASS) using univariate and multivariate linear regression analyses. Rate of RP was assessed as the change in modified total Sharp score ( $\Delta$ mTSS) per year after MBDA testing.

**Results:** The MBDA score increased with age, BMI and leptin concentration. In univariate analysis of the combined OPERA and BRASS cohorts (n=555), the significant variables predicting  $\Delta$ mTSS were leptin-adjusted MBDA score, seropositivity for RF or anti-CCP, BMI-adjusted MBDA score, MBDA score, BMI, CRP, baseline mTSS, disease duration, DAS28-CRP, SDAI, CDAI and DAS28\* (table 1). The leptin- and BMI-adjusted MBDA scores were the first and third most significant univariate predictors of  $\Delta$ mTSS. To compare them directly, DAS28-CRP, MBDA score, BMI-adjusted MBDA score and leptin-adjusted MBDA score were combined in pairs in regression analyses of  $\Delta$ mTSS; the BMI-adjusted (p=0.0027) and leptin-adjusted MBDA score were significant (p=0.00063) after adjusting for DAS28-CRP (p=0.87 and 0.74, respectively) and the leptin-adjusted MBDA score was significant (p=0.024 and 0.020, respectively) after adjusting for either the MBDA (p=0.32) or BMI-adjusted MBDA scores (p=0.094).

**Abstract AB0244 – Table 1.** Univariate Linear Regression Analysis of the Association of Clinical and Laboratory Variables with  $\Delta$ mTSS in the OPERA and BRASS Combined Cohort

Variable	n	F-statistic	p-value
Leptin-adjusted MBDA Score	555	17.1	0.000040
RF or Anti-CCP Status	555	14.8	0.00013
BMI-adjusted MBDA Score	555	14.4	0.00016
MBDA Score	555	12.9	0.00036
BMI	555	10.9	0.001
log <sub>e</sub> (CRP)	555	6.8	0.0093
Baseline mTSS	555	5.3	0.022
log <sub>e</sub> (Disease duration + 1)	401	4.8	0.030
DAS28-CRP	536	4.6	0.032
SDAI	533	4.3	0.040
CDAI	533	3.9	0.049
DAS28*	536	3.1	0.079
Gender	555	1.5	0.23
Smoking Status	478	0.8 (2 df)	0.46
Age	555	0.1	0.76

DAS28\* = DAS28 with no CRP or ESR component, i.e.,  $0.56(\text{TJC28})^{3/2} + 0.28(\text{SJC28})^{3/2} + 0.014(\text{GH})$ .

**Conclusions:** We developed two adjusted MBDA scores that combine molecular and biometric variables to account for age, sex, and adiposity. The leptin-adjusted MBDA score, significantly outperformed DAS28-CRP and the original MBDA score in predicting radiographic progression in RA patients. These results suggest that the leptin-adjusted MBDA score may offer improved clinical utility for the personalised management of patients with RA.

### PERFORMANCE OF THE EULAR DEFINITION OF ARTHRALGIA SUSPICIOUS FOR PROGRESSION TO RHEUMATOID ARTHRITIS IN COMBINATION WITH MUSCULOSKELETAL ECOGRAPHY WITH DOPPLER (USMD) IN CLINICAL PRACTICE

J. Calvo Gutiérrez, I.C. Aranda-Valera, M.A. Sastre Dominguez, R. Ortega Castro, M.C. Castro Villegas, A. Escudero Contreras, E. Collantes Estevez. *Rheumatology, Hospital Universitario Reina Sofia/IMBIC/Universidad de Córdoba, Córdoba, Spain*

**Background:** The treatment at an early stage of rheumatoid arthritis (RA), even in the undifferentiated phase, which can prevent the progression and even the reversal of the inflammatory process<sup>1</sup>. Identification in the preclinical phase is complicated. The detection of joint inflammatory activity through the use of UsMD would be useful for diagnosis in arthralgia suspicious for progression to RA (CSA)<sup>2</sup>.

**Objectives:** To assess the usefulness of the EULAR definition of CSA in clinical practice.

To Describe the clinical, serological and ultrasound characteristics and the CSA evolution over time (0, 3, 6 months).

To determine the clinical and ultrasound characteristics that could influence in the RA progression.

**Methods:** A longitudinal prospective study that includes 27 patients referred from primary care (PC) or Rheumatology consultations with CSA according to EULAR criteria of more than 8 weeks and less than 6 months of evolution. All patients were evaluated at 0–3–6 months, including at each visit: serological parameters (RF, ACPA, ESR, CRP), measures of functionality (HAQ) and activity (DAS28); and image (Xray and UsMD). The ultrasound examination included: carpus (palmar and dorsal planes), MCFs 2°–5°, extensor cubital tendons, ankles, posterior tibialis, 5° MTFs and painful IFPs in a comparative and bilateral model. The Us scans were performed by the same researcher without access to the clinical data of the patients, collected by another independent researcher. Proportions were compared using the chi-square test to see which factors were related to RA development.

**Results:** 27 patients with CSA criteria according to EULAR definition have included. 59.3% were derived from PC, 92.6% were women with a mean age of 48.5 years (DS 11.95) and active labour 77.8%. Ten patients (37%) were smokers and dyslipidemics with an atherogenic index of 3.19 (DS1.04). 60.95% presented slight overweight with a BMI of 27.65 Kg/m<sup>2</sup> (DS 5.7). The most frequent form of presentation was polyarticular 12 (50%) followed by oligoarticular. 57.7% of the cases had symmetric involvement and 81.5% a duration of symptoms between 6–16 weeks. 52% patients presented RF + and 4 ACPA and ANA+. During the follow-up: 8 patients (29.6%) were classified as RA (ACR<sup>1</sup>,<sup>EULAR 2010</sup> all of them derived from Rheumatology, 3 (11.1%) microcrystalline arthritis, 1 Sjogren primary syndrome and 15 (55.5%) presented degenerative or tendinosis pathology.

In those patients who progressed to RA, we only found a statistical association with the presence of high RF +and with the presence of doppler at the carpal level ( $p=0.048$ ).

**Conclusions:** The results of our study suggest that the EULAR definition of CSA, although more useful when used by rheumatologists, does not reach sufficient accuracy for the diagnosis of RA, while the presence of subclinical synovitis detected by UsMD could be useful. The highest levels of RF were related to the presence of synovitis in our cohort, unlike ACPA. Further studies would be needed to recommend its introduction into clinical practice and, in our opinion should be considered in future sets of classification criteria.

#### AB0246 GENETIC VARIABILITY WITH TOLL-LIKE RECEPTOR 10 AFFECTS SUSCEPTIBILITY TO RHEUMATOID ARTHRITIS AND MODULATES RESPONSE TO BIOLOGICAL TREATMENT

B. Wysoczanska<sup>1</sup>, J. Swierkot<sup>2</sup>, M. Puchala<sup>1</sup>, K. Kolossa<sup>3</sup>, S. Jeka<sup>3</sup>, P. Wiland<sup>2</sup>, K. Bogunia-Kubik<sup>1</sup>. <sup>1</sup>Laboratory of Clinical Immunogenetics and Pharmacogenetics, Hirsfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences; <sup>2</sup>Department of Rheumatology and Internal Medicine, Medical University, Wrocław; <sup>3</sup>Department of Rheumatology and Connective Tissue Diseases, Collegium Medicum of Nicolaus Copernicus University, Bydgoszcz, Poland

**Background:** Genetic variability in Toll-like receptor 10 (TLR10) may change the balance between pro- and anti-inflammatory responses, and hence modulate the susceptibility to infection and to autoimmune disease including rheumatoid arthritis (RA).

**Objectives:** Therefore we aimed to assess the possible associations of the TLR10 genetic variants with RA susceptibility and/or response to treatment

**Methods :** *TLR10* gene (rs 11096957, N241H, A>C) polymorphism was genotyped by LightSNIP assay in 303 RA patients (237F/66M) and in 140 healthy individuals from Polish population.

**Results:** RA patients with the AC genotype showed predisposition to disease development [OR 1.99 (1.32–3.01);  $p=0.001$ ], while the AA homozygosity seemed to play a protective role [OR 0.63 (0.42–0.95);  $p=0.034$ ]. Response to treatment with TNF-alpha inhibitors was more effective after 6 months as compared to 3 months ( $p=0.001$ ), especially in female patients ( $p=0.05$ ). Women carrying the A allele responded better to treatment after 6 months of anti-TNF treatment as compared to those with the CC genotype ( $p=0.053$ ). Response to biological treatment was more effective in patients with low stage of disease ( $p=0.01$ ), with rheumatoid factor (RF) positivity ( $p=0.01$ ) and with double positivity against cytrulinated (CCP) protein and RF ( $p=0.003$ ). RF-positive patients (especially women,  $p=0.001$ ) characterised with a higher degree of the disease as compared to RF-negative cases ( $p=0.01$ ). Men had a higher activity of the disease before anti-TNF treatment ( $p=0.05$ ), therefore the remission of the disease was more common in women ( $p=0.04$ ).

**Conclusions:** These results imply that the TLR10 polymorphism has an important role in RA and may potentially influence risk of the disease and effectiveness of biological treatment.

**Acknowledgements:** Supported by the National Science Centre grant No. 2016/21/B/NZ5/01901.

#### AB0247 LACK OF AGEING WITH LONG TERM METHOTREXATE: OBJECTIVE MEASUREMENTS OF COGNITION, AUDIOMETRY, AND SLEEP

K. Greenwald, J. Ball, M. Greenwald, on behalf of Methotrexate and aging. *Rheumatology, Desert Medical Advances, Palm Desert, USA*

**Background:** Methotrexate (MTX) has long been known to improve the cardiovascular system. Myocardial infarction, strokes, and mortality are significantly reduced in patients compliant with long term MTX.<sup>(1)</sup> Hearing loss at middle age is an independent major risk factor for dementia,<sup>(2)</sup> and sleep over 8 hours is associated with better health. MTX use may affect all of these risk factors.

**Objectives:** Our hypothesis is that the cardiovascular benefits of long term MTX treatment would translate into improved cognition, improved hearing, and better sleep patterns.

**Methods:** Cambridge Cognition (CamCog based in Cambridge) developed cognitive objective testing to study brain function. Camcog is widely used to assess cognitive function in atherosclerotic disease, dementia and ageing. The CamCog tests are computer based. Programs used in this trial included "PAL", paired associates learning for new learning memory and "SWM", spatial working memory along with new strategic thinking during the test. These tests provide 22 assessments per patient. In separate testing, each patient was scored on the mini-mental state examination, including serial 7's, WORLD spelled backward, memory retention of 3 items, and drawn forms such as clock faces.<sup>(2)</sup> Sleep patterns were assessed by questionnaire.

**Results:** There were 88 patients with RA between the ages of 80–101 years who had been treated with MTX a minimum of 20 years. The average PALFAM score for the group was 16.3 (sd 2.7) with a maximum score of 20. The SWMBE score for errors for the group was 2.2 (sd 4.4) with the best score 0 errors. In all 22 scoring categories of the CamCog tests, the 88 long term MTX users scored in the top quintile, and better than average for published results for healthy people at age 65. All scores were statistically significant ( $p<0.01$ ) compared to healthy 65 year olds. It was not possible to compare age, sex matched normal individuals because the normative CamCog database only extends to age 90. All 88 subjects scored above 24 on the mini-mental testing (reflecting no cognitive impairment on that test). The audiometry testing was much better than expected for age, in the top tertile. Of the 88 patients on long term MTX, 3 had hearing aides. Sleep duration averaged 8.5 hours/pm which is considered excellent for maintaining cognition.<sup>(3)</sup>

**Conclusions:** This is a subset of people with cardiovascular risk due to age and RA. The CV risk assessment tool\* for our subgroup predicted 10 year risk for MI or CVA at 54%. We did not see MI or CVA over 20 years, despite RA. Expanding on that physiology, we found 88 RA patients on long term MTX had above average cognitive testing, completed mini-mental test, drawings, audiometry close to the scores expected for people 3 decades younger. One reason these preliminary results cannot be generalised to other populations is that only RA patients were studied with long term MTX. Also our group were 80–101 years old and there may be a survival advantage in this subgroup since all were healthy at age 65. A study in a larger general population given MTX for several years would be needed to evaluate the benefit in cognition, hearing, and sleep.

#### AB0248 EVALUATION OF SUBCUTANEOUSLY (SC) INJECTED Tc 99m TILMANOCEPT LOCALIZATION IN ACTIVE RHEUMATOID ARTHRITIS (RA) SUBJECTS BY PLANAR AND SPECT/CT

J. Graf<sup>1</sup>, B. Abbruzzese<sup>2</sup>, F. Cope<sup>2</sup>, S. Behr<sup>1</sup>, J. Sanders<sup>2</sup>, A. Kissling<sup>2</sup>, D. Ralph<sup>2</sup>, J. Shuping<sup>2</sup>, M. Blue<sup>2</sup>, C. Hartings<sup>2</sup>, R. Hershey<sup>2</sup>, H. Bailey<sup>2</sup>, A. Spaulding<sup>2</sup>, M. haynam<sup>2</sup>, A. Ismail<sup>2</sup>. <sup>1</sup>Medicine, University of California San Francisco, San Francisco; <sup>2</sup>Navidea Biopharmaceuticals, Dublin, USA

**Background:** In rheumatoid arthritis (RA), infiltrating macrophages play a critical role in the immunopathogenesis of the disease by generating pro-inflammatory cytokines and chemokines and by contributing directly to joint damage. Current imaging modalities do not directly assess activated macrophage-mediated disease processes in RA. Use of non-invasive imaging to detect macrophage infiltration of synovial joints may allow for more sensitive identification of synovitis and earlier recognition of RA, identify joints at risk for progressive inflammation and destruction, provide a better means of quantifying joint inflammation and disease activity, and measure or even predict response to macrophage-directed therapy. Tc 99 m tilmanocept is a synthetic radiopharmaceutical imaging agent that binds with high affinity to the mannose receptor (CD206) located on the cell surface of synovial macrophages. We investigated whether subcutaneous (SC) administration of tilmanocept labelled with Tc 99 m could specially image macrophage mediated inflammation in RA but not in healthy control (HC) subjects.

**Objectives:** To investigate whether subcutaneous (SC) administration of tilmanocept labelled with Tc 99 m could specially image macrophage mediated inflammation in RA but not in healthy control (HC) subjects.

**Methods:** Subjects received a SC injection of either 50 µg or 200 µg tilmanocept radiolabeled with 2mCi Tc99m in 0.4 mL. 18 subjects were enrolled as follows – Cohort 1: HC: 50 µg/2mCi; n=5; Cohort 2: HC: 200 µg/2mCi; n=4; Cohort 3: RA 50 µg/2mCi; n=4; Cohort 4: RA 200 µg/2mCi; n=5. Subjects were imaged with whole body planar scans at 2–3 hours and 4–6 hours post injection as well as separate 5 min planar images of both hands. If there were areas of increased localization, SPECT images were obtained.

**Results:** Tc 99 m tilmanocept localised most effectively at the 200 µg mass dose 2–3 hours post- administration in RA subjects (cohort 4). Localization was observed in 60% of the subjects in joints of the bilateral wrists, hands, and knees. No localization was observed in HCs receiving the same mass dose (cohort 2).

**Abstract AB0248 – Figure 1.** Contrast of wrist and elbow of SC RA subject

**Conclusions:** Our findings represent a potential advance in the imaging of RA using a novel immunodiagnostic imaging strategy to specifically visualise macrophage-mediated elements of the RA disease process. This study demonstrates the potential for Tc 99 m tilmanocept to be used as an imaging tool for macrophage-mediated synovial inflammation in RA patients. This strategy can be used to identify patients at risk for activated macrophage-mediated joint damage, to quantify synovitis and disease activity, to provide further insight into immune-mediated mechanisms of RA, and to enable future targeted delivery of immunomodulatory therapeutics.

#### AB0249 INFLUENCE OF AUTOANTIBODIES PROFILE ON DISEASE ACTIVITY MEASUREMENT IN A COLOMBIAN COHORT OF RHEUMATOID ARTHRITIS PATIENTS

J.B. Florez, G. Quintana, P. Mendez, P. Coral, on behalf of Reumavance Group. Department of Rheumatology, Fundacion Santa Fe de Bogotá University Hospital, Bogotá, Colombia. *Rheumatology, Fundacion Santa Fe de Bogota, Bogotá DC, Colombia*

**Background:** Traditionally, the role of Rheumatoid Factor (RF) and/or Anti-citrullinated antibodies (ACCP) presence have characterised for diagnosis and prognosis of Rheumatoid Arthritis (RA). However, Anti-nuclear antibodies (ANA) are not routinely measured for the diagnosis of the disease or RA prognosis establishment during first appointment. Recently, evidence showed that positive ANA titles could be considered as poor prognosis factor for RA, and also a higher probability of developing immunogenicity against biologic therapies.

**Abstract AB0249 – Table 1.** Auto-antibodies profile, disease activity by DAS-28 ESR (initial and follow-up to 3, 12, 24 and 36 months) and mean weekly MTX dose in a Colombian cohort of RA patients

PROFILE (FR/ACCP/ANA)	DAS-28 (INITIAL)	DAS-28 (3 MONTHS)	N	DAS-28 (12 MONTHS)	N	DAS-28 (24 MONTHS)	N	DAS-28 (36 MONTHS)	N	MEAN WEEKLY MTX DOSE (mg)
—	3.317	.3072603	73	0.1267188	64	0.9367073*	41	0.8593334*	30	9.26

\*p<-0.05 \*\*p<0.001

**Objectives:** To compare the disease activity measurement from a Colombian cohort of patients with RA, based on their auto-antibodies profile.

**Methods:** The study used a cohort of Colombian patients with RA. A database was developed using the information from the clinical records. The data included were: RF, ACCP, ANA, and the disease activity measured using DAS-28 ESR. Disease activity results were obtained in the following periods of time: 0, 3, 12, 24 and 36 months. Patients were classified based on the different autoantibody profiles (RF/ACCP/ANA:—, +-, ++, +-, ++, ++, ++, +++). Mean DAS-28 ESR results from each period of time were calculated. Also mean weekly Methotrexate (MTX) dose was calculated for each profile. Mean differences between initial, and the follow-up period were calculated using Kruskal-Wallis test. Statistical analysis was made using STATA 12.0 software.

**Results:** 635 patients with RA were included. 32% of them were men, and 68% were women. Mean age was 54.3 years. The most prevalent profile was +++with 118 patients, and the less frequent was +-. Patients with +++profile had the best response to treatment over time, but also they required more MTX dose. Less response during time was observed with +- profile, however the amount of patients from these group was relatively low. As it was expected,—profile patients required less weekly MTX dose (9.26 mg). It was interesting that patients with —+profile present a worst outcome based on DAS-28 activity, and less response to the treatment.

**Conclusions:** Results from the study suggest the importance of including the measurement of ANA titles in the initial categorization and follow-up of patients with RA. The presence of ANA seems to have a worst prognosis. ANA co-existence with ACCP appear to have a worst outcome, compared to +- or ++-profile. Auto-antibody profile in RA could direct the best therapeutic strategy for each patient. Validation of these results are required based on other cohorts.

#### AB0250 ENDOTYPING OF ARTHRITIC PATIENTS USING NOVEL SEROLOGICAL BIOMARKERS

J.P.M. Blair<sup>1</sup>, C. Bager<sup>1</sup>, M. Weinblatt<sup>2</sup>, M. Karsdal<sup>1</sup>, A. Platt<sup>3</sup>, A.-C. Bay-Jensen<sup>1</sup>. <sup>1</sup>Rheumatology, Nordic Bioscience, Copenhagen, Denmark; <sup>2</sup>Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, Massachusetts; <sup>3</sup>AstraZeneca, London, UK

**Background:** Accurate patient stratification is critical if medical professionals are to adopt a precision medicine approach when planning clinical trials or prescribing medication. This approach results in a superior level of drug response in the target group, a reduction in adverse effects and reduced costs for payers.

Best practice treatment recommendations and disease activity markers such as DAS28, as opposed to a treat to target approach, guide current treatment of arthritic disease. There is currently a lack of tools to enable patient stratification, in part due to traditional biomarkers reflecting systemic inflammation rather than the target tissue.

**Objectives:** In this paper, we explore the use of a combination of novel tissue specific biomarkers for patient clustering with the objective of identifying different disease profiles.

**Methods:** Four biomarker substudy cohorts were pooled for this study, including two RA studies; LITHE (n=574) and OSKIRA-1 (n=131) and two OA studies; SMC1 (n=447) and SMC2 (n=81) all of which have been described in detail before. Whilst the principle focus was to examine RA patient profiles, OA studies were included to enrich the cohort with a non-RA population. OSKIRA and LITHE both had measurements at 24 weeks with additional measurements at 52 week s in LITHE.

Several serological biomarkers were measured in each cohort, selected due to the specific tissue metabolite they represent. These included: C2M (cartilage degradation); CTX-1 and PINP (bone resorption and formation); C1M and C3M (interstitial matrix degradation); CRPM (CRP metabolite) and VICM (macrophage activity).

Each biomarker was log transformed and min-max normalised in order to allow for direct comparison of each of the variables. Patient clustering was performed using Ward hierarchical clustering and the number of clusters determined using the GAP statistic. ANOVA test was used to identify differences in delta change in radiographic scores at 24 and 52 weeks in the RA placebo groups (n=271) only.

**Results:** Clustering analysis resulted in five different clusters (A-E). Cluster A and B were both comprised of >98% RA patients. Cluster D was comprised mainly of OA patients whilst clusters C and E were a mix of OA and RA patients.

Clusters A and B were characterised by high levels of all biomarkers compared to other clusters except for VICM, which is significantly lower in cluster A than in cluster B (Tukey test  $p < 0.001$ ). Biomarker levels in Cluster C were all close to the median. Cluster D was characterised by low levels of all biomarkers compared to other clusters with significantly lower C2M levels, whilst cluster E also had low levels of markers, yet with significantly higher levels of CTX-1 compared to cluster D. When looking at the RA placebo groups there were no difference in change in SHP score at 24 weeks between the groups, (n=271, LITHE, OSKIRA), but a significant difference in SHP change 52 weeks (n=83,  $p < 0.05$ , LITHE).

Abstract AB0250 – Figure 1

**Conclusions:** We have identified putative RA profiles based on novel serological biomarker status. Whether patients in particular clusters may benefit from specific targeted treatments, according to their tissue turnover profile, will be investigated further.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3071

#### AB0251 ARE ACPA ASSOCIATED WITH MORE BONE LOSS OVER TIME IN PATIENTS WITH RA?

J.A.M.P. Amkreutz<sup>1</sup>, E.C. de Moel<sup>1</sup>, L. Heimans<sup>2</sup>, C.F. Allaart<sup>1</sup>, T.W.J. Huizinga<sup>1</sup>, D. van der Woude<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Internal Medicine, Leiden University Medical Center, Leiden, Netherlands

**Background:** Anti-citrullinated protein antibodies (ACPA) are one of the most important serological markers for rheumatoid arthritis (RA) and have been suggested to play a pathophysiologic role by directly binding to osteoclasts. However, the effect of ACPA on systemic bone mineral density (BMD) and in particular their effect on changes in BMD over time is currently unknown.

**Objectives:** The aim of this study was to determine whether ACPA associate with changes in BMD over time in patients with RA.

**Methods:** Yearly dual X-ray absorptiometry (DXA) scores were performed during 5 years of follow-up in 412 patients with recent-onset RA participating in the IMPROVED study<sup>1</sup>, a clinical trial in which patients were treated according to a remission- (disease activity score <1.6) steered strategy. The effect of the presence of ACPA on 1) Z-scores of lumbar spine and hip over time, and 2) prevalence of osteopenia/osteoporosis (defined as a T-score  $\leq -1$ ) over time was analysed using generalised estimating equations. Analyses were adjusted for age, gender, BMI, symptom duration, smoking status, disease activity, prednisone intake, usage of bisphosphonates, calcium intake and serum 25-OH vitamin D levels.

**Results:** ACPA-positive patients had a significantly lower lumbar spine ( $p=0.04$ ) and hip ( $p=0.01$ ) Z-score at baseline. There was no difference in prevalence of osteoporosis/osteopenia at baseline between ACPA-positive and ACPA-negative patients (OR (95% CI) 1.02 (0.55 to 1.19)). We hypothesised that ACPA-positive patients would have more BMD loss over time compared to ACPA-negative patients. However, ACPA-positivity did not associate with a stronger decline in Z-score over time at lumbar ( $p=0.43$ ) or femoral sites ( $p=0.67$ ). Additionally, no effect of ACPA-positivity was found on the development of osteoporosis/osteopenia over time ( $p=0.23$ ).

**Conclusions:** ACPA-positive patients have a significantly lower baseline BMD compared to ACPA-negative patients. Surprisingly, ACPA do not associate with a decrease in BMD over time in patients who were treated according to a tight control strategy. These results indicate that ACPA alone do not contribute to bone loss after disease onset in the absence of inflammation/disease activity.

**Background:** DAS28-ESR is the most widely used instrument to assess remission in rheumatoid arthritis (RA) patients. Nonetheless, substantial residual disease activity can be present in RA patients fulfilling DAS28-ESR remission. Therefore, more stringent criteria for remission have been developed. While it is known that patients can fulfil DAS28-ESR but fail ACR/EULAR Boolean remission criteria, the existence of the reverse is less known.

**Objectives:** To test the possibility to loose DAS28-ESR remission while staying in ACR/EULAR remission in patients with RA

**Methods:** Data were obtained from the prospective randomised RETRO study (EudraCT: 2009–015740–42), which recruits RA patients in stable remission. Remission was assessed by the following instruments every three months: DAS28-ESR, DAS28-CRP, CDAI, SDAI, PAS, and ACR/EULAR criteria. In the group of patients, escaping DAS28-ESR remission, but fulfilling ACR/EULAR Boolean remission, the individual components of DAS28-ESR were analysed that determined their escape from remission.

**Results:** 142 patients analysed, which were all in DAS28-ESR remission at baseline. Of them, 140 (98.59%) were in DAS-CRP-remission, 131 (92.25%) in CDAI-remission, 130 (91.55%) in SDAI-remission, 109 (76.76%) in ACR/EULAR remission and 66 (46.48%) in PAS-remission. We analysed upon the 1 year follow up

those patients losing DAS28-ESR remission over time: 58 patients lost DAS-ESR remission at least once during the 4 follow-up visits. Surprisingly, 24% (3 months), 36% (6 months), 24% (9 months) and 28% (12 months) of the patients still fulfilled the Boolean remission criteria. The only plausible reason for failing DAS28-ESR remission but staying in ACR/EULAR remission is an isolated elevation of the ESR, not accompanied by increased signs and symptoms of disease. Indeed all patients losing DAS28-ESR remission but staying in ACR/EULAR Boolean remission had an elevated ESR equal or higher than 15 mm. However, if DAS28 scores were calculated by C-reactive protein in the same patients, they all fulfilled remission criteria.

**Conclusions:** DAS28-ESR remission can be missed even if a patient fulfils the more stringent ACR/EULAR Boolean remission criteria. The reason for this remarkable constellation is an elevated erythrocyte sedimentation rate without any clinical symptoms. Hence, isolated elevations of erythrocyte sedimentation rate should be seen critical. These data show the limitations of individual instruments to assess remission in RA and show that interpretations of the erythrocyte sedimentation rate need to be done in the clinical context

AB0253

### RAPID REMISSION DURING THE FIRST YEAR IN EARLY ACTIVE RHEUMATOID ARTHRITIS IS ASSOCIATED WITH BETTER 5 YEARS STRUCTURAL DAMAGE OUTCOMES

J. Legrand<sup>1</sup>, T. Kirchgessner<sup>1</sup>, T. Sokolova<sup>2</sup>, B. Vande Berg<sup>1</sup>, P. Durez<sup>2</sup>.

<sup>1</sup>Musculoskeletal Imaging Unit, <sup>2</sup>Rheumatology, Cliniques universitaires Saint-Luc – Université Catholique de Louvain – Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium

**Background:** Remission is arguably the best and ultimate therapeutic goal in early rheumatoid arthritis (ERA). ERA patients who reach rapid and sustained remission are likely to retain good radiographic outcomes.

**Objectives:** The aim of this study was to evaluate the radiographic progression and the newly pathological joints in a Belgian ERA cohort during a 5 to 15 years follow-up and to correlate the Sharp score index with different indices of clinical remission observed during the first year.

**Methods:** This was a retrospective analysis of mean (95% CI) change from baseline (BL) to 5 years Sharp/Van der Heijde (SVdH) scoring according to DAS28, SDAI, CDAI and ACR/EULAR Boolean remission scores for patients at Month 3, 6 and 12. Newly pathological joint defined by a SVdH score of 0 at baseline and a score greater than or equal to 1 at follow up were analysed as a secondary objective. 133 ERA patients naïve to DMARDs therapies were analysed (100 women and 33 men) with a mean age  $\pm$ SD (49.9 $\pm$ 13.3), mean DAS 28-CRP (4.89 $\pm$ 1.3), mean HAQ (1.25 $\pm$ 0.67), mean SDAI (28.4 $\pm$ 15.5), mean CDAI (25.8 $\pm$ 14.8) and mean SVdH (6 $\pm$ 14). Differences were statistically tested using t tests.

**Results:** ERA patients were divided in 2 groups: "Xrays Stable" if the delta of SVdH score was <10 (n=90) or "Xrays Progressive" if the delta of SVdH score was >10 (n=43). As expected, presence of ACPA and baseline erosion were significantly higher in the Xrays progressive group. No significant baseline characteristics differences were observed for DAS28-CRP, CDAI, SDAI, HAQ, smoking status, swollen joint count or CRP.% of patients reaching DAS 28CRP, SDAI, CDAI and Boolean remission rates observed at 6 months were statistically significant different between groups (fig). There was no significant difference in clinical responses between subgroups of patients who developed new pathological joints and those who did not.

Abstract AB0253 – Figure 1

**Conclusions:** These results demonstrate that remission is an important therapeutic goal to protect joint damage in ERA. All remission criteria were able to predict the radiological prevention. The identification of a new pathologic joint is not associated with lack of response.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.4940

AB0254

### THE IMPACT OF THE PATIENT GLOBAL ASSESSMENT VARIATION ON THE DAS 28 VALUE

K. ben abdelghani, M. boudokhane, M. chammakhi, A. fazaa, K. oueniche, S. kassab, S. chekili, A. laatar. *Rheumatology, – Mongi Slim Hospital – La Marsa-Tunisia, Marsa, Tunisia*

**Background:** Rheumatoid arthritis (RA) is the most frequent chronic inflammatory rheumatism. The DAS 28 is a disease activity measure method used to assess RA activity. It is a composite score taking into account 4 items: the number of swollen joints/28, the number of tender joints/28, the erythrocyte sedimentation rate (ESR) or C reactive protein (CRP) rate, the patient global assessment (PGA) indicated on a 0–10 cm visual analogue scale (VAS) with 'not active at all' and 'extremely active' as anchors. The DAS28 determination is very important since it guides the therapeutic decision.

**Objectives:** The aim of this study was to determine the different ways of asking about the PGA and to assess the impact of its value variation on the calculation of the DAS 28.

**Methods:** In order to determine how to evaluate the GPA, a questionnaire including 4 propositions was asked to a cohort of Tunisian rheumatologists:

1. how do you assess your health status this past week?
2. what is the degree of the disease impact in your life this last week?
3. what is the degree of the disease activity this last week?
4. other

Then, a DAS 28 calculation was proceeded according to the different choices of GPA question method for 10 Tunisian patients.

**Results:** The questionnaire was proposed to 37 rheumatologists, 15 working in the private sector and 22 in the public sector. These latter were 9 assistants, 3 professors, 5 specialist doctors and 5 associate professors. The first, second, third and fourth propositions were respectively chosen by 2, 14, 19 and 2 physicians. Subsequently DAS 28 was calculated. In the table 1 below, the variation of the DAS 28 value according to the choice of the PGA method is shown:

Abstract AB0254 – Table 1

Patient	DAS 28 (PGA1)	DAS 28 (PGA2)	DAS 28 (PGA3)	DeltaDAS 28(DAS28 max-min)
1	2.95	2.95	2.81	0.14
2	2.53	2.67	2.67	0.14
3	2.1	1.96	1.96	0.14
4	5.82	5.82	5.54	0.28
5	5.30	5.30	5.16	0.14
6	2.87	2.87	2.87	0.00
7	8.22	8.22	8.22	0.00
8	4.97	5.11	5.11	0.14
9	7.49	7.35	7.63	0.14
10	2.03	2.17	1.89	0.28

**Conclusions:** The GPA question is a subjective item taken into account for the calculation of the DAS 28. Despite the different ways of asking about it, our study showed that this factor have no real impact on the DAS28 value variation since it doesn't exceed 0.6. DAS28 remains a reliable tool in the clinical practice.

### DOES MENOPAUSE AFFECT DISEASE ACTIVITY OF RHEUMATOID ARTHRITIS(RA)? AN ANALYSIS FROM THE NINJA COHORT IN 2016

K. Nagahata<sup>1</sup>, S. Tsuzuki<sup>1</sup>, S. Hattori<sup>1</sup>, K. Yomono<sup>1</sup>, S. Suzuki<sup>1</sup>, S. Takenouchi<sup>1</sup>, R. Yokochi<sup>1</sup>, N. Hagino<sup>1</sup>, T. Matsui<sup>2</sup>, S. Tohma<sup>3</sup>. <sup>1</sup>Division of Hematology and Rheumatology, Teikyo University Chiba Medical Center, Chiba; <sup>2</sup>Department of Rheumatology, Clinical Research Center for Allergy and Rheumatology, National Hospital Organization Sagamiara National Hospital, Sagamiara; <sup>3</sup>Department of Rheumatology, National Hospital Organization Tokyo National Hospital, Tokyo, Japan

**Background:** Early menopause may be a risk of developing RA<sup>1</sup>. Although there are many reports about menopause and the onset of RA, it is not yet clear how the disease activity of RA differs for each generation including menopause.

**Objectives:** To clarify how disease activity differs for each generation, especially in menopausal period.

**Methods:** Using the Japanese large RA cohort database (NinJa:National database of Rheumatic Diseases in Japan) of 2016, we divided 12257 RA females into three groups of age (under 44 years old=1, 45 to 55 years old=2, defined as a menopausal group, over 56 years old=3) and analysed them cross-sectionally. We conducted a one-way ANOVA on disease activity indexes such as Tender joint count (TJC), Swollen joint count (SJC), DAS28, HAQ-DI.

**Results:** Table 1 shows the number of people per group, the duration of disease, the titer of RF/ACPA, and the proportion of drugs used. The average usage of prednisone and the use of biologics was the most common in group 1. In table 2, TJC was the largest in group 2 ( $p<0.01$ ). Furthermore, the difference between groups seen in TJC tends to be larger than TJC 28. There was no significant difference in SJC (SJC28) between three groups. Other disease activity indicators (ESR, CRP, DAS 28, HAQ-DI) were the largest in group 3 ( $p<0.01$ ) and the percentage of Boolean remission was also lowest in group 3 ( $p=0.02$ ).

**Abstract AB0255 – Table 1.** Characteristics of the three age groups

group	1	2	3	P-value
Number of patients	1071	1699	9487	
Symptom duration, years	8.2	10.5	15.4	$p<0.01$
RF titer, (IU/mL)	186	233	254	$p=0.06$
ACPA titer, (U/mL)	90	102	132	$p<0.01$
On NSAIDs use, n(%)	392 (36%)	710 (41%)	3668 (38%)	$p<0.01$
Daily mean prednisone dose, (mg/day)	4.31	3.95	3.86	$p=0.01$
On DMARDs, n(%)	984 (91%)	1623 (95%)	8835 (93%)	$p<0.01$
On a biologic, n(%)	435 (40%)	550 (32%)	2570 (27%)	

**Abstract AB0255 – Table 2.** Comparisons of values for disease outcomes of the three age groups

	1	2	3	P-value
Tender joint count(TJC), mean	1.65	2.17	1.97	$p<0.01$
Tender joint count(28 joints, TJC28), mean	1.17	1.48	1.44	$p=0.01$
Swollen joint count(SJC), mean	1.35	1.49	1.52	$p=0.23$
Swollen joint count(28 joints, SJC28), mean	1.05	1.19	1.20	$p=0.12$
ESR, mean, (mm/h)	17.3	18.8	29.7	$p<0.01$
CRP, mean, (mg/dl)	0.32	0.37	0.58	$p<0.01$
DAS28, mean	2.51	2.78	3.12	$p<0.01$
HAQDI score, mean	0.25	0.42	0.77	$p<0.01$
Proportion in Boolean remission, n(%)	351 (32%)	485 (28%)	2145 (22%)	$p=0.02$

**Conclusions:** This study shows that TJC may increase during menopause, unlike other disease activity indicators. Especially in group 2, it is possible that the joints which can't be evaluated at TJC 28 are affecting the results because in TJC, compared with TJC 28, there is a larger group difference. Although further studies are needed, an increase in TJC may reflect menopausal joint symptoms.

#### DIFFERENTIAL DIAGNOSIS OF SERONEGATIVE RA: CALCIUM PYROPHOSPHATE DIHYDRATE DEPOSITION DISEASE

K. Paalanen<sup>1</sup>, K. Rannio<sup>2</sup>, T. Rannio<sup>1</sup>, J. Asikainen<sup>1</sup>, P. Hannonen<sup>1</sup>, T. Sokka<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Radiology, Central Finland Central Hospital, Jyväskylä, Finland

**Background:** Calcium pyrophosphate deposition (CPPD) disease is caused by calcium pyrophosphate (CPP) crystals and seen mainly in elderly. Clinical presentation can be heterogeneous. The arthropathy of CPPD may mimic RA, particularly if involving common joints seen in RA. Diagnosis of CPPD arthritis is based on CPP crystals seen in synovial fluid (SF) analysis, chondrocalcinosis (CC) seen in radiographs and/or on typical clinical presentation for CPPD. Early diagnosis of CPPD can be challenging and a proportion of CPPD patients may be misdiagnosed. We demonstrate 17 cases with CPPD initially diagnosed and treated as seronegative RA.

**Objectives:** To increase awareness that CPPD disease may resemble seronegative RA and to characterise clinical and radiographic phenotypes of these CPPD patients.

**Methods:** Altogether 435 early seronegative early RA patients were clinically diagnosed in a single rheumatology centre and scheduled for 10 year follow-up. All clinical data and radiographs were collected and reviewed. Patients were re-diagnosed as CPPD related arthritis if they had typical radiographic findings and suitable clinical pattern of CPPD or positive CPP crystal finding in SF. These patients are the subjects of this study.

**Results:** 17 patients were identified with a CPPD disease. The mean age at baseline was 71.2 years, and 82% were women. In 7 (41.2%) patients baseline symptoms were polyarticular, and in all these patients' wrist, MCP or PIP joints were affected; other symptomatic joints were hip (1 patient) and ankle (3 patients). The initial symptoms of 6 (35.3%) patients were oligoarticular, including MCP and PIP joint involvement (2 patients) or wrist and MCP, PIP or MTP joint symptoms (4 patients). Four (23.5%) patients were diagnosed as monoarthritis including ankle (1 patient) and wrist (3 patients). Seven patients (41.2%) fulfilled 1987 ACR criteria for RA and the diagnosis of early RA of the other 10 patients (58.8%) was based on clinical judgement. During the follow up period the SF analysis of 4 patients was available, 3 SFs showing positivity for CPP crystals. In 13 patients, SF had not been taken. In retrospect the baseline radiographs of 10 patients showed evidence of CC, either in wrists or knees. During follow up all patients developed typical clinical pattern for CPPD disease: chronic CPP crystal inflammatory arthritis (9 patients), acute CPP crystal arthritis (6 patients) and OA with CPPD (2 patients). All developed similar radiographic findings compatible with CPPD, including CC of triangular fibrocartilage (17 patients), CC of knee (9 patients), CC or narrowing of MCP joints (7 patients), CC of metatarsophalangeal (MTP) joints (4 patients), CC of symphysis pubis (1 patient), CC of glenohumeral joint (1 patient) and SLAC (5 patients). None of these patients developed typical RA-like erosions.

**Conclusions:** The prevalence of CPPD patients in our early seronegative RA patients was 3.9%. CPPD disease can mimic seronegative RA at baseline and is important in the differential diagnosis of seronegative arthritis.

AB0257

#### PHYSICAL ACTIVITY IN EARLY AND LONG-STANDING RA – RELATIONS TO DISEASE ACTIVITY, CARDIOVASCULAR RISK FACTORS AND ATHEROSCLEROSIS

K.M. Hörnberg<sup>1</sup>, L. Ångström<sup>1</sup>, A. Södergren<sup>1</sup>, J. Pomeroy<sup>2</sup>, C. Sandberg<sup>1</sup>, B. Sundström<sup>1</sup>, S. Wållberg-Jonsson<sup>1</sup>. <sup>1</sup>Department of Public Health and Clinical medicine/Rheumatology, Umeå, Sweden; <sup>2</sup>Marshfield Clinic Research Institute, Marshfield, USA

**Background:** The excess risk for cardiovascular disease (CVD) in Rheumatoid Arthritis (RA), is partly attributable to traditional cardiovascular risk factors for CVD<sup>1</sup> and systemic inflammation,<sup>1, 2</sup> factors known to be modified by physical activity.<sup>3, 4</sup>

**Objectives:** The aim of this cross-sectional study was to objectively measure and compare the level of physical activity in patients with early and long-standing RA, and to analyse possible associations with disease activity, risk factors for CVD and measures of subclinical atherosclerosis.

**Methods:** This study included 84 patients with early and 37 with long-standing RA (disease duration, mean [SD] 1.4 [0.4] and 16.3 [2.3] years respectively). Physical activity was measured using a combined accelerometer and heart rate monitor and included total physical activity (counts/min), proportion of moderate to vigorous physical activity (MVPA) and sedentary time. Further assessments were; disease activity (ESR, DAS28), functional ability (HAQ), risk factors for CVD (blood lipids, i.e., triglycerides, high density lipoprotein [HDL], low density protein [LDL], blood glucose, blood pressure, waist circumference, body mass index [BMI]), body fat (Dual-energy X-ray), and early signs of atherosclerosis (pulse wave velocity [PWV], augmentation index [AIx] and carotid intima-media thickness [cIMT]).

**Results:** Physical activity variables did not differ between patients with early and long-standing RA. Thirty-seven% of the patients with early and 43% of the patients with long-standing RA did not reach WHO's recommended levels of MVPA. Univariate linear regression analyses with the two groups combined, showed associations between total physical activity and younger age, lower values for HAQ and disease activity (ESR), as well as more beneficial values

for blood glucose, triglycerides, waist circumference, BMI, body fat, sleeping heart rate (SHR), systolic, diastolic and central blood pressure and pulse pressure, Aix, PWV, and cIMT. More time spent in MVPA was associated with younger age and with favourable values of blood glucose, HDL, LDL, waist circumference, SHR and PWV.

**Abstract AB0257 – Table 1.** Physical activity variables in patients with early and long-standing RA, presented as median with inter-quartile range (IQR). P-value refers to Mann-Whitney U-test.

	Early RA (n=84)	Long-standing RA (n=37)	p
<b>Accelerometry</b> (mean counts/ minute)	35.7 (29.9)	38.1 (24.3)	.915
<b>MVPA</b> (% of wear time)	3.2 (6.6)	2.5 (5.5)	.884
<b>Sedentary time</b> (% of wear time)	53.9 (11.0)	52.0 (13.3)	.328

MVPA=Moderate to Vigorous Physical Activity=time $\geq$ 1.75 x resting heart rate. Sedentary time=heart rate data with zero accelerometer counts.

**Conclusions:** Physical activity behaviour was similar in patients with early and long-standing RA. Total physical activity as well as more time spent in moderate to vigorous physical activity were associated with more favourable risk factors for CVD and measures of atherosclerosis. These results stress the importance of promoting physical activity in patients with RA.

#### IMPACT OF CONTROLLING DISEASE ACTIVITY ON REGAINING NORMAL PHYSICAL FUNCTION, AND ACHIEVING NO OR LIMITED PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BARICITINIB

K. de Vlam<sup>1</sup>, B. Fautrel<sup>2</sup>, M. van de Laar<sup>3</sup>, B.W. Kirkham<sup>4</sup>, R. Alten<sup>5</sup>, K. V. Beneden<sup>6</sup>, F. de Leonardis<sup>7</sup>, P. Lopez-Romero<sup>8</sup>, C. Gaich<sup>9</sup>, A. Quebe<sup>9</sup>, A. Cardoso<sup>9</sup>, R. Fleischmann<sup>10</sup>, P. Emery<sup>11</sup>. <sup>1</sup>Department of Musculoskeletal Sciences, University Hospital Leuven, Leuven, Belgium; <sup>2</sup>Department of Rheumatology, APHP, Pitié-Salpêtrière Hospital, Paris, France; <sup>3</sup>Department of Rheumatology, Medisch Spectrum Twente, Enschede, Netherlands; <sup>4</sup>Rheumatology Department, Guy's and St Thomas' NHS Foundation Trust, London, UK; <sup>5</sup>Schlosspark Klinik, Berlin, Germany; <sup>6</sup>Eli Lilly and Company, Brussels, Belgium; <sup>7</sup>Eli Lilly and Company, Swiss, Switzerland; <sup>8</sup>Eli Lilly and Company, Madrid, Spain; <sup>9</sup>Eli Lilly and Company, Indianapolis; <sup>10</sup>Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas, USA; <sup>11</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds Biomedical Research Centre, Leeds, UK

**Background:** Remission or low disease activity (LDA) are the recommended treatment (tx) targets in rheumatoid arthritis (RA).<sup>1</sup> It is still unknown whether achieving remission/LDA is associated with normalisation of physical function, and limiting pain.

**Objectives:** To describe the impact of baricitinib (BARI) tx on regaining normal physical function, and achieving no/limited pain in patients (pts) who achieved remission or LDA, or remained in moderate or high disease activity (MDA, HDA).

**Methods:** This is a post-hoc analysis of RA-BEAM (NCT01710358) and RA-BEGIN (NCT01711359). Mutually exclusive categories were defined as clinical disease activity index (CDAI) scores of  $\leq 2.8$  (remission),  $>2.8$  to  $\leq 10$  (LDA),  $>10$  to  $\leq 22$  (MDA), and  $>22$  (HDA). Last observation carried forward was used for pain visual analogue scale (0–100 mm VAS) and Health Assessment Questionnaire-Disability Index (HAQ-DI) to impute missing values. Descriptive analyses of the pts achieving normalisation of physical function was defined by a HAQ-DI

score of  $<0.5$  (normative value), and limited/no pain by pain VAS of  $\leq 10$  mm at week (wk) 12 and 24 as a function of disease activity.

**Results:** Overall, 1228 pts in RA-BEAM (448, PBO+MTX; 471, BARI+MTX; 309, ADA+MTX) and 543 pts in RA-BEGIN (190, MTX; 156, BARI; 197, BARI+MTX) were included. In RA-BEAM, among pts in remission at wk 12, % pts achieving limited/no pain was numerically higher in BARI (83%; 33/40) group compared with ADA (73%; 16/22) and PBO (67%; 6/9); at wk 24, these percentages were 81% (61/75), 82% (32/39), and 63% (12/19) for BARI, ADA, and PBO, respectively. Among pts who achieved remission on BARI+MTX tx, normal physical function was reported in 65% (26/40) and 73% (55/75) of pts at wk 12 and 24, respectively (Fig 1). For ADA+MTX treated pts, the proportion was 73% (16/22) at wk 12 and 69% (27/39) at wk 24. In RA-BEGIN, among pts in remission, % pts with limited/no pain at wk 12 was numerically higher for BARI (96%; 21/22) compared with BARI+MTX (82%; 32/39) or MTX (64%; 9/14); limited/no pain at wk 24, was reported in 68% (23/34), 87% (40/46), and 77% (17/22) of pts treated with BARI, BARI+MTX, and MTX, respectively. Among pts in remission, % pts achieving normal HAQ-DI at wk 12 and 24 with BARI monotherapy were 91% (20/22) and 82% (28/34); BARI+MTX, 77% (30/39) and 91% (42/46); and MTX monotherapy, 79% (11/14) and 82% (18/22), respectively.

**Abstract AB0258 – Figure 1.** Percentage of pts who achieved pain VAS  $\leq 10$  mm, and HAQ-DI  $<0.5$  scores for the different disease activity states at wk 12

Percentages indicate the pts who regained normal physical functions (HAQ $<0.5$ ), and less/no pain (pain VAS $\leq 10$  mm) with different disease activities (CDAI scores of  $\leq 2.8$  [remission],  $2.8$  to  $\leq 10$  [LDA],  $10$  to  $\leq 22$  [MDA], and  $>22$  [HDA]) in different treatment groups

\*In RA-BEAM, MTX was given as a background therapy among all treatment groups.

**Conclusions:** These data support that controlling the disease activity by achieving remission or LDA increases the chances to regain normal physical function and relieve pain, independent of the tx. The data from RA-BEAM may indicate that achieving limited/no pain at wk 12 may be more likely with BARI vs ADA, when being in remission.

### AB0259 CLINICAL MANAGEMENT OF SERONEGATIVE AND SEROPOSITIVE RHEUMATOID ARTHRITIS: A COMPARATIVE STUDY

K. Lee<sup>1</sup>, S.-T. Cho<sup>2</sup>. <sup>1</sup>Dongguk University Ilsan Hospital, Goyang; <sup>2</sup>Chung-Ang University College of Medicine, Seoul, Korea, Republic of Ireland

**Background:** Both rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (ACPA) are associated with poor radiologic outcomes in patients with rheumatoid arthritis (RA). In general, RA patients positive for RF or ACPA (SPRA) are considered to manifest an aggressive disease course compared with seronegative RA patients (SNRA). However, the relationship between seropositivity and measures of disease severity other than radiologic outcome is disputed.

**Objectives:** In this study, we sought to compare the clinical presentations and treatment outcomes of SNRA and SPRA patients.

**Methods:** A total of 241 patients diagnosed with DMARD-naïve RA under either 1987 American College of Rheumatology (ACR) criteria or 2010 ACR/European League Against Rheumatism (EULAR) criteria were identified (40 with SNRA and 201 with SPRA). We investigated the disease activity measures including ESR, CRP, patient VAS, 28 tender/swollen joint count (28 TJC, 28 SJC) and DAS28 as well as radiologic outcomes at baseline, 1 and 2 years after conventional treatment with DMARD.

**Results:** Age, sex and disease duration were similar between SNRA and SPRA. However, the baseline 28 TJC (4.7±2.9 vs. 3.3±2.7, p=0.004), 28 SJC (4.3±3.0 vs. 2.9±2.3, p=0.001) and DAS28 (5.1±1.0 vs. 4.7±1.0, p=0.043) components were significantly higher in SNRA than in SPRA. Over 2 years of similar treatment with DMARDs, all disease activity measures significantly improved in both groups. Notably, ΔDAS28 from baseline at 1 year was significantly greater in SNRA compared with SPRA (-2.9±1.2 vs. -2.2±1.8, p=0.002). Radiologic outcomes at baseline and at 1- or 2 year follow-up were similar between the 2 groups

**Conclusions:** SNRA patients manifested more active disease at baseline, but showed a better response to treatment compared with SPRA. SNRA does not appear to be a benign subtype of RA

**Disclosure of Interest:** None declared

### AB0260 ASSOCIATION BETWEEN ANTI-CITRULLINATED PROTEIN ANTIBODY STATUS, EROSIVE DISEASE AND HEALTHCARE RESOURCE UTILISATION IN PATIENTS WITH RA

L.R. Harrold<sup>1</sup>, L. Guo<sup>2</sup>, S.E. Connolly<sup>3</sup>, E. Alemao<sup>3</sup>, S. Rebello<sup>2</sup>, Y. Shan<sup>2</sup>, J. M. Kremer<sup>4</sup>. <sup>1</sup>University of Massachusetts Medical School, Worcester, MA; <sup>2</sup>Corona LLC, Waltham; <sup>3</sup>Bristol-Myers Squibb, Princeton; <sup>4</sup>Albany Medical College and The Center for Rheumatology, Albany, USA

**Background:** Anti-citrullinated protein antibody (ACPA) is a highly specific biomarker for RA<sup>1</sup> and ACPA-seropositive patients have a tendency toward severe erosive disease and more rapid disease progression.<sup>2-4</sup> Little is known regarding the impact of poor prognostic factors, such as ACPA and erosive disease, on healthcare resource utilisation (HCRU).

**Objectives:** To characterise the rate of HCRU between anti-cyclic citrullinated peptide (anti-CCP; a surrogate of ACPA) positive (+) patients with or without erosions who initiated biologic (b)DMARD treatment.

**Methods:** This analysis included patients aged ≥18 years, who were enrolled in a large sequential RA registry (October 2001–August 2017) and who had known erosions, as measured by radiography, and anti-CCP +status at or prior to bDMARD initiation visit and a 12 month (±3 months) follow-up visit. Anti-CCP +was defined as ≥20 U/mL. Rates of HCRU, including all-cause hospitalizations, all joint surgeries (total and partial; all sites), radiographic procedures and use of assistive devices, were estimated over 12 months of follow-up from the bDMARD initiation visit in anti-CCP +patients with or without erosions. Rates of HCRU per 100 patient-years and risk ratios, adjusted by baseline age, were estimated with 95% CI using a Poisson regression model.

**Results:** A total of 2047 anti-CCP +patients were included in this analysis, 868 with and 1179 without erosions. At biologic initiation visit, mean (SD) age was 58.9 (12.5) and 55.9 (12.5) years and disease duration was 11.7 (10.1) and 6.4 (7.5) years, respectively, in anti-CCP +patients with and without erosions. Over 12 months of follow-up, the rates of HCRU were higher among anti-CCP +patients with versus those without erosions at baseline bDMARD initiation visit (table 1).

**Conclusions:** ACPA seropositivity with erosive disease predicts high utilisation of healthcare resources, suggesting that early therapeutic intervention may be

warranted in anti-CCP +patients to achieve better disease control and reduce the complications from RA.

**Abstract AB0260 – Table 1.** Age-Adjusted Rates (95%CI) of HCRU and Adjusted Risk Ratios in Anti-CCP+ Patients With RA With and Without Erosions

	Age-adjusted rate (95% CI)*†		Adjusted risk ratio (95% CI)*†
	Anti-CCP+and no erosions (n=1179)	Anti-CCP +and erosions (n=868)	Anti-CCP+/erosions vs anti-CCP+/no erosions‡
<b>Hospitalisation, all cause</b>	9.44 (7.77–11.37)	15.21 (12.72–18.05)	1.47 (1.14–1.90)

### AB0261 ONGOING GOOD RESPONSE WITH BIOLOGICS. DATA FROM THE AUSTRIAN BIORG REGISTRY

M. Herold<sup>1,2</sup>, G. Eichbauer-Sturm<sup>3</sup>, T. Nothnagel<sup>4</sup>, R. Puchner<sup>5</sup>, B. Rintelen<sup>4</sup>, P. Spellitz<sup>6</sup>, B.F. Leeb<sup>4</sup>, on behalf of BioReg Austria. <sup>1</sup>Department of Internal Medicine II, Innsbruck Medical University, Innsbruck; <sup>2</sup>BioReg Austria, Vienna; <sup>3</sup>Rheumatologist in private practice, Linz; <sup>4</sup>2nd Department of Internal Medicine, Lower Austria State Hospital, Stockerau; <sup>5</sup>Rheumatologist in private practice, Wels; <sup>6</sup>Rheumazentrum Wien-Oberlaa, Vienna, Austria

**Background:** The goal for the treatment of rheumatoid arthritis (RA) should be remission or at least low disease activity. Using data of the Austrian biologic registry we evaluated disease activity in patients with RA and treated with biologics for more than six years.

**Objectives:** The aim of this evaluation was to elucidate long term disease activity in patients with RA who are treated with a biologic. We checked data at baseline and at control-visits every six months after inclusion in BioReg.

**Methods:** Data were extracted from the Austrian BioReg registry (<http://www.bio-reg.at>) which was initiated in 2009 to document patients treated with one of the biologics approved in Austria. Patients with ongoing biologic therapy as well as biologic-naïve patients starting biologic therapy can be included (baseline, BL). Further documentation is recommended about every 6 months (V2, V2 up to V12). Until September 2017, 2132 patients (1157 RA, 497 SpA, 401 PsA, 77 other diseases) have been documented.

Estimation of disease activity was done using DAS-28, RADAI-5, HAQ as well as ESR and CRP.

**Results:** DAS-28 (median values of BL; V2; V4; V10;V12) of our patients with RA are 3,30; 2,51; 2,33; 2,49; 2,58, the respective RADAI-5 values are 3,20; 2,20; 2,00; 2,00; 2,40 and values of HAQ are 0,75; 0,50; 0,50; 0,50; 0,63. Median values of inflammation's laboratory markers (ESR in mm/1st hour and CRP in mg/l) were always within or close to the normal range (ESR and CRP in RA 15; 12; 11,5; 13,5; 11 and 2,1; 2,0; 2,0; 2,4; 3,0

**Conclusions:** Our data confirm the efficiency of therapy with a biologic. During 6 years of continuous treatment more than half of the patients with RA are continuously in remission or low disease activity with a DAS-28 below 2,6, RADAI-5 equal or below to 2,40 and normal values of ESR and CRP.

**AB0262** **SEARCHING PREDICTORS OF ABATACEPT EFFICACY IN PATIENTS WITH RHEUMATOID ARTHRITIS**

M. Borisova<sup>1</sup>, G. Lukina<sup>1,2</sup>, Y. Sigidin Y.A.<sup>1</sup>, E. Aronova<sup>1</sup>, E. Luchihina<sup>3</sup>, D. Karateev<sup>3</sup>, A. Novikov<sup>2</sup>, E. Alexandrova<sup>2</sup>, M. Cherkasova<sup>1</sup>, S. Glukhova<sup>1</sup>, E. Nasonov<sup>1</sup>. <sup>1</sup>V.A. Nasonova Research Institute of Rheumatology; <sup>2</sup>A.S. Loginov Moscow Clinical Scientific Center; <sup>3</sup>Moscow Regional Research and Clinical Institute ("MONIKI"), Moscow, Russian Federation

**Background:** Biologics have revolutionised the treatment of rheumatoid arthritis (RA). Several types of biologics are used in clinical practice, one of them is the blocker of T cells co-stimulation – abatacept (ABA). The search for predictors of biologics efficacy is an important issue in current rheumatology practice.

**Objectives:** To identify predictors of ABA efficacy based on the analysis of various serum biomarkers changes.

**Methods:** 44 RA pts with a history of previous DMARDs and biologics failures and 16 healthy donors as controls were included in the study. The majority of pts were females, RF-positive – 80%, anti-CCP-positive – 79.5%, mean age 49.6 ± 13.9 years, median disease duration 21.4<sup>3</sup> years, with high RA activity (mean DAS28=5.2±0.8). Enzyme-linked immunoassay was used to measure serum concentrations of biomarkers IL-1β, IL-6, IL-17AF, TNF-α, VEGF-A, IP-10, YKL-40, MMP3 at baseline and after 6 months of ABA therapy. Disease activity was assessed every 3 months using DAS28. ABA were administered IV according to standard schedule.

**Results:** RA pts had significantly increased levels of IL-6 (2.4 [1.1–6.4] vs 0.7 [0.62–1.0] pg/ml, p=0.0002), YKL-40 (97<sup>68,4–97,9</sup> vs 64<sup>52,4–107,5</sup> pg/ml, p=0.03), and IP-10 (21<sup>12,9–49,8</sup> vs 14<sup>9,2–15,2</sup> pg/ml, p=0.005) compared to the control group. By the 6-th month ABA significantly reduced the levels of IL-6 up to 1.29 [0.9–2.2] pg/ml, p=0.0006 and IP-10 – to 14<sup>7,5–28</sup> pg/ml, p=0.007, as well as MMP3 and RF from 30.1<sup>13–82</sup> to 10 [7.4–55] pg/ml, p=0.0003 and from 218 [9.6–187] to 159 [9.7–155] pg/ml, p=0.02, respectively. There was a significant correlation between the decrease of IL-6 (r=0.5) and IP-10 (r=0.32) levels and decrease of DAS28 scores (p<0.05). A trend to a more pronounced reduction in disease activity was identified in anti-CCP-positive and anti-MCV-positive pts. By EULAR criteria the percentage of no-responders among anti-CCP-negative and anti-MCV-negative was almost two times higher as compared to antibodies-positive pts, i.e., 27.2% vs 16% and 26.7% vs. 14.8%, respectively, although the difference failed to reach statistical significance. However, by 6 months the percentage of pts with high disease activity among anti-MCV-negative pts were significantly higher than among anti-MCV-positive (20% and 0%, p=0.03, respectively). Higher baseline IL-6 (p=0.03) and YKL-40 (p=0.02) levels were registered among non-responders to ABA therapy.

**Conclusions:** ABA therapy led to a significant reduction in concentrations of pro-inflammatory IL-6 and IP-10 cytokines, as well as of MMP3 and RF. The decrease of IL-6 and IP-10 levels significantly correlated with the decrease of RA activity. There was a trend towards more pronounced reduction of disease activity in anti-CCP-positive and anti-MCV-positive pts. High baseline IL-6 and YKL-40 levels were significantly more frequently registered among non-responders. Therefore, anti-MCV-negativity, high baseline levels of IL-6 and YKL-40 could be used as predictors of insufficient ABA efficacy in this category of pts. A small sample of pts is the major limitation of this study, requiring future studies.

Guzón<sup>3</sup>, E. Perez Fernandez<sup>3</sup>, J. Quirós<sup>3</sup>, R. Mazzucchelli<sup>3</sup>, on behalf of TREND-AR. <sup>1</sup>Rheumatology, Hospital Universitario Puerta de Hierro Majadahonda; <sup>2</sup>H.U. Puerta de Hierro Majadahonda; <sup>3</sup>H. U. Fundación Alcorcón; <sup>4</sup>H. U. Severo Ochoa; <sup>5</sup>HU La Princesa; <sup>6</sup>HU Ramón y Cajal, Madrid; <sup>7</sup>H. U. Guadalajara, Guadalajara; <sup>8</sup>HU 12 de Octubre; <sup>9</sup>HU Clínico San Carlos; <sup>10</sup>H. U. del Henares; <sup>11</sup>HU Móstoles; <sup>12</sup>CS La Rivota, Madrid, Spain

**Background:** There have been important changes in the management of rheumatoid arthritis (RA) in the last 20 years, due to the incorporation of new drugs. An increase in the incidence of tuberculosis infection (TB) has been observed

because of reactivation of latent TB with the use of new treatments. Adequate prevention measures have been implemented.

**Objectives:** To analyse the incidence and trend of hospital admissions for TB in patients with RA in Spain during the period between 1999 and 2015.

**Methods:** This is a retrospective population based study. We analysed a national administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of patients with RA. Period: 1999 to 2015. The TB cases were identified by the presence in primary and secondary diagnosis of ICD 9 codes. The population at risk was estimated through the population census of the National Institute of Statistics, with an estimated prevalence of RA of 0.5%. The crude and adjusted rates of TB were calculated. The trend was analysed using Generalised Linear Models (GLM) using the year variable as the analysis variable.

**Results:** Among all the admissions of patients with AR (338.343), 1209 (0.35%) were due to TB, 665 (55%) in women and 544 (44.9%) in men. The mean age was 63.25 (SD 13.7). The mean of the Charlson index was 1.84 (SD 1.45), in women 1.63 (SD 1.3) and in men 2.09 (SD 1.59) (p<0.001).

There were a total of 94 (7.8%) deaths during admission (6.9% in women, 8.8% in men, p=0.231). The TB age-adjusted rate during the study period was 42.78/100.000 inhabitants RA-year (28.2 in women and 100.74 in men). The TB age-adjusted rate in both sexes remains without significant changes between 1999 and 2015 (IRR 0.225; CI95% 0.985–1.025). During the period 1999–2011 an increase of the incidence is observed, while in the period 2011–2015 it is observed a decrease of the same (fig 1).

**Abstract AB0263 – Figure 1**

**Conclusions:** Conclusion: In Spain, in patients with RA, the income rate in relation to tuberculosis increased from 1999 to 2010 and subsequently decreased in the period from 2011 to 2015.

**Disclosure of Interest:** None declared

U. del Henares, Madrid, Spain

**Background:** There have been significant changes in the management of rheumatoid arthritis (RA) during the past 20 years. The potential impact of these strategies on hospitalisation trend is unknown.

**Objectives:** To analyse the incidence and trend of hospital admissions in patients with RA in Spain from 1999 to 2015.

**Methods:** This is a population based study. We analysed a national administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of patients with RA during the period 1999–2015.

The admission cases in patients with RA were identified by the presence in primary and secondary diagnosis of the ICD9 codes (714.0–714.9). The population at risk was estimated through the population census of the National Institute of Statistics, with an estimated prevalence for RA of 0.5%, with crudes and adjusted admission rates being calculated. The trend was analysed using Generalised Linear Models (GLM).

**Results:** There were a total of 3 38 343 hospital admissions in RA patients during the study period, accounting for a total of 1 76 097 patients (1 17 985 women and 58 112 men). The mean age at admission was 68 years (67.8 in women and 68.5

in men), with a linear increase throughout the study period from 65.3 in 1999 until 70.5 in 2015 ( $p < 0.001$ ).

The main admission code was for Osteoarticular and connective tissue diseases (20%) followed by Circulatory system diseases (16.8%). There were a total of 18 641 in-hospital deaths (5.5% of all the admissions).

The age-adjusted admission rate was 12.03/100 RA patients\*yr (9.12 for women and 1.88 for men). The age-adjusted admission rate increased from 1999 to 2015 (in both genders). An annual increase of admission rate of 3.7% is estimated. When adjusting by age, the largest increase is observed in patients older than 80 years, with an estimated annual increase of 7.5%.

Abstract AB0264 – Figure 1

**Conclusions:** In Spain, despite the improvement in RA management, there is a global tendency to the increase of admissions during the period of 1999–2015, mainly in >60 year, especially in >80 year.

#### AB0265 CLINICAL PREDICTOR FACTORS ASSOCIATED WITH SUSTAINED DISEASE ACTIVITY AMONG PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

M.G. Gonzalez Alvarez<sup>1</sup>, J. Molina<sup>2</sup>, L. Nuño<sup>2</sup>, V. Navarro-Compán<sup>2</sup>, A. Villalba<sup>2</sup>, D. Peiteado<sup>2</sup>, P. Bogas<sup>2</sup>, A. Balsa<sup>2</sup>, on behalf of IdiPaz. <sup>1</sup>Rheumatology, H. Universitario La Paz, IdiPaz; <sup>2</sup>Rheumatology, Hospital Universitario La Paz, Madrid, Spain

**Background:** In patients with rheumatoid arthritis (RA), low disease activity (DA) overtime is associated with favourable outcomes. However, the progression of the disease is faster during the first years. Therefore, it is desirable to identify patients with a high probability of sustained DA in an early stage.

**Objectives:** To identify clinical predictor factors at diagnosis associated with sustained DA after 12 months of follow up in patients with early RA.

**Methods:** Baseline (at diagnosis) and 12 months follow-up data from an early arthritis clinic was analysed. At both visits, demographic, clinical, laboratory and treatment data were collected and clinical DA was assessed using DAS28 and SDAI. For this study, patients with RA according to physician's diagnosis were selected. Sustained DA at 12 months was defined as DAS28 >3.2 and SDAI >11. Univariate and multivariable logistic regression models were employed to identify which factors are associated with sustained DA.

**Results:** In total, 566 patients were included. Out of these, 75.8% were women, 74.7% Caucasian, 77.7% RF + and 65.9% ACPA+. Mean (SD) age was 54<sup>17</sup> years and mean symptoms duration was 16<sup>15</sup> weeks. Regarding treatment, 89.8% patients received methotrexate as first line treatment and 81.1% received glucocorticoids. At baseline, 88.8% had moderate-high DA according to DAS28 (>3.2) and 77.6% with SDAI (>11). After one year of follow-up, 34% (DAS28) and 30.9% (SDAI) remained with moderate-high DA. Univariable logistic regression analysis results are shown in table 1. Sustained DA was significantly associated with baseline index and its individual components, HAQ, and GCs used for both indexes definitions, with smoking and MTX use for DAS28 definition and RF + for SDAI definition. In the multivariable analysis, sustained DA at 12 months remained significantly associated only with baseline DAS28 (OR 1.34;  $p < 0.05$ ) for DAS28 definition and with RF (OR 2.6;  $p = 0.02$ ), HAQ (OR 1.06;  $p < 0.01$ ) and use of glucocorticoids (OR 2.1;  $p < 0.05$ ) for SDAI definition.

Abstract AB0265 – Table 1. Univariable logistic regression analysis results

Baseline characteristics	DAS28		SDAI	
	OR	P value	OR	P Value
Age	1.00	0.6	0.03	1.02
Sex (women)	1.64	0.06	0.599	1.14
Tabaco	0.66	0.1	1.12	0.690
Nonsmokers (ref)	0.58	0.05	1.08	0.804
<b>Past smokers</b>				
<b>Smokers</b>				
RF (+)	1.61	0.09	0.444	0.007
ACPA (+)	0.685	0.1	0.691	0.14
DAS28	1.5	<0.001		
SDAI			1.00	0.008
HAQ	1.05	0.001	1.07	<0.001
ESR	1.01	0.001	1.01	<0.001
PCR	1	0.804	1.0	0.91
Pain	1.02	<0.001	1.01	<0.001
Patients Global Assessment	1.01	<0.01	1.01	0.002
Evaluator Global	1.02	<0.001	1.02	<0.001
<b>Assessment</b>				
Swollen Joint count 28	1.07	<0.001	1.07	<0.001
Tender Joint Count 28	1.07	<0.01	1.06	<0.001
Methotrexate use	8,2	<0.05	2,4	0,2
Glucocorticoids use	1.8	<0,05	2,7	<0.001

**Conclusions:** One out of three patients with RA maintains DA 12 months after diagnosis. The predictors for this status depend on the index employed: DAS28 at baseline is the best predictor for sustained disease activity when using DAS28-definition. Conversely, positive RF, impaired functionality and the need of glucocorticoids at baseline are associated with the SDAI-definition.

#### AB0266 ESTIMATION OF CEREBROVASCULAR REACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Salokhiddinov, U. Anarmetova, G. Haydarova. Tashkent Medica Academy, Tashkent, Uzbekistan

**Background:** Rheumatoid arthritis (RA) is a chronic autoimmune disease with high cardiovascular risk. Arterial hypertension (AH) is the most common comorbid condition in RA and one of the main risk factors for stroke. Chronic immune inflammation, characteristic of RA, also has a damaging effect on the vascular wall and can lead to a marked decrease in the compensatory possibilities of the cardiovascular system. It has been shown that the violation of cerebrovascular reactivity (CVR) significantly increases the risk of developing acute cerebral ischemia

**Objectives:** The goal is to study the condition of the CVR in RA patients, depending on the level of blood pressure (BP)

**Methods:** the study involved 70 patients with RA at the age of 59,2±7,3 years with the duration of RA 13±8,9 years were examined. The DAS28 index was 3.87 ±1.33. Depending on the level of blood pressure, two groups were isolated: group 1 (n=56) – patients with hypertension and group 2 (n=14) – with normal blood pressure. CVR was assessed by means of transcranial dopplerography of middle cerebral arteries (MCA) using hyperoxic (inhalation of 100% oxygen, phase of vasoconstriction) and hypercapnic (inhalation of 4% of a mixture of carbon dioxide with air, phase of vasodilation) of samples.

**Results:** The result showed that 15 (27%) patients of the I group and 3 (21%) – the II group had an adequate decrease in the linear velocities of the blood flow (LVBF) in the MCA. An insufficient reduction in hypervascular hypertension was found in 28<sup>50%</sup> and 8 (57%) patients, a paradoxical increase in the LVBF (perverse reaction) in 12 (21,4%) and 4 (28,5%) patients, respectively. In a hypercapnia trial, only about a third of patients registered an adequate increase in LVBF for hypercapnia. A decrease in the response occurred in 27 (48%) and 9 (61%) patients, excessive increase in LVBF (hyperergic reaction) – in 15 (26%) and 2 (14%) patients, respectively

**Conclusions:** There was a violation of the CVR on metabolic (hyperoxic and hypercapnic) stimuli based on the results of transcranial dopplerography of most RA patients, regardless of the level of blood pressure

**AB0267** **BASELINE PREDICTORS OF RESPONSE TO METHOTREXATE IN EARLY RHEUMATOID ARTHRITIS**

S. Rizvi, M. Bukhari. *Rheumatology, Royal Lancaster Infirmary, Lancaster, UK*

**Background:** The disease activity score (DAS28) is widely used to assess response to treatment in early rheumatoid arthritis. Few studies have looked at the individual components of the DAS at baseline to predict drop in DAS28 in early disease. Specifically at 3, 6 and 12 months. Predicting response early in disease would enable more targeted treatments to be given and patients selected early for more aggressive disease control. Although certain biomarkers have been advocated for use and have shown some promise.<sup>1,2</sup> there is still a place for exploring using more clinically derived indicators.

**Objectives:** To determine whether DAS28 response at 3, 6 and 12 months could be predicted by baseline components of the DAS28

**Methods:** The study used patients from the multicentre UK based RAMS study. All patients with early rheumatoid arthritis starting methotrexate were enrolled. We used data from a single centre in the North west of England for the analysis. DAS28 and its components were recorded at baseline and at 3 6 and 12 months. Baseline components of the DAS28 were used to predict the change in DAS from baseline to 3 6 and 12 months. Linear regression was used with subsequent adjustment for age and gender.

**Results:** 120 patients were enrolled in the study, median age was 62.4 years (IQR42.1, 72.5), 81 (67%) were female. Median das28 at baseline was 5.3 (IQR 4.2,6.2). Duration of symptoms was 9 months (IQR 2,11). There was a drop of DAS28 of 1.49 at 3 months (IQR 0.57,2.45) and at 6 and 12 months it was 1.84 (IQR 0.48,2.91) and 1.63 (IQR 0.72,2.85) respectively. At three months the only baseline predictor of change in DAS28 was the patient global assessment unadjusted and adjusted for age adjusted beta 0.012 95% CI 0.002, 0.023 (p=0.02). At six months the baseline tender joint count adjusted beta 0.08 95% CI 0.015, 0.154 (p=0.01) as well as swollen joint count adjusted beta 0.05 95% CI 0.004,0.095 (p=0.02) also predicted response in addition to the patients global assessment adjusted beta 0.016 95% CI 0.002, 0.03 (p=0.01), but not the ESR or CRP at baseline (p=NS). At 12 months the only predictors of response was the baseline CRP adjusted beta 0.02 95% CI 0.005, 0.04(p=0.02).

**Conclusions:** In this cohort of patients with early disease, response to methotrexate could not be reliably predicted using baseline measures and the ability to predict patients who would improve could not be found in this cohort. Further work on other clinical biomarkers to predict response is needed.

**AB0268** **HOW DO PATIENTS WITH RHEUMATOID ARTHRITIS EVALUATE THEIR GLOBAL ASSESSMENT?**

M. Kojima<sup>1</sup>, T. Kojima<sup>2</sup>. <sup>1</sup>Medical Education, Nagoya City University Graduate School of Medical Sciences; <sup>2</sup>Orthopedic Surgery, Nagoya University Hospital, Nagoya, Japan

**Background:** The importance of patient-reported outcomes (PRO) has been recently recognised. Patient global assessment (PtGA) is one of the most popular PROs in rheumatology. However, the validity of PtGA as a tool for assessment of disease activity and its relevance compared with other tools is still debated.<sup>1</sup> Patients' perspective is essential to achieve treat-to-target. The significance of measuring PtGA in clinical practice should be verified. We previously found that Japanese rheumatologists changed their strategy to ask patient global assessment (PtGA) according to the patients' understanding ability. It is unknown how patients themselves feel PtGA.

**Objectives:** To investigate how patients with rheumatoid arthritis (RA) evaluate and accept PtGA as assessment tool of RA activity.

**Methods:** During the period of August and September, 2016 a 90 min focus group was held four times. Nine or 10 RA patients participated in each focus group. Totally, 34 women and 4 men, average age 56.1±10.9 years old, and disease history 9.39±9.36 years joined the study. The participants freely discussed how to evaluate their conditions of rheumatism and therapeutic effect. We used the "Steps for Coding and Theorization" (SCAT)<sup>2-3</sup> to analyse the focus group data.

**Results:** Patients determined their PtGA based on pain, swelling, inconvenience of daily life, the mood of the day, comprehensively, although they felt confusing

because the criteria of how to evaluate PtGA was unclear. Most patients set 100 of PtGA as "when most painful after onset", while standard of 0 was varied. Many patients had experienced a discrepancy between PtGA and CRP that their doctors denied. Patients were eager that their doctor would understand the discordance between PtGA and laboratory data and ask the patients "what's wrong with you?"

**Conclusions:** Doctors and patients should discuss how to evaluate PtGA at the start of treatment to avoid patients' confusing. By utilising PtGA as a communication tool, relationship between doctor and patients would be facilitated.

**AB0269** **ANKLE SYNOVITIS AND TREAT-TO-TARGET STRATEGY IN CLINICALLY AND SEROLOGICALLY DIFFERENT FORMS OF RHEUMATOID ARTHRITIS, A SINGLE-CENTRE EXPERIENCE**

M. Kedves<sup>1</sup>, J. Gál<sup>1</sup>, K. Töröcsik<sup>1</sup>, D. Balaton<sup>1</sup>, J. Csitos<sup>1</sup>, N. Megyes<sup>1</sup>, G. Nagy<sup>2</sup>. <sup>1</sup>Rheumatology, Bacs-Kiskun County Hospital, Kecskemét; <sup>2</sup>Rheumatology, Semmelweis University, Budapest, Hungary

**Background:** DAS28 based treat-to-target (T2T) strategy<sup>1</sup> was shown to improve outcomes in patients with rheumatoid arthritis (RA). Although previous studies have shown that approximately 1/3 of RA patients have foot symptoms<sup>1,2</sup> ankle and foot joints are not included in DAS28.

**Objectives:** To study the prevalence of ankle synovitis in clinically and serologically different forms of RA, treated according to the updated T2T strategy.

**Methods:** 1109 patients, with RA, treated according to the T2T approach were included in this study. Concurrent tenderness and swelling of the ankle joint were considered as synovitis. Rheumatoid factor (RF) and anti-mutated citrullinated vimentin (anti-MCV) positive and negative patients with different disease activity were evaluated.

**Results:** 8.47% (94) patients had high (DAS28 >5.1); 35.25% (391) moderate (DAS28 ≤5.1;>3.2) and 18.66% (207) low (DAS28 ≤3.2;≥2.6) disease activity. 37.6% (417) of patients were in clinical remission (DAS28 <2.6). 60.71%<sup>17</sup> of anti-MCV and RF positive and 44.8%<sup>13</sup> of anti-MCV and RF negative patients with high disease activity had ankle synovitis (table 1). Regarding patients in remission, 13.7%<sup>18</sup> of anti-MCV and RF positive and 15%<sup>18</sup> of anti-MCV and RF negative patients had ankle synovitis (table 2). Interestingly, ankle synovitis was considerably more common than knee synovitis in all patient groups.

**Abstract AB0269 – Table 1.** Ankle and knee involvement in high disease activity

	DAS28>5.1, 94 patients in total	DAS28>5.1. RF pos., anti-MCV pos: 28 patients	DAS28>5.1. RF neg, anti-MCV neg: 29 patients
Right knee synovitis	21,27%	25%	24,13%
Left knee synovitis	19,14%	25%	10,31%
Both knees synovitis	4,25%	10,71%	0
% of patients with knee involvement	36,17%	39,28%	34,48%
Right ankle synovitis	31,91%	28,57%	34,48%
Left ankle synovitis	37,23%	42,85%	44,82%
Both ankles synovitis	13,82%	10,71%	34,48%
% of patients with ankle involvement	55,31%	60,71%	44,82%

**Abstract AB0269 – Table 2.** Ankle and knee involvement in remission

	DAS28<2.6 417 patients in total	DAS28<2.6, RF pos, anti- MCV pos: 131 patients	DAS28<2.6, RF neg, anti- MCV neg: 120 patients
Right knee synovitis	1,43%	2,29%	0
Left knee synovitis	0,95%	1,52%	0
Both knees synovitis	0	0	0
% of patients with knee involvement	2,39%	3,87%	0
Right ankle synovitis	6,71%	6,87%	6,66%
Left ankle synovitis	7,19%	7,63%	8,33%
Both ankles synovitis	0,23%	0,76%	0
% of patients with ankle involvement	13,66%	13,74%	15%

**Conclusions:** Our present data show that ankle synovitis is rather common in patients with serologically and clinically different forms of RA and highlight the importance of careful medical examination, even in case of clinical remission.

**Background:** Use of biologicals such as Rituximab (RTX) in Rheumatoid Arthritis (RA) is effective and often only licensed in combination with Methotrexate (MTX). In cases of contraindications to or intolerances, other cDMARDs are frequently used in routine care without data from RCTs. Patients with positive antiCCP-status were identified in previous studies to better respond to RTX in combination with MTX.

**Objectives:** Here we present for the first-time data of the impact of antiCCP status on ACR response in the combinational therapy of RTX and Leflunomide (LEF).

**Methods:** A total of 189 patients with active RA (DAS28 >3.2 and at least 3 SJC and 3 TJC) despite stable LEF treatment were screened for a 52 weeks double-blind placebo controlled multicenter RCT. Patients were randomised to receive either two times 1000 mg RTX i.v. or PLA, followed by a second course of RTX of either two times 500 or 1000 mg at week 24. The primary endpoint of the study was superiority of RTX in ACR20 and 50 responses during 24 weeks treatment period. Adult patients who had inadequate response to more than one antiTNF or failed more than three cDMARDs were excluded. Disease activity was measured at each visit and compared according to antiCCP status. For safety evaluation, frequency and severity of adverse events were documented.

**Results:** Of 189 screened patients 148 were randomised. The mean age was 56 years; the mean body weight 76 kg and 74% were female. The disease activity (DAS28) at baseline was 5.57 for RTX and 5.54 for PLA. 57.1% of the patients were antiCCP-positive for RTX compared to 59.6% for PLA. In the RTX group, antiCCP-positive patients' disease duration was 8.8 years compared to 5.6 years in the antiCCP-negative group), DAS28 was 5.73 vs. 5.32 and CRP levels were

11.1 mg/L vs. 5.3 mg/L. RTX demonstrated significant superiority compared to PLA at week 16 in both, ACR 20 and ACR 50 response. AntiCCP-positive patients showed a higher probability to respond to the RTX/LEF treatment than antiCCP-negative patients (figure 1). 43 serious adverse events were reported, 27 of them in the RTX treatment group during the placebo-controlled period.

**Abstract AB0270 – Figure 1**

**Conclusions:** Here we report data of the first RCT investigating the combination of RTX with LEF in RA. The treatment with RTX in combination with LEF demonstrated significant efficacy compared to PLA for ACR20 and 50 responses with highest response level at week 16. AntiCCP-positive patients showed a higher probability for treatment response compared to antiCCP-negative ones. The combination of RTX and LEF demonstrated a reasonable safety profile.

**RS12218 POLYMORPHISM IN SAA1 GENE IN THE RUSSIAN POPULATION OF RA PATIENTS IS ASSOCIATED WITH SECONDARY AMYLOIDOSIS. A PILOT STUDY**

M. Krylov<sup>1</sup>, Y. Muraviev<sup>1</sup>, A. Alekseeva<sup>1</sup>, E. Samarkina<sup>1</sup>, I. Guseva<sup>1</sup>, N. Kononova<sup>2</sup>, D. Varlamov<sup>2</sup>. <sup>1</sup>V.A. Nasonova Research Institute of Rheumatology; <sup>2</sup>All-Russian Research Institute of Agricultural Biotechnology, Moscow, Russian Federation

**Background:** Secondary amyloidosis (SA) is a serious complication of rheumatoid arthritis (RA), which is often fatal. Identification of associated risk factors, including genetic ones, is an important task.

**Objectives:** To assess the role of SAA1 gene polymorphism, encoding serum amyloid-A, as a risk factor predisposing to SA in the sample of Russian RA patients.

**Methods:** The study included 60 patients with RA, fulfilled the American College of rheumatology criteria (ACR) 1987. Of these 35 (mean age 49.5±10.8 y, mean disease duration 18.5±8.9) developed SA manifestations, confirmed histologically: group SA (+). 25 patients (mean age 56.7±11.7 y, mean disease duration 16.3±7.5 y) did not have either clinical or histological SA signs: group SA (-). The control group (C) consisted of 65 healthy employees. SAA1 gene polymorphism rs12218 (-13 T/C), mapped in the 5' flanking region of the gene, was studied in 125 subjects by polymerase chain reaction in real time (RT-PCR) with subsequent melting curves analysis.

**Results:** Statistically significant differences in the rates of TT, TC and CC genotypes of rs12218 polymorphism were established between SA(+) group and the controls (17.1%, 64.0%, 48.6% and 38.5%, 46.1%, 15.4%, respectively, p=0.029). High rate (58.6%) of the mutant C allele in SA(+) group compared to the control group (38.5%) predetermines high risk of susceptibility to SA in RA patients [OR 2.26, 95% CI(1.20–4.28), p=0.010]. Significant differences in rs12218 polymorphism rates were found between SA(+) and SA(-) groups [p<0.001]. The frequency of TC +CC genotype was significantly higher in the SA (+) group compared to SA(-) group [82.9% vs 36.0%, p<0.001]. The risk of predisposition to SA development among RA patients was increased when C allele frequencies in the group with SA (58.6%) were compared with the group without SA (22.0%) [OR 5.01, 95% CI (2.07–12.58), p<0.001]. No significant differences were found in the frequencies of genotypes and rs12218 alleles between SA(-) pts and the controls (p>0.05).

**Conclusions:** Our data confirm that genetic polymorphism rs12218 in SAA1 gene, is associated with the development of secondary amyloidosis in RA patients and mutation in this gene is an important risk factor predisposing to the development of this severe complication in the Russian population.

### MEAN PLATELET VOLUME AS A POTENTIAL BIOLOGICS THERAPY RESPONSE PREDICTOR AND DISEASE ACTIVITY INDICATOR IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Čaić<sup>1</sup>, M. Mayer<sup>2</sup>. <sup>1</sup>University of Zagreb, School of Medicine; <sup>2</sup>Division of Clinical Immunology and Rheumatology, University Hospital Centre KBC Zagreb, Zagreb, Croatia

**Background:** Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease that primarily affects joints. Currently, the most widely used markers of acute phase response are C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). However, in recent years it has been suggested that platelet histogram indices, such as mean platelet volume (MPV) could be predictors of disease activity in patients with RA.

**Objectives:** The aim of this study was to assess whether MPV can be used as a disease activity marker by analysing a possible correlation between MPV and DAS-28, serum CRP levels, and ESR in patients starting with or switching between different biological DMARDs (tocilizumab, infliximab). Finally, we investigate whether MPV value at baseline can be a therapy outcome predictor by comparing two groups of patients (remission and active disease) at the 12 month time point based on DAS-28 value.

**Methods:** Fifteen patients (aged 56.5±9.3 years) fulfilling the American College of Rheumatology (ACR) criteria for RA were retrospectively enrolled in the study from the rheumatology outpatient clinic at the University Hospital Centre Zagreb, Croatia. DAS-28 has been used to evaluate disease activity at baseline, 3 months, 6 months, 9 months, and 12 months after starting biological DMARD therapy. Laboratory assessments included a complete blood count (including MPV), ESR, and CRP levels at each visit.

**Results:** We have observed a significant reduction in DAS-28 within the 12 month assessment period (from 5.33±1.24 to 2.25±1.23). MPV varied between 8.5±0.6 at baseline and 9.0±0.8 at the 12 month time point, with its peak being at the 9 month time point (9.3±0.8). Mean MPV had an inverse correlation with mean DAS-28 ( $r=-0.94$ ,  $p=0.02$ ), as well as mean ESR ( $r=-0.91$ ,  $p=0.03$ ). A weaker correlation was observed with mean CRP ( $r=-0.56$ ,  $p=0.3$ ).

When assessing whether MPV could be used as a therapy response predictor, patients were divided into two groups: those in remission at the 12 month time point ( $n=10$ ) and those with significant disease activity ( $n=5$ ), with remission being defined as a DAS-28 value of 2.8 or less. There was no significant difference in MPV values between those groups (8.5±0.56 for those in remission and 8.52±0.545 for those with active disease).

Abstract AB0272 – Figure 1

**Conclusions:** The results of this study provide additional evidence supporting the previously reported correlation between MPV and other disease activity markers (DAS-28, ESR) to treatment response in RA patients. It seems MPV isn't a viable therapy outcome predictor given that there is no significant difference in MPV value in patients in remission and those not in remission.

### ASSESSMENT OF SERUM LEVELS OF 14–3–3H PROTEIN IN RHEUMATOID ARTHRITIS: IS IT A SPECIFIC MARKER FOR THE DISEASE?

M. Elshahaly<sup>1</sup>, M. Saleh<sup>2</sup>, H. Fahmy<sup>2</sup>, M. Othman<sup>2</sup>. <sup>1</sup>Rheumatology, physical medicine and rehabilitation; <sup>2</sup>Clinical and Chemical Pathology, School of Medicine, Suez Canal University, Ismailia, Egypt

**Background:** 14–3–3η protein was suggested to be significantly higher in serum and synovial fluid of rheumatoid arthritis (RA) patients compared to healthy individuals and other diseases such as osteoarthritis (OA) and ankylosing spondylitis (AS).<sup>1</sup> Accordingly, 14–3–3η is now thought to be a diagnostic marker for early RA. Furthermore, some reports suggest that it correlates well with disease activity.<sup>2</sup>

**Objectives:** To assess the usefulness of serum levels of 14–3–3η protein in the diagnosis of RA in comparison with hands OA patients and healthy controls; furthermore, to correlate its levels with markers of inflammation in RA patients.

**Methods:** This study was carried out as a case control comparative study. Our sample consisted of three groups. Group 1 was made up of 30 RA patients fulfilling 2010 ACR–EULAR classification criteria for RA;<sup>3</sup> Group 2 made up of 30 hands OA patients according to OA ACR criteria<sup>4</sup> and group 3 of 30 healthy volunteers. Patients with other rheumatic and/or systemic diseases or infections were excluded.

Patients were assessed using detailed clinical history and examination. Laboratory investigations included complete blood picture, ESR, CRP, RF, ACPA and serum levels of 14–3–3η protein using manual enzyme-linked immunosorbent assay (ELISA).

**Results:** Mean (SD) age of RA group was 45.5 (9.5) years old; for OA group was 50.3 (8.8) years old, and the control group was 46.2 (6.9) years old. Females represented 96.7% of group 1; 83.3% of group 2, and 86.7% of group 3. RF was positive in 78% of RA group, 6.7% in OA group and 6.3% of control group. Mean (SD) of RF titer was 123 (10.3), 15.3 (5.4) and 14.4 (5.2) IU/ml respectively. ACPA was positive in 96.7% of group 1 and was negative in groups 2 and 3. Mean (SD) ACPA was 64.4 (6.6) U/ml in RA group.

Mean (SD) ESR was 32.5±8.2 in group 1, 22.0 (6.6) in group 2 and 16.1 (7.3) mm/hour in group 3. Mean (SD) CRP was 17.9 (5.04), 5.7 (2.8) in group 2 and 4.9 (2.4) mg/L in group 3.

Mean (SD) levels of 14–3–3η protein were significantly higher among RA compared to OA and control groups (3.63 (1.35), 0.23 (0.14) and 0.28 (0.08) ng/ml, respectively) ( $p<0.0001$ ).

The optimal cutoff point of 14–3–3η protein to diagnose RA was >0.2 with a sensitivity of 80%, specificity of 87%, positive predicted value of 86% and negative predicted value of 81%. The eta protein also had high diagnostic odds ratio (26.1).

No correlation was found between serum levels of 14–3–3 eta and CRP nor ESR ( $p>0.05$ ).

**Conclusions:** 14–3–3η is a specific marker for RA that should be used in conjunction with RF and ACPA for diagnosis of the disease. However, no correlation was found between 14–3–3η and markers of inflammation.

### ASSOCIATION OF SERUM PENTOSIDINE LEVELS WITH INTIMA MEDIA THICKNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Kerkeni<sup>1</sup>, I. knani<sup>1</sup>, O. Ben Omrane Sioud<sup>1</sup>, H. Bouzidi<sup>2</sup>, S. Zrour<sup>3</sup>, S. Hammami<sup>1</sup>, M. hammami<sup>1</sup>. <sup>1</sup>Laboratory Biochemistry LR12ES05, Faculty of Medicine, University of Monastir, Monastir; <sup>2</sup>Laboratory Biochemistry, CHU Tahar Sfar, Mahdia; <sup>3</sup>Rheumatology department, CHU Fattouma Bourguiba, Monastir, Tunisia

**Background:** Advanced glycation end products (AGEs) are formed by a non-enzymatic glycation process. Previously, we showed that pentosidine, as AGEs, was related to the severity of coronary artery disease (Kerkeni et al. 2014). Recently, we showed that AGEs are involved with disease activity in rheumatoid arthritis (RA) (Knani et al. 2017, 2018). No study about the relationship between serum pentosidine levels and intima media thickness (IMT) was evaluated.

**Objectives:** We aim to study the association of serum pentosidine levels with IMT in RA patients.

**Methods:** Our study included 30 control subjects and 40 patients with RA. The carotid IMT was measured using ultrasonography and serum pentosidine levels were determined by ELISA kit.

**Results:** Serum pentosidine levels were increased in RA patients vs control subjects ( $p<0.001$ ) and were increased with disease activity score (DAS28) ( $p<0.001$ ). IMT was increased with disease activity in RA patients ( $p<0.01$ ) and was positively associated with serum pentosidine levels ( $p<0.001$ ).

**Conclusions:** Serum pentosidine levels were increased with DAS28 and were associated with carotid IMT.

### THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE TRACKS RESPONSE TO RITUXIMAB TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS

N.M.T. Roodenrijs<sup>1</sup>, M.J.H. de Hair<sup>1</sup>, G. Wheeler<sup>2</sup>, M. Elshahaly<sup>3</sup>, J. Tekstra<sup>1</sup>, Y.K. O. Teng<sup>4</sup>, C.C. Hwang<sup>5</sup>, X. Liu<sup>5</sup>, E.H. Sasso<sup>5</sup>, J.M. van Laar<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; <sup>2</sup>Department of Biochemistry, The James Cook Hospital, Middlesbrough, UK; <sup>3</sup>Department of Rheumatology and Rehabilitation, Suez Canal University, Ismailia, Egypt; <sup>4</sup>Department of Nephrology, Leiden University Medical Center, Leiden, Netherlands; <sup>5</sup>Crescendo Bioscience, San Francisco, CA, USA

**Background:** A multi-biomarker disease activity (MBDA) score was developed to objectively measure disease activity for patients with rheumatoid arthritis (RA).<sup>1</sup> The MBDA score is calculated by an algorithm using concentrations of 12 serum biomarkers. The MBDA score has been shown to track response to treatment with several DMARDs.<sup>2,4</sup>

**Objectives:** To assess the ability of the MBDA score to track response to rituximab treatment in RA patients.

**Methods:** Data were used from 3 cohorts (1 in the United Kingdom, 2 in the Netherlands) of RA patients treated with rituximab 1000 mg and methylprednisolone 100 mg at days 1 and 15. The MBDA score was assessed in serum samples at baseline (BL, n=57) and at 6 months (n=46). Wilcoxon signed-rank test was used to statistically compare the medians at BL and 6 months. Spearman's rank correlation ( $\rho$ ) was used to analyse relationships between BL and 6 month values and change ( $\Delta$ ) from BL to 6 months for MBDA score vs. the following endpoints: DAS28-ESR, DAS28-hsCRP, ESR, hsCRP and Health Assessment

Questionnaire (HAQ). Logistic regression analysis with adjustment for age, sex, smoking, ACPA and RF was used to assess the association between  $\Delta$ MBDA score and non-response, using EULAR response categories at Month 6.  $p<0.05$  was considered statistically significant.

**Results:** At baseline the median MBDA score and DAS28-ESR were 54.5 (range 15.0–84.0) and 6.3 (range 2.5–8.4), respectively. The improvement in both scores after 6 months was statistically significant ( $p=0.003$  and  $p<0.0001$ , respectively). MBDA score correlated with DAS28-ESR, DAS28-hsCRP, ESR and hsCRP at BL and Month 6 (table 1).  $\Delta$ MBDA score from BL to Month 6 correlated with changes in these measures, except for the correlation with  $\Delta$ DAS28-hsCRP ( $\rho=0.419$ ,  $p=0.053$ ). Spearman's correlation for  $\Delta$ MBDA score vs.  $\Delta$ DAS28-ESR was  $\rho=0.548$ ,  $p<0.0001$  (table 1).  $\Delta$ MBDA score also correlated with EULAR non-response (n=39), with adjusted OR=1.115 (95% CI=1.017–1.223,  $p=0.015$ ), which corresponds to an OR of 2.97 for every 10-unit change in MBDA score. Correlations were not observed between MBDA scores or  $\Delta$ MBDA score and the corresponding HAQ measurements (table 1).

**Abstract AB0275 – Table 1.** Correlations (Spearman's  $\rho$ ) between the MBDA score and clinical or biomarker endpoints based on measurements made at baseline (BL) or 6 months (6M), and of change ( $\Delta$ ) from BL to 6 months.

Endpoint	Timepoint or period for comparison with MBDA score	Available samples (N)	Spearman's $\rho$	p-value
DAS28-ESR	BL	46	0.487	0.001
	6M	40	0.478	0.002
	$\Delta$	37	0.548	<0.0001
ESR	BL	44	0.785	<0.0001
	6M	41	0.670	<0.0001
	$\Delta$	41	0.448	0.008
DAS28-hsCRP*	BL	23	0.488	0.015
	6M	23	0.488	0.032
	$\Delta$	23	0.419	0.053
hsCRP*	BL	24	0.801	<0.0001
	6M	23	0.814	<0.0001
	$\Delta$	23	0.676	0.001
HAQ	BL	39	-0.031	0.654
	6M	40	-0.056	0.730
	$\Delta$	33	0.132	0.486

BL: MBDA score and endpoint at baseline; 6M: MBDA score and endpoint at Month 6;  $\Delta$ : changes in MBDA score and endpoint, both from baseline to Month 6; DAS28: disease activity score using 28 joints; ESR: erythrocyte sedimentation rate; HAQ: Health Assessment Questionnaire; hsCRP: high-sensitivity C-reactive protein; MBDA: multi-biomarker disease activity.

\* United Kingdom cohort only

**Conclusions:** We have shown, for the first time, that the MBDA score tracked disease activity in RA patients treated with rituximab and that change in MBDA score reflected the degree of treatment response.

### COMPARISON OF HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY PROGRESSION IN RHEUMATOID ARTHRITIS PATIENTS WITH PROPOSED SDAI, CDAI, AND RAPID3-BASED MINIMAL DISEASE ACTIVITY AND PATIENTS WITH LOW DISEASE ACTIVITY: RESULTS FROM A JAPANESE NATIONAL DATABASE

N. Yokogawa<sup>1</sup>, A. Komiya<sup>2</sup>, K. Shimada<sup>1</sup>, J. Nishino<sup>3</sup>, S. Sugii<sup>1</sup>, S. Tohma<sup>4</sup>.

<sup>1</sup>Department of Rheumatic Diseases, Tokyo Metropolitan Tama Medical Center, Fuchu; <sup>2</sup>Department of Clinical Laboratory, Sagami National Hospital, National Hospital Organization, Sagami; <sup>3</sup>Department of Orthopaedic Surgery and Spinal Surgery, the University of Tokyo, Tokyo; <sup>4</sup>Department of Rheumatic Diseases, Tokyo National Hospital, National Hospital Organization, Kiyose, Japan

**Background:** By OMERACT, a core-set definition of minimal disease activity (MDA) required a tender joint count (TJC) of 0, swollen joint count (SJC) of 0, and erythrocyte sedimentation rate (ESR)  $\leq 10$  mm/hour or the fulfilment of 5 of 7 core criteria, namely, pain  $\leq 2$ , SJC  $\leq 1$ , TJC  $\leq 1$ , health assessment questionnaire (HAQ)  $\leq 0.5$ , physician's global  $\leq 1.5$ , patient's global  $\leq 2$ , and ESR  $\leq 20$ .<sup>1</sup>

In addition to the original Disease Activity Score 28 (DAS28)-based MDA definition (DAS28  $\leq 2.85$ ),<sup>1</sup> we proposed a Simplified Disease Activity Index (SDAI)  $\leq 5.3$ , Clinical Disease Activity Index (CDAI)  $\leq 4.8$ , and Routine Assessment of Patient Index Data 3 (RAPID3)  $\leq 5$ , each value being two points higher than the respective remission criterion, as cut-offs for the MDA index in routine care for rheumatoid arthritis (RA).<sup>2</sup>

**Objectives:** To compare HAQ disability progression in patients with proposed SDAI, CDAI, and RAPID3-based MDA and patients with low disease activity (LDA) for each index.

**Methods:** We evaluated RA patients with functional remission (HAQ  $\leq 0.5$ ) registered with the Japanese National Database. We excluded patients with any missing values for patient SJC, TJC, physician's global, patient's global, pain, CRP, ESR, HAQ, or MDHAQ, which require the MDA to be assessed and the DAS28, SDAI, CDAI, and RAPID3 scores to be determined. HAQ disability progression from 2015 to 2016 was analysed in patients with MDA vs non-MDA and in those with LDA (or remission) vs non-LDA (or remission).

The interclass correlation of the disease activity categories of LDA and MDA in DAS28, CDAI (SDAI), and RAPID3 were also compared.

**Results:** In total 3798 patients were analysed, 76.5% of whom met the core-set definition of MDA and 40.3% of whom were assessed as being in Boolean remission. Patients with a core-set definition of MDA had less HAQ progression over one year (356 $\pm$ 71 days) than those without the core-set definition, at 0.036 (95% CI: 0.026–0.045) and 0.066 (0.050–0.082) (p=0.002), respectively. The progression of HAQ in each disease activity state is summarised in table 1.

Patients in the DAS28, SDAI, CDAI, and RAPID3-based MDA group showed less HAQ progression. The same results were found for LDA. For the MDA categories, the interclass correlation for CDAI (SDAI) vs DAS28, CDAI (SDAI) vs RAPID3, and DAS28 vs RAPID3 was 0.585 (0.617), 0.568 (0.557), and 0.361, respectively, and 0.449 (0.442), 0.411 (0.410), and 0.371 for LDA, respectively.

Abstract AB0276 – Table 1

Index-based MDA	HAQ progression, mean (95% CI)	Index based LDA	HAQ progression, mean (95% CI)
DAS28 $\leq 2.85$	0.032 (0.022–0.041)	DAS28 $\leq 3.2$	0.034 (0.023–0.045)
DAS28 > 2.85	0.064 (0.051–0.077)	DAS28 > 3.2	0.052 (0.041–0.063)
p	<0.001	p	0.011
SDAI $\leq 5.3$	0.036 (0.026–0.045)	SDAI $\leq 11$	0.040 (0.031–0.048)
SDAI > 5.3	0.058 (0.044–0.072)	SDAI > 11	0.074 (0.049–0.099)

p	0.031	p	0.003

**Conclusions:** Among patients with functional remission, both the MDA and LDA categories showed less HAQ progression over one year.

The interclass correlation for MDA was more acceptable than that for LDA. Index-based MDA, which provides more stringent criteria than LDA, may serve as an alternative target for LDA in patients who have difficulty achieving remission.

### LEPTIN AND ADIPONECTIN LEVELS IN RHEUMATOID ARTHRITIS PATIENTS

N. Nicolaou<sup>1,2</sup>, J. Joseph<sup>3,4</sup>, I.N. Bruce<sup>5</sup>. <sup>1</sup>Clinical Laboratory Department, Aretaio Hospital; <sup>2</sup>Department of Pharmacy, School of Health Sciences, Frederick University; <sup>3</sup>Rheumatology Department, Aretaio Hospital; <sup>4</sup>Medical School, University of Nicosia, Nicosia, Cyprus; <sup>5</sup>Division of Musculoskeletal and Dermatological Sciences, School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, UK

**Background:** Rheumatoid Arthritis (RA) is a chronic inflammatory autoimmune disorder characterised by systemic inflammation of joints, in particular the synovial membrane, cartilage and bone. Leptin (LEP) and adiponectin (ADIP) belong to a distinct group of biological molecules, adipokines which are secreted by white adipose tissue and have a central role in energy storage and metabolism.

**Objectives:** To compare fasting serum LEP and ADIP in RA to healthy controls and to investigate whether fasting LEP and ADIP serum levels change following a change in RA treatment.

**Methods:** Male and female subjects aged 18 years old or above with RA, fulfilling the 2010 ACR/EULAR classification criteria and having DAS28 score >4.2, were recruited and followed up for 90 days. LEP and ADIP levels were measured using ELISA. Fasting glucose, lipids and insulin levels were also measured as indicating factors for co-morbidities. The associations between RA patients at baseline and controls were assessed by uncorrelated/unrelated t-test analyses while associations between RA patients at baseline, day 30 and day 90 were assessed by one-way correlated/related analysis of variance.

**Results:** We studied 30 RA patients with mean (SD) age of 56.33 (13.84) years, of whom 24 (80%) were female and 15 healthy individuals with mean (SD) age of 53.80 (13.97) years, of whom 12 (80%) were female. LEP and ADIP levels for control subjects were 28.36 (15.08) ng/mL (p=NS vs RA at baseline) and 14.76 (4.42)  $\mu$ g/mL (p<0.05 vs RA at baseline) (table 1). Over 90 days DAS28 and HAQ score improved significantly in RA patients. LEP levels for RA patients were 29.65 (18.17) ng/mL at baseline, 30.81 (17.65) ng/mL at day 30 and 25.90 (15.01) ng/mL at day 90 (p=NS) whilst ADIP levels for RA patients were 16.78 (8.73)  $\mu$ g/mL at baseline, 16.65 (8.70)  $\mu$ g/mL at day 30 and 15.44 (7.24)  $\mu$ g/mL at day 90 (p=NS) (table 2).

Abstract AB0277 – Table 1. Demographics and baseline adipokines for RA patients and control subjects. All values are mean (SD) unless otherwise indicated where we use n (%)\*. (\*\*Levene's test for equality of variances value p<0.05)

Variable	RA Patients	Control subjects	Levene's test for equality of variances (p)
Gender (M/F)	6 (20%)/24 (80%)	3 (20%)/12 (80%)	1.000
Age (years)	56.33 (13.84)	53.80 (13.97)	0.850
LEP (ng/mL)	29.65 (18.17)	28.36 (15.08)	0.421
ADIP ( $\mu$ g/mL)	16.78 (8.73)	14.76 (4.42)	0.023**

Abstract AB0277 – Table 2. Change over time in adipokine levels and RA parameters for RA patients at baseline, day 30 and day 90. All values are mean (SD). (\*\*One Way ANOVA significance value p<0.05)

Variable	LEP (ng/mL)	ADIP ( $\mu$ g/mL)	RA parameters			
			DAS28 score	HAQ score	PAIN score	HEALTH score
RA patients (day 0)	29.65 (18.17)	16.78 (8.73)	5.59 (0.56)	1.20 (0.70)	1.80 (0.73)	1.59 (0.55)
RA patients (day 30)	30.81 (17.65)	16.65 (8.70)	4.39 (0.93)	0.84 (0.66)	1.07 (0.82)	1.11 (0.84)
RA patients (day 90)	25.90 (15.01)	15.44 (7.24)	3.92 (1.08)	0.76 (0.74)	1.07 (0.82)	1.32 (0.81)
One Way ANOVA (p)	0.515	0.791	0.000**	0.045**	0.000**	0.046**

**Conclusions:** ADIP was significantly higher in RA patients at baseline compared to control subjects and there was a trend towards normalisation of levels as inflammation improved. The role of ADIP in active RA remains unclear and further examination of the site of origin of ADIP as well as its role in pro- and anti-inflammatory pathways warrants further study.

### INVESTIGATION OF POOR PROGNOSTIC FACTORS AMONG RHEUMATOID ARTHRITIS PATIENTS IN TURKBIO REGISTRY

N. Inanc<sup>1</sup>, Z. Ertürk<sup>1</sup>, G. Ozen<sup>1</sup>, E. Dalkılıç<sup>2</sup>, S.S. Koca<sup>3</sup>, G. Can<sup>4</sup>, A. Karatas<sup>3</sup>, Y. Pehlivan<sup>2</sup>, A. Yazıcı<sup>5</sup>, A. Cefle<sup>5</sup>, S. Akar<sup>6</sup>, S. Senel<sup>7</sup>, B. Oz<sup>3</sup>, N. Akkoc<sup>8</sup>, H. Direskenel<sup>1</sup>. <sup>1</sup>Rheumatology, Marmara University School of Medicine, Istanbul; <sup>2</sup>Rheumatology, Uludağ University School of Medicine, Bursa; <sup>3</sup>Rheumatology, Fırat University School of Medicine, Elazığ; <sup>4</sup>Rheumatology, Dokuz Eylül University School of Medicine, İzmir; <sup>5</sup>Rheumatology, Kocaeli University School of Medicine, Kocaeli; <sup>6</sup>Rheumatology, İzmir Katip Çelebi University School of Medicine, İzmir; <sup>7</sup>Rheumatology, Erciyes University School of Medicine, Kayseri; <sup>8</sup>Rheumatology, Private Practice, İzmir, Turkey

**Background:** TURKBIO is the Turkish version of Danish DANBIO rheumatologic database which has been established in 2011. Patients' data including age, sex, disease type and duration, and previous or current treatment with conventional (cs), targeted synthetic (ts) and biological (b) DMARDs were collected. In 2016, the EULAR RA management guideline recommended assessment of certain prognostic factors while deciding the treatment strategy after the first csDMARD failure.

**Objectives:** We examined the frequency and influence of these poor prognostic factors on treatment response in bDMARD and tsDMARD initiating RA patients enrolled in TURKBIO.

**Methods:** 898 biological and targeted synthetic DMARDs receiving RA patients from 8 participating centres of TURKBIO were studied. Seven investigated poor-prognostic factors were: <sup>1</sup> Moderate to high disease activity (after csDMARD therapy), <sup>2</sup> Elevated acute phase reactants, <sup>3</sup> High swollen joint counts ( $\geq 4$ ), <sup>4</sup> High RF/ACPA titers, <sup>5</sup> Combinations of the above, <sup>6</sup> Erosions, <sup>7</sup> Failure of  $\geq 2$  csDMARDs. The frequencies of these factors at treatment initiation and influence of these on achievement of remission/remission+low disease activity (LDA) according to DAS28-CRP at the 6th month of treatment were evaluated in overall any bDMARD and tsDMARD-receiving patients.

**Results:** Among the prognostic factors; factors 1, 2, 4, 6 and 7 were found in over 60% of patients while factors 3 and 5 were present in about 30%. Factors 1 and 3 were more frequent in patients who were in moderate/high disease activity compared to those in remission +low disease activity (table 1). Same factors 1 and 3 were determined at higher percentage in non-remission than remission group (Factor 1: 93.4% vs. 82.2%,  $p < 0.001$ ; factor 3: 43% vs. 30.7%,  $p = 0.002$ ). These two factors were also significantly more frequent in patients withdrawn from the treatment (Factor 1: 93% vs. 85%,  $p < 0.001$ ; factor 3: 41% vs. 34%,  $p = 0.038$ ). In TNFi group besides factors 1 and 3, factors 5 and 7 were also significantly more frequent in non-remission group whereas, in the RTX group, only factor 1 was significantly more frequent in remission group. For the other bDMARDs and tsDMARD (ABA, TCZ, TOFA), we did not find any difference in poor prognostic factors among patients who did achieve remission and did not.

**Abstract AB0278 – Table 1.** Frequencies of poor prognostic factors in RA patients initiating bDMARDs and tsDMARD by disease activity\* at the 6th month of treatment

Factors	Remission+low disease activity, %	Moderate+high disease activity, %	P value
Factor 1: Moderate to high disease activity (after csDMARD therapy)	95.9	83.6	<0.001
Factor 2: Elevated acute phase reactants	100	99.5	-
Factor 3: High swollen joint counts ( $\geq 4$ )	47.1	31.7	<0.001
Factor 4: High RF/ACPA titers	68.3	71.9	0.465
Factor 5: Combinations of the factors 1, 2, 3, 4	31.3	25.9	0.284
Factor 6: Erosions	56.5	65.6	0.332
Factor 7: Failure of $\geq 2$ csDMARDs	69.4	69	0.918

\* Disease activity was assessed by using DAS28-CRP at the 6<sup>th</sup> month of treatment

**Conclusions:** Five of the seven poor prognostic factors were detected more than half of the RA patients at bDMARD and tsDMARD initiation in TURKBIO. Patients with poor prognostic factors especially factors 1 and 3 achieved remission less frequently. Additionally, there was a relationship between bDMARDs and tsDMARD withdrawal and factors 1 and 3. The influence of these factors was mainly observed in TNFi receiving group.

### RAPID3 IS NOT LONGITUDINALLY ASSOCIATED WITH DAS28-ESR IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Boone<sup>1</sup>, A. Sepriano<sup>2,3</sup>, R. Janknegt<sup>1</sup>, H. van der Kuy<sup>4</sup>, R. Peeters<sup>5,6</sup>, R. Landewe<sup>5</sup>. <sup>1</sup>Department of Clinical Pharmacology and Toxicology, Zuyderland Medical Centre, Sittard-Geleen; <sup>2</sup>Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; <sup>3</sup>Nova Medical School, Universidade Nova de Lisboa, Lisboa, Portugal; <sup>4</sup>Department of Clinical Pharmacy, Erasmus Medical Centre, Rotterdam; <sup>5</sup>Department of Rheumatology, Zuyderland Medical Centre, Sittard-Geleen; <sup>6</sup>Amsterdam Rheumatology and Immunology Centre, Amsterdam, Netherlands

**Background:** The Routine Assessment of Patient Index Data 3 (RAPID3) is a patient reported outcome (PRO) proposed to conveniently measure disease activity in rheumatoid arthritis (RA) based on functioning, pain and global health scores. DAS28 (including PRO and objective measures) is the most frequently used score in clinical practice and research for that purpose<sup>[1]</sup>. It has been suggested that composite scores measuring PROs only (e.g. RAPID3) might add to the assessment of disease activity over time but this claim is yet to be formally tested.

**Objectives:** In this study we evaluated a possible longitudinal association between RAPID3 and DAS28-ESR (including individual components) in patients with RA from daily clinical practice.

**Methods:** Adult patients with RA on stable treatment with either conventional synthetic disease modifying drugs (csDMARDs) and/or biologic DMARDs (bDMARDs), followed in one centre, were included. Patients were followed every 3 months up to 3 years and in each visit both clinical and medication data was collected by rheumatologists/research nurses. The longitudinal association between RAPID3 (range: 0–30) with DAS28-ESR and its individual components [tender joint count (TJC; 0–28); swollen joint count (SJC; 0–28); patient global assessment (PGA; 0–10) and ESR (mm/h)] was tested (in separate models) by longitudinal generalised estimating equations (GEE) with auto-regression. Interactions between RAPID3 with gender (male vs female), VAS pain ( $\geq 5$  vs  $< 5$ ), PGA ( $\geq 5$  vs  $< 5$ ) and age ( $\geq 62$  vs  $< 62$ ) at baseline were tested and if significant ( $p < 0.20$ ) and clinically relevant each model (either using DAS28 or its individual components as outcome) was stratified accordingly.

**Results:** In total, 330 patients were included [mean (SD) age: 62<sup>12</sup> years, 68% female, baseline mean (SD) DAS28: 3.3 (1.4) and RAPID3: 11.5 (6)]. The mean (SD) follow-up period was 10.7 (9.7) months. Although, statistically significant, we only found a poor association between RAPID3 and DAS28-ESR over time (table 1). An increase of one unit in RAPID3 (0–30) was associated with an increase of only 0.1 units of DAS28-ESR. Gender, age, PGA and VAS pain were not found to meaningfully modify the association between RAPID3 and DAS28. A far stronger association was found between RAPID3 and the 'subjective components' [TJC:  $\beta = 0.30$  (95%: 0.20; 0.39); and PGA:  $\beta = 0.31$  (95%: 0.28; 0.35)] of DAS28-ESR, as compared to the 'objective components' (i.e., SJC and ESR; the latter only significant in males) (table 1).

**Abstract AB0279 – Table 1.** Longitudinal association between RAPID3 and DAS28 and each individual component

	Main effect $\beta$ (95% CI)	Males $\beta$ (95% CI)	Females $\beta$ (95% CI)
DAS28 ESR	0.10 (0.10; 0.10)	NA	NA
Swollen joint count	0.10 (0.06; 0.14)	NA	NA
ESR	NA	0.12 (0.03; 0.22)	-0.10 (-0.16; 0.14)
Tender joint count	0.30 (0.20; 0.39)	NA	NA
PGA	0.31 (0.28; 0.35)	NA	NA

Each line is a separate model; NA, not applicable.

**Conclusions:** There is no meaningful longitudinal association between RAPID3 and DAS28. DAS28 captures objective signs of disease activity over time in RA while RAPID3 only captures subjective symptoms of RA.

**AB0280 GENDER-DIFFERENCES IN CARDIO-VASCULAR RISK FACTORS IN PATIENTS WITH INFLAMMATORY RMDs**

*N. Marínez Alberola, C. Fernández-Carballido, R. Martín Domenech, T. Pedraz Penalba, G. Albert Espi, F. Sivera Mascaró. Dpt Rheumatology, Hospital General Universitario Elda, Elda, Spain*

**Background:** Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA) have an increased risk of cardiovascular events when compared to the general population. This increase is probably due to both the deleterious effects of inflammation and the traditional cardio-vascular risk factors (CVRF).

**Objectives:** Analyse the differences by gender in the distribution of traditional CVRF in patients with chronic arthritis included in a screening program.

**Methods:** A program for the detection and management of traditional CVRF in patients with chronic arthritis was implemented following EULAR recommendations. Patients with RA, PsA and SpA followed-up at our department were included in this program. Patients underwent a baseline visit in a nurse-clinic where cardiovascular (CV) risk was assessed. Data on smoking status, diet, exercise, diagnosis of hypertension (HT), diabetes mellitus (DM), hypercholesterolemia (HCh) and prior CV events. The height and weight, the abdominal perimeter and the blood pressure of patients were measured. Results of a blood test previously ordered by the managing physician was recorded.

SCORE index was calculated as applied to Spanish population and then modified according to EULAR recommendations. Treatment targets (previously agreed upon by the department of rheumatology) were set; if pharmacological treatment was needed, patients were referred to their rheumatologist or GP.

Data are presented of all patients included in this screening program.

**Results:** The number of patients assessed at the nurse-led clinic for CVRF assessment and with data on gender, is 416. In the table 1 we present the characteristics of these patients grouped by gender

Abstract AB0280 – Table 1

		Women (n=242)	Men (n=174)
Age years, mean (SD)		59.6 (±11.9)	56.7 (±12.8)
Rheumatic disease	RA	179 (73.9%)	62 (35.6%)
	SpA	25 (10.3%)	70 (40.2%)
	PsA	38 (15.7%)	42 (24.2%)
Diabetes mellitus	Prior diagnosis	25 (10.3%)	31 (17.8%)
	New diagnosis	2 (0.9%)	4 (2.8%)
	Poor control	6 (2.4%)	10 (32.2%)
Hypertension	Prior diagnosis	93 (38.4%)	73 (42%)
	New diagnosis	25 (16.7%)	22 (21.7%)
	Poor control	53 (37%)	33 (45.2%)
Hypercholesterolemia	Prior diagnosis	91 (37.6%)	69 (39.6%)
	New diagnosis	28 (18.5%)	23 (21.9%)
	Poor control	33 (36.2%)	16 (23.2%)
Smoker		48 (19.8%)	60 (24.5%)
Obesity		86 (35.5%)	63 (36.2%)
Prior CV event		9 (3.7%)	20 (11.4%)

Data expressed as n (%) except where specified

\* Poor control of hypercholesterolemia is defined as LDL over the target recommended by European guidelines for each risk stratification.

**Conclusions:** In a similar manner as the general population, there is a greater number of CV events in men than in women. However, the gender-distribution of traditional CVRF is similar except for DM, more common in men.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2018-eular.5722

**AB0281 REDUCTION RATE OF RHEUMATOID FACTOR REFLECTS DISEASE ACTIVITY OF RHEUMATOID ARTHRITIS**

*N. Okumura, T. Kawasaki, T. Yayama, K. Kumagai, S. Imai. Orthopaedic Surgery, Shiga University of Medical Science, Shiga, Japan*

**Background:** Rheumatoid factor (RF) is involved in the pathology of rheumatoid arthritis (RA) and its titer varies during the course of treatment with biological or synthetic DMARD.

**Objectives:** In this study, we examined the relationship between RF change rate and disease activity.

**Methods:** We analysed 287 RA patients (mean age 62.3 years; mean disease duration 13.1 years) in our hospital between 2015 and 2017, who were able to confirm the RF, and 3 groups were classified according to the change rate of RF for 1 year (92 in decreasing less than 80%, 114 in unchanged 80% or more, less

than 120% and 81 in increasing 120% or more). We evaluated disease activity by simplified disease activity index (SDAI).

**Results:** The drugs used are: MTX usage rate 63.1%, mean amount 3.81 mg, PSL usage rate 37.3%, mean amount 1.47 mg, biological drugs usage rate 48.8%. Disease activity change amount in 1 year (delta SDAI) was -0.88 (from 6.90 to 6.02). The median RF titer at baseline was 76 (27.5–178.5), the median RF change rate was 96% (71.5–125) and delta SDAI was significantly improved in the decreasing group (-1.97, 0.005, -0.04, p=0.0011). The swollen joint counts, tender joint counts, global assessment of evaluator and CRP were similarly improved significantly in this group.

**Conclusions:** Although RF dose not decrease in all cases, it suggested that reduction rate of RF reflects disease activity.

**Disclosure of Interest:** None declared

**AB0282 ADJUSTING THE DOSE OF TOFACITINIB TO ACHIEVE OPTIMAL RESULTS IN THE MANAGEMENT OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS (RA) MAY OFFER MORE SUCCESSFUL RESULTS THAN UTILISING A STANDARD FIXED ONE DOSE APPROACH**

*N. Gaylis<sup>1</sup>, J. Sagliani<sup>1</sup>, S. Needell<sup>2</sup>. <sup>1</sup>Arthritis and Rheumatic Disease Specialties, Aventura; <sup>2</sup>Boca Radiology, Boca Raton, USA*

**Background:** We have previously reported results of patients with active RA who had been unresponsive to tofacitinib at 5 mg bid but who had demonstrated significant response after dose escalation to 10 mg bid.<sup>1,2</sup> This extension trial was performed to see if 9 patients who had failed to reach treatment target on 5 mg bid but then responded to 10 mg bid of tofacitinib would maintain their clinical target if the dose was reduced down to 5 mg bid. Furthermore, if the patients could not maintain their clinical response on the lower dose, we explored whether increasing the dose of tofacitinib up to 10 mg bid could again result in a target response.

**Objectives:** The objectives were as follows: to explore the response of patients who achieved a treatment target when taking 10 mg bid of tofacitinib and then reduced the dose down to 5 mg bid; to report the results of the patients who could not maintain the target response at 5 mg bid and then increased the dose back up to 10 mg bid; and to identify if there was any separation between the clinical and structural findings at 5 mg bid vs 10 mg bid.

**Methods:** Nine RA patients who were unresponsive to treatment with tofacitinib at a dose of 5 mg bid plus MTX (10–25 mg weekly) were dose escalated to 10 mg bid and reached low disease activity (LDA) or remission at the increased dose. These patients were maintained on 10 mg bid of tofacitinib for 6 months and sustained a clinical target of LDA or remission. After 6 months, the dose of tofacitinib was reduced back to 5 mg bid which had previously not been an effective dose. The clinical response was measured by the Clinical Disease Activity Index (CDAI) and the structural response was measured by an MRI of the index hand/wrist and blindly read by a musculoskeletal radiologist using a modified OMERACT-RAMRIS score. If the patients could not maintain their positive clinical response for 3 months the dose of tofacitinib was escalated back up to 10 mg bid.

**Results:** Of the 9 enrolled patients, 6 patients maintained LDA or Remission over the next 6 months once the dose of tofacitinib was reduced back down to 5 mg bid. Three<sup>3</sup> patients were unable to maintain their treatment target at the reduced dose and were dose escalated back up to 10 mg bid at which time they achieved the treatment target. (See table 1) The MRI findings showed no difference in structure at either dose and do not appear to demonstrate a relationship to the clinical findings. There were no clinically significant adverse events in either group.

Abstract AB0282 – Table 1

6 Patients who maintain target once reducing dose tofacitinib to 5 mg bid				
Patients	CDAI BSL	CDAI target on 10 mg bid	CDAI 3 months on 5 mg bid	CDAI 6 months on 5 mg bid
003	45.9	2.6	7.2	8.2
004	65.2	4.4	4.7	0.1
005	56.1	3.6	9.4	2.6
007	27.9	2.3	1.7	2.6
012	25.3	5.1	6.4	9.3
014	21.6	1.4	8.5	3.2

3 Patients who could not maintain target at 5 mg bid tofacitinib and were increased to 10 mg bid						
Patients	CDAI BSL	CDAI target on 10 mg bid	CDAI 3 months on 5 mg bid	CDAI 3 months on 10 mg bid	CDAI 6 months on 10 mg bid	CDAI 9 months on 10 mg bid
008	34.3	9.2	19.2 inc dose	2.6	2.5	
018	31.8	2.5	16.2 inc dose	11.9	8.3	
019	27.3	8.9	9.7	11.9 inc dose	1.9	2.7

**Conclusions:** This study confirms the previous findings that 10 mg bid of tofacitinib may be the effective dose needed for some patients with active RA to reach treatment target.<sup>(1)</sup> It also suggests that there is an opportunity to reduce the escalated dose back down to the standard dose once a target response is achieved. This in many ways is similar to the clinical use of other drugs used to treat RA including corticosteroids, MTX and biologics where dose adjustment may well increase the therapeutic benefit of the molecule and allow subsequent dose adjustments to maintain efficacy with a lower adverse event profile. Additional studies will be needed to test the results found in this trial.

#### AB0283 INDICES OF ANTIBODIES TO FIBRONECTIN ASSOCIATED WITH CLINICAL MANIFESTATIONS OF RHEUMATOID ARTHRITIS

O.A. Rusanova<sup>1</sup>, I.P. Gontar<sup>1</sup>, O.I. Emelyanova<sup>1</sup>, N.I. Emelyanova<sup>2</sup>, I. A. Zborovskaya<sup>1</sup>. <sup>1</sup>Research Institute for Clinical and Experimental Rheumatology named after A.B. Zborovskiy, Volgograd, Russia; <sup>2</sup>Volgograd State Medical Universiti, Volgograd, Russian Federation

**Background:** According to available data, fibronectin (FN) is implicated in progressing cartilage destruction in arthritis of varying etiology. It is established that it is not native FN that has the ability to enhance the expression of chondrocyte catabolism gene thus causing. Antibodies enhance both resorption and synthesis of osseocartilaginous tissue; they affect proteoglycan and glycosaminoglycan production in connective tissue, and also block active centres of FN molecule.

**Objectives:** Determining the level of FN antibodies using fibronectin-based magnetocontrollable immobilised adsorbents is an additional criterion of rheumatoid arthritis disease activity. Demonstrating the FN indices and its antibodies in blood serum of healthy individuals, and in that of RA patients depending on the disease activity. Demonstrating that the level of FN antibodies in the blood serum of RA patients reliably differs from that of healthy people.

**Methods:** 117 RA patients receiving hospital treatment at Municipal hospital 25 of Volgograd were examined. The patients' mean age was 49.9±13.9. The mean duration of disease was 9.1±1.57 years. Low (I) disease activity was noted in 14 patients (12%), moderate (II) – in 66 (56.4%), and high (III) – in 37 (31.6%) patients with RA. According to the degree of articular dysfunction the patients were classified in the following way: 11 patients (9.4%) showed articular insufficiency functional class II (intact occupational ability), 87 patients (74.41%)

showed insufficiency functional class III (lost occupational ability), and 19 patients (16.2%) showed insufficiency functional class IV (lost autonomy).

The articular syndrome underlies all clinical presentations of RA. In most patients (102 individuals, 87.2%) RA took the form of polyarthritis; in the remaining 15 people (12.8%) oligoarthritis was noted. 107 patients (91.5%) showed hand joint involvement, 99 (71.8%) – knee joints, 71 (60.7%) – talocrural joints, 61 (52.1%) – elbow joint, 49 (41.9%) – shoulder joints, and 37 patients (31.6%) showed foot joint involvement. Serum from 30 apparently healthy individuals, donors from the regional hemotransfusion centre in Volgograd, was used as control.

The FN antibody titer was determined using an original technique: enzyme immunoassay with FN-based immobilised granulated antibodies with magnetic properties.

**Results:** The mean FN content in the plasma of healthy people was 351.0 ±65.1 mcg/ml. The mean concentration of specific antibodies in donor sera was 0.031±0.0029 optical density units. An elevated concentration of plasma FN was detected in 39 RA patients (33.3%). The mean concentration of serum antibodies to FN in RA patients was 0.095±0.014 optical density units, which exceeded the values in the control group (p<0.05). An elevated content was noted in 49 patients (41.9%).

**Conclusions:** A correlation analysis revealed a positive association between FN antibody concentration, and parameters of ESR (r=0.27, p<0.03), and circulating immune complex (r=0.43, p<0.05), as well as indices indicating the degree of exudative-inflammatory process in the joints, and the extent of pain syndrome (DAS score of 28, articular index, pain score, swelling index) (p<0.05).

#### AB0284 RELATIONSHIP OF BIOMARKERS, ULTRASOUND (US) SIGNS OF JOINT DAMAGE AND RADIOGRAPHIC PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS(RA)

O. Alekseeva, T. Saykovskaya, A. Smirnov, A. Volkov, E. Nasonov, V.A. Nasonova  
 Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory immune-mediated disease, based on the imbalance of biomarkers, leading to the appearance of inflammatory changes in the joints, the progression of bone and cartilage destruction.

**Objectives:** to identify the relationship between cytokines, their dynamic changes, ultrasound (US) signs and radiologic progression in 12 month prospective study in patients RA.

**Methods:** 35 patients (median age 55.0 [48.0; 64.0] years) with early RA use MTX and/or biologic therapy in accordance with the treat-to-target concept. Serum cytokine concentrations were determined using the xMAP multiplexing technology baseline, 3 and 6 months after the start of therapy. US with grey scale (GS), power Doppler (PD) and destructive changes (erosion), according to the criteria of OMERACT, were performed baseline, 3, 6, 9 and 12 months after the start of therapy. We analysed absolutely levels and their changes(Δ). X-ray examination was conducted baseline and at 12 month of therapy with an assessment of X-ray changes by Sharp van der Heijde scores (ΔSHS).

**Results:** Levels of proinflammatory cytokines (IL1β, IL6, IL12, IL15, TNFα) decreased by 3 month. Significant differences in PD-group at the end of observation were revealed only for IL6 and TNFα, and with X-ray progression – for ΔIL17 level at 6 month.

At baseline a positive correlation was found between PD and levels of IL1β (r=0.34), IL6 (r=0.42). We found correlation between PD at 12 month and ΔIL1β by 6 month, ΔTNFα by 3 month. In the PD-group concentration of IL6 baseline was significantly higher: 75.2 (37.9; 101.7) vs 38.7 (19.2; 59.6); by 6 month level of TNFα in this group also higher: 67.6 (34.3;125.5) vs 38.8 (21.9; 67.2). Radiographic progression was detected in 6 of 35 RA patients; this group was with PD and destructive change by US was significantly higher.

We found correlation between ΔIL17 and ΔFGF levels at 3 month with PD at 3 month: r=0.57 p=0.001 and r=0.52 p=0.004, respectively. Also we found significantly correlation between ΔIL17 and ΔFGF at 3 month and ΔIL17 at 6 month with the X-ray examination: the sum of erosions, the sum of the narrowing of the joints and the total score (for IL17 at 3 month r=0.43 p=0.01, r=0.51 p=0.0018, r=0.52 p=0.001, respectively, for the FGF at the 3 month r=0.37 p=0.03, r=0.41 p=0.014, r=0.41 p=0.014, respectively, for IL17 at 6 month r=0.38 p=0.024, r=0.39 p=0.019, r=0.4 p=0.016, respectively).

**Conclusions:** The revealed relationship of active synovitis by US, X-ray progression and biomarkers of inflammation in RA confirm the role of ultrasound as a method of independent evaluation of the course and outcomes of the disease.

**AB0285 DO SPOUSES' ILLNESS PERCEPTIONS AFFECT THE WOMEN WITH RHEUMATOID ARTHRITIS?**

Y. Ulus<sup>1</sup>, B. Tander<sup>1</sup>, Y. Akyol<sup>1</sup>, Y. Terzi<sup>2</sup>, Y. Zahiroglu<sup>1</sup>, G. Sariso<sup>3</sup>, A. Bilgili<sup>1</sup>, O. Kuru<sup>1</sup>. <sup>1</sup>Department of Physical Therapy and Rehabilitation, Ondokuz Mayıs University Medical Faculty, <sup>2</sup>Department of Statistics, Faculty of Science and Arts, Ondokuz Mayıs University, <sup>3</sup>Department of Psychiatry, Ondokuz Mayıs University Medical Faculty, Samsun, Turkey

**Background:** Spouses are often significant source of support and the spouse's views about rheumatoid arthritis (RA) are related to better psychological and physical health in women with RA.

**Objectives:** The aim was to investigate the effect of spouses' illness perceptions on health status of women with RA.

**Methods:** One-hundred and one married women diagnosed with RA and their husbands were enrolled. Husbands' beliefs about RA were assessed by husband-version of the Illness Perception Questionnaire-Revised (IPQ-R). Visual analogue scale-pain (VAS-pain), DAS-28, the Health Assessment Questionnaire-Disability Index (HAQ-DI), and Beck Depression Inventory (BDI) were evaluated in patients. Kolmogorov-Smirnov and Spearman's correlation tests, multiple regression analyses were used for statistical analysis.

**Results:** Median age of patients and husbands were 57<sup>(22-75)</sup> years and 60<sup>(24-77)</sup> years, respectively. There were positive correlations between consequences subscale and VAS-pain, HAQ-DI, and BDI ( $p < 0.001$ ). Positive correlations were detected between emotional subscale and HAQ-DI, BDI ( $p < 0.001$ ) and VAS-pain ( $p = 0.021$ ). Timeline cyclical subscale was positively correlated with HAQ-DI ( $p < 0.001$ ) and BDI ( $p = 0.001$ ). The husband-version of the IPQ-R domains was not correlated with DAS-28. In regression analysis; consequences ( $p < 0.001$ ), emotional representations ( $p < 0.001$ ) and timeline cyclical ( $p < 0.05$ ) subscales were found to be influential variable on HAQ-DI. Significant correlation with VAS-pain was consequences, and BDI was associated with emotional representations ( $p < 0.05$ ).

**Conclusions:** We found that in general having more pessimistic illness perceptions in spouses was related to higher disability, pain and depression levels in women with RA. Having more optimistic perceptions of spouses about RA may result in improved health status in women with RA.

**AB0286 ASSESSMENT OF TREATMENT ADHERENCE IN RHEUMATOID ARTHRITIS ITALIAN PATIENTS USING A VALIDATED VERSION OF THE 5-ITEM COMPLIANCE QUESTIONNAIRE FOR RHEUMATOLOGY (I-CQR5)**

F. Ometto<sup>1</sup>, B. Raffener<sup>1</sup>, C. Botsios<sup>1</sup>, D. Astorri<sup>1</sup>, L. Friso<sup>1</sup>, D. Azzolina<sup>2</sup>, M. Favero<sup>1</sup>, J. Done<sup>3</sup>, D. Gregori<sup>1</sup>, A. Doria<sup>1</sup>. <sup>1</sup>Department of Medicine - DIMED; <sup>2</sup>Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy; <sup>3</sup>Department of Psychology and Sports Sciences, University of Hertfordshire, Hatfield, UK

**Background:** The 5-item Compliance Questionnaire for Rheumatology (CQR5) allows the identification of patients likely to be high adherers (HA) to anti-rheumatic treatment (i.e. taking  $\geq 80\%$  of their medications correctly), or "low" adherers (LA).<sup>1</sup> We have previously validated an Italian version of the questionnaire (I-CQR5) following standardised guidelines.

**Objectives:** The objective was to investigate what factors are associated with high treatment adherence according to I-CQR5 in RA.

**Methods:** RA patients (disease duration  $> 1$  year, undergoing treatment with  $\geq 1$  self-administered biological or conventional synthetic disease-modifying anti-rheumatic drugs (bDMARDs, csDMARDs), capable of completing the questionnaire unaided) completed I-CQR5 on one occasion. I-CQR5 were anonymous and clinical data were retrieved anonymously from the local database. To investigate what factors were associated with high adherence, we included demographic and social characteristics, clinical and treatment information. Factors achieving a  $p < 0.10$  in univariate analysis were included in the multivariate regression analysis.

**Results:** Among 604 RA patients, 328 patients were enrolled, 18 questionnaires were incomplete.

Median age of the patients was 57 years,<sup>48-67</sup> females were 232 (82%), disease duration was 12 years;<sup>7-19</sup> 193 (64.3%) patients were treated with bDMARDs and 107 (54.6%) with csDMARD only; 270 (90.3%) were in low disease activity or remission (figure 1).

HA were found to be 35.2% (109/310) of the patients. 40.2% (79/193) were on bDMARDs and 22.4% (24/107) on csDMARDs. Older age, lower education level, higher prednisone daily dose, use of a csDMARD (particularly hydroxychloroquine and sulfasalazine) and higher patient-VAS were significantly more frequent in LA compared with HA (figure 1). In the multivariate analysis, bDMARD treatment and employment resulted independently associated with high adherence: OR 2.88 (1.36-6.1),  $p = 0.006$  and OR 2.36 (1.21-4.62),  $p = 0.012$  respectively (table 1).

**Abstract AB0286 – Table 1.** Factors associated with high adherence to anti-rheumatic treatment defined by I-CQR5: a multivariate regression analysis model

	OR (95% C.I.)	p value
Female gender	0.79 (1.58-0.39)	0.501

### DECREASE IN 14–3–3ETA PROTEIN LEVELS IS CORRELATED WITH IMPROVEMENT OF CLINICAL DISEASE ACTIVITY IN TOFACITINIB TREATED EARLY RHEUMATOID ARTHRITIS PATIENTS

O. Shovman<sup>1,2,3,4</sup>, B. Gilburd<sup>1</sup>, A. Watad<sup>2</sup>, H. Amital<sup>1,2,4</sup>, P. Langevitz<sup>3,4</sup>, N. L. Bragazzi<sup>5</sup>, M. Adawi<sup>6</sup>, D. Pérez<sup>1</sup>, M. Blank<sup>1,4</sup>, N.K. Biln<sup>7</sup>, A. Marotta<sup>7</sup>, Y. Shoenfeld<sup>1,4,8</sup>. <sup>1</sup>Zabludowicz Center for Autoimmune Diseases; <sup>2</sup>Department of Internal Medicine 'B'; <sup>3</sup>Rheumatology Unit, Sheba Medical Center, Ramat Gan; <sup>4</sup>Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; <sup>5</sup>School of Public Health, Department of Health Sciences (DISSAL), University of Genoa, Genoa, Italy; <sup>6</sup>Padeh and Ziv hospitals, Bar-Ilan Faculty of Medicine, Zefat, Israel; <sup>7</sup>Augurex Life Sciences Corp, Vancouver BC, Canada; <sup>8</sup>Incumbent of the Laura Schwarz-Kipp Chair for Research of Autoimmune Diseases, Tel Aviv University, Tel Aviv, Israel

**Background:** 14–3–3η protein is a proinflammatory mediator that may represent a novel diagnostic and prognostic biomarker for rheumatoid arthritis (RA).

**Objectives:** To assess the disease activity parameters and 14–3–3η protein concentrations in serum of early RA patients treated with Tofacitinib.

**Methods:** Paired serum samples from 35 previously non-treated early RA patients (disease onset less than 1 year) receiving Tofacitinib were obtained at baseline and 5 months after the initiation of treatment. Levels of 14–3–3η were measured by JOINT stat 14–3–3η ELISA test kits (Augurex Life Sciences Corp.). The cut-off was defined as 0.19 ng/ml. We investigated the correlation between changes in serum 14–3–3η concentrations and changes in clinical disease activity index (CDAI), simplified disease activity index (SDAI), Disease Activity Score (DAS) 4CRP and DAS4ESR.

**Results:** Increased concentrations of 14–3–3η were found in 57% of the patients at baseline and in 37% of the patients after 5 months of treatment. Mean ±SD baseline 14–3–3η concentrations [4.92±8.86 ng/ml] were significantly higher (p=0.005) than those found following treatment [1.97±4.59 ng/ml]. Statistically significant improvement (p<0.001) of CDAI, SDAI, DAS4ESR and DAS4CRP was achieved after the 5 month of treatment. No correlation was found between absolute 14–3–3η concentrations and parameters of clinical disease activity at both time points. Decrease in 14–3–3η protein levels were highly correlated with improvement in DAS4ESR (r=0.50, p<0.01) and moderately correlated with improvement in CDAI (r=0.32), SDAI (r=0.33), and DAS4CRP (r=0.46, p<0.01).

**Conclusions:** The study demonstrates that decrease in 14–3–3η protein concentrations in RA patients treated with Tofacitinib is correlated with improvement of clinical disease activity parameters. 14–3–3η protein is a useful biomarker for monitoring Tofacitinib therapy.

AB0288

### LEVELS OF METALLOPROTEINASE-3 (MMP-3) CORRELATE BETTER WITH CLINICAL DISEASE ACTIVITY INDEX (CDAI) AND SIMPLIFIED DISEASE ACTIVITY INDEX (SDAI) THAN STANDARD DISEASE ASSESSMENT SCORE (DAS-28)

O. Vega<sup>1</sup>, Y. Calvo<sup>2</sup>, Z. Torres<sup>2</sup>, R. Gamboa<sup>3</sup>, S. Flores<sup>4</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Laboratory of Immunology, Clínica Reumacenter, Juliaca; <sup>3</sup>Service of Rheumatology, Hospital Nacional Guillermo Almenara, Lima; <sup>4</sup>Nurse Unit, Clínica Reumacenter, Juliaca, Peru

**Background:** The MMP-3 is a matrixin calcium-dependent zinc-containing; the major expressed in rheumatoid synovial tissue; with essential role in the degradation of both aggrecan and collagen fibrils.

**Objectives:** The aim was to evaluate the correlation of MMP3 levels with assessment scores of RA activity.

**Methods:** 109 patients with RA as per the 2010 ACR/EULAR criteria were included in the prospective Study ALTRA. Patients were divided into groups of early arthritis active, established arthritis active, and remission with conventional remissive or biological remissive. The levels of MMP3 and activity scores: DAS28-ERS, DAS28-CRP, SDAI and SDAI were on the basis of predefined cut-offs. The correlation was determined with the Pearson Test for parametric variables and the Spearman Test for non-parametric variables.

**Results:** The levels of MMP3 in patients with early RA Vs established were 63.2 and 39.9 U/ml, p<0.021 respectively. MMP3 levels of patients with activity measured by DAS28-ESR were 62.9 in the active and 35.2 U/ml in remission, p<0.000.

The correlation between serum levels of MMP3 and DAS28-ERS was 0.21 (p<0.25), with DAS28-CRP 0.27 (p<0.004); CDAI 0.26 (p<0.06) and with SDAI 0.35 (p<0.002).

**Conclusions:** Elevated MMP3 levels indicate state of disease activity; besides the addition in the expression of the collagen damage. This finding may help in making decisions in clinical practice.

### PARAOXONASA 1 ACTIVITY IS MODULATED BY ANTI-RHEUMATIC TREATMENT AND L55M POLYMORPHISM IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM SOUTHERN MEXICO

O. Zaragoza-García<sup>1</sup>, M.E. Moreno-Godínez<sup>1</sup>, I. Parra-Rojas<sup>1</sup>, J.E. Navarro-Zarza<sup>2</sup>, N. Castro-Alarcón<sup>1</sup>, I.P. Guzmán-Guzmán<sup>1</sup>. <sup>1</sup>Facultad de Ciencias Químico Biológicas, Universidad Autónoma de Guerrero; <sup>2</sup>Hospital General, Chilpancingo, Mexico

**Background:** Paraoxonase-1 (PON-1) is a high-density lipoprotein (HDL)-associated antioxidant enzyme with anti-atherogenic properties. Although genetic polymorphisms are known to modulate PON-1 activity,<sup>1</sup> other factors as the consumption of disease-modifying anti-rheumatic drugs (DMARDs) and nonsteroidal anti-inflammatory drugs (NSAIDs) can also modulate its function.<sup>2</sup>

**Objectives:** To analyse the association between PON-1 activity according to L55M polymorphism and anti-rheumatic treatment in patients with rheumatoid arthritis (RA) from southern Mexico.

**Methods:** Serum PON1 activity, using 4-chloromethyl phenylacetate (4-CMPA) as substrate<sup>3</sup> was quantified in 246 RA patients (181 treated with DMARDs, NSAIDs and/or corticosteroids, and 65 without treatment). The PON1 rs854560 genotype (L55M) was determined by the PCR-RFLP method.

**Results:** PON-1 activity was decreased in RA patients under treatment anti-rheumatic. In addition, an effect of LM/MM genotype of L55M polymorphism was noted in treated patients who exhibiting the lowest PON-1 activity (10.45 vs 13.91 U/mL, p=0.05). The distribution of L55M genotypes were; 86.8% (LL), 12.8% (LM) and 0.4% (MM). The Leflunamide and diclofenac drugs were associated with the mainly decrease of the PON-1 activity (p<0.05), compared with others DMARDs, NSAIDs and corticosteroids drugs used to RA in pharmacological regimens.

**Conclusions:** PON-1 activity is impaired in association with the anti-rheumatic treatment and L55M polymorphism, so in patients with RA the susceptible background genetic could contribute to increasing the cardiovascular risk linked to PON-1 activity.

### LOWER EDUCATIONAL LEVELS ARE ASSOCIATED WITH A HIGHER RISK OF RHEUMATOID ARTHRITIS IN A SOUTHERN EUROPEAN NESTED CASE-CONTROL STUDY

P. de Pablo<sup>1</sup>, D. Romaguera<sup>2</sup>, S. Panico<sup>3</sup>, A. Mattiello<sup>3</sup>, D. Gavrila<sup>4</sup>, C. Navarro<sup>4</sup>, C. Sacerdote<sup>5</sup>, P. Vineis<sup>6</sup>, R. Tumino<sup>7</sup>, W. Ollier<sup>8</sup>, E. Riboli<sup>9</sup>, P. Venables<sup>10</sup>, B. Fisher<sup>1</sup>. <sup>1</sup>University of Birmingham, Birmingham, UK; <sup>2</sup>University Hospital Son Espases, Palma de Mallorca, Spain; <sup>3</sup>Federico II University of Naples, Naples, Italy; <sup>4</sup>Murcia Regional Health Council, Murcia, Spain; <sup>5</sup>Città della Salute e della Scienza University-Hospital; <sup>6</sup>Human Genetics Foundation, Turin; <sup>7</sup>Cancer Registry ASP, Ragusa, Italy; <sup>8</sup>Division of Population Health, Health Services Research and Primary Care, University of Manchester, Manchester; <sup>9</sup>Imperial College London, London; <sup>10</sup>University of Oxford, Oxford, UK

**Objectives:** To investigate the association between socioeconomic status (SES) on an individual level and incident RA

**Methods:** EPIC is a multicentre, pan-European prospective cohort study of apparently healthy populations. We undertook a nested case-control study to investigate risk factors for RA, by identifying incident RA cases (pre-RA) and matched controls amongst subjects enrolled in four EPIC cohorts in Italy and Spain. The lifestyle, environmental exposure, anthropometric information and blood samples were collected at baseline. Confirmed pre-RA cases were matched with controls by age, sex, centre, and date, time and fasting status at blood collection. The exposure was SES as measured by level of educational attainment categorised as university (referent), secondary school/technical/professional school, primary school completed, and none. The primary outcome was incident RA. Conditional logistic regression (CLR) analysis was adjusted for ACPA seropositivity, smoking status, and presence of shared epitope (SE). A further model also adjusted for other potential confounders, including body mass index (BMI), waist circumference, physical activity, and alcohol intake.

**Results:** The study sample included 398 individuals of which 99 individuals went on to subsequently develop RA. In this analysis, time to diagnosis (defined as time between date of blood sample and date of diagnosis), was 6.71 years (SD 3.43).

A significant positive association was observed with level of educational attainment and RA incidence (secondary/technical vs university: OR 5.60, 95% CI 1.59–19.7, primary school vs university: OR 5.06, 95% CI 1.45–17.6, no education vs university: 7.11, 95% CI 1.37–36.8; p for trend 0.02) independent of ACPA seropositivity, SE and smoking).

A significant positive association between level of educational attainment and RA incidence was confirmed in the fully adjusted model (secondary/technical vs university: OR 5.52, 95% CI 1.53–19.9, primary school vs university: OR 4.87, 95% CI 1.38–17.1, no education vs university: OR 6.48, 95% CI 1.21–34.6; p for trend 0.02).

**Conclusions:** Lower educational levels were independently associated with higher risk of incident RA in this European Mediterranean population.

AB0291

### IDENTIFICATION OF JOINT LOCATIONS THAT ARE POOR PROGNOSTIC INDICATORS AND REQUIRE MORE INTENSIVE THERAPY IN AN EARLY, RAPIDLY PROGRESSING RA COHORT: A POST HOC AGREE ANALYSIS

P. Durez<sup>1</sup>, S. Robert<sup>2</sup>, A. Thiry<sup>3</sup>, H.A. Ahmad<sup>3</sup>. <sup>1</sup>Institut de Recherche Expérimentale et Clinique (IREC), Brussels; <sup>2</sup>Bristol-Myers Squibb, Braine-L'Alleud, Belgium; <sup>3</sup>Bristol-Myers Squibb, Princeton, USA

**Background:** Patients (pts) with early RA often present with multiple areas of involvement. Limited data exist to identify which specific joints or joint locations may be indicative of poorer prognosis and require more intensive initial therapy.<sup>1</sup>

**Objectives:** This analysis investigated which joint locations have the poorest prognosis and compared clinical response rates between abatacept (ABA)+MTX and MTX monotherapy by baseline (BL) swollen joint status for specific joint locations.

**Methods:** Data from AGREE (NCT00122382), a double-blind Phase III study of ABA+MTX (n=256) vs MTX (n=253) in biologic-naïve pts with early (≤2 years [yrs]) erosive RA, were analysed by BL swollen joint status (present, absent) for 8 different joint locations: hands, wrists, elbows, shoulders, jaw, knees, ankles and feet. Overall characteristics and study results were reported previously.<sup>2</sup> Swelling was evaluated at BL and after 6 months (mths) of treatment. Differences between treatment groups in clinical response endpoints (i.e. DAS28 [CRP]<2.6, SDAI≤3.3, CDAI≤2.8, Boolean and HAQ remission ≤0.5 at 6 mths) and swelling resolution at 6 mths were assessed by BL swollen joint status, for each joint location.

**Results:** In an early RA cohort of pts at risk of active, rapidly progressing disease, the proportions of pts (n=509) with a swollen joint at BL were 99% hand, 92%

wrist, 79% ankle, 69% knee, 66% foot, 48% elbow, 34% shoulder and 9% jaw. Pts with a swollen jaw (n=45) had more tender joints (mean [SD] 40.0 [15.1] vs 30.1 [14.1]), more swollen joints (35.9 [13.3] vs 21.1 [9.5]), higher total Sharp score (9.4 [10.1] vs 6.9 [9.1]) and longer disease duration (11.7 [9.2] yrs vs 6.0 [6.9] yrs) than those without jaw swelling (n=464). Higher HAQ-DI was seen in pts with a swollen knee or shoulder (1.8 [0.6] vs 1.5 [0.7] and 1.9 [0.6] vs 1.6 [0.7], respectively). Presence of BL synovitis was not associated with greater BL anti-citrullinated protein antibodies or RF positivity, probably due to the inclusion of mainly seropositive pts.

In general, absence of BL swelling was associated with higher clinical response at 6 mths, both for ABA+MTX and MTX. Independent of BL swollen joint status, ABA+MTX had higher clinical response rates (DAS28, SDAI, CDAI, Boolean and HAQ remission) than MTX, except for the non-swollen wrist. Overall mean Boolean remission rates were 13.7% for ABA+MTX vs 5.5% for MTX with difference in proportions (95% CI) of 8.1% (2.6, 13.7) (p=0.003). The largest difference in Boolean remission rate (95% CI) favouring ABA+MTX was 9.6% (4.2, 15.1) (p<0.001) in pts with a swollen wrist at BL (figure 1). Difference in swollen joint resolution between ABA+MTX and MTX was most pronounced for pts with a swollen hand (mean [95% CI]: 42.7% [36.7, 48.8] vs 27.9% [22.4, 33.4], respectively).

**Abstract AB0291 – Figure 1.** Treatment Group Comparisons of Boolean Remission Rates in Pts with BL Swollen Joint by Joint Location (Proportion [95% CI]).

**Conclusions:** BL swelling in the shoulder, knee and jaw is associated with a more severe RA profile. Remission rates were higher with ABA+MTX than MTX when BL swelling was present, especially in the wrist. Also, swollen joint resolution was more pronounced with ABA+MTX, especially in the hands.

### AUTOANTIBODIES TO A NOVEL PEPTIDE UH-RA.1 ARE ASSOCIATED WITH DISEASE REMISSION IN RHEUMATOID ARTHRITIS

L. De Winter<sup>1</sup>, P. Vandormael<sup>1</sup>, V. Stouten<sup>2</sup>, H.W. van Steenberghe<sup>3</sup>, P. Geusens<sup>1,4,5</sup>, J. Lenaerts<sup>6,7</sup>, A.H.M. van der Helm-van Mil<sup>8</sup>, P. Verschuere<sup>2</sup>, V. Somers<sup>1</sup>. <sup>1</sup>Biomedical Research Institute, Hasselt University and transnationale Universiteit Limburg, School of Life Sciences, Hasselt; <sup>2</sup>Skeletal Biology and Engineering Research Center, KULeuven Department of Development and Regeneration, KULeuven, Leuven, Belgium; <sup>3</sup>Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands; <sup>4</sup>ReumaClinic, Genk, Belgium; <sup>5</sup>Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands; <sup>6</sup>Reuma Instituut; <sup>7</sup>Jessa Hospitals, Hasselt, Belgium

**Background:** Autoantibodies have been found in the majority of RA patients and are used clinically as diagnostic and prognostic serum biomarkers. Before truly personalised medicine is available for RA patients, markers that can predict a patient's response to different therapeutic regimens have to be found. In this study, we further characterise autoantibodies to the novel University of Hasselt

(UH) peptide UH-RA.1, which have predictive value for an early response to therapy. Antibody reactivity to UH-RA.1 was found in 7%–10% of early RA patients. Presence of anti-UH-RA.1 antibodies in baseline samples from the Leiden Early Arthritis Clinic (EAC) cohort (n=600) appeared to be related to a better outcome as 37% of the antibody-positive group vs 21% of the antibody-negative group reached sustained DMARD-free remission (p=0.016) <sup>1</sup>.

**Objectives:** Our aim is to test the relation between antibody reactivity against UH-RA.1 peptide and early disease remission in baseline RA samples from the CareRA cohort.

**Methods:** Using a custom peptide enzyme-linked immunosorbent assay, the presence of anti-UH-RA.1 antibodies was investigated in the well characterised CareRA cohort <sup>2</sup>. Cut-off for seropositivity was defined by 2 × SD above the mean antibody level of the healthy control group <sup>1</sup>. In the CareRA trial, different treatment regimens consisting of synthetic DMARDs combined with a step down glucocorticoid treatment, were studied. We used 223 baseline RA samples, collected before the start of treatment and early disease remission was defined as a DAS28 (CRP) <2.6 at week 16.

**Results:** Antibodies to UH-RA.1 were found in 5% of the baseline samples from the CareRA cohort. Presence of anti-UH-RA.1 antibodies did not seem to be related to early disease remission in the CareRA cohort. Of the antibody positive group, 9/11 (82%) were in remission at week 16, while 152/212 (72%) of the antibody negative group reached early disease remission (p=0.37). However, in UH-RA.1 seropositive patients from the CareRA cohort, antibody levels were found to be significantly higher in baseline samples of patients that reached remission in week 16 (mean rank 120.51 vs 89.9, p=0.001).

**Conclusions:** In RA patients, presence of antibodies against UH-RA.1 peptide at baseline is related to sustained DMARD-free remission and high levels of antibodies against UH-RA.1 were correlated with early remission after combination therapy consisting of classical synthetic DMARDs with a step down glucocorticoid treatment. In combination with other predictive markers, antibodies against UH-RA.1 peptide might therefore contribute to an improved early patient stratification and prediction of therapy response.

#### AB0293 FREQUENCY OF JOINT EROSIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS, TREATED WITH BIOLOGICS IN RELATION TO RF AND ACPA SEROLOGY IN REAL LIFE

L. Heeman<sup>1</sup>, F. Van den Bosch<sup>1,2</sup>, D. Elewaut<sup>1,2</sup>, P. Carron<sup>1,2</sup>, P. Jacques<sup>1,2</sup>.  
<sup>1</sup>Rheumatology, University Hospital; <sup>2</sup>Inflammation Research Center, VIB, Ghent, Belgium

**Background:** Rheumatoid arthritis (RA) is a chronic auto-immune disease, characterised by a symmetric polysynovitis and extra-articular manifestations. In 70% to 80% of patients with RA, serologic factors like Rheumatoid Factor (RF) and Anti-Citrullinated Protein Antibodies (ACPA) are present. Early recognition and treatment with disease-modifying antirheumatic drugs (DMARDs) is important in achieving control of disease and prevention of joint destruction. If it is untreated or unresponsive to therapy, inflammation destroys cartilage and bone, resulting in irreversible bone erosions. The 2016 EULAR recommendations for the management of RA stipulate that MTX is recommended as first-line strategy plus short-term GC, aiming at >50% improvement within 3 and target attainment within 6 months. If this fails, stratification is recommended. Without unfavourable prognostic markers, switching to, or adding another csDMARDs (plus short-term GC) is suggested. In the presence of unfavourable prognostic markers (autoantibodies, high disease activity, early erosions, failure of 2 csDMARDs), any bDMARD or Jak-inhibitor should be added to the csDMARD.

**Objectives:** To determine an association between serology status and prevalence of radiographic erosions, the use of biologics and prevalence of erosions, and serology status and use of biologics.

**Methods:** Data were obtained from the electronic patient files of patients who visited the department of Rheumatology at the University Hospital of Ghent (Belgium) between October and December 2016. Patient characteristics with respect to diagnosis, treatment, serology status and erosion status were collected. The

data has been statistically analysed using  $\chi^2$ -, Fisher's exact, Kolmogorov-Smirnov or Kruskal-Wallis tests with  $\alpha=0.05$ .

**Results:** A total of 2001 consultations were analysed, of which 358 patients were identified with RA. 353 patients were included, of which 116 men (32.9%) and 237 women (67.1%). The mean age of the study population was 62 years with a mean age of 52 years at diagnosis. Of these patients, 36.0%, 49.5% and 29.8% were positive for respectively RF, ACPA and RF +ACPA. 38% has ever been treated with a biologic, whereas 26.9% is currently treated with a biologic. 37.4% of the patients showed erosions on a recent radiograph of hands or feet. A positive ACPA serology (p<0.0001. OR=1.87), a positive RF serology (p=0.010. OR=2.26) and a positive RF +ACPA serology (p=0.007. OR=2.74) was more observed in patients with radiographic erosions. A significant difference in erosions was seen between patients treated with or without biologics (p<0.0001. OR=3.45). Biologics were prescribed more in patients with positive ACPA serology (p<0.0001. OR=3.92) and in patients with positive RF serology (p=0.001. OR=2.67).

**Conclusions:** In a consecutive real life cohort of patients with RA, positive ACPA and/or RF status were associated with an increased risk to develop bone erosions in affected joints. Positive serology was also linked to biologic therapies. Patients who received biological treatment were more prone to have erosions.

**Disclosure of Interest:** None declared

#### AB0294 TREATMENT MODES IN RHEUMATOID ARTHRITIS: FACTORS INFLUENCING PATIENT PREFERENCE

P.C. Taylor<sup>1</sup>, N. Betteridge<sup>2</sup>, T.M. Brown<sup>3</sup>, J. Woolcott<sup>4</sup>, A.J. Kivitz<sup>5</sup>, C. Zerbin<sup>6</sup>, D. Whalley<sup>7</sup>, O. Olayinka-Amayo<sup>8</sup>, C. Chen<sup>9</sup>, P. Dahl<sup>9</sup>, D. Ponce de Leon<sup>10</sup>, D. Gruben<sup>11</sup>, L. Fallon<sup>12</sup>. <sup>1</sup>Botnar Research Centre, University of Oxford, Oxford; <sup>2</sup>Neil Betteridge Associates, London, UK; <sup>3</sup>RTI Health Solutions, Research Triangle Park, NC; <sup>4</sup>Pfizer Inc, Collegeville, PA; <sup>5</sup>Altoona Center for Clinical Research, Duncansville, PA, USA; <sup>6</sup>Centro Paulista de Investigação Clínica, São Paulo, Brazil; <sup>7</sup>RTI Health Solutions, Manchester, UK; <sup>8</sup>Pfizer Inc, New York, NY, USA; <sup>9</sup>Pfizer Inc, Ballerup, Denmark; <sup>10</sup>Pfizer Inc, Lima, Peru; <sup>11</sup>Pfizer Inc, Groton, CT, USA; <sup>12</sup>Pfizer Canada, Montreal, QC, Canada

**Background:** Little in-depth qualitative research has been conducted to investigate reasons for rheumatoid arthritis (RA) patient (pt) preferences for different modes of treatment administration. An understanding of pt preference can help physicians personalise therapy recommendations.

**Objectives:** To describe potential RA pt preferences for RA treatment modes and reasons for these preferences.

**Methods:** Pt demographic information was obtained at screening alongside qualitative interviews conducted using a semi-structured interview guide among adult RA pts in the US, UK, France, Germany, Italy, Spain, Switzerland and Brazil who were currently taking a DMARD (biologic or non-biologic). A 100-point allocation task was used to evaluate the strength of preference (0–100; 100=strong) across 4 treatment modes: oral (OR; once daily), self-injection (SI; weekly), clinic-injection (CI; weekly) and infusion (INF; monthly). Transcripts were developed in English; ATLAS.ti software (v7.5) was used for qualitative coding and analysis.

**Results:** 100 interviews (30 US; 10 in each of 7 other countries) were conducted (female: 75.0%; mean age: 53.9 years; mean time since diagnosis: 11.6 years). Current RA medication mode included OR (60.0%), injection (57.0%) and INF (14.0%); 79.0% and 37.0% of pts had experience with injection and INF medications, respectively; 31.0% of pts were taking a combination of biologic and non-biologic DMARDs. Among the 4 treatment modes, OR was allocated the highest mean (standard deviation [SD]) preference points (47.3 [33.1]) and the greatest percentage of pts with a 1st choice rank (57.0%); this was followed by SI (29.7 [27.7]; 29.0%), INF (15.4 [24.6]; 16.0%) and CI (7.5 [14.1]; 2.0%). Preferences by country suggested that the mean points allocated to OR were greater in the US vs other countries. Across all pts and treatment modes, 56.0% of pts had a 'strong' 1st choice preference (ie, a pt allocation  $\geq$  the mean pts across the 1st ranked choices [70]); of these pts, the majority chose OR (62.5%); SI: 23.2%; INF: 10.7%; CI: 3.6%). Speed of administration was among the most common reasons for choosing OR or SI as a 1st choice, together with ease of administration (OR) and frequency of dosing (SI; table 1). Difficulty remembering was the most common reason for not choosing OR and avoidance of pain was the most common reason for not choosing SI as a 1st choice.

**Conclusions:** More pts preferred OR as an RA treatment mode, followed by SI. Rationales for preference included ease of use, concerns about drug interactions, dosing frequency, feelings of control and avoidance of pain and needles. While 56.0% of pts felt strongly about their 1st choice preference, nearly half did not and may be receptive to and benefit from discussions with their healthcare professional and/or pt support groups about RA treatment mode options.

**Abstract AB0294 – Table 1.** Most frequent<sup>a</sup> reasons for choosing or not choosing each treatment mode as 1st choice

Reasons for choosing OR, n (%) (N=57)		Reasons for not choosing OR, n (%) (N=43)	
Speed of administration	30 (52.6)	Difficultly remembering	15 (34.9)
Ease of administration	30 (52.6)	Possible drug-drug interactions	11 (25.6)
Portability	23 (40.4)		
Reasons for choosing SI, n (%) (N=29)		Reasons for not choosing SI, n (%) (N=71)	
Speed of administration	16 (55.2)	Avoidance of pain due to needles	53 (46.5)
Frequency of dosing	12 (41.4)	Avoidance of needles	30 (42.3)
Having a feeling of control	11 (37.9)	Difficulties when traveling	19 (26.8)
		Need to refrigerate	18 (25.4)
Reasons for choosing CI <sup>b</sup> , n (%) (N=10)		Reasons for not choosing CI <sup>b</sup> , n (%) (N=100)	
Feels comfortable with experts administering	4 (40.0)	Need to go to the clinic	38 (38.0)
Prefers someone else to administer	3 (30.0)	Inconvenience	36 (36.0)
Reasons for choosing INF, n (%) (N=16)		Reasons for not choosing INF, n (%) (N=84)	
Frequency of dosing	13 (81.3)	Time-consuming	51 (60.7)
Feelings of safety and care	5 (31.3)	Hassle and inconvenience	28 (33.3)
		Need to go to the clinic	26 (31.0)

<sup>a</sup>Reported by ≥25% of patients. <sup>b</sup>N includes 2 patients who chose CI as clear 1<sup>st</sup> choice and 8 patients who chose CI as clear 2<sup>nd</sup> choice. <sup>c</sup>Based on total sample.

## AB0295 RISK FACTORS FOR PROGRESSION AND PROGNOSIS OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: SINGLE CENTRE STUDY WITH A LARGE SAMPLE OF CHINESE POPULATION

Q. Fu, Y. Zheng. Department of Rheumatology and Immunology, Beijing Chaoyang Hospital, Capital Medical University, Beijing, China

**Background:** Poor prognosis has been shown in rheumatoid arthritis-associated interstitial lung disease (RA-ILD) patients, and the mortality rate was significantly higher than RA patients without ILD. Studies showed that one-third of RA-ILD patients had progressed within two years. However, factors associated with ILD progression and survival in RA-ILD have not been previously described in a large centre China cohort.

**Objectives:** To investigate the risk factors for ILD progression and explore the prognostic factors for survival in RA-ILD patients.

**Methods:** 791 consecutive RA patients who completed lung HRCT were considered as potential participants. 266 RA-ILD patients were finally included in this retrospective cohort study. To identify independent risk factors for ILD progression, multivariate logistic regression analyses were used. Cox hazards analysis was used to determine significant variables associated with survival.

**Results:** 1, The mean age at diagnosis of RA-ILD was 64.80±10.71 years old. 162 (60.90%) were females and 104 (39.09%) were males. 2, UIP and NSIP pattern were the commonly types of RA-ILD, accounting for 37.22% and 25.94% respectively. Extent of lung involvement analysis showed that limited was predominant (130/266, 48.87%), with smaller numbers of moderate (67/266, 25.19%) and extensive (69/266, 25.94%) lung involvement. 3, The 3 year survival rate of RA-ILD patients was 81.24%, and the 5 year survival rate was 69.71%. A total of 82 deaths occurred during follow-up, of which 56 died of respiratory failure due to ILD progression and/or pneumonia, while 14 with malignancies (8 with lung cancer). 4, Logistic regression analysis showed that an increased anti-CCP antibody titer (OR: 4.03, 95% CI: 1.04–15.69, p<0.05) and DLCO%<45% (OR: 8.31, 95% CI: 2.17–31.75, p<0.01) were independent risk factors for the ILD

progression. 5, Cox hazards analysis revealed that advanced age (>60 years old) of RA-ILD diagnosis (HR: 2.32, 95% CI: 1.27–4.25, p<0.05) and extensive lung involvement on HRCT (HR: 2.19, 95% CI: 1.24–3.87, p<0.05) were associated with worse survival. Treatment with cyclophosphamide (HR: 0.43, 95% CI: 0.26–0.69, p<0.01) was associated with better survival.

**Abstract AB0295 – Figure 1.** Study flow diagram

**Conclusions:** In RA-ILD patients, DLCO%<45% is the strongest predictor for ILD progression. Advanced age and extensive lung involvement on HRCT, rather than the baseline UIP pattern, independently predict mortality after controlling for potentially influential variables. Furthermore, cyclophosphamide treatment helps to improve the prognosis in real-world experience.

## AB0296 14–3–3ETA POSITIVITY IS ASSOCIATED WITH HIGHER RHEUMATOID ARTHRITIS DISEASE ACTIVITY MEASURED BY MULTI-BIOMARKER DISEASE ACTIVITY ASSAY

R. Chao<sup>1</sup>, M. Das<sup>1</sup>, N. Purat<sup>1</sup>, P. Eftthimiou<sup>2</sup>. <sup>1</sup>Internal Medicine, New York Presbyterian Brooklyn Methodist Hospital, Brooklyn, <sup>2</sup>Rheumatology, New York University, New York, USA

**Background:** Early diagnosis of rheumatoid arthritis (RA) is crucial but recognition of its disease activity and prognosis can help tailor treatment for patients in order to avoid debilitating consequences. 14–3–3eta has been described to have diagnostic utility as a biomarker of RA; however its use as prognostic factor is still under investigation.<sup>1</sup> The η (eta) isoform is one of seven from the 14–3–3 family of regulatory proteins and is expressed extracellularly in much higher concentrations in the synovial fluid and serum of patients with RA. A multiple-biomarker disease activity (MBDA) score was recently introduced; 396 candidate cytokines and biomarkers were narrowed to twelve, correlating with disease activity.

**Objectives:** The purpose of our study was to investigate if 14–3–3η can be used as a prognostic factor and if it was associated with higher disease activity in RA patients. We compared the positivity of 14–3–3η in those with low, moderate, and high disease activity based on MBDA scores. In addition, as MBDA scores provide individual biomarker levels, we wanted to determine if there was a correlation between 14–3–3η and specific biomarker patterns.

**Methods:** A retrospective chart review was conducted on 70 RA patients (satisfied the 2010 ACR diagnostic criteria) at an outpatient rheumatology clinic in an inner-city population. Serum 14–3–3η protein was measured by ELISA with a positive threshold range (Quest Diagnostic) of 0.2 ng/mL. The MBDA scoring scale was 1–29 for low disease activity, 30–44 for moderate and 45–100 for high. The t-test was used to analyse for a significant difference in MBDA scores as well as individual biomarker levels in 14–3–3η positive patients.

**Results:** Of the 70 RA patients, 37 were 14–3–3η positive and 33 were negative. Thirty (81%) of 14–3–3η positive patients were on at least one DMARD compared to 16 (48.5%) of negative patients. The mean and median MBDA scores of 14–3–

3η positive patients were 49.4 and 47, while negative patients' scores were 36.9 and 38, respectively ( $p=0.002$ ). Thus, 14–3–3η positive patients had high disease activity while 14–3–3η negative patients had moderate disease activity. Mean levels of matrix metalloproteinase 3 (MMP-3), serum amyloid A (SAA), and CRP in 14–3–3η positive versus negative were 52.3 ng/mL and 28.4 ng/mL ( $p=0.01$ ), 24.3 mg/mL and 6.96 mg/mL ( $p=0.02$ ), and 21.5 mg/L and 9.82 mg/L ( $p=0.02$ ), respectively.

**Conclusions:** 14–3–3η positive RA patients have higher disease activity based on MBDA score and are associated with higher levels of MMP-3, SAA, and CRP. MMP-3 is associated with joint destruction through degradation of the components of extracellular matrix in the synovial joint. SAA and CRP are acute phase reactants but SAA has been linked with increased cardiovascular and renal disease in RA patients. 14–3–3η positive patients should be treated aggressively to decrease disease activity and limit extra-articular manifestations.<sup>2</sup>

**Background:** Inadequate response to treatment in early rheumatoid arthritis (RA) is associated with adverse consequences. We have previously shown high baseline levels of disease activity in Latin American RA patients.<sup>1</sup>

**Objectives:** To identify the baseline predictive factors of inadequate response to treatment in patients with early RA from a GLADAR cohort, at one year from cohort entry.

**Methods:** GLADAR cohort includes 1093 consecutive RA patients with disease <1 year from 46 centres in 14 Latin American countries. For these analyses, patients with complete clinical and laboratory assessments with DAS28-ESR>3.2 at the baseline, and one-year follow up visits were included. Inadequate treatment response was ascertained with the EULAR definition which is based on DAS28-ESR obtained at one-year of follow up [a variation  $\leq 0.6$  in any category of activity (mild, moderate or severe) and a variation  $>0.6$  but  $\leq 1.2$  in the high activity category]. Gender, age at diagnosis, diagnosis delay, socioeconomic status (by the Graffar scale), ethnicity, medical coverage, rural origin, rheumatoid factor (RF) positivity, disability (HAQ-DI), DMARDs use, corticosteroid use, and DMARD treatment delays were examined as potential predictive factors of this outcome. Univariable and multivariable binary logistic regression models, using a stepdown technique were examined in order to determine the predictors of response at 1 year.

**Results:** Four hundred and forty-eight patients were included. Three hundred and eighty-five (85.9%) were female; the mean (SD) age at diagnosis was 46.1 (13.6) years; 78.3% had medical coverage and 347 patients (77.5%) were RF

positive. The mean baseline DAS28-ESR was 6.3 (1.4). EULAR response was met by 347 (77.5%) patients at 1 year. Three hundred patients (67%) have received glucocorticoids, 78.8% at least one DMARD and only 1.1% had received at least one biologic compound. The baseline HAQ-DI was 1.5 (0.0–3.0). Predictors of non-EULAR response at 1 year were: female gender (OR=2.4; CI:1.0–5.6;  $p=0.039$ ), a higher baseline HAQ-DI (OR=1.7; CI:1.2–2.4;  $p=0.003$ ) whereas protective factors were higher DAS28-ESR (OR=0.6; CI:0.4–0.7;  $p<0.001$ ) and having medical coverage (OR=0.5; CI:0.3–0.9;  $p=0.025$ ).

**Conclusions:** We have identified baseline predictors of adverse response to treatment in LA patients with early RA. Absence of medical coverage seems to be an additional adverse factor associated with poor results. Other factors such as early response/remission or adherence to treatment should be taken into account.

#### A LOWER WAIST CIRCUMFERENCE IS ASSOCIATED WITH CLINICAL REMISSION IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS

R.V. Gamboa-Cárdenas<sup>1,2</sup>, M.F. Ugarte-Gil<sup>2,3</sup>, M. Medina<sup>2</sup>, F. Zevallos<sup>2</sup>, V. Pimentel-Quiroz<sup>2</sup>, C. Elera-Fitzcarrald<sup>2,3</sup>, C. **Background:** Abdominal Obesity is highly prevalent in patients with RA and this condition is associated with adverse metabolic outcomes, but information about the impact of this condition in clinical activity disease is scarce, specially in our region

**Objectives:** To assess the association between central obesity with baseline clinical activity in a cohort of patients with established rheumatoid arthritis (RA).

**Methods:** Cross-sectional baseline analysis of a single centre RA cohort. This cohort began at 2011 and includes patients with a diagnosis of RA ACR EULAR 2010 criteria), followed by semestral visits. In this analysis, clinical disease activity was measured by SDAI, clinical remission and low disease activity (LDA) was defining according SDAI categories (a value  $<3.3$ , and  $\leq 11$ , respectively), also definition of remission by the ACR-EULAR 2011 was applied (tender and swollen joint counts  $\leq 1$ , CRP  $\leq 1$  mg/dl, and PGA  $\leq 1$  with patient-reported outcomes on a scale of 0–10, or SDAI  $\leq 3.3$ ). Patients with chronic pain disease (fibromyalgia, neuropathic pain and neurologic disorders such as neuropathies) and diagnosis of depression were excluded. Waist circumference (WC) was measured as a continue variable (cm). Potential basal confounders associated with activity disease were analysed: socio demographics variables (age at diagnosis, gender, disease duration, delay of DMARDs treatment, education), anticitrullinated antibody peptide (antiCCP), medication (use and dose of corticosteroid, use of cDMARDs and bDMARDs). Continuous variables were expressed as means and SDs, and categorical variables as percentages and 95% confidence intervals (95% CIs). Univariable and multivariable binary logistic regression models were examined in order to determine the association between abdominal perimeter and remission.

**Results:** Four hundred and twenty-five from 596 subjects of the cohort were include. The mean (SD) age was 58.5 (11.8) years. Disease duration was 15.2 (14.0) years; 90.4% were women and 75.8% were anti CCP positive. Two hundred and fifty-one patients (59.1%) have received glucocorticoids, 50.1% at least one DMARD and only 5.4% had received at least one biologic compound. The mean WC was 98.2 (11.3) cm and central obesity prevalence was 87.8% in men and 96.7% in woman. The baseline SDAI was 29.9 (24.1). Remission was met only by 1.7% patients and remission/LDA by 13.2% subjects. In the univariate analysis, a less WC was associated with remission (OR=0.9; CI:0.8–0.9;  $p=0.042$ ); this association remained significant in the multivariable analysis (OR=0.9; CI:0.8–0.9;  $p=0.022$ ).

**Conclusions:** A lower waist circumference is associated with clinical remission in patients with established RA. This condition should be taken in account in the baseline measure of activity disease.

**AB0299 THE INCIDENCE RATE AND THE MANAGEMENT OF EARLY RHEUMATOID ARTHRITIS IN A SINGLE CENTRE INTERVENTIONAL CLINIC**

R. Ješe<sup>1</sup>, K. Perdan Pirkmajer<sup>1</sup>, A. Ambrožič<sup>1</sup>, N. Gašperšič<sup>1</sup>, A. Hočevar<sup>2</sup>, B. Lestan<sup>1</sup>, S. Markez<sup>1</sup>, M. Pavić Nikolić<sup>1</sup>, M. Plešivčnik Novljan<sup>1</sup>, S. Praprotnik<sup>1</sup>, Ž. Rotar<sup>1</sup>, A. Šipek Dolničar<sup>1</sup>, D. Šuput Skvarča<sup>1</sup>, M. Tomšič<sup>1</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>University Medical Centre Ljubljana, Ljubljana, Slovenia

**Background:** In patients with rheumatoid arthritis (RA), early diagnosis and adherence to the treat to target recommendations (T2T) limit RA progression and improve patients' quality of life.<sup>1</sup> However, the implementation of T2T has always been a challenge, and real-life data are lacking. Slovenia has 40% less rheumatologists per capita than the European Union average, which makes the implementation of management guidelines even more challenging.

**Objectives:** To determine the incidence of RA and the proportion of patients with incident RA in whom first rheumatology assessment was done within the recommended time frame.

**Methods:** We analysed the prospectively collected data of adult patients diagnosed with RA during years 2014 to 2016 at the Rheumatology Department of the University Medical Centre Ljubljana, Slovenia. The department provides rheumatology services to a well-defined region with a population of 704.000 adult residents. Dates were recorded for inflammatory joint symptom onset, referral to rheumatologist, first rheumatologic assessment and initiation of DMARD therapy. The percentage of patients assessed by a rheumatologist and/or treated with a DMARD within 12 weeks of symptom onset and the median times for delay were then calculated.

**Results:** Between 1 January 2014 and 31 December 2016, 341 incident cases of RA (75% females, median age 61.9 (IQR 52–75.4) years) were identified, resulting in an annual incidence rate of 16/100.000 population (in females: 23.6/100.000; in males 8.3/100.000). Most patients (78.6%) were referred to our early interventional clinic. The median time from symptom onset to consultation was 12.9 (IQR 4.4–26.1) weeks, median time from referral to consultation was 1 (IQR 1–3) day. Median DMARD treatment delay was 16.6 (IQR 8.9–33.3) weeks. Within 12 weeks of symptom onset, 161 (47.2%) new RA patients were examined by a rheumatologist and 123 (36.1%) were started on DMARD therapy.

**Conclusions:** Our prospective data support the recent reports that uncovered a decrease in RA incidence.<sup>2</sup> Moreover, despite the lack of rheumatologists and the heavily protracted nationwide waiting times for first rheumatologist assessment, our early interventional clinic enables us to recognise and manage substantial percentage of RA patients within the recommended time frame.

**AB0300 ULTRASOUND EVALUATION OF ANKLE AND FOOT JOINTS IN RHEUMATOID ARTHRITIS**

S. Fellous<sup>1</sup>, H. Rkain<sup>1</sup>, S. aflal<sup>1</sup>, L. Tahiri<sup>1</sup>, N. Alami<sup>1</sup>, R. Guieu<sup>2</sup>, J. yves<sup>2</sup>, F. Allali<sup>3</sup>, N. Hajjaj-Hassouni<sup>4</sup>. <sup>1</sup>Department of Rheumatology B, El Ayachi Hospital, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco., Rabat, Morocco; <sup>2</sup>UMR MD2 Faculty of Medicine, Aix-Marseille University, Marseille, France., marseille, France; <sup>3</sup>Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco., Rabat; <sup>4</sup>Center for Pedagogical Innovation, Mohammed VI University of Health Sciences, Casablanca, Morocco., casablanca, Morocco

**Background:** The foot and the forefoot particular are often one of the first areas to be affected by rheumatoid arthritis. The joint destruction develops not only as a result of synovitis but also as a result of specific biomechanical stresses leading to deformity

**Objectives:** Evaluate the prevalence of ultrasound signs of rheumatoid arthritis in the joints of the ankle and foot.

**Methods:** This is a cross-sectional study that included 14 consecutive patients (100% female, mean age 55.3 years) with rheumatoid arthritis (median duration of progression of 13.5 years, mean specialised care of 2.1 years). A grey and Doppler ultrasound study was performed by looking for effusions, synovitis, Doppler activity and bone erosions in the joints of the ankle and foot.

**Results:** 28 feet were studied with an ultrasound evaluation of 308 joints. The prevalence of ultrasound signs of RA are shown in table 1 and 2.

**Abstract AB0300 – Table 1.** Prevalence of ultrasound signs of RA in the forefoot (N=28)

Echographic signs	Forefoot				
	MTP1 n=28	MTP2 n=28	MTP3 n=28	MTP4 n=28	MTP5 n=28
Synovitis	57.1	28.6	14.3	21.4	25
Doppler	0	0	3.6	3.6	3.6
Effusion	25	21.4	10.7	10.7	7.1
Erosions	67.9	3.6	10.7	17.9	7.1
Osteophytes	57.1	17.9	14.3	25	25

**Abstract AB0300 – Table 2.** Prevalence of ultrasound signs of RA in the ankle and foot (N=28)

Echographic signs	Ankle		Hindfoot		Midfoot		
	Talocalcaneal N=28	Subtalar N=28	Talo-navicular N=28	Calcaneocuboid N=28	Cubo-metatarsal N=28	Cuneo-metatarsal N=28	
Synovitis	60.7	50	46.4	7.1	7.1	3.6	
Doppler	0	0	0	3.6	0	0	
Effusion	39.3	25	10.7	7.1	0	10.7	
Erosion	10.7	10.7	0	14.3	14.3	3.6	
Osteophyte	28.6	39.3	71.4	39.3	42.9	14.3	

**Conclusions:** This study describes the various ultrasound signs at the joints of the ankle and foot. There is a high prevalence of synovitis in the ankle and hind-foot. Doppler activity has been rarely found.

A large-scale study compared with a control group is necessary to better interpret and complete these preliminary results.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6693

**AB0301 SERUM PYRIDINOLINE IS ASSOCIATED WITH RADIOGRAPHIC JOINT EROSIONS IN RHEUMATOID ARTHRITIS**

S. Rajalingham<sup>1</sup>, A.M.M. Nor Hashimah<sup>1</sup>, S.S. Shaharir<sup>1</sup>, R. Sridharan<sup>2</sup>, A. Abdul Wahab<sup>3</sup>. <sup>1</sup>Medicine; <sup>2</sup>Radiology; <sup>3</sup>Microbiology, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

**Background:** Pyridinoline (Pyl) is a 3-hydroxypyridinium derivative which is an intermolecular cross-link compound of type I and II collagen.<sup>1</sup> It is a marker of bone resorption based on bone biopsy and radioisotope kinetics studies.<sup>2</sup> In rheumatoid arthritis (RA), destruction of bones may contribute to increased levels of serum Pyl.

**Objectives:** The purpose of this study was to compare the serum pyridinoline (Pyl) levels between RA patients and healthy controls and to determine the correlation of serum Pyl levels with radiographic joint erosions.

**Methods:** This was a monocentric, cross sectional, case-control study which was conducted from June 2016 to February 2017 at the Universiti Kebangsaan Malaysia Medical Centre (UKMMC). Serum samples were obtained from 48 patients with RA and 48 healthy controls. The enzyme-linked immunosorbent assay (ELISA) method was used for quantitative analysis of serum Pyl. Besides, all the RA patients were assessed for joint damage based on Modified Sharp Score (MSS), disease activity based on the disease activity score in 28-joints (DAS 28) and functional capacity based on Health Assessment Questionnaires Disability Index (HAQ-DI).

**Abstract AB0301 – Table 1.** Correlation between serum pyridinoline and other clinical variables

	Serum Pyridinoline		
	r	r <sup>2</sup>	p
DAS 28	- 0.010	7.431	0.945
Joint erosion score	<b>0.285</b>	0.086	<b>0.049</b>
JSN score	- 0.076	7.560	0.605
Total MSS	- 0.009	0.005	0.952
HAQ-DI	- 0.186	0.051	0.205

**Results:** The median serum Pyl levels was much higher among the RA patients (110.20 ng/mL [92.30–120.64]) compared to the controls (98.22 ng/mL [85.54–111.41]); p<0.05. RA patients with erosive disease had significantly higher serum

Pyd levels ( $p=0.024$ ). There was a significant positive correlation between serum Pyd levels and joint erosion score ( $r=0.285$ ,  $p=0.049$ ). The serum Pyd levels had no demonstrable association with disease activity or functional capacity. Neither steroid nor biologic therapy influenced the levels of serum Pyd.

**Conclusions:** RA patients had significantly higher levels of serum Pyd compared to healthy controls. The serum Pyd levels had significant correlation with radiographic joint erosions which reflected disease damage.

#### AB0302 THE ROLE OF THE BIOMARKER 14-3-3 ETA IN RHEUMATOID ARTHRITIS: A REVIEW

S. Kilborn, M. Bukhari. *Medicine, Lancaster University, Lancaster, UK*

**Background:** Biomarkers are of much interest in rheumatoid arthritis (RA). Valid, reliable and convenient biomarkers, to detect early disease, predict severity and monitor treatment response are essential to achieving optimal outcomes. Several biomarkers have been suggested but are largely not validated. Validated measures of rheumatoid factor (RF), citrullination antibodies (ACPA), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) do not provide a complete picture. 14-3-3 $\eta$ , a protein from a family of highly conserved regulatory molecules, has promising data as a novel RA biomarker and is the focus of this review.

**Objectives:** This review aimed to identify the literature characterising 14-3-3 $\eta$  and its utility in RA.

**Methods:** Search terms 14-3-3 $\eta$ , biomarker and rheumatoid arthritis were used in Pubmed, Web of Science and Embase databases and reference lists of relevant papers were scanned. Inclusion criteria were confirmed RA, 14-3-3 $\eta$  and English language.

**Results:** Seven key papers were identified on 14-3-3 $\eta$  proteins<sup>1-6</sup> and one on 14-3-3 $\eta$  antibodies (14-3-3 $\eta$ -Ab)<sup>7</sup>. **Detecting RA:** 14-3-3 $\eta$  was elevated in patients with RA compared to healthy controls<sup>2,4</sup> and patients with other diseases ( $p<0.001$ )<sup>4</sup>. Being positive for 14-3-3 $\eta$  ( $>0.19$  ng/mL) showed sensitivity and specificity of 63.3% and 92.6%<sup>4</sup> to detect RA, increasing to 91.7% and 99.6%, respectively when an ROC-determined optimal cut-off of 0.879 ng/mL was used<sup>2</sup>. When combined with current markers RF  $\pm$  ACPA the detection capacity for early RA increased to 78% and for established RA to 96%, compared to 72% and 88%<sup>4</sup>, respectively for RF  $\pm$  ACPA alone. Including the 14-3-3 $\eta$ -Ab further increased detection<sup>7</sup>. The 14-3-3 $\eta$ -Ab appeared at higher levels in early, treatment naïve RA, while no difference was seen in established RA compared to controls<sup>7</sup>. The 14-3-3 $\eta$ -Ab was not associated with inflammatory markers ESR or CRP<sup>7</sup>. Although higher levels of the 14-3-3 $\eta$  protein were detected in early RA ( $p<0.05$ ), rate of detection was higher in established RA<sup>2</sup>. **Predicting disease severity:** Baseline 14-3-3 $\eta$  status was associated with increased disease severity<sup>1,2,3,4,5</sup>, higher median DAS (6.3 vs 5.7,  $p=0.026$ ) and HAQ scores (1.9 vs 1.0,  $p=0.001$ )<sup>4</sup>. Significant associations with baseline DAS28-ESR, CDAI and SDAI ( $p<0.045$  –  $p<0.001$ ) were also reported<sup>3</sup>. Physical symptoms are closely related to 14-3-3 $\eta$  levels<sup>2</sup>; patients achieving DAS28-ESR-defined remission had significantly lower levels than non-remitters<sup>3</sup>. Radiographic progression was significantly associated with higher 14-3-3 $\eta$ <sup>1,5</sup>, OR=6.2 (95%CI 1.3 to 30.2) in early RA and 2.5 (95%CI 1.0 to 1.4) in established RA<sup>5</sup>. Conflicting results on associations with existing markers ESR, CRP, RF, and ACPA have been reported<sup>1,2,3,4,5,6</sup>. **Treatment response:** 14-3-3 $\eta$  levels are dynamic with changing disease activity<sup>1,3</sup>. Also, pre-treatment 14-3-3 $\eta$  levels were an independent predictor of response to some therapies<sup>3</sup>.

**Conclusions:** 14-3-3 $\eta$  protein and Ab are promising biomarkers in RA diagnosis, disease severity and response to treatment. Future research characterising the protein in RA and its relationship with validated biomarkers and composite measures, and expanding on the 14-3-3 $\eta$ -Ab would be well directed.

#### AB0303 ULTRASOUND ASPECT OF POSTERIOR TIBIAL TENDON IN RHEUMATOID ARTHRITIS

S. Afila<sup>1</sup>, H. rkain<sup>1</sup>, S. fellous<sup>1</sup>, L. tahiri<sup>1</sup>, N. alami<sup>1</sup>, R. Guieu<sup>2</sup>, Y. Jammes<sup>3</sup>, F. Allali<sup>1</sup>, N. Hajjaj-Hassouni<sup>4</sup>. <sup>1</sup>Department of Rheumatology B, El Ayachi Hospital, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco., Rabat, Morocco; <sup>2</sup>UMR MD2 Faculty of Medicine, Aix-Marseille University, Marseille, France; <sup>3</sup>UMR MD2 Faculty of Medicine, Aix-Marseille University, Marseille, France.; <sup>4</sup>Center for Pedagogical Innovation, Mohammed VI University of Health Sciences, Casablanca, Morocco, casablanca, Morocco

**Background:** Posterior tibial tendon involvement is common in rheumatoid arthritis. Ultrasound has an important place in the examination of this tendon.

**Objectives:** Evaluate the prevalence of ultrasound signs of posterior tibial tendon involvement in rheumatoid arthritis.

**Methods:** This is a cross-sectional study that included fourteen consecutive patients (100% female, mean age 55.3 years) with rheumatoid arthritis (median duration of progression of 13.5 years, mean specialised care of 2.1 years). A grey and Doppler ultrasound study was performed on affected feet, looking for effusion, thickening or corporal thinning, hypoechoic aspect, fissures, and Doppler activity in the posterior tibial tendon.

**Results:** 28 feet were studied with ultrasound evaluation of the posterior tibial tendon. Figure 1 illustrates the prevalence of the pathological aspects of the posterior tibial found on ultrasound examination.

**Abstract AB0303 – Figure 1.** Ultrasound aspects of the posterior tibial tendon in patients RA

**Conclusions:** This study illustrates the different pathological aspects of the posterior tibial tendon. It highlights the high prevalence of this tendinopathy in the rheumatoid foot. Ultrasound allows accurate assessment of this tendon in RA patients.

A large-scale study compared with a control group is necessary to better interpret and complete these preliminary results.

#### AB0304 THE DELAY IN THE MANAGEMENT OF RHEUMATOID ARTHRITIS BY A RHEUMATOLOGIST IS ASSOCIATED WITH AN ALTERATION OF THE FUNCTION OF THE FOOT

S. Afila<sup>1</sup>, H. rkain<sup>1</sup>, S. fellous<sup>1</sup>, L. tahiri<sup>1</sup>, N. alami<sup>1</sup>, R. guieu<sup>2</sup>, Y. jammes<sup>2</sup>, F. allali<sup>1</sup>, N. Hajjaj-Hassouni<sup>3</sup>. <sup>1</sup>Department of Rheumatology B, El Ayachi Hospital., Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco., Rabat, Morocco; <sup>2</sup>UMR MD2 Faculty of Medicine, Aix-Marseille University, marseille, France; <sup>3</sup>Center for Pedagogical Innovation, Mohammed VI University of Health Sciences, Casablanca, Morocco., casablanca, Morocco

**Background:** Impairment of foot function is known in rheumatoid arthritis.

**Objectives:** Evaluate the functional status of the foot in patients with RA and look for factors associated with impaired foot function.

**Methods:** This is a cross-sectional study that consecutively included 14 patients (100% female, mean age 55.3 years) with RA (median duration of evolution of 13.5 years, mean specialised care of 2.1 years). The functional status of RA was assessed by the HAQ (Health Assessment Questionnaire). RA activity was evaluated by DAS28 and DAS44. The FFI score (Foot Function Index) was used to determine the functional status of the foot. A correlation analysis was made between the FFI score and DAS28, DAS44 and HAQ as well as with the duration of progression of the RA and the delay of specialised management.

**Results:** The median score of the HAQ (Health Assessment Questionnaire) was 1.6. The median score for the Foot Function Index (FFI) was 53.6. The medians of DAS 28 and DAS 44 were 5.3 and 3.8. The median of the different FFI score items was:

Pain Sub-scale: How severe is your foot pain ?

Q1: Foot pain at its worst ? 7 (6; 9,25), Q2: Foot pain in morning ? 5,5 (2; 7), Q3: Pain walking barefoot ? 4 (1,75; 8,15), Q4: Pain standing barefoot ? 5 (3,25; 8,25), Q5: Pain walking with shoes ? 4 (1,75; 5,75), Q6: Pain standing with shoes ? 4,5 (3; 5,5), Q7: Pain walking with orthotics ? 3 (3; 3), Q8: Pain standing with orthotics ? 3 (3; 3), Q9: Foot pain at end of day ? 5 (2,75; 7)

Disability sub-scale: How much difficulty did you have ?

Q10: Difficulty walking in house ? 2 (0; 3,25), Q11: Difficulty walking outside ? 5,5 (3; 8), Q12: Difficulty walking 4 blocks ? 5 (4; 9), Q13: Difficulty climbing stairs ? 6,5 (4; 8,25), Q14: Difficulty descending stairs ? 6 (3,5; 8,25), Q15: Difficulty standing tip toe ? 8,5 (5,25; 10), Q16: Difficulty getting up from chair ? 5 (1,5; 8), Q17: Difficulty climbing curbs ? 4,5 (2; 7,25), Q18: Difficulty walking fast ? 8,5 (4,75; 10)

Activity Limitation sub-scale: How much of the time do you ?

Q19: Stay inside all day because of feet ? 7 (2; 8,25), Q20: Stay in bed all day because of feet ? 5 (2; 3,25), Q21: Limit activities because of feet ? 5,5 (1; 8), Q22: Use assistive device (cane, walker, crutches, etc) indoors ? 0 (0; 3,25), Q23: Use assistiw device (cane, walker, crutches, etc) outdoors ? 0 (0; 0,75).

No correlation was found between the FFI and the HAQ. DAS 28 and DAS44 did not correlate with the FFI either.

Alteration of foot function as indicated by a high FFI score was associated with a delay in specialist management by a rheumatologist ( $r=0.535$ ,  $p=0.04$ ).

**Conclusions:** This study provides insight into the impact of RA on foot function. The HAQ, DAS28 and DAS44 would not reflect the functional deterioration of the foot in RA. In addition, an alteration of foot function would be associated with a delay in specialist management by a Rheumatologist.

A large-scale study is underway to validate and complete these preliminary results.

#### AB0305 REMAINING FOOT SYNOVITIS MAY PREDICT RELAPSE IN RHEUMATOID ARTHRITIS PATIENTS IN DAS28 REMISSION (DAS28-CRP<2.3)

S. Hattori<sup>1</sup>, N. Hagino<sup>1</sup>, K. Yomono<sup>1</sup>, S. Tsuzuki<sup>1</sup>, S. Suzuki<sup>1</sup>, S. Takenouchi<sup>1</sup>, R. Yokochi<sup>1</sup>, T. Matsui<sup>2</sup>, S. Tohma<sup>3</sup>. <sup>1</sup>Division of Hematology and Rheumatology, Teikyo University Chiba Medical Center, Ichihara; <sup>2</sup>Department of Rheumatology, Clinical Research Center for Allergy and Rheumatology, Sagami National Hospital, Sagami; <sup>3</sup>Department of Rheumatology, Tokyo National Hospital, Kiyose, Japan

**Background:** DAS28 (Disease Activity Score based on 28 joints) is widely used to determine remission in rheumatoid arthritis (RA). The problems with DAS28 due to omission of the lower extremity joints have long been discussed. There are reports demonstrating that some patients meeting DAS28 remission criteria still have synovitis in their feet.<sup>1</sup> It is suggested that patients with remaining foot synovitis can experience up to a 2-fold increase in relapse rates.<sup>2</sup> Evidence supporting this hypothesis is still scarce.

**Objectives:** We hypothesised that RA patients in remission according to the DAS28 remission criterion with remaining foot synovitis are less likely to stay in remission. We aimed to test this hypothesis among Japanese patients with RA.

**Methods:** In 2015, 15,071 RA patients were registered in a large nationwide database in Japan (NinJa). Among those patients, those who were in remission based on DAS28-CRP were included. We used DAS28-CRP<2.3 as the remission criteria. The study population was then divided into groups with or without tender/swollen joints in the feet. These patients were followed for one year and the remission rate was then calculated for each group. Comparison was performed with Chi-square test.

**Results:** We included 706 RA patients in remission based on DAS28-CRP with foot synovitis in 2015 and 5182 without foot synovitis. Among patients with foot

synovitis in 2015, 225 (31.9%) were not in remission in 2016 while among those without foot synovitis, 985 (19.0%) were not in remission. ( $X\text{-squared}=62.953$ ,  $df=1$ ,  $p=2.117 \times 10^{-15}$ )

**Conclusions:** In our study, RA patients in remission according to the DAS28 remission criterion with remaining foot synovitis had more relapses than those without it. Remission defined by DAS28-CRP does not take remaining foot synovitis into account. But a thorough foot examination may still be useful in RA patients with DAS28-CRP remission as they may be more at risk for relapse.

#### AB0306 PREDICTORS OF MEDICATION ADHERENCE IN SERBIAN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Zivojinovic<sup>1</sup>, J. Nedovic<sup>2</sup>, T. Jankovic<sup>3</sup>, N. Damjanov<sup>4</sup>, on behalf of Prof Nemanja Damjanov. <sup>1</sup>Clinical V, Institute of Rheumatology, Belgrade; <sup>2</sup>Institute For Treatment and Rehabilitation Niska Banja, Nis; <sup>3</sup>Clinic For Rheumatic disease, Novi Sad; <sup>4</sup>Head of the Institute of Rheumatology, Institute of Rheumatology, Belgrade, Serbia

**Background:** Adherence to pharmacologic therapy is a significant problem in patients with rheumatoid arthritis (RA). Nonadherence in patients with RA using disease modifying antirheumatic drugs (DMARD) may result in unnecessarily high levels of disease activity and function loss.

**Objectives:** The aim of this study was to evaluate the predictive ability of demographic (age, sex, marital status, employment status, education) and clinical factors (duration of disease, patients assessment of pain, concomitant use of biological therapy and presence of comorbidity) for medication adherence.

**Methods:** In the period between March 1 and May 30, 2017, 195 consecutive RA patients who were treated in one of three randomly chosen Serbian clinics were enrolled in cross-sectional study. The inclusion criteria were: age  $\geq 18$  years, current diagnosis of RA per the 1987. ACR Diagnostic Criteria, completing the questionnaire self-reported medication adherence and written informed consent. Demographic and clinical characteristics of adherent and non-adherent participants were compared using independent samples t-tests for continuous variables and Chi square analyses for categorical variables. The associations between investigated demographic and clinical characteristics of the patients and non-adherence to DMARDs were assessed applying logistic regression analysis.

**Results:** Study population was predominantly female (88%), and the average current age was  $57.4 \pm 11.2$  years. The median duration of RA was 9 years. Only one quarter (25%) of participants were employed, those unemployed 26% or retired (48%) comprised the majority of the sample. In terms of education approximately 60% participants finished secondary school. The participants in this study were primarily married (77%). The majority of the patients were prescribed methotrexate (77%), other common DMARDs prescribed for these patients included hydroxychloroquine (13%) and prednisone (18%). Approximately 20% of patients were receiving a biological drug. Half of the patients estimated that they had severe pain on visual analogue scale (VAS >5). The majority of the RA patients had some comorbidity (80%). The most of these RA patients (89.7%) were considered adherent to medication prescriptions and the remainder (11.3%) were non-adherent. There were no significant difference in clinical or demographic factors between groups except for employment and concomitant use of biological therapy. One third (33.3%) of the non-adherent participants were using biologic drug, while only 19% of the adherent patients were using biologics. There were significantly more employees (29%) among the non-adherent patients. According to the results of univariate regression analysis the following factors are significantly associated with non-adherence to DMARDs: employment (OR=2.277;  $p=0.049$ ), and concomitant use of biological therapy (OR=2.312;  $p=0.002$ ). Finally, in the multivariate regression model concomitant use of biological therapy (OR=2.067;  $p=0.017$ ) remained statistically significant and was identified as independent predictor of non-adherence to DMARDs.

**Conclusions:** The results of our study have shown that about 10% of RA patients met the criteria for non-adherence to DMARDs. Concomitant use biologics and employment are independent predictors of non-adherent.

### PREDICTIVE VALUE OF THE BASELINE CLINICAL, LABORATORY AND ECHOSONOGRAPHIC PARAMETERS OF RA ACTIVITY IN PROGRESSION OF STRUCTURAL DAMAGE IN DMARDS NAÏVE EARLY RA PATIENTS – 6 MONTHS FOLLOW-UP-

S.Z. Prodanovic<sup>1</sup>, J. Colic<sup>2</sup>, M. Sefik-bukilica<sup>3</sup>, G. Radunovic<sup>2</sup>, N. Damjanov<sup>4</sup>.<sup>1</sup>Clinical IVb; <sup>2</sup>clinical IVa; <sup>3</sup>laboratory demartment; <sup>4</sup>Head of Institute, Institute of Rheumatology, Belgrade, Serbia

**Background:** The structural damage of RA usually develops within the first two years of disease and the risk of joint destruction is still difficult to predict<sup>1</sup>

**Objectives:** To assess predictive value of the clinical, laboratory and echosonographic parameters activity of early RA in progression of structural damage in DMARDs/gluocorticoid naïve patients in the first 6 months.

**Methods:** Sixty-five pts. (56 females, mean age 53±14.1 years) with early RA (EULAR/ACR 2010 criteria) and symptoms duration of ≤1 years. (mean duration of 3.6 months) were included during the 2012–14 years. and followed up 6 months. Patients were DMARDs/gluocorticoid naïve and had no X-ray visible structural damage. The ESR, CRP, RF, ACPA and MMP3 were measured. DAS28 index was calculated. US assessment was performed blindly to patient's medical history, on the same day when early RA diagnosis was established and repeated after 6 months, using 18MHz linear probe by ESAOTE My Lab 70 machine. Presence of bone erosions and Power Doppler (PD) signal, were recorded at each hand's joint, as well as at MTP1–5 joints of both side, according to OMERACT US group definition. The semi quantitative method (0–3) was applied for assessing US synovitis and total Power Doppler joint score (TPDJs)/pts. was calculated.

**Results:** Fifty-nine pts. had finding of US bone erosions at baseline visit and 62 pts had it after 6 months. The significant increase of bone erosions and significant decrease of TPDJs/pts were found after follow-up (2.2. vs. 3.1 respectively; 10. vs. 4.5 respectively; Wilcoxon test: p<0.001). There was no statistical significant difference between the groups of pts. with (42 pts.) and without (23 pts.) new (≥1) US bone erosion after 6 months regarding value of ESR (41. vs. 39; p=0.973), CRP (18. vs. 11; p=0.255), RF (82. vs. 114; p=0.652), ACPA (184. vs. 319; p=0.784) MMP3 (110. vs. 83; p=0.245), DAS28 (5.7. vs. 5.3; p=0.269), total number of bone erosions (2. vs. 2; p=0.06) and TPDJs/pts (10. vs. 12; p=0.831). Uni-variant logistic regression analysis showed significant predictive value for US bone erosions finding at baseline visit OR 0.68 (0.48–0.98), p=0.04 for progression of structural damage after 6 months of follow up but not for value of: ESR: OR 1.28 (0.45–3.61), p=0.635; CRP: OR 2.75 (0.95–7.93), p=0.06; RF: OR 0.83 (0.30–2.30), p=0.726; ACPA: OR 0.96 (0.33–2.78), p=0.904; MMP3: OR 1.28 (0.42–3.88), p=0.656; DAS28: OR 1.23 (0.82–1.86), p=0.311 and TPDJs/pts OR 0.98 (0.93–1.02), p=0.344.

**Conclusions:** Initial finding of US bone erosion is the most important risk factor for progression of structural damage with our DMARDs/gluocorticoid naïve early RA patients in the first 6 months of disease duration.

### IMPORTANCE OF PATIENT EDUCATION FOR MANAGEMENT OF RHEUMATOID ARTHRITIS PATIENTS

S.H. Senara<sup>1</sup>, W.Y. Abdel wahed<sup>2</sup>, S.E. Mabrouk<sup>2</sup>. <sup>1</sup>Rheumatology and Rehabilitation; <sup>2</sup>Community, Fayoum University- Egypt, Fayoum, Egypt

**Background:** People living with chronic diseases such as rheumatoid arthritis (RA) are extremely in need to Patient education (PE) which enables them to cope and adapt with their disease and treatments. PE comprises all educational activities provided for patients, including aspects of health and therapeutic education and promotion. Evolutions have been seen at the last five decades of the patient/clinicians relationship, where the patients can share in decision-making (*Mwidimi Ndosí and Ade Adebajo, 2015*).

**Objectives:** To evaluate the effect of PE program following the eight evidence-based EULAR-2015 recommendations in the management of RA patients.

**Methods:** Comparative study with randomised parallel two arms with ratio (1:1) conducted on 100 rheumatoid arthritis (RA) patients (both sexes), aged 19–71 years patients were carried out at the Department of Rheumatology and Rehabilitation -faculty of medicine of Fayoum University, Egypt. Patients are excluded if they had evidence of mental disorder or psychiatric diseases. Patients can leave

the study at any time for any reason. Two main comparable groups; group I received health education through designed Health education program, Group II were not prone to health education program. Disease activity and disability of patients were assessed prior to the commencement of the program, (visit I pre-intervention), 3 months later (Visit II post-intervention) and 6 months after the first visit (Visit III post-intervention). **Intervention:** A PE program designed by authors addressed EULAR 2015 recommendation of patient education and tailored according to each patient condition. Groups of 8–10 participants randomised to intervention arm attended 1 session each week for 6 consecutive weeks, with each one hour in duration, and then one session every two weeks until the second assessment visit (Visit II) and then every month until the second assessment visit (Visit III).

**Results:** While 50 patients of group I continued at the end of the study, out of 50 patients of group II, 36 patients were available at 2nd visit, and only 24 patients were available to be assessed at the 3rd visit. By comparing lab investigation and outcome scores at follow up visits; although no significant difference between the two study groups regarding lab investigations, DAS28 and HAQ scores at start of study, difference was reported in follow up visits that a significant decrease of these labs and scores were reported in Group I, while no difference reported in Group II.

**Abstract AB0308 – Table 1.** Lab and measuring scores comparison between GI and GII at 3rd Visit

Lab investigation	G I		G II		P value	
	N (=50)	%	N (=24)	%		
ESR	Positive	20	40.0	23.0	95.8.	<b>0.00</b>
	Negative	30	60.0	1		
CRP	Positive	19.0	38.0	19.0	79.2.	<b>0.001</b>
	Negative	31	62.0	5	20.8	
RF	Positive	50.0	100.0	19	79.2	<b>0.003</b>
	Negative	0	0.0	5	10.8	
DAS28	Mean±SD, range	1.6±0.4		3. 6±1.5		<b>0.00</b>
		1.2: 2.3		1.3:5.1		
HAQ	Mean±SD, range	29.0±7.6		59. 8±23.13		<b>0.00</b>
		15:75		23: 88		

**Conclusions:** Patient education (PE) interventions in patients with (RA) documented significant improvements in behaviour, pain, disability of those patients.

### NEED TO A WALK TO THE COMPLETE REMISSION; FOOT AND/OR ANKLE ARTHRITIS IMPEDE COMPLETE REMISSION IN RHEUMATOID ARTHRITIS –PART 1, CROSS-SECTIONAL STUDY FROM KOREAN COLLEGE OF RHEUMATOLOGY BIOLOGICS (KOBIO) REGISTRY

S.H. Chang<sup>1,\*</sup>, S.W. Lee<sup>2</sup>, M.I. Kang<sup>3</sup>, H.W. Kim<sup>4</sup>, on behalf of Korean College of Rheumatology BIOlogics (KOBIO) registry. <sup>1</sup>Division of Rheumatology, Department of Internal medicine, Soonchunhyang University, College of Medicine, Seongnam-si; <sup>2</sup>Soonchunhyang Univ Choenan Hosp; <sup>3</sup>Dankook Univ Hospital, Cheonan; <sup>4</sup>Bundang Seoul National Univ. Hospital, Seongnam-Si, Korea, Republic of Ireland

**Objectives:** To determine the prevalence of foot synovitis, and the most stringent disease activity index reflecting complete remission among patients with rheumatoid arthritis in Korea.

**Methods:** We conducted a cross-sectional study using data from the Korean College of Rheumatology BIOlogics (KOBIO) registry. Foot arthritis defined as having one or more tender or swollen joints in ankle and/or 1st to 5th metatarsal joints. Functional status and disease activity evaluated by the routine assessment of patient index data3 (RAPID3), the disease activity score 28 ESR (DAS28), the simplified disease activity index (SDAI), the clinical disease activity index (CDAI), and the ACR/EULAR Boolean criteria.

**Results:** Baseline data of 2046 patients were analysed. Patients with foot arthritis showed significantly younger age at the diagnosis, longer disease, duration,

higher DAS-28/SDAI/CDAI/RAPID-3, lower rate of ACR/EULAR Boolean criteria remission, use of higher dose of glucocorticoid, and higher rate of bone erosion not only on foot but also hand X-rays. Among those patients, 174 patients (8.5%) were in DAS 28 clinical remission. Twenty-one of 174 patients (12.1%) had foot arthritis, who showed higher swollen and tender joint count, RAPID-3 score, and patients' global assessment but not physicians' global assessment than those without foot arthritis. Among patients with foot arthritis, rate of complete remission was the highest in patients with CDAI (66.7%).

**Conclusions:** In patients with rheumatoid arthritis, foot and/or ankle arthritis is associated with high disease activity, not achieving complete remission despite of various clinical remission criteria and discordance between patients' and physicians' global assessment.

**Disclosure of Interest:** None declared

AB0310

#### USING TREAT-TO-TARGET STRATEGY BY DETERMINING PHYSICAL DISABILITY AND GLUCOCORTICOID REDUCTION STRONGLY INFLUENCE FUNCTIONAL REMISSION IN RHEUMATOID ARTHRITIS

T. Hagiwara, K. Kamada, N. Namura. *Rheumatology, Takarazuka City Hospital, Takarazuka, Japan*

**Background:** The initial target in the treatment of rheumatoid arthritis (RA) is to achieve clinical remission (CR) through Boolean definition and/or index-based criteria and sustain CR, and the final target is to maximise long-term health-related quality of life (HRQoL) through arthritis control, joint damage prevention, function normalisation and social participation.<sup>1</sup>

**Objectives:** We aimed to determine the factors that inhibit the achievement of functional remission (FcR) in terms of HRQoL.

**Methods:** A total of 227 patients with RA who had underwent first treatment between October 2014 and December 2017 and had not changed/added another disease-modifying anti-rheumatic drugs (DMARDs) for 12 weeks before the observation day were examined. We used daily-life function and social activity participation to evaluate HRQoL. We adopted the Health Assessment Questionnaire Disability Index (HAQDI) as daily-life functional assessment and EuroQoL 5 dimensions–5 levels (EQ5D) for health status with considerable potential assessment. FcR was defined in this study as HAQDI  $\leq 0.5$  and EQ5D  $\geq 0.867$  "0.867 is the lowest QoL score when only one category permits  $\leq 2$  of the 5 levels, but others need 1 in all five categories". We investigated their age at RA onset, sex, Steinbrocker stage and functional class, HAQDI, disease activity level, rheumatoid factor, anti-cyclic citrullinated peptide antibody at the first consultation, age, disease activity level, HAQDI, EQ5D, and status of methotrexate (MTX), glucocorticoids (GCs) and biologic/target synthetic DMARD (b/ts-DMARD) use at the last observational day. First, the assumed remissions were analysed using the FcR as a purpose variable for these factors. Subsequently, the odds ratio and 95% confidence interval (95% CI) were examined using multiple logistic regression analysis for the statistically significantly different factors and risk factors.

**Results:** The CR achievement rate at the last observational day by Boolean definition and Simple Disease Activity Index were 40.5% and 50.2%, respectively. The achievement ratio of HAQ-DI  $\leq 0.5$ , EQ5D  $\geq 0.867$  and FcR was 73.1%, 48.5%, and 46.7%, respectively. The differences in disease duration, stage, class and HAQDI at the time of the first interview; state of MTX, GCs and b/ts-DMARD use; and age at the last observational day for the achievement of FcR were statistically significant. The odds ratios, as determined by multiple logistic regression analysis of the above-mentioned results, were 1.034 (95% CI 0.982–1.088,  $p=0.202$ ) for disease duration (per 1 year), 1.576 (95% CI 1.257–1.977,  $p<0.001$ ) for HAQDI at first interview (per 0.5), 0.615 (95% CI 0.277–1.365,  $p=0.232$ ) and 4.943 (95% CI 1.683–14.524,  $p<0.01$ ) for GCs state (non-use vs temporal use and non-use vs continuous use, respectively), and 1.164 (95% CI 1.037–1.307,  $p<0.05$ ) for age at last observational day.

**Conclusions:** HRQoL is important as they will influence future treatment strategy. Our results indicated the importance of functional assessment at first interview and demonstrated how to use GCs for the treatment of RA. Ageing always contributes to patients' frailty, and it is unavoidable it. To achieve FcR, functional assessment should be performed during the first interview and short-term use of GC is useful for prompt functional recovery, in consideration of ageing.

#### DETERMINANTS OF NON-NOCICEPTIVE PAIN IN RHEUMATOID ARTHRITIS

T.M. Rocha, S. Pimenta, M. Bernardes, A. Bernardo, M. Barbosa, R. Lucas, L. Costa. *Rheumatology, Centro Hospitalar de São João, Porto, Portugal*

**Background:** A neuropathic component (NP) of Rheumatoid Arthritis (RA) pain was described in nearly a third of the patients. Radiographic damage is a reflection of cumulative disease activity and other pathophysiological processes. Some clinical predictors of RA NP were recently identified by our group, but association and adjustment for radiographic damage were not studied.

**Objectives:** To estimate the clinical predictors of NP in RA patients adjusting for their radiographic damage.

**Methods:** Cross-sectional study was performed with RA patients followed at our Rheumatology department. Patients with diagnosed neuropathy or non-RA risk factors for NP were excluded. Selected patients were evaluated in a medical visit. Demographic and clinical data were collected and two questionnaires were applied to assess NP: the Leeds Assessment of Neuropathic Symptoms (LANSS) and the painDETECT (PDQ). Wrists, hands and feet radiographic studies from the previous 12 months were classified according to the modified van der Heijde Sharp's method by one trained reader, blinded for patient clinical variables and treatment allocation. Univariate and multivariate logistic regression were performed adjusting for global radiographic score (GS). Significance level was set as  $<0.05$ .

**Results:** Ninety one RA patients were included. Seventy (77%) were women, with a mean (SD) age of 55.6 (10.8) years and median disease duration of 12 years;<sup>2–41</sup> 84% patients were seropositive for Rheumatoid Factor and/or ACPA; 85 (93%) were treated with DMARDs and 41% with a biological DMARD (bDMARDs). The mean (SD) DAS28 4V CRP was 3.15 (0.77). The median joint erosion score was 28 (range: 3–143) and the median joint space narrowing (JN) was 46 (range: 10–133). Forty-two (46%) patients had LANSS NP ( $\geq 12$ ) and 29% had a possible/likely NP in the PDQ ( $>12$ ). JN was a significant negative predictor of LANSS NP (OR: 0.98,  $p=0.02$ ). After adjusting for GS, gender was not associated with NP. Pain VAS, patient global activity and the tender joint count were positive predictors of NP by both tests. Swollen joint count, ESR or CRP levels were not significantly associated with NP. DAS28 CRP was a significant positive predictor of NP by both tests (OR 1.89 for LANSS and OR: 2.06 for PDQ,  $p<0.05$ ); as well as the HAQ score (OR: 2.68 and OR: 4.85, respectively,  $p<0.05$ ). Positivity for ACPA was a negative predictor of LANSS NP (OR: 0.31,  $p=0.048$ ), as previously described. Current methotrexate treatment had lower odds of LANSS NP (OR: 0.35,  $p=0.04$ ) but did not remained significant after adjustment for DAS28 CRP. Previous/current Hydroxychloroquine (HCQ) treatment was once more a negative predictor for PDQ NP (OR: 0.11,  $p=0.04$ ) and remained significant after adjustment for DAS28 CRP. Previous/current leflunomide (LFN) was newly a positive predictor of NP in both tests (OR: 3.41 for LANSS and OR: 2.95 for PDQ,  $p<0.05$ ), persisting after disease activity adjustment for LANSS NP. No other associations were found.

**Conclusions:** Consistently with our previous data, this study supports an association between NP and disease activity/functional scores but not with objective inflammatory measures. Possible increased risk of NP in LFN treated patients was newly pointed and protective role of ACPA positivity and HCQ was reinforced.

#### INFLAMMATORY ACTIVITY APPEARS WELL CONTROLLED IN MOST PATIENTS WITH RHEUMATOID ARTHRITIS (RA) IN CONTEMPORARY RHEUMATOLOGY CARE, BUT JOINT DAMAGE AND DISTRESS REMAIN AS PROBLEMS OF GREATER MAGNITUDE THAN INFLAMMATION

T. Pincus, I. Castrejón, J.A. Block. *Rheumatology, Rush University Medical Center, Chicago, USA*

**Background:** Rheumatologists traditionally use quantitative measures such as swollen and tender joint counts and laboratory tests to assess inflammatory activity. However, structural damage to joints, as well patient distress seen as fibromyalgia, depression, etc., may be important clinical problems for many RA patients, but are described narratively in the medical record rather than estimated

by the physician as quantitative data. Quantitation only of inflammation, while damage and distress are recorded only as narrative descriptions, may limit the capacity to document optimally both clinical status and the rationale for clinical decisions, such as non-intensification of therapy according to "treat-to-target" in patients who may have moderate or high scores on an RA index<sup>1</sup>. We have used 0–10 visual analogue scales (VAS) to score not only physician global assessment (DOCGL), but also levels of inflammation, damage, and distress.

**Objectives:** To analyse 0–10 VAS for DOCGL, as well as for levels of inflammation, damage, and distress in patients with rheumatoid arthritis (RA).

**Methods:** At one academic site, rheumatologists complete four 0–10 VAS for overall physician global assessment (DOCGL), as well as for inflammation or reversible findings (DOCINF), joint and other organ damage or irreversible findings (DOCDAM), and patient distress such as fibromyalgia, depression, etc. (DOCSTR). In a cross-sectional study, mean values of 4 physician VAS were computed in RA patients, and 3 subgroups were compared according to whether scores for inflammation were 2/10 units higher than for damage, similar for inflammation and damage (within 2/10 units), or 2/10 units higher for damage than for inflammation. Mean levels of the 4 VAS in the 3 groups were compared, using analysis of variance (ANOVA).

**Results:** In 50 unselected RA patients, mean 0–10 DOCGL VAS was 4.2, inflammation VAS 2.2, damage VAS 3.5, and distress VAS 2.2 (table 1). Only 9/50 patients had an inflammation VAS more than 2/10 units greater than damage VAS; in these patients, mean VAS for DOCGL=4.6, inflammation=4.9, damage=2.1, and distress=1.1. In 21 patients in whom inflammation=damage, mean VAS for DOCGL=3.9, inflammation=1.8, damage=2.1, and distress=3.2. In 20 patients with damage >inflammation, mean VAS for DOCGL=4.4, inflammation=1.4, damage=5.7, and distress=1.7.

**Abstract AB0312 – Table 1**

	DOC/INF> DOCDAM	DOC/INF= DOCDAM	DOC/ DAM> DOCINF	TOTAL
<b>N</b>	9	21	20	50
<b>VAS DOCGL</b>	4.6	3.9	4.4	4.2
<b>Mean subscale VAS Scores:</b>				
<b>VAS DOCINF</b>	4.9	1.8	1.4	2.2
<b>VAS DOCDAM</b>	2.1	2.1	5.7	3.5
<b>VAS DOCSTR</b>	1.1	3.2	1.7	2.2

**Conclusions:** Physician VAS scores indicated that a damage VAS was 50% higher than an inflammation VAS in all 50 RA patients (3.5 vs 2.2), and identical (2.1) in the 9 with an inflammation VAS 2 units higher than a damage VAS or 21 with an inflammation VAS within 2 units of a damage VAS. A mean distress VAS was identical to an inflammation VAS (2.2) in the 50 patients. Control of inflammation remains a primary concern for rheumatologists, but has improved considerably in recent years, as damage and distress may have become more prominent in routine patient care. Systematic quantitative VAS assessment of damage and distress, in addition to inflammation, appears of value to document patient status and support clinical decisions.

#### AB0313

**PHYSICIAN GLOBAL ASSESSMENT OF THE STATUS OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) AT THEIR FIRST VISIT TO AN ACADEMIC ROUTINE CARE SETTING ARE EXPLAINED AS MUCH BY DAMAGE AND DISTRESS AS BY INFLAMMATION, ACCORDING TO PHYSICIAN RATINGS: SHOULD THE STRUCTURE OF RHEUMATOLOGY CARE BE MODIFIED?**

T. Pincus, I. Castrejon, J.A. Block. *Rheumatology, Rush University Medical Center, Chicago, USA*

**Background:** A physician global assessment (DOCGL) on a 0–10 visual analogue scale (VAS) reflects inflammatory activity in patients who meet criteria for RA clinical trials, in which DOCGL is more efficient than laboratory tests or joint counts to distinguish active from control treatments.<sup>1</sup> However, in routine clinical

care, patients are not selected for inflammatory activity, and may have joint damage and/or distress (fibromyalgia, depression, etc.) as important clinical problems. Some rheumatologists consider damage and distress in assigning a 0–10 DOCGL; others consider only inflammation. One approach to resolve this matter is for physicians to estimate the proportion of DOCGL attributed to inflammation, damage, or distress (total=100%).

**Objectives:** To analyse a physician 0–10 VAS overall global assessment for estimates of the proportions attributed to inflammation, damage, or distress (total=100%).

**Methods:** Rheumatologists at one academic setting complete a 0–10 VAS for DOCGL, and estimates of the proportion of DOCGL attributed to inflammation, damage, and/or distress (total=100%). These scales were analysed in 38 new patients with RA seen between April and November 2017, using cross-tabulations to compare patients whose DOCGL was 0–4 vs 4.1–10 vs the proportion of inflammation, damage, or distress (total=100%) as 0%–40% or 41%–100%.

**Results:** Physician global assessment was 4–10 in 23/38 patients (61%) at first visit, and 0–4 in 15/38 (39%) (table 1). In all 38 patients, inflammation was rated as explaining 41%–100% of DOCGL in 11/38 (29%), compared to damage in 18/38 (47%), and distress in 6/38 patients (16%). Among the 23/38 patients with DOCGL 4–10, inflammation was rated as explaining 41%–10% of DOCGL in 6/23 (29%), versus 10/23 (43%) for damage, and 5/23 (22%) distress. Therefore, inflammation appear to account for >40% of DOCGL only in a minority of new RA patients, which were explained more by either damage or distress (or both).

**Abstract AB0313 – Table 1.** Number of patients in whom a 0–10 physician global assessment VAS was attributed by the physician to inflammation, damage, or distress (total=100%) at the initial visit of 38 patients with RA

Physician global assessment	All		0–		4.1–		All		0–		4.1–	
	All	0–	4.0	10	4.0	10	All	0–	4.0	10		
% attributed by rheumatologist	Inflammation			Damage			Distress			to...		
0%–40%	27	10	17	20	7	13	32	18	14			
41%–100%	11	5	6	18	8	10	6	5	1			
Total	38	15	23	38	15	23	38	15	23			

**Conclusions:** At one academic rheumatology site, a physician global assessment VAS at the initial visit of patients with RA was explained as much by damage and/or distress as by inflammatory activity. One important limitation of the study is that some patients had already received treatment at other rheumatology sites. Nonetheless, the data indicate that damage and distress appear as prominent as inflammation in contemporary management of RA, reflecting a well-known delay in diagnosis and patient management. The findings suggest a possible need to restructure rheumatology practice to see patients more urgently, including education of primary care physicians, in order to improve outcomes for patients with RA. The data also support the possible value of physician estimates of the proportion of DOCGL attributed to inflammation, damage, or distress.

**SETTING TREATMENT TARGET FOR JOINT SURGERY IN LOWER LIMBS IN PATIENTS WITH LONG-STANDING RHEUMATOID ARTHRITIS BASED ON MULTICENTER PROSPECTIVE COHORT STUDY; VALIDATION AND RELIABILITY OF OBJECTIVE INDEX OF ACTIVITY SPEED, TIMED UP AND GO TEST, FOR MEASURING PHYSICAL FUNCTION**

T. Kojima<sup>1</sup>, H. Ishikawa<sup>2</sup>, S. Tanaka<sup>3</sup>, N. Haga<sup>4</sup>, K. Nishida<sup>5</sup>, M. Yukioka<sup>6</sup>, J. Hashimoto<sup>7</sup>, H. Miyahara<sup>8</sup>, Y. Niki<sup>9</sup>, T. Kimura<sup>10</sup>, H. Oda<sup>11</sup>, K. Funahashi<sup>12</sup>, S. Asai<sup>13</sup>, M. Kojima<sup>14</sup>, N. Ishiguro<sup>13</sup>. <sup>1</sup>Orthopedic Surgery, Nagoya University Hospital, Nagoya; <sup>2</sup>Niigata Rheumatic Center, Niigata; <sup>3</sup>Faculty of Medicine, The University of Tokyo; <sup>4</sup>The University of Tokyo Hospital, Tokyo; <sup>5</sup>Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama; <sup>6</sup>Yukioka Hospital, Osaka; <sup>7</sup>National Hospital Organization Osaka Minami Medical Center, Kawachinagano; <sup>8</sup>National Hospital Organization Kyushu Medical Center, Fukuoka; <sup>9</sup>Keio University School of Medicine, Tokyo; <sup>10</sup>University of Toyama, Faculty of Medicine, Toyama; <sup>11</sup>Saitama Medical University, Morohongo Moroyama; <sup>12</sup>Kariya-Toyota General Hospital, Kariya; <sup>13</sup>Nagoya University Hospital; <sup>14</sup>Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

**Background:** Total management including reconstructive joint surgery and rehabilitation should be needed for further improvements of physical function for long-

standing RA patients. It is very important to set treatment goal for those management.

**Objectives:** The purpose of this study is to set treatment target using Timed Up and Go test (TUG) in relation to achievement of HAQ-DI remission (HAQ-DI <0.5) with joint surgery in lower limbs.

**Methods:** Multicenter prospective observational cohort study was conducted among patients who underwent elective joint surgery for RA from April 2012 to March 2016 (Study registration: UMIN000012649). In this study, we collected data including age, sex, disease duration, drug therapies, and disease activity (DAS), TUG, and patient-reported outcome [HAQ-DI, EQ-5D (QOL), patient's global assessment (PtGA) and BDI-II (depression)] at baseline and at 6 or 12 months after the surgery. Association between TUG and achievement of HAQ remission and cut-off values for HAQ remission were also determined using logistic regression analysis with adjustment of age and sex and ROC curve, respectively.

**Results:** Totally, 139 patients with elective joint surgery in lower limbs were analysed. Mean age, disease duration, HAQ-DI and TUG were 65.4 years, 17.5 years, 1.022, and 12.7 s, respectively. Performed joint surgeries were total hip arthroplasty; 10.1%, total knee arthroplasty; 33.8%, total ankle arthroplasty or ankle fixation; 10.1%, and forefoot arthroplasty; 46.0%. The surgeries can significantly improve the outcome measures, including TUG, DAS, PtGA, pain, EQ-5D and BDI-II other than HAQ-DI. In this study, 45 of 139 patients (32.4%) had HAQ remission status at baseline. 18 of 94 patients (19.1%) who had HAQ-DI >0.5 can achieve HAQ remission with the surgery. Notably, TUG at last observation was significantly associated with achievement of HAQ remission even after adjustment for age, sex, and DAS (1 s increasing of TUG. OR:0.72, 95% CI: 0.53–0.97). The adjusted-TUG at last observation of patients with achievement of HAQ remission was 9.2 s (95% CI: 5.6–12.8) (figure 1). Cut-off of TUG at observation for achievement of HAQ remission was 9.2 s based on ROC analysis (figure 2). Importantly, We confirmed significant more improving of EQ-5D, HAQ-DI and TUG in patients who achieved TUG 9.2 s at last observation than in patients who did not (figure 3).

Abstract AB0314 – Figure 1

**Conclusions:** TUG was significantly associated with PRO; HAQ-DI and EQ-5D. The cut-off values of TUG (9.2 s) should be important to achieve good QOL and physical function for patients with joint surgery in lower limbs and could be suitable target for surgical procedure.

**HIGH DISEASE ACTIVITY AT BASELINE, NOT RF NOR ACPA STATUS, PREDICTS INADEQUATE RESPONSE TO METHOTREXATE (MTX) IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS IN REAL WORLD: A SINGLE CENTRE COHORT IN JAPAN**

T. Aramaki<sup>1</sup>, Y. Ueki<sup>1</sup>, K. Kojima<sup>1</sup>, S. Kurushima<sup>1</sup>, Y. Tsuji<sup>1</sup>, N. Kawachi<sup>2</sup>, N. Iwamoto<sup>3</sup>, K. Ichinose<sup>3</sup>, K. Terada<sup>1</sup>, K. Eguchi<sup>1</sup>, A. Kawakami<sup>3</sup>. <sup>1</sup>Rheumatic Disease Center, Sasebo Chuo Hospital, Sasebo; <sup>2</sup>Rheumatic Disease Center, Sasebo Chuo Hospital, Sasebo-city, Nagasaki; <sup>3</sup>Department of Immunology and Rheumatology, Nagasaki Graduate School of Biomedical Sciences, Nagasaki, Japan

**Background:** In 2016 update of the EULAR recommendations for management of rheumatoid arthritis (RA), the poor prognostic factors include moderate to high disease activity according to composite measures and presence of Rheumatoid

factor (RF) and/or anti-citrullinated peptide antibodies (ACPA), especially at high levels.

**Objectives:** In this retrospective study, we investigated the association between baseline clinical prognostic factors and inadequate response to methotrexate for early RA in clinical practice.

**Methods:** Patients aged 18 years or over whose date of clinical onset of RA was within the previous 12 months to the first visit to our hospital from 2009 to 2016, who had at least 6 months of follow-up data and composite measure score (DAS-SER, DAS-CRP, SDAI, CDAI) recorded at 12 months from MTX treatment were included. Data collected included baseline demographics, rheumatoid factor (RF), ACPA status and the level of its titer, time from symptom onset to treatment and disease activity at baseline. In this study, we define that it was inadequate response to MTX (MTX-IR) when the patient didn't achieve low disease activity in at least three of four composite measures at 12 months after treatment, or was stopped to treat due to any reason or added biologic DMARDs (bDMARDs) in the observation period. Univariate and multivariate logistic regression of Inadequate response to MTX at 12 months after were performed.

**Results:** Data from 486 patients treated with MTX of 571 started to treat as early RA were analysed: 72.0% female; mean age 59.6 years (SD: 14.4); time from symptom onset to treatment is 7.3 months (SD 10.5); 66.1% RF-positive, 66.9% ACPA-positive. The number of patients is 138 (45.8% of ACPA positive) whose ACPA is in the higher level, over 150IU/ml. 411 patients were initially treated with MTX, and 75 were initially treated with other csDMARDs but added or changed to MTX within 1 years after treatment. Concomitant rate of corticosteroid at the start of MTX was 41.5% and mean dose of prednisolone was 5.7 mg/day. 270 (55.6%) patients were MTX-IR in 12 months after treatment. There is no significant difference between the dose of MTX at start in MTX-IR patients and that in others (6.70 versus 6.69 mg/week, respectively) but the dose at 12 months after treatment was 8.29 mg/w in MTX responders and significantly lower than that of MTX-IR, 8.68 mg/dl (p<0.05). The strongest baseline predictor of Inadequate response were Low disease activity at baseline, but there was no statistically significant association with sex, age at onset, RF or ACPA status additionally the level of its titers.

**Conclusions:** In this observational study, patients with early RA at risk of inadequate response to MTX include only with high disease activity at baseline, and the level of ACPA titers or other baseline characteristics don't predict it.

AB0316

**IS THERE A NEED TO RELOOK AT THE CUT OFFS OF RHEUMATOID FACTOR IN INDIAN POPULATION ?**

V. Vasdev. Rheumatology and Clinical Immunology, Army Hospital R and R New Delhi, new delhi, India

**Background:** Population specific cut offs of titers of Rheumatoid Factor (RF) in diagnosis of Rheumatoid arthritis (RA) and the role of anti citrullinated peptide antibodies (ACPA) remains unknown.

**Objectives:** To define cut offs for RF titres in diagnosis of RA in Indian population  
**Methods:** RF titers of consecutive adult RA patients fulfilling ACR 1987 as well as ACR/EULAR 2010 criteria were compared with healthy normal and diseased non RA controls encountered in the rheumatology OPD of a tertiary care Armed forces Hospital using ROC-AUC analysis. Reclassification of disease phenotype as seropositive and seronegative RA using various the cutoffs was looked into and corresponding Anti-CCP titers in the subset of patients with RA was analysed.

**Results:** Overall 589 cases of RA (range: 18–69 years; 29.9% Females) were compared with age and sex matched 192 non RA and 51 controls. Mean (+SE) RF titers in RA cases was 107.7 IU/L (+ 6.17) while that in non RA disease cases was 29.3 IU/L (+ 6.08) and normal healthy controls 14.7 IU/L(0.43). ROC analysis revealed a cutoff titer of 20.3 IU/L (AUC 0.705 (95% CI:0.66–0.74)) with the best combination of sensitivity and specificity for a diagnosis of RA from non RA and healthy controls. With the currently used cut offs of 60 IU/L in our centre as well as high titre RF as per ACR/EULAR 2010 criteria, subjects were seropositive in 286/589 (48.5%) cases. Cutoffs of 40 IU/L and 20 IU/L led to a label of seropositivity in 322 (54.7%) and 396 (67.2%) cases respectively. Simultaneous Anti-CCP was done in 480 (81.4%) cases: 363 (75.6%) of these were positive. Using a cutoff of 60 IU/L as seropositive RA, anti CCP positivity was noted in 246/286 (86%) cases while with a cutoff of 40 IU/L and 20 IU/L it was 278/322 (86.3%) and 334/396 (84.3%) respectively. The RF titers in 117 anti-CCP negative cases was >20, >40 and >60 IU/L in 62 (52.9%), 44 (37.6%) and 40 (34.1%) cases respectively.

**Conclusions:** For this cohort of Indian population, a cut off of 20 IU/L of RF titers has the best performance for a diagnosis of RA with an additional 18.7% cases labelled as seropositive as against the current ACR cutoffs. Anti CCP positivity also no substantially changed by using this lower cutoff. There is a need to reevaluate the population specific RF titers in conjunction with anti-CCP in Indian population.

### DO MECHANICAL AND INFLAMMATORY RHEUMATOLOGIC DISEASES LEAD TO THE SAME SLEEP DISORDERS?

W. Hamdi, M. Boudokhane, I. Cherif, D. Kaffel, K. Maatallah, M. Kchir.  
*Rheumatology, Kassab Institute, Tunisia, Tunisia*

**Background:** Sleep disorders are frequent feature of chronic rheumatologic diseases. They are reported in inflammatory diseases as well as in mechanical disorders but they are not systematically assessed by clinicians. It is necessary to identify the frequency and factors associated to sleep problems in order to reduce their impact on patient's quality of life.

**Objectives:** We aim to describe the sleep pattern in inflammatory and mechanical chronic rheumatologic diseases and to assess factors associated with sleep disorders.

**Methods:** We conducted a cross-sectional study during 1 year including Tunisian patients with chronic inflammatory rheumatism (rheumatoid arthritis: RA according to the criteria ACR 1987 and axial spondyloarthritis: AS according to modified NEW YORK criteria) and patients with mechanical disorders (chronic low back pain and primitive knee osteoarthritis). Sleep has been evaluated by the MOS-SS questionnaire. For each group specific disease parameters were assessed at the same time of the administration of the questionnaire.

**Results:** We collected 120 patients with chronic inflammatory rheumatism (group 1) and 80 patients with mechanical disorder (group2). Group 1 was composed of 70 RA and 50 SPA including 65 women and 55 men. The average age was 46.95 [18.75]. Group 2 was composed of 40 chronic low back pain and 40 primitive knee osteoarthritis including 48 women and 32 men. The average age was 51.95 [18.82]. Sleep disorders were frequent in both groups, but they were more noticeable in Group 1 patients than Group 2 patients 53.68% vs 26.38% ( $p=0.00$ ). Risk factors for sleep disorders in rheumatoid arthritis were disease activity ( $p=0.00$ ) and functional impairment ( $p=0.00$ ). In patients with spondyloarthritis, risk factors for sleep impairment were disease activity (BASDAI ( $p=0.00$ ), ASDAS vs ( $p=0.00$ ) et ASDAS CRP ( $p=0.00$ )) and impaired quality of life ( $p=0.00$ ). The factors involved in sleep disorders in chronic low back pain was the reduced lumbar spine mobility assessed by the finger-to-ground distance ( $p=0.00$ ) and the schober index ( $p=0.01$ ) and functional impairment assessed by Eiffel questionnaire ( $p=0.00$ ). In patients with knee osteoarthritis the Lequesne index ( $p=0.008$ ), the knee extension limitation ( $p=0.00$ ) and the radiological damage ( $p=0.004$ ) were associated to sleep impairment.

**Conclusions:** Our results illustrate the frequency of sleep disorders in chronic rheumatic diseases. They should not be under estimated in patients with mechanical disorders. A better control of the factors associated to sleep impairment for each disease should help promoting a better sleep quality in patients with chronic rheumatologic diseases.

AB0318

### ARE PATIENTS EXPERIENCING DIFFERENT SORT OF FATIGUE DEPENDING ON THE TYPE OF CHRONIC RHEUMATISM?

W. Hamdi, M. Boudokhane, I. Cherif, D. Kaffel, K. Maatallah, M. Kchir.  
*Rheumatology, Kassab Institute, Tunisia, Tunisia*

**Background:** Fatigue is frequently reported by patients with inflammatory chronic diseases as well as in mechanical rheumatologic disorders. But it's not recognised and treated as priority by clinicians. It is necessary to identify the frequency of this symptom and to determinate it's impact on the quality of life of patient.

**Objectives:** We aimed to assess and to compare the frequency and the intensity of fatigue between inflammatory and degenerative chronic rheumatologic diseases, and to identify the factors correlated with fatigue in these diseases.

**Methods:** We conducted a cross-sectional study during 1 year including Tunisian patients with chronic inflammatory rheumatism (rheumatoid arthritis: RA according to the criteria ACR 1987 and axial spondyloarthritis: AS according to modified NEW YORK criteria) and patients with mechanical disorders (chronic low back pain and primitive knee osteoarthritis). Fatigue was assessed by the Chalder questionnaire including physical and mental fatigue.

**Results:** We collected 120 patients with chronic inflammatory rheumatism (group 1) and 80 patients with mechanical disease (group2). Group 1 was composed of 70 RA and 50 AS including 65 women and 55 men. The average age was 46.95 [18.75]. Group 2 was composed of 40 chronic low back pain and 40 knee osteoarthritis including 48 women and 32 men. The average age was 51.95 [18.82]. Fatigue was more significantly observed in group 1 than in group 2: 8.40% vs 5.54% ( $p=0.000$ ). Mental and physical fatigue was noted in 2.1% and 6.25% in group 1 and 1.0% and 4.49% in group 2, respectively. The risk factors for fatigue were in the RA the tender and swollen joint count, the DAS 28

and the HAQ. In AS, factors associated to fatigue were the visual scale of pain, BASFI, BASDAI, ASDAS<sub>ESR</sub> and CRP. In the chronic low back pain fatigue was associated by the functional impairment assessed by the Eiffel questionnaire. Finally knee in osteoarthritis fatigue was associated to Lequesne index and radiological stage.

**Conclusions:** Fatigue seems to be a frequent symptom in rheumatic diseases and mostly associated to severity and activity of the disease.

### MOOD DISORDERS AND CHRONIC RHEUMATOLOGIC DISEASES: ABOUT 200 CASES

W. Hamdi, M. Boudokhane, I. Cherif, K. Maatallah, D. Kaffel, M. Kchir.  
*Rheumatology, Kassab Institute, Tunisia, Tunisia*

**Background:** Mood disorders are frequently associated to chronic diseases. They are reported in inflammatory diseases as well as in mechanical rheumatologic disorders but they are not systematically recognised and assessed by clinicians. It is necessary to identify the frequency of mood disorders in order to reduce their impact on patient's compliance to treatment.

**Objectives:** The aim of this study was to assess the impact of chronic rheumatologic diseases on the mood of patients by comparing inflammatory and mechanical diseases and to identify factors correlated with anxiety and depression.

**Methods:** We conducted a cross-sectional study during 1 year including Tunisian patients with chronic inflammatory rheumatism (rheumatoid arthritis: RA according to the criteria ACR 1987 and axial spondyloarthritis: AS according to modified NEW YORK criteria) and patients with mechanical disorders (chronic low back pain and primitive knee osteoarthritis). Anxiety and depression were assessed by the BAI (Beck anxiety index) and the BDI (Beck depression index), respectively.

**Results:** We included 120 patients with chronic inflammatory rheumatism (group 1) and 80 patients with mechanical disease (group2). Group 1 was composed of 70 patients with RA and 50 patients with AS including 65 women and 55 men. Their average age was 46.95 [18.75]. Group 2 was composed of 40 patients with chronic low back pain and 40 patients with knee osteoarthritis including 48 women and 32 men. Their average age was 51.95 [18.82]. Anxiety was significantly more frequent in group 1 than group 2: 15.52% vs 9.37% ( $p=0.000$ ). Depression was significantly more noted in group 1 than group 2: 16.29% vs 7.16% ( $p=0.009$ ). The risk factors for anxiety and depression were respectively in the rheumatoid arthritis: tender and swollen joint count, DAS 28, the HAQ and the sharp erosion score. In AS, factors associated to mood disorders were the visual scale of pain, BASFI, BASDAI, ASDAS<sub>ESR</sub> and CRP. In the chronic low back pain mood disorders are associated to functional impairment assessed by the Eiffel questionnaire and the reduced mobility of the lumbar spine assessed by the distance finger-soil. Finally knee in osteoarthritis mood disorders were associated to Lequesne index and the reduction of knee extension.

**Conclusions:** Patients with chronic rheumatologic diseases suffer very often from anxiety and depression which was related in majority of cases to functional impairment, hence the need for multidisciplinary management.

### IMPACT OF RHEUMATOID ARTHRITIS ON LIFE QUALITY: BEFORE AND AFTER TREATMENT

X. Grapton<sup>1</sup>, on behalf of CREER, P. Lemesle<sup>2</sup>, on behalf of CREER, L. Arabian<sup>3</sup>, on behalf of CREER, V. Strotz<sup>4</sup>, on behalf of CREER on behalf of CREER. <sup>1</sup>Private Rheumatology Practice, Colombes; <sup>2</sup>Private Rheumatology Practice, Bois-Colombes; <sup>3</sup>Private Rheumatology Practice, Clamart; <sup>4</sup>Private Rheumatology Practice, Antony, France

**Background:** Life quality issues in rheumatoid arthritis (RA) are often spontaneously mentioned by patients or identified by rheumatologists. Besides classic follow up parameters like DAS28, we have to consider those issues to improve our patients life quality.

**Objectives:** Explore and quantify the impact of RA on life quality via everyday's life and psychological items and the effect of treatment on them.

**Methods:** RA cases were collected by a group of 20 private practice rheumatologists in the Paris area. Basic informations about the patient and his disease were provided by his rheumatologist. Questionnaire including 12 themes and 41 items was filled in by the patient.

**Results:** 167 cases collected: 82% women, mean age 57 years, 56% moderate and 14% severe disease, 76% ACPA positive, 73% structural damage. Initial DAS28 4,7. Post treatment DAS28 2,7. Drugs: classic DMARDs 95%, corticosteroids 73%, biological DMARDs 22%, combination therapy 76%.

Life quality issues are spontaneously mentioned by 55% of the patients.

Before treatment, psychological well-being and housework ability are altered in more than 50% of the patients. Impact on economy, food and social life occurs in less than 25% of the cases.

Life quality is mostly altered by pain (85%), then fatigue (75%) and handicap (58%).

We find a correlation between the severity of RA and the importance of the impact on psychological well-being, sexual life and hobbies.

After treatment, psychological well-being improves in 53% of the patients, and social life, work, getting about and sexual life in 45%–32%.

Items improved around 50% of the patients are in order: sleep, relation to other people, feeling excluded, social life, depression, sick leave, concentration problems, anxiety and shopping.

We find and improvement in a third of cases in house-keeping, going out, sports and libido.

72% of the patients feel a lack of listening by their families, even under treatment.

**Conclusions:** Treatment of RA, including drugs and associated measures, reduces the frequency of negative impact on life quality.

We observe that, when DAS28 drops by 43%, the frequency of RA related repercussions diminishes by 31% (14%–50%) on the chosen items. All the items are impacted by RA before treatment and stay impacted after treatment, but less frequently, except family relations. More than one patient of 2 gains correct sleep and almost half of them aren't depressed or anxious anymore. Impact on social activity and house-keeping activity are less frequently improved.

Regarding these facts, the rheumatologist has to accomplish a tight follow-up and suggest, besides drug treatment, associated measures like physiotherapy, professional activity and environment adaptation and rest among others.

A qualitative evaluation of the improvement will be the subject of a further study.

**NEGATIVE CORRELATION OF THE ABSOLUTE NUMBER OF CD4 +CD25+FOXP3+REGULATORY T CELLS TO THE LEVELS OF RHEUMATOID FACTOR IN PERIPHERAL BLOOD OF NEW ONSET PATIENTS WITH RHEUMATOID ARTHRITIS**

X. Jianfang<sup>1</sup>, C. Gao<sup>2</sup>, X. Li<sup>1</sup>, G. Liu<sup>1</sup>. <sup>1</sup>Second Hospital of Shanxi Medical University, Taiyuan, China; <sup>2</sup>Pathology, Brigham and Woman's Hospital, Boston, USA

**Background:** Rheumatoid arthritis (RA) is a progressive immune-mediated disease that can culminate in joint destruction and early mortality. High levels of serum RF are associated with a worse prognosis in RA. The role of is not fully understood. Recently, Our studies have found that the absolute number of peripheral CD4<sup>+</sup> CD25<sup>+</sup> Fxp3<sup>+</sup> regulatory T (CD4<sup>+</sup>Treg) cells decreased in RA patients. Interestingly, regulatory T cell epitopes (Tregitopes) in IgG have been reported as the main component of intravenous immunoglobulin therapy (IVIg) and provide one explanation for the expansion and activation of Treg cells following IVIg treatment. We hypothesise that RF joins with IgG to form large molecular complexes, which interrupts the production of Tregitopes in antigen presenting cells as a cause of reduction of CD4<sup>+</sup>Treg cells.

**Objectives:** The aim of this study is to investigate whether the absolute number of CD4<sup>+</sup>Treg cells is associated with the titers of auto-antibodies in blood of new-onset diagnosed patients with RA.

**Methods:** A total of 57 new-onset diagnosed patients with RA were enrolled and healthy donors as control. The absolute number of peripheral CD4<sup>+</sup>Tregs cells was detected by multicolor flow cytometry combined with an internal microsphere counting standard. 46 of new-onset cases were tested the levels of RF and anti-CCP with ELISA method. IIF method was used to detect APF and AKA. Low titers group and high titers group around with the value 1:80. All data was analysed by SPSS 22.0.

**Results:** The absolute number of CD4<sup>+</sup>Treg cells in peripheral blood of new-onset patients with RA was significantly lower than in healthy controls [25.1 (16.01, 40.75) vs 33.0567 (22.9, 43.18), p<0.05]. Interestingly, the reduction of peripheral CD4<sup>+</sup>Treg cells was negatively correlated to RF titers (correlation coefficient -0.488, p<0.01) but not to other auto-antibodies against CCP, APF and AKA. The absolute number of CD4<sup>+</sup>Tregs in high titers RF group was lower than in low titers RF group [20.5 (14.0,40.0 vs 34.0 (29.7,44.6),p<0.05]. There was statistically significant difference in two titers groups.

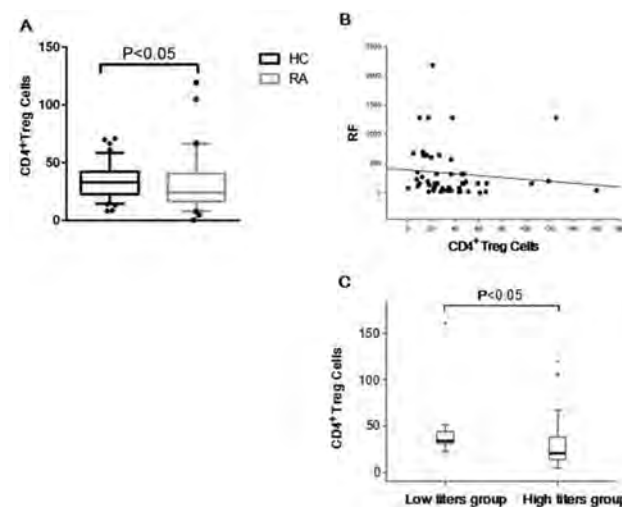

**Abstract AB0321 – Table 1.** Spearman correlation analysis of absolute number of CD4<sup>+</sup> Treg cells and autoantibodies titers in 46 new-onset RA patients

	RF	AKA	APF	a-CCP
CD4 <sup>+</sup> Treg	-0.488**	-0.126	-0.328	0.104

\*\*p<0.01

**Abstract AB0321 – Table 2.** The absolute number of CD4<sup>+</sup>Treg cells Contrast with different titers group

RF	n	M (P <sub>25</sub> , P <sub>75</sub> )	Z	P
Low titer group	13	34.0 (29.7,44.6)	-2.127	0.033
High titer group	33	20.5 (14.0,40.0)		

**Abstract AB0321 – Figure 1.** The absolute number of CD4<sup>+</sup> Treg cells were reduced in peripheral blood of the all enrolled new-onset RA patients (n=57) (A). The reduction of peripheral CD4<sup>+</sup> Treg cells from new-onset patients were negatively correlated with the levels of RF tested in these subjects (B). There was statistically significant difference in two titers groups of RF (C).

**Conclusions:** The absolute number of CD4<sup>+</sup>Treg cells in peripheral blood of new-onset patients with RA was significantly decreased compared with that in healthy controls. Furthermore, the reduction of peripheral CD4<sup>+</sup>Treg cells was negatively correlated to the titers of RF, suggesting that RF contributes to the reduction of CD4<sup>+</sup>Tregs cells. The correlation of decreased CD4<sup>+</sup>Treg and RF may be involved in the pathogenesis of poor prognosis in RA.

**Background:** Combination therapy with DMARDs for treating RA is considered as standard of care. However, certain rates of adverse events (AEs) are unavoidable. The stigma is which drug should be stopped first once AEs emerge. The decisions made by clinicians are always empirically.

**Objectives:** To develop an algorithm for decision making on drug withdraw sequence in face of adverse events with combination therapy based on data mining and machine learning from the SSDM.

**Methods:** SSDM is an interactive mobile disease management tool, including the doctors' and patients' application system (App). The patients can input medical records and perform self-evaluation via App. The data synchronises to the mobiles of authorised rheumatologists through cloud and advices could be delivered. In order to develop the master algorithm, abnormal white blood cell (WBC) counts in blood were first targeted. WBC and medication data was collected, extracted, validated, and then based on Bayesian networks, data mining, modelling, calculating, analysing were performed. WBC under 4,000/ml is defined as leukocytopenia (LP), and over 10,000/ml as infection predisposing (IP).

**Results:** From Jun 2014 to Jan 2018, 24,731 RA patients from 486 centres registered in SSDM. 6099 are male and 18 632 are female with mean age of 49.28 ±16.08 (18 to 99) years. 19 different drugs and 126 types of combination therapies are identified. Lab test results showed LP happened in 87 and IP in 123 treatment regiments. Among them we selected prednisone (Pred), leflunomide (LEF), methotrexate (MTX) and hydroxychloroquine (HCQ) as an example to develop a master algorithm based on Bayesian networks and learning model. Figure 1 shows Bayesian network and data processing, in which, quartet are correlating with 15 different regiments. Based on Bayesian method and network data, the calculation for LP and IP probabilities is generated through 32 modelling, and the algorithm for drug withdraw strategies are generated. Drug withdraw sequence for LP is HCQ, then LEF and then Pred, and the risks of LP are reduced by 64%, 52% and 26%, respectively. For IP, withdraw sequence is Pred, then MTX and then LEF, and the risks of IP are reduced by 57%, 63%, and 14%, respectively.

**Abstract AB0322 – Figure 1.** Bayesian network and data processing: patients' number (black bold as blow showed) and the rate of either LP or IP in 15 regiments.

Pred: prednisone; HCQ: hydroxychloroquine; MTX: methotrexate; LEF: leflunomide; LP: leukocytopenia; IP: infection predisposing

**Conclusions:** Big data system can be built using SSDM via empowering patient. Through data mining, networking, modelling, and Bayesian calculation, a master algorithm for drug withdraw strategy in reduction of adverse events with combination therapy is developed, which can be applied on the other AEs in SSDM and may replicated in other diseases. Following the continuing data inputs and machine learning, an artificial intelligent system in assisting clinical decision making may be achieved.

**Limitations:** This study only focus on rate of AE without considering the efficacy, without stratifying dosing.

AB0323

### RELATIONSHIP BETWEEN SERUM LEVELS OF LEPTIN & HOMOCYSTEIN IN RHEUMATOID ARTHRITIS PATIENTS WITH OR WITHOUT EXTRA ARTICULAR MANIFESTATIONS

Y. Hussein Gazar. Rheumatology Department, Al-Azhar University, Cairo, Egypt

**Background:** Rheumatoid arthritis (RA) is a chronic, systemic disorder with unknown etiology, which is characterised by involvement of hand joints and deformation. Rheumatoid arthritis is characterised by synovial inflammation and hyperplasia. chronic inflammatory process of the joints that progresses through different stages of increasing severity characterises rheumatoid arthritis.

**Objectives:** In this study we aimed to determine the relationship and correlation between serum homocystein and leptin levels in (patients with rheumatoid arthritis (RA) without extra articular manifestation (non Ex RA)(GROUP-A) and RA patients with extra articular manifestation (ExRA) (GROUP B) and disease progression.

**Methods:** 80 patients diagnosed as rheumatoid arthritis (according to ACR/EULAR 2010 classification criteria) (according to ACR/EULAR 2010 classification criteria) and selected as follow:

(Group A)

40 patients without extra articular manifestation (nonExRA) and

(Group B)

40 patients with variable extra articular manifestation (ExRA),

CONTROL GROUP (C)

Another 40 apparently healthy persons as controls.

RA patients were divided into three groups based on Disease Activity Scores in 28 joints (DAS28) as low disease activity, moderate disease activity, and high disease activity groups.

Of the patients (non Ex RA), 11 (27.5%) had low disease activity (DAS28=2.6–3.2), 15 (37.5%) had moderate disease activity (DAS28=3.2–5.1), and 14 (35.0%) had high disease activity (DAS28 ≥5.1). Laboratory investigations were performed for all patients, including determination of haemoglobin concentration (Hb), erythrocyte sedimentation rate (ESR), and C-reactive protein. Serum concentrations of tumour necrosis factor-alpha (TNF-α), IL-6, Homocystein and Leptin were measured.

**Results:** Significant differences were found between RA patients (group A+group B) and controls healthy group (group C) with regard to the mean levels of Hb, ESR, TNF-α and IL-6 (p<0.05).

As regards to serum leptin, non significant level differences between healthy control group (20.43±8.73 ng/ml) and patient groups (group II and III) (22.43 ±7.73 ng/ml).

while A statistically significant higher mean level serum Homocystein concentration (p<0.05) was found in patients (group A and B) (11.79+8.72 μmol/L) than in control (group C) (8.8+1.58 μmol/L).

Significant differences were found between non ExRA (group A) and ExRA (group B) with regard to the mean levels of Hb, ESR, TNF-α and IL-6 (p<0.05).

A statistically non significant differences in mean level of serum Leptin concentration (p>0.05) was found in group A (22.43±5.73 ng/ml) than in group B (24.43 ±5.73 ng/ml).

While a significant mean level of serum Homocystein concentration (P value<0.05) was found in Group B patients (19.43±1.08 μmol/L) than in group A (11.79±13.05 μmol/L) (p<0.05).

Positive significant correlations were detected between serum Homocystein and ESR, TNF-α, IL-6, and DAS-28 (p<0.05) in group B

Multiple linear regression analysis showed that DAS- 28 and ESR were the main variables associated with serum Homocystein in RA patients (p<0.05).

**Conclusions:** Serum leptin can't be considered of value as an inflammation marker in monitoring RA patients.

Seum homocystein can be used as a marker for probability of extra articular complication of RA.

**Disclosure of Interest:** None declared

**AB0324** **DISTRIBUTION AND CLINICAL SIGNIFICANCE OF ANTI-HETEROGENEOUS NUCLEAR RIBONUCLEOPROTEIN A2 ANTIBODY IN CONNECTIVE TISSUE DISEASES**

Y. Wang, F. Mu, Y. Fang. *Department of Rheumatology, Southwest Hospital, the Third Military Medical University, Chongqing, China*

**Background:** The anti-heterogeneous nuclear ribonucleoprotein A2 (hnRNP-A2) antibody is specific for rheumatoid arthritis (RA). But, it is also reported that there is no significant difference between RA and systemic lupus erythematosus (SLE) in terms of the antibody.

**Objectives:** To investigate the distribution and clinical significance of anti-hnRNP-A2 antibody in connective tissue diseases.

**Methods:** Serum anti-hnRNP A2 antibody level was measured by solid-phase enzyme linked immunosorbent assay (ELISA) in 1464 patients with RA, 209 patients with SLE, 204 patients with ankylosing spondylitis (AS), 63 patients with mixed connective tissue disease (MCTD), 133 patients with undifferentiated connective tissue disease (UCTD), 60 patients with Sjogren syndrome (SS), 47 patients with polymyositis/dermatomyositis (PM/DM), and 45 patients with systemic sclerosis (SSc). The positivity rate of anti-hnRNP-A2 antibody was compared among various patient groups, and its correlation to clinical and laboratory parameters and its diagnostic significance were analysed.

**Results:** The positivity rate of anti-hnRNP-A2 antibody was 38.0% (556/1464), 36.8% (77/209), 3.9% (8/204), 52.4% (33/63), 17.3% (23/133), 5.0% (3/60), 4.3% (2/47), and 8.9% (4/45) in RA, SLE, AS, MCTD, UCTD, SS, PM/DM and SSc, respectively. The rate differed insignificantly between the RA, SLE and MCTD groups ( $p>0.05$ ), but was significantly higher than in other disease groups ( $p<0.01$ ). The titers of anti-hnRNP-A2 antibody were significantly higher in the RA, SLE, MCTD groups than in other disease groups ( $p<0.01$ ), but differed insignificantly between the RA, SLE, MCTD groups ( $p>0.05$ ). In RA patients, anti-hnRNP-A2 antibody weakly correlated negatively to anti-Cyclic citrullinated peptide (CCP) antibody ( $r=-0.135$ ,  $p<0.01$ ), but correlated insignificantly to age, course of disease, time of morning stiffness, erythrocyte sedimentation rate, C reactive protein, rheumatoid factor (RF), anti-keratin antibody (AKA) and glucose phosphate isomerase (GPI) ( $p>0.05$ ).

**Conclusions:** Anti-hnRNP-A2 antibody can be found in various connective tissue diseases, and its positivity rate is relatively high in RA, SLE and MCTD. It is not a RA-specific antibody. In RA, anti-hnRNP-A2 antibody does not coincide with other RA-related serological indicators; hence, it may serve as an adjunctive indicator for RA diagnosis.

**AB0325** **CLINICAL OUTCOME OF 2 YEARS TREATMENT OF THE EARLY PHASE RHEUMATOID ARTHRITIS**

Y. Sugimura<sup>1</sup>, T. Kashiwagura<sup>2</sup>, M. Kobayashi<sup>3</sup>, N. Miyakoshi<sup>4</sup>, Y. Shimada<sup>4</sup>.  
<sup>1</sup>Orthopedic Surgery, Nakadori General Hospital; <sup>2</sup>Orthopedic Surgery, Akita City Hospital; <sup>3</sup>Orthopedic Surgery, Hiraka General Hospital; <sup>4</sup>Orthopedic Surgery, Akita University Graduate School of Medicine, Akita, Japan

**Background:** Few studies have reported long term clinical outcome of patients with early phase rheumatoid arthritis (RA).

**Objectives:** The objectives of this study were to investigate outcome of 2 years treatment for RA which was started less than 12 months after RA symptoms first appeared and to evaluate prediction factors of poorly controlled patients at 2 years.

**Methods:** From a total of 1663 RA patients registered in the Akita Orthopaedic Group on Rheumatoid Arthritis (AORA), 66 patients were treated within the first year of RA appearance, and enrolled in this study. Sex, age, RA disease duration, Steinbrocker's stage, Steinbrocker's class, medications and DAS28-CRP at

the baseline and 2 years post-treatment were evaluated. Furthermore, we compared the group of remission (REM) or low disease activity (LDA) with the group of medium disease activity (MDA) or high disease activity (HDA) at 2 years.

**Results:** At the baseline, the patients included 13 males and 53 females. Mean age and RA disease duration were 59<sup>21–85</sup> years and 7<sup>1–11</sup> months, respectively. Fifty-four, 8, 4 and 0 patients were classified into Steinbrocker's stage I, II, III, and IV, respectively. Thirty-nine, 25, 2 and 0 patients were classified into Steinbrocker's class I, II, III, and IV, respectively. Thirty-seven (56%), 24 (36%), and 16 (24%) patients were treated with MTX, DMARDs, and PSL, respectively. In DAS28-CRP, 19 (29%), 13 (20%), 32 (48%), and 2 (3%) patients showed REM, LDA, MDA, and HDA, respectively. Forty-four patients were followed-up for 2 years. At 2 years, 30, 7, 5, and 2 patients were classified into Steinbrocker's stage I, II, III, and IV, respectively. Thirty-one, 12, 1, and 0 patients are classified into Steinbrocker's class I, II, III, and IV, respectively. In DAS28-CRP, 33 (75%), 4 (9%), 7 (16%), and 0 (0%) patients showed REM, LDA, MDA, and HDA, respectively. Compared with the group of REM or LDA, the group of MDA or HDA had significantly older age ( $p=0.018$ ), higher Steinbrocker's stage ( $p=0.012$ ) and higher DAS28-CRP ( $p=0.049$ ) at the baseline.

**Conclusions:** At 2 years, 75% of patients with early phase RA achieved REM. Older age, higher Steinbrocker's stage and higher DAS28-CRP at the baseline could be prediction factors of poorly controlled patients at 2 years.

**AB0326** **MATRIX METALLOPROTEINASE-3 IS A GOOD PREDICTOR FOR JOINT DESTRUCTION ONLY IN MALE PATIENTS WITH RHEUMATOID ARTHRITIS**

Y. Yamada<sup>1,2</sup>, K. Inui<sup>1</sup>, T. Okano<sup>1</sup>, K. Orita<sup>3</sup>, Y. Sugioka<sup>4</sup>, K. Mamoto<sup>1</sup>, T. Koike<sup>3,4</sup>, M. Tada<sup>5</sup>, H. Nakamura<sup>1</sup>. <sup>1</sup>Department of orthopedics surgery, Osaka City University; <sup>2</sup>Department of orthopedics surgery, Yodogawa Christian Hospital, Osaka City; <sup>3</sup>Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama; <sup>4</sup>Center for Senile Degenerative Disorders (CSDD), Osaka City University; <sup>5</sup>Department of orthopedics surgery, Osaka City General Hospital, Osaka City, Japan

**Background:** Serum level of matrix metalloproteinase-3 (MMP-3) is elevated by synovial inflammation. It destroys articular cartilage such as proteoglycans so that it has been used as a clinical biomarker of joint destruction in patients with rheumatoid arthritis (RA).

**Objectives:** The purpose of this study is to investigate a relation between radiographic progression, MMP-3 and other factors such as ultrasonography (US) findings.

**Methods:** 259 patients (213 women) with RA were enrolled in this study. Their baseline data such as age, sex, disease duration, use of glucocorticoid (GC) or DMARDs, disease activity (DAS28), laboratory data (MMP-3, CRP, RF and ACPA), and the Power Doppler (PD) score at digits and wrists by US were collected. The modified total Sharp score (mTSS), erosion score (ERN) and joint space narrowing (JSN) were examined at baseline and 1 year. Their changes from baseline to 1 year ( $\Delta$ ) were calculated. Relationship between baseline MMP-3 and other variables was examined. Predictors for joint destruction was investigated by multiple regression. Statistical analysis was separated by sex because upper limit of MMP-3 is different between men and women.

**Results:** MMP-3 showed no correlations with GC use, DAS28, CRP or mTSS. MMP-3 was correlated with  $\Delta$ mTSS and  $\Delta$ JSN only in men, but PD score only in women (table 1). Multiple regression analysis revealed that MMP-3 was correlated independently with  $\Delta$ mTSS only in men, whereas PD score was correlated independently with  $\Delta$ mTSS in women. PD score, but not MMP-3, could predict joint destruction at 1 year in women (table 2).

**Abstract AB0326 – Table 1.** Correlation with baseline MMP-3; univariate analysis

variables	Male		Female	
	correlation coefficient	P value	correlation coefficient	P value
DAS28-ESR	-0.004	0.980	0.043	0.191
duration	-0.225	0.133	0.088	0.189
RF	-0.083	0.687	-0.192	0.024
ACPA	-0.050	0.797	0.051	0.538
CRP	-0.003	0.986	0.060	0.370
GC use	0.042	0.781	0.109	0.104
mTSS	0.029	0.850	0.100	0.138
$\Delta$ mTSS	0.375	0.010	0.074	0.267
$\Delta$ ERN	0.223	0.137	0.101	0.133
$\Delta$ JSN	0.412	0.004	-0.009	0.891
PD score	0.224	0.143	0.181	0.010

$\Delta$ : difference in values from baseline to 1 year

**Abstract AB0326 – Table 2.** Predictor for joint destruction; multivariate linear regression analysis

	variables	coefficient	P value
Male	MMP3	0.013	0.001
	ACPA	0.010	0.002
	GC use	0.378	0.197
Female	PD score	0.267	<0.001
	ACPA	0.007	0.101
	GC use	-0.449	0.062

**Conclusions:** The baseline MMP-3 was a good predictor for joint destruction at 1 year only in male patients with RA. On the other hand, the baseline PD score was a useful predictor for joint destruction only in female patients with RA.

## Rheumatoid arthritis – comorbidity and clinical aspects

### AB0327 CLINICAL SIGNIFICANCE OF HORMONE-RELATED (ISOLATED) AMYLOIDOSIS OF THE ISLETS OF LANGERHANS – A POSTMORTEM CLINICOPATHOLOGIC STATISTICAL STUDY OF 234 RHEUMATOID ARTHRITIS PATIENTS

Á. Apáthy<sup>1</sup>, M. Bély<sup>2</sup>. <sup>1</sup>Department of Rheumatology, St. Margaret Clinic; <sup>2</sup>Department of Pathology, Hospital of the Order of the Brothers of Saint John of God in Budapest, Budapest, Hungary

**Background:** “All forms of amyloidosis related to the circulation of blood are systemic, and all forms of amyloidosis not connected to the circulation are isolated (localised)”.<sup>1</sup>

Systemic AA amyloidosis (AAa) – characterised by amyloid A deposition – is one of the major chronic complication of rheumatoid arthritis (RA), in most of the cases leading to renal and less frequently to cardiac insufficiency and death.<sup>2</sup>

Islet amyloidosis (IA) (islet amyloid polypeptide – IAPP – prohormone fragment deposition localised to islets of Langerhans) is an isolated (localised) form of amyloidosis of clinical (diagnostic) significance in adult type II diabetes mellitus (DM).

**Objectives:** The aim of this study was to determine the prevalence of AAa and IA in RA, to analyse the relationship between them, furthermore to evaluate the possible role of IA in DM in RA patients.

**Methods:** At the National Institute of Rheumatology 11 558 patients died between 1969 and 1998; among them 234 with RA, and all of them were autopsied. RA was confirmed clinically according to the criteria of the ACR.<sup>3</sup>

The diagnosis of DM based on clinical data. Tissue samples of pancreas were available for histologic evaluation in 150 of 234 patients. AAa and IA was diagnosed histologically, amyloid A and IAPP deposits were confirmed histochemically.<sup>4</sup> The relationships between AAa and IA further more between IA and DM were analysed by Pearson's chi-squared ( $\chi^2$ ) test.

**Results:** AAa complicated RA in 32 (21.33%) of 150 patients. Hormone-related IA localised to the islets of Langerhans was observed in 15 (10.0%) of 150 pancreases: Clinically diagnosed DM was associated with RA in 31 (20.66%) of 150 patients. AAa was associated with IA in 2 (6.45%) of 31 cases. The relationship between AAa and IA was not significant, even the association's coefficient was negative:  $-0.2381$ ,  $\chi^2=0.0785$ ,  $p<0.77$ ). IA associated with clinically diagnosed DM in 8 (53.3%) of 15 patients. There was a positive and significant correlation between clinically diagnosed IA and DM (association's coefficient:  $0.6953$ ,  $\chi^2=10.8475$ ,  $p<0.0009$ ). IA was present without the clinical diagnosis of DM in 7 (46.7%) of 15 patients. The relationship between IA and clinically not diagnosed DM was also positive and significant (association's coefficient:  $0.6037$ ,  $\chi^2=6.8717$ ,  $p<0.008$ ).

**Conclusions:** Systemic or localised types of amyloidosis may exist simultaneously side by side or may be present independently from each other. AAa and IA are independent phenomena based on the negative association's coefficient and not significant relationship between them, and may coexist in RA. According to our interpretation the early stage of IA (involving only a few islets with minimal IAPP deposits) represents a clinically latent DM and the advanced stage of it is clinically manifest DM. The strong positive and significant correlation between IA and clinically manifest DM suggest close relationship between them. Based on the positive and significant correlation between IA and clinically not diagnosed DM, the IA may be a good indicator of potential DM in the latent stage of disease. This correlation may help recognise DM in its early stage. For this reason we recommend that all biopsy material and surgical specimens of pancreas to be tested for IA or IAPP deposition.

### AB0328 CARDIOVASCULAR RISK EVALUATION IN LONG STANDING RHEUMATOID ARTHRITIS: REAL CLINICAL DATA

A. Babaeva<sup>1</sup>, E.V. Kalinina<sup>1</sup>, M.S. Zvonorenko<sup>1</sup>, K.S. Solodenkova<sup>2</sup>, M. A. Osadchuk<sup>2</sup>. <sup>1</sup>Volgograd State Medical University, Volgograd; <sup>2</sup>I.M. Sehenov First Moscow State Medical University, Moscow, Russian Federation

**Background:** According to recent national and EULAR recommendation cardiovascular risk (CVR) in pts with RA should be evaluated using modified SCORE system. But a lot of investigations and real clinical data demonstrate that this system commonly down-estimates CVR in RA pts.

**Objectives:** Aim of our study was to compare standard CVR assessment and additional CVR evaluation on the basis of specific disease-associated risk factors (RF) and CV system investigations in long standing RA.

**Methods:** 118 pts (96 female, 22 male) aged from 34 to 74 years old (mean age  $55.91\pm 5.21$ ) with long standing RA (duration >5 years) were observed. In all pts CVR was stratified according to modified SCORE. We have analysed pts medical cards and standard examination data to determine clinical features of RA and associated conditions to verify severity of CVR. In term to reveal asymptomatic CV disease pts had undergone additional investigations (echocardiography, Dopplerography of carotid arteries, ECG-monitoring).

**Results:** Conventional CVRF were registered in 110 (93.22%) pts. Age>45 (male), >50 (female) was in 85 (72.03%) pts, BMI>25 kg/m<sup>2</sup>; in 10.17%, elevated cholesterol level and/or dyslipidemia in 41.52%, AH with target organ damage was detected in 45.76%, T2DM in 11.8%, CKD 3 stage in 10.17%, history of MI was in 2 (1.69%) pts. According to modified SCORE for RA very high, high, moderate and low CVR was detected in 17.80%, 47.46%, 18.64%, 16.10% cases respectively. High activity of RA was diagnosed in 61.02%, and erosive arthritis in 84.75% pts. Inadequate disease-modifying treatment was qualified in 15.26% cases. Majority of pts (59.32%) received systemic glucocorticoids (GC) in daily doses from 2 to 12 mg of methylprednisolon, among these pts 14 (11.86%) have been taken GC in moderate and high dose for a long period. On the basis of instrumental data asymptomatic atherosclerosis of aorta and/or aortic valve and/or carotid arteries was detected in 44 pts (37.29%). Silent ischemia was revealed in 3 pts (2.54%). High disease activity and long term systemic GC treatment were associated with significantly high CV events in observed pts ( $p<0.05$ ). Using obtained results we reassessed CVR in studied cohort. Revised data of CVR stratification suggest that 49 (41.53%) pts were in VH-CVR, 41 (34.75%) – in H-CVR, 16 (13.56%) in M-CVR and only 12 (10.17%) in L-CVR. The difference in pt ratio for CVR stratification was significant in accordance with  $\chi^2$ ; criterion.

**Conclusions:** Obtained data suggest that modified SCORE is not absolutely reliable tool for precise CVR stratification in long standing RA. Additional investigations to define asymptomatic atherosclerosis and coronary artery disease are required in term to prevent CV complications especially in pts with high active erosive RA treated with systemic GC.

### AB0329 THE METHOD OF EVALUATION OF CARDIORESPIRATORY SYSTEM NEUROVEGETATIVE REGULATION IN RHEUMATOLOGIC PATIENTS

A. Lebedeva, V. Marchenko, I. Mozhaev. Department of Research Institute of rheumatology and allergology, Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation

**Objectives:** To study the characteristics of cardiorespiratory system (CRS) neurovegetative regulation disorders and to define the correlation with disease activity.

**Methods:** 40 rheumatoid arthritis (RA) patients (14 m:30 f; median age  $45\pm 2,32$ ), 18 ankylosing spondylitis (AS) patients (13 m:5 f; m.a.  $39.6\pm 2,44$ ), 17 osteoporosis (OP) patients (3 m:14 f; m.a.  $55.5\pm 1,47$ ), 50 healthy persons (HP, 25 m:25 f; m.a.  $23,8\pm 0,84$ ) were studied. The diagnosis<sup>1</sup> of RA, AS, OP were established by the current diagnostic and classification criteria. The cardiorespiratory system neurovegetative regulation was studied with the use of

Spiroarteriocardiorhythmograph, that was able to synchronously analyse the variability of heart rate (HR), respiration (R), systolic (S) and diastolic (D) arterial pressure, respiratory phase structure, baroreceptor sensitivity and some other cariohemodynamics parameters. Following parameters were calculated: spectrum of fluctuations total power (TP), the activity of suprasedgmental (VLF), sympathetic (LF), parasympathetic (HF), cortical (IC) and subcortical (SNCA) contours and sympatho-vagus balance parameters (LF/Hf) in regulation HR, R, S, D, baroreceptor sensitivity (BR), inhale (Ti) and exhale (Te) time (V. Marchenko, 2004).

**Results:** Different severity dysregulation of CRS at all levels is typical for the AS patients, which expresses in decrease of the variability of the basic contours of regulation of heart rate, respiration, systolic and diastolic blood pressure with a shift of sympatho-vagal balance in favour of parasympathicotonia, reduction baroreceptor sensitivity. The heterogeneity of the analysed groups according to the parameter LF/HF<sub>HR</sub> is shown. The ratio of patients with parasympathotony, normotony, sympathotony in groups made up, respectively, in HP (34:48:18), RA (23:54:23), AS (55:28:17), OP (29:53:18). It is established that a significant number of AS patients had parasympathetic type of regulation, and the rest of the groups were dominated by patients with normotonic type of regulation. It is shown that in groups of patients neurovegetative regulation system was more stringent, as evidenced by the increase in their number of reliable correlations compared with the group of healthy individuals. The features of dysregulation in each analysed group were established, the nature of which requires further analysis. Significant correlations ( $\tau > \pm 0,45$ ;  $p = 0,029$ ) between the parameters of the neurovegetative regulation of cardiorespiratory system on the one hand and the clinical and laboratory parameters of inflammatory activity (in the first place, DAS28, CRP, ESR) on the other hand in patients with RA; with parameters BAS-DAl, the activity of the inflammatory process (ESR, CRP) in patients with AS; densitometric parameters in patients with OP were identified. The close connexion between vascular component and the activity of the inflammatory process is shown, which may be a manifestation of endothelial dysfunction.

**Conclusions:** Thus, the method of variability of cardiorespiratory allows to detect the neurovegetative dysregulation of the cardiorespiratory system in rheumatologic patients and can be recommended for the evaluation of the system of regulation in general, the possible role of its disorders in the pathogenesis of clinical manifestations of diseases, and assessing the dynamics of regulatory processes in the treatment of patients.

#### OSTEOPOROSIS, SARCOPENIA AND OSTEOSARCOPENIA IN WOMEN WITH RHEUMATOID ARTHRITIS

A. Feklistov, N. Demin, N. Toroptsova. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Rheumatoid arthritis (RA) is a systemic inflammatory disease associated with polyarthritis, progressive joint damage, and physical impairment that can lead to osteoporosis and sarcopenia, increasing the risk of fractures and leading to a greater loss of autonomy in RA patients.

**Objectives:** To assess frequency of osteoporosis, sarcopenia and osteosarcopenia in women with RA.

**Methods:** 40 female patients with RA (mean age 63±7 years) and 40 female controls without RA (mean age 64±9 years) were enrolled in this study. Body composition and bone mineral density (BMD) in lumbar spine and proximal hip were assessed by using dual X-ray absorptiometry (DXA, Hologic Discovery A). Sarcopenia in women was defined as a skeletal muscle index (SMI)  $\leq 5.67 \text{ kg/m}^2$  and osteosarcopenia – if sarcopenia and low BMD were present together.<sup>2</sup> The participants performed Short Physical Performance Battery (SPPB) and handgrip strength was measured. Body mass index (BMI) and Disease Activity Score (DAS28) were calculated.

**Results:** Low BMD at least in one of measured area was found out in 19 (48%) RA persons and in 18 (45%) controls. Sarcopenia occurred in 10 (25%) RA patients and in 5 (12,5%) people without RA ( $p > 0,05$ ). Among them osteosarcopenia was found in 6 (15%) RA women and 2 (5%) controls. Skeletal muscle index (SMI) was lower in patients with RA ( $6.43 \pm 0.978$ ) than in controls ( $7.01 \pm 1.064$ ,  $p < 0,05$ ). In RA patients SMI had a positive correlation with BMI ( $r = 0,58$ ,  $p < 0,05$ ) and handgrip strength ( $r = 0,34$  for right,  $r = 0,30$  for left,  $p < 0,05$  for both). Sarcopenia was more common in RA patients who were normal or underweight than in those who were overweight or obese according to their BMI ( $p < 0,01$ ). There was no correlation between SMI and DAS28, drug use, frequency of falls during the last year, SPPB in the RA group

**Conclusions:** In RA patients 48% had osteoporosis and 25% – sarcopenia, among them 15% women – osteosarcopenia. The risk of sarcopenia and osteosarcopenia was higher in nonobese patients.

#### INCIDENCE OF MALIGNANCY IN PSORIATIC AND RHEUMATOID ARTHRITIS PATIENTS LIVING IN NEWFOUNDLAND AND LABRADOR

A.F. Lewis<sup>1</sup>, I. Landells<sup>2</sup>, G. Mugford<sup>3</sup>, M. Khraishi<sup>3</sup>. <sup>1</sup>*Clinical Epidemiology*, <sup>2</sup>*Dermatology*, <sup>3</sup>*Rheumatology, Memorial University of Newfoundland, St. John's, Canada*

**Background:** Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) are reported to be associated with an increased risk of malignancy. Newfoundland and Labrador (NL) has one of the highest cancer rates in Canada. There is a paucity of literature on the prevalence of malignancy in NL patients with PsA and RA.

**Objectives:** Evaluate the incidence of malignancy in a cohort of PsA and RA patients and compare rates with the general population. Evaluate the impact of therapy of these two diseases.

**Methods:** Data was extracted from the charts of 200 PsA and 500 RA patients seen at a rheumatology clinic in St. John's between 2011 and 2014. Statistical analyses were performed using SPSS version 21.0 for Windows (IBM Inc.). Person-time Rate (PYs) per 100,000, stratified by age and gender, were used to estimate overall cancer risk and proportions between the two cohorts. Observed rates were compared with Statistics Canada reported general NL rates.

**Results:** We identified 37 (5.3%) malignancies: 34 (91.8%) solid and 3 (8.1%) hematologic. Mean (SD) age was 58.4 (12.28) and age at diagnoses of disease was 46.8 (12.88). Four hundred and eighty (68.6%) were females. No difference was observed in rates between the study population and the NL general population ( $p < 0.3217$ ). The most common solid tumours were breast 8 (21.6%) and skin 8 (21.6%), followed by five bowel and lung cancers in equal proportions (13.5%). Distribution of cancers between the two cohorts were similar.

**Conclusions:** The results suggests there is no difference in the cancer rate between our cohorts and the NL general population. We acknowledge study limitations related to shorter duration of follow-up and lower sample size.

### COMORBIDITIES PREVALENCE AND CHARLSON INDEX IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS

A.B. Azuaga-Piñango, R. Castellanos-Moreira, S.C. Rodríguez-García, S. Mandelíková, B. Frade-Sosa, A. Diaz-Castillo, N. Sapena, C. Gonzalez-Delaurens, V. Ruiz-Esqüide, O. Camacho, A. Cuervo, J. Ramirez, M. V. Hernández, J.A. Gómez Puerta, J.D. Cañete, R. Sanmartí. *Rheumatology, Hospital Clinic de Barcelona, Barcelona, Spain*

**Background:** The Charlson comorbidity index (CCI) is a prognostic scale, which gives a numerical value that indicates the burden of comorbidities in a patient. This index is obtained from the sum of 19 medical conditions that have been related to mortality and has been validated in several studies. Patients with rheumatoid arthritis (RA) are more at risk than the general population of developing comorbidities. However, these often go unnoticed despite the impact on the disease activity and to treatment response, as shown by different studies such as COMORA.

**Objectives:** To determine the prevalence of comorbidities in a cohort of patients with RA and estimate CCI.

**Methods:** Cross-sectional descriptive study, patients diagnosed with RA according to the EULAR<sup>ACR 2010</sup> classification criteria were included. All patients were followed up in a rheumatology service in a tertiary hospital. Comorbidities were obtained from the medical records. To measure comorbidities, CCI was calculated, the diagnosis of RA was not included in the index. We defined three categories of comorbidity according to CCI: 0 (no comorbidity, applied to patients with no previous record of conditions included in the CCI), 1 to 2 (moderate) and 3 or more (severe). Others comorbidities not included in CCI, such as hypertension (HTN), dyslipidemias (DLP), thyroid disease (TD), osteoporosis (OP) were collected.

**Results:** 130 patients (103 women) were analysed; mean age was 58.6±12.9 years and disease duration of 6.0±4.4 years. 82.8% were seropositive for rheumatoid factor (n: 83) and/or anti-CCP (n: 97). 44.6% had previous smoking history, 22 were current smokers. The most observed comorbidities in our cohort were: overweight and obesity (BMI ≥25; 63%), DLP (38.8%), HTN (31.5%), chronic kidney disease (32.3%; 6.9% ≥Stage III) and chronic lung disease (23.8%). Other diseases included TD (18.5%), OP (17.7%), diabetes mellitus (9.2%) and liver disease (9.2%). Five patients with a history of tumour (2 metastases) and 2 lymphomas in the last 5 years. Four patients had a heart disease, in 3 as an ischaemic event.

According to CCI, 20.8% of the patients had a Charlson 0, 43.8% Charlson 1–2, and 35.4% Charlson ≥3.

**Conclusions:** In our cohort, despite being a relatively young population, the presence of comorbidities and cardiovascular risk factors is relatively high, in agreement with what has been observed in other studies. 1 out of 3 patients has a severe comorbidity burden.

**Disclosure of Interest:** None declared

### ANALYSIS OF THE ASSOCIATION OF COMPOUND INDICATES OF DISEASE ACTIVITY AND QUALIFICATIONS OF FUNCTIONAL CAPACITY AND QUALITY OF LIFE RELATED TO HEALTH IN PATIENTS WITH RHEUMATOID ARTHRITIS

B.F. Althoff<sup>1</sup>, I.A. Pereira<sup>1</sup>, T. Fontana<sup>1</sup>, Y. Alfaro<sup>2</sup>, C.J. Ferreira<sup>1</sup>. <sup>1</sup>Medicina; <sup>2</sup>Universidade do Sul de Santa Catarina, Florianópolis, Brazil

**Background:** The correlation analysis of ICADs with questionnaires of functional evaluation and quality of life is essential, since it is the outcomes that matter to the patients.

**Objectives:** To evaluate the correlations between ICADs with questionnaires of functional capacity (HAQ) and health-related life quality (SF12).

**Methods:** Cross-sectional study with 100 out-patients of Santa Catarina, participants of a multicenter cohort, followed between August 2015/January 2016. Evaluated ICADs were: DAS-28 VHS, DAS-28 PCR, SDAI, CDAI, RADAI. The questionnaires were: HAQ and SF12. Tests Qui Square, test t Student, prevalence ratio and Pearson's correlation were used, with reliability interval 95%. Approved by Ethics Committee in Research of UNISUL.

**Results:** Moderate correlation between ICADs and HAQ (variation r 0,52–0,65). Weak correlation between ICADs and SF12 (Physical: variation r 0,15–0,24 and Mental: variation r 0,40–0,45).

**Abstract AB0333 – Tabel 1.** Correlation between Laboratory Parameters and Functional Capacity (HAQ) in patients with Rheumatoid Arthritis of Santa Catarina.

Variables	HAQ*
	r
ESR† (mm/1 <sup>h</sup> )	0,238
CRP‡ (mg/dl)	0,287
DAS-28§ ESR	0,580
DAS-28 CRP	0,551
SDAI	0,524
CDAI ¶	0,524
RADAI**	0,655

\*Health Assessment Questionnaire † Erythrocyte Sedimentation Rate ‡ C-Reactive Protein § Disease Activity Score-28 || Simplified disease activity index ¶ Clinical disease activity index \*\*Rheumatoid arthritis disease activity.

Source: Elaboration of the author, 2017.

**Conclusions:** ICADs correlate poorly with quality of life, assessed by SF12, but moderately with functional limitation, assessed by HAQ.

### NEOPLASM RISK IN A RHEUMATOID ARTHRITIS COHORT: A RETROSPECTIVE STUDY

C. Ambrósio, A. Barcelos. *Rheumatology, Hospital Infante D. Pedro-Aveiro, Aveiro, Portugal*

**Background:** It is well known that the risk of neoplasms is increased in rheumatic patients, especially in Rheumatoid Arthritis (RA), SLE and inflammatory myopathies. Although the relationship between neoplasms and some factors involving the pathophysiology and immunomodulatory therapy of this diseases is well known, we still don't know all the mechanisms underlying this process. Thereby, this theme has been of ongoing interest and research.

**Objectives:** To determine whether the incidence of neoplasm is increased in patients with RA compared to a matched comparison cohort and to identify risk for any individual malignancy in RA.

**Methods:** A cohort of 243 RA patients, who fulfilled 1987 ACR criteria for RA and a comparison cohort, sex and age matched without RA (non-RA) were evaluated retrospectively for cancer occurrence. Demographic, epidemiological, clinical, laboratorial and imaging data were collected through medical record review. All paraneoplastic cases were excluded. Descriptive statistics were used to summarise data of the RA and comparator group.

**Results:** 243 RA patients (mean age 62,9 y, 68,7% female, mean disease duration 10,6 y) were enrolled. 148 RA patients had rheumatoid factor (RF) present

and 120 had anti-citrullinated peptide (anti-ccp) positive. Erosions were present in 106 RA patients. The prevalence of neoplasms was similar in RA and non-RA groups ( $n=24$  vs  $23$ ,  $p=0,8$ ) and 5 of the deaths occurred in the RA-neoplasm group were due to the cancer. Of the 24 neoplasms in RA group, 9 appeared after the RA diagnosis was established (mean 10 years) and 17 before (mean 9,65 years). In RA patients correlation was found between male sex and neoplasm ( $p=0,04$ ) as well as absence of RF rheumatoid factor and neoplasm ( $p=0,049$ ). No correlation was found between the presence of neoplasm and anti ccp presence or erosions ( $p=0,3$  and  $p=0,51$  respectively). In this study, the overall risk of neoplasms in patients with RA was not associated with conventional or biological DMARD's. No differences were found between the type of tumour in RA patients vs non-RA, except for colon cancer, more prevalent in RA patients ( $p=0,03$ ). Only 21 non-RA patients vs 19 RA patients were smokers and for so, it wasn't possible to establish any correlations.

**Conclusions:** In this study we found a prevalence of colon cancer in RA patients, as was found in other studies whoever, the increased risk for lung cancer and lymphoma often reported, was not found. It seems that male sex and the absence of rheumatoid factor are responsible for an increased risk. However we have several limitations: a very small sample, the population of the study was predominately Caucasian. Further studies examining specific aspects such as treatments, smoking or other lifestyle factors are needed to investigate the underlying mechanisms for the increased or decreased risk of specific cancers observed in patients with RA compared with the general population.

#### ARE EULAR RHEUMATOID ARTHRITIS (RA) MANAGEMENT RECOMMENDATIONS APPLICABLE AT THE COUNTRY LEVEL? SIMILARITIES AND DIFFERENCES WITH THE RECENT FRENCH RA MANAGEMENT RECOMMENDATIONS

C. Hua<sup>1,2</sup>, C. Daien<sup>2</sup>, C. Gaujoux-Viala<sup>1,2</sup>, A. Cantagrel<sup>2</sup>, M. Dubremetz<sup>2</sup>, M. Dougados<sup>2</sup>, B. Fautrel<sup>2</sup>, X. Mariette<sup>2</sup>, N. Nayral<sup>2</sup>, C. Richez<sup>2</sup>, A. Saraux<sup>2</sup>, G. Thibaud<sup>2</sup>, D. Wendling<sup>2</sup>, L. Gossec<sup>2</sup>, B. Combe<sup>2</sup>. <sup>1</sup>Nîmes University hospital, EA2415, Montpellier University, Nîmes; <sup>2</sup>SFR Recommendations Working Group, Paris, France

**Background:** Recently, EULAR updated the rheumatoid arthritis (RA) management recommendations.<sup>1,2</sup> In 2018, the French Society of Rheumatology (SFR) updated their recommendations regarding the management of RA.<sup>3</sup> This gave us the opportunity to compare the recommendations.

**Objectives:** To update the 2014 French recommendations for the management of RA and to compare them to the EULAR recommendations.

**Methods:** The SFR approach was based on the literature and on expert opinion. A systematic literature review (SLR) was performed by 2 fellows, collecting data to answer 11 questions. The previous (2014) recommendations were updated by a committee including 11 rheumatologists, 2 patients and 1 healthcare professional, during a 1 day meeting in January 2018. The recommendations were compared to the recently issued EULAR recommendations.<sup>1,2</sup>

**Results:** The SLR included 137 papers. The consensus process led to 4 overarching principles and 15 recommendations. The overarching principles emphasise the need for shared decisions between the rheumatologists and the patient and the importance of a global approach of RA including pharmaceutical and non-pharmacological management. The recommendations address the diagnostic phase of RA, early initiation of disease-modifying antirheumatic drugs (DMARDs) and the usefulness of regular disease activity assessments through validated composite indices with a target of clinical remission or low disease activity. As first strategy, the expert committee recommends methotrexate (MTX). In case of intolerance or inadequate response to MTX, treatment must be optimised. If unfavourable prognostic markers are present, adding a targeted treatment (either biologic or synthetic) can be proposed, at best in combination with MTX; if not, switching to another conventional synthetic DMARD (csDMARD) or combined csDMARDs therapy can be proposed. While waiting for csDMARDs efficacy, short term (less than 6 months) glucocorticoids (GC) can be proposed. Second-line and further treatments and management of remission are also addressed, as well as the importance of managing comorbidities and of non-pharmacological measures.

**Conclusions:** These recommendations are designed to improve the management of RA and are concordant with the recent EULAR recommendations on several items. Main differences concern the place of GC and of combined csDMARD therapy, as well as additional points on diagnosis, non-pharmacological measures, comorbidities and the importance of a global approach.

#### HEPATITIS B VIRUS REACTIVATION IN RHEUMATOID ARTHRITIS PATIENTS WITH HBSAG-NEGATIVE/ANTI-HBC-POSITIVE STATUS

C.-H. Ho<sup>1</sup>, M.H.A. Leung<sup>2</sup>. <sup>1</sup>Department of Medicine; <sup>2</sup>Queen Elizabeth Hospital, Kowloon, Hong Kong

**Background:** Hepatitis B virus (HBV) reactivation in rheumatoid arthritis (RA) patients with positive hepatitis B surface antigen (HBsAg+) is one of the treatment-related complications. The risk of reactivation in patients with negative hepatitis B surface antigen but positive anti-hepatitis B core antibody (HBsAg-/anti-HBc-) is less well defined compared to their HBsAg +counterparts.

**Objectives:** This retrospective, single centre study aimed to study the prevalence of HBV reactivation (defined as HBV DNA becoming detectable) among RA patients with HBsAg+/anti-HBc +status, and to investigate any factors predicting reactivation.

**Methods:** RA patients attending the rheumatology specialist clinic in a local tertiary hospital between 1st January 2011 and 31st December 2016 were included if they had of<sup>1</sup> HBsAg-/anti-HBc +status and<sup>2</sup> undetectable HBV DNA at baseline. Demographic data, clinical parameters including treatments for RA and any use of antiviral prophylaxis, and laboratory results including anti-hepatitis B surface antibody (anti-HBs) and serial HBV DNA levels were obtained. Chi-square (or Fisher exact test if number was less than 5) was used for analysis of categorical variables. Student's t-test and Mann Whitney test were used for analysis of parametric and non-parametric continuous variables respectively.

**Results:** Majority (80%) of the 107 included patients included were female and the mean age was 62.5-year-old (SD 12.09). All the patients were receiving disease modifying anti-rheumatic drugs (DMARDs), 43% of which (n=46) were on biological therapy (with or without concomitant synthetic DMARDs) and the remaining (n=61) were only on conventional synthetic DMARDs (8 on monotherapy, 53 on combination therapy). As antiviral prophylaxis was not mandatory in HBsAg-/anti-HBc +patients according to local guideline, only 13 patients (12.1%) were on antiviral cover (12 on entecavir and 1 on lamivudine).

Ten patients (9.3%) experienced HBV reactivation during their disease course. Three of them were on antiviral prophylaxis and four had positive anti-HBs. All of these reactivations were only transient low-grade viraemia with HBV DNA level <20 IU/ml. Spontaneous resolution of viraemia in less than 12 months' time were observed in all of these patients. None of the reactivation resulted in any adverse clinical event including acute hepatitis, hepatic failure or mortality.

Among all synthetic and biological DMARDs, only the use of methotrexate was found to be a significant predictor of HBV reactivation ( $p<0.05$ ). Other parameters including age, the lack of antiviral prophylaxis, negative anti-HBs status and anti-HBs titre did not predict HBV reactivation.

**Conclusions:** HBV reactivation among RA patients with HBsAg-/anti-HBc +status and undetectable HBV DNA at baseline was infrequent. Reactivation may occur in patients with positive anti-HBs or on antiviral prophylaxis, but was unlikely to be associated with adverse clinical outcome. The use of methotrexate was a predictor of HBV reactivation in these patients.

### ASSESSMENT OF NUTRITIONAL STATUS IN WOMEN WITH RHEUMATOID ARTHRITIS MEASURED BY DUAL ENERGY X-RAY ABSORPTIOMETRY

D. Reina<sup>1</sup>, C. Gómez Vaquero<sup>2</sup>, J.M. Nolla<sup>2</sup>. <sup>1</sup>Rheumatology, Consorci Sanitari Integrat; <sup>2</sup>Rheumatology, Hospital Universitari de Bellvitge, barcelona, Spain

**Background:** As many other chronic diseases, rheumatoid arthritis (RA) has been related to an impairment of the nutritional status of multifactorial etiology. Even if Body Mass Index (BMI) has traditionally been used, it is not always a valid method, and there are still lots of questions without answer in how to evaluate ideally the nutritional status in these patients. Only very few studies had evaluated it by Dual Energy X Ray Absorptiometry (DXA).

**Objectives:** 1) To evaluate the nutritional status in women with RA and to compare with a population of same age women without RA using DXA for the analysis of whole body composition, 2) differences between the prevalence of alterations of the nutritional status measured by DXA and by the classical methods used in clinical care, 3) relation of RA time of evolution, inflammatory activity, physical function and dietary intake on altered nutritional status evaluated by DXA.

**Methods:** Case-control study including 89 patients that were diagnosed with RA and a control group (100) composed by patients affected by other non-inflammatory rheumatic diseases as soft tissue diseases. All the clinical charts were revised in order to record the following data: age, BMI, RA duration, history, activity and disability, serum albumin, Dietary intake, Whole body DXA assessment and Skeletal muscle index (SMI).

**Results:** Mean age of patients was 62±8 years. Mean duration of RA was 13.7±9.3 years. Mean DAS28 was 3.7±1.4 and mean Health Assessment Questionnaire was 0.88±0.77. BMI of the patients was 27.43±5.16 and 27.78±3.98 in controls (p: ns). Albumin was within normal range in all patients.

RA patients presented a statistically significant lower lean mass than controls in all locations and lower fat mass in limbs, along with a higher fat trunk.

RA duration was found to be inversely correlated to BMI and lean mass and directly correlated with fat mass.

Neither BMI nor albumin correlated with DXA parameters.

RA patients fulfilled criteria of sarcopenia in 44% of de cases vs 19% of controls (p<0,001). In RA patients, regarding SMI, BMI showed a high specificity to detect sarcopenia (94% of the patients with low BMI had sarcopenia) but low sensitivity (47% of the patients with normal or overweight BMI had sarcopenia).

**Conclusions:** RA patients have an impairment of nutritional status associated to time of evolution that resembles sarcopenia and that is not predicted by BMI.

AB0338

### CLINICAL CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO USED COMPUTER TERMINALS FOR SELF-ASSESSMENT OF DISEASE ACTIVITY AND QUALITY OF LIFE

E. Pogozeva, V. Amirdzhanova, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Objectives:** To present the clinical features, pharmacotherapy, activity and quality of life in pts with rheumatoid arthritis (RA) who used computer terminals for self-assessment of pts with rheumatic diseases.

**Methods:** The study included 976 RA patients from the cohort of "TERMINAL" multicenter study, envisaging pts' self-assessment of disease activity and quality of life using a designated computer system ("Computer terminals for self-assessment of pts with rheumatic diseases) before the visit to the rheumatologist. Mean age 52,3±13,3 years, mean disease duration 10,2±8,5 years, 85% female. Baseline clinical parameters and pharmacotherapy were assessed, as well as disease activity (using DAS 28 and RAPID-3), and quality of life (using HAQ and EQ-5D).

**Results:** 83% of pts were RF positive, and 60% ACCP positive. Almost all (91,2%) pts received conventional DMARDs. 70,2% of them received methotrexate: 56,7% 15 mg/week and 13,5% >15 mg/week (from 17,5 to 40 mg/week). 20,5% pts were treated earlier with low doses of glucocorticoids. 6,6% pts received Infliximab, 16,4% – Rituximab and 9,8% pts were treated with more than 1 biological agent in anamnesis. 46,2% of pts had high disease activity, 40,9% moderate, 4,5% low and 1,5% pts achieved clinical remission (mean DAS28 score 4,2±1,8, RAPID 13,6±3,6). Only 14,3% pts achieved general population HAQ values. The remaining showed significant reduction in the quality of life (mean HAQ 1,7±0,9, EQ-5D 0,6±0,2). 7,4% of the pts had prosthetic joints.

**Conclusions:** In the studied population almost all patients were treated with DMARDs (mostly methotrexate), and about 30% received biological agents. High to moderate disease activity and reduction in quality of life were typical for this population. Persistence of disease activity and functional insufficiency in pts who received DMARD therapy may be explained by poor monitoring in real clinical practice. The introduction of computer system for self-assessment of disease activity and quality of life in the out-patient facilities will improve the interaction

between doctors, nurses and patients, providing better control of therapy efficacy in RA patients.

### SARCOPENIA AND EARLY FRAILITY SYNDROME IN RHEUMATOID ARTHRITIS

E. Trujillo<sup>1</sup>, M.R. Garcia-Marrero<sup>2</sup>, M.I. Fuentes<sup>2</sup>, M.D.M. Trujillo<sup>3</sup>. <sup>1</sup>Servicio de Reumatología, Hospital Universitario de Canarias, la laguna; <sup>2</sup>Gerencia de Atención Primaria, Tenerife; <sup>3</sup>Funcanis, Fundación Canaria de Investigación, Canarias, Spain

**Background:** Sarcopenia and frailty are common in older persons and pose particular challenges for health and social care systems.

Sarcopenia, the loss of skeletal muscle mass, is a core component of physical frailty that together impact negatively on an individual's capability to live independently.

Frailty is defined as a syndrome of physiological decline in late life, characterised by marked vulnerability to adverse health outcomes. Frail adults are less able to adapt to stressors such as acute illness or trauma than non-frail adults. This increased vulnerability contributes to increased risk for multiple adverse outcomes, including procedural complications, falls, institutionalisation, disability, and death.

Rheumatoid arthritis (RA) is a chronic disabling disease, which leads to functional limitations and diminishes health-related quality of life. The presence of comorbidity and polypharmacy are both related to RA severity.

**Objectives:** The aim of this study was to assess the prevalence of sarcopenia and frailty syndrome in patients with RA.

**Methods:** Cross-sectional, observational and descriptive study in patients with RA (ACR criteria) older than 50 years.

Sarcopenia was defined as per the European Working Group on Sarcopenia in Older People definition as Skeletal muscle mass index (SMI) ≤8.87 kg/m<sup>2</sup> in men and ≤6.42 kg/m<sup>2</sup> in women. Body composition analysis was performed using bioelectrical impedance analysis (BIA).

Fragility was measured according to the 5 criteria proposed by Fried, using the Frail scale, and it was considered fragile to the patient who met at least 3 and pre-fragiles to those who met at least 2.

Frail scale: Based on five items, reflecting performance, self-reports and common co-morbidities (Morley JE et al. *J Nutr Health Ageing* 2012;16(7):601–8).

**FRAIL SCALE**

Did you feel worn out? or Did you feel tired?

Ability to climb one flight of stairs

Ability to walk 100 m

Self-report of >5% wt loss

≤5 of: dementia; heart Disease; depression; arthritis; asthma; bronchitis/emphysema; diabetes; hypertension; osteoporosis; stroke.

**Results:** 283 consecutive RA patients were included, 83.4% were female. Mean age was 63.3 years and mean disease duration was 10.4 years.

Mean number of comorbidities was 1.48, with systemic hypertension and obesity as the most frequent ones (33.8% and 26.4%, respectively). Polypharmacy was found in 96.8% and 64.7% received more than five drugs simultaneously.

31% presented some degree of sarcopenia. 21.5% met frailty criteria (42% in ≥65 years old patients).

**Conclusions:** Prevalence of sarcopenia and frailty syndrome in this study was high. Rheumatologists should make an early detection of signs of frailty.

The screening and early detection of frailty can spur reforms to make routine care less hazardous, can focus on outcomes most relevant to patients and can aid in understanding effectiveness of health care interventions, including at the population level.

### ASSOCIATION BETWEEN MICROALBUMINURIA AND METABOLIC SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Baraka<sup>1</sup>, S. Abdel Moneim<sup>1</sup>, R. El Tanawy<sup>1</sup>, A. Shoshan<sup>1</sup>, Y. Ismail<sup>2</sup>. <sup>1</sup>Rheumatology, Rehabilitation and Physical medicine; <sup>2</sup>clinical pathology, Benha Faculty of Medicine, Benha University, Cairo, Egypt

**Background:** Rheumatoid arthritis (RA) is an autoimmune, symmetrical polyarticular disease characterised by chronic inflammation of the synovial joints. Microalbuminuria (MA) occurs as a leakage of small amounts of albumin into the urine. Metabolic syndrome (MetS) describes risk factors for cardiovascular diseases such as dyslipidaemia, obesity, hypertension and diabetes.

**Objectives:** The aim of this study is to detect the prevalence of MA in patients with RA and study its correlation with disease activity and severity. Our aim extends to identify the association of MA with MetS in rheumatoid arthritis

**Methods:** This study was carried out on 30 adult RA patients, 30% male patients and 70% female patients (mean  $\pm$ SD 42.27 $\pm$ 10.99 years). Their mean disease duration was 12.8 $\pm$ 7.06 years. Twenty apparently healthy adults of matched age and sex served as a control group. All the patients were subjected to full history taking, full clinical examination, laboratory investigations and assessment of disease activity using DAS 28 Score. Urinary microalbumin level was measured in all subjects in early morning samples by the immunoturbidometry method. MetS was assessed in all subjects according to Grundy's criteria.

**Results:** The RA patients' group had highly significantly ( $p < 0.001$ ) elevated mean values of urinary microalbumin and urinary albumin to creatinine ratio compared to the control group (63.9 $\pm$ 2.57 mg/dl vs 21.95 $\pm$ 13.88 mg/dl, 46.6 $\pm$ 35.28 ug/mg vs 14.9 $\pm$ 11.45 ug/mg respectively).

The frequency of the metabolic syndrome according to Grundy's criteria was 60% in the RA patients' group. This frequency was highly statistically significant ( $p < 0.001$ ) compared to the control group (10%). The MetS was prevalent in 13/15 (87%) of RA patients with microalbuminuria (MA), while 5 normo-albuminuric RA patients (33%) had the MetS. A statistically significant difference was observed among these groups ( $p < 0.05$ ). On the other hand, 13/18 (72%) of RA patients with MetS had MA.

Although RA patients with MA had and increased mean values of disease duration, body mass index, waist circumference, fasting blood sugar, triglycerides, high density lipoprotein, DAS 28 and Larsen's score, they had no statistically significant differences compared to normo-albuminuric patients.

RA patients with the MA had a statistically significantly higher mean disease duration ( $p = 0.004$ ) than patients without the MetS. There were highly statistically significant positive correlations ( $p < 0.001$ ) of urinary microalbumin levels with disease duration, duration of morning stiffness, number of tender joints, number of swollen joints, ESR 1st hour, C-reactive protein, Larsen's score, DAS 28, and A/CR.

**Conclusions:** MA and MetS are frequent in RA, particularly in those with long standing disease. Early detection of albuminuria allows early intervention with the goal of reducing inflammation development in RA, CV risk. MetS is frequent in RA patients with MA.

#### AB0341 METATARSOPHALANGEAL JOINTS HAVE MORE EROSIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Alagoz, E. Emlakcioglu<sup>1,2</sup>, A.C. Tunc<sup>3</sup>, on behalf of Meram Study Group, A. Kucuk<sup>2</sup>, on behalf of Meram Study Group, T. Gulen<sup>2</sup>, M. Kocabas<sup>2</sup>, R. Tunc<sup>2</sup>, on behalf of meram study group. <sup>1</sup>Internal Medicine, <sup>2</sup>Rheumatology, Meram Tip Fakültesi, Konya; <sup>3</sup>Academy of Sports Science, Gazi University, Ankara, Turkey

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease characterised by destruction of synovial joints, especially in the hand and feet, leading to severe disability and premature mortality. The erosions seen in RA differentiate it from other rheumatological diseases.

**Objectives:** The aim of the study was to evaluate the relationship between attack frequency and erosions seen in RA.

**Methods:** Forty-four patients according to 2010 ACR/EULAR Classification Criteria for RA were included into the study. Involved joints and number of attacks were recorded. The X-rays of the involved joints were assessed on admission and after 3 months in terms of joint erosion as a blinded manner. Comparison of erosions were calculated by chi-square.

**Results:** Kappa value of intra-observer agreement of reading of x-ray films was 0.68. Erosions were detected in 16 of 44 patients with RA. The Ratios of erosion in joints with more than 10 attacks were different according to involved joints. The ratios of erosions were 10% for metacarpophalangeal (MCP), 8% for proximal interphalangeal (PIP), 0% for knee, 5% for ankle and 69% for metatarsophalangeal (MTP) joints. When compared MTP joints with MCP, PIP and wrist joints, it was seen that the erosion rate was higher in MTP joints than the other joints ( $p < 0.01$ ). Knee and ankle joints were combined as a single group and compared with MTP joints in terms of erosion. It was seen that the erosions in the MTP joints were significantly higher than the erosions in the knee and ankle joints ( $p < 0.01$ ).

**Conclusions:** In RA, the erosion ratio of MTP joints was significantly higher than seen in MCP, PIP and wrist joints. On the other hand the erosion rate in knee and

ankle joints was rare. These results show us the erosion in MTP joints may not related to mechanical overload. Therefore foot imaging with x-ray may be important in the following of patients with RA. In addition existence of false positive erosions in MTP joints of healthy people should be studied.

#### AB0342

#### THE CHRONIC HAND PAIN IN RHEUMATOID ARTHRITIS, OSTEOARTHRITIS, AND FIBROMYALGIA: THE ROLE OF CENTRAL SENSITISATION

F.F. Ayhan<sup>1,2</sup>, M.A. Güler<sup>1</sup>, Ö. F. Çelik<sup>1</sup>. <sup>1</sup>Department of Physical Medicine and Rehabilitation, Divisions of Rheumatology, Pain Medicine, Health Science University, Ankara Health Research and Training Hospital, Ankara; <sup>2</sup>Department of Physical Therapy and Rehabilitation, Usak University, High School of Health Sciences, Usak, Turkey

**Background:** Modern pain medicine divided chronic pain as nociceptive, neuro-pathic, central sensitisation (CS) and mixed pain. CS syndromes are a group of disorders characterised by chronic non-neuropathic and non-nociceptive pain.<sup>1</sup> Central sensitisation inventory (CSI) suggest the tool generates reliable and valid data that quantify the severity of several symptoms of CS.<sup>2</sup>

**Objectives:** Hand pain in RA, OA, and FMS have different features. The aim of this study was to show the role of CS pain in these patients.

**Methods:** Totally 151 patients with chronic hand pain (56 RA, 45 OA, and 50 FMS) were included. CSI was used for evaluation of CS.<sup>2,3</sup> CSI consists of 2 parts: CSI-A scoring 0–100 and CSI-B including 10-CS related syndromes (restless leg, chronic fatigue, fibromyalgia, temporomandibular disorders, migraine/tension type headache, irritable bowel, multiple chemical sensitivity, whiplash, anxiety/panic attack, and depression).

**Results:** Sixteen patients (28.57%) had active (DAS28  $\geq$  2.6) RA. Disease activity was not related with CSI-A and CSI-B scores. Rheumatoid hands was less painful compared with them of OA and FMS ( $p < 0.001$ ). The CS pain was detected in most of the patients with FMS, compared with OA and RA patients ( $p < 0.001$ ). Similarly, CSI-A score was the highest in patients with FMS group ( $p < 0.001$ ) and similar in both OA and RA groups ( $p > 0.05$ ). CS-related syndromes were also detected in both RA and OA groups, but less than FMS group ( $p < 0.005$ ). The numbers of CS syndromes were similar in both RA and FMS ( $p = 0.084$ ) and higher than OA group ( $p = 0.036$ ). Table 1 shows the demographic and pain parameters in all groups. CSI-A score was correlated with VAS-pain score ( $r = 0.364$ ,  $p < 0.001$ ).

**Conclusions:** Central sensitisation should be considered in patients with chronic persistent pain, not only having FMS, but also half of the patients having RA and OA. It is not a rare phenomenon and if it exists, effective pain management strategies could be needed in addition to the specific pharmacologic treatment.

#### MYOCARDIAL INVOLVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS EVALUATED BY TWO-DIMENSIONAL SPECKLE TRACKING ECHOCARDIOGRAPHY BEFORE AND AFTER 18 MONTHS OF TREATMENT WITH ANTI-TNF DRUGS

F. Atzeni<sup>1</sup>, L. Gianturco<sup>2</sup>, L. Boccassini<sup>3</sup>, P. Sarzi-Puttini<sup>3</sup>, M. Turiel<sup>4</sup>.

<sup>1</sup>Rheumatology Unit, University of Messina, Messina; <sup>2</sup>Cardiology Unit, "Beato Matteo" Hospital, GSD Hospitals, Vigevano (PV); <sup>3</sup>Rheumatology Unit, L. Sacco University Hospital; <sup>4</sup>Cardiology Unit, IRCCS, Galeazzi Orthopedic Institute, Milan, Italy

**Background:** Cardiovascular (CV) mortality and morbidity is increased in rheumatoid arthritis (RA). Studies found a more than two- three-fold higher prevalence of ischaemic heart disease in RA patients compared to controls. However, a number of studies indicate that RA is also associated with various non-atherosclerotic CV manifestations. The inflammatory processes in RA may affect different structures of the heart: the most characteristic lesions are conduction defects, but other less frequent manifestations are pericarditis, cardiomyopathy and valve disease.

**Objectives:** The aim of this study was to evaluate left ventricular myocardial function with two-dimensional speckle tracking echocardiography (STE), in addition to conventional Doppler and tissue Doppler echocardiography, in order to detect subclinical left ventricular myocardial dysfunction in patients with RA.

**Methods:** The study involved 30 outpatients who fulfilled the 2010 ACR/EULAR criteria for RA (11 males and 19 females; mean age 54.63±9.36 years, median disease duration 2 years), at baseline and after 18 months of treatment with anti-TNF drugs and 30 healthy controls matched in terms of age, gender and other anthropometric characteristics. All patients underwent a complete physical examination and routine laboratory analysis. CV risk profiles were assessed by means of standard ECG, conventional and stress trans-thoracic echocardiography with the measurement of CFR, carotid ultrasonography and pulse wave velocity (PWV). Two-dimensional echocardiographic images were obtained using the apical 4-chamber view at a high frame rate of 70–80 frames/s, and three cardiac cycles were stored in cine-loop format for off-line analysis using commercially available QLAB 9 software (Philips Medical System, USA) in order to assess global longitudinal strain (GLS).

**Results:** None of the patients showed any signs or symptoms of CV disease, pulmonary involvement, or any other complication. The results of the speckle tracking analysis were significantly different between the two groups, with GLS being significantly lower in the RA patients compared to healthy controls (GLS%: 18.51±9.63 vs 20.23±2.71; p<0.05). Right and left PWV (PWV right, m/sec: 7.52±1.64 vs 6.85±2.02; p=0.06 and PWV left, m/sec: 7.56±1.60 vs 6.88±2.11; p=0.07) and right and left coronary intima media thickness (cIMT) (cIMT right mm: 0.90±0.22 vs 0.75±0.13; p<0.05 and cIMT left, mm: median 0.89±0.18 vs 0.75±0.09; p<0.05) values were all higher in the RA patients and the differences of cIMT were statistically significant. Furthermore, a significant improvement in GLS in RA patients at 18 months of anti-TNF treatment was observed (GLS%: 18.51±9.63 vs 19.09±9.72 p<0.01).

**Conclusions:** GLS measured by means of speckle tracking echocardiography was impaired in RA patients in the absence of any clinical evidence of CV disease and echocardiographic evaluations negative. This data suggests an early myocardial alteration.

AB0344

#### DOES THE PRESENCE OF ILD INFLUENCE THE CHOICE OF DMARD AND BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS?

F. Coath<sup>1</sup>, S. Siddiqui<sup>1</sup>, A. Himashi<sup>2</sup>, A. Bharadwaj<sup>3</sup>, S. Dubey<sup>2</sup>, F. Hayes<sup>1</sup>, G. Koduri<sup>1</sup>. <sup>1</sup>Rheumatology, Southend University Hospital, Westcliff-On-Sea; <sup>2</sup>Rheumatology, University Hospital Coventry and Warwickshire, Coventry; <sup>3</sup>Rheumatology, Basildon University Hospital, Basildon, UK

**Background:** Interstitial lung disease (ILD) is a progressive fibrotic disease of the lung parenchyma. It is the only complication of rheumatoid arthritis (RA) reported to be increasing, accounting for around 7% of all RA deaths.<sup>1</sup> Prognosis of patients with RA-ILD is reported to be poor, with usual interstitial pneumonia (UIP) being the predominant pattern associated with poor survival.<sup>2</sup> It is a challenge to determine specific pattern of ILD and formulate an appropriate treatment plan to achieve stabilisation. Early use of Methotrexate (MTX) and biologics in RA has improved outcomes and quality of life. However, this causes difficulty when RA patients develop ILD. There are reports of ILD with biologics and DMARDs, although it is difficult to establish a causal relationship or if an exacerbation of pre-existing ILD. There are no evidence based guidelines regarding introducing biologics in such patients and clinicians face a dilemma as to whether they should be denied.

**Objectives:** The aim of this retrospective study is to:

- Check the overall management of RA and ILD.
- Examine whether ILD diagnosis influences treatment of RA.

**Methods:** We reviewed 37 patients with RA-ILD from 3 hospitals (2001–2017). We collected data on demographics, clinical, Pulmonary function tests, imaging, time from diagnosis to treatment and outcomes.

**Results:** The majority developed ILD after RA except for 3 patients. Mean age of onset of RA was 67 years, 22 (60%) were female. 32 (87%) were RF or ACPA positive, 25 (68%) patients smoked. 29 (78%) patients had baseline PFTs. HRCT showed 13 had NSIP, 20 UIP and 4 were unclassified. Following the diagnosis of ILD, MTX was stopped in 16 patients, reduced in 3 and unchanged in 2. Leflunomide was stopped in 4 and SLZ stopped in 4, of which 1 had definite alveolitis. Infliximab was stopped in 2 patients.

**Specific Treatment for ILD:** 12 patients received Rituximab, of those 8 were for ILD and 4 for RA. 4 Patients continued Anti-TNF. 26 patients received steroids, 4 received MMF and 2 Cyclophosphamide. 2 received Abatacept for ILD with active RA and one received Etanercept. 3 were on Carbocysteine, 2 on NAC and 3 on oxygen.

**Outcomes:** 20 ILD patients were stable and 8 (21%) progressed and died despite treatment. RA disease activity was low to moderate in 23 patients. RA progressed in 8 patients and 1 who received Etanercept was in remission. MTX was stopped in the majority of patients. Steroids were the commonest treatment for RA in the presence of ILD. Rituximab was the drug of choice for RA with severe ILD, followed by MMF and Cyclophosphamide. DMARDs such as HCQ, Leflunomide and SLZ were used for RA in milder ILD and biologics were generally avoided.

**Conclusions:** There appears to be significant variation in the treatment of RA in the presence of ILD. However Rituximab seems to be the preferred option for severe ILD. There is a need for stratified and standardised guidance for management of RA-ILD.

#### DOES IRON DEFICIENCY CONTRIBUTE TO FATIGUE OF PATIENTS WITH RHEUMATOID ARTHRITIS WITHOUT ANAEMIA?

F. Vidal<sup>1</sup>, A. Gillibert<sup>2</sup>, M. Quillard<sup>3</sup>, P. Fardellone<sup>4</sup>, S. Pouplin<sup>1</sup>, O. Vittecoq<sup>1</sup>, T. Lequerré<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Biostatistics; <sup>3</sup>Biochemistry, Rouen University Hospital, Rouen; <sup>4</sup>Rheumatology, Amiens University Hospital, Amiens, France

**Background:** Iron deficiency (ID) without anaemia is a cause of fatigue, which is itself a recurring complaint of patients with rheumatoid arthritis (RA).

**Objectives:** The objective of the study was to determine the prevalence of ID in patients with RA without anaemia and to analyse the relationship between ID with fatigue, disease activity and depression.

**Methods:** This study included patients with RA according to the ACR/<sup>EULAR</sup> 2010 classification criteria (American College of Rheumatology/European League Against Rheumatism) followed up in the Rheumatology Department of Rouen University Hospital and who had a haemoglobin >12.5 g/dl. Patients were either from the single-centre monocentric longitudinal cohort or from the seventh visit of the VERA (Very Early Arthritis) High-Norman regional cohort. For each patient of the longitudinal cohort, DAS 28 ESR (Disease Activity Score – erythrocyte sedimentation rate) the FACIT – version 4 fatigue score (Functional Assessment of Chronic Illness Therapy) and a depression score (Hospital Anxiety and Depression Scale) were collected. Serum ferritin, transferrin, serum iron and saturation coefficient of transferrin were measured for each patient. ID was defined as serum ferritin <50 µg/L.

**Results:** One hundred and forty-one patients were included in the longitudinal cohort (78.7% women, mean age 13.50±9.51 years, positive rheumatoid factor and anti-citrullinated peptide antibodies in 83.6% and 86.5% of patients) and 74 RA patients from the VERA cohort (70.3% women, mean disease duration 2.74 ±0.24 years). The prevalence of ID was 15.6% in the longitudinal cohort (n=22/141) and 14.9% in the VERA cohort (n=11/74). In the longitudinal cohort, there were no significant differences between ID patients and non-deficient patients in fatigue (mean FACIT of 27.80±12.4 vs. 32.3±12.0; p=0.14), disease activity (mean DAS 28 VS 2.85±1.38 vs. 2.96±1.48; p=0.74) and depression (mean HAD score 5.86±4.12 vs. 5.80±3.84; p not calculated).

**Conclusions:** The prevalence of ID without anaemia was similar between early and old RA and was similar to that of the general French adult population (15.5%).<sup>1</sup> ID does not appear to be a major cause of fatigue in RA and does not affect the activity of the disease. The search for an ID is of limited value in exploring fatigue of RA patients.

#### AB0346 INVESTIGATION OF ALEXITHYMIA IN PATIENTS AFFECTED BY RHEUMATOID AND PSORIATIC ARTHRITIS: CROSS-SECTIONAL OBSERVATION

G.L. Fonti, M.S. Chimenti, P. Conigliaro, J. Hitaj, M. Galluzzo, M. Talamonti, B. Kroegler, E. Greco, R. Perricone. *Policlinico Tor Vergata, Rome, Italy*

**Background:** Rheumatoid arthritis (RA) and Psoriatic arthritis (PsA) are chronic inflammatory diseases that lead to an overthrow of articular structure, functional limitation and disability. Alexithymia is a personality trait characterised by deficits in cognitive processing and regulation of emotions. A broad association between alexithymia and symptoms as depression, inflammation and pain has been demonstrated.

**Objectives:** to evaluate the prevalence of alexithymia in patients affected by Rheumatoid and Psoriatic arthritis.

**Methods:** We prospectively enrolled, from January to December 2017, patients affected by RA diagnosed according to the ACR revised criteria and PsA diagnosed according to the CASPAR criteria referred to the out-patients clinic of the Rheumatology Unit of Policlinico Tor Vergata, Rome. The 20-item Toronto Alexithymia Scale (TAS-20) was used to assess alexithymia. Disease activity, function and quality of life, clinimetric tests as well as ESR and CRP were assessed.

Statistical comparisons were performed using Pearson's Coefficient of Skewness, the unpaired t-Test and Mann-Whitney test.

**Results:** A total of 50 RA patients and 51 PsA patients were enrolled (table 1). The TAS-20 score showed that 38.6% (39/101) of patients had alexithymia, 26.7% (27/101) patients were in the borderline of alexithymia and 34.7% (35/101) patients had not alexithymia. A statistical significant association was observed between alexithymia and inflammatory indexes (ESR: p=0.029, CRP: p=0.043, figure 1 and 2) and also between alexithymia and clinimetric parameters (ptVAS, pVAS, GH, p<0.0001 for all comparisons). No correlations were observed between alexithymia and disease duration, gender, therapies with bDMARDs. A significant trend has been demonstrated between alexithymia and corticosteroidal therapy

**Abstract AB0346 – Table 1.** Characteristics, therapies and clinimetric evaluation of the study population

	RA	APs	Total
Female Sex - No. (%)	41 (40.6%)	31 (30.7%)	72 (71.3%)
Male Sex- No. (%)	20 (19.8%)	9 (8.9%)	29 (28.7%)
Age (years) (in mean ± (DS))	59.5 ± (11.46)	52.6 ± (12.84)	56 ± (12.66)
Mean Disease Duration ± (DS)	6.19 ± (3.82)	6.29 ± (3.96)	6.24 ± (3.89)
Patients on csDMARDs - No. (%)	10 (9.9%)	34 (33.6%)	44 (43.5%)
Patients on bDMARDs - No. (%)	12 (11.8%)	38 (37.6%)	50 (49.5%)
Patients on steroids - No. (%)	37 (36.6%)	12 (11.9%)	49 (48.5%)
patient VAS (0-100)	42.6 ± (20.95)	58.23 ± (26.52)	50.49 ± (25.17)
pain VAS (0-100)	38.1 ± (20.87)	56.9 ± (26.59)	47.59 ± (25.71)
GH (0-100)	44 ± (23.08)	49.7 ± (22.58)	46.88 ± (23.01)

Data are expressed as Mean ± Standard Deviation; csDMARDs: conventional synthetic disease-modifying antirheumatic drugs; bDMARDs: biological disease-modifying antirheumatic drugs; VAS: Visual Analogic Scale; GH: Global Health; percentages calculated for total population.

**Abstract AB0346 – Figure 1**

**Conclusions:** This study suggests that alexithymia assessment should be a part of the comprehensive care of patients with RA and PsA. We are in the process of extending this investigation on a larger sample population to improve our investigation field and to consolidate our dates.

#### AB0347 BODY COMPOSITION IN PATIENTS WITH RHEUMATOID ARTHRITIS KAZAKH NATIONALITY

G. Gabdulina, A. Tokarev, D. Mussabaeva. *Kazakh Medical University, Almaty, Kazakhstan*

**Background:** Chronic inflammation in rheumatoid arthritis (RA) leads to a decrease in fat and muscle mass [Baker J.F., Von Feldt J. Mostoufi-Moab S. et al., 2014 Low muscle mass in RA is considered as the main criterion of sarcopenia.

Recently, much attention has been paid to various phenotypes of sarcopenia, among which osteopenic sarcopenia, sarcopenic obesity and osteosarcopenic obesity (most unfavourable in terms of functional disorders) are distinguished.

In the modern literature there are works devoted to changes in the composition of the body in the aspect of abdominal obesity and its influence on cardiovascular risk in RA [Crowson C.S., Myasoedova E., Davis J.M., 2011]. Studies with the evaluation of muscle mass and sarcopenia in RA are few. In Kazakhstan, the composition of the human body was not studied.

**Objectives:** The purpose of the study was to study the body composition (muscle and fat mass) of patients with RA of Kazakh nationality using bioelectrical impedance analysis.

**Methods:** In our study we used Bioimpedance analyzer 101 (BIA 101, Italy).

Bioimpedansometry was performed in 585 participants, including 295 patients with RA and 290 of their siblings.

**Results:** In patients with RA, in contrast to the comparison group (sibs), BMI (pro-bands – 25.34±5.1, siblings – 24.86±4.45), the girth of the waist and hips were slightly higher than those of the siblings. The ratio of RT/OB in both groups was virtually the same. At the same time, a decrease in the lean mass was found

(probands – 45.37±12.2, siblings – 48.67±11.01), which, in all probability, is due to sarcopenia. The presence of sarcopenia is also confirmed by a decrease in the sarcopenia index (probands 0.6884±0.1, sibs 0.6947±0.1). On the contrary, the fat content of RA patients is higher than that of siblings.

**Conclusions:** Thus, in our patients cachexia is formed in RA, which is characterised by loss of muscle mass with the preservation or even growth of fat mass, which stabilises body mass indexes, and in some cases even leads to its increase (so-called cachexial obesity).

#### AB0348 GRIP POWER AND INDEPENDENT DAILY LIVING IN THE PATIENTS WITH RHEUMATOID ARTHRITIS

H. Ishikawa<sup>1</sup>, A. Abe<sup>1</sup>, T. Kojima<sup>2</sup>, M. Kojima<sup>3</sup>, N. Ishiguro<sup>2</sup>, S. Ito<sup>1</sup>, A. Murasawa<sup>1</sup>. <sup>1</sup>Rheumatology, Niigata Rheumatic Center, Shibata city, Niigata; <sup>2</sup>Orthopedic Surgery, Nagoya University Hospital; <sup>3</sup>Medical Education, Nagoya City University Hospital, Graduate School of Medicine, Nagoya city, Japan

**Background:** Grip power is known to be a simple and useful objective index that can be used in the self-assessment of disease activity in patients with rheumatoid arthritis (RA)<sup>1</sup>. However, the clinical significance of this physical function is unknown.

**Objectives:** The objective of this study was to clarify the relationship between the grip power and the level of activities of daily living (ADL).

**Methods:** The grip power was measured in 221 inpatients of our hospital with RA using a mercury dynamometer. The independence level (0: impossible, 1: incomplete and not practical, 2: practical but the means thereof are unusual, 3: normal) for 44 ADL items, including most daily activities was investigated. For each item, the site with the problem (shoulder, elbow, forearm, wrist, thumb, fingers, lower extremity and trunk) and cause of disability (pain, loss of power, decreased range of motion, abnormal prehensile pattern and fatigue) were investigated by interviewing the patient. There were 33 male and 188 female patients. The average age of the patients was 64.6 years, and the average duration of the disease was 13.3 years. Biological therapy had been given to 23% of the patients. The average grip power of the right and left hands was used.

**Results:** There were 14 items requiring others' assistance (level 0 or 1) in more than 10% of patients. For these 14 items of ADL, the grip power increased with the increase in the independence level ( $p < 0.001$ )<sup>2</sup>. The site with a problem was, in order of frequency, the fingers (26.1%), wrist (14.8%) and lower extremity (14.0%). The cause of disability was, in order of frequency, pain (38.8%), loss of power (32.8%) and a decreased range of motion. Based on the results of a stepwise regression analysis, the first factor, consisting mainly of "reaching function", including "hair dressing", "washing one's body", "taking on and off one's shoes", "clipping nails", "buttoning", etc., was most strongly related to a loss of grip power and problems at the elbow, the shoulder and the wrist. The second factor, consisting mainly of the "prehensile function", including "opening a plastic bottle", "opening lids", "squeezing towels", etc., was most strongly related to a loss of grip power and problems at the wrist and the thumb. The third factor, consisting mainly of "activities involving changing body position and transfer", including "getting in and out of the bathtub", "standing and sitting", etc., was most strongly related to ageing and problems with the lower extremities and at the elbow and the wrist. In the receiver operating characteristic (ROC) curve, the grip power with the maximum Youden index was 136.5 mmHg (11.8 kg) in females and 152.5 mmHg (13.5 kg) in males. Most activities were performed independently with the grip power more than 136.5 mmHg in females (figure 1). The explanatory variables for the grip power in the female patients were ageing; a long disease duration; a high disease activity score (DAS) 28; problems at the fingers, the thumb and the elbow; decreased flexion at the shoulder and a decreased range of forearm rotation.

**Abstract AB0348 – Figure 1.** Minimally required grip power to perform daily activities independently in females with level 3 after age adjustment

**Conclusions:** The grip power was a determinant of independent daily living in patients with RA in our study.

#### AB0349 OTO-RHINO-LARYNGOLOGICAL MANIFESTATIONS OF RHEUMATOID ARTHRITIS

S. Zrou<sup>1</sup>, H. Mouana<sup>1,2</sup>, N. kolsi<sup>3</sup>, H. Hachfi<sup>2</sup>, A. Arfa<sup>1</sup>, M. Jguirim<sup>1</sup>, I. Bejjia<sup>1</sup>, T. Mongi<sup>1</sup>, M. Youness<sup>2</sup>, J. Koubaa<sup>3</sup>, N. Bergaoui<sup>1</sup>. <sup>1</sup>Rheumatology Departement of Monastir University Hospital, Monastir; <sup>2</sup>Rheumatology Departement of Mahdia University Hospital, Mahdia; <sup>3</sup>ENT Departement of Monastir University Hospital, Monastir, Tunisia

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disorder that can damage a wide variety of body systems. Ear, nose and throat (ENT) involvement is frequent but not often reported. The purposes of our work are to determine the prevalence of ENT involvement during RA and to evaluate its correlation with RA disease activity.

**Objectives:** The purposes of our work are to determine the prevalence of ENT involvement during RA and to evaluate its correlation with RA disease activity.

**Methods:** This is a cross-sectional study of 90 consecutive RA, followed at the Rheumatology department of Monastir Teaching Hospital in Tunisia, during 06 months (November 2016 to April 2017) and 46 matched volunteers. ENT clinical examination with tonal audiometry and thyroid tests (TSH, T4, anti-Thyroperoxidase Ab (Anti TPO Ab) and Anti-Thyroglobulin Ab (Ab anti Tg) were performed.

**Results:** ENT involvement prevalence was 78%. The most frequent functional signs were intermittent dysphonia in 50% and dysphagia in 42% of cases. The neck examination revealed painful larynx mobilisation in 58% cases and cervical lymph nodes in 7% of cases. Indirect laryngoscopy, performed in the 67% of symptomatic patients, noted inflammatory mucosa in 38% of cases and decrease in vocal cord mobility in 8% of cases. Seventy percent patients had temporomandibular Joint (TMJ) involvement. Tonal audiometry revealed 42% of cases of deafness: 27% sensorineural deafness, 13% conductive deafness and 2% cases mixed hearing loss. The ENT manifestations significantly associated to RA compared to the witness group ( $p < 0.01$ ) were intermittent dysphonia, dysphagia, painful larynx mobilisation, inflammatory nasal mucosa, painful TMJ and deafness. Active disease (DAS 28>3.2) is statistically associated with deafness ( $p < 0.048$ ) and TMJ involvement ( $p < 0.009$ ). Logistic regression study shows that RA duration over 10 years was associated to laryngeal dyspnea (OR=4.4,  $p < 0.012$ , IC (95%) [1.377, 14.134]) and deafness (OR=3.8,  $p < 0.03$ , IC(95%) [1.142, 12.882]). In the other hand, RA moderate functional handicap is a protective factor (OR=0.123,  $p < 0.016$ , IC (95%) [0.076, 0.772]) of ENT involvement and biotherapy use was associated to thyroid involvement (OR=7.8,  $p < 0.017$ , IC(95%) [1.431, 43.175]).

**Conclusions:** ENT involvement is a very common, usually asymptomatic extra-articular manifestation during RA. It is, mainly, TMJ involvement, deafness and dysphonia. The main relevant determinants are RA disease activity and duration.

### AB0350 TEMPORO-MANDIBULAR JOINT INVOLVEMENT IN RHEUMATOID ARTHRITIS

S. Zour<sup>1</sup>, H. Mouanaa<sup>1</sup>, A. Arfa<sup>1</sup>, H. Hachfi<sup>2</sup>, M. Jguirim<sup>1</sup>, I. Bejjia<sup>1</sup>, T. Mongi<sup>1</sup>, M. Youness<sup>2</sup>, N. bergaoui<sup>1</sup>. <sup>1</sup>Rheumatology Departement of Monastir University Hospital, Monastir; <sup>2</sup>Rheumatology Departement of Mahdia University Hospital, Mahdia, Tunisia

**Background:** Temporomandibular joint (TMJ) disorder in rheumatoid arthritis (RA) may be associated with significant osteoarticular destruction and may be responsible of significant functional impairment.

**Objectives:** We aimed in this study to determine the prevalence of TMJ involvement and its correlations with RA parameters.

**Methods:** We report a descriptive monocentric cross-sectional study of 90 consecutive RA, followed at the Rheumatology department of Monastir Teaching Hospital in Tunisia, during 06 months (November 2016 to April 2017) and 46 matched volunteers. Clinical assessment and stomatological examination were performed in all cases.

**Results:** Sixty-three RA patients out of 90 (70%) had TMJ involvement. TMJ painful mobilisation, mastication difficulties, swollen TMJ, dental malocclusion and limitation of mouth opening were noted in 55 (81%), 49 (74%), 20 (30.3%), 19 (29%) and 8 (12%) of cases, respectively. Compared with the control group, painful palpation of TMJ ( $p < 0.000$ ) was significantly associated with RA.

In RA, TMJ disorder is more common in adults between 40 and 60 years of age, patients with HAQ>0.5 and a high total Vander Heijde Sharp radiographic score (SS). TMJ painful mobilisation is significantly associated with increased body mass index (BMI). Swollen TMJ is significantly associated with age (more frequent in elderly subjects), increased BMI, high RA disease activity (high DAS 28 ESR and/or DAS 28 CRP) and HAQ>0.5. Limitation of mouth opening is significantly associated with age (more common in elderly subjects), overweight, high methotrexate dose (20 mg/day), leflunomide and biotherapy use. Dental malocclusion was significantly associated with high doses corticosteroids (more than 5 mg/day). Mastication difficulties are significantly associated with more than 10 year RA duration, HAQ>0.5 and radiological impairment.

**Conclusions:** Temporomandibular disorder is frequent in RA (70%). TMJ disorder is observed especially in active (high DAS 28), serious (radiological impairment, HAQ>0.5) and advanced (more than 10 year duration) RA. Physicians must be careful to assess systematically TMJ in RA patients.

### AB0351 DIFFERENTIAL PERCEPTION ABOUT THE CSDMARDs ON DRUG-INDUCED INTERSTITIAL LUNG DISEASE BETWEEN RHEUMATOLOGISTS AND NON-RHEUMATOLOGISTS

H. Kobayashi<sup>1,2</sup>, T. Okubo<sup>1</sup>, H. Oka<sup>1</sup>, A. Aoki<sup>1</sup>. <sup>1</sup>Rheumatology, Tokyo Medical University Hachioji Medical Center, Tokyo; <sup>2</sup>Internal Medicine, Aihara Hospital, Sagami, Japan

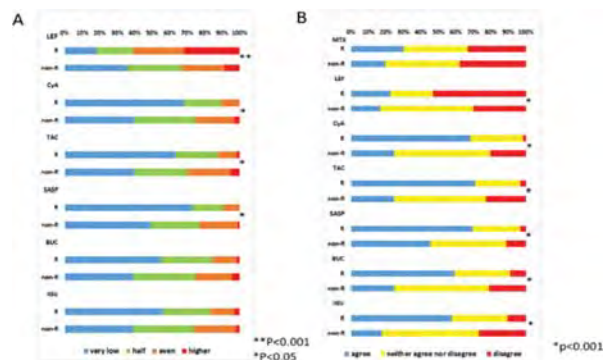

**Background:** As disease modified anti-rheumatic-drugs (DMARDs) were the mainstay in the treatment of rheumatoid arthritis (RA), the opportunity for general physicians to also prescribe DMARDs has recently increased in Japan. After DMARDs were initiated by specialists, subsequent drug prescription by general physicians during remission should be expected<sup>1</sup>. However, general physicians

are more likely than rheumatologists to feel it difficult to accept patients taking even conventional synthetics (cs) DMARDs but not biologics and such discomforts may be potential barriers to cooperative management between specialists and general physicians<sup>2</sup>. One of the reasons is because some csDMARDs such as methotrexate and leflunomide may induce pneumonitis or worsen RA-related pre-existing interstitial lung disease (ILD) as a rare but severe adverse event<sup>3</sup>. To minimise the risk, rheumatologists may choose low-risk csDMARDs smartly when the patients are concomitant with risk factors on ILD.

**Objectives:** To measure the physicians' perspective toward the risk of each csDMARDs on drug-induced ILD and their attitude in prescribing the csDMARDs to a pre-existing ILD case.

**Methods:** A questionnaire was given in an internet survey to registered physicians who take care of more than ten patients with RA in Japan. Topics covered were i) how is the risk of each csDMARD for drug-induced lung injury compared to methotrexate, ii) which csDMARDs should be applied to a case with mild pneumonitis on the chest CT. Cross tabulation analysis and  $\chi^2$  test as a statistical analysis was performed.

**Results:** A total 184 physicians consisting of 66 rheumatologists (36%) and 118 non-rheumatologists (64%) responded. The physicians' mean age was 45 years old. The rheumatologists tended to belong to rheumatology and take care of more than 200 RA patients per month in university hospitals. On the other hand, the non-rheumatologists tended to belong to general medicine and manage less than 50 patients per month in their clinics. The csDMARDs except for methotrexate were more significantly prescribed by the rheumatologists. All rheumatologists but 24% of non-rheumatologists had managed RA patients with exacerbated ILD. On physicians' perspective toward the risk of each csDMARD, the rheumatologists considered that LEF was equal to or higher than MTX and that cyclosporine A (CyA), tacrolimus (TAC), salazosulfapyridine (SASP) was relatively safer (Figure A.). In cases with pre-existing ILD, more rheumatologists agreed to use the csDMARDs except for methotrexate and leflunomide. (Figure B.)

**Abstract AB0351 – Figure 1.** A) Physician's opinion about how is the risk of the following csDMARDs for drug-induced ILD compared to methotrexate. B) Physician's opinion about if the following csDMARDs should be applied to a case with mild ILD on the chest CT.

R: rheumatologists, non-R: non-rheumatologists, MTX: methotrexate, LEF: leflunomide, CyA: cyclosporine A, TAC: tacrolimus, SASP: salazosulfapyridine, BUC: bucillamine, IGU: iguratimod

**Conclusions:** We can find the gap of risk perception about each csDMARDs between rheumatologists and non-rheumatologist and the difference of attitude in prescribing to patients concomitant with risk factors. Considerable consensus and additional enlightenment to general physicians should be necessary.

### SIGNIFICANCE OF OCCULT INFECTIONS IN INFLAMMATORY ARTHRITIS PATIENTS RECEIVING BIOLOGIC THERAPIES IN EAST LONDON

H. Alkomy, G. Qadir, O. Etomi, H. Tahir, A. Pakozdi. *Rheumatology, Barts Health, London, UK*

**Background:** Chronic hepatitis B virus (HBV) infection remains a significant global health problem. In high endemic areas like African and Asian countries, most infections occur from vertical transmission, whilst in western countries HBV is primarily acquired in adulthood. Either way, HBV can persist in infected hepatocytes lifelong, even if undetectable in the serum, allowing reactivation during immunosuppression. HBsAg carriers, those with detectable HBV viral load, or receiving concomitant corticosteroids are at greater risk. Most guidelines recommend screening for occult infections prior to starting biologic treatment including testing for HBV, HCV, HIV and TB infection.

**Objectives:** This study was carried out to estimate the prevalence of occult infections, particularly chronic HBV, in an East London rheumatology population receiving biologic therapies, and to evaluate the rate of HBV reactivation after starting treatment.

**Methods:** Inflammatory arthritis patients starting biologic therapies in Barts Health NHS Trust between August 2014 and August 2017 were identified from databases of Whipps Cross and Mile End Hospitals. Health records were reviewed focusing on HBV core antibody (HBcAb), HBV surface antigen (HBsAg), HBV DNA, HCV and HIV antibody status. Latent TB tests included IGRA and ELI-Spot assays.

**Results:** 757 patients were included in the study. Of those, 51 (6.7%) were HBcAb positive, 6 patients (0.8%) were HBsAg positive and two patients had low level HBV viraemia with detectable DNA antibody at baseline. 61% (n=31) of HBcAb positive patients were female, whilst 39% (n=20) were male, with median age of 58 years (IQR, 43–65). The ethnic distribution was the following: 43% asian (n=22; Bangladeshi or Pakistani), 29% african or afro-Caribbean black (n=15), and 18% white caucasian (n=9). The underlying rheumatological conditions included rheumatoid arthritis (59%), ankylosing spondylitis (33%) and psoriatic arthritis (8%). Fifteen patients (29%) received concomitant prophylactic anti-viral therapies (lamivudine, entecavir or tenofovir). After commencing biologic therapies, no HBV reactivation was noted in the HBcAb positive cohort. Intermittent mild transaminitis were detected on monitoring blood tests in 22% (n=11). The rate of latent TB infection was 11.5%; HCV IgG was detected in three patients, whilst HIV infection was absent in our cohort.

**Conclusions:** Approximately 50% of the patient population of Barts Health NHS Trust is coming from minority ethnic groups. Likely because of the diversity of the population, the prevalence of chronic HBV infection (HBsAg and HBcAb positives) in our East London rheumatology population receiving biologic therapies was higher than the national average (0.8% vs. 0.3%, respectively). No HBV reactivation was observed in the follow up period indicating that the risk of reactivation is relatively low. Nevertheless, for patients with evidence of previous infection (HBcAb positive) careful surveillance continues to be recommended.

**Disclosure of Interest:** None declared

### GENETICALLY PREDISPOSITION AND PRO-INFLAMMATORY DYSREGULATIONS – CONNECTING RHEUMATOID ARTHRITIS AND MENTAL DISORDERS

I.C. Filipescu<sup>1</sup>, L. Ghib<sup>1</sup>, P. Juan Sainz<sup>2</sup>, C. Perez-Sanchez<sup>3</sup>, C. Lopez-Pedraza<sup>4</sup>, A. Escudero<sup>5</sup>, L. Damian<sup>1</sup>, L. Muntean<sup>1</sup>, E. Collantes-Estévez<sup>5</sup>, S. Rednic<sup>1</sup>.  
<sup>1</sup>Rheumatology Clinic, University of Medicine and Pharmacy, Cluj-Napoca, Romania; <sup>2</sup>GENYO Centre for Genomics and Oncological Research, University of Granada, Granada; <sup>3</sup>Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), University of Cordoba; <sup>4</sup>Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC); <sup>5</sup>Reina Sofia University Hospital/University of Cordoba, Cordoba, Spain

**Background:** Depressive and anxiety disorders are reported as the more prevalent psychiatric comorbidities in chronic inflammatory diseases and their occurrence has been correlated with higher serum levels of cytokines and chemokines (IL-6, IL-1, IL-12, IL-18, TNF- $\alpha$ , and even TNF-RI and TNF-RII). Some single nucleotide polymorphisms (SNPs) in TNF- $\alpha$  gene have been found to play a common part in pro-inflammatory alterations in patient with rheumatoid arthritis (RA) and depressive symptoms.

**Objectives:** To investigate the possible influence of four single-nucleotide polymorphism in the tumour necrosis factor receptor II (TNFR2) genes and development of psychiatric disorders in patients with active RA. The second aim was to evaluate some correlation between these SNPs, the level of four chemokines and the incidence of mental disorders.

**Methods:** We included 89 Caucasian patients with active RA treated in a tertiary Department of Rheumatology from Cluj-Napoca. All demographic, clinical, and biological data and RA comorbidities were completed. The presence of

depressions or anxiety was confirmed at the baseline by psychiatrist. Four potentially functional SNPs within TNFR2 (rs1061622, rs1062624, rs1061631, rs3397) were selected to be genotyped in all patients using PCR (KASPar) asASys (KBiosciences, Hoddesdon, Hertfordshire, UK) at the Centre for Genomics and Oncological Research (GENYO), Granada, Spain. Plasmatic levels of soluble tumour necrosis factor receptor II (sTNFR2), interleukin (IL)-6, monocyte chemoattractant protein (MCP)-1 and vascular endothelial growth factor (VEGF) was quantified using cytofluorometry-based ELIAS technique in accordance with manufacturer's instructions using FlowCytomix kit (eBioscience, UAS) at Instituto Maimonides de Investigacion Biomedica de Cordoba – Reina Sofia Hospital, Spain.

**Results:** According to DAS28 (CRP) all the patient have active arthritis (5.87  $\pm$  0.6) with median disease duration of 9 (4–14) years. Most of the patients were diagnosed with depression (n=33), 84.8% were female. Anxiety was present at 21 subjects (80.9% female). In 3 cases these two mental disorders coexist.

In a subgroup with depression the polymorphism rs1061631 (GG) was significantly associated with increased level of VEGF (p=0.007). A significant correlation was also found between the polymorphism rs3397 (CC/TT) and MCP-1 level (p=0.01).

In a subgroup with anxiety the significant association was found between the polymorphism rs1061631 (GG) and the level of MCP-1 (p=0.04).

**Conclusions:** Pro-inflammatory dysregulation might be particularly relevant in some patients with RA and psychiatric illness. Amongst genetic factors that influence the susceptibility to the development of RA and psychiatric disorders some single nucleotide polymorphisms (SNPs) in TNF- $\alpha$  gene have been considered with increasing interest. Further investigation in a larger cohort is needed.

### FACTORS OF THE POSITIVE OR NEGATIVE ANSWER ON THERAPY WITH DENOSUMAB IN WOMEN WITH RHEUMATOID ARTHRITIS AND OSTEOPOROSIS

I. Dydykina, P. Kovalenko, A. Smirnov, E. Nasonov. *Nasonova Reumatologic Research Institute, Moscow, Russian Federation*

**Objectives:** To define a contribution of factors: anamnesis, clinical/laboratory markers, glucocorticoids (GC) intake, etc. on the response to therapy with denosumab in women with rheumatoid arthritis (RA) and osteoporosis (OP).

**Methods:** 66 postmenopausal women (mean age 59.6 $\pm$ 7.4) with RA (mean duration 17.7 $\pm$ 10.4 years) and OP received s/c denosumab 60 mg every 6 months pro 1 year. RF- positive were 72%, ACCP – 74% of patients. 34 (49%) continued GC. At baseline and after 12 months it was carried out the dual energy x-ray absorptiometry at 3 sites: lumbar spine (L1-L4), hip neck (HN) and distal forearm (DF) and x-ray of hands and feet (Sharp/van der Heijde (SVH) score). After therapy it was noted the increase of BMD in L1-L4 and HN, a tendency to increase (p=0.0529) in DF. Positive dynamics (increase or stabilisation of BMD) was noted in 89% patients at L1-L4, 67% – at HN and 60% – at DF. The erosion score was increased in 12% (n=8) patients, the joint space narrowing score (JSN) – in 9% (n=6) (p=0.0117 and p=0.027, respectively). The Statistica 6.0 was used.

**Results:** Results of analysis of influence of statistically significant factors on the response to therapy in BMD showed that the negative response in L1–L4 is associated with GC intake (>3 months in anamnesis) (p=0,034) and the beginning of GC intake after menopause onset (p=0,023). In HN positive response is associated with higher concentration of the RF (initially and in dynamics) (p<0,05) and the beginning of menopause later than RA onset (p=0,024), the negative response – with GC intake (>3 months in anamnesis) (p=0,024). In DF positive response on therapy is associated with RF-positivity (p=0,02), the negative response back correlates with increase in erosion score and total SVH score: r=–0360 (p<0,05).

In table 1 it is shown the most significant factors, which influence on SVH score dynamics (increase) after 12 months of denosumab therapy.

**Abstract AB0354 – Table 1.** The factors which influence on SVH score increase (n=66), p<0.05.

SVH score	The score increase is associated with
Erosion score	- lower BMD in L1-L4 (at baseline and after treatment) - higher cumulative GC dose - back correlates with BMD increase in DF - back correlates with bone alkaline phosphatase (BAP) base level - correlates with increase in JSN
Joint space narrowing score (JSN)	- presence at patients in anamnesis a surgical menopause - lower value of BMD dynamics (%) in DF - correlates with increase in erosion score and total SVH score.

**Conclusions:** There was established that positive response on therapy with denosumab in BMD in NH and DF is associated with RF-positivity. The particular contribution to the negative response in L1-L4 and HN is associated with GC intake (previous intake more than 3 months in the anamnesis), purpose of the GC after menopause onset. There was note that the increase of erosion score is associated with either lower BMD in L1-L4 (at baseline and after treatment) or back correlation with BMD increase in DF. Also the higher cumulative GC dose and back correlation with BAP base level were observed at patients with increased erosion score. The only factors that we could reveal in patients with increased JSN score were surgical menopause in anamnesis and lower value of BMD dynamics (%) in DF after treatment. In general it was a direct correlation between erosion score and JSN score.

#### THE RELATIONSHIP BETWEEN HAND PREHENSILE STRENGTH, CLINICAL ACTIVITY AND FUNCTIONAL CAPACITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

I.P. Guzmán Guzmán<sup>1</sup>, J.E. Navarro-Zarza<sup>2</sup>, G.A. Alonso-Silverio<sup>3</sup>, A. Alarcón-Paredes<sup>3</sup>, D. Jerez-Mayorga<sup>4</sup>, I. Parra-Rojas<sup>1</sup>. <sup>1</sup>Facultad de Ciencias Químico Biológicas, Universidad Autónoma de Guerrero; <sup>2</sup>Hospital General; <sup>3</sup>Facultad de Ingeniería, Universidad Autónoma de Guerrero, Chilpancingo, Mexico; <sup>4</sup>Facultad de Ciencias de la Rehabilitación, Universidad Andres Bello, Santiago, Chile

**Background:** The hand is an anatomical structure with a large number of joints; its prehensile grasp capability constitutes a highly specialised biomechanical function. In rheumatoid arthritis (RA), the structures of the joint are damaged by the characteristic inflammatory process<sup>1</sup>. The *Disease Activity Score* (DAS28) considers twenty hand joints in the evaluation of rheumatoid arthritis (RA). While the *Health Assessment Questionnaire* (HAQ) *disability index* (DI) (HAQ-DI) is the most frequently used instrument for measuring self-reported physical function in rheumatoid arthritis and considers the ability to dress and groom, get up, eat, hygiene, reach, grasp, situations in which the functional capability of the hand is crucial.

**Objectives:** To assess the relationship between hand prehensile strength, the DAS28 index and HAQ-DI score in patients with diagnosis of RA.

**Methods:** The prehensile strength was obtained by the dynamometry method from 105 AR patients, the maximum strength levels in the dominant and non-dominant hand were considered. The Disease Activity Score in 28 joints using the erythrocyte sedimentation rate (DAS28-ESR) and HAQ-DI were recorded.

**Results:** The maximum prehensile strength, on average, was 14 kg, and the weak force category was more prevalent. The prehensile strength of both hands was negatively correlated with the HAQ-DI score and DAS28 index. In an adjusted logistic regression model, the "weak" strength category of the non-dominant hand was associated with "moderate clinical activity" in the DAS28 score (OR=8.59, p=0.02), while the category of "weak" strength of the dominant hand was associated with the presence of "some difficulty" of HAQ-DI score (OR=4.75, p=0.10).

**Conclusions:** The decrease in prehensile strength represents a marker associated with the DAS28 index and HAQ-DI score in the patient with RA, regardless of age, muscle mass, total fat or body mass. The measurement of the prehensile strength can be a useful and inexpensive tool to be considered in the clinical evaluation of the RA.

#### BUILDING A PATIENT-CENTRED CARDIOVASCULAR RISK REDUCTION PROGRAM FOR PATIENTS WITH INFLAMMATORY ARTHRITIS

I.Y. Navarro-Millan<sup>1</sup>, S. Young<sup>2</sup>, S. Shurbaji<sup>3</sup>, C. McDavid<sup>3</sup>, A. Cornelius-Schechter<sup>1</sup>, B. Johnson<sup>3</sup>, A. Cherrington<sup>3</sup>, L. Fraenkel<sup>4</sup>, J. Curtis<sup>3</sup>, M. Safford<sup>1</sup>. <sup>1</sup>Weill Cornell Medicine, New York; <sup>2</sup>Binghamton University, Binghamton; <sup>3</sup>University of Alabama at Birmingham, Birmingham; <sup>4</sup>Yale University, New Haven, USA

**Background:** Cardiovascular disease (CVD) is the most common cause of death among patients with inflammatory arthritis (IA) such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS).

**Objectives:** This study is the formative work to help design a patient-centred intervention for a CVD risk reduction program for patients with IA.

**Methods:** We conducted a qualitative study guided by Bandura's Social Cognitive Theory, placing special focus on knowledge about the relationship between arthritis and CVD as well as barriers and facilitators to receiving healthcare related to CVD risk such as screening and management for hyperlipidemia. Participants had to have either RA, PsA or AS and were recruited from a single academic centre. Data were analysed thematically.

**Results:** We conducted three focus groups with a total of 17 participants. Mean age of participants was 56 (SD ±7.7) years; 15 were women; 3 were on a statin; and 1 previously had a stroke. The majority of the participants were Five themes emerged: 1) Need for more information about IA and medications; 2) Lack of education about CVD risk and IA; 3) CVD risk reduction as an integrated lifestyle modification; 4) Uses for peer support around relevant CVD risk factor mitigation approaches; and 5) Improving doctor-patient communication about RA. The themes that emerged in our study showed that the majority of these IA patients were not aware of the relationship between CVD and IA, and were very interested in learning about IA, medication side effects, and prognosis of IA. These participants wanted to learn first about IA and, as a secondary goal, learn about their CVD risk in the context of their IA rather than as a new condition.

**Conclusions:** Providing a clear understanding about systemic effects of IA and how to treat it will be needed before focusing on CVD risk reduction. By doing so, there will be better opportunity for the CVD risk reduction program to succeed.

#### THE SUPPORT OF MEDICAL CLERKS IN RHEUMATIC DISEASE CLINIC AIDS T2T PRACTICE FOR RHEUMATOLOGISTS AND IMPROVES DISEASE ACTIVITIES OF PATIENTS WITH RHEUMATOID ARTHRITIS

I. Matsushita<sup>1</sup>, H. Motomura<sup>1</sup>, T. Hiraiwa<sup>1</sup>, S. Arai<sup>2</sup>, C. Ota<sup>2</sup>, T. Kimura<sup>1</sup>.

<sup>1</sup>Orthopaedic Surgery, University of Toyama; <sup>2</sup>Orthopaedic Surgery, Sainou Hospital, Toyama, Japan

**Background:** With treat-to-target (T2T), the physician always has to evaluate disease activity and joint damage of rheumatoid arthritis (RA) patients exactly to maintain the activities of daily living of the patient for the long term. However, the amount of work required by physicians to complete T2T can be onerous, so the cooperation of medical staff is necessary to practice T2T.

**Objectives:** The purpose of this study is to clarify the role and effectiveness of medical clerks (MCs) in a rheumatic disease clinic.

**Methods:** In our rheumatic disease clinic, MCs have supported rheumatologists since April 2011. We individually evaluated 50 RA patients in May 2010 (before MC support: "preceding period"), April 2011 (1 year after the start of MC support: "early period"), April 2013 (3 years after the start of MC support: "middle period"), April 2015 (5 years after the start of MC support: "late period") and April 2017 (7 years after the start of MC support: "last period"). We assessed the prevalence of T2T practice, disease activity, and drug use. When all components of the Simplified Disease Activity Index (SDAI) of patients had been listed in the medical record and radiography of hand and foot joints had been undertaken more than once a year, the medical examination was defined as "T2T practice". Disease activity was assessed using the SDAI and Clinical Disease Activity Index (CDAI).

**Results:** Prevalence of T2T practice was 50%, 86%, 94%, 100% and 100% at preceding, early, middle, late and last periods, respectively. Prevalence of T2T practice increased after the start of MC support. Accordingly, disease activities improved gradually. SDAI remission was 30.8% in the preceding period, 28.5% in the early period, 30% in the middle period, 58% in the late period and 56% in the last period, respectively. CDAI remission improved towards the last phase, similar to that seen with the SDAI. The mean dose of methotrexate (MTX) increased gradually towards the last phase, but the prevalence of MTX use did not show a remarkable change. Prevalence of use of biological disease-modifying anti-rheumatic drugs did not increase during the study period.

**Conclusions:** MC support in rheumatic disease clinics aids T2T practice for rheumatologists. The disease activities of RA patients can be improved by MC support.

**AB0358 PHENOTYPES OF SECONDARY SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS**

R. Yatsyshyn, I. Stoika. *Internal Medicine #1, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*

**Background:** Secondary sarcopenia may be caused by low physical activity, eating disorders, chronic inflammation. In patients with rheumatoid arthritis (RA), sarcopenia co-occurs with osteoporosis as well as obesity and, in most cases, both osteoporosis and obesity co-occur with sarcopenia. Therefore, 3 phenotypes of sarcopenia can be identified: sarco-osteoporosis, sarcopenic obesity, osteosarcopenic obesity.

**Objectives:** The aim of the research was to study the features of sarcopenia and her phenotypes in patients with RA. There were examined 40 women with stage II-III RA, Rtg stage II-III, functional limitation stage II. The patients average age was 40.7±2.25 years.

**Methods:** The algorithm for diagnosing phenotypes of sarcopenia recommended by the European Working Group on Sarcopenia in Older People (2009) was used. Body mass index was determined. Dynamometry (the measurement of hand-grip strength using handgrip dynamometer) was performed and the evaluation of physical fitness. Serum levels of leptin and creatine phosphokinase MM (CPK MM) fraction were determined. The dual-energy X-ray absorptiometry DEXA (to calculate a T-score) was performed

**Results:** According to the results of laboratory tests and methods of evaluating functional muscle disorders, 87.5% of patients were diagnosed with sarcopenia. The mean values of dynamometry were within 18.3±0.7 kg being significantly lower as compared to healthy individuals – 28.3±0.5 kg. After the evaluation of physical fitness, the average score was 7.9±0.7, while in healthy individuals, it was 11.3±0.4. The mean CPK MM concentration was 175±2.34 U/L, while in healthy individuals, it was 144±3.5 U/L. The average T-score were within the limits (–1.83±0.17) SD and was significantly lower than in healthy (–0.56±0.10) SD. After conducting studies in 17 patients were diagnosed with osteosarcopenic obesity in 11 – sarco-osteoporosis, 7 – sarcopenic obesity, 5 patients sarcopenia has not been diagnosed.

**Conclusions:** RA leads to muscle metabolism disorders which result in the development of secondary sarcopenia. Therefore, a high-protein diet, physical exercise, namely aerobic exercise (swimming, cycling) and medical preparations that improve muscle metabolism should be included in therapeutic measures and preparations of calcium.

**AB0359 CLINIC PROFILE OF PATIENTS WITH RHEUMATOID ARTHRITIS AND PULMONARY AFFECTON IN A COHORT FROM A UNIVERSITY HOSPITAL**

I. Casafont Solé<sup>1</sup>, Á. Prior-Español<sup>1</sup>, S. Hologado<sup>1</sup>, J. Roca<sup>2</sup>, L. Mateo<sup>1</sup>, Y. García-Mira<sup>1</sup>, J. Camins<sup>1</sup>, L. Gifre<sup>1</sup>, A. Riveros<sup>1</sup>, M. Martínez-Morillo<sup>1</sup>, M. Aparicio<sup>1</sup>, A. Olivé<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Epidemiology, Hospital Universitari Germans Trias i Pujol, Badalona, Spain

**Background:** Pulmonary affection is a serious complication in Rheumatoid Arthritis (RA) with an important impact on mortality and morbidity.

**Objectives:** To describe the clinical and radiographic characteristics of patients with RA in our centre, and specifically from those with interstitial lung disease (ILD).

**Methods:** Retrospective analysis of patients with RA and pulmonary affection from a University Hospital with a referral area of 85.000 inhabitants. Clinical, laboratory, imaging and pulmonary function test (PFT) data was recorded.

**Results:** Data from 85 patients, 37 (43.5%) male and 48 (56.5%) female, were recorded. The mean time from RA diagnosis to pulmonary disease was 9.2 years, with mainly erosive (58.8%) and seropositive (84.7% were positive rheumatoid factor (RF) and 84.2% anti-citrullinated protein antibodies (ACPA)) disease. The 56.5% of the patients were smokers or ex-smokers. PFT results were documented in 75.3% of the patients: diffusing capacity for carbon monoxide (DLCO) baseline values were over 60% in a 38.8% of cases and forced vital capacity (FVC) baseline values were over 50% in a 69.4% of patients. The most frequent High Resolution CT scan pattern was the presence of bronchiectasis (64.7%), followed by ILD (31.8%) and, specifically, the Usual Interstitial Pneumonia pattern (UIP, 66.6%); lung infections (25.8%), rheumatoid lung nodules (22.4%), pleural effusion (15.3%), lung tumours (9.4%) and bronchiolitis (5.8%). The presence of extra articular manifestations as rheumatoid nodules (27%), episcleritis (2.3%) and vasculitis (9.4%) was registered. The coexistence of Chronic Obstructive Pulmonary Disease (COPD) was recorded too (24.7%). Related to treatment, 84.7% of patients had received Methotrexate and in a 40% of cases, at least one

biological disease-modifying antirheumatic drug had been administrated. Though the causes were not registered, a 25.9% of deaths were documented. In parallel we did a subanalysis of ILD related to RA cases, summarised in table 1 (n=27):

**Conclusions:** Bronchiectasis is the most common pulmonary manifestation of RA patients in our area. The most frequent clinical profile is a non-smoker woman with seropositive disease.

ILD affects approximately one third of RA patients in our area and is an underdiagnosed entity. We consider that it is necessary to establish a screening program to diagnose and treat it early.

**Abstract AB0359 – Table 1**

Gender, male (%)	44.4%

**AB0360 LEFT ATRIAL DILATION IS INCREASED IN PATIENTS WITH RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY**

D.A. Galarza-Delgado<sup>1</sup>, J.R. Azpiri-López<sup>1,2</sup>, I.J. Colunga-Pedraza<sup>1</sup>, J.A. Dávila-Jiménez<sup>2</sup>, E.E. Abundis-Márquez<sup>1</sup>, A.H. Guillén-Lozoya<sup>1</sup>, F.J. Torres-Quintanilla<sup>2</sup>, R.E. Ramos-Cázares<sup>1</sup>, R. Vera-Pineda<sup>2</sup>, J.A. Cárdenas-de la Garza<sup>1</sup>.

<sup>1</sup>Rheumatology; <sup>2</sup>Cardiology, Hospital Universitario "Dr José E. Gonzalez", UANL, Monterrey, Mexico

**Background:** Rheumatoid arthritis (RA) is a chronic, systemic inflammatory disease, which mainly affects synovial joints.<sup>1</sup> Heart structural abnormalities are more prevalent in RA-patients than in general population, such as pericarditis, increased left ventricle mass and valvular disease.<sup>2</sup> Left atrial (LA) dilation predicts atrial fibrillation and congestive heart failure. It also increases the risk of developing thromboembolic events.<sup>3</sup>

**Objectives:** The aim of this study was to determine the prevalence of LA dilation in RA-patients and compare it with matched controls.

**Methods:** An observational, cross-section, case-control study was designed. Patients who fulfilled 1987 ACR and/or 2010 ACR/EULAR classification criteria for RA, 40–75 years old, with no overlap syndromes or atherosclerotic cardiovascular disease were included. The control group was matched by age, gender and comorbidities. A standard transthoracic echocardiogram was performed by a board-certified cardiologist. LA structure alterations were evaluated according to the American Society of Echocardiography guidelines.

**Results:** A total of 63 RA-patients and 41 control subjects were included. Demographic characteristics are shown in table 1. LA dilation, defined as a LA indexed volume (LAIIV) >34 mL/m<sup>2</sup>, was found in 9 (14.3%) patients of the RA-group, whereas no control subjects presented that condition (p=0.011). Mitral regurgitation was detected in 39 (62%) RA-patients and 7 (17%) control subjects (p<0.001).

Mitral regurgitation, n (%)	39 (61.9)	7 (17)	<b>&lt;0.001</b>
LVMI (gm/m <sup>2</sup> ), mean±SD	70.96±18	70.29±16.3	0.854
Diastolic dysfunction, n (%)	34 (53.9)	14 (34.1)	0.07
LVCR, n (%)	21 (36.8)	6 (15)	<b>0.022</b>
LVCR or LVCH, n (%)	27 (42.8)	7 (17)	<b>0.01</b>

LVCR – Left ventricular concentric remodelling, LVCH – Left ventricular concentric hypertrophy, LVMI – Left ventricular mass index

**Conclusions:** LA dilation is more prevalent in RA-patients when compared to matched controls. Prospective studies are needed to evaluate the influence of this condition in cardiovascular outcomes.

#### AB0361 THE IMPACT OF OBESITY IN CLINICAL AND ULTRASONIC ACTIVITY OF TUNISIAN RHEUMATOID ARTHRITIS

K. ben abdelghani, A. feki, A. fazaa, K. ouenniche, S. miladi, S. kassab, S. chekili, A. laatar, L. zakraoui. *Rheumatology, Mongi Slim Hospital – La Marsa, Tunis, Tunisia*

**Background:** Obesity is one of the most frequent comorbidities among patients with rheumatoid arthritis (RA). It has been proposed as a risk factor of poorer response to treatment and lower likely chance of achieving RA disease remission.<sup>1</sup>

**Objectives:** The objective of this study was to evaluate the effect of obesity on clinical and musculoskeletal ultrasound (MSUS) disease activity.

**Methods:** Cross-sectional clinical and laboratory data were collected on 44 RA patients. MSUS assessment of power Doppler (PDUS) and grey scale (GSUS) hypertrophy and effusion was performed on 11 joints of dominant hand (wrist, metacarpal-phalangeal 1–5 and proximal interphalangeal 1–5). PDUS and GSUS were scored semi-quantitatively on a scale of 0–3. The max score of the views obtained for each joint was computed and then was these maximums were summed across all 11 joints to obtain total PDUS (range 0–33) and GSUS (range 0–33) scores. DAS28/ESR was calculated. Patients were categorised by BMI (kg/m<sup>2</sup>): <25 (group 1), 25–30 (group 2), and >30 (group 3). Demographic, clinical and ultrasonographic characteristics were compared across BMI groups. P values < 0.05 were considered statistically significant.

**Results:** The overall cohort was 88.6% female, 43.2% ACPA positive and 63.6% RF seropositive with a mean age of 53.8 and disease duration of 12.9 years. The mean BMI was 28.6. Eighty two percent of patients were on sDMARD, 18.2% were on Biologics, and 68.2% of patients were on prednisone. There were no significant differences in these characteristics across the BMI categories. The overall median and interquartile ranges (IQR): 4.1 (1.3) for DAS28/ESR, 3.9 (4.1) for GSUS scores and 4 (5.1) for PDUS scores. The disease activity as measure was not significantly different across the BMI groups (p=0.61). Both GSUS and PDUS scores were not significantly different across BMI groups. Concerning GSUS score: the median (IQR) scores was 5.3 (5.4) for group1, 4.4 (4.3) for group2 and 2.6 (2.7) for group3 (p=0.41). For the PDUS scores the median (IQR) scores was 6 (8.6) for group1, 4.3 (4.1) for group2 and 2.3 (2.7) for group3 (p=0.37). There was no statistically significant correlation of BMI with ultrasound scores (r = -0.19, p=0.2 for GSUS score and r = -0.22, p=0.14 for PDUS score).

**Conclusions:** Our study didn't proved differences in clinical or ultrasonic disease activity of RA among BMI. This finding doesn't exclude the hypothesis suggesting that obesity is risk factor of refractory RA which requires a larger number of patients to confirm.

#### AB0362 FACTORS ASSOCIATED WITH THE DEVELOPMENT OF ARTHRITIS IN PATIENTS WITH ARTHRALGIAS CLINICALLY SUSPECTED OF EVOLVING INTO ARTHRITIS: EXPERIENCE OF A PRE-ARTHRITIS CLINICS

L. Nuño, D. Peiteado López, I. Monjo Henry, A. Villalba Yllán, M.E. Miranda Carús, P. Fortea Gordo, E. De Miguel Mendieta, A. Balsa Criado. *Rheumatology, Hospital Universitario La Paz, Madrid, Spain*

**Background:** Despite the fact that genetic and serological risk factors have been studied in rheumatoid arthritis (RA), the symptoms phase of preclinical RA is poorly characterised. Taking into account the importance of early diagnosis and effective treatment for the prevention of structural damage and long-term disability in RA, it is important to find clinical or image variables that identify patients with clinically suspected arthralgias at risk of developing a chronic arthritis (CSA).

**Objectives:** To identify baseline clinical, immunological and ultrasound variables in patients with arthralgias clinically suspected of progression to chronic arthritis.

**Methods:** Longitudinal prospective study of patients with CSA and follow-up from November 2015 in pre-arthritis clinics. Patients were assessed at baseline and every 6 months until 2 years, with clinical, laboratory and ultrasound data using standardised protocols. The criteria for eligible patients for inclusion in the study were: ≤12 months of symptoms onset, inflammatory arthralgias (predominance in nights or mornings, improvement during the day or with movement, and morning stiffness of ≥30 min), and the involvement of small joints of hands or feet. Patients with clinical synovitis at baseline visit, patients with fibromyalgia or osteoarthritis were excluded.

**Results:** Twenty-six patients were recruited in 26 months of the study (1 male, 25 female), with an average baseline age of 44.7±12.6 years, an average delay time of symptoms to first visit of 8.7±3.3 months, a mean follow-up time of 7.7±8.1 months an average body mass index (BMI) of 27.7±7.2. Five patients had familial background of autoimmune diseases in first degree relatives (RA, psoriasis, inflammatory bowel disease), 6 (23.1%) were seropositive (RF and/or ACPA), 7 (26.9%) had increased baseline acute-phase reactants (PAR), and 11 (47.8%) were smokers or former smokers. Most of the patients reported a progression of the arthralgias (55%) and a subjective joint swelling at some point (70%). Of 24 patients, 8 (33.3%) developed clinical arthritis (7 RA, 1 undifferentiated arthritis), with a longer follow-up (15.7±7.4 vs. 7.5±7.2 months, p=0.016), greater baseline HAQ (11.8±8.3 vs. 3.9±4.8, p=0.033) and higher percentage of moderate inflammatory activity in the baseline ultrasound (83.3% vs. 8.3%, p=0.004), compared to patients that didn't develop arthritis. There was a trend towards a higher seropositivity, (37.7% vs. 18.8%), a higher patient global disease assessment (45±29 vs. 30±27 on a 100 mm scale), higher patient pain scores (using a visual analogue pain 100 mm scale) (58±41 vs. 34±23) among patients who eventually developed arthritis, although not statistically significant. No differences were found with PAR, BMI, age, smoking habit or painful joint count at baseline visit.

**Conclusions:** In our pre-arthritis clinics of patients with clinically suspicious arthralgias, 33% progressed to arthritis, underlying the importance of these clinics. Functional disability and ultrasound at baseline visit are especially useful in predicting future progression to arthritis. It is necessary to recruit more patients in order to obtain more robust conclusions.

#### AB0363 RHEUMATOID ARTHRITIS AND SICKLE CELL DISEASE: CLINICAL, BIOLOGICAL, RADIOLOGICAL AND THERAPEUTICS SPECIFIC ASPECTS. A RETROSPECTIVE OBSERVATIONAL STUDY

L. Steffko-Comte<sup>1</sup>, F. Eymard<sup>1</sup>, A. Habibi<sup>2</sup>, F. Galacteros<sup>2</sup>, M. Michel<sup>3</sup>, X. chevalier<sup>1</sup>, P. bartolucci<sup>1</sup>, S. guignard<sup>1</sup>. <sup>1</sup>rhumatologie; <sup>2</sup>maladies génétiques du globe rouge; <sup>3</sup>médecine interne, APHP, Créteil, France

**Background:** Thanks to medical advances in sickle cell disease (SCD) treatments, practitioners have to be aware of new comorbidities, as rheumatoid arthritis (RA).

**Methods:** We conducted a retrospective, observational and monocentric study about clinical, biological and radiological specific aspects of RA in SCD patients and studied the impact of anti-rheumatic drugs, comparing the number of SCD

flares occurring six months before/after their introduction, using medical files and phone inquiry.

**Results:** Twenty-three patients were included in this study. Data about RA treatments and SCD flares could be collected for 15 patients. Middle age at RA diagnosis was 32.9 years-old, sex ratio was 4.75F/1M. 74% of the patients were RF positive, 65% were ACPA positive. 74% of the patients had articular damages. Among them, 100% had severe carpite which appears to be the major radiological expression of RA in SCD patients, occurring sometimes without finger bone erosion. 100% received at least one specific drug for RA, 35% a biotherapy. There was no significant difference in the number of crisis before and after methotrexate introduction ( $p=1$ ) or anti TNF alpha drugs ( $p=0.35$  IC95% [-1.26;0.51]). Methotrexate had to be stopped for 3 patients because of acute chest syndrome, which did not occur with anti TNF. No infection was noticed.

**Conclusions:** In conclusion, in SCD, RA occurs sooner in life course and to be more severe with a particular pattern: carpite and tarsite without finger bone erosion. The use of biotherapy appears to be safe, with a close monitoring.

Opris-Belinski<sup>5</sup>, A. Puzsai<sup>7</sup>, E. Santos<sup>8</sup>, J. da Silva<sup>8</sup>, Z. Szekanez<sup>7</sup>, K. Zeiner<sup>3</sup>, D. Zhang<sup>2</sup>, M. Boers<sup>1,9</sup>. <sup>1</sup>Amsterdam Rheumatology and Immunology Center ARC, Amsterdam; <sup>2</sup>Rheumatology, Medical Center Leeuwarden, Leeuwarden, Netherlands; <sup>3</sup>Department of Rheumatology and Clinical Immunology, Charité – University Medicine Berlin, Berlin, Germany; <sup>4</sup>Department of Rheumatology and Clinical Immunology, Maastad Hospital, Rotterdam, Netherlands; <sup>5</sup>Department of Internal Medicine and Rheumatology, "St. Maria" Hospital, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania; <sup>6</sup>Instituto Português de Reumatologia, Lisbon, Portugal; <sup>7</sup>Department of Rheumatology, University of Debrecen Faculty of Medicine, Debrecen, Hungary; <sup>8</sup>Reumatologia, Faculdade de Medicina e Hospitais da Universidade de Coimbra, Coimbra, Portugal; <sup>9</sup>Department of Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands

**Background:** GLORIA is an ongoing large pragmatic trial that examines harm, benefit and costs of low-dose glucocorticoids added to the standard treatment of RA patients of 65 years or older. The eligibility criteria are non-restrictive: RA, age  $\geq 65$  years, disease activity score (DAS28) of  $\geq 2.6$ , and no current glucocorticoid treatment. Patients with comorbidity are expressly included, and the impact of trial procedures on normal care is minimal. Nevertheless, inclusion proves to be challenging. We have prospectively sampled all the reasons for ineligibility across a number of centres in different countries participating in the GLORIA trial.

**Methods:** Rheumatologists from 8 centres in Germany, Hungary, The Netherlands, Portugal and Romania screened the patient list of at least two full clinic days. For each patient, the eligibility and all possible reasons of exclusion were recorded.

**Abstract AB0364 – Table 1.** Percentage of patients ineligible for the GLORIA trial, per reason (patients can have more than one reason)

Center	n	Percent ineligible for:				
		Age	Disease Activity	Current GC	Temporary	Other
<b>Total</b>	<b>370</b>	<b>58</b>	<b>58</b>	<b>28</b>	<b>5</b>	<b>11</b>
<b>The Netherlands</b>						
Amsterdam	156	54	70	22	5	11
Rotterdam	43	63	58	12	2	9
Leeuwarden	46	51	70	11	4	19
<b>Germany, Berlin</b>						
	23	52	52	65	0	17
<b>Portugal</b>						
Coimbra	21	58	21	8	4	17
Lisbon	10	60	60	80	80	10
<b>Hungary, Debrecen</b>						
	46	75	43	55	0	2
<b>Romania, Bucharest</b>						
	18	56	22	44	0	6

**Results:** In total, 385 patients were screened. Of these patients, 15 (4%) were eligible to participate in the GLORIA trial. In Germany, Romania and Portugal (Lisbon) none of the screened patients proved eligible.

The most common reasons for ineligibility were inactive disease and age (both 58%) (table 1). Current glucocorticoid use was reported in 28%, 5% had a temporary reason (i.e. recent switch of therapy or glucocorticoid use), and 51% had more than one reason for ineligibility. We found remarkable differences between the sites in the distribution of the main reasons for ineligibility (table 1).

Of the eligible patients, 1 was already participating, 3 were included after this screening, and 2 were currently considering participation; 9 declined participation (most common reasons: fear of glucocorticoids, not interested to participate, preference for GC injections or declining additional therapy).

**Conclusions:** In this prospective study, we found remarkable differences between countries in reasons for non-participation in our ongoing GLORIA trial. The willingness of eligible patients to participate was low in this elderly population, despite the pragmatic design. Earlier studies also showed that it is challenging to include elderly patients in a clinical trial.<sup>1,2</sup> Pre-screening of patients in potential sites can provide important information on the potential to recruit patients in a trial, but the actual willingness of patients to participate remains hard to predict.

### AB0365 THE INSULIN RESISTANCE, METABOLIC SYNDROME AND TYPE 2 DIABETES MELLITUS DEVELOPMENT RISK ASSESSMENT IN RHEUMATOID ARTHRITIS PATIENTS

L. Kondratyeva, T. Popkova, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** The insulin resistance (IR) is the known risk factor of type 2 diabetes mellitus (DM) and potential cardiovascular complications. But it's not feasible in routine practice to calculate special indices to determine IR, as insulin levels monitoring is not a standard procedure in RA pts. Metabolic syndrome (MS) criteria and questionnaires designed to assess the risk of DM development can help to differentiate a subgroup of pts, requiring more accurate evaluation of their IR status.

**Objectives:** To determine how IR relates with MS and DM development risk assessment in RA patients.

**Methods:** A total of 46 RA pts (39 women, 7 men, 57 [39; 64] years old) without established DM were enrolled in the study, including 14 pts with IR and 32 pts without IR, matched by age and sex. IR was defined as Homeostasis Model Assessment of Insulin Resistance (HOMA-IR) index  $>2.77$ . National Cholesterol Education Program/Adult Treatment Panel III (NCEP/ATPIII) and International Diabetes Federation (IDF) criteria were used to confirm MS. The abdominal obesity was determined as waist circumference (WC)  $\geq 80$  cm for women and  $\geq 94$  cm for men (by IDF), and WC  $\geq 88$  cm for women and  $\geq 102$  cm for men (by NCEP/ATPIII). If the total score of questionnaire Finnish Type 2 Diabetes Risk Assessment Form (FINDRISK) was  $\geq 12$ , the DM development risk was considered as moderate or high.

**Results:** The body mass index was higher in pts with IR than in those without IR (28,5 [24,8; 32,5 kg/m<sup>2</sup> vs 22,4 [20,1; 25,4 kg/m<sup>2</sup>,  $p<0.001$ ). Abdominal obesity was documented in 100% pts with IR and in 41% pts without IR by IDF criteria ( $p=0.002$ ), in 64% and 22% pts, respectively, by NCEP/ATPIII criteria ( $p=0.01$ ). There were no differences in DAS28, CRP and ESR values and glucocorticoids users proportions. MS by IDF criteria was diagnosed in 57% pts with IR and 19% pts without IR ( $p=0.02$ ), and MS prevalence by NCEP/ATP III criteria was similar in both groups (36% vs 16%, respectively,  $p=0.2$ ). Higher rates of moderate and high risk for DM development were found in pts with IR compared to pts without IR (71,4% vs 31,2%,  $p=0.03$ ).

**Conclusions:** The FINDRISK and IDF questionnaires, but not the NCEP/ATP III criteria of MS, can be helpful in selecting RA pts with potential IR. Abdominal obesity was the key factor indicative of IR in RA pts. On the other hand, IR may not be there even in the presence of several traditional DM risk factors. Therefore further clarification of potential contribution of RA-related risks is needed.

AB0366

### CLINICAL, EPIDEMIOLOGICAL CHARACTERISTICS AND COMORBIDITIES IN A COHORT OF PARAGUAYAN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Roman, S. Riquelme-Granada, J. Losanto, M. Duarte, S. Cabrera-Villalba.  
Reumatología, Hospital de Clínicas, San Lorenzo, Paraguay

**Background:** Rheumatoid arthritis (RA) is a chronic rheumatic inflammatory disease with a higher risk of developing some cardiovascular pathology compared to the general population. The presence of comorbidities in patients with RA represents an increase in the cost of care, work disability and hospital admissions.

**Objectives:** To describe clinical, epidemiological characteristics, frequency of comorbidities and their association with clinical and analytical characteristics in Paraguayan patients with rheumatoid arthritis.

**Methods:** Descriptive, cross-sectional study of a cohort of patients with established rheumatoid arthritis, followed in the Department of Rheumatology of the Hospital de Clínicas. epidemiological (i.e. sex, age, origin), clinical (i.e., comorbidities (i.e. HBP was defined as BP  $\geq$ 140/90), obesity BMI  $\geq$ 30, dyslipidemia according to lipid profile levels), time of evolution of the disease, DAS28, etc.), laboratorial (i.e. RF, anti-CCP) and radiographic variables were recorded. Qualitative variables were expressed in frequencies and percentages and quantitative variables were characterised by their means and standard deviations. The comparison of clinical, epidemiological, serological variables was performed using the chi-squared test and the student test respectively for qualitative and quantitative variables. The statistical analysis was performed with the statistical program SPSS V.23.0.

**Results:** 177 patients with RA were included, 82.5% were women, with a mean of age at onset of 44.8 $\pm$ 13.8 years, mean disease duration of 8.64 $\pm$ 8.3 years. 68.3% came from Asunción and Gran Asunción, 44.6% of the patients were married, the average number of children per patient was 3.55 $\pm$ 2.2. Most of the patients (43.6%) were from social stratum 1–2, according to the GRAFFAR questionnaire. Family income with minimum salary or less was found at 55, 7% of patients with an average household income of 2.350.515 $\pm$ 1.6220.409 Guaranes. Most patients work at home, 54. 5% were housewife, and only 11.9% had a university degree. Only 15.3% had extra-articular manifestations, mainly rheumatoid nodules. The average body mass index was 29.6 $\pm$ 12.7. 75.9% were RF positive, with a mean of level of 436.7 $\pm$ 301 UI/L and 85% were anti-CCP positive, with a mean of level of 224,7 $\pm$ 201 UI/L. Methotrexate was the most frequent treatment (87%), 57.7% were using prednisone, with a median dose of 7.9 $\pm$ 4.8 mg. 40.9% had erosions. In this cohort median disease activity was 3.5% $\pm$ 1.2. 30.7% of patients were in remission by DAS 28 (<2.6). Regarding comorbidities, 38% presented hypertension, 11.9% had dyslipidemia, 5.3% type-2 Diabetes Mellitus, 39.4% were obese and 35% were overweight. Only 5% were smoker, and 16.5% had osteoporosis. When comparing the presence or absence of comorbidities with the clinical, epidemiological, serological and radiological characteristics, we did not find significant differences between them.

**Conclusions:** In this cohort of patients with established RA a little more than half receive a monthly income less than or equal to the minimum salary, and only the minority had university studies. The most frequent comorbidities were obesity, hypertension and dyslipidemia. One third of patients were in clinical remission, only with DMARDs.

### "THE STRUCTURAL INDEX SCORE – SIS" FOR RHEUMATOID FOOT AND ITS RELATION TO FOOT FUNCTION, DISABILITY AND PHYSICAL PERFORMANCE TESTS

J.Z. Gaino<sup>1</sup>, M.B. Bertolo<sup>1, 2</sup>, C.S. Nunes<sup>1</sup>, C.M. Barbosa<sup>1</sup>, Z. Sachetto<sup>2</sup>, M. Davitt<sup>1</sup>, E.D.P. Magalhães<sup>2</sup>. <sup>1</sup>UNICAMP, CAMPINAS, Brazil; <sup>2</sup>Rheumatology, UNICAMP, CAMPINAS, Brazil

**Background:** Feet are involved in 90% of Rheumatoid arthritis (RA) patients. The Structural Index Score (SIS) is a score that evaluates forefoot and rearfoot aspects. Although it has been used as a clinical tool to quantify foot deformities in RA, its relevance in clinical practice is uncertain.

**Objectives:** The aim of this study was to evaluate the relation of SIS with foot function, disability and physical performance tests in RA.

**Methods:** 104 RA patients of the outpatient clinic of Rheumatology/Unicamp were evaluated for SIS total, forefoot, rearfoot and its items (hallux valgus, metatarsophalangeal (MTP) subluxation, 5th MTP exostosis, claw/hammer toe deformities, calcaneus varus/valgus angle, ankle range of motion (ARM) and planus/cavus foot deformity). Subjects also performed Foot Function Index-FFI, Health Assessment Questionnaire Disability Index-HAQ-DI, lower limb HAQ-LL-HAQ and physical tests: Berg Balance Scale-BBS, the Timed Up and Go-TUG and the 5-time sit down-to-stand up-SST5 tests. SIS items were compared with HAQ, LL-HAQ, FFI and physical tests through Kruskal-Wallis test and Spearman correlation coefficient with a 5% level of significance.

**Results:** SIS-Forefoot score did not correlate with any variables. Among the SIS-forefoot items, hallux valgus was associated with FFI-pain ( $p=0.007$ ), FFI-disability ( $p=0.005$ ) and FFI-total ( $p=0.016$ ); MTP subluxation was weakly correlated with FFI-disability ( $r_s=0.196$ ) and 5th MTP exostosis was associated with FFI-pain ( $p=0.018$ ). SIS-Total, SIS-Rearfoot and its associated and correlated items are shown in table 1.

Abstract AB0367 – Table 1

Variables	SIS-Rearfoot items			SIS-Rearfoot total score	SIS-Total
	Planus/Cavus foot deformity	Calcaneus valgus/varus angle	Ankle range of motion		
	p-value <sup>a</sup>	$r_s$ #/p-value	$r_s$ #/p-value	$r_s$ #/p-value	$r_s$ #/p-value

SST5	0.716	0.047/0.630	0.306/0.001**	0.306/0.001**	0.024/0.808
BBS	0.063	-0.107/0.276	-0.360/0.000**	-0.360/0.000**	-0.055/0.574

<sup>a</sup> Mann-Whitney's test; # Spearman's rank correlation coefficient; \*\* significant p-value

**Conclusions:** It is not clear if the use of SIS may be related to function and disability in RA. Forefoot SIS did not show correlation although hallux valgus, MTP subluxation and 5th MTP exostosis may be related to foot function. Rearfoot SIS and its items seem to be most correlated with function and disability in RA.

### THE OCCURRENCE OF ANTIBODIES DEPENDING ON THE DURATION OF RHEUMATOID ARTHRITIS

M. Volkava. BeMAPGE, Minsk, Belarus

**Background:** Recently heterogeneous nuclear ribonucleoproteins (hnRNPs) were identified as antigenic targets for autoantibodies in RA. Autoantibodies to RNP B1, B2 and heterogeneous complex A2/b are the most studied and are referred to as "antigen RA33". Clinical value of anti-RA33 in RA continues to be studied, so the question is about the diagnostic and pathogenic significance of these autoantibodies in patients with RA remains open.

**Objectives:** The aim of this study was to investigate the frequency of occurrence of anti – RA33y patients with RA and compare them with clinical manifestations and immunological parameters of disease.

**Methods:** The study included 139 patients with RA. The diagnosis was verified according to the classification criteria of ACR/EULAR 2010 Autoantibodies to RNP B1 IgG was assessed in samples of blood serum by enzyme immunoassay (ELISA; Medipan AG, Germany). A recombinant human RNP antigen B1 was used as the antigen, which was synthesised in the E. coli. system of the protein production. Anti-CCP, RF and antibodies to Sa-antigen (anti-Sa) was evaluated by ELISA according to the manufacturer's instructions (Euroimmun AG company, Germany). The results were expressed in relative units (U/ml). Statistical data processing was carried out using the software Statistica 7.0 (StatSoft, USA) and

Medcalc 12.5.0.0 (USA), including standard methods of parametric and nonparametric analysis. Differences were considered significant at  $p < 0.05$ .

**Results:** Levels and frequency of occurrence of anti-RA33, anti-CCP, RF IgM and anti-Sa were analysed for the examined patients depending on disease duration. Patients were divided into two groups: patients with early RA (disease duration less than 12 months) and patients with established RA (disease duration over 12 months). In the analysis it was found that the incidence of anti-Sa in established RA are much higher in comparison with the early RA (77.98% vs. 52.00% respectively,  $p < 0.05$ ). The levels of anti-Sa autoantibodies were lower in early RA than in established RA 21,57 U/L; 95% CI 12,10–27,42 vs. 33,10 U/L; 95% CI 27,58–37,71 respectively,  $p < 0.05$ ). Frequency of occurrence of anti-CCP and RF IgM is no different in the early and developed stage of RA. The frequency of occurrence of anti-RA33 in early RA was higher than in established RA (52.00% vs. 32.45% respectively,  $p < 0.05$ ).

**Conclusions:** Thus, anti-RA33 is a perspective independent biomarker of RA, which has its own potential. Further study of the anti-RA33 as a diagnostic biomarker of early stage RA is promising. Based on preliminary studies the anti-RA33 could have diagnostic and prognostic value in diagnosis and evaluation of patients with early RA, and its differentiation from other small joint disorders, particularly when the other serologic tests are negative.

To clarify the diagnostic and pathogenic value of anti-RA33 further research with a large sample size, comparison of immunological data with genetic factors, the results of other laboratory and instrumental studies, clinical manifestations of the disease are required. The obtained data will allow us to more thoroughly study the pathogenesis of RA and contribute to the search for new therapeutic options.

#### AB0369 ADULT-ONSET STILL'S DISEASE TREATMENT PREDICTORS AT 1-YEAR FOLLOW-UP IN A SINGLE RHEUMATOLOGIC CENTRE EXPERIENCE

M. Giannotta, F. Cacciapaglia, M. Giannini, M. Nivuori, R. Fanizzi, G. Lopalco, G. Laselva, C. Scioscia, F. Iannone. *Department of Emergency and Organ Transplantation, Rheumatology Unit University of Bari, Bari, Italy*

**Background:** Adult-onset Still's disease (AOSD) is a rare systemic inflammatory disorder mainly characterised by persistent high spiking fevers, evanescent rash, and joint involvement. Data on the efficacy of biologic therapy in the management of AOSD<sup>1</sup> is increasing and represents a breakthrough in the management of patients with AOSD refractory to corticosteroids (CS) or conventional (c) DMARDs.

**Objectives:** We aimed to evaluate possible predictor on the need to use a biologic agent in the management of AOSD patients.

**Methods:** In this retrospective monocentric study we evaluated AOSD patients followed in our outpatient's clinic since 2010 with at least 1 year follow-up. Clinical manifestations, joint involvement, CS and c- or bDMARD use were main outcome measures. T-test or ANOVA and Chi-squared were used to compare continuous or categorical data, when appropriate, and the odds ratio (OR) for which condition had an influence on clinical outcome was calculated.

**Results:** We evaluated 28 AOSD patients (mean age  $43 \pm 14$  years; median disease duration 3 (95%CI 2.5–17.3) months). All patients at baseline were treated with a median CS of 18.7 (95%CI 14.3–24.8) mg/die prednisone equivalent dose, and median methotrexate (MTX) dose of 15 (95%CI 13.4–16.28) mg/week. After 1 year follow-up, in the 8 patients (28.6%) that needed to start a bDMARD (4 anti-IL1; 3 anti-IL6 and 1 anti-TNF), we observed that baseline joint involvement was the more prevalent manifestation of the disease with higher DAS28 compared to those patients still on CS +MTX (DAS28  $3.8 \pm 1.2$  vs  $2.8 \pm 1.1$ , respectively  $p = 0.03$ ). Moreover, we showed that clinical manifestations of systemic involvement (i.e. fever, rash, organomegaly and anaemia) were associated with a protective risk to start a bDMARD at 1 year (OR 0.4 95% CI 0.2–0.76). Consistently, in those patients with concomitant elevated ESR ( $> 20$  mm/h), CRP ( $> 15$  mg/L) and ferritin ( $> 250$  ng/ml) levels at baseline, we observed a low risk to start a bDMARD at 1 year follow-up (OR 0.4 95% CI 0.18–0.87).

**Conclusions:** In our cohort about one third of AOSD patients required to be treated with a bDMARD at 1 year follow-up, mainly if joint involvement was the predominant clinical manifestation at disease onset. Systemic manifestations of the disease seem to benefit from high dose CS+MTX combination therapy. Further studies with more extensive cases are necessary.

#### AB0370 LOW SERUM IGF1 IS ASSOCIATED WITH HIGHER CARDIOVASCULAR RISK IN THE MIDDLE-AGED WOMEN WITH RHEUMATOID ARTHRITIS INDEPENDENTLY OF THE DISEASE RELATED PARAMETERS

M.C. Erlandsson<sup>1,2</sup>, S.T. Silfverswärd<sup>1</sup>, M. Nadali<sup>1,2</sup>, R. Pullerits<sup>1</sup>, M.L. Bokarewa<sup>1,2,3</sup>,  
<sup>1,2</sup> *Rheumatology and Inflammation Research, GOTHENBURG UNIVERSITY;*  
<sup>2</sup> *Rheumatology Clinic;* <sup>3</sup> *Department of Clinical Immunology and Transfusion Medicine, Sahlgrenska university hospital, Gothenburg, Sweden*

**Objectives:** To analyse the relation between serum levels of IGF1 and cardiovascular risk (CVR) in women with rheumatoid arthritis (RA).

**Methods:** The risk of dying of CV disease within 5 years was calculated using the strategy proposed by Pocock et al. *BMJ* 2001 in 185 women with RA (mean age 51.7 years) with no previous history of CV events. The CVR and characteristics related to it were analysed with respect to serum IGF1. IGF1 levels below the median of the total cohort were considered low.

**Results:** The RA women with low IGF1 ( $n = 91$ , mean 104 pg/ml) had significantly higher CVR compared to those with normal IGF1 ( $n = 94$ , mean 194 pg/ml) with the predicted risk of 0.51% and 0.17%, respectively ( $p > 10^{-5}$ ). Among the traditional CVR factors, the low IGF1 group was 10 years older (mean 56.8 vs. 46.9 y,  $p = 10^{-5}$ ), lower in height (165 vs. 168 cm,  $p = 0.013$ , 21% of the patients being  $< 160$  cm) and had high prevalence of hypertension (24% vs. 8.5%,  $p = 0.004$ ), while current smoking was similar between the groups (15% vs. 14%).

The low IGF1 group displayed the unfavourable metabolic profile with higher BMI ( $p = 0.002$ ) and obesity in 22%, higher predicted body fat content (mean 39.5 vs. 35%,  $p = 10^{-5}$ ), and higher total and LDL cholesterol ( $p = 0.0014$  and  $p = 0.0053$ , respectively). The levels of adiponectin ( $p = 0.032$ ) and HDL-cholesterol ( $p = 0.25$ ) tended to be higher in the low IGF1 group, which resulted in the comparable total cholesterol to HDL ratio between the groups. This could also explain that the prevalence of diabetes mellitus and metabolic syndrome were low.

With exception of the disease duration, the groups displayed no significant difference in the RA-related CVR factors such as the disease activity measured by DAS28 (3.29 vs 2.99), systemic inflammation measured by serum IL6 (mean 8.46 vs. 5.99 pg/ml) and IL1 $\beta$  (mean 19.47 vs. 23.1 ng/ml), and the prevalence of seropositivity (91% vs. 92%). The prevalence of treatment with MTX monotherapy was higher in the low IGF1 group (56% vs. 39%,  $p = 0.024$ ), while the use of TNF-inhibitors and other biologic and synthetic anti-rheumatic drugs was similar within the groups.

**Conclusions:** Serum IGF1 levels in the normal low range are associated with higher CVR in RA female patients. This increase in CVR seems to be independent of the RA-related characteristics. The combination of low height and hypertension argues for the important role of congenital factors in defining serum IGF1 levels in the studied RA women.

#### AB0371 THE EFFECT OF CUMULATIVE EXPOSURE TO CIGARETTE SMOKING ON VASCULAR DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Aguilar-Zamora<sup>1</sup>, M. Robustillo-Villarino<sup>1</sup>, L. Montolio Chiva<sup>1</sup>, A.V. Orenes Vera<sup>1</sup>, Á. Martínez-Ferrer<sup>1</sup>, É. Valls Pascual<sup>1</sup>, D. Ybáñez García<sup>1</sup>, A. Sendra García<sup>1,2</sup>, I. Torner Hernández<sup>1</sup>, V. Núñez Monje<sup>1</sup>, J.J. Alegre-Sancho<sup>1</sup>.

<sup>1</sup> *Rheumatology, Hospital Universitario Dr. Peset;* <sup>2</sup> *Foundation for the promotion in health and biomedical research (FISABIO), Valencia, Spain*

**Background:** Smoking is described as a classic cardiovascular (CV) risk factor and we also know the beneficial effect on the CV system of smoking cessation. However, there is contradictory data about its effect in patients with rheumatoid arthritis (RA). It is possible that the measure of cumulative exposure to tobacco expressed in pack-year gives us more information than the smoking status.

**Objectives:** To explore the relation between smoking exposure, measured in pack-year, and subclinical vascular damage, mortality and vascular events in patients with RA.

**Methods:** Observational ambispective study. We included, consecutively, RA patients controlled in a tertiary hospital. We gathered demographic (sex, age, body mass index [BMI]), clinical (characteristics of RA, classic CV risk factors and history of vascular events) and analytical variables (CRP, ESR). We estimated the modified SCORE. We explored the extracranial branches of the carotid artery

with an Esaote MyLab70XVG ultrasound device with a linear probe (7–12mHz) and an automated program measuring intima media thickness (IMT) by radiofrequency ("Quality intima media thickness in real-time, QIMT"), and registered the presence of atheroma plaques (per Mannheim consensus). We determined pulse wave velocity (PWV) by a validated MobilOGraph device. We considered as pathological an IMT >900  $\mu$  and a PWV  $\geq$ 10 m/s and the presence of plaque and/or pathological IMT. We prospectively collected mortality and the development of new vascular events over four years and the current smoking status and exposure calculated in pack-year. Statistical analysis was performed using SPSS 17.0 software.

**Results:** We included 198 patients, excluding 15 because of previous CV events. The mean age was 66.5 years (SD 13.44) 76% were women and the mean BMI was 27.35 (SD 4.82). 31.1% were smokers, 43.2% hypertensive, 47.5% dyslipemic and 10.4% were diabetic. The mean duration of RA was 19.95 years (SD 11.88). 76.5% of patients were seropositive and 75.4% had erosions. The mean CRP and ESR were 9.51 mg/L (SD: 32.29) and 13.83 mm/h (SD:14.26), respectively. The mean modified SCORE was 1.81 (SD: 1.81). Regarding the vascular study, 48.1% had atheroma plaques, 32.2% a pathologic PWV [mean value of 9.13 (SD 2.12)], and 16.7% had a pathologic IMT [mean value of 748  $\mu$ (DE 168.73)].

31.1% of the patients (57) were smokers or former smokers. The average pack-year was 24.17 (SD: 21.37). No relation was found between current or previous use of tobacco and any of the outcome measures described. However, when considering cumulative exposure to tobacco, there was a trend to correlate with higher values of PWV ( $p=0.07$ ) and a higher plaque presence ( $p=0.089$ ) was detected. After 4 years of follow-up, 3 deaths were recorded among smoking patients, but a higher incidence of CV events was not detected in relation to cumulative exposure to tobacco ( $p=0.99$ ).

**Conclusions:** The quantification of the exposure by pack-year of cigarette smoked could give us more information about vascular damage in patients with RA. The limitation of our study is the small number of smokers in the time they were followed.

#### LEFT ATRIAL FUNCTION IN RHEUMATOID ARTHRITIS PATIENTS

M. Fawzy, S. bahoom, . Ashour, M. sheik. *kaser el Aini, giza, Egypt*

**Background:** Rheumatoid arthritis (RA) is a common autoimmune systemic inflammatory disease affecting approximately 1% of the worldwide population. The interaction of genetic and environmental factors results in a cascade of immune reactions, which ultimately lead to the development of synovitis, joint damage, and structural bone damage.<sup>1</sup>

The importance of the left atrium in cardiovascular performance has long been acknowledged. Quantitative assessment of left atrial (LA) function is laborious, requiring invasive pressure-volume loops and thus precluding its routine clinical use. In recent years, novel postprocessing imaging methodologies have emerged, providing a complementary approach for the assessment of the left atrium. Atrial strain and strain rate obtained using either Doppler tissue imaging or two-dimensional speckle-tracking echocardiography have proved to be feasible and reproducible techniques to evaluate LA mechanics.<sup>2</sup>

#### Objectives:

1. To screen cardiac affection in rheumatoid arthritis patients
2. To assess subclinical echocardiography affection in RA patients

**Methods:** 30 healthy control, and 45 RA patient subjected to full clinical assessment, DAS 28 ESR score, full laboratory evaluation, conventional and tissue Doppler imaging (TDI) and strain (S) and strain rate (SR) analysis by two-dimensional speckle tracking of the left atrium.

**Results:** we found statistically significant difference in 2 Left atrial PEF, 2 Left atrial EI, 2 Left atrial TEF, TDI mitral lateral annulus e', TDI mitral lateral annulus S, Average SR E 1/s between patients and controls, and negative correlation between TDI lateral e, TDI lateral s, and Strain rate e and rheumatoid factor, There was negative correlation between 2LA PEF, 2LA EI, and 2LA TEF. Rheumatoid factor is correlated to strain rate e, and negatively correlated with left atrial passive emptying

**Conclusions:** RA had alteration in left LV longitudinal myocardial function, left atrial expansion volume can be a predictor of AF in RA. RA patient had more left atrial stiffness. Our study concluded cardiac affection is more in seropositive RA patients.

AB0373

#### SARCOPENIA COULD NOT PREDICT FALLS IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM THE CHIKARA STUDY

M. Tada<sup>1</sup>, Y. Yamada<sup>2</sup>, K. Mandai<sup>2</sup>, N. Hidaka<sup>1</sup>. <sup>1</sup>*Orthopaedic Surgery, Osaka City General Hospital*, <sup>2</sup>*Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan*

**Background:** The falls ratio is higher among patients with sarcopenia than among healthy individuals. We reported that the prevalence of sarcopenia was 28% and locomotive syndrome (locomo) was 52% in patients with rheumatoid arthritis (RA)<sup>1</sup>. Whether patients with RA complicated by sarcopenia show a higher ratio of falls compared to those without sarcopenia remains unclear.

**Objectives:** We investigated events of falls and fractures, and predictors of those events in patients with RA.

**Methods:** We used data from a prospective observational study (CHIKARA study, UMIN000023744) started in 2016. Sarcopenia was diagnosed using the criteria of the Asia Working Group on Sarcopenia<sup>2</sup>. We counted the number of patients and events of falls and fractures they had per year[A1], and investigated correlations between those events and disease activity, body composition and sarcopenia. Predictors at baseline influencing those events were analysed by uni- and multivariate analysis.

**Results:** Participants comprised 100 patients with RA (females, 78%; mean age, 66.1 years). Falls occurred in 21 patients (19 women), as 33 events (mean, 2 times/patient). Fractures occurred in 4 patients (4 women), as 5 events. Table 1 shows predictors for falls, with positive correlations for bone mass index, obesity level, fat percentage, and locomo, and negative correlations for height, trunk muscle mass, and grip strength. No relationships were seen between falls and CRP, DAS28ESR, skeletal muscle mass, and sarcopenia. Height (odds ratio, 0.912;  $p=0.003$ ) and obesity level (odds ratio, 1.04;  $p=0.006$ ) were independent predictors by multivariate analysis (table 1). In terms of fracture events, falls was the only predictor ( $r=0.469$ ,  $p=0.001$ ).

**Abstract AB0373 – Table 1.** Predictors of falls in patients with RA

	Univariate		Multivariate		
	R	P	Odds ratio	95% CI	P
Body mass index	0.195	0.040			
Obesity level	0.194	0.040	1.040	1.011–1.069	0.006
Fat percentage	0.211	0.025			
Locomotive syndrome	0.237	0.012			
Height	–0.263	0.005	0.912	0.858–0.968	0.003
Trunk muscle mass	–0.188	0.048			
Grip strength	–0.198	0.036			
CRP	0.063	0.512			
DAS28ESR	–0.008	0.932			
Skeletal muscle mass	0.091	0.337			
Sarcopenia	–0.093	0.327			

**Conclusions:** Falls have been reported as significantly more frequent with sarcopenia. However, no relationship was seen between fall events and sarcopenia in this study. We may need to evaluate not only skeletal muscle mass, but also muscle function to predict falls.

AB0374

**NONTUBERCULOUS MYCOBACTERIUM INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTRE EXPERIENCE IN JAPAN**

M. Hayashi, K. Funamura, M. Maeda, T. Kanamono. *Departments Of Orthopedics Surgery And Rheumatology, Nagano Red Cross Hospital, Nagano, Japan*

**Background:**

**Objectives:** Nontuberculous mycobacteria (NTM) infection has been increasing in both general population and immunocompromised patients in Japan. This study aimed to identify the incidence and clinical characteristics of NTM infections in patients with rheumatoid arthritis (RA).

**Methods:** We performed a cross-sectional analysis and assessed 11 RA patients, who were all female, complicated with NTM (mean age, 66.6 years) at our institute. We examined Steinbrocker Stage and Class, disease duration, positivity of anti-CCP antibody and rheumatoid factor, HAQ-DI, DAS28-ESR, NTM species, radiological features, methotrexate use and dosage, prednisolone use and dosage, biological agent use, and anti-NTM therapy.

**Results:** Average values obtained with SD were as follows: age (years), 66.6 ±8.0; Steinbrocker Stage I, 1; II, 0; III, 1; and IV, 9; Class 1, 2; 2, 5; 3, 4; and 4, 0; disease duration (months), 274.9±126.9; positivity of anti-CCP antibody, 80.0%; positivity of rheumatoid factor, 100%; HAQ-DI, 1.35±0.72; DAS28-ESR, 3.61 ±0.90; detection by sputum culture, 81.8%; NTM species, *M. avium*, 8 cases and *M. intracellulare*, 3 cases; bronchiectasis, 90.9%; interstitial pneumonia, 0%; methotrexate use and dosage (mg/week); 63.6% and 7.4±3.4; prednisolone use and dosage (mg/day); 81.8% and 4.3±2.0; biological agent use, 45.5%; and anti-NTM therapy, 36.4%.

**Conclusions:** At our institute, RA patients complicated with NTM were long-standing, had high disease activities and worse HAQ-DI. In all five patients (45.5%) who were treated with biologics, 3 who had preceding episodes of NTM infection were treated with anti-NTM therapy before treatment with biologics, and the other 2 who had asymptomatic NTM infection after treatment with biologics were not treated with anti-NTM therapy thereafter. In RA patients who are treated with biologics, it is necessary to perform sputum cultures constantly to detect possible NTM infections. This finding is important in the management of RA complicated with NTM.

**A SYSTEMATIC LITERATURE REVIEW OF OMEGA 3 IN THE TREATMENT OF RHEUMATOID ARTHRITIS**

M. Prince<sup>1</sup>, M. Bukhari<sup>2</sup>. <sup>1</sup>Lancaster Medical School, Lancaster University; <sup>2</sup>Rheumatology, Royal Lancaster Infirmary, Lancaster, UK

**Background:** Many different elements and variations of diet in the management of rheumatoid arthritis (RA) have been studied over the years such as vegan or Mediterranean diets.

**Objectives:** This systematic literature review covers one food stuff, omega-3 polyunsaturated fats efficacy in the management of RA alongside or independent of conventional DMARD therapy.

**Methods:** A systematic review of the literature between 1966–2017 was conducted using MEDLINE, CINAHL and EMBASE databases, with key words "RA" and "omega-3" for English-language articles producing 209 hits. We then refined to publications within the last 10 years, giving 96 results. Only including clinical trials gave 12 hits pertaining to 8 trials.

**Results:** The table above shows a summary of the evidence found. In total, 751 were exposed to omega-3 versus 1733 controls with the smallest study being an

RCT involving 13 people and the largest a case-control study with 1569 participants. A notable difference between these studies was the use of DMARD therapy as part of the inclusion or exclusion criteria. Another difference noted was the RA stage eligible for a trial. Some studies required a diagnosis of RA of <12 months whereas most required stable RA ongoing for >12 months.

**Conclusions:** This review concludes that omega-3 leads to clinical and statistically significant improvements in RA. There was a significant heterogeneity in the trials published with different inclusion criteria especially regarding disease duration and concomitant DMARD therapy. It would seem prudent to include dietary advice in our advice to patients when treating RA. Possible reasons for this evidence would include altering the microbiome.

**RAPAMYCIN INDUCES REMISSION IN PATIENTS WITH NEWLY DIAGNOSED RHEUMATOID ARTHRITIS**

M. Chen<sup>1</sup>, Z. Li<sup>1</sup>, H. Yao<sup>1</sup>, F. Hu<sup>1</sup>, J. Liang<sup>1</sup>, N. Yan<sup>1</sup>, H. Niu<sup>1</sup>, C. Gao<sup>2</sup>, X. Li<sup>1</sup>, C. Wang<sup>1</sup>. <sup>1</sup>Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; <sup>2</sup>Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, USA

**Background:** Rheumatoid arthritis (RA) is an autoimmune disease characterised by chronic inflammation of the joints. We found that there was an imbalance between Th17 and Treg cells in the patients with active refractory RA, reduced absolute number of Treg cells was found in these patients.

**Objectives:** To observe the medium-term curative effect of rapamycin in the treatment of 25 cases newly diagnosed rheumatoid arthritis.

**Methods:** Collecting 25 patients of newly diagnosed rheumatoid arthritis, which accorded with RA diagnosis standard of ACR in 1987. The patients were treated with rapamycin at a dose of 0.5 mg every 2 days for 24 weeks, then we observed the change of clinical improvement and immunological assessments after 24 weeks.

**Results:** There was 25 patients enrolled. After rapamycin treatment for 24 weeks, the mean DAS28 of them was decreased from 5.36 [1.42] to 3.45 [1.29](p=0.001). The absolute number of Treg<sup>CD4+CD25+Foxp3+</sup> cells significantly higher than baseline (30.24 [14.44],46.64 [27.54],p=0.025). The absolute number of Th17 cells was not significantly different (6.40 [4.46],7.03 [5.60],p>0.05), and the same as the ratio of Th17/Treg cells (0.25 [0.18],0.19 [0.16]),p>0.05). Meanwhile, the mean dose of prednisone was decreased from 11.25 mg/d to 9.6 mg/d.

**Conclusions:** Rapamycin could induce the balance of Th17 cells and Treg cells, especially up-regulate the absolute number of Treg cells, thus induce remission in patients with newly diagnosed RA.

**AB0377** **ARE CO-MORBIDITIES DURING RHEUMATOID ARTHRITIS DIFFERENT FROM THOSE IN ANKYLOSING SPONDYLOARTHRITIS ?**

M.A. ElAcheh, on behalf of Jguirim.M, Farhat.A, Braham.M, Bejia.I, Touzi.M, Zrour. S, Bergaoui.N. *Rheumatology, Fattouma Bourguiba Hospital, Monastir, Tunisia*

**Background:** Patients with inflammatory rheumatic diseases are certainly not unscathed from a lot of comorbidities which may be due to the systemic inflammatory activity of rheumatic diseases themselves, immune dysfunction, or iatrogenic, they may also occur independently.

Cardiovascular morbidity remains one of the most important to detect and is increased during these diseases.

So are there significant differences between co-morbidities associated with rheumatoid arthritis (RA) and those with ankylosing spondyloarthritis (AS)?

**Objectives:** To highlight the difference between comorbidities in RA and AS.

**Methods:** This is a retrospective study of 111 patients followed for RA ACR 1987 criteria, and 60 patients followed for AS, compiled between January 2005 and December 2016.

**Results:** The mean age of patients with RA was 51.04 years [18–80 years] with a sex ratio (M/F) of 0.18. The average duration of disease progression was 6.54 years [0–29 years]. The mean age of patients with AS was 40.4 years [18–61] with a sex ratio (M/F) of 19. The average duration of disease progression was 16.8 years [1–45 years].

About cardiovascular comorbidities, 16.2% of patients with RA and 5.1% with AS were diagnosed with high blood pressure. Dyslipidemia was found in 2.7% of patients with RA and in 0% with AS.

31.5% with RA and 21.7% of AS have overweight and obesity was illustrated in 22.5% of RA and 11.7% of AS.

Heart and coronary failure were documented in 5.4% of RA and 1.7% of AS. Likewise renal failure in 3.6% of RA and 3.4% of AS. Diabetes was found in 18% of RA and 10% of AS. Hypothyroidism in 5.4% of RA and 1.7% of AS. Gout attack in 0.9% of RA and 0% with AS and osteoporosis in 21.3% of RA and 40% of AS.

**Conclusions:** Our study concluded at the frequency of comorbidities and mostly cardiovascular in rheumatoid arthritis compared with AS. Osteoporosis is also more common in our studied population with RA, although not rare with our patients with AS. This can be explained by the prescription of corticosteroid therapy in RA.

**AB0378** **PULMONARY AFFECTION IN EGYPTIAN PATIENTS WITH RHEUMATOID ARTHRITIS**

M.S. Abdel-Baky<sup>1</sup>, D.F. Mohamed<sup>1</sup>, S.H. Hamza<sup>1</sup>, D.A. El Sherbiny<sup>1</sup>, M. Rezk<sup>1</sup>, A. A. Gomaa<sup>2</sup>. <sup>1</sup>Department of Medicine Division of Rheumatology; <sup>2</sup>Department of Chest diseases, Ain Shams University, Cairo, Egypt

**Background:** Rheumatoid arthritis(RA) is a disabling autoimmune systemic inflammatory disease. It manifests as peripheral symmetric inflammatory polyarthritis and produces a wide range of extra-articular manifestations. Interstitial lung disease (ILD), a diffuse progressive disease of the lung parenchyma, is the most serious manifestation of RA lung affection, it remains as a significant source of morbidity and mortality.

**Objectives:** To evaluate the frequency and pattern of pulmonary affection in a cohort of Egyptian rheumatoid arthritis (RA) patients and the relation to disease activity and severity.

**Methods:** Seventy RA patients who fulfilled 2010 (ACR/EULAR) classification criteria underwent full clinical assessment, plain X ray chest, chest high-resolution computed tomography (HRCT) with assessment of the extent and severity of pulmonary affection by Warrick score. Pulmonary function tests (PFTs) including diffusion lung capacity for carbon monoxide (DLCO) were done. Transthoracic echocardiography to screen for pulmonary hypertension (PH). Assessment of disease activity by DAS28 score and of radiographic joint damage by modified Larsen score.

**Results:** The mean age of the patients was 44±10.8 years; females(87.1%) and males (12.9%), mean disease duration 7.3±6 years. PFTs were abnormal in (45.7%) with restrictive pattern in (24.3%) of patients followed by small airway affection in (10%), mixed pattern in (8.6%), the least is the obstructive pattern in (2.8%) of patients. DLCO was abnormal in (72.86%) with mild affection in (48.57%), moderate in (15.7%) and severe affection in (8.6%) of patients. HRCT abnormalities were found in 30 patients (42.85%). Interstitial abnormalities were detected in (35.7%). Septal or reticular lines, ground glass appearance, pleural irregularities and bronchiectasis were the most common findings. Most common HRCT pattern was nonspecific interstitial pneumonia (NSIP) in 12.8% (9/70), usual interstitial pneumonia (UIP) in 7% (5/70), organising pneumonia (OP) in 1.4% (1/70) and indeterminate subtype in 14% (10/70). HRCT total score (Warrick score) was correlated with age, disease activity (DAS ESR 28), ESR, modified Larsen score, FVC, FEV1 and DLCO. Age, dyspnea and DLCO impairment were

significant predictors for development of HRCT chest abnormalities. Pulmonary hypertension(sPAP >30 mmHg) was detected in (14%) of patients.

**Conclusions:** Pulmonary abnormalities are common in Egyptian RA patients. HRCT and PFTs including DLCO can be used effectively for early diagnosis and monitoring of pulmonary affection in RA patients. DLCO can detect pulmonary abnormalities early in clinically asymptomatic patients. Age, disease activity and severity, PFTs and ESR are correlated with the pulmonary affection in RA. Age, dyspnea and DLCO impairment are significant predictors of pulmonary affection in RA patients. Echocardiography can be used as a screening tool for detection of pulmonary hypertension.

**AB0379** **MUSCULOSKELETAL INVOLVEMENTS IN GIANT CELL ARTERITIS**

M. Tougorti, T. Ben Salem, M.S. Hamdi, M. Lamloum, I. Ben Ghorbel, M. H. Houman. *Internal medicine, RABTA HOSPITAL, Tunis, Tunisia*

**Background:** Joint involvement is frequent in Giant cell arteritis (GCA), mostly polymyalgia rheumatica (PMR). The aim of this study was to describe clinical features of joint involvement in GCA.

**Objectives:** To compare patients according to the presence or not of PMR.

**Methods:** A retrospective and descriptive study of 96 patients with GCA diagnosed between 2000 and 2015. ACR 1990 criteria were used for the diagnosis of GCA. Clinical, biological and histological features were recorded and analysed.

**Results:** Joint involvements were noted in 67 patients with GCA (69.8%); 34 women and 33 men. Mean age at diagnosis was 72.4±6.36 years. PMR was diagnosed in 45 patients (46.8%) and revealed the disease in two patients. Neck pain was noted in 48 patients. Twenty one patients (21.8%) complained of peripheral arthralgias which revealed GCA in five cases. Joint manifestations were associated to cardinal symptoms of GCA: headache (97%), jaw claudication (62%), scalp tenderness (49.3%) and ophthalmologic manifestations (36.9%). Erythrocyte sediment rate and C-reactive protein were high in 89.2% and 82.7% of cases respectively.

Constitutional symptoms (60% vs 39.2%; p=0.042), jaw claudication (68.2% vs 47.1%; p=0.038) and neck pain (62.2% vs 39.2%; p=0.024) were significantly more frequent in patients with PMR. Peripheral arthralgias (28.9% vs 15.7%) were more frequent in patients with PMR without significant differences. Giant cell vasculitis on temporal arterial biopsy was more frequent in patients with PMR (57% vs 30%; p=0.037).

Corticosteroids were given in 97% of patients while methotrexate was used in 20.9%.

**Conclusions:** PMR in patients with GCA seem to be associated to different joint manifestations.

**AB0380** **DELAY IN TIME TO DIAGNOSIS INCREASES THE RISK OF SUFFERING CLASSIC CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

M. Robustillo Villarino<sup>1</sup>, A. Sendra García<sup>2</sup>, J.J. Alegre Sancho<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital Universitari Dr Peset i Aleixandre; <sup>2</sup>Rheumatology, Foundation for the Promotion of Health and Biomedical Research of Valencia (FISABIO), Valencia, Spain

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease that constitutes an independent cardiovascular risk factor (CVRF). In addition, patients with RA have a higher prevalence of CVRF than the general population.

**Objectives:** To assess whether delay in time to diagnosis of the disease may increase the risk of CVRF in patients with RA.

**Methods:** Patients diagnosed with RA, according to the EULAR/ACR 2010 classification criteria, were consecutively selected and recruited for a period of 12 months. Delay in time to diagnosis was calculated as the interval between the beginning of first joint symptoms and the diagnosis of RA with start of specific treatment. Furthermore, the presence or absence of arterial hypertension (AHT), dyslipidemia (DL) and diabetes mellitus (DM) were recorded. Whether its diagnosis was prior or subsequent to the diagnosis of the inflammatory disease was also recorded. SPSS version 17.0 software was used for statistical analysis, considering statistical significance for p<0.05.

**Results:** A total of 244 patients were studied, 73.8% (180) of whom were women and 26.2% (64) men. The mean age was 60.42 years (SD 13.24). Mean Delay in time to diagnosis was 2.1 years (SD 5.5). Mean age at diagnosis was 48.9 years (SD 15.7). Regarding classic CVRF, the percentage of patients with AHT, DL and DM before RA diagnosis were 17.6% (43), 6.1% (15) and 6.1% (15), respectively.

After RA diagnosis, 22.5% (55), 43.4% (106) and 3.3% (8) of patients were diagnosed with AHT, DL and DM. Delay in time to diagnosis was significantly associated with AHT, DL and DM diagnosis after RA diagnosis.

**Conclusions:** A higher inflammatory load, such as that accumulated in RA patients who have delayed the start of treatment, is associated with a higher probability of developing CVRF, which are associated with the appearance of vascular structural damage in the long term. These results are consistent with the effect of inflammatory cytokines on peripheral tissues (increased lipolysis in adipose tissue, increased insulin resistance, increased arterial stiffness).

#### AB0381 CLINICAL AND RADIOGRAPHIC CHARACTERISTICS OF AIRWAY DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Konda<sup>1,2</sup>, Y. Katsumata<sup>1</sup>, Y. Seto<sup>1,2</sup>, M. Hasegawa<sup>3</sup>, F. Sakai<sup>4</sup>, H. Katsura<sup>3</sup>, H. Yamanaka<sup>1</sup>. <sup>1</sup>Institute of Rheumatology, Tokyo Women's Medical University, Tokyo; <sup>2</sup>Division of Rheumatology; <sup>3</sup>Division of Respiratory Medicine, Tokyo Women's Medical University Yachiyo Medical Center, Chiba; <sup>4</sup>Department of Diagnostic Radiology, Saitama International Medical Center, Saitama Medical University, Saitama, Japan

**Background:** Airway disease (AD) has drawn attention both clinically and etiologically in rheumatoid arthritis (RA), but is still poorly understood.

**Objectives:** We aimed to elucidate the clinical and radiographic characteristics of AD in patients with RA.

**Methods:** We retrospectively reviewed high-resolution computed tomography (HRCT) images and clinical data of 131 consecutive RA patients in whom HRCT were scanned for clinical purposes and screening. Overlap patients with other collagen tissue diseases and patients complicated with active infection or lung cancer were excluded. Patients who had a history of drug-induced lung disease, thoracic radiation, or exposure to dust were also excluded. HRCT images were reviewed independently by a pulmonologist and a radiologist in blind fashions, and cases of disagreement were discussed to reach a final consensus. AD was radiographically sub-categorised into 3 sub-groups: central AD, small AD, and middle lobe and lingular bronchiectasis. The associations between AD and interstitial lung disease (ILD) and each pair of the subtypes of AD were analysed by Fisher's exact test. The risk factors for AD and subtypes of AD were identified by multivariate logistic regression analyses.

**Results:** The mean age of the patients was 65 years old, the mean disease duration of the patients was 123 months, 69% of the patients were women, and 42% of the patients had past/current histories of smoking. The mean Disease Activity Score 28 (DAS28)-erythrocyte sedimentation rate (ESR) value was 2.87. AD and ILD were observed in 53 (40%) and 36 (27%) patients, respectively, and both in 19 (15%) patients. AD and ILD were not significantly associated ( $p=0.11$ ). By multivariate logistic regression analyses, rheumatoid factor (RF) was identified as risk factors for whole AD (odds ratio [OR] 2.7; 95% confidence interval [CI], 1.0 to 6.9;  $p=0.04$ ). Central AD, small AD, and middle lobe and lingular bronchiectasis were observed in 45 (34%), 31 (24%), and 17 (13%) patients, respectively. Each pair of these 3 subtypes were significantly associated with each other ( $p<0.001$  in all comparisons). By multivariate logistic regression analyses without considering the overlaps with multiple subtypes of AD in the same patients, age and RF were identified as risk factors for central AD: the OR for age was 1.04 (95% CI, 1.00 to 1.08;  $p=0.04$ ); the OR for RF was 3.0 (95% CI, 1.1 to 8.5;  $p=0.034$ ). In contrast, DAS28-ESR values was identified as a risk factor for small AD: the OR for DAS28-ESR values was 1.5 (95% CI, 1.0 to 2.4;  $p=0.0498$ ). Lastly, no significant risk factor was identified for middle lobe and lingular bronchiectasis by the multivariate logistic regression analysis, although disease duration tended to be longer in the patients with middle lobe and lingular bronchiectasis than in those without ( $p=0.12$ ). In contrast, smoking histories was not significantly associated with whole AD or any subtypes of AD.

**Conclusions:** Radiologically defined AD was frequent comorbidity in RA patients, and multiple subtypes of AD were observed and coexisted. Furthermore, AD may be related to the pathology of RA, and different AD subtypes may have

distinct risk factors. Prospective studies with early RA patients were warranted to further clarify these findings and clinical impact of AD.

#### AB0382 RAPAMYCIN SELECTIVELY INCREASES CIRCULATING TREG CELLS AND MAINTAIN REMISSION OF PATIENTS WITH RHEUMATOID ARTHRITIS

N. Yan<sup>1</sup>, H. Yao<sup>1</sup>, F. Hu<sup>1</sup>, J. Liang<sup>1</sup>, H. Niu<sup>1</sup>, X. Li<sup>1</sup>, C. Gao<sup>2</sup>, C. Wang<sup>1</sup>. <sup>1</sup>The Second Hospital of Shanxi Medical University, Taiyuan, China; <sup>2</sup>Brigham and Women's Hospital, Boston, USA

**Background:** It is thought that Rheumatoid arthritis (RA) arises from a breakdown in immunological self-tolerance. We have given a direct evidence for this conception that absolute number of peripheral CD4<sup>+</sup>Regulatory T-cells (Tregs) decreased in RA patients<sup>[1]</sup>. Furthermore, rapamycin can significantly induce immune tolerance through up-regulate Tregs and down-regulate Th17 cells<sup>[2]</sup>.

**Objectives:** To investigate the effect of rapamycin on the absolute numbers of Th17 and Treg cells and on maintenance of disease remission in RA patients instead of DMARDs.

**Methods:** Thirty-two patients, who achieved remission (DAS28  $\leq 2.6$ ) by the treatment with two kinds of DMARDs for more than half a year, received rapamycin at a dose of 0.5 mg every other day for 12 weeks. Before and after treatment with rapamycin, the disease activity and immunological assessments of them were performed. In this study, BD Trucount tubes with the lyophilized pellet of a known number of internal counting beads were used for determining absolute counts of total CD4<sup>+</sup> T cells in peripheral blood and then calculating the absolute number of Th17 cells and CD4<sup>+</sup>Tregs.

**Results:** At week 12, 65.6% of the patients maintained remission (DAS28  $\leq 2.6$ ). The DAS28 was increased from a median of 2.03 (at week 0) to 2.15 (at week 12) ( $p>0.05$ ). The absolute number of Treg cells was increased significantly from a median of 22.16 (at week 0) to 32.19 (at week 12) ( $P=0.039$ ). The absolute number of Th17 cells was decreased from a median of 5.98 (at week 0) to 5.56 (at week 12) ( $p>0.05$ ). The ratio of Th17/Treg cells was also decreased from a median of 0.245 (at week 0) to 0.19 (at week 12) ( $p>0.05$ ). At the same time, the mean dosage of prednisone decreased from 6.29 mg/d to 5.35 mg/d and that of DMARDs were also reduced from 93.75% to 56.25%.

**Conclusions:** Rapamycin was effective in the maintenance of remission (DAS28  $\leq 2.6$ ) by increase of Treg cells and correcting the imbalance of Th17/Treg cells. Meantime, the mean dosage of conventional drugs such as glucocorticoid and DMARDs gradually decreased. In the future, rapamycin may replace current immunosuppressant for treatment of RA.

#### AB0383 CHANGES OF METABOLIC BIOMARKER LEVELS UPON ANTI-TNF THERAPY IN RHEUMATOID ARTHRITIS PATIENTS

N. Bodnár<sup>1</sup>, A. Pusztai<sup>1</sup>, E. Végh<sup>1</sup>, Á. Horváth<sup>1</sup>, S. Szántó<sup>1</sup>, G. Szűcs<sup>1</sup>, A. Hamar<sup>1</sup>, A. Domján<sup>1</sup>, K. Hodosi<sup>1</sup>, I. Seres<sup>2</sup>, G. Kerekes<sup>3</sup>, Z. Szekanez<sup>1</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Department of Internal Medicine; <sup>3</sup>Intensive Care Unit, Department of Internal Medicine, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

**Background:** Rheumatoid arthritis (RA) has been associated with cardiovascular disease and metabolic syndrome. Numerous pro-inflammatory cytokines (e.g. TNF- $\alpha$ , IL-1, IL-6) are released, which cytokines cause increased reactive oxygen species (ROS) production and thereby contribute to the increased lipid peroxidation and reduction of many antioxidants. These processes not only lead to the deterioration of joints and other tissues but may also contribute to comorbidities, such as atherosclerosis.

**Objectives:** The aim of this study was to assess the effects of anti-TNF therapy on different metabolic markers, such as PON1 (paraoxonase 1), arylesterase, chemoerin and adiponectin. We also investigated whether these biomarkers correlated with various demographic, clinical and laboratory markers.

**Methods:** We treated 37 RA patients with either etanercept (ETN) or certolizumab pegol (CZP) in a 12 month follow-up study. Assessments were performed at baseline, and 3, 6 and 12 months after treatment initiation. Serum chemerin and adiponectin concentrations were measured by commercially available ELISA kits (R and D System, MN and USA). PON1 and arylesterase activities were measured by spectrophotometry. In addition, age, disease duration, disease activity (DAS28), CRP, anti-CCP, IgM rheumatoid factor and plasma lipid levels were also assessed. Arterial flow-mediated vasodilation (FMD), carotid intima-media thickness (cIMT) and arterial pulse-wave velocity (PWV) were assessed by ultrasound.

**Results:** Anti-TNF treatment resulted in a significant decrease in the levels of chemerin ( $p<0.001$ ) and adiponectin ( $p<0.007$ ) after 12 months. There were no significant changes in the levels of other metabolic biomarkers. We found the following correlations between the baseline values: the PON1 levels correlated with the age of patients ( $R=0.466$ ,  $p=0.004$ ). The adiponectin correlated with the disease activity ( $R=0.385$ ,  $p=0.030$ ), HDL-C ( $R=0.417$ ,  $p=0.012$ ) and the triglyceride levels ( $R=0.481$ ,  $p=0.003$ ). The total cholesterol correlated with the PWV ( $R=0.449$ ,  $p=0.021$ ) and the levels of the LDL-C ( $R=0.911$ ,  $p<0.001$ ). The baseline triglyceride correlated with the IgM rheumatoid factor ( $R=0.343$ ,  $p=0.021$ ); and the levels of LDL-C correlated with the PWV values ( $R=0.444$ ,  $p=0.023$ ).

**Conclusions:** Metabolic factors, such as certain adipokines, PON1 and arylesterase may play a role in oxidative stress and atherosclerosis associated with RA. Anti-TNF treatment may affect adipokine levels.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.2122

#### AB0384 RHEUMATIC ARTHRITIS PATIENTS WITH VERY HIGH CARDIOVASCULAR RISK: POOR RESULTS IN CHANGES IN LIFESTYLE DURING FOLLOW-UP

N. Vegas-Revenga<sup>1</sup>, V. Portilla<sup>1</sup>, L.C. Domínguez-Casas<sup>1</sup>, J.L. Martín-Varillas<sup>1</sup>, B. Atienza-Mateo<sup>1</sup>, M. Agudo<sup>1</sup>, J. Rueda-Gotor<sup>1</sup>, J.L. Hernández<sup>2</sup>, R. Blanco<sup>1</sup>, M. A. González-Gay<sup>1</sup>, A. Corrales<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Internal Medicine, Hospital Universitario Marqués de Valdecilla, Santander, Spain

**Background:** Rheumatoid arthritis (RA) is associated with accelerated atherosclerosis, which results in high cardiovascular morbidity and mortality. The European Atherosclerosis Society recommends a strict control of cardiovascular (CV) risk factors, focusing in a healthy lifestyle, for the prevention of future CV events.

**Objectives:** Our aim was to assess the characteristics of healthy lifestyle in patients with RA and very high risk of CV events.

**Methods:** Prospective study that included a group of 113 patients, of whom 65 presented carotid plaques on carotid ultrasound study and, due to this, were categorised as having very CV high risk at the baseline visit. At this time, patients were informed about the risks associated to their disease and the high risk of having CV events. They were even warned of the need of healthy lifestyle habits.

Data on lifestyle, smoking, obesity and diabetes mellitus were collected at baseline and last visit (with an interval of more than 5 years)

**Abstract AB0384 – Table 1.** Clinic characteristics of 65 patients with RA and very high CV risk.

CLINIC CHARACTERISTICS	LAST VISIT (n = 65)
Age (years): Mean (SD)	67 (8.7)
Sex: Women (%)	44 (68%)
Duration of RA (years): Mean (SD)	17 (7.7)
Baseline Visit- Final Visit (years): Mean (SD)	5.5 (0.95)
Dyslipidemia: Yes (%)	47 (72%)
High blood pressure: Yes (%)	40 (62%)
Diabetes Mellitus: Yes (%)	12 (18%)
Smoking: Yes (%)	17 (26%)
Obesity: Yes (%)	26 (40%)
Total Cholesterol (mg/dl): Mean (SD)	186 (42.4)
Waist circumference: Yes (%) ( $\geq 102$ cm, $\geq 88$ cm)	42 (65%)
LDL- Cholesterol (mg/dl): Mean (SD)	104 (34.6)
Atherogenic index: Mean (SD)	3.37 (0.88)
Systolic blood pressure (mmHg): Mean (SD)	136 (14.2)
Diastolic blood pressure (mmHg): Mean (SD)	80 (8.2)

**Results:** The results of the 65 patients at the last visit are shown in table 1. The average age was of 67 years, with a disease duration of 17 years and high prevalence of dyslipidemia (72%), HTA (62%) and obesity (40%).

Data obtained at the basal and last visit (with an average difference of 5.5 years) were compared in table 2. At last follow-up none of the smokers at baseline had discontinued smoking. There were no significant differences in the body mass index (BMI) average. Nevertheless, there was increase in the number of patients

with a BMI  $<30$  (36% vs 31%). Only a few patients claimed to go on any type of diet (20%), although the majority (88%) had classic CV risk factors (DM, HTA, obesity or dyslipidemia) at baseline that required adequate diet regime. Yet, more than half of the patients (62%) made regular exercise ( $>3$  times/week) and did not have a sedentary lifestyle (50%), despite having a mean age of 67 years and long disease duration at baseline. Poor control of diabetes mellitus (DM), was found in more than half of the patients.

**Abstract AB0384 – Table 2.** Variables assessed at baseline visit and last visit of 65 patients with RA and very high CV risk.

Variables	BASILINE VISIT (n = 65)	LAST VISIT (n = 65)
Smoking: Yes (%)	17 (26%)	17 (26%)
Discontinued smoking: Yes (%)	-	0
Obesity: Yes (%)	24 (37)	26 (40%)
BMI: Mean (SD)	28.2 (5)	28.6 (5.5)
BMI $> 30$ : Yes (%)	22 (36%)	19 (31%)
Diet: Yes (%)	-	12 (20%)
Exercise: Yes (%)	-	38 (62%)
Sedentariam: Yes (%)	-	30 (50%)
Diabetes Mellitus (DM): Yes (%)	6 (9%)	12 (18%)
DM. Treatment: Yes (%)	4 (67%)	6 (50%)
DM. Higher Glycosylated Hemoglobin: Yes (%)	-	7 (58%)

**Conclusions:** Despite having been informed on the high risk of CV events, patients with RA included in the category of very high CV risk performed poor long-term control of factors that include a healthy lifestyle.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.4207

#### AB0385 COMPARATIVE ASSESSMENT OF BMD IN PRE-, POSTMENOPAUSAL WOMEN AND MAN WITH RHEUMATOID ARTHRITIS (RA)

O. Garmish, A. Romanovskiy, T. Orlyk. Institute of Cardiology, Kyiv, Ukraine

**Background:** RA doubles the risk of hip and vertebral fractures, regardless of the use of GCs, and disease activity is consistently associated with low BMD. But now, it is not clearly identified predictors of the individual risk of bone loss depends on sex and menopausal status patients with RA

**Objectives:** To compare BMD in man, pre- and postmenopausal women with RA

**Methods:** The study was performed on 145 patients: 117 women (mean age 45.4  $\pm$  13.0 years, mean disease duration 9.7  $\pm$  7.7 years, 41% (n=48) postmenopausal) and 28 man (mean age 46.4  $\pm$  16.9 years, mean disease duration 4.2  $\pm$  4.1 years) with RA. 91.6% have moderate/high disease activities by DAS 28. 68.4% women and 64.3% men received prednisolon  $\leq 10$  mg/day more than 3 month, 87% of patients received MTX. BMD was measured in 3 part of the skeleton: hip, lumbar spine, distal part of forearm. Female patients were divided in two groups by menopause: premenopausal (PreM) in mean age 36.9  $\pm$  9.3 years and postmenopausal (PM) in the mean age 57.6  $\pm$  5.9 years.

**Results:** BMD was decreased in 44.5% of women and 42.9% of man. BMD of hip, lumbar spine, distal part of forearm were respectively decreased in 26.1%, 26.1%, 18.8% PreM women and 66.7%, 70.8%, 79.2% PM women. 39.3% of man had decrease BMD in the hip and 42.8% – in the lumbar spine. In women the age was strong associated with BMD decrease, in man no association with age was found. In PreM women was not found association between BMD, disease duration, DAS28 and X-ray changes in hands and feet, only cortical index was correlated with BMD in all part of the skeleton. In PM women the disease duration was negatively correlated with BMD in total hip and forearm, in men – with BMD in lumbar spine and hip neck ( $p<0.01$ ). It was found association between BMD and X-ray stage by Steinbrocker in PM women and man. DAS28 was strong associated with low hip and forearm BMD in PM women and low spine BMD in men. According to dispersion analysis PM women with III-IV X-ray stages has significantly lower BMD in the hip (total:  $Z=2.16$ ,  $p=0.04$ ; neck:  $Z=2.61$ ,  $p=0.01$ ) and medium part of forearm ( $Z=2.92$ ,  $p=0.001$ ). Man had significantly lower BMD in all part of the skeleton since II X-ray stage ( $p<0.001$ ) and negative correlation between BMD and presence of erosion.

**Conclusions:** A sexual differences in BMD loss was observed in different parts of the skeleton. In man the most affected part of the skeleton was spine and BMD changes were more likely to PreM women, had high association with disease activity by DAS28 and presence of erosion, and no association with age. In PreM women only cortical index had high predictive value for decrease BMD in all parts of the skeleton. Age, disease deration, duration of menopause, DAS28 and x-ray changes in hand and feet was strong associated with decreased BMD in the hip and forearm in PM women.

**AB0386** RELATIONSHIP BETWEEN EXTRA-ARTICULAR MANIFESTATIONS AND JOINT SURGERY IN RHEUMATOID ARTHRITIS

O. Saidane, M. Sellami, R. Barhoumi, A. Ben Tekaya, H. Ajlani, R. Tekaya, I. Mahmoud, L. Abdelmoula. *Rheumatology, Charles Nicolle Hospital, Tunis, Tunisia*

**Background:** Extra-articular organ involvement is a serious condition in rheumatoid arthritis (RA) associated with increased mortality. These manifestations may affect the course of the disease, but could they accelerate the joint destruction and shorten the pre- joint surgical period?

**Objectives:** Our objective was to study the impact of extra-articular manifestations (EAM) on joint surgery during RA management.

**Methods:** It is a retrospective comparative study involving 500 RA patients (according to 1987 ACR or 2010 ACR/EULAR criteria) in rheumatology department between 2000 and 2014. The assessment of EAM was systematically done in RA diagnosis and during management. We compared 2 groups of RA patients according to the presence or not of EAM.

**Results:** We enrolled 422 women and 78 men with mean age of 53.3 years (21–83) and mean disease duration of 12 years [2–40]. RA was Rheumatoid Factor positive and erosive in 71.4% and 90% cases respectively. A surgical procedure was considered necessary in 59 cases (11.8%). An EAM was diagnosed in more than a half of patients (62.4%) with a predominance of ocular and bone manifestation, mainly xerophthalmia (173 cases, 34.6%) and osteoporosis (120 cases, 24%). Secondary Sjögren's syndrome was confirmed in 70 cases. Pulmonary manifestations related to RA were noted in 70 patients (14%), especially diffuse interstitial pulmonary in 48 cases (9.6%). Renal involvement was present in 45 patients, of which interstitial renal disease was the most common manifestation (29 patients, 64.4%). Rheumatoid nodules (4.6%) and small vessel vasculitis (0.6%) were the most frequent skin manifestations. A significantly higher incidence of joint surgery was noted in osteoporotic RA patients (OR=1.91; p=0.029). There was no significant correlation between joint surgery resort and other EAM (table 1).

**Abstract AB0386 – Table 1.** Correlation between EAM and joint surgery during RA

EAM (N)	Joint surgery (+)	Joint surgery (-)	p
Xerophthalmia	22	151	0875
Secondary Sjögren's syndrome	9	61	0633
Osteoporosis	31	89	0029
Pulmonary manifestation	3	67	0601
Renal manifestation	3	42	0257
Skin manifestation	1	25	0502

**Conclusions:** Our study concluded to a higher incidence of EAM during RA management. Osteoporosis was the only EAM associated to greater frequency of joint surgery.

**AB0387** IS RHEUMATOID ARTHRITIS A RISK FACTOR FOR DEMENTIA ?

O. Saidane, M. Sellami, I. Mahmoud, A. Ben Tekaya, H. Ajlani, R. Tekaya, L. Abdelmoula. *Rheumatology, Charles Nicolle Hospital, Tunis, Tunisia*

**Background:** A direct link between chronic inflammation and dementia was well established by different epidemiological studies. Nevertheless, data on impaired cognitive function during rheumatoid arthritis (RA) are still controversial and doubtful.

**Objectives:** To assess the association of RA and impaired cognitive function.

**Methods:** This is a case-control study involving patients with RA according to ACR/EULAR criteria 2010 and randomly-chosen controls by matching on age and gender during 4 months. The Mini Mental State Examination (MMSE) was used to evaluate cognitive functions. Cognitive impairment was defined by a MMSE score

lower than 24 (or 26 in patients with primary education). The activity of RA was evaluated using Disease activity score (DAS28).

**Results:** A total of 20 RA patients (12 women and 8 men) with a mean age of 52.6 years [31–72] and 20 healthy controls (15 women and 5 men) with a mean age of 55.8 years [50–77] were included. No significant differences for age or gender between RA patients and controls were observed. Rheumatoid factor was positive in 95% of cases. Mean disease duration was 3.2 years [2–6]. Thirteen RA patients had active disease with mean DAS28 of 4.73. Three-quarters of RA patients had been treated with methotrexate and only 8 patients received biotherapy: 5 anti TNF alpha and 3 Rituximab. Forty percent of RA group were illiterate versus 49% in control group. Eleven RA patients (55%) had a normal cognitive function versus 15 (75%) in control group. A moderate cognitive impairment (mean MMSE of 18.62) was found in 8 RA patients (40%) and 2 controls (10%) primarily affecting constructional apraxia. No severe cognitive impairment was found in the 2 groups. Significant positive association was found between cognitive impairment and RA (p=0.001). Patients with RA using methotrexate had higher risk for cognitive impairment comparing to patients using biotherapy (p=0.02).

**Conclusions:** Our study highlighted a serious psychological expression of RA which was early onset of cognitive impairment and dementia. This is a possible effect of inflammation and vascular disease caused by RA.

**AB0388** SLEEP DISTURBANCES IN INFLAMMATORY RHEUMATIC DISEASES

O. Addimanda<sup>1,2</sup>, M. Burattini<sup>1,3</sup>, L. Baldelli<sup>1,3</sup>, G. Chiaro<sup>1,3</sup>, E. Pignotti<sup>2</sup>, F. Provini<sup>1,3</sup>, R. Meliconi<sup>1,2</sup>. <sup>1</sup>Department of Biomedical and Neuromotor Sciences, University of Bologna; <sup>2</sup>Medicine and Rheumatology Unit, Rizzoli Orthopaedic Institute, IRCCS; <sup>3</sup>Neurology Unit, Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy

**Background:** Inflammatory rheumatic joint diseases such as Ankylosing Spondylitis (AS) and Rheumatoid Arthritis (RA) have recently been found to be associated with sleep disturbances especially obstructive sleep apnoea.<sup>1,2</sup>

**Objectives:** The aim of our study was to evaluate the occurrence of sleep disturbances, especially REM Sleep Behaviour Disorder (RBD), in inflammatory rheumatic diseases, (rheumatoid arthritis -RA and Spondyloarthritis -SpA).

**Methods:** We enrolled 103 consecutive patients affected by inflammatory rheumatic diseases [RA (64, 62.1%) or SpA (39, 37.9%)]. Patients underwent a neurologic and psychopathological assessment, including identification of sleep disorders by means of the Pittsburgh Sleep Quality Index (PSQI), the Berlin and the REM sleep behaviour disorder (RBD) questionnaires, a structured interview on sleep terrors and sleep paralysis, Beck Depression Inventory (BDI-II) and the Spielberger State-Trait Anxiety Inventory (STAI). Statistical analysis was performed utilising SPSS software.

**Results:** No significant differences were found between RA and SpA patients in age at diagnosis, disease duration, smoke habit, alcohol consumption, anamnestic comorbidities (especially metabolic diseases, anxiety or depression), disease activity/remission and biologic Disease Modifying Antirheumatic Drugs use. No differences demonstrated in BDI-II, STAI, PSQI and RBD questionnaires; only the Berlin Questionnaire showed significant differences (17.2% in RA vs 35.9% in SpA, p=0.036). No differences in sleep paralysis (10.9% in RA vs 7.7% in SpA, p=0.74) and sleep terrors (37.5% in RA vs 20.5% in SpA, p=0.0826) which were found to be increased if compared with general population (2.6%).

**Conclusions:** Our data show an increased prevalence of sleep terrors in rheumatic patients when compared to the general population although no differences were highlighted between RA and SpA; also increased risk of sleep apnoea (Berlin Questionnaire) has been demonstrated in patients with SpA compared with RA.

**AB0389 HIPERTRIGLYCERIDEMIC-WAIST PHENOTYPE: A MARKER OF CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS PATIENTS**

I.P. Guzmán Guzmán<sup>1</sup>, O. Zaragoza-García<sup>1</sup>, J.E. Navarro-Zarza<sup>2</sup>, J. Maldonado-Anicacio<sup>2</sup>, N. Castro-Alarcón<sup>3</sup>, I. Parra-Rojas<sup>1</sup>. <sup>1</sup>Facultad de Ciencias Químico Biológicas, Universidad Autónoma de Guerrero, Chilpancingo; <sup>2</sup>Hospital General, Chilpancingo, Guerrero; <sup>3</sup>Universidad Autónoma de Guerrero, Chilpancingo, Mexico

**Background:** The risk of cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA); about 50% of associated deaths in rheumatoid arthritis (RA) are attributed to CVD.<sup>1</sup> Both traditional cardiovascular risk (CVR) factors and inflammation contribute to this risk. The hyperuricemia (HUC) and metabolic syndrome (MetS) are considered parameters of CVR, both closely related,<sup>2</sup> and recently the hypertriglyceridemic-waist (HTGW) phenotype has been defined as well a marker to identify HUC in the general population.<sup>3</sup>

**Objectives:** To determine the prevalence of HTGW phenotype and to evaluate its association with CVR parameters among RA patients.

**Methods:** HTGW phenotype was defined as waist girth  $\geq 102$  cm in male and  $\geq 88$  cm in female and TG  $> 150$  mg/dl in 250 patients diagnosed with RA according to the ACR/EULAR 2010 criteria. The levels of uric acid  $> 5.5$  mg/dL defined HUC. The MetS and its individual components (NCEP-ATPIII) were evaluated as parameters of CV risk.

**Results:** We identified 51 AR patients (20.4%) with HTGW phenotype. Adjusting for covariates in a logistic regression model, it was observed that the HTGW phenotype is associated with the presence of HUC (OR=6.14,  $p < 0.001$ ), and MetS (OR=5.7, IC95%, 2.7–12.2,  $p < 0.001$ ).

**Conclusions:** HTGW is prevalent in RA patients from southern Mexico. The HTGW phenotype can be considered at low cost marker, used as a tool screening to predict high metabolic risk during the clinical course of the rheumatic disease.

**AB0390 RELATIONSHIP BETWEEN BODY MASS INDEX AND PERSONALITY IN AN EARLY ARTHRITIS COHORT OF PATIENTS**

P. Moreno Fresneda, D. Martínez-Quintanilla Jiménez, N. García Castañeda, T. Velasco Ripoll, A.M. Ortiz García, I. González Álvaro. *Rheumatology, HOSP. Universitario La Princesa, Madrid, Spain*

**Background:** According to previously reported data from our early arthritis registry (PEARL, Princess Early Arthritis Register Longitudinal), patients with a higher BMI have higher scores in pain and disability scales. We also described some years ago that, in the same population, the structure of personality explored with the PANAS questionnaire (Positive and Negative Affect Scale) affects some outcomes in arthritis measures. Specifically, higher scores on the negative affect subscale associate higher scores in pain and disability scales.

**Objectives:** To analyse the relationship between BMI and the structure of the affect in the PEARL cohort.

**Methods:** PEARL registry includes patients with early arthritis (less than one year of duration), in whom, sociodemographic, disease related and treatment data are recorded in five protocolised visits. We analysed data from those patients in which the PANAS questionnaire data were available and whose classification, after 2 years of follow-up, were rheumatoid arthritis -according to the 1987 ACR classification criteria – or undifferentiated arthritis. The structure of the affect was evaluated with the PANAS questionnaire administered in one single occasion. This questionnaire is used to evaluate the components of positive (PA) and negative affect (NA). It consists of 20 questions and the score obtained from its administration ranges between 10 and 50 points for each affect. The WHO definition was used for low weight, normal weight, overweight and obesity (BMI  $< 18.5$ , 18.5–25, 25–30 or  $\geq 30$  kg/m<sup>2</sup> respectively). The statistical analysis were performed with

ANOVA and Pearson's correlation tests, as well as multivariate linear regression (including as independent variables sex, age and study level) using the Stata 12.1 software.

**Results:** We analysed the data of the 71 patients for whom PA values were available and of the 65 patients with NA values available. There was not a statistically significant relationship observed between PA and NA and BMI when analysed as a continuous variable ( $R = -0.12$ ,  $p = 0.25$  and  $R = -0.1$ ,  $p = 0.36$ , respectively) or as a categorical variable. However, there was a non-significant trend to lower scores for both PA and NA in patients with a higher BMI (figure 1). The multivariate analyses, adjusted for sex, age and study level, also showed no statistically significant relationship between the BMI (analysed as continuous or categorical variable) and the PA and NA; but there was also a non-significant trend that sets a relationship between lower scores of both PA and NA and higher BMI values.

**Abstract AB0390 – Figure 1**

**Conclusions:** In our early arthritis registry there is no relationship between the BMI and the structure of the affect evaluated through the PANAS questionnaire. However, it is necessary to evaluate this relationship in a greater number of patients and in different populations before discarding this relationship definitely.

**AB0391 CLINICAL, SEROLOGICAL AND TREATMENT ANALYSIS OF RHUPUS SYNDROME: A RETROSPECTIVE MONOCENTRIC STUDY**

P. Rottenberg<sup>1</sup>, F. Jouen<sup>2</sup>, I. Marie<sup>3,4</sup>, T. Lequerré<sup>1,4</sup>, O. Vittecoq<sup>1,4</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Clinical Immunology Laboratory; <sup>3</sup>Internal Medicine, Rouen University Hospital; <sup>4</sup>U1234, INSERM, Rouen, France

**Background:** Rhupus syndrome is a rare condition in which rheumatoid arthritis (RA) features overlap with systemic lupus erythematosus (SLE) manifestations. Disease characterisation tends to improve, but some uncertainties remain, and therapeutic management has still to be defined.

**Objectives:** We aimed to perform a study of the patients followed at the Rouen University Hospital with rhupus diagnosis using both recent criteria and expert diagnosis, in order to perform an analysis of the clinical, radiological and biological characteristics, and to report the therapeutic procedures carried out.

**Methods:** We performed a retrospective research work covering a period of 10 years, using diagnosis code extraction for both RA and SLE from database of the medical information department, as well as biological data extraction concerning ACPA testing, anti-dsDNA and anti-RNP antibodies. Patients satisfying both ACR/EULAR 2010 and SLICC 2012 classification criteria for RA and SLE respectively, or with an expert diagnosis of rhupus were included. A screening of medical records was performed to collect clinical, biological and treatment data for each patient.

**Results:** Sixteen patients were identified and 12 fulfilled both classification criteria. RA most often preceded rhupus, and clinical analysis found a predominant articular pattern at initial and established disease, with erosive arthropathy ( $n = 11$ ). Skin involvement was the most frequent associated manifestation ( $n = 12$ ). Among other associated manifestations, serious events were reported, including active glomerulonephritis ( $n = 2$ ), ischaemic stroke ( $n = 1$ ) and myocardial infarction ( $n = 1$ ). Immunological profiles showed positivity for ( $n = 14$ ), anti-dsDNA ( $n = 9$ ) and ACPA ( $n = 9$ ). Ten patients required biological DMARD, in addition to conventional treatment. All types of RA approved bDMARD were used. Rituximab was the most prescribed ( $n = 9$ ) and the most effective, with sustained response in 5 patients.

**Conclusions:** Rhupus is a rare condition, with predominant articular pattern, but serious SLE-related manifestations can occur. In rhupus refractory to conventional treatment, biologics, and particularly rituximab, are a promising therapeutic approach.

### AB0392 RHEUMATOID ARTHRITIS AND RISK OF INCIDENT CHRONIC KIDNEY DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF COHORT STUDIES

P. Ungprasert<sup>1</sup>, S. Raksasuk<sup>2</sup>. <sup>1</sup>Research and development; <sup>2</sup>Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

**Background:** Patients with rheumatoid arthritis (RA) may have a higher risk of developing chronic kidney disease (CKD) compared with general population. However, the data on this risk are limited and not well-characterised.

**Objectives:** This systematic review and meta-analysis aimed to comprehensively investigate the risk of incident CKD among patients with RA by reviewing all available studies.

**Methods:** A systematic review was performed using MEDLINE and EMBASE database from inception to December 2017 to identify all cohort studies (either retrospective or prospective) that compared the risk of incident CKD in patients with RA versus individuals without RA. Adjusted point estimates were extracted from individual studies and the pooled risk ratio and 95% confidence interval (CI) were calculated using random-effect, generic inverse-variance method of DerSimonian and Laird. Visualisation of funnel plot was used for evaluation for publication bias.

**Results:** A total of 4 retrospective cohort studies with 1,627,981 participants were included. The risk of incident CKD was significantly increased among patients with RA with the pooled risk ratio of 1.52 (95% CI, 1.28–1.80). The statistical heterogeneity of this study was high with an  $I^2$  of 82%. The forest plot of this systematic review and meta-analysis is shown as figure 1. The funnel plot was relatively symmetric and, thus, did not suggest the presence of publication bias in favour of positive studies.

**Abstract AB0392 – Figure 1.** Forest plot of the meta-analysis on the risk of CKD among patients with RA

Abbreviation: SE, standard error; IV, inverse variance; CI, confidence interval, RA, rheumatoid arthritis; CKD, chronic kidney disease

**Disclosure of Interest:** None declared

### AB0393 ELECTROCARDIOGRAPHIC DISTURBANCES IN PATIENTS WITH RHEUMATOID ARTHRITIS USING ANTIMALARIAL DRUGS

P. Rodríguez Henríquez<sup>1</sup>, F.J. Reyes-Muciño<sup>2</sup>, L.M. Amezcua-Guerra<sup>3</sup>.  
<sup>1</sup>Rheumatology; <sup>2</sup>Internal Medicine, Hospital General Dr. Manuel Gea González;  
<sup>3</sup>Immunology, Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico

**Background:** Cardiac involvement is present in 7% to 35% of patients with rheumatoid arthritis (RA). Anecdotal case series have associated the use of antimalarial drugs with the presence of electrocardiographic disturbances in patients with RA

**Objectives:** To assess whether the use of antimalarial drugs is associated with the presence of electrocardiographic abnormalities in RA patients. The main clinical associations were also evaluated

**Methods:** A single-centre, case-control (1:1 proportion) medical chart review study was performed. A total of 144 patients with RA (ACR/EULAR 2010 criteria) were studied, and grouped as follows: 72 with a history of antimalarial drug use (case) and 72 who never used antimalarial drugs (control). We excluded individuals with a history of ischaemic heart disease or an already diagnosed disturbance of the cardiac rhythm/conduction.

**Results:** A total of 37 cases of electrocardiographic disturbances were found in patients receiving antimalarials (51%), but only 18 cases (25%) in the control group ( $p=0.001$ ), giving an odds ratio (OR) of 3.17 (95% CI, 1.57 to 6.42).

Rhythm disturbances observed in the antimalarial group were: left anterior branch hemiblock ( $n=12$ , 32.4%), right branch block ( $n=10$ ; 27.02%), 1st degree AV block ( $n=5$ ; 13.5%), bifascicular block ( $n=4$ ; 10.8%), posterior hemiblock of the left branch ( $n=3$ ; 8.1%), incomplete left bundle branch block ( $n=2$ , 5.4%), and left bundle branch block ( $n=1$ , 2.7%). Right bundle branch block was the only statistically significant conduction disorder (27.02% vs 5.5% with  $p$  value of 0.004 [OR 11.45 1.43–92]).

The average dose of hydroxychloroquine was  $3.02 \pm 0.41$  mg/kg, while the dose of chloroquine was  $2.23 \pm 0.13$  mg/kg. A history of prednisone consumption also was associated with an increased risk to present an electrical cardiac disturbance ( $p=0.005$ ; OR 9.73, from 2.00 to 47.32).

#### Abstract AB0393 – Table 1

Outcomes	Antimalarial (n=72)	No Antimalarial (n=72)	p	OR (IC 95%)
Cardiac conduction electrocardiographic abnormalities	37	18	<b>0.001</b>	3.17 (1.57–6.42)
1st Degree AV Blocking	5	1	0.095	5.3 (0.6–46.54)
Left Branch Block	1	5	0.095	0.19 (0.02–1.66)
Right Branch Block	10	1	<b>0.004</b>	11.45 (1.43–92)
IBRB	0	1	0.315	-
IBLB	2	1	0.559	2.03 (0.18–22.88)
AHLB	12	5	0.070	2.68 (0.89–8.05)
PHLB	3	0	0.080	-
Bifascicular block	4	4	1.000	1 (0.24–4.16)

**Conclusions:** In this study, the use of antimalarial drugs was associated with an increased risk to present disturbances of the cardiac rhythm/conduction in patients with established RA.

### AB0394 OBSERVATIONAL STUDY OF THE INCIDENCE OF CARDIOVASCULAR EVENTS AND ASSOCIATED COMORBIDITIES IN A COHORT OF PATIENTS WITH RECENT ONSET RHEUMATOID ARTHRITIS

R. Ortega Castro<sup>1</sup>, R. Jimenez-Gasco<sup>1</sup>, A.M. Cabezas-Lucena<sup>2</sup>, J. Calvo Gutiérrez<sup>1</sup>, M.C. Castro-Villegas<sup>1</sup>, M. Romero-Gómez<sup>1</sup>, A. Escudero-Contreras<sup>1</sup>, E. Collantes-Estévez<sup>1</sup>, P. Font-Ugalde<sup>1</sup>. <sup>1</sup>Rheumatology, Reina Sofía University Hospital/IMIBIC/University of Cordoba; <sup>2</sup>Rheumatology, University of Cordoba, Córdoba, Spain

**Background:** Rheumatoid arthritis (RA) is a systemic autoimmune disease whose main characteristic is persistent joint inflammation that results in joint damage and loss of function. and can involve other tissues and organs (extra-articular manifestations).<sup>1, 2</sup> RA is associated with a high risk of morbidity and premature death secondary to the earlier development of cardiovascular, lung diseases and malignancy, being cardiovascular disease secondary to accelerated atherosclerosis the main cause of morbidity and mortality in these patients.<sup>3, 4</sup>

**Objectives:** Main objective: To calculate the incidence of comorbidities and CV events in patients with recent onset RA. Secondary objectives: -To determine the clinical disease features according to baseline RA profile. To analyse the relationship between CV event and the different variables. To describe classic CV risk factors evolution throughout the follow-up.

**Methods:** We conducted a retrospective longitudinal observational study of 70 patients with recent onset RA according to ACR/EULAR 2010 or ACR 1987 criteria, at 5 years of follow-up. A descriptive study of the variables was carried out. For the bivariate analysis, the Chi-square test was used for the qualitative variables and the Mann Whitney U test for the independent quantitative ones. For the paired data, the McNemar test was used for the qualitative variables and T Student for the quantitative ones. A logistic regression model was used to associate the main variable with the rest of the variables. Finally, the analysis of survival and regression of COX was carried out. All the contrasts were bilateral and were considered significant when  $p < 0.05$ . The statistical analysis was performed using SPSSV17.

**Results:** The incidence of CV event was 18.57% (31% acute myocardial infarction). During follow-up, an improvement in inflammatory and quality of life

parameters (DAS28, ESR, CRP and HAQ) was observed ( $p < 0.05$ ). Likewise, the % of hypertensive and dyslipidemic patients increased during follow up ( $p < 0.05$ ), while the levels of cholesterol, triglycerides, glucose and diabetic patients remained similar. The presence of CV event was related to high levels of ESR, male sex and hypertension, ( $p < 0.05$ ).

#### Conclusions:

- The incidence of cardiovascular event in our recent onset RA cohort resembles that previously described in the literature, with the majority occurring during the first 5 years of follow-up.
- The development of hypertension and dyslipidemia occurs mainly during the first 5 years of follow-up.
- The presence of a cardiovascular event was related to male sex, high blood pressure and high ESR levels.

#### AB0395 CORRELATION BETWEEN CARDIOVASCULAR RISK CALCULATORS IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS

R. Castellanos-Moreira, S.C. Rodríguez-García, S. Mandelikova, V. Ruiz-Esqueda, B. Frade-Sosa, A.B. Azuaga-Piñango, S.D.C. Rodríguez-García, N. Sapena, C. González-Delaurens, O. Camacho, J. Ramírez, M.V. Hernández, A. Cuervo, J. A. Gómez-Puerta, J.D. Cañete, R. Sanmarti. *Rheumatology, Hospital Clinic de Barcelona, Barcelona, Spain*

**Background:** EULAR recommends for patients with rheumatoid arthritis (RA) a cardiovascular (CV) risk assessment at least once every five years. Several risk calculators are available but most of them are based on data from general population, so they may underestimate the risk of RA patients. To obtain a more accurate estimation they should be adapted for RA by a 1.5 multiplication factor, unless the instrument includes RA as a variable. To date, there are no studies analysing the concordance and correlation between different CV risk calculators in Spanish population.

**Objectives:** To analyse concordance and correlation of CV risk calculated using different tools and to determine the proportion of CV risk factors in a cohort of patients with RA.

**Methods:** We performed a cross-sectional study including patients with RA according to ACR/EULAR 2010 criteria, treated in a tertiary hospital. Individuals with previous CV events, diabetes and chronic kidney disease were excluded.

Ten-year CV risk was obtained with the following calculators: Framingham-body mass index (FRS-BMI), Framingham-lipids (FRS-L), SCORE CV risk calculator (SCORE) and the Expanded CV Risk Prediction Score for RA (ERS-RA). A 1.5 multiplying factor was used to adapt the results for RA patients in those which didn't include it in their models. CV risk was categorised as low or high using 10% as a cut-off for FRS-BMI and FRS-L and 5% for SCORE y ERS-RA. Correlation was evaluated using Spearman correlation coefficient (Rho) and concordance with weighted kappa.

**Results:** We included 88 patients (18 male), 87.5% Caucasian, mean age 56.9  $\pm$  10.6 years, mean disease duration 5.8  $\pm$  3.3 years. 67% and 76% had positive RF and ACPA respectively and 15% presented extra-articular manifestations (rheumatoid nodules, interstitial lung disease, pleuropericarditis). Regarding CV risk factors: 14.8% were active smokers, 60.2% were overweight or obese, 25% had hypertension, 47.8% had dyslipidemia.

The median CV risk predicted at 10 years was 15% (1.5–70.20) for FRS-IMC, 11.8% (1.2–54.0) for FRS-L, 1.5% (1.1–16.5) for SCORE and 6% (0.6–27.8) for ERS-AR. 64 patients were categorised as low risk and 22 as high risk for ERS-AR. No significant differences were observed in the means of risk obtained by the different calculators or in the risk categories according to ERS-RA when stratified by disease duration (more or less than 5 years).

For the correlation between ERS-RA and FRS-BMI, FRS-L and SCORE, Spearman's Rho coefficients were 0.84, 0.79 and 0.80. ( $p < 0.005$ ).

For the concordance between ERS-RA vs FRS-BMI a weighted  $\kappa = 0.29$  ( $CI_{95\%}$ : 0.15–0.42) was obtained. For ERS-AR vs FRS-L,  $\kappa = 0.34$  ( $CI_{95\%}$ : 0.19–0.50) and for ERS-AR vs SCORE,  $\kappa = 0.70$  ( $CI_{95\%}$ : 0.52–0.87).

**Conclusions:** A strong correlation was observed between the CV risk calculators evaluated and good agreement only between ERS-AR and SCORE. Additionally, overweight, obesity and dyslipidemia were the most prevalent comorbidities.

#### AB0396 RELATIONSHIP BETWEEN PATIENT GLOBAL ASSESSMENT AND PAIN ASSESSMENT IN THE DISEASE ACTIVITY INDEXES IN RHEUMATOID ARTHRITIS, AND ITS CORRESPONDENCE WITH SONOGRAPHIC ALTERATIONS

R. Menor Almagro, R.M. Martínez, E.M. Rubio, M.M. Fernández. *Rheumatology, Hospital Universitario Virgen del Rocío, Sevilla, Spain*

**Background:** Disease activity indexes in rheumatoid arthritis (RA) provide information of different parameters in a single value. It is very useful in the evaluation of the disease activity and its progression. The subjective component of these indexes can modify the index final value.

**Objectives:** The aim of our study was to describe the relation between the patient global assessment (PGA) and pain assessment (PA) with the sonographic alterations in AR.

**Methods:** Transversal study describing the ultrasonographic changes and disease activity indexes in AR. We included patients with RA according to ACR/EULAR classification criteria. They were sent by their usual clinician, in random selection. They were reviewed in the same day by a rheumatologist and blind sonographer. PGA, PA, HAQ, tender and swollen joint count, CDAI, SDAI and DAS28 were evaluated. The ultrasound were realized by grey scale and doppler in 12 joints (wrists, second to fifth MCF and fifth bilateral MTF).

**Results:** A total of 48 patients had PGA  $< 50$  and 37 PGA  $\geq 50$ . The mean age was 53.2  $\pm$  11.7 for group 1 and 56.5  $\pm$  10.2 for group 2, women 64.6% and 83.8% respectively. The positive rheumatoid factor resulted in 72.9% vs 73%. The evolution of the disease in months presented a median of 96 (47.2–132.7) vs 108 [48–138],  $p = 0.564$ . The Body Mass Index in the groups was 26.6 (23.5–29.7) and 26.0 (22.8–30.0),  $p = 0.647$ , and the tobacco consumption of 11 patients group 1 and 12 in group 2 ( $p = 0.397$ ). No significant difference was found in the treatment at the time of the evaluation with methotrexate, median of 10 (0–15) vs 7.5 (0–15),  $p = 0.350$ , or corticosteroids 1.4 (0–2.3) vs 2.5 (0–4.5),  $p = 0.05$ . 23 patients in the group 1 and 19 in the group 2 were in biological therapy. The results referring to the patient's assessment of their disease, acute-phase reactants, clinical examination, ultrasound and disease activity indexes are presented in table 1.

**Abstract AB0396 – Table 1**

	Group 1 (PGA<50)	Group 2 (PGA>50)	P value
ESR: median (p25-p75)	9 (4,2–17)	8 (4,5–16)	0578
CRP: median (p25-p75)	2,4 (1,02–4,7)	5 (1–5,7)	0996
DAS 28 (CRP)	2,1 $\pm$ 0,97	3,37 $\pm$ 1,19	0000
DAS 28 (ESR)	2,6 $\pm$ 0,72	3,25 $\pm$ 0,92	0000
Pain assessment, 100 mm VAS: median (p25-p75)	20 (0–40)	70 (50–80)	0000
HAQ: average $\pm$ DE	0,8 $\pm$ 0,14	2,27 $\pm$ 0,18	0000
Tender joint count: median (p25-p75)	0 (0–2)	2 (0–3)	0001
Swollen joint count: median (p25-p75)	0 (0–1)	1 (0–3)	0090
CDAI: median (p25–75)	5 (1–8,8)	13 (9,4–17,4)	0000
SDAI: average $\pm$ DE	8,69 $\pm$ 5,82	17,67 $\pm$ 6,49	0000
Synovitis in grey scale: median (p25-p75)	1 (0–3)	2 (0–4)	0159
Synovitis in doppler: median (p25-p75)	0 (0–1)	1 (0–2,7)	0231

**Conclusions:** Disease activity indexes in AR have been established as a very useful measure, both in the homogenization of the results obtained in the research and in the daily clinical practice. In our study, we observed the modification in the values of disease activity indexes due to PGA and PA, even those in which its contribution is less decisive than other parameters, as it happens in the DAS 28.

Those variables no related in their value with the patient assessment of his disease status did not show statistical significance between the groups. The patients' valuation about activity of their AR and the modification of the indexes in which it participates in our study were not concordant with the echographic alterations found in grey scale and doppler echo.

### PREVALENCE AND FACTORS ASSOCIATED WITH DEPRESSION AMONG PATIENTS AFFECTED BY CHRONIC INFLAMMATORY ARTHRITIS: PRELIMINARY RESULTS OF A SINGLE-CENTRE EXPERIENCE IN ITALY

S. Pezzato<sup>1</sup>, S. Tomassi<sup>2</sup>, E. Fracassi<sup>1</sup>, A. Giollo<sup>1</sup>, C. Caimmi<sup>1</sup>, F. Martinis<sup>1</sup>, M. G. Gnatta<sup>2</sup>, D. Cristofalo<sup>2</sup>, C. Bonetto<sup>2</sup>, M.L. Marognoli<sup>1</sup>, S. Tosato<sup>2</sup>, A. Carletto<sup>1</sup>.  
<sup>1</sup>Rheumatology, Reumatologia – AOU Verona; <sup>2</sup>Section of Psychiatry, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy

**Background:** Depression and anxiety disorders are more common in chronic inflammatory arthritides (CIA) than in the general population.<sup>1</sup> In rheumatoid arthritis (RA), depressive and anxiety symptoms have been associated with disease activity and pain perception,<sup>1</sup> physical disability,<sup>2</sup> health care costs,<sup>3</sup> and mortality.<sup>4</sup> To our knowledge, data on the prevalence of depression in Italian patients with RA are scarce.

**Objectives:** To estimate the prevalence and factors associated with depression among patients affected by RA.

**Methods:** During an one year period, patients affected by RA have been consecutively enrolled. For each patient demographics and disease characteristics were recorded; the Hospital Anxiety and Depression Scale (HADS) was administered. HADS is a validate questionnaire to assess depressive and anxiety symptoms in patients affected by somatic disorders admitted to general hospital. An HADS  $\geq 11$  was considered diagnostic for depression.

**Results:** The table summarises the main results. We recruited 231 patients affected by RA, finding a prevalence of depression of 13.9% (95% CI 9.4%–18.3%). Overall, patients with depression, when compared with patients without, were older, more frequently females, with a lower education, higher physician global assessment and patient global assessment, more comorbidities. In particular, they had any cardiovascular, neurologic or musculoskeletal issue ( $p=0.018$ ,  $p=0.032$ ,  $p=0.014$ , respectively) and more often used glucocorticoids or NSAIDs. Conversely, no association was found between depressive symptoms and the use of biologic therapies or the presence of inflammatory markers. Interestingly, a positive history of depression was present only in few patients with an HADS  $\geq 11$ .

Abstract AB0397 – Table 1

	Non-depressed (n=199)	Depressed (n=32)	P value
Age, years	57.5 (12.3)	63.5 (11)	0.008
Female sex	152 (76)	29 (91)	0.049
Employed	86 (43)	5 (16)	0.002
Higher education	89 (45)	8 (25)	0.036
Disease duration, years	12 (9.2)	14.2 (8.3)	0.202
Erosive disease	72 (36)	12 (38)	0.516
TJC 0–28	1.9 (3.4)	2.3 (2.6)	0.500
SJC 0–28	0.9 (2.2)	1.1 (2.0)	0.688
PhGA 0–10	3.9 (2.7)	5.6 (2.4)	0.001
PGA 0–10	4.9 (2.4)	6.8 (2.0)	<0.001
ESR, mm/h	19.2 (16.1)	22.2 (13.5)	0.326
CRP, mg/L	6.4 (14)	4.4 (3.8)	0.425
Comorbidities	176 (88)	32 (100)	0.027
csDMARD	136 (68)	18 (56)	0.127
bDMARD	129 (65)	24 (75)	0.177
Glucocorticoid	87 (44)	20 (63)	0.037
NSAID	32 (16)	12 (38)	0.007
Antidepressant	18 (9)	11 (34)	<0.001

**Conclusions:** These preliminary results suggest that more than one every seven patients with RA could suffer from depression, thus depression might be undiagnosed in a significant number of patients. Comorbidities, anti-inflammatory medications and both physician- and patient- driven evaluation of disease burden were the most striking factors associated with depression in this cohort of patients with RA.

### INVESTIGATION OF PREOPERATIVE INTRANASAL COLONISATION IN ORTHOPAEDIC SURGERY FOR PATIENT WITH RHEUMATOID ARTHRITIS

S. Tsuji<sup>1</sup>, J. Hashimoto<sup>1</sup>, T. Noguchi<sup>2</sup>, S. Akita<sup>2</sup>, K. Yachi<sup>2</sup>, M. Saito<sup>2</sup>, S. Ohshima<sup>1</sup>, Y. Saeki<sup>3</sup>. <sup>1</sup>Department of Rheumatology and Allergology; <sup>2</sup>Department of Orthopaedic Surgery; <sup>3</sup>Department of Clinical Research, National Hospital Organization, Osaka Minami Medical Center, Kawachinagano City, Osaka, Japan

**Objectives:** Coagulase-negative staphylococci (CoNS) is listed as the major SSI causative organism in the field of orthopaedic surgery, but detailed report on the presence or absence of methicillin-resistant CoNS of intranasal colonisation is not found.

**Methods:** In 13 months from July 2016 to the end of July 2017, 1000 cases of consecutive cases in which nasal cavity culture was performed within one month prior to hospitalisation for patients scheduled for our orthopaedic surgery. 223 men, 777 women, average age 66.4 years old, 197 cases of RA patients, 803 cases except RA patients.

The method of intranasal culture is as follows. After culturing for 18 hours at 35 °C using blood agar medium (daily water) and CHROMager MRSA selective medium (Kanto Kagaku), identification of bacterial species of the genus *Staphylococcus* grown and cultivation of drug susceptibility tests It was carried out by BD Phoenix according to the method of the Association (CLSI).

**Results:** The results of intranasal culture showed that *S. aureus*, *S. epidermidis*, CoNS (excluding *S. Epidermidis*) and culture negative were 18.2%, 27.8%, 7.8%, and 23.9%, respectively. MRSA, MRSE and MRCoNS (excluding MRSE) with methicillin resistance were 3.2%, 22.1% and 1.7%, respectively, and 27.0% of methicillin resistant bacteria were found to exist.

Especially in patients with RA, the methicillin-resistant bacterial colonisation rate was significantly higher ( $p<0.05$ ) than 38.6% compared with 24.2% other than RA patients.

**Conclusions:** Methicillin-resistant *Staphylococcus* was found to be 27.0% intranasal colonisation of patients in orthopaedic surgery. Especially in RA patient, it was high rate of 38.6%. In the future, we need to consider the selection of perioperative preventive antibacterial drugs.
